The oldest manured tea very favourably compares with unmanured tea of the same age, especially on old land where the difference is very marked. The important question for planters is how to obtain their fertilizers *pure*. To pay for such a useless thing as sand, and go to the extra expense of rail fare and cart hire as well, is very grievous. In the Manual of Mr Hughes, fish manure, for example, is said to have contained as much as 50 per cent of sand when he was in the island; but owing to increased interest on the part of buyers and also to local analysis, fish manure can be had today with from 15 to 20 per cent only. As the fish itself contains no sand there is still much room for improvement. The above example is put in another way on the basis of the most valuable of manurial ingredients, *viz.*, nitrogen. I find that when Mr. Hughes analysed it (*vide* "*Cochran's Manual*") it contained from 4 to 4½ per cent, whereas now numerous analyses from Mr. Cochran show that it can easily be procured with from 5½ to 6 per cent nitrogen. This means an increase in the manurial value—taking the highest figures in each case—of about 40 per cent. What all that is to the planter who is spending his money on fertilizers is patent enough.

On the other hand white eastor cake in Mr. Hughes' day showed I think about 7 per cent of nitrogen, whereas it is at present difficult to get it much above 6 per cent.

This means that for every seven tons of the superior article, you require fully eight tons to produce the same effect.

The crying need of today on this question is to be able to get manures of guaranteed composition.—Yours truly, HANTANE.

No. X.

Holmwood, Dec. 31.

DEAR SIR,—In reply to your questions *re* manure:—

- (1) Manuring estates has only become general, in my opinion, in the old districts, and in the old districts it is chiefly confined to the older estates.
- (2) Bulky manure is very little used except where it is purchased at a cheap rate.
- (3) Manures are almost always mixed with castoreake and bones, or castoreake, fish and bones.
- (4) I think it probable that we are drawing on our capital by the use of such unscientific manures as those now in general use. In my opinion they are forcing to the bushes at the expense of the soil and that unless a change is made, a day of reckoning will come.
- (5) So far as my experience goes the oldest manured tea gives about twice as much as unmanured tea of the same age.

As to your query about values—I think we have reached the limit of the swing of the pendulum, though I do not anticipate any immediate reaction owing to the difficulty of obtaining investment for the enormous amount of money in the hands of capitalists. Shares may be forced up by interested operators, but there is small margin even now for them to work upon. 6% and 7% seem to be the outside interest procurable in sound Companies.—Yours truly, B.

No. XI.

Upper Maskeliya, Dec. 30.

DEAR SIR,—I cannot say whether manuring has become general in other districts or even in the lower part of this district. At this end of Maskeliya most estates are applying artificial

manure composed of bones; castor cake or bones, castor cake and fish. Very little bulky manure is applied, but in some cases the artificial manure is applied when the prunings are buried. I don't think nitrates have been much used as yet.

I think that the manure has temporarily very much improved the size and apparent strength of the bushes and has increased the yield and not perceptibly reduced the quality or the value of the teas made.

Manuring is only in its infancy up here; but I am told by planters who have done much that each application improves the yield.—Yours truly, W.

No. XII.

Central Province, Jan. 1.

DEAR SIR,—In reply to your Circular of the 23rd inst. in re manuring I should say:—

1. In several of the older districts it is being generally resorted to and the younger ones are following suit. A few years hence it will, I anticipate, be general throughout the whole country.

2. Bulky manure is used to a very limited extent nowadays except under favourable conditions as regards supply. Cattle manure is too expensive and gives in so many instances a very unterminate idea of the fertilizing matter you are supplying to your bushes. The organic matter can be secured at less cost by burying prunings green.

3. Artificial manures are chiefly used, white castor cake, bone meal, and fish being the favourites. The former, if of good quality, is an excellent nitrogenous manure, but its value in fertilizing matter varies from R40 to R80 per ton. The finest I have had of late years showed 8% nitrogen; but of this quality I am informed there is only a very small supply available in India. Bone Meal is more definite in character, unless clearly adulterated containing 24 per cent phosphoric acid but this it's main element is only required by tea in limited quantity, so that any large application of this can only be a waste of money. The Nitrogen it contains some 3 per cent can be purchased cheaper in other forms. Fish apart from the sand and moisture, it generally contains, is an excellent manure; but manure vendors do little to supply it pure. It in most cases contains from 30 to 50 per cent moisture and sand; though it can be purchased to contain under 15 per cent showing close on 7 per cent nitrogen and 5½ per cent phosphoric acid. Nitrates and Ammonia are being used with distinct advantage. When applied in combination, on sound common sense lines, they cannot in any sense be detrimental, or exhausting, if so used. Used indiscriminately of course, they would be harmful and exhausting.

4. My own experience is that well compounded artificial manures, increase the yield, improve the quality of the tea and steadily improve the healthy appearance of the bushes especially on old coffee land, giving in a few years, what were miserable stunted diseased bushes, fine luxuriant ones.

5. Systematically manured tea for a period of years with the essential elements of fertility in due proportion, gives an average of 700 lb per acre, while similar unmanured tea gives 350 lb. per acre and as regards appearance of the bushes the latter is simply not in it. D.

MANURING OF TEA:

LETTERS I TO XII REVIEWED.

If any proof were called for, of the necessity of the inquiries we have instituted touching the manuring of tea and its effects, it is to be found in the varied and interesting replies which we have received, and hope yet to receive, from all parts of the island. It may at first sight seem superfluous to make any inquiry about a matter which some think can lead to but one answer. It is almost an axiom in agriculture that land, out of which anything is taken, should be manured—that is, be given back some at least of the constituents taken out of the soil; and it would seem to be inevitable that crops must improve under the stimulus of manures. These, perhaps, may be accepted as truths of general application; but what is true of man and of animals is equally true of plants. The same food is not beneficial to all classes alike; indeed, the sustenance of one may prove poison to another. But, apart from the regulation of manuring according to the crops sought and gathered, and the character of the soils to be dealt with, a further element of doubt has been introduced by the belief expressed in some quarters, that manuring—at any rate manuring with certain substances—injurious affects the quality of tea and its flavour. In these circumstances, inquiry and the free interchange of ideas cannot fail to contribute to the common good; and it is in this view we have circulated our questions which have called forth most encouraging and instructive answers from far and near. In our review of the replies which we owe to the courtesy and public spirit of our correspondents, we shall deal first with the first twelve communications, given above.

The answers to the first question:—Whether the manuring of tea estates has become general in all districts or only in the older ones, shew, as was to be expected, some variety, according to the standpoint of the writer. The general result may be said to be that, while manuring is not resorted to by every estate in a district, whether old or new, it is decidedly on the increase both on new estates and old; and all but general on the older ones. This is a most hopeful feature, as it was not very long ago that we lamented the poor show which manures made both among our importers in our railway traffic returns. The increase we would trace, not alone to faith in the efficacy of manures, but also to what is more potent than faith in such things, the ability of the purse to bear the charge. Still, we fear, there are not a few who do not take sufficient thought for the morrow; but are selfishly content to take what they can from their land, in the happy-go-lucky belief that things will somehow continue much as they are. These would do wisely to study the answers to our fifth question, which point to the conclusion that manure has done much more than arrest the deterioration of old land which has been under cultivation for a generation or more—that it has improved it, and has led to heavier crops, and thereby to more remunerative returns.

The answers to the second question—Whether bulky manures are chiefly used?—are distinctly disappointing; but they can scarcely surprise one.

Few estates are within easy reach of cattle sheds; and the cart roads passing through or along side estates are seldom main arteries of communication. The cattle establishments of the coffee era have almost all been dismantled, and we fear that the thoroughness and sense of permanent settlement, which distinguished men of the type of "R. B. T.", Logie Elphinstone and Mat-takelle Smith, are to some extent, at least, wanting among individual proprietors of the present day? This drawback should be cured by the resources of the big Companies which are taking the place of large proprietors; for, the experience of places like Mariawatte would seem to establish that, for leaf crops, cattle manure answers splendidly; and, of course, bulky manures are more beneficial to worn out and long-cropped lands than artificial compounds. Curiously, the very first letter in our series contains a warning against "bazaar manure"—but why?—and questions whether cattle and farmyard manure is as beneficial to tea as it was to coffee. Surely it should be the other way?

The third question—Whether the manure sent by train is used by itself or in combination with other stuff?—elicits replies which point to the desire of planters generally to mix it with bulk, and to the difficulty of securing the latter, except in favoured situations. Castor-cake would seem to be a prime favourite, mixed with fish manure, and a small proportion of bones—though the latter is objected to as producing seed. Here we have an example of how science and experience meet, and how valuable the observation of even the most ignorant may become. The *go'ya* readily uses bone dust for his paddy fields, but he abhors cattle manure as producing straw rather than grain?

There is a strong consensus of opinion—all but general—in response to the fourth question, not only that no harm is done by the use of artificial manures, but that the bushes and crops are distinctly improved. The only exception is to be found in E. G. R.'s vigorous condemnation of artificial manures as "doing harm to the tea enterprise," of castor and bones as giving "a fictitious energy to the plants which sooner or later must produce the worst results." Yet, even E. G. R. would use artificial manure mixed with bulk; so that it really becomes a question of applying only suitable manures; and that brings us to one of the propositions with which we started, that what is food to one may be poison to another. It is thus, not the intelligent use, but the thoughtless abuse, of manure which is to be guarded against, and what more effectual safeguard can one have, coupled with close observation, than the analysis of soil and the analysis of manures both as a means of checking fraud and using the right thing? We are by no means disposed to provoke a contest between "Killaloe" and "E. G. R." whether with shillelagh or rifle, the more so as the decline of the former cannot apply to the latter, but as a set-off to the growl from Ratnatenna, we would place the cry from Talawakele, that artificial is to be preferred even to bulk manure and that "persons who object to manuring 'on principle' are usually hand-to-mouth men, who have no money to pay for it, or who wish to pump their properties"! And that brings us to our last question—How the oldest manured tea compares with unmanured of the same age?—the answers to which are most gratifying and encouraging. With almost one voice they record a great improvement in the appearance of the bushes and

greatly increased yields. "E. S. A." from Dikoya estimates the increase in yield at 200 to 250 lb. per acre; "B" from Holmwood, while strong in condemnation of "unscientific manures," estimates manured tea to give twice the yield of unmanured; "D" from the Central Province, puts down the average at 709 lb. per acre from manured tea and 350 from unmanured, in a suggestive letter; while our other correspondents testify to the improvement both in appearance and yield of the bushes. It is impossible to resist the effect of such evidence; and when we take into account the acreage of young tea coming into bearing or to maturity, the proved and ascertained effects of manuring which is becoming more general, and even the new clearings, though they are not particularly extensive, we cannot understand how any intelligent person can speak of tea in Ceylon having reached its maximum production.

(Letters Continued.)

No. XIII.

Lower Ambagamuwa, Jan. 1.

DEAR SIR,—1. With the exception of one or two estates, manuring is not done systematically in this district; most estates do a little manuring each year, but the manure is chiefly applied to their ridges, or fields that show signs of weakness.

2. The bulk manure is very little used, in fact hardly at all, except by estates situated near villages, where town manure can be had.

3. Manure sent up by Railway is used alone, the mixture generally applied being crushed bones and castoreake, 1 of the former, to 3 of the latter; 5 ozs. of the mixture being as a rule, applied to each tree.

4. Certainly not.

5. Favorably.

To get the best results from manuring, the manure should be applied (dug in if the land be not too steep) as soon as possible after a severe cutting down.—Yours faithfully,

TEA FARMER.

No. XIV.

Balangoda, Jan. 1.

DEAR SIR,—Thanks for your circular. Sorry I cannot tell you much about manuring tea, as down here little or nothing has been done as yet. Though, I believe they are beginning to do more in Haputale. Personally I am in favour of bulk manure, one basket full between four trees. Have done two or three acres here with good results. This past year has been an awful one for rain, and as I write 8 a.m. its pouring steadily.—Yours truly,

BALANGODDE.

No. XV.

Matale N.E.

1. A few estates here manure with excellent results.

2. When bulky manure is available it is always applied, but it is very limited.

3. So far as I am aware the chief manures are castor cake and bones mixed—also fish manure with a mixture of the above.

4. *No*—wherever manure has been judiciously applied, it has greatly improved the appearance of the tea and increased the production of leaf.

5. On old coffee land the oldest manured tea gives nearly double the yield that the unmanured tea does, that is, where manure has been regularly applied.

I am of opinion that more manuring would be done on old coffee lands, but for the insufficient and uncertain labour supply.

W.

No. XVI.

Kadugannawa, Jan. 2.

DEAR SIR,—In reply to your queries *re* manuring of tea,—

1. Becoming general in old districts and on an experimental scale at least in new districts. On old coffee land it is indispensable.

2. Artificial manures chiefly used, except where road-side cattle sheds and town refuse are available.

3. Castorcake and bonedust in proportions of 4 or 5 to 1 the most general application, and occasionally nitrate of potash and fish manure.

4. No harm from effects of manure, but inevitable loss of soil from repeated applications in steep land.

5. Manured tea compares favourably with unmanured and yields better returns.

"OUTLOOK."

No. XVII.

Hatton, 1st Jan.

DEAR SIR,—Many thanks for your circular of the 26th December *re* Manuring of estates. I can't speak for other districts; only that I hear manuring is more general than it was two or three years ago:

1. Manuring is more general in all old districts. Manuring has been pretty general in this district. Castorcake and bonedust—5 cake to 1 bonedust.

2. Bulk manure is very little used unless on a few estates close to caddies, such as Hatton and Dikoya. The large number of cattle that is required to manure an estate say of 200 acres prohibits bulk manuring.

3. The manure sent by rail is mostly used alone; castorcake and bonedust and a *little nitrate* of potash.

4. I do think that castorcake and bone dust hurt the flavor of the tea; this I am sure of.

5. Manured tea in old land certainly compares favourably with unmanured tea, and I am positive manure pays well on old estates where the tea is backward. As I have already said castorcake and bones do affect the flavor of the tea to such an extent that it affects prices considerably; but against this you get a greatly increased yield, say of 200 lb. per acre, for at least two years. But, Mr. Editor, what is the good of all this manuring when many estates that have manured regular, can't pluck their leaf year after year for want of labour? It would thus be far better if some estates were satisfied with the 450 lb. per acre in place of 600 lb. and not plucking it. This is a very large question which I don't feel inclined to enter into just now. In fact, as I want to keep my dearly-bought experience to myself unless I get a large fee from the Creeper "Association."

In conclusion, I challenge any of my brother planters to say if their prices have increased since they commenced regular manuring with castor-cake and bones? I am, however, convinced half of them know nothing about the subject! This is a bold assertion from

A NOVICE.

No. XVIII.

Upper Maskeliya, Jan. 1st 1897.

(1) I believe the manuring of tea estates has become general and in all districts—new as well as old—but my experience is confined to this district where manuring *has* become general.

(2) Very little bulky manure is used here with the exception of line sweepings and a little stable manure.

(3) The manure sent up by railway is usually mixed in Colombo—the favourite proportion being 3 of castorcake to 1 of bonedust.

Fish manure is used a good deal. An excellent mixture is, castorcake 40 per cent., fish 40 per cent., and bonedust 20 per cent. The great objection to fish manure is that it contains a large proportion of sand and is not ground fine enough to admit of its being thoroughly mixed with other manures. Fish manure should only be applied to those parts of estates where there is no possibility of its contaminating the streams from which the coolies draw their water.

I have not heard of nitrates being used in this district, and should not care to use such stimulating manures, except by the advice of an Agricultural Chemist.

(4) No harm whatever is being done by the use of artificial manures. Quite the reverse.

(5) Unmanured tea is quite out of it in comparison with manured fields of the same age. Manure not only gives a large increase of leaf; but it increases the size of the bush and gives an abundance of strong healthy brown wood for pruning.

NORTH.

No. XIX.

UVA SIDE.

No. 1. Being a comparatively new district, manuring has not been generally carried on here.

No. 2. I have used cattle manure chiefly.

No. 4. When artificial manure is used without due analyses of soil being previously procured to discover the chief chemical ingredients required, I think it likely that harm may be done and the quality of the manufactured tea adversely affected.

No. 5. I have no actual figures to go upon, as the fields have not been kept separate, but the manured bushes flush better and longer than those not manured.

G. H. G.

No. XX.

Jan. 2nd. 1897.

DEAR MR. EDITOR,—We would all manure if we could, but where is the labour? Not only individual estates, but whole districts are crying out for more coolies. We are rubbing on now, but what shall we do in April and May? What is the use of increasing the yielding capabilities of our tea, if we cannot pluck the extra leaf? Now for your questions:—

I. I don't think the manuring of tea is *general* in any district. It is more so in the new districts, because they are better provided with *cart road transport*—an estate without a cart-road to the boundary, or nearly so, cannot indulge in manure, not only is the cost of transport prohibitory, but labour is not available. Tavalam cattle in olden times carried our manure, but they have long ago disappeared from all the old districts.

II. Very few cattle are kept now-a-days, no coolies can be spared to tend, or cut bedding for them, so we have no bulky manure to apply.

III. The principal manures used by estates connected with a cart-road are castorcake, bonemeal, and fish.

IV. I have used all sorts of manure during the last 6 years, and unhesitatingly say that it has been of the greatest possible benefit.

V. Manured tea has the great advantage that it flushes more evenly, and steadily all through the year, being less affected by variations in the weather.

What we want all over the country are *more roads*, and *more labour*; then manuring will be general, and the country far more prosperous.

I wonder how many of your readers have read the articles in your issue of Dec. 21st and 22nd:—"The Germ Life of the Soil," and "Finger and Toe in Turnips." After reading these, I think few men could continue that objectionable habit of poisoning the soil, by *burying tea prunings*: burn and manure with the ashes if you like; but failing this, leave them on the ground, the sun will very soon destroy any harmful matter, and the leaf covering left on the ground is beneficial in retaining moisture, and preventing wash.

Cacao Planters will learn in time to pay attention to the refuse husk of the pods after taking out the beans. It is a source of danger always; the only safe way to deal with it is to throw them all into a pit, and cover with a good dressing of *quick-lime*, a supply of which should always be on hand during the crop season, but it must be *freshly* burnt.

If it takes 5 or 6 years to destroy the harmful effects of refuse from the turnip shed, what must be the results of burying cocoa husks, almost fresh, year after year in the same soil, and to the same tree;—quite sufficient to account for the serious bark disease of which we hear so little, but which is doing incalculable harm to the Cacao Industry.

OLD PLANTER IN OLD DISTRICT.

No. XXI.

Knuckles, Jan. 2nd.

DEAR SIR,—In reply to your circular of 26th December, I beg to hand you the following:—

(1) Manuring is pretty general over all this district, *i.e.*, on all tea fields planted on old coffee land. I have not as yet heard of any one manuring tea planted on virgin land. Many of the estates here manure regularly from 50 to 100 acres per annum.

(2) Bulk, *i.e.* cattle manure is being used less and less every year.

(3) Bones and castorcake, either mixed or separately, seem to be the favourites. I myself have extensively gone in for fish (whole fish from Tellicherry) applied in the form of a compost made of fish, manna-grass and ravine soil with the best results.

(4) I can see nothing as yet but good resulting from manuring.

(5) Tea manured from the commencement is fitter today than ever it was. I doubt if it would have been in cultivation without such assistance.—Yours faithfully, T. D.

No. XXII.

LOWER MASKELIYA.

DEAR SIR,—Replying to your circular of the 26th ultimo: I should not say that manuring had become general but it is on the increase and there certainly is a preference for artificial of sorts. Fish manure seems to be gaining in favour; but, in my opinion, its properties are such that it does not give such good value for its cost as castorcake. To bring tea into heart cattle manure is decidedly the best, but for forcing crop its action is not so immediate or pronounced although more

lasting. A free use of bones I am decidedly averse to although a *small* admixture with castorcake is advantageous. Much depends on the soil to which manure is added and *where and how it is applied*—judicious manuring is certainly most desirable and remunerative notwithstanding that it, for a time, somewhat depreciates quality. W.

No. XXIII.

DEAR SIR,—Manuring tea. We have done little at that here, but are to have a try this year with 73 acres. 1896 is the best year we have had: over 480 lb. per acre. DIKOYA.

MANURING OF TEA:

LETTERS XIII TO XXIII REVIEWED.

We find that letters (XIII to XXIII) support generally the conclusions of the twelve letters we had first noticed. These come from Lower Ambaganuwa, Balangoda, Matale N. E., Kaduganawa, Hatton, Upper Maskeliya, Uva-side, Old District, Knuckles, Lower Maskeliya and Dikoya; and from none of them do we learn that manuring has decreased, that any one has had reason to lose faith in the efficacy of fertilizers or that harm has come from their application. The note from all sides is, that manuring is going ahead, that experiments have begun, or are about to commence, on places which have not hitherto tried manures, and, in fact, that manuring is becoming general throughout the Tea Districts. This is the key-note of the letters now under review, with scarcely an exception. The scarcity of bulky manures seems to be as deeply regretted as it is widely experienced, only estates in close proximity to Bazaars being in a position to secure a supply. As we noticed previously, cattle establishments seem to be things quite of the past. There is something pathetic in the experience of an Old Planter in an Old District, who reports that even Tavalam cattle have vanished from the scene—so that the new districts, being better provided with cart-road transport, enjoy greater facilities for manuring than the old.

While there seems to be a very general, almost universal, preference for cattle or bulky manures over all others for the leaf-crops which are now the mainstay of the planter and the country; yet, as a matter of experience, artificial manures have generally to be used. Though the use is in most cases from necessity, not choice, the general verdict is that the result fully answers expectations. G. H. G., however, from the Uva side, utters a word of warning, lest the use of artificial manures without analysis of the soil, may work harm; but he himself is in the happy, exceptional position of having cattle manure. We certainly do not underrate the importance, and even absolute necessity in some cases, of soil analysis; but, so far, the ordinary combinations of castorcake, bones and fish have not been found to be in any way injurious to the trees. And that brings us to the very emphatic testimony of "A Novice" from Hatton, who protests that "castorcake and bonedust hurt the flavour of tea." It is in connection with an opinion like this that the value of analytical work becomes manifest—not only that the chemist may furnish a careful analysis of the soil operated on and the special ingredients of the manure applied, but that he may find out wherein the tea

reported to be injuriously affected differs from tea plucked from unmanured fields, or from fields to which other manures than castor and bone have been applied. We hesitate to quote the experience of our numerous correspondents who have nothing but good to report of artificial manures and of this special combination of them; for "A Novice" retorts, in anticipation, that "half his brother-planters know nothing about the subject," while he challenges anyone to say that "their prices have increased since they commenced regular manuring with castorcake and bones." But, then, who can report any recent improvement in prices, whether after manuring or before? We should say such estates might be counted on the fingers of one hand; and it would be scarcely fair to lay at the door of manuring the general declension of prices which has been experienced for the past few years. On the other hand, we by no means discredit the verdict, but would ask for more light on the subject, and for closer investigation; and this is one of the benefits which we anticipate may result from the Circular we have issued among the more thoughtful and experienced of our planters in the various districts.

Indeed, the side-lights thrown on the tea enterprise by the correspondence we are publishing, are quite as important as the direct information which is placed at our disposal; and the side-issues which so many raise are quite as interesting and suggestive as the answers to our specific questions. Thus "A Novice," despite his verdict against castor and bones, as injurious to the flavour of tea, concedes a greatly increased yield from their application—estimated at 200 lb. per acre, for ten years; but he inquires, What is the good of all this manuring when many Estates cannot do justice to the plucking of the leaf they have, for want of labour? The question is a very pertinent one, as also whether it would not be better to be content with 450 lb. per acre than to force out 600 lb. and not be able to take it all in? The prime importance of the labour question is emphasized by "Old Planter" who pleads lack of labour, not only for harvesting enhanced crops, but even for the transport and application of manures; and the Government would do well to note in connection with the discussion of this question, the way in which the shortness of labour comes constantly to the surface, and the demand for more roads and better roads is urged from many quarters. If the prosperity of the Colony is intertwined with tea, the continued success of tea clearly depends on abundant labour and efficient means of communication; and these should receive the special attention of Government, as we are glad to think they have begun to do with the Governor, whose proposals for the extension of roads we recently commended.

An "Old Planter" however, deals thoughtfully with certain side-issues, which we should wish to see discussed by other planting friends, and on which, we fancy the Agricultural Chemist will be able to throw a good deal of light. Among these are the burying of green tea prunings, against which "Old Planter" is particularly strong, and the careless heaping or burial of the husks of cacao pods. We can quite understand harm being done by the accumulation of fermenting pods, both from a sanitary point of view, and as a nidus for insect and fungoid pests, which would attack the soft wood of the tree with fatal effect. We should like, however, to hear more on this and the other

subjects we have indicated. Meanwhile, we would make one reservation, in view of a possible misapprehension of our own leanings. While convinced believers in the efficacy of manures and their need on most Ceylon estates, we do not counsel their blind application, or any forgetfulness of the fact that the soil on some local plantations may not need renewal for many years.

(Letters Continued.)

No. XXIV.

DEAR SIR,—With regard to your questions *re* manuring tea, I should have thought that this subject was so simple that more ventilation was unnecessary. If we have virgin soil, or rich alluvial lands like the Assam fields, then by all means save expense by abstaining from manuring. But with our played out coffee-estates, if we wish to make ends meet, we *must* manure. It hardly matters what manure is used so long as facilities are considered. One estate near this has become a mine of wealth to its proprietors by bulky-manuring. But it is not every estate that can stand the costly arrangements which bulky manure entails; such as cattle-sheds, grass fields, &c. I have found fish manure very effective; but I have had very little experience in manuring tea. I would avoid manuring if I could possibly do so. The wash on our steep-hillsides means a very wasteful system of manuring. If we consider the distant future of our staple then I should say that manuring means the drawing on the capital of the "unearned increment" of every estate. But we must consider the present, and at present we must make ends meet.

The local "Times" has been very much exercised that we are a half-penny or two behind India in prices. Is India struggling with old washed-out coffee estates? Is India attempting to cultivate every acre of hard gravel or cabook? Is India pruning all the year round and reducing expenses as Ceylon has done? Let us hear what India is putting tea F.O.B. for.—India has its rich loam and its regular season of annual pruning, so all the resources of an estate are concentrated in a short busy season.

Surely every Ceylonese knows that tea is made in the field. Supposing the critical editor had his way, and the European changed places with the Tea-maker, then what about close and irregular plucking, and coarse leaf? The very essence of the science of the matter is a smooth revolution of the wheels, a steady careful round of the fields—*careful plucking*. The routine of the Factory is properly placed in the hands of an educated native. The routine of the plucking rounds should be in the hands of a European. Are we all wrong and the editor, "Times of Ceylon" right?

1897.

No. XXV.

SIR,—*Re*—manuring tea. My own experience is rather limited and peculiar, my tea being all young I have not begun regular manuring; but permitted the Municipality a "free coup" of Kandy refuse, the only result being that all the tea with which it came in contact sickened and died!—and no supplies will now grow on the spot where the stuff was emptied.

Perhaps one of the most methodically manured estates in the Central Province is New Peradeniya. I have visited the fields and examined the carefully kept returns, noting that cattle manure comes out an easy first, doubling the yield;—the

best artificial only showing about $\frac{1}{3}$ rd increase over the unmanured. But it must be borne in mind that cattle manure is the most costly.

I hope that the painstaking and indefatigable manager of this fine property will let you have full details of his interesting experiments *pro bono publico*.
O. C.

—
No. XXVI.

Dikoya, Jan. 3.

Manuring in both old and new districts is vretty general; but the scarcity of labour presents many from going in for it on a large scale.

2. There is very little bulky manure used, as few keep cattle in these days. In my opinion artificial manure when properly applied gives quicker returns, and compares favourably with bulk in every way.

3. Steamed Bones and Castor Cake, in the proportion of 1 part of the former to 4 of the latter finds most favour, though some add fish to this mixture with advantage.

4. I do not think any harm is being done by the use of artificial manures; at all events, I know several estates that have been systematically manured with Bones and Castor Cake for the past 8 or 9 years, the appearance of the tea now, is decidedly finer, than on the adjoining estates of the same age and the yield is certainly not less than 200 lb. made tea, per acre. better. There is a well known estate in Dikoya where manuring with artificial was carried out on a liberal scale for several years; some four years ago manuring was discontinued, and at present the tea is looking superb, and I am assured by the manager, that the yield is quite as good as it was before manuring was commenced. This proves that tea does not suffer from the discontinuance of manuring up country.
ORAM.

—
No. XXVII.

Kotmale, Jan. 4.

In this district manuring is systematically carried out on two or three estates and with the best results as regards yield and improvement of the bushes.

Cattle manure does not tell on the flush till six or eight months after application, nor does it give the heavy yields obtained from artificial manures in the first year; but has a more lasting effect on the bushes and need not be repeated till four years have elapsed from the first application. If practicable the best results would be obtained by giving a light dose of artificial two years after the cattle manure was applied or mixing some stimulating manure with the cattle manure when applied.

So far the best mixture appears to be Castor Cake. Fish and Nitrate of Potash in the proportions of about 6. 3. 1. applied in semi-circular holes and 10 cwt. to the acre.

Tea to which Castor Cake (only) was applied in 1892 and not since manured is now yielding flushes equal to the same tea which has never had manure and shows no injurious effects from manuring. I do not, however, approve of letting the tea run more than three years without a second application and should say when once begun, it should be followed out systematically as a means of keeping up the condition of the bushes and maintaining the increased profits resulting from careful and judicious manuring of fields which will respond to the manure.

It is questionable if it pays to manure tea which without it only yields 250 lb. per acre. Preference ought to be given to fields from which a higher yield is got.

It is difficult to say whether on the whole, quality is impaired or improved by manuring; careful comparisons for two years showed little difference, but was slightly in favor of manured tea.

Manured tea does not feel the effects of a long drought to the same extent as unmanured tea and unless the drought is prolonged for several weeks no material difference is noticed in the yield of leaf.
A. F. S.

—
No. XXVIII.

Bogawantalawa, Jan. 2.

The manuring of tea is carried on a good deal on many estates throughout the tea districts whose transport facilities are easy, where long cultivation or poor soil makes it more or less necessary to reap the full advantage. Some proprietors however do not believe in the efficacy of artificial manuring considering it too stimulating and not sufficiently lasting in its results. But I think there can be no doubt as to the fact that planters generally are applying large quantities of artificial manure on many estates with very good results both in the low country and on the hills. And where this is applied with care, systematically good results in increased yield and stronger growth of wood are generally apparent. I have never used Nitrates nor have I known any one who has done so recently. Bones and Castor Cake seems to be the favourite mixture in proportions suited to the elevation, soil, climate and other conditions.

Bulk manure which was so much used in the coffee days seems to have now become confined to what is made by a few bungalow cattle or from cart bullocks and roadside cattle sheds. Fish manure is applied by some—and I have heard of it being made into a compost heap with layers of the succulent portion of jungle growth, fish manure and jungle soil, but I do not know of any being applied straight to the tea trees.

“TEA BUSH.”

—
No. XXIX.

Arapatana, Jan. 4.

DEAR SIR,—In response to your letter I send the following replies to your questions *re*-manuring:

No. 1. In old districts I believe the best paying estates generally manure their tea. In this district it is not general, but only the few manure, or at any rate to any extent.

No. 2. There are very few estates that are able to do bulky manuring other than burying prunings, any attempt at cattle manuring for tea, means a large acreage of good land being used for grass and at the present value of land this means very much. Anything less than thorough provision for up-keep of sufficient cattle, to do this work efficiently, is simply playing at manuring.

No. 3. The artificial manure most used is Castor Cake and Bone-dust with a little Nitrate, &c. mixed in suitable proportions.

No. 4. No, certainly not. If properly applied and well mixed with earth in the hole I have only found good results, and very much so, in most cases. Extended over 3 or 4 manurings (4 to years) I have seen the yield doubled in some instances, and always after first year or so, the appearance improved, and yield considerably increased; and I have not found that the made tea loses quality or flavor through this manuring.

No. 5. The only manured tea of same age I have, is where soil was naturally better and tea was already giving exceptionally large yields. My object is to work up the other fields to same yield as nearly as possible with these, by manuring. In some cases this has been already done, while in others it is gradually being effected. I think that all manuring should be occasionally, at least, changed; and that artificial manure is best applied for 1st or 2nd time in semi-circular holes direct to each tree, but that the succeeding application is best (in many instances) (in 4 times the quantity) dug well into the large holes where previous years' prunings were buried and have well decayed. In any case where artificial manuring is done, I think all prunings should be buried and I have found that this alone gives very good results, *i.e.*, burying prunings only in most soils and that in certain soils I have had first-rate success; with distinct flavor; where a little coral lime was applied with the green prunings. W. B. J.

No. XXX.

Kotagala, Jan. 5.

No. 1. I cannot say that manuring is general: a large number of estates manure in a small way, but few go in for systematic applications, uncertainty of the labour force is rather against this at present.

No. 2. I should say artificial manures are used to a much larger extent than bulky, in most districts. Castor-cake is the principal ingredient in most; manures, applied in the district (Dimbula.)

No. 3. Bones, Nitrate of Potash, and lime are sometimes added with good results also fish mixture.

No. 4. A deal of good is being done, in my opinion, by the application of artificial manures, especially where good tillage is gone in for, when applying; harm can only result from bad application.

No. 5. Tea manured 7 to 8 years ago compares most favourably with the unmanured, alongside of it.

A BELIEVER IN MUCK FOR TEA.

No. XXXI.

Rangalla, Jan. 5.

DEAR SIR,—In answer to your circular *re* manuring tea, I have to say.

1. Manure (Castor-cake and Bones) has been applied to a few estates in this district; the little that has been done has greatly improved the tea (mostly on land over 40 years in continuous cultivation) and on one estate doubled the yield in nine months after application.

2. Bulky manure has not been used to my knowledge, up this way; it is a thing of the past.

3. The manure used has been Castor Cake and Bones—4 parts of the former to 1 of the latter—4 ozs. to a tree or hole.

4. Decidedly not: there is no doubt the use of artificial manure has been beneficial.

5. A great difference, the manured tea looking greener and healthier, and flushing much better.—Yours faithfully,

ALL FOR CULTIVATION.

No. XXXII.

Kelebokka, Jan. 6.

I can scarcely contribute any information of any value in *re* manuring as I have never applied any manure to tea except cattle manure, coffee pulp, and lime sweepings, all of which latter are collected and carried to the manure heaps daily. We get over a good deal of ground in this way with the best results the effect of

our manuring—merely forking in, in lines, as nearly as possible parallel to the drains—lasting apparently for years.

I think all the estates in this district, (my own excepted) or very nearly all, apply Cake, Bone-dust, and Nitrates to a greater or less extent. I don't suppose much harm is being done, but cannot see where the profit comes in at present prices. Rutherford and his co-director Talbot and others agree with me, that powerful chemical manures are better avoided. PROPRIETOR.

XXXIII.

DEAR SIR,—1. Manuring is increasing; but has not yet become general either in old or new districts.

2. As a rule few cattle are now kept for manuring purposes and only small areas are manured with lime refuse and manure from bungalow and kangany's cattle, except where estates have the use of manure from road-side cattle-sheds and bazaars.

3. The manure sent up by railway is mostly used alone and Bone-dust, Castor-cake and fish in varying proportions are the principal manures used.

4. Over-doses have done harm; but artificial manure in small doses at frequent intervals, say once in two or three years, mixed in such a manner as to supply the constituents which tea removes, appears to have done much good, both in improving the bushes and the yield.

5. So far as experience goes, the oldest regularly manured tea compares very favourably with unmanured tea of the same age, and bushes manured only once and then left unmanured, have finer frames and are in better condition to respond to further manuring than the same tea never manured.

The most important and the most difficult point to ascertain is the effect of manuring on the quality of tea made.—Yours faithfully,

OYA.

No. XXXIV.

Dimbula, 7th Jan. 1897.

DEAR SIR,—(1) The manuring of tea has only been carried on to a limited extent in this district as the soil here is as a rule first-class and the yield in consequence is very satisfactory without the aid of stimulants.

(2) Bulky manure is not generally available as but few estates keep large cattle establishments.

(3) The artificial manure used is usually Castor-cake with a small addition of Bone-meal, and occasionally an admixture of fish manure, and it is generally applied in small doses along with the burial of prunings, or what bulky stuff there may be in the shape of farm-yard manure or lime sweepings, though I have seen the mixture applied solely by itself.

(4) The results are altogether beneficial in my opinion and especially so where manure has been applied to poorish looking tea as it improves the size of the bushes and increases the yield immensely. I do not think the prices suffer to any appreciable extent—at all events my experience which, however, is comparatively limited, has been the reverse.

(5) Old tea manured some 5 or 6 years ago is looking as well and doing as well as ever it did—so I have no hesitation in giving my opinion in favour of manure, bulky or artificial, but I should think twice before applying the latter to really fine fields which were yielding heavily and paying well.—Yours truly,

FARMER.

No. XXXV.

Kalutara, Jan. 6.

DEAR SIR,—In reply to your letter of 26th ultimo :—

1. As far as this District is concerned manuring is more or less general.

2. Not in this District : Bones and Castor, mixed about one bone to three castor, and varying from three oz. to 4 oz. per tree is the rule.

3. It is usually mixed in Colombo. I have not heard of much fish-manure being used here.

4. I believe in doing without manure, as long as possible without detriment to the tea, but with the race for dividends one must apply manure or fall back in yield. I am no believer in these light foreign manures, and believe they are sweating the tea out. These opinions, however, do not find favour with most people who want profits, and plenty of them.

5. Manured tea is far finer and bigger in the frame, but once manure has been started you must go on with it, say every two years, or the tea falls back again.—K. T. B.

MANURING OF TEA :

LETTERS XXIV TO XXXV REVIEWED.

THE third batch of letters on this subject are, if anything, more interesting and suggestive than their predecessors—covering, as they generally do, wider ground, and dealing with new side issues. Like the letters we had previously reviewed, they come from all parts of the country, and are written by Planters fully qualified to speak on the matters on which they dwell.

Bulky manures continue to be regarded as the great desideratum for tea by most writers; and none are able to anticipate freer use of cattle manure than at present. The manure at present in use comes from bungalow and milch cattle; and, on estates which border the high road or are situated in close proximity to it, from the bazaars and road-side cattle sheds. Cattle establishments would necessitate grass reserves; and the prevailing opinion is that land would be better utilized if planted up with tea or quick-growing fuel and timber trees. In these circumstances, artificial manures—chiefly bones and eastor-cake, as in the earlier letters—and the results of their application, form the subject of comment in most letters. The general result is satisfactory. “1897,” recognising the fact that “played-out coffee estates” account very largely for the acreage under tea, is emphatic in the opinion that, “if we wish to make ends meet, we must manure,” though he would rather avoid manuring, if possible. The same writer suggests as the explanation of the better averages which Indian teas fetch, that the estates on the neighbouring continent have been chiefly opened on virgin soil, and adopt a different system of pruning, while they do not pluck all the year round. That is a point on which more light is required; for we do not despair of better prices with greater care in plucking and manufacture. O. C.’s unpleasant experience with Kandy refuse is noteworthy; but was the “insidious defunction” of his plants due to the quality of the muck, or to its quantity? It is well known that there may be too much, even of a good thing. It is interesting to learn that careful records are kept on New Peradeniya; which is described as one of the most methodically manured estates in the Central Province, and that cattle manure comes an easy first—doubling the yield, against an increase of only one-third from the best artificial manure. That, we suppose

is explained by the character of the soil. On the other hand, “Oram” from Dik-oya, backs artificial manures for quicker returns, and superiority in every way to bulky applications. The difference in the soil under the notice of the two writers probably accounts for their apparently incompatible views; but it is satisfactory to know that the systematic application of eastor and bones for 8 or 9 years, has led to no untoward results, that the bushes look improved, that the yield has improved at least 200 lb. per acre, and that cessation of manuring for four years has not thrown the bushes back. A. F. S. from Kotmale reports more lasting effects from cattle manure, while artificial yields quicker returns; and his suggestion that where possible, the two kinds should be applied turn about, is worthy of attention. Manuring at intervals of 2 or 3 years seems to find most favour, and it is a great point that manured tea feels the effect of drought less than unmanured. The testimony of A. F. S. runs directly counter to that of “A Novice” in the second batch of letters, as he reports not only no deterioration in the quality of tea, but even a slight improvement after manuring; but surely, the dictum that it would not pay to manure fields yielding less than 250 lb. per acre, needs qualification. We should think that generally these would require special attention, unless they are hopelessly bad.

The general conclusions above-noted are supported by our correspondent from Bogawantalawa, who reports increased yield and stronger growth of wood as a result of careful application of artificial manures; by W. B. J. from Agra-patana, who distinctly denies any deterioration in quality or flavour, while the yield has been increased twofold by systematic manuring extending over 5 or 6 years; and by “A Believer in Muck for Tea” from Kotagala, and “All for Cultivation” from Rangala who, as his *nom de plume* implies, believes in naught but good from manuring. “Proprietor” from Kele-bokka, on the other hand, fails to see where the profits are to come from at present prices by the application of artificial, but he himself has obtained the best results by the use of cattle manure, line sweepings and coffee pulp regularly collected in manure heaps. “Oya” favours manuring at intervals of 2 or 3 years, and pronounces distinctly in favour of the appearance of manured fields; “Farmer” from Dimbula supports this opinion, and speaks of altogether beneficial results from manuring, “especially from poorish looking tea”—thus running counter to A. F. S.’s lack of faith—while he would think twice before applying artificial manures to really fine, well-bearing fields. K. T. B. from Kalutara counsels caution in the use of manures having a forcing tendency, in which we agree with him; but surely, it is not merely love of dividends which would take steps against a “falling back in yield.” If decreasing crops mean lessened vitality, science and true wisdom alike would suggest the supply of adequate plant food to arrest decay.

SMOKERS SHOULD USE

CALVERT'S DENTO-PHENOLENE, A FRAGRANT LIQUID DENTIFRICE AND MOUTH-WASH.

Editor of *Health* says:—“The most effective preparation for ridding the mouth of the aroma of tobacco, and leaving a pleasant taste.” Sold in 1s. 6d., 2s. 6d., and 1 lb. 7s. 6d. bottles, by Chemists, & c.

CEYLON TEA IN RUSSIA.

Jan. 6th.

DEAR SIR,—In a letter addressed to Mr. Rogivue and informing him of a grant made by the Thirty Committee towards his work in Russia, I told him the fact which had come to my notice that "certain firms in Colombo and London have made our grants to you the subject of a grievance, and say that you are thereby enabled to undersell competitors." To avoid such complaints it will be necessary for you to devote the grants in accordance with your letters of 8th May 1895 and October 1896."

To this Mr. Rogivue makes a very full reply, and I think what he says justifies the grants which have been made to him, and the confidence of the Committee.—I am, dear sir, yours faithfully,

A. W. S. SACKVILLE.

Copy.

Moscow, 20th November, 1896.

Maroseika, House Lebedieff, 2nd December.

A. W. S. Sackville, Esq., Drayton Estate, Kotagala, Dimbula, Ceylon.

My dear sir,—I beg to thank you for your letter of the 9th November, the contents of which had my careful attention.

I also have to tender my best thanks to the "Thirty Committee" for their last vote in my favour for a new grant as the "Times of Ceylon" gives it in one of its last issues for £2,000 out of which, I understand by your letter under reply a sum of £500 or about, has to be specially devoted for the lecturing and advertising tours mentioned in my letter to you of the 25th October last.

I may here inform you that previous to your sanction for the above scheme I had already started the man I selected, Mr. W. Stramberg, on his first tour through the Baltic West and partly Centre Provinces to visit about an hundred towns and villages of which the principals are Klm, Twer, Istashkow, Whisny, Wolostshoe, St. Petersburg, Gamberg, Wesenberg, Rewal, Hapsal, Weissenstems, Fellin, Darpat, Dolmar, Wenden, Riga, Mitau, Libau, Dwinnss, Deeuaburg, Wilna, Mensk, Smolensk, Vitbsk, etc. He took with him 2,500 packets of 1/32d of a pound and numerous samples of good, middling and lower quality of Ceylon tea, with a large quantity of pamphlets printed for the purpose and has instructions to distribute tea and pamphlets right and left *gratis* in whatever manner he can desire while travelling or stopping in a place, but more especially by going to principal "Tractores"—tea drinking places—ordering a Samowar and collecting as many people as he can, treating them to the tea and at the same time giving them a sort of lecture in a conversational way on the history, the merits and various advantages of Ceylon tea, pointing out to them and praising the rapid progress of consumption the article has already made in Russia and its great extension all over the world.

I hope he will do well and that this first trip will bring in good results. Mr. Stramberg will be travelling in this way for about two months and return here before Christmas when I shall let your Committee have all the details of this first tour and of its apparent result.

Now you will kindly allow me to refer to a paragraph of your letter of which I must confess, I do not understand the cause, but which appears to infer very unjust complaints about my work and has caused me considerable surprise.

I need not repeat to you that since I came in this country in 1890 for the *special* purpose of introducing Ceylon tea in Russia, I devoted all my time, my energy and labour to the cause of furthering the interests of *Ceylon, Ceylon planters, and Ceylon tea*, in preference of *my own*, for, my experience proves it, I could *in business*, have done *here* much better as a general merchant, buying and selling tea (Ceylon or other kinds) in chests and or other produce than selling *exclusively pure Ceylon tea in packets* which was *absolutely* the only method to adopt in order to spread a knowledge of, and create the demand for, Ceylon tea as I soon saw. To this I have devoted myself and left the field open to existing Moscow, London and Colombo firms to supply the *wholesale demand for tea in chests* consequent on my labours in the packet and retail branch to reach the *consumer*. Had the "Ceylon Tea Fund" given me from the time of my arrival in this country say 50 to 100 thousand pounds a year of duty-paid tea to be distributed or sold for them in Russia and paid my expenses and trouble for doing the work, I would *never* have started business here *on my own account* and would have perhaps attained quicker results. Many people in Ceylon will remember how often in the beginning of my stay in Moscow, I have asked for help in the way of consignments of tea and begged Colombo and London firms to open business *in or with Russia*; but no one came to the front, they were all afraid if not, of losing their money with me, at least to trade with a so, at the time, little known country as Russia.

My business here is the sale of *pure Ceylon tea in packets* and in this kind of trade I can say I have no or little competition because, for the present, most of the Ceylon tea, except mine, imported into Russia serves for the blending of other teas, and the few merchants all Russian firms who sell it *pure in packets*, have prices for retail and wholesale equivalent to mine. I therefore fail to understand how I can *undersell* the competition and know of no firms in London or Colombo, doing a business in packet teas in Russia whom I could compete with or undersell.

I shall not attempt here to urge that I have always utilized the funds granted to me by the "Tea Fund" and the "Thirty Committee" besides a great deal of my own money, entirely for the furtherance of the Ceylon trade generally; my reports and accounts in conjunction with results are my best advocates, the total import of Ceylon tea in Russia being now nearly eight million pounds, while my own import is not yet $\frac{1}{2}$ a million.

That I am regarded with *envy now* by firms who have tried here *lately* to start with Russia business in tea on the *order system*, I can understand, for their success like mine may not come in one or two or even more years, because such a way of business is not suited to the style and ideas of the Russian merchants. Large and smaller importers of Ceylon tea, firms *established* in Russia and there are many who now keep *stocks* of Ceylon tea, are certainly not complaining of my underselling them, on the contrary, being now forced to deal in Ceylon tea as a recognized article of Russian trade, they are very pleased with my advertisements.

I am making for Christmas a new line of advertisement, *viz.*, giving away as presents very pretty little *tea pots* with the words "*Ceylon Tea*" and instructions as to its preparation and my name as your representative printed on the sides and lids. These tea pots to the number of 5,000 will be distributed through my own magazines, and also by my agents in the Provinces,

I have been very busy of late and unable to finish my report and accounts of the Nijni Exhibition, but they will soon follow.

You can use your discretion as to publishing this letter, personally I should like it.—Believe me, dear sir, yours faithfully,
(Signed) M. ROGIVUE.

SILK CULTIVATION IN CEYLON.

Gammadua, 11th Jan.

DEAR SIR,—When writing you on this subject some months ago, I mentioned that a supply of Japanese eggs was expected. I am glad to say they have arrived in excellent order. I shall be happy to supply small quantities to owners of mulberry trees who may be willing to rear the worms. These varieties will do best in our higher districts.—Yours faithfully,

PERCY N. BRAINE.

[We wish Mr. Braine all success.—ED. T.A.]

CEYLON TEA IN AMERICA.

Drayton, Jan. 20.

DEAR SIR,—The interest of the enclosed letter from Mr. Mackenzie will, I hope, allow you to grant the space required for its publication. In the part excised he complains of a delay in the advice of further funds. This delay was caused by the routine required under the Ordinance, that "the proceeds of the said levy be subject to the approval of the Governor in Executive Council." The Committee met on December 12, passed the vote, and received the sanction required on the 30th. On the 31st December a telegraphic credit was sent, and was acknowledged by Mr. Mackenzie under date January 1st.

Considering the intervention of Christmas holidays, and probable dispersal of the Council at the time, though I regret the delay, I cannot consider it excessive.

I am in receipt from a well known firm of the enclosures. (Marked A.) They write "the teas referred to are being shipped by us. I need only add that the firm mentioned seems determined to push Ceylon tea, and think they deserve the support of the Tea Fund which Mr. Mackenzie has already given them to some extent."

I would also draw public attention to Messrs. Gow Wilson and Stanton's report (Enclosure B), and send you for your inspection a few ads, arrived by this mail, showing the extent of ground covered. Any firms, who can convince our Agents of their desire and ability to push Ceylon teas, and influence trade, are in equally favoured position as to receiving assistance. Mr. Mackenzie, with his local knowledge, can however, be trusted to discriminate, but his "allies," are constantly increasing in number.

As this will probably be the last letter which I shall address you, as Chairman, I wish to take the opportunity of thanking you for the kind way in which you have always placed your columns at my disposal, and for the useful discussions contributed for the cause of Ceylon tea. Long may it flourish.—I am, Yours faithfully,

A. W. S. SACKVILLE.

MR. MACKENZIE'S LETTER.

London, Dec. 31.

Dear Sackville,—Referring to that circular I sent you from the Boston firm you will see they say "only about 10 per cent of the tea used in the States is of the breakfast sort (that is fermented tea) while more than two-thirds of 90 per cent is green tea, the balance being Oolong; which, while black in dry leaf is only slightly fermented, and resembles more

in leaf the green tea," etc. This bears out what I have so often written as to the narrowness of the field when we compete with teas used in America. To get any footing among the green tea drinkers advertising is of no use unless we at the same time *demonstrate*, canvass, issue samples, circulars, etc. Now what Colombo house is to undertake that work? If the thing is to be left to private enterprise such work will not be done. The trade will be content with selling China and Japan teas, which need no canvassing nor advertising, and yield more profit. Messrs. ——— and many others, now stimulated by us to push machine-made teas, would, if we stopped now, gradually glide into the trade they found most profitable and least expensive.

Colombo Houses, whatever they may think, would not benefit, and planters would find a really promising field (up to 15,000,000 lb. in two years, I believe) lost to them. To stop at present would be suicidal. After June the matter may be again considered. — one of our best allies came over to New York, when I was there last, to decide whether his firm should withdraw entirely from America. As you know it was due to our aid that they persevered so long. He told me three weeks ago it would be decided when he returned and reported to his partners, but that the decision would depend on what the Committee did. . . .

I enclose two of the Committee's advertisements also circulars which are worth studying. I send 4 advertisements showing that "Salada" Ceylon tea is being vigorously pushed there. These advertisements are from 4 different firms. All this is due to the inducement I gave to—push teas in Buffalo. Can private enterprise shew anything of this sort?

I also send a paper containing a picture and advertisement of the large new store in New York, where so many firms were demonstrating our tea.

In their store in Chicago I found 4 Ceylon tea stalls, where different allies of ours were exhibiting their teas, and giving away cups, samples, directions for making, etc. You will notice a picture of the Ceylon branch in the corner. In Boston, Toronto, Buffalo, Detroit, Chicago, Pittsburg and Philadelphia I found our friends pushing direct to the consumer in many ways. In Philadelphia I found Miss Parkinson, the Ceylon lady I sent out to our best American allies, running an immense exhibit in a food store, with fourteen girls assisting her. It was the first thing of the kind I have seen in America. Hundreds tasted the teas daily, were shewn how to make them, were given samples, and large quantities of packets were being sold. The ubiquitous Tetley had a booth also. Our Pittsburg advertising and assistance has made 5 wholesale firms advertise our teas there, and they can be bought in about 600 shops in Pittsburg, Alleghany (separated only by the river) Homestead, and other suburbs. How many years would it take private enterprise in Colomboto do this?

Private enterprise executes orders, but with the exception of—no Colombo merchant does any more.

There was such a great rise in shipments to "other countries" last year of both Ceylons and Indians, that no rise was anticipated this year, but it is believed the figures will shew

1894	1895	1896.
28	38	42 millions of lbs.

It is difficult to get American figures; but I anticipate no rise in imports, although a great increase in *consumption*. Large stocks were on hand at the beginning of the year, then the Presidential election damped energy, and no new article had any chance. But during the last quarter shipments were very large. In fact there has been a rush of orders from the States and Canada, many of which have not yet been executed.

I think it will be found that London shipments of Indian teas to America were nearly as large in November as during the previous six months.—Yours truly,

(Signed) WM. MACKENZIE.

A. W. S. Sackville, Esq.,
Chairman, Thirty Committee.

The enclosures "A" are copies of circulars issued by Messrs. Franklin MacVeagh & Co., on behalf of "Naban Unfermented Ceylon Tea" as "the finest and most delicious tea ever offered to lovers of choice teas."

The enclosure "B" readers are already familiar with being Messrs. Gow, Wilson and Stanton's circular which we issued as a Supplement on Tuesday.

The advertisements are copies of attractive notices extolling our staple product, one having a coloured picture of a native boy gathering tea leaf.

RHEA.

London, E.C.

SIR,—I have from time to time noticed interesting and valuable correspondence in the Press concerning the above fibre and my attention has been specially drawn to recent correspondence on the subject in the *Ceylon Observer*. The success of this unrivalled Fibre has been greatly retarded by a simple but all-important matter. Kindly grant me a little space for the purpose of clearly putting the present position before your readers.

There has long been a link missing in the commercial chain between the rhea grower and the manufacturer, hence the troubles and difficulties experienced for many years in introducing the Fibre. The grower has produced an article called "Ribbons;" which the purchaser has not been able to utilise practically; consequently both have been discouraged: the former because his product has neither obtained nor merited the commercial classification in the fibre market necessary for ensuring profit on the growth, and the latter because he has not seen his way to invest the necessary capital in new machinery for manufacturing a fibre offered him in a form that as a practical man he cannot accept and the supplies of which have heretofore been very irregular, both in quality and quantity.

Ribbons are the stems of the plant freed from most of the internal woody pith. They contain the coagulated juice of the stem, called "gum," some of the woody pith and all the outer cuticle or pellicule, which has for years been the despair of the machine maker and the chemist. When dry it assumes a brown colour and adheres to the fibre by a peculiarly tenacious gum, insoluble except under very severe chemical treatment.

The position viewed commercially, may be stated as follows —

The Ribbons contain an enormous percentage of useless material, very difficult to eliminate in the dry state and on which freight and carriage have to be paid. Furthermore they cannot be properly compressed into bales suitable for cheap transport to this country, as the cubic measurement is out of all proportion to the weight.

Fibre Brokers, experts in the classification and valuation of Fibres, have not been able to classify ribbons and give them a practical market quotation for the simple reason that they represent an unknown quantity, it being impossible to know by ordinary tests what percentage of Fibre they contain what loss of weight will result through subsequent treatment, nor of what quality the Fibre will ultimately prove to be, as regards strength, length, lustre, ductility, etc.

A moment's reflection will show that the link so long missing must be a machine capable of extracting the clean fibre direct from the green Rhea stems and removing every particle of wood, the great bulk of the gum, and the outer cuticle, so obstinate when dry.

The Link is no longer missing. A French Engineer has produced a Machine which, in the opinion of Experts places the Rhea Fibre question on an absolutely new footing and ensures the commercial success of this magnificent Fibre. By means of this Machine the natives on the Plantations are able *by one operation* to transform the green stems into clean fibre, which when dry can be packed under great pressure into bales, in the same way that Manilla, Sisal Hemp and other

fibres are packed, and forwarded to the Manufacturer at a very small cost for freight, carriage, etc.

The practical result of the new Machine is that the fibre it produces obtains a proper classification and price quotations in the market, Mr. Faure has important machine making works, large means, is an experienced scientific engineer and grows Rhea on his own estate. His first machine produced Ribbons and gained the gold medal at Paris in 1889, Great success has crowned his efforts. His two crops of Rhea in July and October were decorticated by the new machines in the presence of many experts in this fibre. The results were marvellous. I send you a post sample of the fibre just as it left the machine. Chemical inventors have had to face a very difficult problem in endeavouring to deal with rhea ribbons containing a considerable amount of woody particles and of coagulated juice called "gum" and especially the dreaded outer skin or cuticle. The greatest evil in connection with many of the degumming processes in the after effect of the chemical treatment on the fibre itself. Rhea fibre has five leading qualities—enormous strength—splendid lustre—extreme fineness—great ductility and wonderful adaptability for taking and retaining colours. All these qualities are liable to be very injuriously attacked by the action of the chemicals employed in the majority of degumming processes. Many cases have occurred where the damage has developed only after some months, when the goods manufactured from rhea have been found to be rotten, or the lustre quite gone. Now that ribbons are doomed to disappear and the actual rhea fibre takes their place, the degumming part of the business assumes an entirely different aspect, because the fibre needs only to be freed from the little gum that is left in it, which can be done, either in India or Europe at a very cheap rate by a simple process, absolutely independent of all patents. The fibre can be degummed in 2½ hours at a cost of less than £3 per ton. In this matter I am not giving my opinion, but stating facts, based on practical working in France. The question of the cultivation of rhea in India is thus completely metamorphosed. Practical machines can be bought at a moderate price (£36) to extract the rhea fibre from the stems in one operation on the plantations. This fibre when dry can be packed in bales and forwarded to the European markets, where it at once obtains a classification and can be sold at a very remunerative price. Contracts can easily be made for immense quantities of fibre, seeing that the grower is now sure of his production of fibre and the Manufacturer can be equally assured of his supply of raw material.—Your obedient servant,

MANUFACTURER.

[If the machine is capable of accomplishing all that is claimed for it and if it is once made clear that the indigenous plant in Northern Bengal is not likely to swamp markets and prices, those who have already gone in for its culture in Ceylon might extend the area of rhea with advantage.—ED. T. I.]

USEFUL PLANTS AGAINST MALARIA AND INSECT PESTS.

DEAR SIR,—It is a known fact that there are many members of the Vegetable Kingdom (trees, plants, shrubs, orchids, and parasites,) some indigenous to Ceylon, possessing properties which enable them to ward off malaria and absorb noxious gases, detrimental to animal life. Yet how many of them are known? How many utilized? A common plant known to the Sinhalese as *Maduru Tala* and to Botanists as the *Ocimum Sanctum*, so named from its being found in the precincts of almost every Hindu and Buddhist temple in Ceylon and India is well known either from its inhaling or exhaling powers, to effectually keep away malaria, and although (speaking for ourselves) so many hotbeds of fever of different types, exist in our midst, has this humble plant been even given a trial?

The leaves of this plant have a strong aromatic smell, which the Sinhalese assert is noxious to the *Madura* or *Mosquito*, and they hang clusters of branches over their sleeping places, in order to rid themselves of these nocturnal pests.

Plants of the *Madurutala* are easily procurable and could be successfully grown in pots.—Yours truly,
HOUSEHOLDER.

MAURITIUS GRASS: THE GREAT FODDER PLANT.

SIR,—During the past few years the cultivation of Mauritius or water grass (*Panicum Molle*) has immensely increased, every available space has been taken advantage of. Cinnamon has been uprooted and large tracts of ground which were before entirely reserved for the spicy shrub, are fast disappearing, to make room for the great fodder plant which sustains our equine and bovine stock. Yet the demand for grass is not equal to the supply and resort has to be had to imported hay and chaff. Besides the regular daily supply to houses in the town and its suburbs, numerous carts heavily laden with grass, wend their way every evening to the Municipal and other markets, in the Pettah, Slave Island, Kollupitiya, Grandpass, &c., where a brisk trade is carried on. Each bundle is priced at 3 cents, and before nightfall almost every bundle is sold; these sales are almost entirely confined to the natives who own and hire carts and hackeries. Apart from the sale of this (imported variety) grass, there is a fairly large quantity of country grass or *Kattu millu* supplied for the consumption of horses; this trade is exclusively in the hands of the town Menatchies, who thus materially supplement the monthly wage of the town Ramasamies—(their husbands).—Yours truly,
HOUSEHOLDER.

COFFEE AND TEA IN SOUTHERN INDIA.—The following is an extract from *Planting Opinion*, Jan. 23:—

On the Nelliampatties, we note the average yield of coffee is said to be about 3 cwt. per acre, while on the Lower Pulnics the yield runs out to slightly under 2 cwt. per acre, though it must be noted that almost half of the individual returns in this case are marked as "uncertain, probably considerably underestimated." In Central Travancore the average works out to a little over 1½ cwt. per acre. No figures are given for the other districts. The only figures relating to tea yields are from Travancore. The Central District, with a probable yield of slightly under 11.5 million pounds, averages 390 lb. per acre for tea over two years; and South Travancore shows a yield of 360 lb. per acre, or say about 2 million pounds. We assume the total plantation area to be about 650,000 acres, of which 324,540 are cultivated, with coffee (300,900), tea (18,000), and cinchona (6,500). We estimate Mysore at 143,030 acres of coffee, Coorg at 84,000, Nilgiris and Wynaad at 48,000, Shovaroys at 11,000, Travancore at 6,000, Nelliampatties at 5,000 and the Pulnics at 3,000. Of the 18,000 acres of tea we have reckoned that Travancore has about 10,000 acres, the Nilgiris 6,500 and the Wynaad about 1,500 (the figures for the latter district will probably be 3,000 acres at least by the end of the next planting season).

How can there possibly be 300,000 acres kept up under coffee and a total annual export of less than 300,000 cwt. of coffee!

DEAFNESS. An essay describing a really genuine Cure for Deafness, Ringing in Ears, &c., no matter how severe or long-standing, will be sent post free.—Artificial Ear-drums and similar appliances entirely superseded. Address THOMAS KEMPE, VICTORIA CHAMBERS, 19, SOUTHAMPTON BUILDINGS, HOLBORN, LONDON.

TEA IN MATALE: A BIG YIELD.

Mr. H. Storey has supplied a contemporary with the following figures showing the yield on Warakamure Estate, Matale for a series of years. No manure has been used, and Mr. Storey says, the figures he quotes have been equalled if not exceeded by neighbours:—

Warakamure Estate, Matale, 23rd Jan., 1897.

Year.	Acreage.	Total crop.	Yield per acre.	Rainfall.
1892 ..	73	52,225	715	76 inches.
1893 ..	194	134,966	695	59 "
1894 ..	194	136,310	702	61 "
1895 ..	194	157,552	812	87 "
1896 ..	198	196,681	993	104 "

The year 1894 was characterised by a heavy drought in January, February and March, of 68 days' duration. 1893, though showing a smaller total, had a better distribution.

INDIAN TEA SALES.

(From *William Moran & Co.'s Market Report*.)

CALCUTTA, Jan. 27.

The sale of the 21st inst. comprised 11,497 chests, all of which were sold. There was no material change to note in prices. For this week's sale about 10,000 chests are advertised.

Reuter's Telegrams, received since our last report are as follows:—

INDIAN TEA:—

January 21st—Auctions.—“Offered 59,000 packages. Sold 49,000 packages. Firm with a good demand. Average price, 9½d.”

CEYLON TEA.—

January 21st—Auctions.—“Offered 23,000 packages. Sold 22,000 packages. Firm. Pekoe souchoug, 6d. Average price 8½d.”

Total quantity of Tea passed through Calcutta from 1st April to 25th Jan.

	1896-97.	1895-96.	1894-95.
Great Britain	127,491,724	116,189,865	109,371,426
Foreign Europe	420,358	271,085	240,144
America	1,825,853	1,071,664	548,460
Asia	4,014,985	4,277,740	3,598,401
Australia	5,573,055	6,380,521	4,692,213
	139,325,975	128,190,875	118,450,644

TEA IN CEYLON:—THE YIELD OF THE SCRUBS ESTATE.—Everybody is acquainted with the Scrubs estate. No one can enter or leave Nuwara Eliya without noticing how vigorous its tea appears, and how complete a cover it forms on the steep hill side. Situated at nearly 7,000 feet elevation, the yield per acre is a great deal higher than the average of any district in the island, and higher than that of most estates in the lowcountry. The following figures speak for themselves:—

YIELD OF THE SCRUBS ESTATE.

1894	..	507 lb. per acre.
1895	..	671 " "
1896	..	667 " "

We do not think we are far wrong in saying that this yield on an estate at the great altitude of the Scrubs, and without the aid of manure is more remarkable than even the yield from the 101-acre field in Mariawatte, seeing that the latter can be matched in India, we believe, but we do not know of any estate at 7,000 feet in India, or elsewhere, giving the fine field which the Scrubs estate is doing. We may add that the average yield for the nineteen estates belonging to the Ceylon Tea Plantations Co. for 1896 was 470 lb. per acre.—Local "Times."

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From Lewis & Peal's Fortnightly Prices Current, London, January 19th, 1897.)

THE AGRICULTURAL MAGAZINE, COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for February:—

Vol. VIII.]

FEBRUARY, 1897.

[No. 8.

SEASON REPORT FOR DECEMBER.

WESTERN PROVINCE.—Maha paddy in blossom or in ear, fair supply of fruits and vegetables in the Colombo district, but scarce in Negombo and Kalutara. Rainfall generally above the average.

Harvest prospects fair.

Central Province.—Paddy crop in various stages, much damage done by rain in the Matale district, prospects good in the Kandy district, very promising in the Nuwara Eliya district. Rainfall above normal. Health of cattle good, some hoof disease in Laggala.

Northern Province.—In the Mannar district the rainfall was unprecedented, in Mannar town rainfall 19.05 in. Paddy and dry grain in ear, what was not washed away in good condition.

Southern Province.—Ploughing and sowing for Maha crop going on in Hambantota district, vegetables plentiful, and food supply sufficient. Health of cattle good, some hoof disease in Walasmulla.

Eastern Province.—Munmari crop much damaged by rain; Indian corn, kurakkan and tobacco also damaged. Rainfall in Batticaloa, 19.18 in., in Trincomalee, 27.58 in. A gale on the 15th caused much damage, many houses and over 700 coconut trees having been blown down.

North-Western Province.—Though much damage caused by rain, generally speaking prospects fair. Rainfall in Puttalam, 11.55 in. The excessive rain has done most damage in the Chilaw district.

Province of Uva.—Heavy rain all throughout the Province, harvests prospects in Wiyaluwa good, health of cattle good.

Province of Sabaragamuwa.—In many parts of the Ratnapura district, Maha crops coming into maturity, in Kolonna Korale fields just being prepared. Lowlying fields have suffered on account of too much rain. In the Kegalla district, paddy prospects are good in spite of some damage by rain. Dry grain prospects satisfactory. Health of cattle good.

RAINFALL TAKEN AT THE SCHOOL OF AGRICULTURE DURING THE MONTH OF DECEMBER, 1896.

Greatest amount of rainfall in any 24 hours—
on the 24th day of December, 2.40 inches.

Recorded by A. R. JEREMIAH.

OCCASIONAL NOTES.

Errata.—In record of rainfall for November given in our last issue, for 1.6 given on the 20th of the month read .16, the mean rainfall should be .67 in.

The present issue deals largely with the subject of cattle-plague, containing both local and foreign contributions with reference to the scourge. Its terrible ravages in South Africa have no doubt been the cause of bringing it to the notice of the great German bacteriologist, Dr. Koch, as well as, it is said, of the Royal Society. We can but hope that some good will come of the fresh enquiries as to the possible preventive measures (for treatment of any sort is said to be "playing with fire") against a disease which causes so much loss in the villages of Ceylon.

The present number brings to a close the account of "Nitragin" or "Pure Cultivation Bacteria" for the inoculation of leguminous crops. The account has run through several issues, but we doubt not that many of our readers have been glad of the opportunity of becoming thoroughly acquainted with a subject which refers to an important discovery in Agricultural Science, that has been much written about and discussed in Agricultural Journals, and may possibly come to be intimately connected with the everyday *practice* of agriculture. We may mention that we have placed ourselves in communication with the manufacturers of "Nitragin" at Höchst-on-the-Main, who have kindly replied to our enquiries through their local agents, Messrs. Böhringer. As yet, however, there are but few purely tropical leguminous plants for which the special innoculating material has been prepared, but we hope before long to receive some samples of nitragin for trial on such introduced plants as we grow here.

The Colonial Veterinary Surgeon, Mr. G. W. Sturgess, returned from Karachi on the 19th January, bringing with him 25 well-selected cows for the Government Dairy; and Mr. Hoole, who was doing duty for Mr. Sturgess, in Colombo, has gone back to Anuradhapura. At the end of January, the dairy herd, after having been augmented by the new additions, was constituted as follows:—96 cows, 7 bulls, and 52 calves, bringing up the total of all classes of animals to 155.

Writing under date of 24th December last, the Secretary of "Jadoo Limited" advises us that he is shipping us $\frac{1}{2}$ ton of the fibre packed in 10 bales. He goes on to say that from numerous reports which have reached the Company there can be no doubt that Jadoo is eminently suitable for bringing on supplies, and the matter being of such public interest is their excuse for "troubling" us with a consignment for distribution. Jadoo, he remarks, is in no sense a *forcing* medium, its effect being to encourage *fibrous root* action, and thus to form a strong healthy plant. It is said to have been severely tested in France for "growing on" young vines, and its great value for this purpose may be judged from the facts that the Company is selling many tons to wine growers at Cognac and in the Médoc. We can assure the Company that we do not consider ourselves troubled by

them, as we are most anxious to test the value of Jadoo fibre, and afford our readers an opportunity of giving it a trial. We shall, therefore, be glad to forward samples on application, and also send copies of a circular of instructions which have been supplied us.

We are glad to find that the editor of the "Ceylon Forester" has determined to continue the publication of the Magazine, and we heartily wish it all success in the future.

The experiment in the cultivation of Agriculture has come to an end. We should like to make this fact public owing to the numerous enquiries we are receiving with reference to grape growing. The termination of the experiment we should state is not due to failure, (for indeed it was very promising as long as the vineyard was attended to). It is a matter of disappointment to us, as well as to many interested in vine-growing that the experiment could not have been carried on till the vines came into full bearing; but it is at the same time satisfactory to know that the trial at the school has made more than one person venture upon vine-growing. In the case of a "new product" like this the Ceylon Government might well imitate the example of some of the Australian Colonies and offer an annual *bonus* for every acre of vines maintained in an efficient condition during the year, so as to encourage the new industry.

THE FOREST LAWS OF CEYLON.

(Continued).

VILLAGE FORESTS.

The Governor may by Proclamation in the *Gazette* constitute a portion of forest a village-forest for the benefit of any village community or group of village-communities. (§ 34.)

The rights of any person in or over any village forest was not affected, but power is given to the Governor to direct that claims to any such rights, other than the rights of the village-community or group of village-communities should be inquired into, recorded and provided for in the manner prescribed for settling a Reserved Forest. (§ 37.)

Rules may be made for the management of village-forests, prescribing the conditions under which the community or group of communities for the benefit of which such forest is constituted may be provided with timber or other forest-produce, or with pasture, and what duties the village has for its protection and improvement.

The Government is thus left with a wide discretion either to assume the management itself or partly manage it; or keep its management under control and supervision. The chapter on Village Forests in the Ordinance is so worded that any land which is at the disposal of the Crown may be made a village forest; rights already existing in favour of the village would be no obstacle, and a settlement of rights, where necessary, can be ordered under the usual procedure. Such settlement may be made in the interest of the village, either with reference to rights *other* than those of the village, or with reference to cer-

tain rights of individual villagers which are adverse to the interest of a body as a whole as may be necessary.

The Government have published certain Regulations under section 36 of the Ordinance regarding Village Forests. (Notif. 24, Ap. *Gazette*, May 1, 1896.)

OF THE PROTECTION OF FORESTS AND FOREST-PRODUCE.

Chapter IV. of the Ordinance deals with the Government control over forests in certain cases.

Unless it is essentially necessary that it should be so, as in the case of constituting Reserved Forests, Government are content to keep the forests in their present state, and it is often found sufficient to prevent their being totally cleared off and cut down, without expropriating the whole estate.

As you are aware it is essential to preserve forests in order to increase the rainfall, and in addition to this there are other reasons which make the interference of the Crown a valid ground in law. The Governor is therefore empowered by Notification in the *Government Gazette* to declare that any tree in any forest is a reserved tree. The Ordinance itself (Schedule B.) enumerates certain trees which shall be deemed to be reserved trees. And power is given to the Government Agent to make rules in certain cases whereby persons are authorised to deal with the reserved trees, and authority is also given to a Forest Officer under the authority of the G. A. to grant permission to deal with the reserved trees.

Under section 41 of the Ordinance no person shall clear, set fire to or break up the soil of or make use of the pasturage or of the forest produce of any forest and not included in a reserved or village forest except in accordance with rules which the G.A. may make, subject to the approval of the Governor with the advice of the Executive Council. Such rules may :

- (a) Regulate or prohibit the cutting of or setting fire to chenas or the issue of grants or leases by Government with respect to land on which trees enumerated in schedule B. of the Ordinance are growing ;
- (b) Regulate or prohibit the kindling of fires and prescribe the precautions to be taken to prevent the spreading of fires ;
- (c) Regulate or prohibit the cutting, sawing, conversion and removal of trees and timber and the collection and removal of forest-produce ;
- (d) Regulate or prohibit the building of houses or huts, the quarrying of stone or coral, or the digging for plumbago or gems, or the burning of lime or charcoal ;
- (e) Regulate or prohibit the cutting of grass and the pasturing of cattle, and regulate the payments (if any) to be made for such cutting or pasturing ;
- (f) Regulate or prohibit hunting, shooting, fishing, poisoning water, and setting traps or snares or guns ; or the use of explosives ;
- (g) Regulate the sale or free grant of timber or other forest produce ; and
- (h) Prescribe, or authorize any forest officer to prescribe, subject to the sanction of the Governor, the fees, royalties, or other payments of such timber or other forest-produce, and the manner in which such fees, royalties or other payments shall be levied, whether in transit, or partly in transit or otherwise.

The Ordinance enacts that nothing in this section should affect any existing rights of any person in or over pasturage. A breach of any of the provisions of or regulations or rules made under this Chapter is punishable with a fine of R100 or 6 months' imprisonment. But nothing is an infringement of any rule if done with the permission in writing of G.A. or A.G.A.

It has been held that rules made under section 40 of the Ordinance by the G.A. should be proved in a prosecution for a breach of rules (P.C., Awisawella, 7530, 9 S.C.C.-60.) Per Burnside C.J. :—" The rules which the G.A. may make under section 40 of Chapter IV. in question do not require the approval of the Governor with the advice of the Executive Council in the same way as rules made under section 41 do, and not being made or approved by the Governor with the advice of the Executive Council, they do not have the force of law by being published in the *Government Gazette* as mentioned in Sec. 81."

Therefore, following the above decision, in a prosecution for breach of any of the rules made under section 41, the rules themselves need not be proved, inasmuch as such rules require the approval of the Governor in Executive Council, and after publication in the *Government Gazette* have the force of law.

COLLECTION OF DRIFT, STRANDED AND OTHER TIMBER.

Chapter VI. of the Ordinance No. 10 of 1885 as amended by 16 of 1892 deals with the above kinds of timber, and declares that all unclaimed timber found adrift, beached, stranded or sunk ; all timber bearing marks which have not been registered under regulations made under section 44 ; all timber which has been supermarked, or on which the marks have been obliterated, altered or defaced by fire or otherwise, and in such areas as the Governor directs, all unmarked or unstamped timber shall be deemed to be the property of the Crown, unless and until any person establishes his right thereto.

Public notice of the collection of timber must be given by a forest officer, and such notice must contain a description of the timber, and any person claiming the same, must within one month from the date of the notice present to the forest officer a written statement of such claim. The forest officer is empowered, after making such inquiry as he thinks fit, either to reject the claim or deliver the timber to the claimant. If there be more claimants than one, the forest officer either delivers the timber to the person whom he deems entitled thereto, or may refer the claimants to a Civil Court and retain the timber pending the receipt of an order from such court for its disposal. Any person whose claim has been rejected may within one month from the date of such rejection institute a suit to recover possession of the timber claimed by him. Compensation against the Crown or the Forest Officer on account of any rejection or detention or removal of any timber, or delivery thereof to any person, cannot be claimed. If no statement is presented as above set forth, or if the statement has been presented and the claim has been rejected and the claimant omits to bring an action within one month to recover possession of such timber, the ownership of such timber vests in the Crown free from all incumbrances ; or, when such timber has been delivered to another person, in such other person free from all incumbrances not created by him.

Before the claimant can recover possession of any timber collected or delivered, he must pay to the forest officer or other person entitled to receive it, such sum as may be due for collecting, moving, storing and disposing of the same.

PECULIARITIES OF COCONUT CULTIVATION IN INDIA.

III.—MYSORE (*contd.*)

Every year the garden is cultivated with ragi (S. Kurakkan) and other field crops the soil is fitted for, and is well manured with cattle dung. At the same time four loads of red mud are laid on the garden for every tree that it contains, while a little fresh earth is gathered up towards the roots of the palms. The crop of grain is but poor, and injures the palms; it is always taken, however, as in order to keep down the weeds, the ground must at any rate be ploughed, the manure must be given, and no rent is paid for the grain.

On this kind of ground the coconut palm begins to bear in 12 or 13 years, and continues in perfection about 60 years. It dies altogether after bearing for about 100 years. They are always allowed to die, and when they begin to decay a young one is planted near the old one to supply its place.

In Mysore toddy is never extracted from the palm, for that operation destroys the fruit. Some of the young nuts are plucked in the hot season for the refreshing water which they contain, and to make coir-rope, but this is considered to injure the crop. The coir made from ripe nuts is considered to be very bad, and the husks are generally burnt for fuel.

The crop begins in the second month after the summer solstice and goes on for 4 months. A bunch is known to be ripe when a nut falls down, and it is then cut. Each palm produces from 3 to 6 bunches which ripen successively. A middling palm produces from 60 to 70 nuts. As the nuts are gathered they are collected in small huts raised from the ground on posts. When any one purchases them they are husked at the expense of the purchaser. The man who husks the nuts also breaks the shell by giving each a single blow with a crooked knife, leaving the kernel intact. The kernel in this form is called *koppari*, and is now ready for the market. A man can daily clean 1,300 nuts. From 20 to 30 per cent of them are found to be rotten.

IV.—NICOBAR ISLANDS.

On these Islands the palm is very abundant, although it exists only under recent cultivation on the Andaman Islands, but re-appears still further north on the Cocos Islands. Sir W. W. Hunter gives an interesting account of the Nicobar trade in coconuts, which may here be quoted: "At present the principal products of these Islands is the coconut palm, and its ripe nuts form the chief exports. The Northern Islands are said to yield annually ten million coconuts, of which about half are exported. The estimated number exported in 1881-82 was 4,750,000. As this important product is six times cheaper here than in the coast of Bengal, or in the Straits of Malacca, the number of English and

Malay vessels that come to the Nicobars is every year increasing. The trade in coconuts is carried on chiefly by native craft from Burma, the Straits Settlements, Ceylon, &c. Forty vessels of an aggregate tonnage of 6,270 tons visited the Islands for coconuts in 1881-82." The Administration Reports for 1885-86 gives the exports as 4,510,000 nuts, and 5,730 bags of copra. In that year 49 vessels with an aggregate tonnage of 8,218 tons, obtained permission to trade with the Nicobars for coconuts, &c. The same report states that there are now 112,000 coconut palms under cultivation at Port Blair.

V.—BURMA.

Of Burma it is reported that the coconut is "largely cultivated and might be much more so in many places along the Arakan Coast as it is in Ceylon, and as doubtless it would be but for the sparseness of the population, the difficulties of approaching the coast except at a few spots, and the absence of the means of land communication between the ports and the sites fitted for the production of the trees."

In the Bassein district of Pegu it has been stated that there are 10,000 acres under coconuts.

VI.—BENGAL.

In Bengal, while the palm is plentiful along the lower Gangetic basin, it exists only in garden cultivation, and the produce is not much in excess of the total demand. There are no large plantations such as have been described in Madras, Mysore and Bombay, because in Bengal the date palm is used as the source of toddy. It is, however, fairly abundant in Noakkally, Backerganj, Jessore and the 24-Paragannas.

Further North (in Upper India) the coconut is not cultivated at all.

CATTLE.

We read in the *Agricultural Journal* of the Cape that hyposulphite of soda is the best agent for getting sulphur into cattle. It has no bad taste or smell, and it can be conveniently used for saturating the system of an animal and rendering it obnoxious to ticks. For external treatment the common lime and sulphur dip made by boiling will be the best against ticks and the damage caused by their bite. But for internal use the hyposulphite of soda which is a form in which this soluble sulphur can always be had at a low price, will recommend itself to stockowners. It can be given as a drench—three ounces to the quart of water; or it can be dissolved in the water which cattle drink when it will be inimical to all parasitic worms as well. Considering how great a trouble ticks are to cattle-breeders in Ceylon, the remedy recommended above is well worth a trial, being cheap and easily administered.

An American correspondent to the *Pastoralists' Review* referring to the tick pest says that internal treatment with sulphur is the only sure cure. "Dipping," he says, "may kill all the pests on a cow, but how about those which are waiting their turn. You will have

to dip her for every fresh lot of ticks, and it will become a case of 'and last of all the cow died also,' and she will have cost you more than her hide and your trouble are worth twice over."

The largest official record of a Holstein cow was that given by "De Kol 2nd." This cow produced in one week 536 $\frac{3}{4}$ lbs. of milk, which made by the Badcock test 26 $\frac{1}{4}$ lbs. of butter, containing 80 per cent. fat. The largest yield in one day was 83 $\frac{1}{4}$ lbs. of milk, producing 4 $\frac{1}{4}$ lbs. of butter.

Another common trouble with us is what is commonly spoken of as "worm complaint" in calves, generally causing a diarrhoea which weakens the young animals to such an extent that nothing will help to bring back their strength. Veterinary Surgeon Crawhurst, a Government Veterinary Surgeon of the Cape, recommends the following treatment:—Give half a drachm of sulphate of iron twice or three times a day with food, and after continuing this treatment for 3 days, give one dessert spoonful of turpentine in 4 oz. of castor or raw linseed oil.

Professor Koch, the well-known German Scientist, is making a study of rinderpest in connection with the outbreak of the plague in South Africa. We also learn from a communication in *Nature* that the Royal Society is likely to take up the question of the cattle plague.

The following extract from the *Mark Lane Express* of Nov. 9th while giving some statistics with reference to animal diseases in England, also shows us how they stamp out or prevent the spread of these disease there:—

The weekly report in the *Mark Lane Express* of November 9th states:—"That the number of cases of rabies during the 44 past weeks of the year were, in dogs, 406, and in other animals 226, swine fever 4,689 outbreaks and 70,391 infected slaughtered. There have been during the year 2 cases of imported cattle suffering from lung-sickness, which disease was promptly stamped out by the slaughter of the diseased cattle and 183 more which had been exposed to infection."

In a paper read by the Russian Minister of State Domains before the French National Agricultural Society of France in October last, we find it stated that the Prince of Oldenburg who devoted a large sum of money to the founding of the St. Petersburg Bacteriological Institute had "brought forward a new discovery—that of the bacillus of cattle plague, which up to the present had evaded discovery." It will be remembered that early last year the same discovery was announced by Dr. Simpson, the Health Officer of Calcutta, and the fact recorded in our pages. It still, however, remains to be seen which of the discoverers of the bacillus will be the first to prepare a preventive vaccine for the disease.

Professor Henry of the Wisconsin Experimental Station writes as follows in recommendation of pumpkins for milch cattle:—

"The pumpkin is a splendid feed for dairy cows in the fall, and our dairy farmers cannot use them too liberally. The dairy cow likes variety, and pumpkins can be grown so easily, and yield so well when planted by themselves, that a prudent dairyman will not forget this useful adjunct to his usually rather short list of feeding stuffs. The pumpkin containing much nourishment and being very palatable, tends to produce a large flow of milk. The seeds of the pumpkin are said to increase the action of the kidneys, and I think the statement entirely reasonable. It is well therefore, in feeding pumpkins in quantity, to rid them first of seeds, which can be done easily and rapidly."

A writer to the *American Breeder* writes in high praise of rape as a fodder for stock:—"I think rape a grand crop for sheep and profitable for cattle, either as pasture or soiling." As containing a larger percentage of sulphur than most fodder crops, rape is highly recommended, together with other cruciferous crops, as a healthy diet for stock.

NITRAGIN OR THE USE OF PURE CULTIVATION BACTERIA FOR LEGUMINOUS CROPS.

While every one interested in Agriculture, and in Agricultural Science in particular, must feel that a great advance has been made in our knowledge of the hitherto unexplained and peculiar action of leguminous field crops, and must conclude that the matter is one that ought to be put to a trial, yet the need must be very apparent of thorough experimentation before one can absolutely come to a decision as to the practical value of the discovery.

It behoves every agriculturist, therefore, to put the discovery to the test, and should it prove successful to avail himself of its advantages.

In England some experiments have been begun at the Woburn Experimental Farm with "Nitragin" brought over by Dr. Voelcker on a variety of crops. Some members of the Council of the Royal Agricultural Society have also commenced a trial upon one or other field crop.

If the atmosphere can be brought under contribution not only to supply the means for leguminous crops to grow luxuriantly, but also to supply the fertilizing ingredients required either to the succeeding annual crop or to a contemporaneous perennial crop, then it must be far better to grow a leguminous nitrogen-collecting than a non-leguminous non-nitrogen collecting one.

Nor can this be a matter of indifference, for it must be admitted that farmyard manure is expensive to produce and conserve in the most approved way, that it is difficult and often expensive to procure in good condition, and that, owing to its bulk, it is costly to transport, so that it is quite worthy of consideration whether it might not be, in some cases, at least, economically replaced by the growing of leguminous green crops either for feeding-off or ploughing-in.

The following are among the advantages claimed for nitragin when used as directed:—

1. That every single seed is surrounded with a covering of bacteria, which, after germination, penetrate into the root hairs and begin their activity in collecting nitrogen, so that without nitrogenous manuring and even in soils poor in nitrogen a good yield is assured.

2. That through the activity of the bacteria the soil becomes richer in assimilable nitrogen which goes to benefit the succeeding crop also.

3. That the disadvantages of the method hitherto adopted of necessity, of inoculating with earth obtained from a field are avoided.

4. That a manuring with nitrogen in the form of nitrates, ammonia salts, &c., is rendered superfluous.

The experiments of Dr. Nobbe and others certainly offer strong evidence in favour of these conclusions. The practical question, however, that it seems to us we have to take into account is whether, as a matter of agricultural experience, we do find soils under ordinary cultivation in which there is a deficiency of the organisms which are required for the proper development of ordinary leguminous crops, and which enable them to assimilate the nitrogen of the atmosphere; and whether in consequence of such deficiency in quantity, or absence of those kinds most favourable to the development of the particular crop, we should obtain a better yield of the leguminous crop, and at the same time lay up a larger store of nitrogenous food for the succeeding or contemporaneous one, if we were to inoculate the seed or the land in the way proposed. These are questions which can only be answered by practical trial.

Certain, however, it is that difficulty is not infrequently experienced in the raising of a healthy growth of leguminous crops, particularly in succession on the same land, and sometimes in different parts of a tolerably limited area.

The main point appears to be whether it may not be wise to ensure, by means of such inoculation, that the organisms peculiar to each leguminous crop are present in sufficiency, so that the crop may grow luxuriantly while the soil is enriched in nitrogen for another crop, and both rendered independent of any special nitrogenous manuring.

Altogether a vast field of enquiry has been opened up, and though first experiments must be necessarily tentative in character, a year or two should give us the results of extended trials on a commercial scale and on different classes of land.

(The End.)

PREVENTATIVE MEASURES FOR RINDERPEST.

The following are extracts from a Government Notification published in the *Natal Farmer's Magazine*, being taken from a Minute by the Principal Veterinary Surgeon to the Commissioner of Agriculture in that Colony:—

If an animal is found shivering with a staring or hide-bound coat and moist eyes, he should without delay be isolated and kept under observation,

and if a second case manifests itself the fact should be at once reported to the nearest authorities, and a caution given to neighbours that suspicion exists. On no account should the rest of the herd be removed to another place, as if the disease unfortunately should prove to be rinderpest, the infection of the entire herd, though apparently in perfect health, is a matter of almost absolute certainty. Such removal cannot be carried out without either danger to others or of the infection of fresh ground, which may be of great value subsequently as a pasturage above suspicion on which healthy stock may be kept. In any case I would emphasize the futility of changing one's ground. If a change is made it should be a concentration of all animals not visibly ailing, which have been in contact, towards the centre of the farm, as far distant from one's neighbours as possible. This cannot but be the duty of every right-minded man who has at heart the welfare of his neighbour and the direct interest of his country. The present feeling of panic now so prevalent is much to be deprecated. A timorous apprehension cannot be the best front to show to danger of any sort, and anyone caring to investigate the preparations made for the reception of the disease must exonerate these concerned in the defence of the colony from the opposite and equally fatal mistake of underrating the danger. It is in my opinion highly improbable that the disease is going to decimate or even grievously injure the colony. We may not be so fortunate as to exclude it absolutely, but I am convinced that a determined and level-headed resistance to its progress foot by foot will first check and then exterminate the disease. Failure can only come through panic and half-hearted measures. The prevalent conception that the disease possesses some supernatural power of spontaneously generating itself or making a long jump of a hundred miles without being carried is most erroneous and contrary to the dictates of reason and science. It should be strongly impressed upon the memory that the disease goes *only where it is taken*, and that it is a deficiency of evidence only which prevents our tracing the cause of each fresh outbreak as it occurs. Strict cleanliness of person should be observed on the part of those in contact with the disease, more particularly if they contemplate leaving the infected district. Boots should be changed, or if this is impossible, they should be thoroughly scraped upon the sole and scrubbed with a ten per cent. solution of Quibell's or Jeyes' fluid, or some similar compound duly authorised. The hands should receive the same treatment as far as the scrubbing with an antiseptic solution is concerned; the nails should be kept short and thoroughly clean by brushing, after handling a sick or suspected beast. Tools used for the burial of carcasses are infected, and cannot be brought back to the homestead without risk until disinfection has taken place. Natives employed in the herding or burial of affected animals—(treatment of any sort is playing with fire and is worse than useless)—should be considered highly suspicious as transmitters of the disease, and their thorough disinfection is a duty of every employer personally. Where possible, carcasses should be burnt. This process is tedious, but absolutely safe when carried out.

MILK AND MILK PRODUCTS.

BY MR. JAMES MOLLISON,

Superintendent of Farms, Bombay.

Cream, after it has been separated from the milk, is ripened in an earthenware jar, covered with muslin and not with an air-tight lid. During ripening the cream should be frequently stirred at least once every two hours. The time required to ripen cream depends upon the temperature. Cream will be sufficiently ripe in 12 hours if the temperature of the dairy is from 65° to 75° F., in less time if the temperature is higher. A greater period must elapse if the temperature is lower. During the early monsoon rains cream will ripen more quickly than in the hot weather. Cream is ripened with the object of making it yield a greater proportion of butter of fine flavour than that obtained from fresh cream. The flavour is believed to be developed by the growth of a microbe in the cream. The fermentation which proceeds during the ripening process causes the cream to thicken. Cream is not pure butter fat, for milk in variable proportion is always present, and this milk sours as the cream ripens and the lactic acid precipitates the casein. The curd thus formed may during churning become incorporated more or less with the butter. Butter thus made will not keep long. If the sourness of ripe cream is excessive the curd forms in lumps; if the ripe cream is only slightly acid the precipitated casein breaks up into particles of minute size during churning, and these particles always form a constituent portion of the butter which ordinarily by thorough washing can be separated from the butter. The butter which will keep longest is made from fresh cream, while the butter with the finest flavour is made from ripened cream. The combination of keeping quality and flavour is a point of value. It has been authoritatively stated that this has been accomplished now by inoculating fresh cream with a pure culture of the cream-ripening microbe. Cream should only half fill the churn, so that agitation may be due to the cream falling upon itself at each revolution of the churn; if it completely filled the churn there would be no agitation at all. If the cream is so thick that it sticks to the churn, pure cold water should be added. The lid of the churn is now fixed down and the churn turned at the rate already indicated. The cream will froth up and swell after the first few revolutions. The air which was incorporated with it is driven out, and because it is impure air and in consequence may taint the butter, it ought to escape through a valve placed on the lid of the churn for that purpose. A small pane of glass is inserted in the lid of the churn. By careful observation the dairy-man can see from time to time what is going on inside, and can determine when the butter begins to form. So soon as this takes place cold water (about 1/10th of the cream quantity) should be added. The object is to lower the temperature when the butter is forming in order to get it firm, also to dilute the butter-milk so that it may be easier separated from the butter granules. The necessity of lowering the temperature arises because the agitation which the process of churning requires has raised considerably the initial temper-

ature. The churning is again continued until specks of butter on the glass are easily discernible and are seen distinctly separate from the butter milk. Experience and judgment are necessary to decide the right moment when to stop churning. If stopped too soon butter is lost in the butter-milk because the granules are so small that they pass with the butter-milk through the meshes of the finest strainer. If carried on too long the butter granules aggregate and the butter becomes greasy; moreover it is difficult to separate the butter-milk completely by subsequent washing and working without spoiling the grain or texture of the butter. When churning is sufficiently advanced the butter-milk is drawn off through the tap hole at the bottom of the churn, and is strained through a sieve; and any butter caught is returned to the churn. The churn is half filled with pure cold water and given a few more revolutions and then kept at rest for a short period. If curd is present in quantity, it will settle to the bottom of the churn whilst the butter floats on the water. As the water is drawn off the curd may also be removed. If curd is present the butter caught on the sieve should not be returned to the churn, because it necessarily must be mixed with pieces of curd. If there is any considerable quantity it can be made into *ghi*. The churn is again half filled with water and given a few more revolutions. This water is likewise strained through a sieve as it is drawn off, and if there is no curd present, the contents of the sieve are again returned to the churn. The butter is now comparatively free of butter-milk, but in order that it may be washed, as far as possible, whilst still in a granular condition, brine is now added, the solution consisting of 1/4th lb. salt to a gallon of water. The churn is again half filled and slowly revolved a few (say 3 or 4) times. The brine is drawn off and strained as before through a sieve.

(To be continued.)

THE ROOTS OF PLANTS.

A late report of the Kansas Agricultural Department distinguishes two classes of roots in plants, explaining the text by means of an illustration which we regret we are unable to reproduce. The two kinds of roots are (1) the feeding roots which grow along in the true or cultivated soil where the plant food is abundant, and (2) roots which go down deep into the soil in search of water.

"We say search of water as though it were a matter of instinct, but the influence which encourages these roots to take a downward direction is the flow of moisture constantly coming up by capillary attraction from below to the surface.

"The young roots are attracted by the moisture, and grow and go down deeper and deeper. There is a case recorded of a willow which grew to be a large tree in apparently a dry soil, but it was found that there was a small leak in an underground tank, several feet away and deeply below the soil, guided by the moisture which came up through the soil, the roots found it out and formed a large mass of fibrous roots in the tank itself.

"The depth to which some of these moisture-seeking roots will go down is remarkable. One day on Earl Ducie's example farm at Whitefield

a party of young men thought they would ascertain how deep wheat roots went down into the subsoil, and one of them held the root in his hand to shield it while the others dug out the earth and gravel to enable them to follow its course. They dug out tons of stuff, which carried their digging down eight feet four inches, and, as they believed, the root was then broken off. Roots of onions have been found nine feet down or more, and could be distinguished by their taste. Where deep cuttings were made across a field of sainfoin for a waterworks culvert, the roots of the plant were found twenty feet from the surface, and lucerne roots have been found even deeper; in fact, it is believed they go down to the bed-rock even.

"The habit of grasses, whether deep-rooting, or growing with shallow roots, determines their suitability for this country.

"Now, it is easy to see that a field with a hard and almost impenetrable subsoil, or pan, created by constant shallow ploughing, will not allow of this deep-rooting, and therefore in absence of rain for even a short time, the crops must suffer, while on other lands which have been subsoiled and the impediment of a pan broken up, the crop may hold out and come to maturity. Besides the advantage of the deep-rooting, the feeding-roots of the plant will find food in the broken-up subsoil when they can be distributed amongst it."

ALLEGED CURES FOR CATTLE PLAGUE.

The following correspondence on the above subject, which has been transmitted by His Excellency the Governor and High Commissioner of the Cape, is herewith published for the information of our readers:—

Wellington Club, Grosvenor Place, S. W.,

April 15th, 1896.

To the Right Honourable JOSEPH CHAMBERLAIN, M.P., Downing-street, S. W.

Rinderpest in South Africa.

SIR,—I have been interested in tropical agriculture for the last 30 years in British East India, and the rinderpest used to give us much trouble and cause much loss. An animal once attacked never recovered. Of late years we adopted a novel and most efficacious treatment, and we now no longer dread the disease.

The treatment consists simply of boiling down the first victims and feeding those attacked with the broth, giving each animal a half to one pint three times a day. I cannot, of course, say if the same success would follow a similar treatment in South Africa, but it is, I am persuaded, worth a fair and careful trial. Personally I believe anthrax, if not pleuropneumonia, could be successfully treated by similar means, but of these both I cannot speak from experience. The broth should be given for two days or so after the animal begins to eat.—Your obedient servant,

(Sd.) C. TOTTENHAM.

Downing Street, 21st April, 1896.

SIR,—I am directed by Mr. Secretary Chamberlain to request you to lay before Secretary Lord G. Hamilton the enclosed copy of a letter respecting a method of treating rinderpest, which the writer states was successful in British East India, and I am to state that Mr. Chamberlain

would be glad to be supplied with any information that may be in the possession of your Department as to the efficacy of the treatment described.—I am, &c.,

(Sd.) EDWARD FAIRFIELD.

The Under Secretary of State, India Office.

India Office, Whitehall, London, S.W.,

14th May, 1896.

SIR.—I am directed by the Secretary of State for India in Council to acknowledge the receipt of your letter, with enclosure, of the 21st April, and in reply to state, for the information of Mr. Secretary Chamberlain, that this office is not in possession of any information with reference to the treatment of rinderpest in India in the manner described by Mr. C. Tottenham. Lord George Hamilton has caused inquiry to be made on the subject, but no confirmation has been obtained of the statement submitted to the Colonial Office by Mr. Tottenham.—I am, &c.,

(Sd.) A. GODLEY.

The Under Secretary of State, Colonial Office, S. W.

The following is taken from the *Agricultural Gazette* of the Cape:—

With much regret I saw in the last number of *Ons Land*, that the dreadful Rinderpest has already appeared on this side of the Orange River, and that up to the present no remedy has been discovered to prevent this enemy among our cattle.

In the hour of need man grasps at a straw to save himself. In 1892, when so many horses and asses died in our district from horse-sickness, I tried a remedy for my horses and asses as a preventive against the disease. I took ten parts of salt and one pint of Cooper's Dip, ground the salt fine and mixed the Cooper's Dip with it. I gave each horse and ass a tablespoonful of this dry.

My animals grazed in a large veld amongst a good many other horses and asses which all contracted the disease and died, while all of mine remained healthy, although they as well as the other animals were exposed to cold and damp. I have used the same remedy for my healthy sheep as a preventive for Geel Ziekte, and with good results.

Well, would it not be worth trying this remedy on the healthy animals where the Rinderpest begins to show itself? It can do no harm, and I think inasmuch as a beast is stronger than a horse, men may safely give each beast a tablespoonful and a half of the abovenamed mixture. Who knows perhaps by the use of such an unfailing remedy thousands of cattle may be saved, and much heartrending and misery be prevented thereby.

(Sd.) S. C. LOUW

Spes Bona, Ceres, Oct 3rd.

I have no remarks to make, except to say that Cooper's Dip has been found useful in horse-sickness and geel-ziekte. And if given to cattle it might have a tendency to keep them in good health. I have no faith in it as a cure for Rinderpest, and I doubt whether it would act as a preventive.

J. W. CROWHURST, F.R.C.V.S.

We give below an extract from the report of the Director of Land Records and Agriculture in the N.W. Provinces and Oude, India, is interesting as giving the experience with most of the various devices for the protection of trees in roadside arboriculture. The tree called "babul" in the report is the *Acacia arabica*, which is found chiefly in the drier parts of the Island, but which can be replaced by other thorny acacias that are more common than the species named. We have seen the troublesome "lantana" pressed into service and grown as a protection for coconut plants without any apparent injury to the latter:—

The district reports give evidence both of the difficulties connected with this most important part of the work and of attempts in several districts to provide a cheap and effective guard. In Maiupuri, tree guards of wood were tried; in Garhwál, stone fences; in Meerut and Basti, brickwork guards; and in Meerut, Muzaffarnagar, Dehra Dun and Jalaun wire guards have been constructed. In Dehra Dún, tree guards of barbed wire fixed to four rough wooden posts are used and are said to be effective; but, as stated last year, the use of barbed wire should not be encouraged on public roads. The guard costs R2 and lasts only four years, the time a single tree should ordinarily want protection, so that it is far too expensive for general adoption. I do not, therefore, consider this guard a success. The brick guards costing R2 each, introduced by the Collector of Meerut last year, are reported to have done very well, though to protect them from being knocked down by animals it has been found necessary to surround them with thorn fences. The bricks are available for erection at another place when the tree, round which they were erected, is established, and the brick guard is, therefore, cheaper than that of barbed wire above referred to. I doubt, however, whether their liability to collapse on a cart coming into contact with them and the expense of re-erecting them does not make them also too expensive. Mr. Wyer has this year introduced another guard, costing R1-5-0 each, made of wire netting supported on an iron frame. He considers it preferable to the brick guards on account of its being cheaper, neater and equally efficacious. It gives better ventilation and is available for a second tree when it can be moved from its first position. Filled with thorns to prevent goats getting at the trees over the top, it appears to me as satisfactory a guard as could be devised. A somewhat similar guard has apparently been tried in Muzaffarnagar, but the information at my disposal is not sufficient to permit me to describe it. It is said to be a wire framework intended to protect and keep together a hedge of dried thorns. For districts with ample funds at command Mr. Wyer's guard might probably be adopted on a considerable scale. In the East, however, it is improbable that even R1-5-0 can be paid for each tree guard, and the cheaper methods of protection by ditches and mounds, by growing cactus plants, or by dry babul thorns, must be continued. The ditch and mound is, where the soil is stiff and the road wide, probably the least troublesome; but on the major-

ity of roads it is impracticable, and the choice lies between babul thorns, which have often to be carried for miles, and the cactus. I have, during my late tour, seen very excellent results obtained by means of cactus fencing. It is troublesome to establish, but, once established, last till the tree protected is well-grown and affords material, when destroyed, for many other guards. It might be feared that injury would be done to the young tree by the air being shut out by the close-growing cactus, but the very flourishing young trees one sees when they are well-protected by cactus and properly tended sufficiently prove that this is not the case. When babul thorns have to be employed the advantage of having a temporary avenue of babuls, as suggested by the Government review on last year's report, is obvious.

CATTLE DISEASE IN THE VILLAGES OF THE WANNI.

Rinderpest is enzootic in certain parts of Ceylon, especially in the interior adjoining thick jungles. During the past few months I have had much to do with this disease both in the Sinhalese and the Tamil Wanní. It seems to prevail in one village or other all the year round. Its virulence and the rapidity with which it spreads varies in different parts of the year. During the rainy season it is observed to be more virulent. When it is hot and dry the outbreak is of a more benign type. Heat is said to have the tendency of attenuating the virus.

The degree of malignancy is greater in certain animals than in others. For instance, the mortality among buffaloes is proportionately greater than among neat cattle. It will be interesting to have reliable statistics as to the percentage of deaths caused by rinderpest among these two species of cattle. Certain wild animals, such as the deer and the elk are attacked with, probably, a comparatively mild form of the disease; and they form a means of keeping up and spreading the disease although this fact is often overlooked.

Prevention and Suppression.—Animals that recover from one attack of rinderpest are proof to subsequent attacks at least for a period of six or seven years. The general belief is that one attack confers immunity through life. Even the most ignorant Ceylon goyiya and Indian ryot that owns cattle is aware of this. On account of this protective power, experiments were carried on by Veterinary Surgeons with a view to find out whether inoculation with the virus will answer as a preventive measure. The results were, however, unsatisfactory as inoculation tends to reproduce the disease in as malignant a form as that contracted in the natural way.

In Europe, when any outbreak of rinderpest is detected, it is at once stamped out by destroying the infected animals and burying or burning their carcasses. But such a method of suppression is unsuitable to most parts of Ceylon for two reasons, viz., (1) It is antagonistic to the religious feelings of most of the people. (2) The disease is so common, so frequent and so scattered that a large number of animals will have to be killed.

In villages, however, where only a few solitary cases occur, this plan may be adopted if the

owners are willing. But the chief preventive method which we should have recourse to in Ceylon is the isolation of the sick animals and the segregation of the healthy, supplemented by thorough disinfection and the frequent burning of the excreta and litter of the sick ones. The proper disposal of the carcasses of cattle and other animals that die of rinderpest is important. They should be either thoroughly cremated or buried at a depth of five feet.

A fact that is apt to be overlooked in connection with the preventive measures is that this disease is not only directly communicable from the sick to the healthy cattle, but also indirectly through the air and water as well as by men and animals that have been in contact with the infected cattle. For this reason cattle which are themselves proof to rinderpest, but have been in contact with or close proximity to the sick should not be herded with the uninfected ones; and the attendants that nurse the infected should likewise keep aloof from the latter.

The common watering places and pasture lands form a very fruitful source of mediate contagion. In most villages there is only one tank where all the cattle of the place flock to drink, and only one large green where they are herded to graze. Hence it often becomes impossible to check the progress of an outbreak unless suppressive measures are adopted at the very outset. One important step towards facilitating the suppression of the disease will be gained if the people can be induced to dig wells and water their cattle from them and to divide the common pasture into separate lots for their animals by means of fences.

The ignorance of the villagers as to the real nature of rinderpest is a great obstacle to its prevention. We should not relax in our attempts at disseminating correct ideas about it. Many cattle owners act as though they have not realized that it is a contagious disease. They sometimes go on counting the number of the dead and the dying as one after another animal falls a prey to the disease, without making any rational attempt to protect those that are still left. The explanation of this strange fact is that they believe the disease to be a visitation by their deities whose wrath, they think, will be only increased by any commonsense measures employed to arrest its progress. Actuated by this belief they sometimes make vows and offerings to pacify the deities. This, no doubt, is more easily done than the carrying out of proper preventive and suppressive measures, for such measures have to be most strictly enforced in order to satisfy the demands of veterinary science and to be thoroughly effectual.

E. T. H.

(To be continued.)

GENERAL ITEMS.

The Reporter on Economic Products to the Government of India (Dr. Watt) suggests the use of a paint, made up as follows, against white-ants:—

- 1 part, resin of *Gardenia gummifera*.
- 2 parts, *asafoetida*.
- 2 parts, bazaar aloes.
- 2 parts, castor-oil cake.

Pound, mix and keep in water for about a fortnight, when it becomes a thick compound. Now add water to bring to the consistency of paint, and add the red colouring matter got from *Morinda tinctoria*. Thoroughly apply for about 2 ft. from the ground for white and red ants. The effect is said to last for 2 years or more.

A trial of this paint was made at the instance of the Director of Agriculture in the N.-W. Provinces, by applying it to a number of mango and other trees badly attacked by white ants. The experiment proved that the paint is an effective preventive against the attack of white ants, if applied *directly* to the bark of attacked trees, so that all earthy ant deposits must first be removed from the trunks. The cost of treating per tree comes to nearly 25 cents, which is considered too expensive for extended use on large trees, but would not be prohibitive where it is found difficult to establish young trees or saplings along roadsides owing to white-ant attack.

A shoe without nails has been invented which appears to be entirely satisfactory. It had been tried in the German army for a year with the best results, and a very favourable report upon it has been presented to our own army authorities by Lieutenant-Colonel Graham. The new shoe is being adopted by the Glasgow Corporation and the Great Northern Railway Company, and it is to be tried in the stud of Her Majesty the Queen. Instead of the nail a two-pronged clamp, with a couple of turned points at the single end, is placed along a slight groove on the outside shell of the hoof, following the line taken by the nail in the ordinary shoe. At the point where the nail usually emerges and is turned down, the points, or hooks, of the clamp are pressed into the hoof, and the two prongs pass downward beyond the edge of the hoof, into a slot in the shoe, similar to the present nail-hole. The foot is then lifted, and a small wedge driven into the slot from beneath, passing between the prongs and fixing them firmly into the shoe. It is found that the shoe, thus fixed, looks neat and workmanlike, cannot be shaken off by any amount of kicking and plunging, and can be taken off and replaced in a few minutes in the stable, so that changes necessary in frosty weather can be effected without trouble. A company is in course of formation to place the shoe on the English market, and specimens may be seen at the offices of the Minerva Horse-Shoe Syndicate, 11, Queen Victoria-street, E.C.

The results obtained from tests which have been made at the Canadian Government Experimental Farm during the past eight years as to the action of fertilizers on crops show that the action of fresh manure is almost equally beneficial, ton per ton, to that of rotted manure in the growing of nearly all the staple crops. The question of the best and most economical methods of handling farmyard manure is, therefore, one of the greatest importance to farmers everywhere, since animal manure form one of their most valuable assets. As a result of many analyses, it is estimated that twenty tons of good farmyard manure contain about 196 lb. of nitrogen, 128 lb. of phosphoric acid, and 172 lb. of potash, which, if estimated by their cost as obtainable from the cheapest artificial sources, represents a sum of not less than £9.

LIEUT.-COLONEL H. C. BYRDE.

COLOMBO, MARCH 1ST, 1897.

[No. 9.]

“PIONEERS OF THE PLANTING ENTERPRISE IN CEYLON.”

(Second Series)

LIEUT.-COL. HENRY C. BYRDE (NO. 2).

PLANTER AND MERCHANT IN CEYLON,

AND AFTERWARDS DEPUTY LIEUTENANT AND J.P. FOR CO. MONMOUTH; CHAIRMAN OF PONTYPOOL PETTY SESSIONAL DIVISION; AND HONORARY COLONEL OF 4TH VOL. BATTALION SOUTH WALES BORDERERS.

GEO. BIRD, THE FIRST OF CEYLON PLANTERS.

HE late Lieut.-Col. H. C. Byrde occupied for many years a leading position among the planters and merchants of Ceylon. Apart from owning several coffee plantations, he was the founder of a Planting Agency House in Kandy, which bore his name and that of his son—the Colonel Henry Byrde*, still of the central capital—for many years; and his family had also the prominence and prestige naturally associated with the opening of the very first coffee plantation in the island. The King of Kandy had a so-called coffee garden at Hanguranketa; but the bushes were allowed to grow at their sweet will and undoubtedly the first regularly formed plantation was in 1824 at Sinnapittia, near Gampola, the planter being Mr. Geo. Bird (the name was originally so spelt†)—the uncle of the subject of this memoir—who was

* One of the heroes of the Redau and who if he had been left in the Army, in place of being turned into civil life, would probably have proved one of the youngest as well as most active Generals in the British Army.

† The change was made by Colonel Byrde after retiring from Ceylon. A wag, who had the ear of the editor of *Punch*, sent to that publication a *bon mot* to the effect that although a gallant colonel down in Monmouthshire had had his “i” (eye) put out by Royal letters patent, he was doing as well as could be expected under the circumstances, and had found

aided by Col. Henry C. Byrde the first of the name in Ceylon and father of the gentleman whose portrait we give.

The subject of our memoir is, therefore, the middle one of three Colonels Byrde who have been identified with Ceylon from 1823 onwards. The first was Colonel Henry C. Bird of the 16th Regiment, who arrived in the island in 1823, (accompanied by his brother, Mr. Geo. Bird,) and who became Commandant of Kandy. George Bird himself had been a Cavalry Officer and had come to Ceylon especially to engage in agricultural or planting pursuits. He was a personal friend of the Governor Sir Edward Barnes whose great desire was to see the fine hill country of Ceylon opened up by European capital and planters. Accordingly, Geo. Bird, supported by his brother, set to work and opened in 1824 Sinnapittia near Gampola; while the Governor himself soon after put his money into the opening of Gangarooma (still known as the “Rajah Totum”) opposite the Royal Botanic Gardens, Peradeniya, having Mr. Wm. Northway, senior, for his Superintendent. We cannot do better at this stage than quote the account furnished by the sub-

the operation really a painless one.—The joke is not so good as that related to us a few months ago by Sir James Gell, Attorney-General of the Isle of Man. We had previously met Deemster Gill; and referring to the similarity of names, “Yes,” said Sir James, “but we are quite distinct families, and on my marrying a sister of the Deemster, it was all the talk that I had put out the eye (i) of Miss Gill!”—Ed. T. L.

ject of our memoir (then "Major Bird") to our "Planting Gazetteer" of 1859, of his uncle's career, and the history of his life-long struggles against an adverse fortune. Our prosperous planters of the present day may well regard with respect and honor the name of "George Bird" as the very earliest plantation pioneer in Ceylon—a man of striking character, of superb physical development and strength, unwearied energy and indomitable pluck—and that honor, in a connected degree may be extended to all the "Birds" or "Byrdes" of those early days who gave both time and money to the work of carving coffee estates out of the primeval jungle. George Bird in his early years made a great impression through his work, physical prowess and personal character, on the Kandyans who both respected and feared him. The account supplied to us in 1859 by the subject of our Memoir, was as follows:—

The first Coffee Estate in Ceylon was opened in this District so far back as the year 1821, by Mr. George Bird, who accompanied his brother (Colonel Bird of the 16th Regt.) to Ceylon in 1823 for the purpose of engaging in such agricultural undertaking as inducements in the Island should appear to offer; and the attention of the brothers, (Col. Bird being at that time Commandant of Kandy,) was directed to the cultivation of *Coffee*; and the valley of Gampola was selected as an eligible locality wherein to carry out their intended speculations.

Sir Jas. Campbell, then Lieut.-Governor, gave encouragement to the proposed undertaking by promising a grant of land for the purpose which was afterward confirmed by Sir E. Barnes, and thus commenced that cultivation on the site of two ancient Kandyan Places, Royal lands (Singapetia and Weyangwatte)—which has been of such importance in the subsequent history of our Island.

The mode of cultivation adopted and the enormous protective duties then in favor of the British West Indian Colonies, rendered this, and two other Coffee Estates at Ganga Orowa and Matelle that soon followed the one at Gampola, equally unprofitable; and Col. Bird's death of cholera in 1829* so paralysed the operations at Gampola that Mr. George Bird was induced to abandon the property in 1833 and remove to Kondasally and subsequently to Imboolpitia in Oudabulattamma. After having been engaged in the production of Coffee for 33 years with singular want of success he died in Kandy on the 1st March 1857, having been the means of conferring signal advantages on others by the energy of his character, while to himself, the Pioneer of Coffee cultivation, his best efforts served only to prolong his disappointment.—Although a good practical man and possessed of great experience, accumulated through many years of toil, his experience did not avail him until failing health, had destroyed that energy which repeated disappointment could not impair.

The Gampola Estate being beautifully situated in the valley of Gampola, was in 1846 sold to Messrs. Hudson Chandler and Co. for the purpose of farming it on the English principle and combining this with the cultivation of Sugar, and a farmer and his family were brought from England to carry out the intention of converting the already fine pasture lands into a grazing farm—when the decaying stumps of the old Coffee trees gave place to guinea grass to maintain a stock of horses and cattle, with the hope of eventually securing breeds of superior quality;—but on the failure of Messrs. Hudson

Chandler and Co. during the crisis of 1848, this establishment was again broken up, and the estate reverted to the Bird family. Within the last 2 or 3 years it has been again formed by Major Bird into a Coffee estate of 300 to 400 acres which give promise at length of great success, now (1859) that the culture and preparation of Coffee are better known, and the equalization of duties gives the agriculturist in the East a fair chance of competition with other parts of the world.

From Mr. Charles Byrde of Ambalangoda, son of the subject of our Memoir, we have the following:—"Mr. George Bird spent his later years at Kondesale Estate with his daughter, Isabella, who married the late Mr. W. B. R. Wyllie of Messrs. Keir, Dundas & Co. and Mr. Geo. Bird died at Lake House, Kandy, early in 1857, as I was living at this time with my father and mother who went to England in May 1857 after Mr. Wyllie's marriage with Isabella Bird."

We need only add to the above, that when misfortune overtook Major Byrde's firm and properties generally, Sinnapittia had to be taken over by Mr. John Bonstead, and again it changed hands when the final collapse of Ceylon coffee took place. It is now the property of the Oriental Estates Co., Ltd., and like so many other old coffee plantations, has been turned into a flourishing tea garden of 300 acres out of the total area of some 756 acres.

We cannot do better next than repeat some notes written at our request by the subject of our Memoir, Colonel H. C. Byrde (the 2nd) in 1895, after seeing our first volume of "Pioneers" in which he was greatly interested. The old colonist in his Welsh retirement reminded us that he had been a reader and admirer of the *Observer* from the first day it appeared in 1834, down to (what proved) the closing year of his life, and with his "kindest regards to the Editor" he sent the following very interesting autobiographical sketch accompanied by portraits of himself and other senior members of his family from which we were to select the one to appear in our *Tropical Agriculturist* Gallery:—

I was transferred to the Ceylon Rifle Regiment in July 1834, and waited for three months before there was a ship sailing for Ceylon. My fellow passengers in the "Symmetry" were Mr. (afterwards "Sir") Chas. Peter Layard, Lady Layard, James Gay Layard, Beville Layard, Miss Sophia Mooyart, and Mr. Self, passenger for Mauritius—all gone to their rest.

My uncle George Bird came down to Colombo to greet me and I returned with him to Nau Oya, where he was then living, having commenced the cultivation of his estate at Kondasally, which he was then planting. On my arrival at Colombo I found that there was no notification of my appointment. The ship with Naval stores to Trincomalee and Military stores to Colombo had been ordered to the former station first. There were about two or three ships in those days that graced the Colombo roadstead. Letters for England were sent by tappal to Madras to await an East Indiaman and it was considered satisfactory to get an answer to a letter from Ceylon *within the year*. What a contrast to the present day:—when mail after mail is advertised, the *open* roadstead enclosed by a break-water and

* Col. H. C. Bird No. 1 died of cholera in Colombo in 1829 and his remains are interred in the old military cemetery at Galle Face.

the harbour full of steamships, and Colombo full of visitors, instead of the solitary Military Officer, who probably came out to fill a death vacancy in one or other of the Regiments then stationed in Ceylon. It is worth noticing the mighty change that has taken place in the distant Colony of Ceylon which has in these latter days been brought so near to the mother country.

My uncle had a big horse—one of the Delft stud which had been sold off by order of the Home Government, when Sir Edward Barnes was Governor. My uncle drove me as far as Ambepussa the first day and what astonished me more than anything I can remember was that the *Affghan* horsekeeper ran the whole distance of 36 miles holding on by the back of the buggy. This was marvellous to an Englishman, just arriving in the Island and would probably be marvellous even in Ceylon at the present time, though many such wonders have been wrought in Ceylon since that day.

ORIGINAL COFFEE PLANTING AND PREPARATION.

My first visit was to the old Gampola estate, Sinnapiitiya, the trees on this property as well as at Peradeniya the Government plantation, and on Ganga Orowa, were grown in the *native* fashion, no other then being known. The preparation was equally original—the Gampola Store was a four-sided building enclosing an open space used for drying ground. The coffee in husk was, at this time, dried ready for grinding; this was done by *grooved rubbers* sloping to one side, and fixed on 3 legs with a hopper on top. This contrivance (an invention of my uncle's) ground off the husk, and the whole was then winnowed by a corn-winner and finally prepared for shipment and bagged on the estate. It is worthy of remark that up to about this time, the sale price of Ceylon in the London market was about 28s or 30s per cwt. This was caused by the excessive duty of 9d per lb. on all coffee shipped *eastward of the Cape*, while West Indies' coffees were admitted at 6d. This unjust difference was equal to about 28s per cwt., but for this, Ceylon coffee might, in the early stages, have sold for 56s instead of 28s. The duty was however equalized and levied at 6d. after some strong representations to the Home Government, but the earliest planters had this terrible "odds" to contend with, and rejoiced when the duties were equalized. I need hardly mention that at this time all the cultivation of coffee was in the *native fashion*, and required a great amount of manure to maintain; this was the case on the 3 plantations then known:—Gampola, Peradeniya, and Ganganarawa, and subsequently on Major Forbes's at Matale.

Some mention is due of Hanguranketa—this was the site of a former palace of the King of Kandy and of a Buddhist Temple, at one time of some eminence. About this palace and temple were coffee trees grown, of course, in the *native* fashion and rising above was a mountain side of coffee *jungle*. The Kandyan legend of this, is that before coffee was known as a beverage, some pilgrims brought the *seeds* (coffee in husk) from Arabia to grow flowers for offerings to the Temple, and that the coffee beans had been distributed in course of years throughout the adjoining forest by the small green parrots which abound in that district.

On the failure of the Gampola plantation, partly in consequence of my father's, Colonel Byrde's death of cholera in 1829, as he had provided the necessary funds,—Mr. George Bird applied to the Governor to have the Old Palace at Hanguranketta coffee jungle sold and it was put up for sale by auction, the limit of £600 was prescribed by Messrs. Acland and Boyd was exceeded by Mr. De Soysa, who became the purchaser at £630, and thus formed the nucleus of his subsequent fortunes, which grew rapidly as arrack renter.

The Governor, after this, made Mr. George Bird a grant of 600 acres of land at Kondasally, where he renewed his cultivation of coffee in partnership with Messrs. Acland Boyd & Co. of Colombo. On my first arrival in the Kandyan

country I was taken to visit this new *venture*, the coffee planted was with stumps and it was affirmed that the *greater* the number of shoots the better, nothing like a good *bushy tree*, it was said (again *native* fashion). This was, however, soon altered; for, in 1837, our good trusty friend, o Rober Boyd Tytler, made his appearance with the knowledge he had gained by a residence for instruction on the Blue Mountains of Jamaica, and the great change was partly brought about by an old copy of *The Coffee Planter of St. Domingo* by M. Laborie which Mr. William Boyd had picked up on a second-hand book-stall in London. All was now changed. Trees were to be grown on *one stem*. The plants to be reared from seed, the trees topped at certain heights. M. Laborie gave even plans of the "grater mill" as it was called—Barbacues for drying the parchment coffee and the *peeling mill* for grinding the coffee when dry, with divers instructions for the cultivation. This book and our friend Tytler's knowledge and guidance caused a stir and a revolution that *after-comers* could hardly realize, who flocked to Ceylon to find matters so settled, as if there had been no change, albeit one improvement after another was carried out in improved cultivation and preparation, which produced the fortunes of many, until the climax of leaf-disease *prostrated* the enterprize of coffee cultivation almost entirely. I would next notice the remarkable success of the coffee planting experiment

AT BLACK FOREST.

M. Laborie in his St. Domingo Coffee Planter, lays it down as a rule that the soil for the successful cultivation of coffee should be loose, *friable* and if possible on *virgin cleared* forest land. Our friend Tytler visited Gampola with me and gave it as his opinion that the soil was too *compact* for the successful growth of coffee which grew splendidly under the old "jak" trees where it was nourished by the leaves, and the soil kept moist and loose. I mention this peculiarity, as it equally applies to Peradeniya and Ganga Orowa where the soil was of the same character, and the coffee trees equally *impeded* in their growth. My attention was therefore directed to the forest called "the Black Forest of Pussellawa" which for magnificent trees was the finest forest in the Central Province, many of the "Doon" trees measuring 100 feet without a branch. I was so enamoured of this forest land that I determined to try the *experiment* of planting coffee—although this was the *very first* idea of planting coffee in *forest land* at such an elevation, of over 3,000 feet. It was easy then to obtain land; the Governor gave *immediate possession* of 10 acres on which to form a nursery and put up 100 acres for sale at the upset price of 5s. an acre including survey fees *payable in 12 months*, and I obtained 100 acres on these terms—I had prepared a nursery of young plants, and my first cultivation was of 8 acres and was certainly conducted in the most *thorough manner*.

I had only 3 or 4 of our old Kandyan labourers from Gampola. With the aid of an elephant I had all the land "*stocked up*" and the roots buried and the ashes distributed over the surface; the elephant pushed down all the small trees with his head, and pulled up the roots with his trunk. The large timber trees being left, the surface of the ground was, I hear, reduced to a fine pulverized bed, like a garden—such as in future experience never was found necessary. The coffee trees were allowed to grow to the height of 5 feet; no roads or drains were necessary as all the rain that fell was quickly absorbed by the loose earth. I had a small picking of coffee in the second year which I sold in the island.

FIRST PREPARATION OF COFFEE IN PARCHMENT IN THE ISLAND.

Instructions in M. Laborie's old Treatise I could not obtain. What he designates as a *grater mill* I had at Gampola, two groove cast iron cylinders of only 6 or 7 in diameter. I fitted these to work together and crushed out the cherry beans between them, and had a caned (rattened) sieve suspended below worked by a coolie. When the parchment

was separated from the pulp I put it to ferment in a cistern made for the purpose and dried it on mats; but leaving the dried parchment the difficulty was a substitute for a *peeling mill*, and I had to resort to the old paddy pounder; but had a winnowing machine from the old Gampola estate. I then had planks sawn of the keena tree and made into square boxes. These I lined with talipots to keep out the damp, and sent my *first crop* down to Colombo for shipment to Messrs. Price & Son this being the *first shipment* of Ceylon coffee consigned to them,—afterwards Price & Bonstead. My total crop was cwt. 167 or just about cwt. 21 *per acre* off my 8 acres. It sold in London for 108s per cwt. or a total of £870, which was just about *double* the amount of expenditure in the *purchase* of 105 acres of land the *cultivation* and *curing* of the coffee, erection of a shed in place of a store, and the building of a bungalow for my family in the hot season at a cost of £26. The heavy crop was doubtless owing to the high cultivation of the land, and the high price obtained was probably due to the fine greenish blue color of the bean similar to the mountain coffee of Jamaica.

The cultivation of the Black Forest Estate went on; additional land was purchased and it finally amounted to 260 acres of coffee when it was sold to the Venerable Archdeacon Glenie for Count Septimir, a friend of the Baron Delmar for the sum of £25,000.

The grooved new cylinder suggested the idea to Mr. John Brown, then engineer to Messrs. Worms, of the *Crusher* to be combined with the Pulper, which was afterwards found to work so well.

THE KEKUNA GRINDER.

It was supposed by Sir Edward Barnes that the kakuna nut which contains a large quantity of oil might be utilized as a *new product* from Ceylon in the manufacture of cotton cloths at Manchester and the experiment was tried, but the oil was rejected by the Trade, and the kekuna trees were found to be injurious to the coffee instead of being beneficial by their shade.

PERSONAL.

My object is not to write my personal history, but I may mention that when the Governor Sir Henry Ward gave the nomination of the member of the Legislative Council to the Planters' Association, I had the honour of being the *first elected* member and occupied that honourable position for about, seven years, and I was afterwards appointed by Sir Hercules Robinson as one of the Commissioners to report on the Military Expenditure of the island, the proceedings of which form a voluminous document in the annals of the Councils of Ceylon. My colleagues in this were Colonel Laffan, (R.E.) Major Skinner, Sir Charles Peter Layard, and others, and our report was received with favour.

I might take some credit to myself for having been the *first* to introduce or import *Indian coolies* to work on a Coffee Estate in Ceylon, but that this was dictated by self-interest. My Conductor at Black Forest was a man from Trincomalee, half Tamil and half Sinhalese, and I sent him to Trincomalee to obtain the services of a Tamil to go over to the Coast, to bring some coolies. My Sinhalese friends from Gampola having in the season their own work to attend to, my coast messenger in due course returned with 14 men from South India which formed the nucleus of the gangs which supplied the Black Forest Estate in after years, with 200 to 300 labourers, the descendants of whom have followed the fortunes of the Byrde family for the last 50 years, and I believe that some of the descendants of the same villagers are now with one of my sons at Awissawella, proving their faithfulness, so long as they are well treated and cared for.

Ceylon is so much indebted to, and dependent on labourers from Southern India, that planters have reaped the benefit and all friends of the Coffee enterprise have had full consideration for them which has been the *characteristic* of the treatment of the Coffee planters of my time, pre-eminently of our good friend Tyler at Pallakelly, and of that steady old Scotch planter of Mattakelle, our friend Mr. Smith.

ENGLISH EXPERIENCES.

After nearly 30 years of ups and downs in Ceylon, I took to English life. On my arrival in England, I was asked to take the command of a Corps of Volunteers which grew to a Battalion, of which I became the Lt.-Col., and when I retired, after a number of years of Command, I was appointed Hon. Col. of the 4th *Battalion South Wales Borderers*, which position, I have now the honour to fill. I was appointed J.P. for the County of Monmouth and subsequently Deputy Lieutenant for the County. I have been Chairman of the Pontypool Court for 27 years in which the trials number from 1,000 to 1,200 per annum. I have also been Chairman of the Pontypool U.S.A. Highway Board for a number of years, also of the Rural Sanitary and School Attendance Committees, and for the last 30 years a Commissioner of Inland Revenue.

On the County Council being formed I was elected a member representing 7 parishes, and became Chairman of the Asylum Committee of which I had been a member for 30 years, it belongs to 3 Counties and has about 1,000 members. I was appointed by the Quarter Session one of their Representatives on the Joint Police Committee.

But my own responsibilities, and our work prostrated me, and I have now been confined to my bed-room for the last 18 months; but by the mercy of Divine Providence, my health is now improving.

My experience as the first Coffee Planter on Black Forest land was in many respects quite unique and made me one of the Pioneers of that enterprise which raised Ceylon from a mere Civil Military Station to a Colony of European settlers and Colombo to a shipping port of the first importance.

Colonel Byrde was married at Cotta near Colombo on the 5th January 1837 to Rebecca daughter of Mr. Charles Mais of Bristol. After paying one or two visits to the old country, Mr. and Mrs. Byrde retired thither in the early sixties. In 1871 Col. Byrde paid his last visit to Ceylon, when he came out on business, and took back one of his grand-children with him—the eldest son of Mr. Charles Byrde of Amblangoda. The deceased lost tens of thousands of pounds in the downfall of coffee, but up to the last was interested in tea, owning, in conjunction with his youngest son, the Rev. R. A. Byrde, of Honiton, Devonshire, Honiton estate, in the Kelani Valley, besides being interested in other properties. In the fall of 1891, Mrs. Byrde, was so ill that the doctors thought that she would not last through the winter then approaching. Her devoted husband during that period was in attendance on her day and night, and her life was prolonged for two years. Col. Byrde, however, never recovered his former robustness, and when his wife died on the 23rd of December, 1893, at the advanced age of 84, and he lost the partner of 57 years of his life, he felt the bereavement very much.

After his retirement to England, in the "sixties," Colonel Byrde made more than one visit to Ceylon connected with the settlement of his properties. These included, among others, a good deal of the land on which the famous Mariawatte Tea Garden is now situated; but as a coffee estate it was deemed of little or no value, the land being too flat and the soil too stiff: in tea it has proved a veritable gold mine.

Settling in Monmouthshire, Colonel Byrde became known as of "The Goytre" near Pontypool and made himself exceedingly useful in the neighbourhood and county. His loss was much regretted by his brother Magistrates and other county magnates as the following extracts from the Monmouth papers will show:—

THE LATE COLONEL BYRDE.

REFERENCES AT PONTYPOOL POLICE COURT.

Feeling references to the death of the late Colonel H. C. Byrde, D.L., the chairman of the Pontypool Bench of magistrates, were made at the Pontypool Police Court. Mr. C. J. Parkes (in the chair.)

The Chairman said: Before proceeding to the ordinary business of the Petty Sessions, I desire to refer to the very great loss which this division has sustained through the death of Colonel Byrde—one whose face was so familiar to this court, one whose urbanity, kindness, and courtesy endeared him to all who had the privilege of knowing him, and who knew how to appreciate his Christian and kindly character. I cannot sufficiently express the regret I feel personally at the loss of my old and valued friend. I feel that the loss to this division is one that cannot easily be replaced, and one that none of us can very well fill. I believe, further, that such a man as Colonel Byrde cannot pass from amongst us without its being a loss not only to this division but a loss to the county. I simply say that those who had the privilege of knowing him knew how to appreciate his singularly upright character, his love of justice, and his sympathy with the distressed; and it was always his anxiety to throw the shield of protection around the young and inexperienced, and occasionally to offer them more the advice of a father than of a magistrate presiding at this court. I beg to propose a vote of condolence with the family in what we feel is an irreparable loss, and ask our clerk to be kind enough to convey it.

Mr. H. Bythway: On behalf of the practitioners at this court. I would respectfully ask you to allow us to associate ourselves with the kind expressions to which you have given utterance. We cannot forget that as advocates in this court we received

from Col. Byrde the utmost kindness and consideration, which were of the greatest assistance to us and were very much appreciated by us.

FUNERAL.

The funeral of the deceased gentleman took place on Monday afternoon, his remains being laid to rest in the little "God's acre" attached to Goytre parish church amid many circumstances which bore eloquent testimony to his private worth and public services. Seldom has such a large and representative assemblage been witnessed in the district. All classes of the community appeared to vie with each other to do honour to the memory of the departed gentleman; and the funeral afforded a striking illustration of the extraordinary influence which he had for many years exerted in relation to all institutions having for their object the social and moral elevation of the county. The mourning coach contained Miss A. Byrde (daughter), Miss L. Byrde (sister) and Mrs. R. Byrde and Mrs. C. Byrde (daughters-in-law.) The other relatives present included the Rev. F. L. Byrde, Keynsham (son), the Rev. R. Byrde, Honiton, (son); the Rev. H. Byrde, Broadwater, Sussex (grandson); and Mr. and Miss Dix, Mamhilad. The coffin, which was of polished oak with brass mountings, had an engraved breast plate—

Col H. C. Byrde.
Died Oct. 15, 1895.
Aged 79 years.

Colonel Byrde left five sons and a daughter—three are well-known in Ceylon: Col. Henry Byrde of Kandy; Mr. Charles Byrde of Sinnegolde, Ambalangoda; and Mr. Frank W. Byrde of Awissawella. In England one son, the Rev. R. Byrde, is headmaster of Honiton Grammar School, the other being chaplain of an asylum at Bristol.

We must hope to see the portrait of Col. H. C. Byrde—the first Planting Member of the Legislative Council—among the earliest placed on the walls of the new Hall of the Association when completed in Kandy.

(Writing of Col. H. C. Byrde, No. 2, accompanying the notes of his career.)

*To Mr. Eicher
Ceylon Observer
Colombo,
With Col. Byrde's recollections
yours
July 1895*

Agricultural Pests:

WITH METHODS OF PREVENTION.

BY MISS E. A. ORMEROD

(LATE CONSULTING ENTOMOLOGIST TO THE ROYAL AGRICULTURAL SOCIETY OF ENGLAND).

(Special for "Tropical Agriculturist.")

III.

BEETLES INJURIOUS TO CROPS AND PASTURES.

From the fact of there being a very large number of different kinds of beetles (*Coloptera*), and also from a great number of these injuring the crop, both in the grub, and in the beetle state, this order

is, perhaps, the most important of all to the farmer.

For a long time "Ground Beetles" were supposed to live almost entirely on animal food, and, therefore, to help very much in keeping other insects in check; but now it is found that various kinds injure growing grain, seeds of grass, and other vegetables. In the United States it has been found, by watching the habits and examining the contents of different kinds of *Harpalus*, that these feed on rootlets, seeds, and other parts of grass or corn, besides other matters animal and vegetable. In Prof. Forbes' experiments it was found that of twenty-eight specimens of *Carabidae* examined, twenty specimens, and these belonging to eleven species, had eaten vegetable food.

So far as I am aware, no further observations were recorded on the subject until about the end of the winter and early spring in the year 1888, when specimens of a grub, minutely resembling that of this species of Corn Ground Beetle, were forwarded to me as doing much mischief to young wheat plants in various parts of the south and east of England. In the summer of 1885 the night-feeding Ground Beetle, *Steropus madidus*, was sent me from near Bishop's Stortford, Herts, where specimens were captured in act of feeding on mangold roots. These beetles are partially carnivorous, as one of these forwarded to me killed one of its companions, and consumed its contents; but their field work, being about three in the morning, is seldom noticed. These observations make it very desirable to keep an eye to the habits of the many kinds of these pitchy or brownish "Ground" Beetles that we see so active in summer in corn-fields, and which have generally been supposed to be employed in clearing off insect vermin.

The second section, the *Brachelytra*, commonly called Rove Beetles, may be generally known by the short wing-cases, and, in the case of the very common beetles, sometimes known as Devil's Coach Horses, by their habit of arching up their tails when annoyed. Some feed on animal matter, including other living insects, and they much frequent rotten animal and vegetable matter. The grubs are very like those above described, but may be known by the fork above the tail being double-jointed, and furnished with stiff hairs. Both grubs and insects help us in clearing off other insect presence.

The third section is that of the *Necrophaga*, or *Clavicornes*, which includes beetles of very various habits, but for the most part feeding on decayed matter (especially the division often known as Sexton Beetles, which live for the most part in dead animals, carrion, and what we may shortly describe as "filth" generally). Their horns are usually enlarged or club-shaped towards the tip, or bent as if they had an elbow; and the wing-cases usually bend down at the sides, so as to cover the sides of the abdomen.

Some, like *Cadelle*, and the Corn *Cucujus*, are Corn feeders, and various kinds frequent flowers. Of these some species of *Meligethes*, or Turnip Flower Beetles, are very injurious, and furnish one of the few examples of infestations which may be satisfactorily lessened when established on the plant by remedial measures. The little green *Meligethes* Beetles may sometimes be found on the flowering shoots or rape, cabbage, and turnip, and cause great loss where the crops are being grown for seed.

The beetles feed on the pollen in the flowers, and lay their eggs in the unopened blossoms; the maggots from these feed in the bud and base of the flowers, and the seed pods. As a remedy it is found to answer well to have the infested tops and early blooms of the turnips picked, and put, with the beetles and maggots, into bags which are tied up as soon as full, and the contents destroyed. Under this treatment the growth of flowering shoots is much thickened, a great deal of the infestation is got rid of, and the crop is thrown back about a fortnight, which gives the rootlets increased time or action, and the plan is considered certainly beneficial in increase of crop, independently of clearing the insects.

The fourth section is the very important one of the *Lamellicornes* or Chafer. Some of these do us little harm, like the Stag Beetles, of which the grubs, so far as I am aware, live in rotten wood; or, again, the Click or Dor Beetles (*Geotrupide*), which bore down into the ground, especially where droppings are lying in cattle pastures, and carry the dung into the soil as food for their grubs. But there are many kinds, such as the Small May-bug or Garden Chafer (*Anisoplia horticola*), of which the grub does much harm in pasture land, together with another much rarer kind, (the *A. agricola*); also the Common Cockchafer, the Groat Golden Chafer, and others which, in this country, feed, in

the beetle state, on leaves of trees, or within flowers, and as grubs on the roots of grass, corn, or other ground crops, as well as trees; and, in the colonies, on the roots of coffee and sugar-cane, and altogether cause most serious loss.

The beetles are generally to be known by having a club of several leaves on their horns, such as the fan-like one that we see to the horn of the Cockchafer; and the grubs are large (sometimes as thick as the finger) and fleshy, with the end of the tail curved downwards and enlarged, as if it was swollen, so that the grub usually lies on its side. By this swollen tail and arched shape, and also by having three pairs of longish legs and strong jaws, you may commonly know the chafer grubs.

The habits of different kinds of chafers vary in such matters, as the depth to which the grubs bury themselves, or at which they turn to chrysalids, the length of time they pass in these two states, and also the time of day, or evening, when the beetles are at rest, which is a very important point in regard to getting rid of them; but the life-history of the common cockchafer gives a good general idea of that of the kinds that we are most troubled by. These beetles appear in early summer, and feed on leafage of many kinds of trees. The females lay their eggs in ground which is either cracked, or will allow of the female burrowing down into it to lay (the state and kind of ground is an important matter); she lays from twelve to as many as thirty eggs, from about four to eight inches deep. The grubs from these hatch in a few weeks, and feed on roots; maybe devastating young fir plantations, or attacking flax, or carrots, or many other crops, or ruining grass fields; there is a surprising variety in the kind of crop infested. After feeding for three or four years, they go as much as two feet or more down into the ground to turn to chrysalids, from which the beetles come up in the following summer, that is, the fourth (or, according to other opinions, the fifth) summer after they were hatched.

A great point is to keep the female from going down into the ground to lay her eggs. Sometimes, where the soil is of soft vegetable remains (as amongst the coffee plantations in Ceylon), it is found that laying a coat of the clay subsoil on the top answers; and, for field treatment, it has been advised to lay a good covering of some harder material, as marl or road-scrappings, on the surface, or to give a top-dressing of salt or gas-lime, or some application which might make the surface unsuitable for laying. Probably gas-lime would be very serviceable, and the washings down from this would be likely to drive any grubs near the surface away, for a time at least, and thus give the crop a respite. Gas-water applied at a strength which would not hurt the grass has been found to act well; the strength, of course, must be found by trial, as this varies much.

Where grubs are in unoccupied ground, that is, after the grass or crop has been killed or gathered, a great many may be got rid of by ploughing or digging deep enough to turn them up, and calling in the help of children to collect and destroy them, or that of the pigs, which will do much work without pay. The wild birds also, such as sea-gulls and rooks, should on no account be driven away.

There is, however, another treatment, not nearly enough thought of, which is applicable to all cases of infested land free of crop, and that is putting on a heavy killing dressing. Caustic gas-lime may thus be used, and alkali waste is excellent for the purpose. These are very much alike in their nature and effects; at first they destroy everything they touch, whether plant or insect, and the alkali waste is also used to clean the ground of deep-rooted weeds, such as conch-grass, coltsfoot, and thistles, and is washed down by rain into the soil, so as to make the drains run milky at a depth of three feet. This is procurable for little, if any, outlay, beyond cost of carriage from chemical works, where it is thrown out as waste. Now attention has been drawn to its value, and it is likely to be made available.

When it (or the gas-lime) has done its first work in the caustic state, the action of the air gradually turns the poisonous properties to sulphate of lime, and they become a good manure of the nature of gypsum.

If a heavy dressing of this kind was spread on land infested by any grub at the time when it is near the surface, and without disturbing the land, we should thus take it, as it were, unawares, and it would be destroyed by the poison before it had time to get out of the way, instead of, as is often the case, being merely made to go down to a safe depth, from which it presently comes up again to attack the new crop.

The fifth section of beetles belonging to the great division of the *Pentamera*, or those having customarily five joints to their feet (*tarsi*), is that of skip-jacks and their allies, scientifically the *Sternovi*. These do little, if any, harm, in the beetle state, but in the grub-state—that is, as what we know as wireworms—the mischief and loss they cause to the country are beyond calculation.

The wireworms will feed on the roots of almost all crops excepting mustard, which they frequently have been found to avoid, and live for five years before they cease eating to turn to chrysalids, and thence to chick beetles. They are commonly of a yellowish colour, and take their name from their power of regaining their position when laid on their backs by a sudden jerk or skip up in the air, accompanied by a click.

The female beetle lays her eggs on, or a little below, the surface of the ground, amongst leafage or roots, and especially in such places as grass meadows, or clover leys where the surface is undisturbed for a time, possibly for years, and consequently the ground below swarms with wireworms of all ages. When the pastures are broken up, these rough-skinned grubs are in no way hurt, but remain in the ground, ready to feed on each succeeding crop that is put in, until the time for their change comes.

Clover leys and pastures are the main starting-point of wireworm-attack to our field crops, and the method of treatment may be considered under the two heads: firstly, how to prevent egg-laying, and clear infected land, before re-cropping or sowing; secondly, how to lessen ravage, or support the plant under it, if wireworm is found present in the growing-crop.

To prevent egg-laying the ground should be made as unsuitable as it can be for the purpose. It is advised to feed down the grass as bare as possible before ploughing, or to go further, and pen sheep on it, gradually moving the hurdles forward, so that every part of the field may be thoroughly trodden. The sheep in this case are fed with turnips and other regular feeding stuffs, and the amount of liquid and other manure thus worked into the land thoroughly prevents the field being inviting for eggs to be laid on it, and destroys any eggs that might be on the surface. Dressing pasture-land with lime brought fresh from the kiln, and spread hot so as to burn the grass, answers well. Sowing salt, at the rate of 5 to 8 cwt. per acre, on grass or ley before breaking up, has also been found to answer, and good dressings of caustic gas-lime, or of alkali waste strong enough to destroy all live matter on the surface, are very serviceable. Paring the surface, and collecting and burning the parings, gets rid of a deal of wireworm, if the burning is done whilst the wireworm is in it; and in any case gathering up the surface rubbish, and burning it, is useful as a preventive, for, even if the wireworm has left the locks of roots for a time, we thus get rid of the knotted lumps to which it would have presently returned, and which would have kept the land open for its passage.

The habit of the wireworm in feeding is to keep near the surface, gliding about, as its smooth glassy surface enables it to do, from one plant to another, eating out a piece here and a piece there, and thus injuring the whole crop; and, if this happens whilst the crop is in its first growth, the value even of those plants that struggle through is much lessened.

For this reason the main points, in preparation of ground to carry the plant over attack, consist in treatment that will give a good seed-bed, and mixing the soil with such chemical manures as will be good for the plant and unsatisfactory at least to the wireworm; also so to clear the ground of rubbish and work it that it may be sufficiently firm (or admit of being sufficiently "firmed" by treatment afterwards) to prevent the travelling of the wireworm. For this purpose it is advised to plough in good time in autumn, and work the land well so as to get it in good order and consolidated, and either by burning, rotting, or whatever means may be preferred, prevent it being kept open and full of harbours for wireworms; stubble and roots, cabbage stalks or beanhaulm, and all such matters, are wireworm-helpers. If we took down the notes of special applications found serviceable to plough in, we see constantly repeated: salt, salt, salt, gas-lime, gas-lime, hot lime, lime and salt; and in a less degree (probably because it is not so well-known) alkali waste is also highly recommended. Kainite also is useful, and regular fertilisers, as superphosphate and nitrate of soda. But it is worth notice, especially in preparation of ground for turnips, that there is a great doubt whether wireworm is not often encouraged by the use of farm manure. The wireworms of two of the commonest kinds of click beetle have been found respectively in dung, and in well-rotted horse dung. It is considered by some farmers that crops so manured are the most infested, and if we consider that in this manure a large portion of the material is still unchanged vegetable matter, of much the same kind as wireworms would naturally feed on, it gives a reason for attention to this point. Thorough salting of farm manure has been advised to get over this difficulty. It should also be remembered that heaps of decayed turf are headquarters of wireworm, unless treated with caustic lime, salt, or the like dressings; also that (take what pains we will) if grass headlands or grass strips are left across or by our fields, there we make homes for the wireworms, and they will add all requisite comfortable provision from our crops. The only crop which wireworm appears to have customarily a great objection to is mustard. This, therefore, is sometimes useful as a cleaning crop.

When wireworm is present, strong fertilisers—such as nitrate of soda, guano, superphosphate, or others—are serviceable; and mechanical means, such as heavy rolling, are of use, for thus the creature is prevented travelling, and some of the pests are probably set fast and killed. Treading by sheep or cattle, or by the heavy iron-shod feet of horses, similarly firms the soil serviceably. The wireworm can be drawn away from the attacked plants by dressings of rape-cake or Indian rape, that is, mustard-cake, and in the latter case has been found by experiment to perish in about a fortnight where it had no other food, and, connecting this with the power of mustard as a cleaning crop, it suggests that further experiment would be useful.

These are some of the main points of wireworm prevention:—Prevent egg-laying; clear the ground of wireworm, and get a good start for the plant; keep up the strength of the plant under attack, and keep the power of the wireworm in check; and also do not dress your land with wireworm, either in decayed turf, or by letting grass homes for it be amongst your crops. The subject is one of great importance.

AGRICULTURE IN THE ALPES MARITIMES.

The visitor who goes to the Riviera in search of health or pleasure during the winter months, and who confines himself to the fashionable towns on the coast, would not be inclined at first sight to consider the department of the Maritime Alpes as an agricultural district. It is, however, strictly one of the agricultural departments of France. There are few manufactures. The most important are the perfumery

factories of Grasse, which consume a great quantity of cultivated and wild flowers, as well as aromatic plants grown on the coast, and among the mountains of the department. The Acting British Consul at Nice, in his last report, states that the department contains 373,800 hectares (hectare=2.47 acres), of which 73,764 hectares are ploughed land, 61,411 hectares are planted in vines, 19,513 hectares in timber, 20,774 hectares are meadows, and 90,000 hectares grazing ground, or "Alpes;" of the remaining territory, 55,942 hectares are built over, or used for roads and ways of communication, while 52,363 hectares are uncultivated, or barren. The soil is naturally fertile, and produces well where it can be irrigated by means of the canals. A great deal of the cultivation is done on the terraces made on the mountain sides, every kind of crop being grown on them, from olives to cereals. Wheat, meslin, rye, barley, and oats are grown, but not to any very great extent. In 1894, 20,941 hectares out of 61,414 hectares planted in vines, gave 36,298 litres of wine, as against an average of 49,092 litres. The wine produced 1895 was very abundant, but not of such good quality as vintage of 1894. The wines, as a rule, inferior, but near Bellet they make a wine which some consider excellent. Besides the wine grown in the country, and the *vins fins* imported for the consumption of the well-to-do classes and foreign visitors, large quantities of inferior wines are imported from Spain and Algeria into Nice, Cannes, Antibes, and Mentone. These wines are often doctored, and generally are what is termed *plâtré*, and are not very wholesome. There is more wine drunk per head of the population in Nice than in any town of France. Market gardening is carried on chiefly near Nice, towards the Var, at St. Laurent-du-Var, Cagnes, Antibes, Vallauris, and Cannes. Some of the gardeners make a specialty of *primeurs* for the London and Paris markets. At Nice there is a trade in dried vegetables. These, as well as candied fruits, are largely sent to Bordeaux, from whence they are exported to England. Fruit culture has made great strides of late years, owing to the extension of the candied fruit trade. Among the fruit trees whose cultivation can be considered of the first importance come the peach, the fig, the plum, cherry, orange, and, at Mentone, the lemon. The olive tree of the Riviera is cultivated for its oil. The dry and calcareous nature of the soil being admirably suited to the cultivation of the peach, the *Persica Amsden Puncé*, a native of the United States, is successfully grown in the open air, the fruit ripening from about June 1 to June 10; the peach tree suffers principally from the presence of ants. The fig tree is much cultivated in the department, and its fruit is both sold fresh in the market, or candied and dried. The dried figs of Nice are consumed locally. Three lb. of fresh figs give one lb. of dried figs. Dried figs of prime quality fetch from 40 to 60 francs the 100 kilogrammes. The Arabs of Algeria manufacture a kind of spirit, known as *Araki*, from the dried figs, and the peasantry of Nice and the Genoese Riviera make a kind of sweet wine from this fruit. The tree gives two crops every year. It requires careful cultivation, and to be judiciously cut. Like all other fruit trees in the Riviera, the fig suffers greatly from insects. Cherries are very plentiful, and the fruit is largely used locally in the manufacture of bonbons, preserved in brandy and candied. The crop has not been so good this year as in 1895 or 1894. Orange and lemon trees are largely cultivated all over the coast districts; besides the climate, the soil is very favourable to these trees, as they require a calcareous one, rich in lime and potassium. They generally die, if the temperature falls below 23° Fahrenheit. The common orange tree, cultivated at and near Nice (the *Citrus aurantium*), produces its maximum at about 20 years of age. This may be calculated at 600 to 1,000 oranges per annum, 1,000 oranges weighing about 150 kilo-grammes. They are, however, principally cultivated for their flowers, which are sold at 40 centimes per kilogramme, or about twopence per lb. With the skins of the orange an essential oil is made, both at Nice and Grasse, which is called essence de Portugal. The bitter orange

tree, or *Citrus Bigardia*, is cultivated for its flowers, which produce a kind of water muc., used in France called *eau de fleur d'orange*, and also an essence. The skins of these oranges are dried in the sun, and are exported to England, where they are used for making cakes and puddings. Dr. Emile Sauvaigo, in his book, "Les Cultures sur le Littoral Méditerranéen," estimates that the average annual income in the Alpes Maritimes derived from the cultivation of the olive, is £320,000. In spite of this, the cultivation is on the decline. Dr. Sauvaigo gives the following reasons for this—"The competition of grain oils, such as cotton seed, &c., and the numerous frauds and adulterations practised in the olive oil trade, and besides these there are the dearth of labour, faulty pruning and insufficient manuring, and last, but not least, the increase of the parasites of the olive tree." The tree grows best on slopes, and prefers a dry soil, rich in carbonates of potassium, lime, and magnesia. It suffers from cold, and dies at 14° Fahrenheit. On the Riviera, a tree planted from a seed begins to bear fruit in about 13 to 14 years, and those planted from cuttings in about 8 years. It flowers in April. In August, when the fruit is well-formed, it suffers most from its enemy the *Keiroun*. One of the most difficult things in olive culture is the pruning of the trees, and this has to be done as soon as the crop has been gathered, or after severe cold weather. As regards reproduction (and this, says Consul Jerome, may be of special interest, as on one or two occasions the consulate has been asked by the London representatives of Colonial Government to obtain seeds and young grafted olive plants, to be sent to the Colonies for plantation), this is effected, first by seeds. The ripest and finest olives are chosen, the stones are separated from the pulp, and they are spread out to dry in the autumn, and planted in the spring. They take about a year to come up, but if the stones are broken, without any damage being done to the kernels, and by sowing these in February or March, the young plant makes its appearance much sooner. The seedlings, after having been kept in a nursery garden for about four years are grafted. Dr. Sauvaigo recommends graftings on the wild olive (*oleaster*), or on suckers, and these should be chosen as far from the parent tree as possible. Olive trees are also reproduced from cuttings. In all cases care must be exercised that the young plants should be taken from the nurseries just before winter or the rainy season, so that they should benefit by the natural moisture of the soil. The crop is gathered by women and children at the rate of 1 franc to 1 franc 50 centimes per day. The fallen fruit is picked up under the trees during the winter, and in April or May the trees are beaten. If the olives cannot be immediately taken to the mill, they are stored in heaps, which have to be stirred to prevent fermentation. The olives are usually sold to the manufactures of olive oil, at the rate of from two to four francs the double décalitre (20 litres), according to the quality. The oil produced at the mill can be divided into several kinds:—(1) Virgin oil, or the oil pressed out and carefully filtered several times; (2) the first quality oil of commerce, or the oil scalded in vats, which is a much quicker process, but somewhat spoils the quality of the oil; (3) *Huile de resence*, or refuse oil, used as a rude sort of lubricator oil by the peasantry. An olive orchard brings in an average income of £20 per annum for each hectare, and the land is valued at from £200 to £180 per hectare. The diseases the tree suffers from are numerous, the most formidable being known in the district as *la fumagine*, caused by a small fungus. The mills where the olive oil is made are, as far as machinery goes, of a very primitive character, generally driven by water wheels. These are defective in construction, and the fall of the water badly arranged. The machinery inside the mills is made of clumsy wooden cogs and contrivances. Consul Jerome says he is sure that improved machinery for making olive oil would find a ready sale in the South of France and Italy, providing that it was not of too complicated or expensive a character.—*Journal of the Society of Arts.*

CEYLON EXPORTS OF COCONUT PRODUCTS:

THE SPREAD OF THE PALM-GROWING INDUSTRY.

The revised table of exports, as amended by the Chamber of Commerce, which we give as a *Supplement* to this issue, throws some light on the position and the development, in some directions, of the Coconut Palm Industry within the last 10 years. It is still a native industry, in the sense that it is chiefly in the hands of natives, just as tea planting is chiefly in the hands of Europeans. The *Tropical Agriculturist* was among the first to counsel the encouragement of natives to plant up their little ex-coffee patches with tea, and it had to face not a little ridicule and impotent snarling in this matter, as in its agitation for Railway Extension, before men saw that there was room for both European and native in tea cultivation and manufacture and that there were many conditions favourable to the growth of the industry in native hands. At the present day, it is not in little patches only that our native friends are interested, but in extensive blocks as well, both on the hills and in the low-country. What we looked to specially was a very considerable and yearly increasing local consumption of tea. In old days we reckoned that 50,000 cwt. of coffee were used by the people of Ceylon and we do not see why we should not have a native consumption of tea equal to several millions of lb. a year before long.

If Ceylonese of all classes are becoming alive to the profits derivable from the tea industry, not less marked is the confidence which European capitalists at home, and hard-headed colonists on the spot, are showing in the old coconut industry. It would be a great mistake to suppose that European capital never found an investment in palm culture till of recent years. When coffee was the rage in the mountain zone, the palm groves of the Northern and Eastern provinces attracted not a few Europeans. Their experience, aggravated by difficulties of transport, was not very encouraging; and the minimum of profit with the maximum of waiting did not help the industry in competition with products from which quick, and for a time large, returns supplied the precise conditions which prove attractive to strangers in a strange land. The European looked askance at coconuts, and we doubt whether a single agency firm had a single coconut estate on its books 20 to 30 years ago, or was prepared to make or sanction, an advance on coconut property. All that is changed now; and one of our largest and most uniformly successful Tea Companies set a striking example a few years ago by investing its reserve fund, or a good part of it, in coconut plantations. Since then the confidence in coconuts as a safe investment, yielding by no means insignificant returns, has grown; and we hear of extensive tracts being opened up for coconuts by European firms and Companies, while a larger number of proprietors are combining tea and coconut culture in the same fields, with, in some cases, encouraging results, though in others we have heard fears expressed that the one product interferes with other. Indeed, it is evident, that the shrub, hardy though it is, will have ultimately to yield to the great umbrageous tree with its matted network of roots; but not, we trust, before the enterprising proprietors are assured of a return from coconuts, hastened by the cultivation of the tea, sufficient to compensate for the diminution, or the stoppage, of the income from tea. Mean-

while, there is a brisk demand for good nuts from selected trees for nurseries on lowcountry and upcountry estates—up to almost 2,000 feet in elevation; and we learn from a Veyangoda proprietor that scarcely a month passes without his having to despatch seed nuts from his estate on orders by cart or rail.

Though the cultivation of this most useful palm is yet, and probably always will be, chiefly in native hands, the development of the industry is principally due to European enterprise and capital. Coconut oil mills first encouraged the extension of plantations, as their voracious maw began to demand far larger feeds of copra, than the slow and primitive checkoo; and now the desiccating mills, also the outcome of the inventive genius and restless enterprise of European capitalists, are again stimulating the demand for nuts, which had slackened somewhat, through new illuminants, lubricants and fatty substances necessary in soap-manufacture competing with, or elbowing out the oil from some of its old markets. We thus fail to note any actual growth in coconut oil exports. Last year they amounted only to 343,000 cwt.—positively the lowest figure for the decade, if we except 1887, which showed a falling-off as compared with some earlier years; while in 1892 the exports ran as high as 550,000 cwt. The difference of 217,000 cwt.—an average year's exports—represents at 500 nuts to the cwt, about 108½ million nuts; and our readers can understand what a rundown in the price of nuts this slackened demand for oil would have involved, were it not for the Desiccating Mills which have continued to absorb a growing quantity of nuts, year after year, if we except 1894, when there was a temporary falling-off caused it is believed, by slackening work in the Mills to discourage competitors. The first record of the desiccating business is to be found in the Export figures for 1891 when 416,330 lbs. were exported. The next year there was a leap up to over 3 million lbs; in 1893 over 6 million; while in 1896 we exported over 10 million lb. of Desiccated Coconuts, representing at 3 nuts to the lb., no less than 30 million nuts! We have seen that the difference in the output of oil between 1892 and 1896 represents a difference of 108½ million nuts. Now, the difference in the desiccating business of the two years, accounts only for 7 million lb., or 21 million nuts; so that last year is to the bad, as compared with 1892, to the extent of 87½ million nuts. It is no wonder that the price of nuts has receded this year and is lower than it has been for three years back. It will not, indeed, be safe to expect higher prices until the demand for oil has quickened. The shipment of unmanufactured nuts, last year, shows a considerable increase over that of 1895—as much as 3 million nuts; but a total of 13 million nuts exported, though the highest on record, cannot count for much in considering the shrinkage of oil. Still the demand for shipment and for desiccating purposes helps to keep up prices on the seaboard and in the districts surrounding the Mills; while another element in the calculation is the increased demand for culinary purposes, which grows with the growth of population and specially with the growth of general prosperity. We suppose the better part of the nuts exported finds its way into the coconut butter business. Of Copra, or the dried kernel of the nut, 50,000 cwts. were exported. The figures, though better than for the three years preceding are not to be compared with those of some years ago. Within the past decade the

exports ran into six figures on four occasions, and on every one of these, the exports were more than double those for 1896, and almost treble! So that in that direction too, there is little ground for satisfaction. Of Poonac an average quantity was exported in 1896, though less than for the previous six years, in natural correspondence with the diminished outturn of oil. But we never lament a falling-off in poonac exports, as the more of it we retain for feeding stock and for manure, the better. The Coir business—whether in rope, yarn or fibre—was an average one, and from all accounts the trade in these articles has been overdone, and the profits desirable from them are not very dazzling. Altogether, Coconuts have not shown up as well last year as the year before; and the slack demand for oil in European and American markets must tell to some extent on business this year, until a brisker demand springs up, and Indian competition begins to tell.

PRODUCE AND PLANTING.

TEA IN THE UNITED STATES.—The difficulties of pushing Indian and Ceylon tea successfully in the United States are well-known. It requires plenty of pluck and perseverance. The following letter from the Philadelphia correspondent of the *Grocer* is of interest as showing the state of the tea trade. Writing of that portion of the city where the relics of the Revolutionary period most abound, the correspondent says: "In this section of the city are many tea importers and jobbers, some being the largest in the United States. One firm reports sales in a private way of 88,000 half-chests in ninety days, an exceptionally large distribution for a firm in this country where tea is not in popular favour. Most of this tea was sold by travellers who go as far west as the Rocky Mountains. This house does not speak enthusiastically of the prospects of Ceylon and Indian teas, because their flavour is so different from the green tea and Oolongs in favour here for 125 years. On the other hand, I found those who think that Ceylon and Indian teas are the teas of the future. They are certainly very much in evidence at the Food Show now being held under the auspices of the Philadelphia Retail Grocers' Association. I found that the main exhibit was by the Ceylon and Indian tea interests. A very large space has been fitted as a tropical tea garden wherein maidens passably fair invite you to tarry and sup. You are served, as you elect, with a cup of hot or cold tea, together with a biscuit. Upon conversing with the manager, I found him quite an enthusiastic American advocate of Ceylon tea. He states that the greatest drawback is that consumers are not careful in brewing, as they use as great a quantity of Ceylon or Indian tea as of the China or Japan sorts, and the result is a very heavy-bodied liquor, sweetish and with too much tannin. It is to overcome this fault that demonstrations in the proper use of Ceylon and Indian tea are given. Tolley's teas were represented in a separate pavilion, where consumers could also obtain a cup of the delicious beverage, and go away provided with a beautiful lithographed *brochure*, somewhat humorous in character, but of a kind to provoke the recipient to carry it home and preserve it for amusement and reference."

WHAT THE AMERICANS DRINK.—"The Americans are not given to tea-drinking. They go in for coffee and beer, using both very freely—about nine pounds of coffee and sixteen gallons of beer *per capita*, while of tea they use about one and a third pounds. It is seldom I have found a cup of tea decently brewed, except when made to order in some first-class hotel or famous restaurant. Certainly, 70,000,000 consumers, with tastes varying greatly, offer a fair field for the push, pluck, and persistency of the Ceylon and Indian tea people. Everywhere I find photographs of scenes in the tea-gardens of Ceylon, and others

illustrating methods of manufacture. All of this is calculated to make a bigger demand for machine-made tea. I was also presented with a private statement of the position of tea, prepared by one of the oldest firms of brokers in the land. It shows an estimated supply for the season of 1896 and 1897 of 82,350,000lb. against 195,300,581lb; in 1895-96. The supply is made up as follows:—Green tea 14,000,000lb; Japan, 40,000,000lb; Formosa Oolong, 16,000,000lb; Amoy Oolong, 1,250,000lb; Foochow Oolong, 3,600,000lb; Congou, 7,500,000lb; total, 82,350,000."

BRAZILIAN COFFEE.—An important sale of Brazilian coffee on spot took place at Hamburg on Thursday week, 24,000 bags, mostly Santos, lying in steamer now in port, being disposed of by the banking house of L. Behrins and Sons. The buyers were local firms. There is reason to believe that this coffee was a consignment made by the Brazilian Government, in place of bills in discharge of amount required for payment of interest on Brazilian bonds. The coffee was consigned to Messrs. Rothschild in London, who had it sold in Hamburg.

COFFEE IN 1896.—In the coffee market values receded from 77s to 62s in August for ordinary Colombian, while middling sorts of other Central American moved from 94s to 85s. East Indian fell proportionately for the common and pale kinds, and Bahia, African, and Santos dropped about 25s, 50s being touched for good average Santos, while, on the other hand, good to fine qualities have, with slight fluctuations, maintained very full rates. One noteworthy feature was that when supplies were at the heaviest prices were relatively high, as both dealers here and on the Continent ran their stocks so low that they were compelled to buy. After they had filled their requirements prices gradually declined, and with heavy Brazil receipts pointing to a large crop the downward movement became more pronounced. In August, however, when supplies had fallen off and demand became more active, values recovered 4s to 6s. Towards the close, with supplies of new Colombian coming forward rather freely, prices again gave way slightly. Ceylon, in consequence of leaf disease and the gradual decadence of cultivation, has been in small supply and commanded extreme prices. A parcel of native, the first seen for many years, brought full rates. East India, considering the quality, which was not altogether up to the usual standard, averaged well. Costa Rica has been in larger supply, and quality generally was better, especially fine marks. Offerings of Nyasaland (grown from Indian seed) have increased and high prices were realised. The growth, being of good colour and make, promises to rank well with other descriptions in the favour of the trade, but so far the parcels have been very mixed with defective berries, showing the necessity for more thorough hand-picking. In the terminal market business has ruled exceptionally quiet, even the change altering the minimum quantity dealt in from 500 to 250 bags falling to stimulate speculation, but during the latter part of the year there has been a little more doing in Santos futures. Prices have steadily declined, good average Santos being quoted 70s in the beginning of January and closing at 50s, after having been as low as 47s 6d. Fair Channel Rio, opening at 61s 9d, is now 48s, having been as low as 43s in the beginning of October.

COCOA DURING 1896.—Cocoa experienced unexampled depression during the greater part of the year. For the first six months supplies poured into the Port of London to such an extent that the accumulated stock in bond was about double the average stock of the last ten years. Manufacturers were consequently able to purchase on their own terms, and values gradually declined until the lowest level ever recorded was reached. For in-

stance, Trinidad cocoa became a complete drug in the market, so much so that the principal buyers of this description refrained from purchasing for nearly half the year, and to effect sales importers had to accept a very considerable reduction, values for the first time sinking below those for the produce of neighbouring islands. Some relief was experienced during the latter portion of the year, this being caused by a shortage from Ecuador, which country continues to be the principal source of the world's production. Notwithstanding an increased acreage under cultivation in that country, the total crops, after a record yield in 1893, have yearly diminished. Other sources of supply, such as Ceylon, St. Thomé and Brazil, produced average quantities. The lessened yield from Ecuador caused a rapid falling off in the accumulated stocks, which at the present moment have sunk below those of the corresponding period of last year. At the later sales of the year a better demand was apparent, and prices of some growths showed a tangible recovery. It is worth noting that a considerable reduction in prices made by German manufacturers caused an immediate and important increase in consumption amounting to 40 per cent in the short space of two years, as is shown by the official duty payments. The principal English manufacturers retain practically the high prices based on the values of the raw product of years gone by, consequently no increase can be seen in the consumption of the United Kingdom. A feature of the year and an object lesson to home manufacturers was the inclusion in auction of considerable quantities of German and Dutch prepared cocoa, which, notwithstanding an extra duty, was sold at price greatly below those of English makers.—*H. and C. Mail*, Jan. 8.

CEYLON TEA IN 1896.

Messrs. Tudor, GoodLiffe, and Co. in their Report for 1896, say :—

CEYLON TEA.—Ceylon tea has during the year marked a further advance in popularity, both deliveries and production showing an increase on the previous year. The colonies and other countries have drawn rather larger supplies direct, and Russian demand has now become such an established factor on our market that many lots of fine quality Pekoes are now placed beyond the reach of home trade buyers. Unfortunately, however, the bulk of last year's import leaves much to be desired in both leaf and liquor, some of the shipments reflecting little credit on their manufacture. The crop, generally, ruled thin and poor, with a low average of prices, quality often being sacrificed to quantity, although any invoices possessing strength and flavour always commanded good prices and brisk competition. The trade has received little encouragement even to buy beyond immediate requirements, no improvement being noticeable in the retentive properties, and rapid deterioration in quality has as usual often deprived holders of any benefit arising from a harder market. Broken Pekoes have been in abnormally large supply, and as leaf is becoming more in request for packing purposes, the former have marked a declining demand. Prices have ranged from 4d up to about 1s 8d. All grades have been comparatively cheap throughout the year, except when affected by the dearer Indian market in the spring, and buyers have generally been able to obtain a fair supply of leaf under 6d.
—*H. and C. Mail*.

THE FINANCIAL PRESS ON THE TEA INDUSTRY AND TEA SHARES.

The position of the tea industry is frequently commented by on the several financial papers, and these comments are, as a rule, very favourable. We ap-

pend recent extracts from the *Financial News* and the *Financial Times* :—

THE "FINANCIAL NEWS."

One of the features of last year was the increased attention paid to investments in tea companies, and it seems fully justified by the statistics that are to hand. In 1895-96 the Indian output reached 146,000,000 lb, against 136,000,000 lb in the previous year, and that of Ceylon 106,000,000 lb, against 98,000,000 lb. Consumption, however, very nearly kept pace with the larger production, for the home market absorbed 201,000,000 lb of British-grown tea, against 190,000,000 lb in 1895, and foreign markets took 42,000,000 lb, an increase 5,000,000 lb over 1895. The consumption of China tea, on the other hand, decreased from 26,000,000 in 1895 to 20,000,000 lb last year, and the percentage of China to the other teas has now fallen to nine, which compares with 54 for Indian, 35 for Ceylon, and two Java, etc.

THE "FINANCIAL TIMES."

We have referred to experts with regard to the outlook, and we find them agreed in endorsing this view. Taking the question on the broadest lines, we do not find that great improvements in dividend are to be looked for in the near future, but it is thought that there is a reasonable prospect of the present rates distribution being maintained. If such a view be correct, it is quite clear that tea company shares, considering the large yields they give at present, must tend to increase in market value, independently of any increase in the dividend. The returns to purchasers at present prices are, on the basis of recent dividends, of the kind which one only looks for on highly speculative investments. If those recent dividends turn out to be, on the average, stable, there is obviously a margin for a moderate improvement in prices, and tea shares will go into a higher category in the classification of market securities. A consideration which has adversely affected their market value hitherto is the limited character of the market, and this disadvantage still prevails to a considerable extent. In view of that fact, it will not be amiss to give a word or two of advice and explanation to readers who contemplate investment in tea companies' shares. It may appear paradoxical to recommend purchases of individual shares when the market in them is depressed; but, nevertheless, it is the sound policy under the present circumstances of a limited market, mostly conducted by means of negotiation, and not, as on the Stock Exchange, by a free quotation. On such a limited market the seller even of a few shares may very probably depress the quotation to an abnormal extent. This is the buyer's opportunity; and the converse applies to the seller. While the market is developing we should advise both buyers and sellers, in the first place, to satisfy themselves as far as possible regarding the intrinsic merits of the company whose shares they propose buying; in the second place, to see that they buy at reasonable prices, and not on the top of a rise, brought about by some fortuitous circumstances; and in the third and last place, we would commend to their notice the mixed metaphorical advice, conveyed to us for the benefit of our readers by one who knows as much about this market as anybody does: "Don't put all your eggs into one teapot." In other words, while believing in the hopeful character of the outlook, he recognises the speculative nature of the industry, and would not recommend pinning one's faith upon any individual company. The prospects as regards the working for 1896 are that they will probably be better than for 1895, which was a lean year, but that they will not be so good as those for 1894, when the success was phenomenal.

There has been a good deal of talk about the danger of over-production. That is a matter which will one of these days have to be seriously faced. But at present it is not a thing to arouse concern. The experience of tea-growers has been that increased production has far created fresh outlets, notably in Australian colonies, Canada, the United States, and, to a lesser degree, the European con-

continent. This is due to the increasing activity shown in pushing trade by the planting community and by the Mincing Lane traders. While undoubtedly the risks attending on a tea-planting business are great, there is this point to be noted—that the sales of the produce are not regulated by speculative market conditions to anything like the same extent as prevails with regard to nearly every other class of produce. It is, we believe, the fact that seventy to eighty per cent. of the tea grown is shipped home to be sold at current market prices on account of the producer, whether that producer be a private person or a public company. There is no organised speculative market such as exists with regard to wheat, for instance. To all intents, we may say that the produce is sold by auction. It is not held up at a price to prohibit or curtail the normal demands of customers. There is another check to overproduction in the limited supply of labour. The coolies gravitate to the old-established fields, because, amongst other things, there is on these much less danger of fever and other diseases arising from the miasma so prevalent in the jungle until an estate has been opened up. Consequently, competitors to those old-established companies are handicapped by the difficulty of getting suitable labour. In various parts of the world attempts have been made to compete with Indian and Chinese tea, but they have not come to anything; beyond that comparatively restricted tea-producing districts in Central Ceylon, no other substantial production threatens, unless, perhaps from Java, whose produce goes almost entirely to Holland. Attempts have been made in Natal to grow tea, and these may ultimately come to something. But even so, all that she could produce would be absorbed in South Africa itself, and the chief markets of the world would still be left to the Eastern tea-producers. In Virginia, in the Caucasus, and latterly in Brazil, efforts at tea-growing have been made, but the results have not been such as to cause alarm to the Indian tea-growers. Taking everything into consideration, therefore including the large yield at present obtainable, Indian tea shares promise well to the discreet investor who recognises the fact that the present limitations of the market may prevent a sale at an exact moment. He must lay his account for ups and downs in prices, but the market in tea shares is daily becoming more free, and this, as also the rise in prices of shares, is largely attributable to the recent consolidation and amalgamation of companies engaged in the business. There are fewer companies now than a year ago, but their several capitals being larger, their shares are more readily marketable, and the members of the Stock Exchange who deal in such shares are in close touch with the outside merchants, who devote to them their special attention.

NEW COFFEE FIELDS IN COLOMBIA.

I have the honor to forward an account of the new coffee country of the Sierra Nevadas of Santa Marta. It has been found that coffee does well in that section, and large tracts of land are being secured for plantations. I am indebted to William Crane, Esq., an American now growing coffee in the Sierras, for much of the information.

Until two or three years ago, the Sierra Nevada mountains, whose snow-crowned summits are the first to meet the gaze of the traveller hitherward, had invited in vain the explorer, the miner, and the botanist; and the scanty knowledge of them gained by the Spaniards, in unsuccessful attempts to subdue their aboriginal inhabitants, had been forgotten.

At last, three hundred and sixty years after the settlement of Europeans upon these shores, the inhabitants are awakening to the fact that at their doors lies one of the most-favored districts of South America for the cultivation of coffee.

For many years, coffee has been grown in the interior departments, notably Santander, Cundina-

marca, the Tolima, and its export from these departments has steadily increased for fifteen years, but the difficulties in the way of getting the crop to tide water or to a navigable stream have been a serious deterrent to a general development of the regions adapted to coffee culture.

The cost of carriage for several days' journey upon pack mules to reach the Magdalena river or some tributary, navigable only by rafts or canoes, and the loss and damage suffered in transit, have made such inroads into the profits that would otherwise result from its production that, although the coffee is of a high grade, little attention was paid to its cultivation until the sudden collapse of the market for cinchona bark drew the attention of commerce to coffee as the most available article of exchange for foreign importations.

Some effort has been made toward the improvement of transportation, many concessions have been granted for railway, and vast sums wasted in subsidies; but no considerable betterment is noticeable in the means of land or water carriage over those of a quarter of a century ago.

In the latter years of the last century, a single small plantation of coffee was established on the northern slope of the foothills of the Sierra Nevada, but was abandoned for two generations, on account of the low prices and small demand for coffee of that time. This and a few small plantations in the lowlands were all that saved the entire region from being an unbroken wilderness.

The favourable reports of a few lookers about who have explored this range or rather group, of mountains have attracted attention, and, latterly, beginnings have been made upon a dozen or more plantations, chiefly within a radius of as many miles from Santa Marta.

The conditions of soil, temperature, rainfall, and available water power can hardly be surpassed. While the greater part of the section is composed of slopes of greater or less steepness, little of it is so steep as to be unavailable for planting, and there are frequent intervals and high table-lands of considerable extent.

At a height of 2,500 ft., the mean temperature is 70° F., 80° and 60° being the maximum and minimum throughout the year. The climate is salubrious, and the European can perform a full day's labor without undue fatigue. All the vegetables and many of the fruits of the temperate zone flourish. Upon the northern and north-western slopes, coffee is found growing wild in considerable tracts of the forest.

The supply of young plants in such profusion is of great value in the making of a plantation, shortening by a year or more the time which would otherwise elapse before a crop could be produced.

But perhaps the most important advantage which this region presents is its nearness to the excellent harbor of Santa Marta, to which port the product of plantations can be carried at trifling expense, and with no risk of loss or damage. Santa Marta is a port of call for several lines of steamers, besides a regular trimonthly service of fruit steamers, soon to be made weekly.

While considerable tracts of the land near the port have been taken up, there still are hundreds of square miles of the public domain well adapted for coffee planting; and the land laws of the republic are very liberal, offering equal conditions to native and foreign settlers.

The quality of coffee grown here is fully equal to the best grades produced in the country, and as an indication of the duration of a plantation, the old plantation, before mentioned may be cited, for, although no care and but trifling expense have been bestowed upon it during at least half a century, the present owner still gathers from the portions not smothered entirely by forest growth, enough fruit to give him a profit over maintenance of plant, while employing only the most antiquated and crudest methods of preparing the crop for market.

JOHN BIDLAKE, Consul,
Barranquilla, June 5, 1896.
—Rio News, Dec. 15.

RHEA: A NEW FIBRE.

How many bankruptcies does it take to establish a new industry? British manufacturers are by all accounts among the most conservative of mankind, and if the name "ramie" suggests anything to a Lancashire cotton-spinner it is the recollection that a great many people have dropped money over this particular fibre. Nevertheless, it seems probable that the British manufacturer will have to take ramie seriously. It is by no means a new invention; no one can say for how many centuries Orientals have used the fibre, which is found in the bark of a particular kind of nettle, to make themselves rough, strong cloths and nets or lines for their fishing. But as an article of European commerce it is so new as hardly to be counted among our imports; and, though the plants which produce it have for many years been cultivated under European supervision, it has only been for the purposes of speculative experiment. The plants can be seen growing any summer at Kew; one of them, *Rhea nivea*, the Chinese variety, flourishes in the open air. It grows like a Michaelmas daisy in a clump of tall shoots springing from a perennial root, and has big palm-shaped leaves with the under side white, like those of the wild guelder-rose or cherry-apple. If you strip the bark from one of these shoots and fray it with a knife there is disclosed a white, silky fibre, very fine in the strand and extraordinarily strong. What is called China-grass is simply these ribbons of bark carefully decorticated by hand till the fibre is left bare. It is, however, still coarse and hard, and the immensely laborious process of cleaning makes it cost too much to be of any use in general trade. The ramie of commerce, which is to supersede flax, hemp, and all other textile fabrics (according to the true believers), is the same fibre more cheaply and better prepared from a tropical variety of the same species, *Rhea tenacissima*. This differs from *Rhea nivea* only in having a green leaf; but the essential point of the matter is that it is tropical, and will produce at least four crops a year, while the Chinese plant can at most yield two. The intrinsic value of the fibre has for a long time been fully admitted; so much so that the Indian Government twice offered a prize of £5,000 for rhea filasse of high quality produced at a limited cost. The prize was never won. The difficulty lay, as it has lain always, in the production, for which two distinct operations are necessary. First, the stems have to be stripped of their bark, which is done by hand or machinery, though no machine has yet been invented which does the work so well as the cheaply purchased Oriental hand labour. Secondly, in the ribbons so striped off, the fibre, has to be disengaged from the gummy bark, and this is only possible by a chemical process. No mechanical method can thoroughly separate the gum and the fibre, although at least two companies exist which aim at preparing ramie wholly by machinery. Various chemical processes were applied, all of which succeeded in turning out a clean "filasse" of fibre; but unfortunately when the filasse was worked up into yarns, threads, or stuffs, it was found to perish after a few months. The strong chemicals employed rotted the fibre. This happened particularly with the products of rhea prepared in France, where about ten years ago great interest was taken in the matter. After the French, the Americans took it up and prophesied great things; but they also dropped money over it. Now it really seems that England is going to step in and solve the problem. Mr. Gomess, a chemist trained in this country but of Indian origin, has patented a method which turns upon the employment of zincate of soda. A company has been formed, patents taken out all over the world, and a sort of experimental factory is actually at work in London which turns out about two tons a week of ramie ready for spinning.

The process is simple to the last degree. Two things have to be guarded against. First, fermentation of gum in the ramie-ribbons before they come to be manufactured; this is avoided by steeping

them in a solution of soda. At present, of course, the preparation of these ribbons is by no means perfect, since no regular market has existed for them. Now, however, in many tropical countries plantations of ramie are being set, and in time planters will learn to send their ribbons carefully packed and cut, with proper precautions against the fermentation which rots them. Secondly, the chief trouble has been to find chemicals which would convert the ribbons into filasse with a sufficiently weak solution. This is what Mr. Gomess has done. The ribbons are first steeped in tanks with a little infusion of nitric acid to soften the gum; after twelve hours of this they go into a bath of alkaline solution. Then they are boiled in a tank of water impregnated with the zincate of soda, and what comes out is pure fibre; the gum and epidermis of the bark is completely dissolved. At no stage is anything used stronger than a 1 per cent solution. The filasse when washed and bleached, may be mixed with inferior silk, or worked up by itself; and it can be sold at a profit for 3d a pound. Flax in the same stage of preparation costs from 8d to 1s. Thus the ramie-fibre can be sold almost as cheaply as the cheapest cotton; it has strength sufficient for any use, and it will neither shrink nor stretch. It is very light, and as much sail-cloth can be made from six pounds of ramie as from ten pounds of flax; indeed its advantage in this respect has been already recognised. The 'Defender's' canvas was made of rhea-fibres, which had to be bought up piecemeal in England and were woven in America. It will take dyes of all shades, and from it are made fabrics resembling damask linen, silk, plush, and tapestry. These were good enough to look at, but all somewhat harsh to handle. It is fair, however, to remember that the manufacture is in its infancy, and that the weavers do not yet know how to use the stuff to the best advantage. But there seems no doubt that in the qualities of cheapness and durability it will be a real addition to the wealth of mankind. The filasse is naturally so glossy that it seems specially fitted to compete with linen, and Belfast merchants would probably be well advised to look into the matter at once. Silk it will probably never rival, but it might very well sweep off the face of the earth, all the innumerable cheap combinations of silk and wool, which are used in upholstery and the like; and for towels, dish-cloths, and the whole paraphernalia of washing up it ought to be unsurpassable. These, however, are high matters, too hard for anything but the far-reaching experience of woman. The most interesting point about ramie is that the new industry, when created, may not improbably solve a very awkward problem in the management of Great Britain's enormous tropical estate.

The West Indies are in a bad way, as every one knows, because there is no price for sugar, and because the sugar-growing colonies have imported coolie labour to an immense extent. Demerara, for instance, has half a million of them. These coolies must, by the contract made with the Indian Government, receive constantly their shilling a day, or else Demerara must pay their passage and expenses back to India. Say that costs £10 a head. Demerara cannot get rid of her coolies without paying a fine of five millions; she must therefore go on sugar-growing whether she likes it or no. But wherever sugar can be grown rhea can be grown also; and coolie labour is quite sufficiently skilled not only for cutting the crop and stripping the bark by hand or machine, but also for preparing the filasse. There is everything to be said in favour of employing the Gomess process at the place where the crop is grown. First, a plant which yields four or five crops a year exhausts the soil with great rapidity. The fibre is only 5 per cent. of the whole, and the other 95 per cent. should go back into the ground,—the leaves as leaf-mould; the sticks, after they have served for fuel, in the form of ashes. Secondly, the less chemicals used the better: and if the process is applied when the bark is soft and freshly peeled, a weaker solution will suffice to dissolve the gum. Also, out of a ton of rhea-ribbons only sixty

per cent of filasse is produced, so that to import filasse instead of ribbons would save forty per cent of freightage. It is not to be supposed, of course, that any casual person can go and make his fortune by starting a ramie-farm. But it does seem probable that much of the tropical soil and cheap labour which cannot be productively employed in growing sugar will be turned to this account. Practically, the question resolves itself into this,—Can rhea-fibre be produced cheaply? And does any existing process produce it cheaply without impairing its qualities? It is too early for a final answer. But cloth made from fibre prepared by the Gomess process is two years old by now, and shows no sign of any defect; nor is there reason to apprehend any, since no chemical of any injurious power is used in the preparation. And as to the cheapness, rhea-ribbons can be brought here 'for about £12 a ton, leaving a good profit to the grower; from these filasse can be produced, which will fetch about £50 a ton, having cost in all perhaps £30 to turn out. These are facts which every one would do well to consider who has an interest in the matter. To put the case concisely, ramie is a fibre which can supplant flax and compete with silk, and it can now be produced almost as cheaply as cotton. If that is true, as a careful inquiry leads us to believe it is, can the tropical colonies do better than cultivate ramie?—*Spectator*, Jan. 2. [See correction on page 603.—Ed. T.A.]

PLANTING IN BRITISH NORTH BORNEO.

The average crop of the Lohat Datu Estate is, we learn, 8 piculs per field. In some cases 9½ have been gathered but 8 is the average of the whole—and a very good average too. The Kinabatangan Estates also are not, in the main, dissatisfied.

REPORT TO 2ND NOVEMBER.

SAPONG.—Tobacco into shed 30,533 trees and amount stripped, weighed and stapled 17.21 pikuls. I am still cutting and hope to finish some time next month, weather allowing. Am getting a good crop of second growth. Directly Mr. Wheatley comes up I shall begin to cut rentises and give out jungle cutting for next year's crop, which will be at the back of Amboi Hills. Good soil and free from floods.

Ramie looking healthy and strong, also coffee. Ground is being prepared for the transplanting of the Ramie. The last lot sent up by Mr. Wheatley are looking in good condition; the climate suits the plants up here exceedingly well.

Coffee seedlings sent down by Mr. Barraut are looking healthy. I shall plant out the pods sent down from the North, also poppy seeds. I have ordered Orang Kaya Si Bandar to procure 2 pikuls of "Tingang" Fibre from the Peluans:—1 pikul of the raw stuff and one pikul of the prepared. Orang Kaya reports that it grows abundantly at the Padas where the Peluans manufacture it into coats which they use when they go on head-hunting, as they say that it resists the poisonous darts.—*British North Borneo Herald*, Jan. 1.

COFFEE IN THE STRAITS:

Mr. Donald Mackay, well-known in Ceylon, first in connection with the construction of certain sections of the Ceylon Government Railways and later as a proprietary planter, arrived at Colombo last month from the Straits and transhipped to the "Masillia" sailing on that vessel in the afternoon to Australia. Mr. Mackay has been to the Straits inspecting his property in Perak. Mr. Mackay has 600 acres in that State planted in coffee, cocoa, and pepper. He informs us that coffee in Perak is looking up wonderfully, indeed, there has been quite a boom in it lately and not only are Europeans taking it up, but wealthy Chinamen have also begun to compete with them as planters.

CEYLON TEA IN RUSSIA.

The following is the letter from Mr. M. Rogivue to the Ceylon Planters' Association:—

Moscow, 10/22 Dec. 1896.

Maroseika, House Lebedieff.

A. Philip, Esq., Secretary to the Ceylon "Thirty Committee," Kandy, Ceylon.

Dear Sir,—My last report was on the 18/30 July. The Ceylon Tea Pavilion erected in Nijni Novgorod, on the ground of Hotel "Franzia" except the entrance gate of the Exhibition, was opened on the 1st of July, and closed on the 17th October 1896.

It was built at relatively very high cost on account of enormous rates of materials of all kinds, labour and workmanship, which were ruling there during the whole time the Exhibition was in preparation, in some instances more than three fold the ordinary rates to be paid.

During these three months of its operation the Pavilion was visited by the regretably small number of only between 13,000 and 14,000 persons, but they came from all parts of Russia and very few were foreigners. Among this number and the visitors to the Fair were distributed *gratis* 12,000 1/32 lb. packets of pure Ceylon tea of a good middling quality representing 375 lb. and over 10,000 persons were given tea *in cup* representing 55 lb. or over 21,000 cups. Besides sales made in the Pavilion were as follows:—

896	of	1 lb.	Packets
1,303	"	½ "	"
2,035	"	¼ "	"
2,670	"	⅛ "	"
340	"	1-16 "	"
465	"	1-32 "	"

7,709 packets or 2,335 25-32 lb. which together with the above 12,000 packets went into consumption all over Russia.

Ceylon tea was also used in many of the hotels, tea houses and restaurants inside the Exhibition and its surroundings, in the Fair and in the town.

The *special* advertising through the press, placards, pamphlets and otherwise, done in connection with the Pavilion is specified in my *Exhibition account* which I herewith enclose, under a special heading and was the best that could be done for the money spent, viz. R2,204.20.

Now as to whether *all* this advertising done at Nijni at such a considerable cost of R9,908.57 has been successful and effective and will bring in good results is rather difficult to say at present, the future only will prove it. The Exhibition itself has been a *fiasco* as regards the number of visitors which has not been even one-tenth of the number expected, but I had many inquiries and orders from persons who have visited the Pavilion and I am told that numbers of wholesale merchants dealing in Ceylon tea had also numerous enquiries. Unfortunately for me by far the greatest number of my intending purchasers asked credits for three to six months which I am not in position to give as being too risky a business in Russia.

In order to still continue the advertising which I considered had to be kept constantly before the public and ought not to be allowed to drop, I have since the above, in the months of October and November, inserted several further advertisement in newspapers of many Governments or provinces of Russia, as per enclosed cuttings and have now given out a large advertisement samples inclosed in a Christmas Supplement issued by an important Firm of Publishers 500,000 copies to be distributed with the Christmas newspapers in almost every town and village of Russia.

As already mentioned in my last letter to the Christian of the "Thirty Committee," I have ordered, at the cost of R1,000—from the well-known Potteries of M. S. Ruzaitgow & Co., Limited, the leading manufacture of China, etc., in Russia—5,000 pretty little Tea-pots with the words, *Ceylon Tea* (large) and *M. Rogivue, Moscow*, printed in red and blue colours on the sides, and *two spoonfull of Ceylon Tea being equal to three spoonful of*

China Tea you make a saving of thirty per cent in the drinking the former on the lids (small) those to be distributed as X'mas presents, through my own magazines and by my agents throughout the Provinces, followed by an advertisement as per enclosed lithographed print of a Tea-pot with the words

Translation Fine flavour	30 0/0	The best Tea in the world
	Economy	
	Ceylon Tea	
	M. Rogivue, Moscow Maroseika, House Lebedief.	

Representative of the Ceylon Planters' Association to appear during December and January 3 times in 54 of the best newspapers, magazines and illustrated papers of Moscow, St. Petersburg and the Province, and of which the "Neva," an illustrated family Journal has alone a circulation of 175,000 weekly.

I had news from Mr. Stramberg who has, as mentioned in my last letter to the Chairman of the "Thirty Committee" since the 29th October visited many places, he is now in Riga and will return here by the end of the year. So far as I can judge by his letters he has been pretty well successful in assembling people together in order to listen to his lectures and taste Ceylon Tea and a proof that this first tour has had a good effect is that I have received from some places he visited, where Ceylon Tea was not or little known, orders for over 5,000 lb. of my tea in packets. But, here again I am placed in a difficult position for, nearly all of these orders being on the *credit* principle for 3 to 6 months and my business being established and based on the *Cash* system—I am not in position to execute them and have had therefore to refuse the greater number. It is certain that if I had been willing to adopt the former. (Credit) system and to give my tea, on the terms generally asked to every recommendable merchant who sent me orders, I would have disposed during the past six years on account much larger quantity of Ceylon Tea and increased also the General Import in Russia to a considerable extent. This makes me think that a good method of increasing the distribution of pure Ceylon Tea through Russia would be,—in order, to enable myself or any other Ceylon or London merchant selling *pure* Ceylon Tea in packets, and *credit* without too great a risk,—to establish a fund or guaranteed sum of say R25,000—£2,000 or about to stand as *Del credere* for sales at 3, 4, or 6 months term *recommendable* merchants wishing to buy pure Ceylon Tea, to sell and push it in their shops, this same to cover any eventual losses accruing from the kind of business. The actual losses should not be very great after all if the scheme were judiciously managed because:—

1.—By only allowing credit on Promissory Notes and to merchants of good standing (as far as their solvency can be ascertained) the bulk of invoices would be paid and the losses a very small percentage.

2.—Merchants thus ordering Tea at first never give larger orders than for 50 or 100 lb. at a time and each invoice seldom amounts higher than 80 to 100 Rubles so that the risk is pretty well divided amongst many.

This I feel certain, would still more spread the knowledge of Ceylon Tea in Russia, and allow it to be sold to the public in many thousand shops all over the country in places hitherto unreached; I felt very often annoyed when I was compelled to refuse this chance to Ceylon tea in declining the sale, on credit, to many merchants, perhaps very good and solvent, who were willing to buy it and push it I wish the "Thirty Committee" would give this suggestion its earnest consideration for, I think, it is worth it, and I will here mention *confidentially* the reason why I do not adopt *myself* the credit system. They are as follows:—

1 2 3. * * *

I notice from the last "Times of Ceylon" that the direct export of Ceylon Tea from Colombo to Russia

shows a diminution in 1896 of 45,500 lb for the corresponding period from 1st January to 17th November—in 1895, which is however largely counter-balanced by the increase of export from United Kingdom to countries in Europe, (Russia receiving the bulk) as shown by the figures given in Messrs. Gow, Wilson and Stantou's, London Tea Report of the 11th December, 1896 being very nearly half a million more in this year for the five months of June to November than in 1895. But it may perhaps interest Ceylon to hear that, although the general increase is quite noticeable, it would have been still larger had the Russian Government (Custom's Department) not issued lately a circular from the Finance Minister for a project to come in force on the 1st January, 1897, in order to reduce the cost of control necessitated in every tea packing-room that no merchant not being able to pack with the obligatory Banderoll at least 200,000 lb of tea in a year should be allowed to pack at all but should get his tea already packed and banded in bigger merchants.

This has greatly slackened the wholesale tea trade in general for the small merchants, grocers and retailers who are now packing themselves, fearing the new law may come in force at once, have for the last three months reduced their purchases and in many instances, stopped them altogether and will not hold any stock at all, the wholesale tea trade suffering thus immensely until something definite has been settled by the Ministry of Finance.

I was the other day very much interested by an article reproduced in a Russian paper published in German in St. Petersburg (*The Herald*) headed "Russian Trade with China" emanating from the Russian Consul in Fukshow and pointing out the fact that the tea trade from Fukshow has considerably decreased during the past years on account of the strong competition of Indian (Ceylon) teas which in consequence of the energetic efforts of English Tea Planters and Merchants, find every year an increased sale on all the European markets. The article, which I herewith enclose, says that Ceylon tea is very much liked by the Russian Tea Merchants on account of its strength and fine taste which, without altering their qualities, blends very advantageously with the lower sorts of China tea and consequently the China tea—from year to year produced in decreasing quantity,—is condemned to lose its most important markets.

Therefore the Russian Consul in Fukshow is of opinion that it would be wise, in order to keep up the Russian trade in China to protect the Chinese tea cultivation, thus preventing the English merchants from monopolising the tea trade of the world. "Unfortunately" continues the Russian Consul, "we must place against it the want of enterprising spirit prevailing in Russia where our tea merchants do not possess the necessary energy. As a very characteristic example of this, we may mention the unfortunate experience of a Russian firm in China who tried to introduce on Russian markets some of "chops" Fukshow tea particularly known for their fine aroma. The tea bought by this firm was sent to Moscow and was condemned by the firm for whom it was bought as being *unsuitable*, whilst the next season the very same quality of tea of same "Chops" was bought by a London firm and sent with a good profit to a Russian tea merchant though no Moscow tea merchant was willing to buy it *direct* from Russian firm.

I hear that the Russian Government experiments of tea planting in Caucasus (Batumi) under the direction of Mr. Klingen who visited Ceylon two years ago, have not yet given results worthy of mention; seven China men have been engaged and a 10 years contract and seedling have already been planted."

I now have the pleasure to enclose my accounts of expenditure made up to 30th November, 1896 and beg to advise the despatch by this same post of a small registered parcel to your address containing one of my new placards and two photos of the Nijni Pavilions and electric train advertisements,

Speaking of photos, I think that some more of the last and newly taken in Ceylon (typos, estate views, scenerics, &c.), like the ones you gave me when in 1890 I left Ceylon for Russia, could be of great use and attractive for our lecturing tours.

With the compliments of the season.—I am, &c.,
(Signed) M. ROGIVUE.

NEW TEA COMPANY.

The New Sylhet Tea Estates, Limited, has been registered with a capital of £100,000, divided into 5,000 £10 and 50,000 £1 shares. Object, to adopt and carry into effect an agreement, expressed to be made between C. A. Goodricke and C. Porter of the one part and this Company of the other part, for the acquisition of certain tea estates; to purchase and obtain grants or leases from Government, and to purchase, take on lease or in exchange, hire, or otherwise acquire from any other company or companies, person or persons, any tea or other estates or lands or property of any description situate in British India or elsewhere, or any right or interest therein, or any rights or privileges, including any copyrights or trade marks; to cultivate tea and other produce; and as cultivators, winners, and merchants of and in every kind of vegetable, mineral, or other produce of the soil; to construct, purchase, lease, maintain, and alter any buildings, sawmills, railways, warehouses, and other erections, roads, tramways, and other works, and any steamers, locomotives, or machinery which may be necessary or convenient for the purposes of the company, or to acquire and hold shares in any company formed for the above purposes or any of them. The signatories who take one share each are:—C. A. Reiss, 51, Lime Street, E.C.; C. A. Goodricke, 96, Leadenhall Street, E.C.; E. H. Hancock, 28, Mincing Lane, E.C.; C. Porter, 96, Leadenhall Street, E.C.; H. A. Hancock, 28, Mincing Lane, E.C.; J. C. Ridge, 28, Mincing Lane, E.C.; D. B. Crane, 28, Mincing Lane, E.C. The number of directors is to be not more than eight nor less than four. The first are C. A. Reiss, W. Johnson, H. A. Hancock, W. H. Ingram, and C. A. Goodricke. Qualification, £250. Remuneration, 10 per cent of the net profits after the payment of the dividend on the preference shares. Registered office: 51, Lime Street, E.C.—*H. and C. Mail*, Jan. 15.

THE DUNKELD ESTATE CO., LD.

The annual ordinary general meeting of shareholders of the above Company was held at the Company's offices, No. 7, Queen Street, Fort, Colombo, at 11-30 a.m. on the 6th Feb.

Present:—Mr. A. Thomson in the chair, Mr. C. A. Leechman, Directors; Messrs. E. S. Anderson and C. J. Donald. Mr. W. H. G. Duncan was represented by his Attorney.

The report and accounts of the Company as published were adopted, and a final dividend of 9 per cent (making 17 per cent for the year) was declared and made payable forthwith.

Mr. Alexander Thomson was re-elected a Director, and Mr. T. J. Stephen was appointed Auditor for this year.

The report was as follows:—

ACREAGE.	
Tea in full bearing ..	383 acres
Jungle, &c. ..	53 ..
—	
Total Estate ..	436 acres

The Directors have pleasure in submitting to the shareholders the accounts of the Company for the past year.

The quantity of tea secured amounted to 166,262 lb., being an increase of 8,525 lb. on the crop of

1895. The net average sale price was about 45 cents per lb., and the cost laid down in Colombo was about 26½ cents per lb., as compared with about 51 cents and about 29 cents in 1895 respectively.

After making the usual ample allowance for depreciation of buildings and machinery, and including a small balance brought forward from 1895, the amount at credit of profit and loss account is R26,578·12, equal to about 17¼ per cent on the capital of the Company.

An interim dividend of 8 per cent was declared on 8th August last, absorbing R12,000, thus leaving a balance of R14,578·12 now to be dealt with.

The Directors recommend the payment of a final dividend of 9 per cent, making 17 per cent for the year, and that, after payment of R200 additional fees to the Directors in terms of the resolution passed on 18th February 1893, the balance of R878·12 be carried forward to the new year.

The crop estimated for 1897 is 170,000 lb. tea, against an estimated expenditure of R45,580. This is exclusive of outlay to a moderate extent which will be necessary for an extension to the factory, but for which no estimate has yet been framed.

On the 23rd December last the Directors intimated by circular letter to each shareholder on the register particulars of a proposal received by them for the inclusion of the Dunkeld property in the Alliance Tea Company of Ceylon, Limited. As this proposal appears to be acceptable to the general body of shareholders, the Directors have arranged to submit the matter to an extraordinary general meeting of the Company to be held after the closing of the annual ordinary general meeting to which this report will be presented.

In terms of the Articles of Association Mr. Alex. Thomson retires by rotation from the office of Director, but is eligible for re-election. Mr. Charles Young has resigned his seat on the Board and does not seek re-election.

Mr. R. L. M. Brown having resigned the post of Auditor to the Company, the Directors, under the Company's Article No. 92, appointed Mr. T. J. Stephen to fill the vacancy thus occasioned.

The appointment of an Auditor for the current year will rest with the meeting.—By order of the Directors,
WHITTALL & Co, Agents and Secretaries.

Colombo, 21st January 1897.

At the extraordinary general meeting of shareholders of the above Company held the same day there were present:—Mr. A. Thomson in the chair, Mr. C. A. Leechman, Directors; Messrs. E. S. Anderson and C. J. Donald. The following shareholders were represented by the holders of their powers of Attorney.—Messrs. W. H. G. Duncan and John MacLiesh. The following shareholders were represented by proxy:—Messrs. T. J. de Havilland, R. Wade Jenkins, W. S. R. Cox, H. S. Rix, Harcourt Skrine, Charles Campion, W. H. Walker, Robert Webster, J. B. Spence, W. H. Crowe, W. P. Metcalfe, W. F. Keith, Charles Young, C. Ruinat, Mrs. A. S. Donald, Hon. T. N. Christie and Mrs. M. E. Bois.

Mr. Thomson having taken the chair, the notice convening the meeting was read.

The CHAIRMAN read letter of this date from the Agents of the Alliance Tea Company of Ceylon, Ltd., regarding their offer for Dunkeld estate, when it was proposed by the CHAIRMAN, seconded by Mr. ERIC S. ANDERSON, "That the Dunkeld Estate Company, Ltd., be wound up voluntarily," which resolution was carried unanimously.

A vote of thanks to the chair closed the proceedings.

CHINA GRASS.

During the past twelve months several factories have been established in this country for utilising the remarkable fibre of the well-known "China grass"—by the way it is not a grass, but a nettle—which has been more or less under the attention of manufacturers for fifty years past. The fibre yielded by the plant is exceedingly strong, and so light that it has been employed as the material for sails of first-rate yachts. The "Valkyrie," for instance had her sails made of this material. When manufactured it has much the appearance of silk, and is used for a very superior kind of lace, damask, and even velvet. The spinners of Lancashire and Yorkshire are using it for these purposes, and there is a factory near Westbourne-park that is turning out a ton week. The very valuable character of the fibre has long been recognised, but it has not hitherto been much utilised for manufacturing purposes owing to the great difficulty that has been experienced in extracting the fibre from the stems. The plant is of a gummy character, and it has been found very difficult to get at a satisfactory method of "degumming." Decided advances have however been made of late, and the prospects of complete success appears to be good. It seems likely that the West Indies may be able to take up the cultivation of this China grass or ramie. —*Home Paper.*

A NEW FIBRE.—A CORRECTION.

[TO THE EDITOR OF THE "SPECTATOR."]
SIR,—In the very interesting article on "A New Fibre" in the *Spectator* of January 2nd there is a statement which needs correction,—“Demerara alone has half a million of them,”—coolies. The last census returns of British Guiana—which includes Berbice and Essequibo as well as Demerara—give the population of the entire Colony as 278,382, and the number of coolies as 105,463.—I am, Sir, &c.,

Leeds, January 4th. JOHN GRIMSHAW.
[The word "alone" was not in our article, but, of course even as it was, the coolie numbers were overstated.—Ed. *Spectator.*]

KANAPEDIWATTIE TEA CO., LD.

This Company has just been incorporated. The capital is R340,000, (with power to increase) in 3,400 shares of R100 each, of which only 3,340 will at present be issued. The directors are Hon. T. N. Christie, Mr. George Christie and Mr. W. Kingsbury, and the Bankers, the National Bank of India, Ltd.

Proctors:—Messrs. Fisher & Borrett (Kandy.) Agents and Secretaries. Messrs. Lee Hedges & Company.

This Company is formed for the purpose of purchasing Kanapediwattie, Blackford and St. Cuthbert Estates situated in the Pussellawa and Ulapane Districts. The approximate acreage of the properties is as follows:—Tea 345, Cocoa 6, Cardamoms 6, Timber, Patna, &c. 61. Total 418.

The properties have been valued by Mr. W. P. Metcalfe at R321,845, being on a basis of 8½ years' purchase on the profits of the past three seasons. No agreements for the purchase of the Estates have been made, but negotiations have been opened with the Shareholders of the Ceylon Cinchona Association, Limited, (the owner of Kanapediwattie Estate), and the proprietors of Blackford and St. Cuthbert Estates to sell their properties to the Company as from the 1st of January, 1897, for the sum of R322,200 payable in fully paid up shares,

TEA GROWING IN THE CAUCASUS.

Some time ago attention was prominently drawn in home papers to the possibilities of the Caucasus as a tea producing region. Not only was the opinion expressed that Russia, herself a great tea drinking country, would be able to supply her own wants independent of the East, but in course of time she would compete with these countries in the markets of Europe. A gentleman who is himself qualified to speak on the matter informs us that he recently had a conversation on the subject with a Russian visitor. The Russian who knows the region well and who has had a look round Ceylon assured our informant that tea could only be grown in isolated pockets in the Caucasus. The hillsides, he said, were valueless owing to the intense frosts that were experienced. If this description be accurate so much the better for Ceylon, so much the worse for Russia.

FLOWERING PLANTS AND FERNS:

IN 2 VOLS.*

MR. WILLIS'S NEW BOOK.

We are indebted to the Director of the Royal Botanic Gardens for a copy of his excellent contribution to the "Cambridge Natural Science Manuals," edited by Mr. Shipley, the accomplished Fellow and Tutor of Christ's College, Cambridge. The book is evidently very carefully compiled, and must prove an exceedingly useful manual. There are a good many engravings illustrating the text, and the indexes and glossary are particularly full. The contents of the 1st volume are indicated as follows:—

Outlines of the morphology, natural history, classification, geographical distribution and economic uses of the phanerogams and ferns.

The second volume contains:—

The classes, cohorts, orders, and chief genera of phanerogams and ferns, alphabetically arranged under their Latin names.

The following extract from Mr. Willis's preface will show the object held in view by the author:—

The aim with which I commenced, nearly seven years ago, to prepare this book, was to supply within a reasonable compass, a summary of useful and scientific information about the plants met with in a botanical garden or museum, or in the field. The student, when placed before the bewildering variety of forms in such a collection as that at Kew, does not know where to begin or what to do to acquire information about the plants. The available works of general reference are mostly very bulky and often out of date, and as a rule refer only to systematic or economic botany, and say nothing about morphology or natural history. I have endeavoured to bring together in this book as much information as is required by any but specialists upon all plants usually met with, and upon all those points—mor-

* Now ready. Crown 8vo. Cloth. 2 Volumes. Vol. i pp. 1—224. Vol. ii, pp. 1—429. Price 10s 6d. [Cambridge Natural Science Manuals Biological Series. General Editor,—Arthur D. Shipley, M.A. Fellow and Tutor of Christ College, Cambridge.] A Manual and Dictionary of the Flowering Plants and Ferns, by J. C. Willis, M.A., Director of the Royal Botanic Gardens, Ceylon, sometime Frank Smart student, Gonville and Caius College, Cambridge, and Senior Assistant in Botany in the University of Glasgow. Cambridge: at the University Press; London: C. J. Clay & Sons, Cambridge University Press Warehouse, Ave Maria Lane; and H. K. Lewis, 136, Gower Street, W.C., Medical Publisher and Bookseller.

phology, classification, natural history, economic botany, &c.—which do not require the use of a microscope. * * * The principal part of the book consists of a dictionary in which the whole of the families and the important genera of flowering plants and ferns are dealt with. The families are treated very fully, more so than in any ordinary text-book of systematic botany, whereas the genera are treated much more briefly unless they show some feature of special interest that is not common to the family.

We may now give a very few specimens of the information contained in the second volume; selecting two palms and our staples tea and coffee:—

Areca Linn. *Palmae* (iv. 6). About 15 sp. Malacca to New Guinea. *A. Catechu* L. is largely cultivated in trop. As. for its seeds (*Areca* or *Betel* nuts). The infl. is below the oldest living leaves, monœcious, with the ♀ fls. at the bases of the twigs, the ♂ above. The seed is about as big as a damson; it is cut into slices and rolled up in a leaf of *Betel* pepper (*Piper Belle*) with a little lime. When chewed, it turns the saliva bright red: it acts as a stimulus upon the digestive organs, and is supposed by the natives (who use it habitually) to be a preventive of dysentery. For *A. oleracea* Jacq. see *Oreodoxa*.

Cocos Linn. *Palmae* (iv. 7). 30 sp. trop. S. Am., W. Ind. *C. nucifera* L. (coconut palm) in all trop. countries, and largely cultivated. It grows especially well close to the sea and its fruit is capable of floating long distances uninjured, hence it forms a characteristic feature in the islands of the Pacific (p. 199). It is a tall palm with pinnate leaves and dense monœcious infl. The fruit is one-seeded. The outer layer of the pericarp is fibrous, the inner extremely hard (the shell of the coconut as sold in shops). At the base are three marks corresponding to the three loculi of the ovary, two of which have become obliterated. Under one of these marks is the embryo. The testa is thin and is lined with white endosperm, enclosing a large cavity, partly filled with a milky fluid which serves as a water-supply in germination. The uses of this palm are many; it furnishes many of the necessities of existence to the natives of tropical regions—edible fruit, palm wine (cf. *Borassus*), sugar (cf. *Arenga*), leaves for thatching, palm-cabbages (the young bud cut out of the top of the tree), &c. The fibre (coir) of the pericarp is used in many ways—in making coconut matting, cables, brushes, &c. Coconut oil is obtained from the endosperm; by pressure it is separated into a solid part (stearine, used for candles) and a liquid (oleine); the remains of the endosperm (coconut cake) are used in cattle-feeding. The outer wood of the tree is hard (porcupine wood) and is used in making ornaments, &c.

Coffea Linn. *Rubiaceae* (ii. 14). 25 sp. trop. Old World. *C. arabica* L. is the coffee plant, largely cultivated in the tropics. It is a shade-loving plant, and is cultivated in the shade of larger trees. The fruit resembles a cherry in appearance; it is a 2-seeded drupe. The pulp and the endocarp are mechanically removed. The seed ("coffee-bean") has a deep groove on the ventral side. By soaking it in water the endosperm may be softened and the embryo dissected out. The plant is subject to the attacks of many insects and fungi; one of the latter (*Hemiteia vastatrix*) was the cause of the ruin of the coffee industry of Ceylon. [See *Haberlandt's Tropenreise*, p. 241.]

Thea Linn. (excl. *Camellia* Linn). *Theaceae*. 8 sp. India to Japan. Often united to *Camellia*; *T.* has stalked nodding fls., *C.* sessile upright ones. The chief sp. is *T. sinensis* L., the tea plant, largely cultivated in China, India, Ceylon, &c. When growing wild it forms a tree, but in cultivation it is kept pruned into a small bush. The young shoots are nipped off at certain stages (according to the kind of tea desired) and undergo various subsequent treatments (see *Tschirch, Indische Heil und Nutzpflanzen*). [Synonymy: *T. Bohea* L. and *T. viridis* L.=*T. sinensis*; *T. Camellia* Hoffmgg.=*Camellia japonica*.]

Theaceae. Dicotyledons (Archichl. Parietales). 16 gen. with 175 sp. trop. and subtrop. Trees or shrubs

with alt. leathery leaves. Fls. usually solitary, ♀, often partly spiral. K 5, 6 or 7, imbricate, persistent; C 5, rarely 4, 9 or ∞, imbricate; A ∞, rarely 5, 10 or 15, free or in bundles or united into a tube; ovary superior, 2-3-5-10-loc. f with 2, 4 or ∞ anatropous ovules in each loc. Capsule or drupe. Embryo usually curved; endosperm little or none. The only important economic plant is *Tea*; *Camellia* is a favourite in green-houses. *Chief genera*: *Thea*, *Camellia*, *Gordonia*, *Ternstroemia*, *Eurya*. *Benth-Hooker* unite to *T.* several other genera to form the order *Ternstroemiaceae* (q.v.). Warming places *T. Cistiflorae*.

The preface is dated from Glasgow, August 10, 1896.—In respect of tea, Mr. Willis knows by this time doubtless, that the plant chiefly cultivated in Ceylon, as in India, is not the China species, but the Assam hybrid and indigenous kinds. In making the above extracts we feel injustice is done to Mr. Willis, in not giving the explanation of the abbreviations used, such abbreviations as well as other explanations being prominently shown in the pages before us. Altogether, however, we feel sure these two handy manual volumes will be much appreciated in Colleges and Schools, as well as by botanical students everywhere, making the name of our new Director and his good work, familiar, not only in the mother country, but throughout all British Dependencies.

KANDAPOLA TEA COMPANY, LIMITED.

Registered January 14, by Mullens and Bosanquet, 11, Queen Victoria-street, E.C., with a capital of £200,000 in £10 shares, 10,000 of which are six per cent cumulative preference shares and 10,000 ordinary shares. Object, primarily, to acquire the following estates or plantations—viz, the Kandapola estate, and the Monkwood estate, adjoining thereto, both situate in the district of Kandapola, in Ceylon; the Proft estate, and the Rushbrook estate adjoining thereto, both situate, in the district of Ramboda, in Ceylon; and the Erroll estate, situate in the district of Dikoya, in Ceylon; to develop, deal with, and generally turn to account the same in such manner as the company shall see fit, and, generally to carry on in all or any of their respective branches the businesses of tea planters, tea merchants, tea exporters, general planters and growers, fruit and vegetable producers and preservers, coffee, cocoa, sugar and cinchona merchants, wine and brandy makers, brewers, manufacturers of all kinds of vegetable products, farmers, pasturers, cattle and horse breeders, graziers and agriculturists, mine owners, colliery and quarry owners, shipowners, charterers of vessels, shipbuilders, metallurgists, dealers in gold, silver, and other precious metals, pearls and other precious stones, and as carriers by sea and land; to lay out towns and villages, and to promote immigration thereto. The signatories are:—

	Shares.
R. A. Bosanquet, 38, Mincing-lane, E.C.	.. 1
G. F. Traill, Co'ombo, Ceylon	.. 1
J. H. Alexander, 66, Inverness-terrace, W.	.. 1
W. R. Alexander, 66, Inverness-terrace, W.	.. 1

E. T. S. F. Harvey, 35, Lithos-road, South Hampstead	.. 1
W. H. Courthope, 20, Birch-lane, E.C.	.. 1

The number of directors is to be not more than seven nor less than three; the first are the first three signatories to the memorandum. Qualification, 50 shares. Remuneration £100 each per annum, and £150 for the chairman. Registered office: 38, Mincing-lane, E.C.—*H. & C. Mail*, Jan. 29.

THE CULTIVATION OF LIBERIAN COFFEE: a Pamphlet on the Opening up and Management of a Liberian Coffee Estate in the Malay Peninsula, by H. Hilttenbach (reprinted from the *Selangor Journal*), which has been sent us: it seems very useful.

THE CLUNES ESTATES COMPANY OF CEYLON, LIMITED.

At the extraordinary General Meeting of shareholders of the above Company held on Saturday, February 13th, 1897, at 12-30 p.m. at the Company's Offices No. 7, Queen Street, Fort, Colombo, the following were present:—Mr. W. Forsythe, Chairman, Mr. S. L. Harries, Directors; Messrs. A. Thompson, Jas. Forbes, L. E. Edwards, E. H. A. Vanderspar, George Vanderspur, and W. E. Mitchell. Mr. E. John was represented by his Attorney Mr. R. John.

Mr. Forsythe having taken the Chair the notice convening the meeting was read.

An interim dividend for 1896-1897 of 5 per cent was declared and made payable forthwith.

A vote of thanks to the Chair closed the proceedings.

PRODUCE AND PLANTING.

RUBBER PLANTATION.—Planters on the look-out for profitable products to cultivate might, where possible, turn their attention to the rubber industry. In the course of a single year the exports of this commodity from Lagos increased from 5,867 lb. to 5,069,576 lb., a growth of trade probably without parallel. But the natives who obtain the rubber in the forests employ such wasteful and destructive methods of "tapping" that the supply is sure to dwindle away, as has happened through the same on the upper waters of the Amazon. If, then, this young and most profitable industry is to become a permanent source of wealth, whether at Lagos or elsewhere, some method of insuring constancy of supply must be adopted. There are two ways by which that might be accomplished. The rubber-producing forests could be leased on such conditions as would give the lessees personal interest in preventing destructive "tapping." Or, better still, as not confiscating native rights of free search, plantations may be established at suitable places. Once the trees reached maturity, they would continue to yield the precious juice for many years if properly treated. Before science turned its attention to the matter the invariable practice was to bleed a tree to death, and it is that barbarous method which still obtains at Lagos. But by a new and improved process sufficient vitality is left in a "tapped" tree for complete recovery and future fruitfulness.—*H. & C. Mail*, Jan. 15.

THE COMING RIVALRY IN TEA MANUFACTURE.—It is of course very gratifying to the feelings of Indian and Ceylon tea planters to learn that their methods of manufacture are worth imitating by the Chinese and Japanese tea growers, and if that were all it would be quite pleasant. The Chinese and Japanese, however, are not proud, and they wish to learn all about everything as soon as possible. We see by the *Ceylon Observer* that an enterprising Chinese "creeper" is in Ceylon yearning for information. It is mentioned, too, in another Ceylon paper that an enquirer of Japanese nationality is also believed to be searching for more light. It is a proud and happy position for Indian and Ceylon planters to control the tea markets of the world, and they may be lifted up at the idea that their rivals recognise their supremacy, and would adopt that way of doing business. It is not, however, desirable that these competitors should find the path of knowledge readily accessible. Supremacy in the tea market was fought for keenly, and won by pluck and perseverance. It must be held tightly, and with as much reserve as is possible in these days of universal knowledge. The game may become a very keenly contested one before long, and no one can afford to give away a point. Of course, if the Chinese and Japanese mean to manufacture tea on the same lines as India and Ceylon they will find out all about it soon enough. There is no mystery about the process of manufac-

ture. That the Far East is becoming very much alive to the value of machinery we are ourselves aware, illustrations and descriptions of machinery and newspapers containing them being in demand just now in that quarter. But this is no reason for hurrying up events or assisting competitors in their task of competition.

A CHANGED TEA ROUTE.—Commenting on the tea routes from China and India to Russia, the *Grocer* says:—"The way in which railways and tariffs modify the conditions of trade and effect great changes is illustrated by what has taken place in regard to the tea routes from China and India to Russia. Now that the railway has linked Merv, Bokhara, and Samarkand with Russia proper, the Russian Government has absorbed the Bokhara customs, and since the beginning of 1895 has levied equal customs duties along the whole line of the frontier from the Caspian to the Pamirs. Consul-General Elias' reporting on Persian trade, states that the altered conditions have led to a deflection of the tea route of the greatest importance to Persia and India—teas formerly sent to Russia *via* Meshed being sent now *via* Batoum, and Persia thus losing £8,000 a year in customs alone. The Collector of Customs at Bombay, reporting on the matter, states that the green tea trade is by far the most important branch of the trade between Bombay and the Russian possessions in Central Asia. The tea is imported from China into Bombay, and re-exported from there to Bandar Abbas, chiefly by Mogul merchants. A considerable quantity of Indian tea is also shipped to Bandar Abbas from Bombay. The figures of China tea to Persia show, however, a serious falling off in the first nine months of 1895-96. The Bombay Collector remarks that 'Indian tea has benefitted by the new customs regulations, while the trade in China tea has suffered, though not as yet very severely. There is, however, some risk of Bombay losing its position as the centre of the trade in China tea, in consequence of the opening of the Batoum route.' In the opinion of the Persian Consul, it is wrong to surmise that Indian tea has benefitted by the changes—in fact, he thinks China is now sending a good deal of tea to Russia *via* Batoum, and that 'India will probably lose the handling of the tea by which she has, up till now, profited.' The whole of the tea trade for Central Asia twenty years ago was in the hands of British Indian tea planters. Today they do not supply a leaf. It seems strange that it should have come to pass that while Indian black tea has been steadily driving the Chinese article out of most of the far-distant markets of the world, Chinese green tea in a short space of time, and apparently without an effort, drove the Indian article clean out of its own market. Apparently the duty on Chinese tea at Bombay, though only 5 per cent., together with the saving in freight direct from China to Batoum, are the causes which have thus dislocated a branch of trade in which are concerned the interests of Indian Indian tea growers, Afghan and Persian carriers, and merchants, the Persian Government revenue."

THE TEA INDUSTRY AND THE FAMINE.—The community in London interested in tea are, as will be seen from the report of a meeting in another column, well to the fore as regards the Famine Fund. The sums contributed by members of all branches of the tea industry are notable evidence alike of the promise of tea enterprise in connection with India and of the desire on the part of those who constitute it to join with alacrity in the movement for alleviating the distress of the native population in the famine-stricken districts. The same feeling, we are sure, exists throughout the financial world of commerce here. The movement in the large towns for gathering contributions towards the Famine Fund is proof that the appeal to private charity, tardy though it was, will not be made in vain.

THE FAMINE AND THE LABOUR QUESTION.—The following letter signed "Tea Planter" appears in today's *Standard*: "In view of the terrible sufferings of our

fellow-subjects in the North-West and Central Provinces of India, may I suggest a measure which would tend to relieve, even in a slight degree, some of the existing pressure? At this season of the year it is usual for the tea gardens in Assam, Cachar, Sylhet, and other places, to recruit labourers from the famine districts by head men sent from the different gardens. It is a very unsatisfactory and expensive method, as these men frequently return without a single recruit, after having received advances of hundreds of rupees from their garden managers, on the faith of glowing reports as to the number of labourers collected. What I would suggest is that the Indian Government should appoint immigration agents in each of the affected districts, to whom the managers of gardens could apply direct for the number of labourers required, and who would send them up under proper supervision. Many gardens are short of labour, on account of the difficulty and expense of getting it; but if each garden manager could notify his wants direct to the Government, and could be supplied with the labour required quickly and cheaply (he, of course, paying all expenses), it would be to the mutual benefit of the Government and planter. From my knowledge of the tea districts work could be found for at least another half million of labourers, who would be rescued from starvation, and would enjoy a degree of happiness and prosperity unknown in their own country."

THE CANE SUGAR QUESTION.—The sugar planters of the Mauritius have followed the example of those in the West Indies, and are asking that their lot may be ameliorated without indicating how it is to be done. On Friday Lord Stanmore and the Mauritius Delegates' Committee attended by appointment at the Colonial Office, and presented to Mr. Chamberlain a petition from Mauritius, signed by over 10,000 persons interested in the sugar industry, praying that measures may immediately be taken by the Government to relieve the critical position of the colony and enable its produce to compete in the markets of Great Britain and her dependencies on equal terms with beetroot sugar from foreign countries. Lord Stanmore, in introducing the deputation, pointed out that the position of Mauritius in the event of the failure of the sugar industry would be worse than that of the West Indies, as the colony had no other industry to fall back on. He claimed the sympathy and assistance of the Government. Mr. Chamberlain, in his reply, assured the deputation that the Government was fully aware of the gravity of the situation, and sympathised with hardships that were not the result of natural causes, but of artificial interference. He could give no indication of the course Her Majesty's Government would think fit to pursue until the Commission lately sent out to the West Indies had reported, which it was expected to do in about three or four months' time.—*H. and C. Mail*, Jan. 22.

CLOSE OF THE INDIAN TEA SEASON FOR 1896.

The following figures and comparisons from the latest circular of Messrs. Watson, Sibthorp & Co. of Calcutta are of special interest:—

Exports, Stocks, &c., of Indian Tea.			
	1896.	1895.	1894.
	lb.	lb.	lb.
Exports from Calcutta to Great Britain from 1st Jan. to 31st Dec. . .	128,482,030	121,140,686	116,280,876
Exports from Calcutta to Great Britain in December . . .	12,023,512	10,264,420	10,494,415
Stocks in London on 31st December . . .	54,100,000	52,638,498	47,930,601

Deliveries in London from 1st Jan. to 31st December . . .	121,667,006	115,033,291	117,423,711
Do in Dec. . .	11,600,000	9,933,268	9,320,911
Landings in London from 1st Jan. to 31st December . . .	125,385,831	119,806,191	115,323,648
Do in Dec. . .	18,500,000	17,305,803	13,808,490
Exports from Calcutta to Australia & New Zealand from 1st Jan. to 31st Dec. . .	5,482,881	6,172,486	5,489,390
Do in Dec. . .	589,718	608,795	434,314
Do from Calcutta direct to America from 1st Jan. to 31st Dec. . .	1,164,279	939,040	505,679

Exports from Calcutta to all other places from 1st Jan. to 31st Dec. . .	5,828,365	4,177,528	4,462,270
Do in Dec. . .	604,604	670,717	359,553

"RESERVE FUNDS OF TEA COMPANIES."

Some days ago a local daily contemporary had a deliverance on the above subject and, quoting from a London Sharebroker, he afforded but a poor picture of the stability of Ceylon Tea Companies so far as "reserves" were concerned. This may be judged by the extract we append:—

"The following table compiled by one of the best-known London sharebrokers doing business in Ceylon stock tabulates the information so that the position of affairs in this respect can be seen at a glance:—

STATEMENT OF THE RESERVE FUND OF SOME ESTATE IN CEYLON.			
OF 45 STERLING COMPANIES:—			
Total indebtedness	£5,936,999
Deduct Consolidated Tea and Lands Company	1,800,000
			<hr/> £4,136,999
Total Reserve £144,482, or 3.49 per cent.			
Of this total reserve the Ceylon Tea Plantations Co. has £70,000			
The indebtedness of the C. T. P. Co. is			218,460
			<hr/>
Leaving for the other 23 Companies			£3,888,539
And the balance of the Reserve Fund, £144,482 less £70,000, allows £74,482, equivalent to a percentage of 1.91			
OF 29 RUPEE COMPANIES:—			
Total indebtedness	R7,141,458
Total Reserve R262,000, or equivalent to a percentage of 3.6			

But these figures present the case in a much too favourable light, seeing that the R262,000 set down as the reserve of the Rupee Companies are strictly speaking no reserve at all, being chiefly sums passed to "extension fund account," and have all been expended in developing the estates. They are not reserves in the proper sense of the word in such a liquid form as reserves should be."

Now in referring to the above statement, we notice in the first place that the London Sharebroker talks of the "indebtedness" of the Companies, under which term he evidently includes the *share capital* which, of course, is *not* indebtedness. Next he proceeds to draw a comparison between the Reserve Fund, and the so-called "indebtedness." In the opinion of reliable mercantile authorities, this is not sound—unless it is contended that in the case of Tea Companies a *Cash Reserve Fund* should be built up as against the possibility of a loss of the capital of the Company, or in other words a collapse of the Tea Industry. Such an eventuality we are not going to discuss, at any rate for the present; and we think for our contemporary or his sharebroking friend to suggest such a thing in the way they have done, is far more likely to do harm than to do good. The more general opinion

seems to be that so far as Tea Companies are concerned, there are only two uses for a *Cash Reserve Fund*:—1st, to provide money to pay off debts, such as Debentures; and 2nd to equalize dividends in the case of Companies which have a proportion of their capital in Preference Shares.

Where a Company is indebted under a mortgage, or by a Debenture issue, or in any other way, there must, of course, be a date when the principal of such debt falls due, and we quite think that such a Company should, out of its current profits, build up a *Cash Reserve Fund* to pay off such debt. And again, as regards Companies, the capital of which is divided into Preference and Ordinary shares, although the Preference shares are not "indebtedness" in the ordinary acceptation of the term; yet they may be said to operate as a mortgage on the future profits of the Company (assuming that they are "Cumulative" Preference shares, as is usually the case); and it is in such cases also very advisable to provide ahead—by means of a *Cash Reserve Fund*—for the payment of interest on such preference shares in view of the possibility of a falling-off in returns, coupled with the necessity of payment of the preferential interest, entrenching in the fair earnings of the ordinary capital. But in the case of Companies which are not indebted in any way, and have their capital only on one class of shares, we cannot really see that there is any special necessity for a *Cash Reserve Fund*.

Again, our contemporary talks of Reserve Funds adding to the "stability" of Tea Companies. If he refers to those with Debenture or Preference share issues we may agree with him; but let us take the case of a Company with only one class of shares: if a "Reserve Fund" is created the value of the shares will of course go up correspondingly, but the value will at the same time fluctuate in accordance with the increase or falling-off of the annual profits of the Company. We must continue to hold, in fact, that the "stability" of our Tea Companies, depends mainly on the stability of the Tea Industry—Reserve Fund or no Reserve Fund.

When, however, we look down the Colombo and London Tea Share lists, we do find one point of general difference of considerable importance, namely that nearly the whole of the London concerns have "Debenture or Preference issues"—or both; while in Colombo such a thing is a rare exception. In other words—and speaking generally—Colombo Companies are not indebted and their future earnings are not mortgaged. That being so, our prosperous local Companies may be regarded as occupying a first-class position; for, so long as the Tea industry exists, they can divide their profits among those shareholders. The contention, however, seems to be that in view of the possibility of a time coming when there may be no profits to divide, the Reserve Fund will be there to provide a dividend; but would that fact really improve matters? Out in Ceylon, every shareholder, or his representative, knows pretty well all about the position of the Tea-planting industry, and we rather think there would be a general outcry if Directors commenced to pay smaller dividends and announced that they intended in future, to combine with Tea-planting a species of Savings Bank business to guard against the shareholders, like small boys, spending their pocket-money injudiciously!

Let it not be forgotten too that there are extremely limited means here for the profitable investment of money of the character of Reserve

Funds which practically become Trust Funds. Even with fairly good security, shareholders can themselves do better with their dividends, than Directors would be able to do for them if the money went to a Reserve Fund. On the whole, therefore, so far as local Companies are concerned, we cannot say that a case for "Reserve Funds" has been made out; while in respect of London Ceylon Companies, considering the keen business criticism to which they must be liable in the "City," we should like to see financial authorities at home, lead the way, before we presumed from this end, to dictate to their Chairmen and Directors what would be the best course for them to pursue.

INSECT PESTS AND THEIR ENEMIES :

AN INTERCHANGE BETWEEN CEYLON AND SOUTHERN INDIA PROPOSED BY MR. E. E. GREEN.

Mr. E. E. Green of Eton, Pundaluoya, writing on the 4th Feb. gives us the following interesting information:—

"I have been interested in the copy of the *Hawaiian Planters' Monthly* with the interesting report on Insect Pests by Mr. Kœbele. There seems to be no doubt that the introduction of the natural enemies of the several insect pests has been most successful in Hawaii—thanks to the personal supervision of such an expert as Mr. Kœbele has proved himself to be.

"I am glad to note by a letter published in your January number of the *T. A.* that the Indian Planters' Associations are taking up the subject of the introduction of Lady Bird Beetles and are anxious to join us in securing the services of Mr. Kœbele. The letter in question—headed *Notes on Lady Birds and Coffee Bug on the Lower Pulneys*—gives some interesting particulars of an indigenous species of Lady Bird (*Chilocorus Nigritus*) that appears to prey upon the Green Bug (*Lecanium Viride*) in that country. Mr. Newport, however, reports that though the beetles are doing good work in a small way they are not increasing in numbers as rapidly as could be wished. This is only what might be expected from an indigenous insect which has no doubt its own natural enemies to keep it in check in its native country. But it has struck me that this same Indian beetle, if introduced into Ceylon, might have a freer hand—and might prove a real service on the few coffee plantations remaining in Ceylon. This little experiment would, at any rate, be inexpensive and easily carried out. I should be glad to correspond with Mr. Newport with a view to the interchange of natural enemies of insect pests between India and Ceylon. We, on our side, might be able to supply the Indian planters with a few species which—hampered by their own parasites—are unable to do appreciable service in this country, but which if sent to India—minus their enemies—might increase as the Australian beetles did in Hawaii."

We certainly hope the experiment will be made.

HORREKELLY ESTATE COMPANY LIMITED.

The annual general meeting of shareholders of this Company was held in the Registered office (Messrs. Lewis Brown & Co.'s) on Feb. 6th at noon. Mr. C. E. H. Symons presided and those present or represented, were, Mr. F. W. Bois, Mrs.

Mary Bois, Mr. Percy Bois, Mr. Henry Bois, Mr. A. H. Christian and Mr. W. J. Carver, by their attorney, Mr. F. Bois; Mr. F. Liesching, the Estate of H. Ledward by the Administrator, Mr. F. Liesching, the Estate of Mrs. Ledward by Mr. F. Liesching, hon. C. P. Layard, and Messrs. Julius and Creasy by Mr. F. Liesching; Messrs. S. Green, F. Beven, F. C. Loos, F. J. de Saram, R. W. Nunn, Hon. Sir J. J. Grinlinton, by his proxy, Mr. R. L. M. Brown, and Mr. R. L. M. Brown (Secretary.)

Notice calling the meeting were read and minutes confirmed.

THE REPORT AND ACCOUNTS.

The Chairman submitted the report and accounts. The report is in the following terms:—

1. In submitting the accounts for 1896 the Directors have much pleasure in calling attention to the increasingly satisfactory position of the Company, the result for the year showing a sum of R40,518.57 available for distribution, after writing off R7,000 as depreciation of plant and machinery.

2. The Directors recommend that a dividend at the rate of 10 per cent for the year on the capital of the Company be declared. This will absorb R40,000 and leave R518.57 to be carried forward to 1897.

3. During the past year a further sum of R15,000 has been paid in reduction of the mortgage debt, which now stands at only R10,000.

4. The crop of coconuts in 1896 was a large one, and was sold as nuts, and not made into copra as hitherto. It gives ample testimony to the value of manure, which is now being applied systematically and on an increased scale, thus justifying the enhanced expenditure sanctioned under this head by the Directors.

5. The working of the estate for the years 1894, 1895, and 1896 compares as follows (the item of interest being excluded):—

	1894.	1895.	1896
and in Colombo office	R33,243.74	32,747.69	30,463.23
Quantity of Coconuts produced	No. 1,002,237	1,332,965	1,548,081
Do. Coir Fibre made	Ballots 40,245	25,703	23,859

6. The Directors are happy to report that the prospects of crop for 1897 are favourable, and with a normal season the result should be satisfactory.

7. Two Directors—Messrs. Percy Bois and F. J. de Saram—retire by rotation, and are eligible for re-election.

8. The shareholders have to appoint an Auditor for 1897.

The Chairman remarked that the report and accounts had been sent round and as every shareholder had received a copy he moved that they be taken as read. (The meeting having acquiesced) the Chairman went on to say that he thought the report spoke for itself. It showed that they had had a very prosperous year, owing to the climate as well as the systematic manuring they had been carrying out. The result was in the report and a very creditable one he thought it was. Next year promised to be quite as good, but whether the prices they would get for their produce would be as good was another matter. They had sold half the crop of coconuts already on the same terms and conditions as last year but at 50 cents less a thousand, but if exchange fell towards the end of the year the price of coconuts might rise and they would be able to get as good a price as they got last year. The work done by their Superintendent, Mr. Beven had been very satisfactory. There had been a good deal of difficulty with labour but that was not uncommon every where. With these few words he moved the adoption of the report and accounts.

In answer to Mr. Green the Chairman explained that half of the forthcoming year's crop had been sold for R36.50 per 1000 as against R37 per 1000 for the last half year.

The report and accounts were adopted.

THE MORTGAGE ON THE PROPERTY.

The Secretary (Mr. Brown) said it had been brought to his notice by some of the shareholders that the accounts were not particularly clear as regarded the reduction of the mortgage. This item did not appear on the face of the Company's accounts as issued, but of course it appeared in the report of the Directors. What appeared in the accounts was a balance sheet not a working sheet; it showed the balance after all the work had been done. In one of the columns the mortgage stood at R10,000 and in the previous accounts it stood at R25,000 so that was where the R15,000 came in. The amount remaining was R10,000 and it was for the Directors to say, when an opportunity occurred, whether that amount should not be paid off also.

Mr. BEVEN proposed that a dividend of 10 per cent be declared in accordance with the recommendations contained in the Director's report.

The SECRETARY pointed out that as a rule the dividend was paid on 1st April because the crop was allowed to mature for some time on the estate before delivery. The crop plucked in the end of December required time to mature and it was some time before it could be converted into money. They were, however, able to declare a dividend a little earlier this year because the crop was not in copra, but he hoped that in fixing a date the meeting would not fix it too early a date for the shareholders next year, when the crop might be in copra would be grumbling if the dividend was not paid so early date. He suggested that the dividend be payable on 1st March.

Mr. BEVEN adopted this suggestion and moved accordingly.

Mr. GREEN seconded and the motion was carried unanimously.

ELECTION OF DIRECTORS AND AUDITOR.

On the motion of Mr. GREEN seconded by Mr. NUNN, Messrs. PERCY BOIS, and F. J. DE SARAM were re-elected Directors and on the proposal of Mr. NUNN, seconded by Mr. GREEN Mr. H. J. SCOTT was re-elected Auditor of the Company at a fee of a R100.

A vote of thanks to the Chairman terminated the proceedings.

LONDON REVIEW OF THE TEA MARKET.

INDIAN.

(From *Stenning, Inskipp & Co.'s Indian & Ceylon Tea Market Review for 1896*)

LONDON:—14, Mincing Lane, Jan. 1897.

POSITION AND PROSPECTS.—A reference to the figures given below will show that Imports during the twelve months ending 31st December last, mark an increase of 5,604,000 lb., and the deliveries during the same period an increase of 9,584,000 lb., compared with 1895. The total imports for the season are expected to reach about 127,000,000 lb., against 117,932,000 lb. last season, and this additional quantity should not be difficult to deal with. The quality of the crop generally is good, and as the range of prices is extremely moderate, the consumption, which last month made a great stride, may be expected to proceed at a rate that will absorb the extra supply.

On the whole, the season's results to producer should prove encouraging. Those who have maintained a good standard of quality will have found compensa-

tion in a steady market at satisfactory prices throughout; while others who cannot successfully compete in the production of high-class teas will have been benefited by a more abundant output. The recent rise in Exchange, and the dearness of native food in the districts, caused by the Indian famine, are rather serious drawbacks which will, we fear, have to be contended with for some time. But some offset to these will be found in a more plentiful supply of labour. As regards the future, the demand for teas of sterling character should not be prejudiced by the larger crops of coming seasons from districts which, owing to conditions of climate, soils, &c., have largely to look to quantity. But for the common and medium classes the outlook is less reassuring, because neither in India or Ceylon has the limit to production been reached, certainly nor in India were large additional areas of cultivation will soon be coming into bearing, and thus, with ever increasing quantities coming on the market, the tendency must be to a further weakening of prices. In these circumstances the grower naturally watches with some concern the progress in the demand for British grown tea in other countries. During 1895 the quantity sent from London to America, the Continent, and other countries amounted to 3,924,551 lb., and it is disappointing to find that the figures for 1896 show an increase of only 381,000 lb., and this, in spite of the preserving efforts being made to extend the business. The shipments direct from Calcutta to countries other than the United Kingdom show a falling off of 658,000 compared with last year. Against this, however, 1,255,000 lb. more of all teas have been sent to United Kingdom for transhipment to other ports, the figures being 6,395,000 lb. during 1896 and 5,140,000 lb. in 1895.

The importation of a consignment of machine-made tea from Foo Chow has excited some interest in the China market, owing to its novelty. This tardy innovation in Chinese methods if it were applied systematically would no doubt lessen the cost of production, but it would not go far towards resuscitating their lost trade. China tea has passed out of favour by reason of its inherently poor character compared with the teas of India and Ceylon, and the use of machinery in its manufacture could not overcome this difficulty.

CEYLON.

THE COURSE OF THE MARKET.—Contrary to 1895 a dull tone with lower prices marked the opening of business due to heavy supplies and less attractive teas. A slow enquiry was experienced in February and although auctions were smaller inactivity continued until the latter part of March, when there was a slight recovery, especially in the lower priced teas, and after the holidays in April a good demand set in at dearer prices which continued throughout May, early in June arrivals were heavy, and prices fell. Better quality and less pressure to realize throughout July and August led to a steadier tone at higher prices. September auctions were rather small, the quality was good and the market hardened throughout. Larger supplies early in October caused quotations to give way slightly but they steadied again as quantities fell off, and with continued good quality in November the market was strong; less attractive quality in December made lower quotations and the market continued weak until the close business for the year, more particularly for such of the higher grades as lacked quality.

SMALL BREAKS.—Since the 1st October, lots of less than 18 Chests, 24 Half-Chests or 40 Boxes have been reckoned as Small Breaks.

QUALITY.—Fine Invoices were somewhat scarce until April; afterwards the general character became indifferent; but from August to November an improvement was noticeable which was, however, succeeded by some falling off in December. On the whole we consider the year's imports to have been up to the average though a great quantity of very poor tea has been produced which has come here chiefly on Colombo purchase account. The prices now obtainable for tea of this low class can leave but a slender margin of profit,

and, owing to the tendency to lower prices generally, its production may at no distant date become altogether unprofitable, especially since China tea at the same price is better in appearance, if not in liquor also.

OTHER MARKETS.—From Colombo, shipments as follows (to the 22nd December):—

To Australia and New Zealand, 11,746,500 lb., against 9,314,200 lb. in 1895.

From London the Exports are as follows:—

	Continent.	America.	Canada, &c.	Other Countries.	Total.
	lb.	lb.	lb.	lb.	lb.
1896..	4,535,100	1,386,020	1,346,188	975,130	8,242,438
1895..	3,786,178	1,420,262	1,113,165	773,836	7,093,441

In previous years when the destination of Exports was not distinguished the Totals were as follows:—

	1894.	1893.	1892.
	lb.	lb.	lb.
	5,123,862	4,065,709	3,273,955
		Pkgs. Aver.	Per lb.
Average Price ..	1896 ..	1,066,912	8½d
	1895 ..	965,052	8½d
	1894 ..	889,573	8¾d
	1893 ..	846,762	9½d
	1892 ..	789,231	9½d
	1891 ..	755,552	9¾d
	1890 ..	535,611	10½d
	1889 ..	431,043	11d
	1886 ..	303,284	11½d
	1887 ..	182,955	10¾d

USEFUL HINTS :

LOSS IN WEIGHT.—As this occasionally gives rise to much dissatisfaction we offer the following suggestions: that the gross weight of the package should be a few ounces, say four or five, above an even number of pounds, and that the empty package, complete with lead, nails, bands, &c., be to a like extent below an even number of pounds. In weighing here the gross weight is reduced to the even number of pounds, whilst the tare is increased to an even number of pounds.

With regard to Garden Bulked Teas, it is imperatively necessary to put an equal quantity into each package of the break, and this quantity should be four or five ounces over the desired weight of contents, viz., if the packages are invoiced to contain 100 lb. Tea each, not less than 100 lb. 4 ozs. should be weighed in; test packages, weighing here a fraction under 100 lb. are reckoned as 99 lb. only, or a loss of 1 lb. on each chest of the break.

Careful observance of the foregoing precautions would no doubt prevent much loss and disappointment.

DRAFT of 1 lb. per package on all packages grossing 29 lb. and upwards is allowed to the buyer.

WEIGHT OF PACKAGES.—When a gross weight of 129 lb. is exceeded, there is an additional charge of 5d. per chest up to 159 lb. The following scale of charges fully explains this and deserves attention:—

Management rate per package, subject to an uniform discount of 10 per cent.

GROSS.—160 to 199 lb., 2/9; 130 to 159 lb., 2/3; 90 to 129 lb., 1/10; 80 to 89 lb. 1/8; 60 to 79 lb., 1/5; 45 to 59 lb., 1/2; 35 to 44 lb., 1/-; 17 to 34 lb., -/7.

MARKS ON CHEST.—Nothing is wanted oris of any service here beyond (1st.), Garden Mark; (2nd.), Description of tea; (3rd.), Garden Numbers. Gross, tare, or net, are not of the least use, and should be discontinued.

METAL PACKAGES.—Although not especially objected to, these do not yet find generally favour with buyers.

PACKING SMALL BROKENS AND DUSTS.—Special care should be taken to pack broken descriptions, which are so liable to lose in weight, in strongly made wooden packages. Dust should only be packed in half chests, either of metal or of strong iron hooped wooden packages; canvas coverings should in no case be used, as they disguise injury done to the packages by rough handling, and any tea retained in the canvas becomes of no value,

INDIAN PATENTS.

Whereas the inventors of the undermentioned inventions have respectively failed to pay the prescribed fees, it is notified that the exclusive privilege of making, selling, and using the said inventions in British India, and of authorizing others so to do, has ceased:—

IMPROVEMENTS IN THE MANUFACTURE OF TEA LEAF INTO BLACK TEA.—No. 158 of 1892.—Samuel Cleland Davidson's invention for improvements in the manufacture of tea leaf into black tea. (Specification filed 14th October 1892.)—*Indian and Eastern Engineer*, Jan. 30.

COFFEE PLANTING IN NYASSALAND,
B. C. AFRICA.

(From an *ex-Ceylon Planter*.)

Mlanji, B.C.A., Dec. 8.

Our dry season this year has been very hot and trying for our coffee. Most of our blossoms in November which is usually our best has failed, consequently our crops will be short. Although we had a lot of rain, it was badly distributed; it was late in coming and we had almost two months dry with a blossom hanging in spike all the time. I have not (during my six years in Nyassaland) known such a bad year during our blossoming season. Our rainy season usually begins about the middle of November, but this year we have been anxiously looking for the rain to date, and just as I am writing thunder and lightning has begun and it rains in torrents. I only hope it will continue so that we may secure the little crop we have left, and make some decent wood for next year, for we have had a terrible scorching:

COFFEE AND TEA IN AMERICA.

REVIEW OF 1896.

COFFEE.

Coffee opened January 2 at 14½ cents for No. 7 Rio, ruled comparatively steady until June, when a downward movement began, which carried the price to 9½ cents in November, and left it at 10½ cents on December 31.

The high prices of the past ten years stimulated the setting out of new plantations in Central and South America, the full influence of which was not felt until the size of the crops of 1895-96 were known. For several years the world's requirements and the world's crops were so close to each other that prices were maintained at a high level until 1895, when they began to recede, and continued a downward movement throughout the past year, the closing price of No. 7 Rio being 4½ cents below that ruling January 1, 1896. The year 1896 is notable in that the increase in the crops of the world has been large enough in the crops of the world has been large enough to force a decline in the cost of Brazil sorts of over 4 cents per pound. The high prices which have ruled since 1886 stimulated the setting out of the new plantations all over the coffee belt of the world, particularly in Mexico, Central America, the United States of Colombia and Brazil. In 1795 the exports of coffee from the United States were 1,244,066 pounds greater than the imports. In 1896 the net imports were 572,971,840 pounds, valued at \$83,534,366. The average value of imports was 14½ cents per pound.

TEA.

Tea sold at the lowest prices ever made in this market until October, when it became certain there was a shortage in the crops of China and Japan, and prices advanced 2 to 3 cents per pound and held the gain until the close of the year.

Oversupply kept this market in a depressed condition until it became apparent that a large deficiency in the supplies for the present season, estimated from

20,000,000 to 23,000,000 pounds led to a large fall business and an advance of several cents per pound, most marked in medium and low-grade tea.

The year opened with Formosa Oolong steady, as receipts were limited, but Foochow and Amoy sorts were weak, as they were freely offered at auction, touching the lowest values recorded for cargo grades. Amoy, old crop, common to fair, sold in January at 7 to 8½ cents; Foochow, new crop, 9 to 10 cents; Greens, owing to the full supply, were in buyers' favour, Country teas and Pingsneys were freely offered at public sale; cargo Young Hyson sold at 7½ to 8½ cents; Twankay, 4½ to 6 cents; extra first Young Hyson, Moyune, 25 to 30 cents; first, 15 to 19 cents; new crop Pingsneys were covered by prices ranging from 7 to 25 cents. During the spring the market ruled week, and prices fell below those quoted above on low-grade teas. All grades of Japan declined, and in May good medium brought 12½ to 13 cents; common to good common, 9 to 10½ cents; fine or finest, 14 to 15½ cents; choicest, 20 to 22 cents. During May from 4,000 to 5,000 half-chests Formosa, grading on superior, sold at private sale at 17 cents; common grades Foochow and Amoy at 7½ to 7½ cents at auction.

In the fall it became evident that there would be a marked deficiency in the supply of Greens and Japans; aggregating 13,000,000 to 15,000,000 pounds for the seasons 1895-97. There was considerable speculative buying, and low grades advanced 1½ to 3 cents per pound in October, and have held the gain up to the present. From October to November 15 the sales in first hands covered 18,000 packages Japan; 3,000 Country and 12,000 Pingsney Greens; 15,000 Formosa; 7,000 Foochow; 10,000 Amoy and 6,000 packages Congou. This proved the largest wholesale business in tea outside of the auction room, for the same period, in two years.

The year closes with demand slow, but with the statistical position strong, as the estimated supply for 1895-97 is about 12,000,000 pounds less than requirements, which may be fairly estimated at 93,000,000 pounds, while the estimated supply for the present season is placed at 82,350,000 pounds.

In 1796 the net imports of tea into the United States were 2,355,755 pounds; one hundred years latter (1896) they were 93,340,248 pounds. The per capita consumption is smaller now than from 1880 to 1882 inclusive, and less than from 1886 to and including 1889, since which date it has not varied one-tenth of a pound. The reason—large importation of trash.

The imports, re-exports and net imports of tea, the latter representing consumption, were for the year ending June 30, 1896, as follows:

	Pounds.	Dollars.
Imports	93,998,372	12,704,440
Exports	658,124	118,699
Net imports—Consumption	93,340,248	12,585,741
Per capita consumption ..	1.33	
Average imp. cost per pd.		13.50c.

The above quantity of tea was imported from the following countries:

	Pounds.
China	49,178,277
Japan	38,169,652
United Kingdom	2,729,695
Other parts of Asia	2,363,676
East Indies	1,261,671
Other countries	295,401

Total 93,998,372

China furnished 52 per cent. and Japan 40.5 per cent of the total imports.—*American Grocer*, Jan. 6.

ROYAL GARDENS, KEW.—Bulletin of Miscellaneous Information, May and June. Contents:—Botanical Enterprise in British Houduras, Sugar-Cane Disease in British Guiana, Hand-list of Coniferæ grown in the Royal Gardens, Tropical Fodder Grasses (continued), Cotton in British Central Africa, Sisal Cultivation in the Turks and Caicos Islands, Sacred Tree of Kum-Bum, Miscellaneous Notes.

COFFEE NOTES FROM NYASSALAND.

Coffee prospects for the coming season are good. We are informed that the heavy rains in the end of October brought out a good blossom, and there has since been pleasant sunny weather, which has in most cases caused it to set well.

A coffee plantation, which we think we are right in describing as the first which has been started in the districts west of Lake Nyasa, is now being formed by Mr. Kahu of Kotakota. He informs us that he expects to have 100 acres in before long. It has always appeared to us somewhat singular that none of the planters in this country have as yet opened up plantations in the districts lying immediately west of Lake Nyasa, even right to the north end. Water carriage is so cheap, compared with land transport in this country, that coffee could probably be transported from Karonga to Matope as cheaply, or nearly so, as it could from Southern Angoniland to Matope, and by choosing a district in which labour is cheap, as indeed it is in almost all of the Nyasa Districts, the cost of production would probably, in the first instant at any rate, be very much less than it is in the Shire Highlands.—*British Central Africa Gazette.*

INDIAN TEA COMPANIES.

To the Editor of THE "FINANCIAL TIMES."

Sir,—Your article about Indian tea companies seems to have drawn some attention to them, judging by the inquiries addressed to men who, like myself, are supposed to know all about their position and prospects. May I, therefore, say a word by way of guidance, to point out that discrimination should be used by investors, as a very distinct movement is in progress tending to enhance the value of one class of property and to depreciate another? The average of profits of past years is not always a reliable guide to the future profitableness of the estates, inasmuch as the value of the produce from certain districts is steadily appreciating while that of others is declining. This is due to the fact that only a certain amount of land in India, and very little in Ceylon is found to be capable of continuously yielding fine tea, with the result that practically all the increased production of recent years is of a lower quality, for which the market value is falling unpleasantly near cost of production. A further rise in exchange and freight, added to the increased cost of feeding coolies at a loss on the rice and the continually growing difficulty of obtaining the sort of coolie required, would certainly reduce the profit of some concerns to a very low point. There will, of course, be a set-off in the check given to further extensions of the area planted. On the other hand, there is apparently no limit to the prices obtainable for tea from the finest plantations in Darjeeling and Assam. It is not my purpose to specify any company, but any stockbroker can obtain information by coming to a tea broker. This leads to a comment on what is a matter of general experience—namely, that if a client asks his stockbroker what he thinks about Indian tea, the answer is nine times out of ten that he "doesn't like it" with the advice to "leave it alone," sometimes followed by a suggestion to take a few shares in some wild-cat land company. Hence it is that during the last few years several tea brokers have started a stock and share department for their speciality, and are reputed to be making incomes that would make many a man in the "House" rich. A market has, in fact, been established with success independent of the Stock Exchange. I will conclude by adverting to the real grounds of the confidence in the best class of tea plantations shown by those who have been connected with this industry for a lifetime—to which you did not allude. They are:—

1. That such a thing as a failure of a tea crop (as distinct from its failure to be highly profitable) is unknown,

2. That there is no visible limit to the world's consumption, which steadily grows, as some think, because, in spite of doctors, it is found that the tea

of British India is a food as well as a drink, nourishing and stimulating at the same time.

Just look at these figures. Consumption of tea per head per annum—Australasia, $7\frac{1}{2}$ lbs; Great Britain and Canada, 5 lbs; United States about $1\frac{1}{4}$ lb—the rest of America, Europe, and Asia from 1 lb to nothing per head per annum. What a field there is for a trader with the real thing in his store to push trade to dimensions hitherto undreamed of! And it is being done by the new tea-man owning a proprietary mark with an unpronounceable name, by means of a showy packet containing the genuine article.—I am, &c.,
BROKER.

THE FORMATION OF SAND DUNES.

[? A LESSON FOR HAMBANTOTA.]

At the meeting of the British Association at Liverpool Mr. Vaughan Cornish contributed one of the most valuable and original papers read to the Section, in the form of a practical study of the formation and distribution of sand dunes. He said that in the sorting of materials by wind the coarser gravel is left on stony desert or sea-beaches, the sand is heaped up in dune tracts, and the dust (consisting largely of friable materials which have been reduced to powder in the dune districts itself) forms widely-scattered deposits beyond the limits of the dune district. Three principal factors operate in dune tracts, viz., (1) the wind, (2) the eddy in the lee of each obstacle, (3) gravity. The wind drifts the fine and the coarse sand. The upward motion of the eddy lifts the fine-sand, and co-operating with the wind, sends it flying from the crest of the dune. The backward motion of the eddy arrests the forward drift of the coarser sand, and thus co-operate with the wind to build the permanent structure of the dune. Gravity reduces to the angle of the rest of any slopes which have been forced to a steeper pitch either by wind or eddy; hence in a group of dunes the amplitude cannot be greater than (about) one-third of the wave-length. This limit is most nearly approached, owing to an action which the author explained, when the wind blows alternately from opposite quarters. Gravity also acts upon the sand which flies from the crests, causing it to fall across the stream lines of the air. To the varying density of the sand-shower is due the varying angle of the windward slope of dunes. When there is no sand shower the windward becomes as steep as the leeward slope. When the dune tract is all deep and the lower part of the eddy gouges out the trough, and, when the sand-shower fails, the wind by drifting and the eddy by gouging, form isolated hills upon a hard bed. In a district of deep sand, negative dunes ("Suljes") may be formed. The encroachment of dune tract being due not only to the march of the dunes (by drifting) but also to the formation of new dunes to leeward from material supplied by the sand-shower, it follows that there is both a "group velocity" and a "wave velocity" of dunes. Since the wave velocity decreases as the amplitude increases, a sufficiently large dune is a stationary hill, even though composed of loose sand throughout. Where material is accumulated by the action of tidal currents, forms homologous with the ground plan of dunes are shown upon the charts. The vertical contours and the movements of subaqueous sand dunes are conditioned by the different tactics of sand-shower and sand-drift.—*Nature.*

THE DIMENSIONS OF TREES.

Your comparison between the heights of St. Paul's Cathedral, the spire of the dome of Cologne and the *Eucalyptus amygdalina* are extremely interesting; but, whereas the heights of those buildings are correctly known, that of the tree is, to say the least, problematical. No doubt Baron Von Mueller in some of his earlier publications claims the enormous length quoted for some of the trees measured by him, but it is generally understood in Australia that those measurements were made of old fallen

trees portions of which had been destroyed by bush-fires, and it is considered quite feasible that in this way the trunk of one tree and the crown of another supplied the data, the intervening portion being added and destroyed by fire.

The fact remains that, so far as I am aware, the extreme proportions quoted have never been found to exist by Forest officers of the Colonial Governments who examined the forests, though some of the mightiest kings of the forest have been carefully preserved by them. The measurements of Big Ben, or Big Bog, I am not sure which, is growing in the Melbourne water-supply reservoir, and which is considered the king amongst the foids of the forests, are well known. I forget what they are said to be, but as given to me they fall far short in length of those quoted in your extract, which failing further verifications of their accuracy, cannot be accepted as authoritative.

10th December 1896.

A FORESTER.

—*Indian Forester*, for January.

INDIAN PATENTS.

Specifications of the undermentioned inventions have been filed under the provisions of the Inventions and Designs Act of 1888:—

Drying and warming oil-seeds by steam-power.—No. 118 of 1896.—Temulji Dhanjibhai, mill manager, of No. 125, Harrogonge road, Sulkea, Howrah, for drying and warming oil-seeds by steam-power, (Specification filed 31st October 1896.)

Packing Tea.—No. 169 of 1896.—Henry Sabow (the late), some time engineer of Kurseong, Darjeeling, for packing tea, the invention being called "Sabow's Patent Vibrating Tea Packer." (Specification filed 16th January 1897.)—*Indian and Eastern Engineer*, Feb. 6.

PROGRESS IN B. C. AFRICA.

DEPUTATION FROM THE BRITISH CENTRAL AFRICA CHAMBER OF COMMERCE.

On the 23rd November a deputation from the B.C.A. Chamber of Agriculture and Commerce interviewed Mr. Sharpe, the Acting Commissioner, at the Court House, Blantyre. There were present:—Messrs. Israel (planter and merchant), Duncan (representing Messrs. Gardiner & Co., coffee brokers, merchants, &c., London, and also the firm of Buchanan Brothers), Beaton (acting manager of the African Lakes Corporation), Macrone (Civil Engineer), Hastings (planter), and Paolucci (planter and merchant).

SHADE TREES FOR COFFEE.

Mr. Israel also stated that a misunderstanding had arisen with regard to their letter to the Acting Commissioner referring to the importation of shade trees from India. They had no wish to import trees from districts infected with coffee leaf disease, but wished the Commissioner to enquire of the Government of India whether there would be any risk in importing shade tree seeds from certain districts of India.

ANALYST OF SOILS.

He also stated, in speaking of the appointment of a Government Analyst, of soils, that Sir Henry Johnston had expressed himself favourably about it. He spoke of the advantages which would accrue from the appointment of a Government Analyst, and of the possibility of the discovery of phosphates, &c., and trusted that a sum might be set aside for the appointment of a Government Analyst. He thought the expense might even be met by the fees charged.

RAILWAY.

Mr. Israel said, it had been proposed by the Chamber to call a meeting on the 4th December and pass certain resolutions which they would ask the Commissioner to forward to the Home Government with reference to the proposed railway.

Mr. Macrone produced plans of the alternative route and explained that although the gradients were steeper than by the first proposed route, the line was four miles shorter and would save about £2,000 in construction, but he would recommend the original capital to be adhered to (£200,000). He said that what they hoped Government might do was to guarantee a dividend of 3 per cent for a few years. Mr. Macrone had estimated the line would produce 1½ per cent at first, and they wanted the Home Government to guarantee the remaining 1½ per cent probably amounting to a sum of about £3,000 per annum. This was a very small sum, while the benefits to the colonists would be very large. They considered that in the face of the large Uganda vote, the settlers in British Central Africa who had exploited a new country, established a new industry, and proved its success, were entitled to ask for some small assistance in the railway question. The trade for a railway in British Central Africa already existed, and would pay a dividend now and would largely increase with railway facilities.

LABOUR REGULATIONS.

Mr. Paolucci stated that in his opinion there was not sufficient safeguard in the Labour Regulations against labourers deserting their work before their time was finished.

Mr. Hastings said that planters object to the Labour Regulations fee of 1s.

After some discussion about the cash payment of taxes Mr. Israel mentioned Sir Harry Johnston's last official Report on B.C.A. taking exception to certain paragraphs concerning the payment of labourers.

In replying to the foregoing observations made by the various gentlemen on the deputation, Mr. Sharpe said that Lord Salisbury had not definitely declined to do anything in the way of helping a railway, but that he had stated that the Foreign Office could not consider the proposals until a definite scheme was placed before them.

He proposed to get all information possible from the Government of India with regard to shade trees, and asked the Chamber to formulate their wishes in this respect in a letter.

With regard to an analyst, he recognised the importance of the agricultural interests in the future of this country, and would convey to the Home Government the feeling of the Chamber in this matter. He would endeavour to make some provision for a Government Analyst coming out, and if, as he was informed, Sir Harry Johnston had expressed a favourable opinion, he had little doubt the matter could be arranged, but not till next year.

It was true that the Ocean mail service was not satisfactory. The Home Government was aware of the facts and recognised our difficulties in this respect out here. The question had also arisen at home in the beginning of the present year. We required a fixed service at regular dates to Chinde; and he had some hopes that before long something might be done in this direction.

With regard to the Shire Highland proposed railway, Mr. Sharpe said there would be little gained by his forwarding indefinite resolutions. The Home Government had already stated that it would be impossible to consider the matter until a definite scheme was submitted. They should meet and form a committee to go into details, prepare careful plans and estimates, and make the whole thing as complete as possible. Government would want to know to whom it was proposed that such guarantee should be made. Their best policy would be to form a definite scheme and he would submit it to the Foreign Office. He had heard that, with regard to the existing schemes, some amalgamated arrangement had been come to by the promoters at home.

Regarding the Labour Regulations, these were drawn up with the view of instituting a formal agreement between the employe and the employer, and there was no doubt that the act of registration was now looked upon by the labourers as a necessary formal preliminary. The registration fee of one shilling was small. In some countries it was as high as 10 shillings. Collectors were always ready to

assist in endeavouring to find and return labourers who had broken their agreements and run away before the completion of their time. These regulations were framed quite as much for the protection of the labourer as the employer. He did not think they had much to complain of in the matter of the Labour Regulations, which were working well.

Referring to Sir H. H. Johnston's last official report on B. C. A., Mr. Sharpe felt sure that the Commissioner had no intention of suggesting (as they seemed to consider,) that labourers were unfairly treated by employers in this Protectorate, but that the labour regulations were so framed by him that just dealing was secured for both employer and squarer.—*British Central Africa Gazette.*

PRODUCE AND PLANTING.

THE SHARES OF CEYLON TEA COMPANIES.—As a set-off to the outcry in some papers against tea shares and the absurd talk about "booms" and investment in tea companies being overdone, the *Echo*, in its money article, has something to say in favour of Ceylon companies. After giving the price and the yield per cent of some of the better known companies, similar to that which appears in our columns week by week, our contemporary states that "investors who have hitherto held aloof from these shares may see what a far better holding they have proved to be than gold or silver mines. Yet a company like the Barnato Bank can obtain its millions of pounds without a prospectus in a few hours, and can find hundreds of small capitalists ready to sell out of Consols in order to pay £4 for a £1 share, while it has taken these same people six or seven years to be persuaded into buying Ceylon tea shares which were at one time obtainable at par, and which have ever since their formation as limited liability companies paid handsome and steady dividends. The rise in value of the Eastern Produce and Estates Company is remarkable," says the writer of the article, "when one remembers that this Company is the successor to the old Ceylon Company, Limited, which was brought down during the years 1880 to 1884 by the utter failure of the coffee crops. At the time of the first suspension of the Oriental Bank in April, 1884, the Ceylon Company, Limited, owed the bank a sum of about £570,000. Indeed, the bank and the Company were so mutually involved in each other that they were bound to fall together. With the rise of other tea planting the Eastern Produce Company has risen also. Its 10,000 acres under cultivation represent some of the finest old coffee properties in the island, as well as some of the largest Rothschild Estate in Pussellawa and Meddecombra Estate in Dimbula were almost the best-known coffee plantations in the Central Province, the former having been successfully worked for nearly forty years before giving out. This company's debentures must be well secured, and should prove a suitable purchase for anyone desirous of holding an actual mortgage as well as a share in profits."

INDIAN AND CEYLON TEA IN THE UNITED STATES.—The *American Grocer* bears testimony to the success which is attending the efforts of Messrs. Blechyn-den and Mackenzie towards popularising Indian and Ceylon teas in the United States. The prejudice against these teas is giving way, and dealers who formerly prognosticated the failure of any attempt to place them on the market or anything like a large scale now admit that the growth of the trade is marvellous, and will continue to grow.

PACKET TEA.—The growth of the tea planting industry has been accompanied by a similar development of enterprise in regard to the packet tea trade. Those concerns whose proprietors have had faith in the value of advertisements and also the necessary capital to spend on this all-important department have found

the packet tea trade pay, and the extent of the business is considerable. In their report, recently issued, the directors of the Mazawattee Tea Company, Limited, state that they have thought it wise in this year's accounts to provide for the whole of the exceptional expenses in connection with the opening up of new business in fresh centres, including development outlay in Ireland, so that they have been entirely written off this year's profits. The net profit, after providing for these payments, is the sum of £54,270 2s 5d; and after payment of the managing director's remuneration, directors' fees, preliminary and office expenses and other charges and interest, making the necessary reserve for discounts, and for depreciation of leases and plant, there remains a balance available of £31,613 6s 5d. From this is to be paid the dividend due upon the preference shares at the rate £5 per cent. per annum, which will absorb £4,476 15s; and the directors recommend a dividend upon the ordinary shares at the rate of £8 per cent. per annum for the half-year ending December 21 last, which will amount to £13,533 6s 8d. They propose to set aside out of the profits of the current year the sum of £12,000 as a reserve, and, after making this provision the amount of £1,604 4s 9d will, subject to such sum as may be voted for the commission of the directors, form the balance to be carried forward to the next account.

IN PRAISE OF TEA.—In an article on tea drinking, which appears in the *Globe*, the writer says:—"We can scarcely in the present day conjure up the vision of a tealess world. Yet our stalwart ancestors drank ale to their breakfast; and even when their overnight potations had been deep were constrained to call for 'small beer.' Modern civilisation has provided substitutes for these refreshments and our less robust age revolts at the idea of them. But modern civilisation has done more than give us substitutes; it has supplied us in the tea-table with an institution whereof no prototype exists. The glories of the punch-bowl have departed; the guinea-decorated ladle is profaned to the service of various degenerate and soulless compounds known as 'cups'—it is enough to make our convivial great-grandfathers turn in their graves. The hospitable mahogany has its cheerful surface veiled with a cloth, and might as well be simple deal; but we maintain in its perfection the rite of tea-drinking. It is not a rite of such dignity as those practised by our forefathers; the teapot soothes rather than elevates; it is domestic rather than convivial; its function is not so much to create a bond of unity between an assembly as to supply a solace to the individual. But such as it is unequalled. Moreover, tea is a link between all classes of society; for it no longer costs, as in the times when fashionable society rhymed it to 'obey,' twenty shillings in the pound. It sheds its grateful influence upon palace and cottage alike; it is no longer merely an 'elegant regale'; it has become popular, and that without losing its charm."

THE TEA INDUSTRY.

INDIAN AND CEYLON IMPORTS.

Year by year the growing importance of British-grown tea is showing itself in statistics and Board of Trade returns. If the official Britons take money out of India and live at home in something resembling ease, it can at least be urged that the commercial Briton takes his capital out to the East, where he often lives in considerable discomfort, working hard himself, and employing native labour by the hundred thousand at a time.

The official prays for a rise in exchange, and considers that he is being robbed with every fraction that it declines. The planter, or capitalist, employed in the tea enterprise would be glad enough to see the Rupee down to a shilling, as any gold he sends out to India to pay for the opening up of more jungle land becomes nearly doubled *en route*, while the product grown on the estates is shipped to London and sold for gold.

Subjoined are the imports of tea into the United Kingdom from the 1st January to the 31st December 1896, as shown by the Custom House returns, together with the figures for the two previous years. The first line (a) relates to British India, the second (b) to Ceylon, the third (c) to China, and the fourth (d) to all other countries, including Java and other Dutch settlements.

	1894.—Lb.	1895.—Lb.	1896.—Lb.
(a) ..	118,400,000	123,300,000	128,800,000
(b) ..	76,300,000	83,400,000	94,600,000
(c) ..	43,900,000	40,000,000	35,200,000
(d) ..	5,600,000	8,400,000	7,400,000
	<u>244,300,000</u>	<u>255,300,000</u>	<u>266,000,000</u>

Thus, while China imports have steadily declined from 43,000,000 lb. to 35,000,000 lb., those from Ceylon have risen from 76,000,000 lb. to 94,000,000 lb.—*Echo*, Jan. 23.

CEYLON TEA IN CANADA.

Mr. Mackenzie, our American Tea Delegate, in communicating with us by a recent mail, sends us the following extract from a letter he had received from the Salada Ceylon Tea Company:—

"The *Canadian Grocer* of this week made a bad mistake. They stated that there were 'ten million' pounds of tea imported in that year, 1895. They must have given the returns for the Province of Ontario instead of the Dominion of Canada, as there were twenty-three million' in 1894. I am enclosing you a page with it in. I have just called their attention to it, over the phone.

"You will also notice an article on that page about the Japanese gentleman who was interviewed in Montreal a day or two ago."

The extract from the *Canadian Grocer* is as follows:—

DUTY ON TEA AND RAW SUGAR.

"If I could only foresee what the Government intends to do, I could make a barrel of money," said a leading Montreal wholesaler to the *Canadian Grocer* this week.

This expression sums up the situation in a sentence. There is a pretty general impression that a duty on both tea and raw sugar will be among the methods that the Government will adopt to make up for decrease in revenue caused by readjustment in other directions. But though this belief is general throughout the trade it has so far failed to induce any buying as far as Montreal is concerned either of tea or sugar in anticipation of profiting by the change.

From the opinions generally expressed by the Montreal jobbers, they would all welcome a duty on tea. With a duty they think that it would sensibly reduce the importations of low-priced Japan and China tea into Canada.

As is well known, the great bulk of the tea turned over in Montreal costs from 10 to 15c. in a wholesale way.

In the old days of the duty, with 7c. per pound and 15 per cent. and valorem on Japans and greens, and 4c. per pound and 15 per cent ad valorem on blacks, it hardly paid to import these very low-grade teas, hence their consumption has enormously increased since tea imported direct was made free.

No trader is prepared to specify what the duty should be, but many declared that they would not object to a specific duty of 5c per pound on all teas and a certain ad valorem charge. They figured that the increased cost to the consumer would not be of the kind that is keenly felt, while it would be one of the quickest means of the Government's securing the increase in revenue that it requires.

During 1895 there were 10,083,310 pounds of tea entered for consumption in Canada. This will afford some idea of the increase in revenue the proposed duty would bring in. With regard to raw sugar, on which many expect that the present duty will be maintained or increased, 309,302,296 pounds were entered for consumption in 1895.

The other article we will quote in another issue.

THE CLYDE TEA ESTATES COMPANY, LIMITED.

The annual ordinary general meeting of shareholders was held at the office of the Secretaries Messrs. Lewis Brown & Co., Fort, at noon on the 15th Feb. when the following were present personally or represented:—Mr. R Lewis M. Brown (in the chair) Messrs. Frank M. Laurie, W. Forbes Laurie, G. H. Ansten, Leybourn Davidson, Robert Davidson, Mrs. Holdich, and Mr. A. VanRaeen.

After the notice calling the meeting had been read, the Chairman moved the adoption of the report and accounts as published. This having been duly seconded and carried, the payment of a final dividend to 31st December 1896 payable on 1st proximo was formally proposed and agreed to.

The re-election of Mr. Frank Laurie as a Director and of Mr. Hercules J. Scott as Auditor concluded the meeting.

The Directors' report was as follows:—

ACREAGE.		
Tea in full bearing	..	460 acres.
" " partial "	..	61 "
Jungle, &c.	..	172 "
		<u> </u>
		Total.. 693

Your Directors beg to submit their Report and Accounts for the season running from the formation of the Company, viz:—1st October, 1895, to 31st Dec. 1896.

The quantity of tea made during that period (including bought leaf) was 220,884 lb. which realized R93,931.07, an average of 42.53 cents per lb.

An Interim Dividend of 5 per cent absorbing R13,500 was paid on 5th August, last and the sum now available for distribution after writing off R1,122.34 on account of Preliminary Expenses and R1,161.35 for depreciation of Machinery is R9,155.86, out of which the Directors recommend payment of a final dividend of 3 per cent leaving 1,055.86, to be carried forward to 1897.

The Working Expenditure during the period now accounted for was in excess of the estimated amount, and, while the Directors much regret this, they will endeavour to prevent a similar excess in future.

On his departure for Europe in October last, Mr. A. VanRaeen handed over the Estate Superintendence to Mr. M. J. Alderson, whose management of the property is giving much satisfaction.

The prospects for the current year are good, and with normal weather and prices the shareholders may confidently anticipate a very favourable return.

Mr. E. D. Harrison having left for Europe in October last, his place as a Director was filled by Mr. Leybourne Davidson. Mr. Frank M. Laurie retires from the Board by rotation, and being eligible offers himself for re-election.

CEYLON PATENTS.

The following Grants of Exclusive Privilege have been granted under the Inventions Ordinance, No. 16 of 1892, during the half-year ended December 31, 1896:—

No. 504.—To William Jackson, of Thorn Grove, Marnofield, Aberdeen, North Britain, engineer, for improvements in or connected with machinery or apparatus for drying tea leaf or the like.—July 7, 1896.

No. 505.—To William Jackson, of Thorn Grove, Marnofield, Aberdeen, North Britain, engineer, for improvements in or connected with webs, trays, flaps, or carriers, for carrying tea leaf or other substances in drying machines.—July 7, 1896.

No. 492.—To Dick Edward Radelyffe, of 56, Gloucester Crescent, Regent's Park, London, England, gentleman, and Taylor Burrows, of 88, Upper Kensington lane, London, England, engineer, for improved apparatus or method or system for preparing

chena grass or rhea fibre or hem, or similar fibres for combing or spinning.—July 7, 1896.

No. 462.—To George Murray Collom, engineer and tea planter, care of W. G. Forbes, Esq., Her Majesty's Mint, Calcutta, for invention for improved patent tea sorting and sifting machine for tea or grains, &c., to be called Collom's Patent "Acme" tea sorting machine.—July 9, 1896.

No. 503.—To Samuel Cleland Davidson, of Sirocco Engineering Works, Belfast, Ireland, merchant, for improvements in the trays or carriers of apparatus for exposing tea, coffee, cocoa, grain, and other substances to the drying or other action of air, vapour, or gases.—July 23, 1896.

No. 493.—To Samuel Cleland Davidson, of Sirocco Engineering Works, Belfast, Ireland, merchant, for improvements in tea rolling machines.—August 21, 1896.

No. 501.—To Bruno Wesselmann, engineer of Göttingen, Frieland, Weg 45 in the German Empire, for improvements in or relating to drilling or boring tools.—August 21, 1896.

No. 496.—To William Walker, the younger, of Birmingham, England, electrician, and Frank Richard Wilkins, of Handsworth, England, chemical merchant, and Jabez Lones of Smethwick, England, manufacturer, for improvements in primary voltaic batteries.—September 1, 1896.

No. 508.—To Samuel Cleland Davidson, of Sirocco Engineering Works, Belfast, Ireland, merchant, for improvements in tea leaf rolling machines.—September 17, 1896.

No. 507.—To James Thomas Hawke, of Orion estate, Gampola, and Charles Northway, of Deviturai, Elpitiya, in the Southern Province of Ceylon, planters, for improvements in machinery or apparatus for a tea cutter.—September 26, 1896.

No. 509.—To Sydney Lawrence, of 159, Queen street, Melbourne, in the County of Victoria, Australia, engineer, for improvements in mechanism for and mode of marine propulsion.—October 10, 1896.

No. 514.—To Henry Bingham, of 365, Mount Alexander road Ascot Vale, in the Colony of Victoria, Australia, dentist, and John Alston Wallace, of Ludstone Chambers, Collin street, Melbourne, in the Colony of Victoria, Australia, for improvements in bicycle and like tyres.—November 13, 1896.

No. 511.—To Samuel Cleland Davidson, of Sirocco Engineering Works, Belfast, Ireland, merchant, for improvements in tea equalizing or cutting mills.—November 30, 1896.

No. 512.—To Samuel Cleland Davidson, of Sirocco Engineering Works, Belfast, Ireland, merchant, for improvements in apparatus for filling tea or other substances into chests or the like while being packed.—Nov. 30th, 1896.

No. 515.—To Herman Frasch, of Euclid avenue, corner of Kennard street, in the City of Cleveland, in the County of Cuyahoga and the State of Ohio, one of the United States of America for improvements in mining gold and similar metals.—Dec. 15th, 1896.

No. 518.—To John Coryton Roberts, of 16, Cromwell Grove, West Kensington, in the County of London, England, planter for improvements in the manufacture of tea chests and other packing cases or boxes.—Dec. 24th, 1896.

No. 523.—The Pennington Motor Foreign Patents Syndicate, Limited, of 5 and 6, Great Winchester street, London, England, for improvements in explosion engines.—Dec. 24th 1896.—*Gazette*.

BRITISH HONDURAS.—The products of our cultural industries, still really in their infancy, are chiefly represented by bananas, plantains, coconuts, coir, coffee, henequen, Indian corn, limes, mangoes, oranges sour and sweet, pineapples, avocado pears, rubber, to which there should be added, in time, anatto, cacao, groundnut, indigo, jute, ramie, spices, manila, and doubtless other marketable commodities.—*Kew Bulletin*

VISIT OF A JAVA ESTATE PROPRIETOR:—

COFFEE,—CACAO,—TEA.

Mr. Van Sohn—the owner of extensive tea, coffee and cinchona property in Java, who has just closed a brief visit to our planting districts, —is an exceptionally bright intelligent Dutchman, speaking English admirably and entering with gusto into all modern improvements connected with a planter's life. In his Tea Factory in Java he has a turbine developing 24 horse-power, half-a-dozen rapid rollers, 3 or 4 Britannia driers, and all needful accessories, and he has just bought a Roll-breaker at the Colombo Iron Works. His factory and bungalow are lighted with electric light, and that he and his partner are fully alive to the difference between high and low prices and coarse and fine plucking may be judged from the fact that while in 1895, as much as 595,000 lb. of tea was made in his factory, for 1896 the return is only 330,000 lb. from the same acreage of 550 acres—chiefly due to finer plucking, though partly to a drier season. Mr. Van Sohn's prices have gone up to 11½d per lb. and he can turn out his tea for 3½d per lb. (but that perhaps was with the larger crop). He confirms our view that the basis of the Java Currency is a gold standard, though they use silver chiefly—exchange affecting the Java planters no more than 3 cents above and 3 cents below the 12 guilders they count to the £.—In coffee, fresh planting is confined to the Liberian variety in the older and more settled districts of Java; although in East Java, the Arabian variety is persevered with, notably by the Ceylon planters who are there interested. Mr. Van Sohn has only a few bushes of cacao: and he says the industry generally is not at all promising in Java any more than in Ceylon. Its worst enemy in Java is a boring beetle. Mr. Van Sohn's tea is chiefly in the lowcountry not more than 1,000 feet above sea-level, and helopeltis is sometimes troublesome, his only effective remedy being cleaning the stems of the bushes and letting in light and air generally.

Very important for Ceylon planters to know is the fact that Mr. Van Sohn does not expect that the Java Tea Exports will increase by more than half-a-million lb. per annum for some years to come. Quite as interesting, too, is it to know that all the tea from Mr. Van Sohn's property goes direct to Holland and that successful efforts are being made to extend the consumption of tea (in place of coffee) in the Netherlands and Belgium.

Mr. Van Sohn, who, besides visiting Nuwara Eliya, passed through Dimbula and Dikoya to Maskeliya, was much astonished to see some of the soil in which tea grows and flourishes in Ceylon as compared with the rich deep volcanic soil of Java. "Even on little more than bare rock, tea seems to grow with you" is one of his remarks; but in such cases, the roots doubtless find their way unobserved far into a subsoil.

Without benefitting by exchange, Java planters prosper because of cheaper labour and a more regular supply and also we suppose, on the whole, through richer tea crops. Our visitor left last month by the French steamer for Singapore; and some day we trust to be able to look in upon him on his fine Java property and get an idea of the island generally with its great planting riches and capabilities.

LON HILLS TEA ESTATES CO., LD.

The annual general meeting of the shareholders of this Company was held on the 15th Feb. in the office of Messrs. Bosanquet & Co. Present—Messrs. J. H. Renton in the Chair, W. W. Kenny, G. C. Walker by his Attorney Mr. J. W. Forbes, W. C. Brodie, A. V. Renton, A. W. Theuring, J. D. Balfour by proxy. The home shareholders were all represented by proxy. In laying the Directors' report and statement of the Company's accounts as for the 21st December last before the meeting, the Chairman explained how it was that the estimate of crop had not been fully realised and pointed out that better results might reasonably be expected this year. Mr. J. H. Renton proposed the adoption of the report, Mr. Walker seconded and the motion was carried unanimously.

Mr. Walker proposed and Mr. Brodie seconded that a dividend at the rate of 5 per cent. per annum be paid. Carried unanimously. Mr. Unwin proposed and Mr. Brodie seconded that Mr. W. W. Kenny, the retiring Director, be re-elected. Carried unanimously.

STINSFORD TEA COMPANY.

The first ordinary general meeting of the shareholders of this Company was held on the 15th Feb. in the office of Messrs. J. M. Robertson & Co. Mr. W. Forsythe presided and the others present were Messrs. F. W. Bois and W. Moir by his attorney Mr. V. A. Julius.

The report of the directors was submitted as follows:—

The Directors have now to render their first Report and Accounts, being those for the season ending 31st December, 1896.

The quantity of tea received from the two Estates was 185,317 lb. which is considerably under the estimate, the shortfall being upon the Ivies estate, where the result of the year has been most disappointing. In consequence of a scarcity of labour at the commencement of the season pruning was unduly delayed. The Tea Factory also was not finally completed until the 30th of June and the crop for the first half of the year was manufactured in a neighbouring factory at a cost of 10 cents per lb. Prospects for the new season are favorable on both properties.

The Directors trust that their next annual Report will indicate better returns, as labour is now plentiful and the 1897 crop is estimated at 217,500 lb. of made Tea.

25 acres of young Tea upon Stinsford will be in partial bearing the latter half of 1897, and the 26 acres planted in 1896 with Nahaketti Indigenous is now growing satisfactorily.

30 acres of new land are being opened this year upon Ivies and the work is well in hand.

The result of the season shows a profit of R21,941.46, and the Directors recommend that a dividend of 6 per cent on the capital of the Company be paid, absorbing R18,000, and that the balance of R3,941.46 be carried forward to the next account.

In accordance with the Articles of Association all the Directors retire, but being eligible offer themselves for reelection.

It will also be necessary to appoint an auditor for season 1897.

The report and accounts were passed and a dividend of 6 per cent was declared. The directors were re-elected and Mr. John Guthrie appointed auditor for 1897.

THE GLASGOW ESTATE COMPANY, LD.
TEA AND COFFEE.

The annual ordinary general meeting of shareholders of the above Company was held at the Company's Offices, No. 7, Queen Street, Fort, Colombo, on Saturday, February 13th, 1879, at 12 noon.

Present:—Mr. J. G. Wardrop, Chairman; Directors; Messrs. A. Thomson, Thos. Mackie, E. J. Young. The following shareholders were represented by their attorneys:—Mr. E. John by Mr. R. John; Mr. G. C. Walker by Mr. Jas. Forbes; Mr. G. W. Carlyon by Mr. A. Thomson; Mr. W. H. G. Duneau by Mr. A. Thomson.

Mr. Wardrop having taken the chair, the notice convening the meeting was read.

The report and accounts of the Company as published were adopted, and a final dividend of 9 per cent. was declared and made payable forthwith.

Mr. Alex Thomson was re-elected a Director and Mr. Hercules J. Scott was appointed Auditor for this year.

A vote of thanks to the Chair closed the proceedings.

REPORT.
ACREAGE.

Tea in full bearing ..	433 acres.
Do. partial bearing ..	157 „
Do. not in bearing ..	46 „
Grass ..	2 „
Jungle, &c. ..	76 „

Total Estate .. 714 acres.

The Directors have pleasure in submitting to the Shareholders the accounts of the Company for the past year.

The crops secured amounted to 232,013 lbs. of Tea and 260 bushels Coffee, as against 232,239 lbs. Tea and 562 bushels Coffee in 1895. The net average prices realized were 58.01 cents per lb. for Tea and R16.94 for Coffee respectively, as against 58½ cents and R18 respectively in the preceding year.

After making the usual provision for depreciation of Buildings and Machinery, the result of the year's working, including a small balance from 1895, shews a profit of R64,538.98, equal to about 19½ per cent on the Capital of the Company, as against 21½ per cent in the previous year. The reduced revenue is due to the smaller Coffee crop secured. This latter product having ceased to be profitable, the trees remaining on the Estate are now being cut out and larger returns from the Tea fields from which they are being removed will doubtless result.

An interim dividend of 8 per cent was declared on the 8th August last, and the Directors now recommend the payment of a final dividend at 9 per cent, making 17 per cent for the year. They further recommend that the sum of R8,000 be added to the Extension Fund, and that after payment of R200 extra fees to the Directors in terms of the resolution passed on 18th February, 1893, the balance of R1,088.98 be carried forward to the current year's account.

During the past year good progress has been made with the Turbine Installation referred to in the last Annual Report, and the Directors look for its completion during the current month. The work has been found to be much heavier than was anticipated, and as will be seen from the accounts now submitted, the sum expended under this head to 31st December last amounted to R26,696.94. It is expected that a further sum of about R6,700 will be required to complete the undertaking, the total cost of which the Directors suggest should be charged against the Extension Fund. The Capital Account outlay incurred during the past year amounted to R6,214.48 for additions to Buildings and Machinery and on the opening of a new Tea clearing of 15 acres in extent.

The estimates for the current year are 250,000 lbs. made Tea against an expenditure on Working Account of R67,597.50. It is proposed to open a further clearing of 15 acres during the year in connection with

which and with other items chargeable to Capital Account the outlay estimated under that head amounts to Rs. 3,005.

Messrs. G. W. Carlyon and C. A. Leechman having during the year resigned their seats on the Board, the remaining Directors appointed Messrs. Alex. Thomson and Herbert Tarrant to fill these vacancies respectively. In terms of the Articles of Association Mr. Alex. Thomson retires by rotation from the office of Director, but is eligible for re-election.

Mr. R. L. M. Brown having resigned the post of Auditor to the Company, the Directors under the Company's Article No. 92 appointed Mr. Hercules J. Scott to fill the vacancy thus occasioned.

The appointment of an Auditor for the current year will rest with the Meeting. By order of the Directors.

Colombo, Feb. 3rd 1897.

THE MADRAS AGRICULTURAL COLLEGE.

The following questions by an unofficial member of the Madras Legislative Council and the answers of the Government are of interest in view of a similar proceeding which took place in the Legislative Council of Ceylon:—

COST OF THE AGRICULTURAL COLLEGE.

Q.—What is the approximate amount spent till now towards the maintenance of the Agricultural College and the Farm, &c., at Saidapet?

A.—THE HON'BLE MR. GROSE:—

12. The approximate cost comes to about 8 lakhs of Rupees.

BENEFITS FROM THE AGRICULTURAL COLLEGE.

Q.—In what way has the country benefited by it?

A.—THE HON'BLE MR. GROSE:—

Among the benefits which the country has derived from the College of Agriculture may be enumerated—

- (i) The spread of agricultural education.
- (ii) The supply of trained subordinates for the Agricultural and Civil Veterinary Departments.
- (iii) The supply to the Revenue and Forest Departments of a number of subordinates who are acquainted with the theory and practice of agriculture.
- (iv) The diffusion of a knowledge of improved implements, of stock and dairy management, of deep cultivation, of manure and of other matters intimately connected with improvement in agriculture through the agency of the students.
- (v) The general awakening of interest in agricultural matters.

THE INFLUENCE OF THE AGRICULTURAL COLLEGE ON AGRICULTURE.

Q.—Has the agriculture of the country been in any way improved? If so, in what way?

A.—THE HON'BLE MR. GROSE:—

The question covers so vast a field that it is impossible for the Government to furnish the Hon'ble Member with a simple answer. So far as the Madras Presidency is concerned, information in regard to such improvements as have been effected will be found in the published administration reports of the Departments of Land Records and Agriculture, to which the Hon'ble Member will be referred.

INADEQUACY OF AGRICULTURAL IMPROVEMENT.

Q.—Does not the Government think that steps hitherto taken towards the improvement of agriculture are not enough, and the ryots are too poor and helpless to improve it themselves?

A.—THE HON. MR. GROSE:—

The Government considers that further measures should be adopted from time to time for improving agriculture, and this difficult subject consequently continues to engage its attention. The Government does not believe the ryots to be generally "poor and helpless"; but, on the contrary, is convinced that, as a class, they are well able to take care of their own interests in this respect and will readily adopt improvements in agricultural methods which are brought to their notice when the advantage to be derived therefrom is demonstrated to their satisfaction.

FACULTIES FOR AGRICULTURE.

Q.—Will the Government be pleased to adopt better measures than have hitherto been adopted for the purpose, as for instance, of obtaining lease of ten to fifteen acres in each taluk from ryots, and prove by actual improved means of cultivation the advantage of the new system as a practical lesson to the owner of the land and his neighbours.

A.—THE HON. MR. GROSE:—

The Government does not consider the scheme suggested by the Hon. Member to be practicable; but he will, no doubt, be glad to hear that orders have recently been issued directing the establishment for a similar purpose of an experimental farm at Bellary or Coimbatore. Should the working of this farm prove a success, the Government will, in all probability, establish others in different parts of the Presidency.

LANDS GIVEN UP AND BOUGHT BY CEYLON PLANTERS IN THE STRAITS.

The District Officer, Klang (Mr. W. W. Douglas), Reports:—

Block Nos. 32 and 33 on the Langat Road, recently surrendered by Mr. William Forsyth, form part of the areas mentioned above. The applicants are principally Javanese, but in block 32, which contains 64 holdings of about 4½ acres, the applicants are Malays, Chinese and Tamils. Block 37 surrendered by Mr. T. N. Christie, is being alienated to natives in a like manner, and up to the end of the month 62 applications had been made leaving room for about eight more. Blocks 32 and 33 are at present being demarcated.

At the land sale held on 7th December, 15 blocks in the Kapur Mukim, one in the Klang Mukim, and one in the Damansara Mukim, in all comprising 5,682 acres 1 rood, were offered for sale by auction at an upset price of \$1 per acre. Of the 15 blocks in the Kapur Mukim six were sold, one being purchased by Mr. E. V. Carey for Mr. A. Orchard, three by Mr. A. D. Douglas for Dr. Graham and Bodo Von Bulow, one by Mr. T. Gibson for the Klang Planting and Estates Syndicate, Limited, and one by Mr. John Iuch, of Klang. One block in the Klang Mukim, between the 6th mile on the Langat Road and the Langat River, was bought by Mr. J. D. Toynbee for Colonel W. Ellis, and at Damansara a small block, No. 18 was bought by Mr. R. S. Meikle for Mr. T. N. Christie. In the sale of these blocks the upset price was realised.—*Selangor Govt. Gazette.*

LONDON PRODUCE CLEARING HOUSE.

REFERENCE TO CEYLON COFFEE AND INDIAN TEA: GOLD AND SILVER.

The yearly general meeting of the London Produce Clearing House, Limited was held yesterday (Jan. 25) at the Cannon-street, Hotel, under the presidency of Mr. Francis John Johnstone.—The Secretary (Mr. John Culbertson) having read the notice convening the meeting,

The Chairman said:—Gentlemen, When an increased dividend is proposed and when that dividend is the highest paid since the company was formed, we have a practical proof, more telling than words, that our business is progressive. This increased dividend is chiefly due to our larger dealing in sugar, in which the range of prices, from the highest to the lowest point, during the year, has been about 35 per cent. It is severe fluctuations like this that the security afforded by our system becomes specially evident, and this fact has not failed to impress itself strongly on operators through the stern logic of events. While we have secured to our clients in sugar, as in other articles, the due and prompt fulfilment of engagements, we have not only been able to do so without any loss, but also without a single dispute or case for arbitration, so smoothly has our business worked. In short, our operations have been conducted on the admirable business rule of safely, swiftly and pleasantly. While, however, sugar has

afforded us the fluctuations on which we chiefly live, our business in silver has been checked by the steadiness of its value. This may, however, be but a prelude to better things. For if the production of silver is to be reduced by its present moderate price, while that of gold increase by leaps and bounds, we may see the present relative position of the two metals changed by the natural laws of trade, provided, of course, present silver-currency countries do not abandon its use.

COFFEE, &C. AND SILVER.

There seems to be no reason why they should, as there can be no question that the trade of countries like Mexico, for instance, is being greatly advanced by the depreciation in silver, as wages there remain stationary, while much higher silver prices are being paid to producers, whereby a great stimulus is being given to the production of coffee and other agricultural products, which are now becoming leading articles of export, and which, when once developed, will remain so, even with a recovery in the value of silver. In Indian tea and in Santos coffee the new types have led to increased transactions, which it is to be hoped will prove permanent and progressive. We hear in some quarters, not well versed in business, of the depressing influence of speculation on the prices of produce. Yet those who are acquainted with the Continental sugar trade could tell you that refiners there have had to suffer from an insufficient margin between the prices of raw and refined sugar, a difficulty which can be explained by the fact that raw sugar, being the chief medium of speculation, has commanded a price above its relative intrinsic value. The law that the more current you make a thing the higher is its value is well understood on the Stock Exchange, where with securities identical as to intrinsic merits, that which is most dealt in always commands the highest price. There was a striking instance of this some 40 years ago, which some of us are old enough to remember, when native Ceylon coffee, being the medium for speculation, was always relatively dearer than plantation Ceylon, and was called the Consols of the coffee market, commanding even on some occasions a price equal to plantation, though intrinsically its inferior by many shillings per cwt. Make crystals and granulated sugar a medium for speculation rather than raw, and the refiner's position is at once improved. To ourselves it is naturally the same whether speculation fastens on raw or refined sugar so long as there is speculation which requires our system to keep it sound and wholesome.

AN UNASSAILABLE AXIOM.

It may further be laid down as an unassailable axiom—(1) That there will always be speculation, (2) that speculation is desirable in the interests of trade, and (3) that it is to the advantage of all that speculation should be kept sound and sober by the rules on which we act. It is on this rock that we stand, and we know, therefore, that our foundations are true. In the accounts there is nothing which seems to call for special remark. The investments are all taken at the prices quoted at the close of the year; since when any change has been to their advantage. Our American securities are all of the highest class, and being all in sterling, are free from the risk of currency experiments. Their quality is proved by the fact that they all stand at a premium, and that the railways whose bonds we hold are now able to borrow at rates much below the interest our bonds carry: in the case of the Pennsylvania and the New York Central at little more than half—say, at $3\frac{1}{2}$ per cent, against 6 per cent, so there can be no question as to the payment of our bonds as they fall due. With these remarks I beg to move that the report and accounts be received and adopted. (Appaluse.)

Mr. B. D. Tabor seconded the resolution, which was carried unanimously.—*Financial Times*, Jan. 26.

CENTRAL AFRICAN NEWS.

Mr. Alexander Whyte has, during the last ten days, been collecting zoological and botanical specimens on the top of Mlosa mountain and plateau. He reports that he has procured some interesting specimens, several of which he thinks are new to science. The top of Mlosa plateau consists of rolling hills covered with fine short grass, well wooded in the gullies and with a plentiful supply of water. The plateau is not quite equal in extent to the Zomba plateau, but lies at about the same elevation (between five and six thousand feet above the sea), and the scenery is even finer than that of Zomba. Access is obtained to the Mlosa plateau by more easy gradients than the Zomba plateau or that of Mlanje. At this time of the year Mr. Whyte finds the climate very pleasant.

The first foal bred in British Central Africa, the property of the Administration, is now two years old, and in a few months time it will be broken in. It would, we think, be very advisable for those who import horses to get in as many mares as possible, and in this manner by degrees to get a true Nyasaland breed.

VARIOUS PLANTING NOTES.

ROYAL GARDENS, KEW.—Bulletin of Miscellaneous Information, Appendix I.—1897, contains list of seeds of hardy herbaceous plants and of trees and shrubs, which for the most part, have ripened at Kew during the year 1896. These seeds are not sold to the general public, but are available for exchange with Colonial, Indian, and Foreign Botanic Gardens, as well as with regular correspondents of Kew. No application, except from remote colonial possession, can be entertained after the end of March.

THE BULLETIN of the Botanical Department, Jamaica, for November 1896, edited by William Fawcett, B.Sc., F.L.S., Director of Public Gardens and Plantations, has for contents: Soil Ferments Important in Agriculture II; Micro-Organism's & Tobacco; Orchid for Naturalisation; Coccidæ or Scale Insects.—IX, Jaffa Orange; Ferns: Synoptical List.—XLII; Contributions to the Department; Castleton Gardens. Mr. R. Thomson's paper on the new orchid is interesting: have we *Odontoglossum crispum* in Ceylon?

COFFEE.—Mr. A. G. Beeston, brother of Mrs. Mackenzie-Stewart, has, I hear, accepted the post of Secretary of the Serapiqui Coffee Co., Ltd., which has recently been formed for working the property in Costa Rica visited last summer by Mr. J. L. Shand. The capital for this venture has, I understand, been now subscribed, and Mr. Rothe, the vendor of the land, returns at once to Costa Rica to begin operations in earnest. The proceedings of this Company, and also of the Dnment Coffee Co., Ltd., in Brazil, will be watched with much interest by all old Ceylon Coffee Planters.—*London Cor.*, local "Independent."

THE "INDIAN FORESTER," a Monthly Magazine of Forestry, Agriculture Shikar and Travel, edited by J. W. Oliver, Conservator of Forests, and Offg. Director of the Forest School, Dehra Dun, for January 1879, has the following contents:—Original Articles and Translations: The American Resin Industry (Translation); Correspondence: What Constitutes a Thinning? letter from F. Gleadow; The Dimensions of Trees; letter from "A Forester"; The Official Designation of Forest Subordinates: letter from "Miles"; Review: The Forest Administration Report of the Jammu and Kashmir State for 1895-96; Extracts, Notes and Queries: The Grievances of the Forest Department; The Formation of Sand Dunes; Wealth based upon Elastic Gum; Wood Paving in Rangoon; Wood used by Cabinet Makers; Rudyard Kipling on the Indian Foresters; A Spider that eats Birds; Timber and Produce Trade: Churchill and Sim's Circular, December 1897; Market Rates of Produce; Average Selling Rates of Timber in the N.-W. P. in November 1896; Extracts Official Gazettes.

THE MANURING OF TEA ESTATES.

(Continued from page 570.)

The following is another instalment of the letters we have received in reply to our circular to representative planters asking information on the following points:—

1. Has the manuring of tea estates become general in all, or only in old, districts? or, if your experience is local, in your own district?
2. Is bulky manure chiefly used?
3. Is the manure sent up by railway used alone or mixed, and is there much of bone-dust and nitrates as well as of eastoreake and fish manure now used?
4. Do you think harm is being done to any extent by the use of artificial manures in the case of tea?
5. How does the oldest manured tea compare with unmanured tea of the same age?

No. XXXVI.

High District, Jan. 7.

1. Manuring is general in all districts, probably fifteen to twenty per cent of estates use artificial manure.
2. Artificial manure is usually used, with the exception of a few estates with special facilities. Only small acreages can be manured with bulky manure.
3. Nearly all the manure is mixed;—one-third of Bones to two-thirds of Castor, is the usual proportion.
4. So far no harm appears to have been done to the tea, but a great deal of soil must be washed away by manuring steep slopes.
5. Manured tea gives 150 to 200 lb per acre more than unmanured.—M.

No. XXXVII.

Jan. 8.

DEAR SIR,—In reply to your questions *re* manure:—

1. I cannot say whether manuring has become general in all districts or even in this district, but it is being done here.
2. Where bulky manure can be had it is applied and preferred for its lasting qualities, but more is being done with artificial, mostly white Castor and Bone Meal.
3. Manure is generally mixed in the Colombo mills before being sent off, (unfortunately we have not yet a railway to bring it); it mostly consists of Castor and Bones in the ratio of three to one.
4. Far from thinking harm is being done, I am confident much good is being done by manuring tea. I began at first with fear and trembling; but now I am a staunch advocate of manure, as it increases the yield, and gives a more healthy appearance to the bush, but I think the quality suffers somewhat. The only really serious charge lying at the door of artificial manure, is the contamination of the water supply, hence the greater prevalence of typhoid fever "*et hoc genus omne.*"
5. Compares favourably in every way, only manure when once begun must be continued at least every three years, or the bushes will go back, as the artificial stimulant must be kept up.

KELANI VALLEY.

No. XXXVIII.

OLD, AND MEDIUM ELEVATION, DISTRICT.

1. Manuring in this district is very general and appears to be carried on to a large extent on estates at a medium elevation and where transport is easy. It is by no means general in all the planting districts, at very high elevations scarcely any artificial manure is applied; and on estates to which transport is far and difficult, but little is carried out.
2. Bulk manure is applied whenever procurable, but on many estates there is little or no bulk manure worth speaking of.
3. When systematic manuring is carried on a mixture of Castor-cake and Bone-meal appears to be most generally applied, though fish manure and nitrates are also used, but not to so large an extent. In some instances fish manure is mixed with Castor-cake and Bone-meal.
4. I do not think that harm is being done to tea by the application of artificial manures; on the contrary I think the bushes are strengthened thereby, though I think when artificial manuring is started it must be continued or the bushes would cease to yield profitable flushes.
5. Old manured fields compare very favorably with unmanured fields of the same age, the bushes being larger and much more healthy in appearance, and the fields present a much finer cover. I might mention however two drawbacks to manuring, viz., the additional cost of weeding, and the loss of soil by wash, caused by the constant cutting of holes; this of course refers chiefly to wet districts and to steep land.

ÆQUUS IN ARDUIS.

No. XXXIX.

Matale, Jan. 9.

DEAR SIR,—In reply to your favor, I only manured 22 acres with bulk, last year, and this year I have manured with Castor-cake and Bones 45 acres. I therefore really have not the necessary experience to give an opinion. There is very little manuring of tea in West Matale. I cannot speak of other districts, and I have not heard of any one in Matale West using artificial manures except myself. The little manure used in Matale is nearly all bulk, I believe. I cannot say, that the artificial manure, I have used this year, has reduced the price of my tea, and it has certainly increased my yield. The 45 acre field manured with Castor-cake and Bones has given 1,050lb. per acre, and the 22 acres manured with bulk last year has given 950lb. per acre.

The Bones and Castor-cake I got were mixed in Colombo. The bulk manure used was bought from natives, and was not anything like equal to manure made on the estate.

MANAGER.

No. XL.

Wattegama, Jan. 9.

1. Not general yet, though some estates have adopted it with marked benefit.
2. No—too costly except near towns and villages and where lay of land permits of easy cart transport.
3. Mixtures vary; but Castor-cake, Bones and Sulphate of Ammonia and Nitrate of Potash are favorites, and fish is largely used, and kekma near villages.
4. Less chance of harm would exist here; artificial manures always mixed with bulk. It

is most important to mix well with plenty of soil.

5. No comparison in old coffee land, yield doubled and more.

T. KOKO.

P.S.—Beware of the practice of burying prunings. No tree feeds on its own refuse, or the result would be as in animal life? (by analogy, and probably experience will prove the truth later on if men are not careful.) *Absit omen!* Vegetable typhoid in tea would be a fell follower of *Hemileia vastatrix* in coffee.

No. XLI.

DEAR SIR,—Replying to your inquiries *re* manuring tea, I am sorry I cannot tell you much about it as very little has been done in that line as yet in the district; but there can I think be very little doubt about the beneficial effects from the manure already applied. In my opinion manuring is in many cases delayed too long on lowcountry estates and artificial manures do not seem to have much or any effect on *its worn-out soils*. A stitch in time would save nine.—Yours truly,
L. A. W.

No. XLII.

Kandy, Jan. 14.

DEAR SIR,—The manuring of estates in this District is being tackled as the state of labour will permit. As far as one can judge moving about the country, older districts are getting more attention than new. Labour is more plentiful in the older districts than new.

II. Bulk manure unfortunately is a too scarce and expensive luxury.

III. Castor, Fish, Bones, with a small pinch of Nitrates added, are the manures most in vogue. Not so much Nitrates added last year owing to unfavourable exchange.

IV. In older districts, on our side Tea will derive benefit from manure of any kind. Bulk and artificial or either applied singly.

V. Where manuring has been carried out systematically over a term of years on the Kandy side, manured tea takes the upper seat. Manured tea will easily show returns of 550—600 as against 300—350 on unmanured fields.

In a forcing climate, it would be risky to say if Tea of a very high jät will give the results that an ordinary hybrid jät will, after an application of artificial manure.—Yours faithfully,

A NORTHERN PLANTER.

No. XLIII.

Udapussellawa, Jan. 11.

DEAR SIR,—I have done no manuring yet with *Artificial* manure to our tea; but my neighbours have and are doing a good deal and I am much interested in watching the results. A controversy will be most interesting if we can get the opinions of men who have watched the results of, say, 4 years. From what I hear the quantity is largely increased *without* sacrificing quality; but after the deadly effect that artificial manures had on our coffee, particularly salts of sorts, I should like to know more about its effects on tea before applying it to a large acreage.

Tea made off say 9-year old bushes never manured should be compared with tea made off bushes of the same age that have been manured say twice during the last four years. The yield will be recorded in the books. QUERIST.

No. XLIV.

Jan. 11.

SIR,—In reply to your circular *re* manuring of tea,—

I have very little experience, as I very seldom have time to travel about; but from what I know and hear, I should say that very few estates in what may be called the new districts or very few estates anywhere would use manure of any kind so long as the trees were of vigorous growth and tea yield satisfactory. If any manure were used, nothing but cattle would be applied in such case. On the contrary on old worn-out land in the old districts manure both cattle and artificial has no doubt been of great benefit in increasing the yield and in building up the framework of the trees. When the land is not worn out and tea is yielding well, I think manure of any kind is a mistake. In old districts and on worn-out estates the result of manures both cattle and artificial has been most marked both in growth of the trees and increased return of leaf, but I think the leaf is produced so much more rapidly that the tea is inferior to that obtained from unmanured fields. Good fields on good soil on the place that I am in charge of I have not manured, nor would I think of manuring, unless there was a most pronounced falling-off in the yield.

Those people who have good yielding estates and apply artificial manures will, I believe, kill "the goose that lays the golden eggs." I cannot see however that it is possible for any harm to be done by the use of cattle manure.

Those people who have estates planted on worn-out land can no doubt by artificial manure very largely increase the yield: in fact in many cases double it, but whether artificial manure can be applied beneficially for a long series of years is a problem that has yet to be solved.

I am sorry I have not answered under the different headings: but it is most difficult to do so and write anything but pure generalities.—Yours faithfully
W. J. G.

No. XLV.

Matale, Jan. 20.

Re manuring tea, about 30 to 50 acres have been manured with cattle manure on this estate every year for the last six years with very good results. No patent manure has been tried as yet.
Z.

No. XLVI.

Jan. 14.

DEAR SIR,—I am afraid I am rather late in replying to your queries *re* manuring of tea.

(1). I do not think the manuring of tea has yet become general in any District, though it is likely to become more of a necessity in the near future especially in the older Districts.

(2). Only a comparatively small number of Estates have facilities for obtaining and applying bulky manure in any quantity. It is decidedly preferable to artificial manure, and gives very satisfactory results where it can be regularly and cheaply procured, an application of about 24 tons* per acre being sufficient for three years at least.

(3). I am not in a position to give an opinion.

(4). I have not heard of harm being done in any case by the use of artificial manure. Of course, such manuring would have to be kept up,

* Sic in copy; but our correspondent means surely "cwt."?—ED. T. A.

and there are cases of Tea Estates where very fine crops have been regularly got by the systematic use of artificial manure.

(5). I have not had any opportunity of making a comparison; I have only seen the wonderful improvement in tea and its yield on old and poor soil after the application of bulky manure.—Yours faithfully,
I.

No. XLVII.

Badulla, Jan. 1.

DEAR SIR,—I have little or no knowledge of what is being done in the way of manuring tea outside this district. So far, a very limited area has been treated in this neighbourhood and that has been chiefly with bulky manure.—The results of a fairly liberal application of well-rotted bulk—cattleshed and street refuse chiefly—have been most satisfactory as regards increased yield, but whether quality has in any way suffered I cannot say.

Repeated doses of artificial manures, such as Nitrates or Bone Dust might show good results for a time, but I fear a sudden cessation of these doses would leave the bush in a worse condition than they found it. There can be little doubt, however, that a liberal application of suitable bulk brings the bush into a healthy and vigorous condition, largely increasing the yield and presumably—until the contrary is proved—not interfering with the quality. The cost of such manuring is, however, high and for this reason it is not likely to become very general.—Yours faithfully,

“OUVAH.”

No. XLVIII.

DEAR SIR,—I send you the following replies to the queries in your circular of 26th ult. :—
No. 1 My experience is very local—(Kotagala Valley). A little manuring is being done on some estates.

(2) Bulky manure is no doubt always used, where procurable, but the supply must be very limited.

(3) Bone-dust, Castor-Cake and Nitrates, &c., are mostly applied alone—well-mixed with the soil.

(4) None—that I know of—altho' it may be prudent to guard against loss of “flavour” by the indiscriminate use of artificial manures,—or by too large doses at one time.

It is a fact that many plants lose their natural scents or oils—by manuring or cultivation. Take the wild carrot or celery, for instance. These are nauseous, naturally—but become edible when cultivated.

In my experience—the tea made after manuring with our ordinary manure—has lost some of its “pungeney”—while it has gained in “body” and “maltiness.” The yield is increased at least one-third.

For tea, our soils, as a rule, are too deficient in potash, and this is difficult to remedy by manuring, the salts being so very soluble, that much loss may be sustained—by their getting too deep in the soil—ere the plant can assimilate them.

(5) The oldest manured tea is *twice* as good in appearance—as the unmanured of the same age.

Without manuring (where required) tea will hardly pay—in future.

Analysis of the soil and of the manure to suit it, is indispensable. Or one may “be carrying coals to Newcastle.”—Yours faithfully,

“SENEX.”

No. XLIX.

Southern Province, Jan. 14.

DEAR SIR,—In reply to your favor of 8th idem, my experience of manure is as follows :—

1st As I have not worked tea estates in the old Districts, I can only write of the new.

2nd. No artificial.

3rd. I use 2 oz. Castor and 1 oz. Bone-dust to each bush well mixed with the soil.

4th On the contrary; but it must be kept up.

5th Unmanured tea compares unfavourably both in wood and leaf with manured.

Referring you to statement below.

100 acres gave in 1894, 190 lb.

Manured in			
March 1895	„	1895, 272 „	gain 82 lb.
Not manured in			
March 1896	„	1896, 420 „	230 „
			312 „
		Increase over 1894	312 „

I am, yours faithfully,
B.

No. L.

Udapussellawa, Jan. 8.

DEAR SIR,—The following are my replies to your questions about manuring tea :—

1. A few estates in this district have applied manure, but as yet it has not become general.

2. Bulky manure is being used where it is obtainable at a reasonable cost; but on most estates the conditions are unfavourable for the keep of live stock. There is, however, little doubt that cattle manure is the best, as it gives good returns and does not force the bushes to such an extent as artificial manures do. The effects last a fairly long time, and regular flushes are secured; but the difficulty, in most cases, is to produce and apply it at a paying figure.

3. The manures principally used are Castor-cake, Fish, Crushed Bones, and Bonemeal. Sulphates and Nitrates are to be given a trial on a few properties, but they are to be mixed with Castor-cake and Bones, and in some instances the prunings will be buried at the same time. In my opinion when these manures are applied every effort should be made to bury all prunings and dead leaves obtainable, as I think they materially help to carry on the bush after the artificial manures are exhausted, especially in thin, gravelly soils, and in a comparatively dry climate.

4. On this side of the country I do not think any harm has been done by manuring yet, but this may happen in time if large doses of artificial manures have to be resorted to. The question which presents itself to me at present is,—Will the bushes continue to give satisfactory yields without increasing the quantity at each application? If they will, my opinion is that little or no harm will be done (but the reverse); if they will not, then larger and larger applications will become the order of the day until the cost becomes prohibitive. This may be a danger looming ahead of us, as if manuring is suddenly stopped the bushes which have become accustomed to it will doubtless suffer considerably.

5. As far as we have got in this district (the lower and older end of it) there can be little doubt that in most cases the manure, whether bulky or artificial, has worked wonders upon the frames of the bushes, and also has given a fair profit, but as it is only within the last few years

that manuring has been started here, it will take sometime yet to form a correct opinion of what it may or may not do in the future.—Yours truly,

G. T. R.

No. LI.

Kelani Valley, Jan. 20.

DEAR SIR,—Replying to your circular letter of the 26th ultimo:—

1. Manuring is decidedly on the increase in both old and new districts.

2. Very little bulky manure is used as coolies cannot be spared to look after cattle or to carry out the manure to the field.

3. The principal manures used by estates are Castoreake, Bonedust and Fish manure.

4. In my opinion both the bushes and crops are distinctly improved by the use of artificial manure.

5. Favourably in every way. I believe that manuring would be done on a much larger scale than it is at present, but for the insufficient supply of labour.—Yours faithfully,

J. B. C.

No. LII.

St. Leonards, Nuwara Eliya, Jan 22.

DEAR SIR,—In reply to your circular *re* manure:—

1. Local experience is that very little manuring is done.

2. On this estate *only* cattle manure has been applied; no artificial.

3. On neighbouring estates some Cake, Bones and Nitrates are being applied.

4. Undue use of *any* stimulants in any form *must* in time prove noxious.

5. Where soil is good the effects of manure are not noticeable; old worn-out spots are much improved by cattle manure, also by a judicious mixture of Cake and Bones. In this district—the upper end all land is comparatively *new* and does not require manure.

You will be doing a public benefit by inveighing all you can against *undue* applications of artificial manures. Planters have money now and are not averse to liberal (?) cultivation. In a short time we cannot expect the same profits. Starvation cultivation will then be resorted to, and tea will be much in the same position as coffee was.—I am, Dear Sir, Yours faithfully,

C. H. B.

No. LIII.

Talawakele, Jan. 24.

Every acre now in cultivation could by manuring be made to yield from 200 lb. to 300 lb. (on all fine soils even more) per acre additional and the area under the bush could be doubled. Conceive then what Ceylon output might be! Double the labour force now in Ceylon and in 15 years you would ship 2½ times what we are doing.

The question of manuring is one there need be no hesitation in facing, having regard to the fact that life is short.

Unquestionably if you cut holes or dig about a bush for the purpose of manuring you must cut a certain period off its natural life as you cannot help breaking or cutting the large roots; in fact any artificial method of forcing leaf or fruit must in the nature of it interfere with the natural period of its life whatever that may be.

My view of it is: if you cultivate your bush you will take out of it, in possibly 30 or 40

years, what it will give if not forced in 55 or 60. Few people would object to that, if there is anything in a bush in the hand being worth two in the bush.

Of course, care must be exercised in selection of fertilizers and the sooner an Ordinance is passed the better, to protect planters from spurious manures.

I see infinite harm being done in manuring where care is not taken in cutting roots, as they never grow again—I mean the large roots.

Then as to the question of manuring doing injury to the quality of the Tea you may just as well say that rich soil produces an inferior Tea to poor soil!!

S.

Talawakele, Jan. 1.

Manuring of tea is yet in its infancy and we are all more or less groping in the dark—so far we know that certain fertilizers produce certain results in the way of increased flush and that is about all.

What is wanted is a full knowledge of such manures as are available, and what their effects are in not alone increasing flush, but in *improving* or *otherwise* the quality of teas.

To find out this, systematic and carefully conducted experiments on a large scale are necessary and it is to be hoped that some of our wealthy proprietary planters will take the matter up.

T. F.

No. LV.

Ramboda, Jan. 20.

DEAR SIR,—In reply to your enquiry on the subject of manuring tea. There seems to be an inclination to put out bulky manure, if procurable in preference to artificial.

However the expense of a cattle establishment and the occupation of so much good land for cultivation in grass is a preventive to any extensive or general application of bulky manure.

I believe most of the V. A.'s are advocating the use of artificial manures in old tea.—Yours faithfully,

II.

No. LVI.

Jan. 25.

In older districts, where tea has supplanted coffee, Castoreake and Bonedust have been applied with advantage, and the returns increased. Cattle bulk and compost also, but the latter manures have in many instances proved much too expensive on the extra returns. Unless facilities are exceptionally good, artificial manures are more satisfactory.

Personally, I think the less tonics applied where tea is giving a fair yield, the better for the bushes, although in worn-out soil something must be done to encourage flushes. I question very much if a really serious interest has been taken in having the soils analyzed to enable those who manure to return what is wanting.

A perusal of Mr. Kelway-Bamber's Text Book on the Chemistry and Agriculture of Tea would be of valuable assistance to those manuring. Copies can be obtained from the *Observer Office*.—I am, Yours,

R. W.

No. LVII.

East Hapmtale, Jan. 29.

My experience of Manuring Tea is so very slight that it is not worth while publishing. I only manured one field with Bones and Castor-

cake—one of the former to three of the latter—in Sept. 1894. Results have been most satisfactory; the field was pruned in July last, the results since pruning have been more apparent than before. It is flushing now like fun, and giving 20 to 30 lb. leaf per cooly every eight days. Unmanured fields no way near it.

Manuring with bulk, I have only done a few acres with lime refuse, &c., near cooly lines. Results are highly satisfactory, but unless your land is fairly level and soil sufficiently free to admit of forking in the manure, the expense of applying bulky manure would be prohibitory. Imagine cost of cutting and filling in 3,600 holes to an acre and if you give $\frac{1}{2}$ a basket to a tree with any distance to carry. On fairly flat land free soil that could be forked, application might be brought within reasonable limits. How much of this land is there in Uva? PLANTER.

No. LVIII.

Kotagala, Feb. 3.

DEAR SIR,—So far as I have observed, manuring is pretty general on tea estates but not very extensive. I mean that most estates manure a little, both in old and new districts.

2. Bulky manure is not available in large quantities with a few exceptions,—and application is necessarily expensive unless for fields near a cart road.

3. The manure sent up by railway is generally used alone, sometimes mixed with prunings and with bulk when available such as Lime and Factory sweepings, Bazaar refuse, etc. Bone-meal and Castoreake appear to be most generally used, with occasionally Nitrate of Potash in small quantities, and there is also an appreciable quantity of Fish manure used. I have no experience of the latter, but would fear its use would encourage blossom and seed on the bushes.

4. I do not think any harm is being done to the bushes from the use of artificial manure—rather the opposite. On poor land an application of manure even to comparatively young tea is beneficial as it improves the wood and expands the bushes. On very rich soil artificial manure appears to give the tea a rankness which I do not think improves the quality. In fact on rich land I think it is a mistake to manure, as it makes the flushes too fibrous and coarse.

5. Unless overdone manured tea compares favourably with unmanured especially on poor old land.

To enable planters to give necessary manurial assistance to land requiring such, Government ought to give all possible assistance in providing cart roads to stations as otherwise transport is prohibitive.—Yours faithfully, W. H. W.

No. LIX.

Ambagamwa, Feb. 12.

DEAR SIR,—Now that you are about to close your columns to the “Manuring” discussion, if you think it worth publishing my experience in that line I now submit it. Since 1890 I have manured this estate both with artificial and bulk; the former comprised of either fish, kapok, and blood manure mixed 6 ounces to the tree, or castoreake and bones mixed—same quantity applied. This was resorted to only on inaccessible fields, I always found that in 3 months the manure had begun to act and its effects were appreciably noticed up to say from 15 to 16 months after application, the bushes responded in a marked manner, the yield was $\frac{1}{3}$ more than it was before application, but after the run of

16 months I always noticed a falling-off; and at about the end of two years you were no better than when you started, if anything worse; the bushes presented an all-gone seedy appearance suggesting as it were “I want a stimulant to fig me up,” a second application of a like quantity (6) ounces did not by any chance result in the same way as at first although it did some good. I am therefore of opinion that if artificial manure is to be applied it will become necessary to increase the dose at every subsequent manuring; just likens one to an opium-eater; first a minute quantity hardly perceptible, till in after years $\frac{1}{2}$ an ounce would be about the sufficing quantity to allay his craving. Will artificial manure pay in the end?!

Bulk.—Situated as I am and being possessed of grazingland I keep a stock of native cattle which yearly gives me enough manure for from 40 to 50 acres; a basket of cattle manure to 4 trees; this application takes longer to tell; but once it does, the bushes present such a luxuriant growth with a strong healthy dark green appearance which makes the heart of man glad to look at; its effects will last out a good 2 $\frac{1}{2}$ to 3 years, and a second application will only require to be made after that time, the quantity being far less than on the first application. Say a basket to 6 trees, your bushes never present that unhealthy woe-begone look which is noticeable after the effects of artificial manure have ceased to tell, so that there can be no two doubts that the stability of tea will in a great manner depend on the kind of manure you apply; the yielding powers from bulk manure may not be quite so much as from forcing artificial, but the fact remains that there it is in paying quantity and will remain so long as you last. C. T.

No. LX.

Feb. 15.

DEAR SIR,—I have not been asked for my *obiter dicta* regarding manuring and yet intended writing you before now, since it seems to me I have more data on the subject than anybody else this end of tea-land. The season 1895-1896 saw the completion of a systematic cycle of cultivation and the estimate realized nearly 100 per cent increase on the 1894-1895 crop. Experimental handling of artificial manures has given Castoreake and Crushed Bones the laurels, and a schedule should show manuring to be no outlay of capital for the crop doubled—your tea is cheaper f.o.b. Colombo. Here are a few blocks as examples:—

1 Fields, all old					
coffee land	21	35	41	27	43
of say 35	} Acres	} Acres	} Acres	} Acres	} Acres
years					
2 1894-1895 yield					
per acre	204 lb.	304 lb.	143 lb.	186 lb.	305 lb.
3 Manured	Dc.'95	Mr.'95	Jn.'96	Nv.'96	Dc.'95
4 1895-1896 yield					
per acre	425 lb.	726 lb.	310 lb.	317 lb.	637 lb.

There are so many factors to be remembered in cultivation that space forbids enumeration. Pruning and character of tea to be treated, rainfall dates and nature of soil, being the chief. Then has to be considered method of application, for loss of soil cannot be permitted and is easily obviated on steepes. The mamoty is a sorry cultivator compared to the fork; but don't spread manure broadcast, get it into the ground with an alavangu followed by forking, treading down the new earth exposed. You would not ask me “why,” for the primary question is what is the crop—fruit or leaf! Manuring is demanded by

the crop every third year. Experience bids me say that Sulphate of Ammonia is playing with fire unless one knows what he is handling and Bamber's "Chemistry and Agriculture of Tea" gives an emphatic warning should one be elated by such monstrosities as twin stalks and triple "bangee" laves after applying Sulphate of Ammonia, however mixed with wood ash, bones or fish or etcetera.—Yours truly,

HOMO PLANTAT, HOMO IRRIGAT, SED
DEUS DAT INCREMENTUM.

No. LXI.

DIMBULA.—I thoroughly believe in manuring, but we should have more coolies or manuring is of no use; on old fields the first application of manure does not result in much more leaf, but the trees fill out and strengthen the wood on them, and the following year you get the benefit. I have manured for over 6 years a portion of the estate each year with Castorcake and Bones, only one part of the latter to 5 of the former—cattle manure does not tell for many months after the application, but it lasts double the time of artificial and does not leave any bad effects afterwards as artificial sometimes does.—J.J.

[This closes the series of letters kindly sent to us on the Manuring of Tea: the whole are being reproduced in our *Tropical Agriculturist* with our several reviews; and afterwards some copies will be printed in pamphlet form for ready reference: one copy of which will be sent with our compliments and thanks to each contributor to the series.—ED. T.A.]

THE AGRAOUVAH ESTATES COMPANY, LTD.

The annual ordinary general meeting of shareholders of the above Company was held at the Company's Offices, No. 7, Queen Street, Fort, Colombo, at 3.30 p.m. on Feb. 11th.

Present:—Mr. A. Thomson, Chairman; Mr. C. A. Leechman, Director; Messrs. A. Stevenson, H. Tarrant, Jas. Forbes, Geo. Noel, and C. J. Donald. The following shareholders were represented by the holders of their Powers of Attorney:—Mr. Wm. Watson, by Mr. J. G. Wardrop; Mr. E. John, by Mr. R. John; Mr. G. C. Walker, by Mr. Jas. Forbes; Mr. G. H. Alston, by Mr. A. Thomson; Mr. W. H. Figg, by Mr. Thomson.

The report and accounts of the Company as published were adopted, and a final dividend of 14 per cent (making 22 per cent for the year), was declared and made payable forthwith.

Mr. C. A. Leechman was re-elected a Director, and Mr. Hercules J. Scott, was appointed Auditor for this year.

A vote of thanks to the chair closed the proceedings.

The following is the report:—

Acreage, 31st December 1896.		
Agra Onvah.		
Tea in full bearing	..	302 acres
Tea not in bearing	..	20 "
Grass in Jungle	..	9 "
Total Estate	..	331 acres
Fankerton.		
Tea in full bearing	..	165 acres
Timber clearing	..	10 "
Grass, Patana and Scrub	..	18 "
Total Estate	..	193 acres
Grand Total	..	524 acres

The directors have pleasure in presenting to the shareholders the accounts of the Company for the past year.

The crops secured were 257,004 lb. tea, as against 191,685 lb. in 1895, and 487 bushels coffee, as against 1,291 bushels in 1895.

The average net prices obtained were 61.29 cents per lb. for the tea crop and R16.64 per bushel for the coffee crop, against about 66½ cents per lb. and R17.85 per bushel respectively in 1895. The receipts for manufacturing tea for other estates shew an increase of R6,856.43 as compared with the figures for the preceding year.

The expenditure on capital account during the year amounted to R17,798.50, this outlay being for additions to buildings and machinery and on a new clearing of 20 acres tea on Agra Onvah.

After making the usual ample provision for depreciation of Buildings and Machinery, and including the balance of R6,439.10 brought forward from 1895, the amount at credit of Profit and Loss account is R94,301.82, being rather over 25 per cent on the paid up Capital of the Company. An interim dividend of 8 per cent was declared on the 8th August last, absorbing R30,000, thus leaving a balance of R64,381.82 now to be dealt with.

The Directors recommend the payment of a final dividend of 14 per cent, making 22 per cent for the year, and that the balance of R11,881.82 be carried forward to the current year's account.

The crops estimated for in 1897 are 265,000 lb. Tea and 100 bushels Coffee, on an expenditure on the Estate of R79,557.50, which outlay is inclusive of the cost of manufacture of 135,000 lb. Tea expected from other Estates for that purpose, and the upkeep of the 20 acres clearing planted last year. No expenditure on Capital account is expected to be necessary this year.

At Extraordinary General Meetings held on 24th October and 14th November, 1896, special resolutions were passed increasing the Authorized Capital of the Company to R750,000, thus placing the Directors in a position to add to the properties of the Company on any favorable opportunity for so doing presenting itself.

Messrs. G. W. Carlyon and W. H. Figg having resigned their seats on the Board on their departure respectively from the Island, Messrs. A. Thomson and G. H. Alston were appointed by the remaining Directors to fill the vacancies thus created. In terms of the Articles of Association Mr. C. A. Leechman retires by rotation from the office of Director, but is eligible for re-election. On 8th January of this year Mr. Alexander Stevenson resigned his appointment as Director, but in the opinion of the Board it is unnecessary to fill up this vacancy.

Mr. R. L. M. Brown having resigned the post of Auditor to the Company, the Directors, under the Company's Article No. 92, appointed Mr. Hercules J. Scott to fill the vacancy, thus occasioned. The appointment of an Auditor for the current year rests with the meeting.

CHINA'S AWAKENING.

A CEYLON TEA PROPRIETOR ON CHINA TEA.

Mr. T. Fairhurst, who is well known in Ceylon as the owner of Ferham and St. Andrew's estates, Dimbula, but who spends his time mostly at Foochow, is at present on a visit to the island. Speaking to the representative of a contemporary he said:—"Well, I suppose the point of most interest is the introduction of machinery for tea manufacture into China, but I am afraid that, so far, I can tell you but very little. You see, things are very different in China from what they are, here. Here you get tea all the year round; but in China they only get it in crops—three crops in a year—and of those the finest and best crop is the first one, which is gathered in April. That is always equal to about half or a little more than half—of the total crop from the Foochow district in a year, and, as far as the use of machinery will affect the teas, we had little opportunity of judging in 1896, for, when the machinery that is now there was erected, the first

crop had been gathered, and the machinery could therefore only be used for the later crops, which are much inferior and do not afford a proper test."

"The machinery then was used for the second and third crops?"

"Yes, and it had a noticeable effect on the tea, as far as appearance and the strength of the liquor went but it made no alteration whatever in regard to the flavour of the tea—not the slightest improvement being noticeable. Asked what increase in the cost of manufacture was brought about by the use of machinery in regard to the teas on which it had so far been tried, Mr. Fairhurst said; "Well they reckon it means an additional outlay of about 1½d, and whether that will be made up by a longer price being got for the tea in England and in the other markets, I cannot yet tell you, for the total quantity of machine-manufactured tea sent home last year was not more than 1,500 or 1,600 packages, and that, of course, was largely bought as a curiosity, being competed for in an exceptional manner on account of its novelty, and so affording no guide. Everything is to be learned this year, and all depends on the first crop. If it answers in regard to that, then machinery will be adopted on a larger scale, and it may be that then China will once again be a rival with Ceylon and India in regard to the better classes of tea. As far as the Foochow district is concerned we shall learn the first results of machinery manufacture in May, and we shall know the financial result of the experiment in July when we learn what the teas fetch. But the experiment will not be a very large one, there will be only ready for use some five rollers and about three dryers; but in addition there are men who intend going on rolling the leaf by the old manual process, but who have consented to try indoor withering instead of sun withering and to use Ceylon methods of fermenting. They seem to have realised that indoor withering is preferable to the other system, and they are now putting up the necessary buildings for doing this work; but, taking all these improvements in manufacture, they will not affect more than a tenth of our output in Foochow—say about 40,000 half-chests." Foochow, according to Mr. Fairhurst, is the pioneer district in China as far as this movement is concerned. He passed through Amoy on his way here, and he assured us that we had been wrongly informed in respect to that district when we were told that machinery had been already introduced there. So far nothing has been done there beyond talk, and they are evidently going to wait and see the outcome of the Foochow experiment. In the latter district the movement has been entirely the result of the introduction of European capital, with the result that the Europeans who have found the money have persuaded the Chinese, who have to take up the lands (no European being allowed to take lands) to adopt the new methods. The principal movers in this respect have been the Foochow Tea Improvement Company, which, he says, consists of about 6 Europeans and 6 Chinese, each of whom have put one thousand dollars into the concern.

The new methods are only to be applied to the higher grades of tea. In one respect, according to Mr. Fairhurst, the position of Foochow is unassailable, that is, in regard to its power of producing cheap common teas. These it can turn out at a price of 4½d to 5d, and in this respect it leads other tea-producing countries easily.

Asked if the water supply was good, Mr. Fairhurst said: "Far from it; there are a lot of streams all about the district, but the force of any of them is scarcely more than sufficient to drive a 16 feet wheel, which amount of power is just about what one Excelsior roller only requires. Steam will have to be largely restored to, therefore, and in producing this the Chinese have at present no coal of their own to help them;—the cheapest available coal is that which they can get from Japan. Another difficulty arises from the short space of time they have in which to gather and manufacture the first and most important crop. It will all have to be dealt with in the short space of six weeks, think of the vast amount of machinery they will have to get to do that."

NO CHANGE OF JAT LIKELY TO SUCCEED.

Asked if he thought it likely the Chinamen would go in for new *jats* of tea in connection with this progressive movement, Mr. Fairhurst said he did not think any innovation of this sort would be likely to prosper. "The Tea Improvement Company," he said, "are getting down some Indian teas; but I do not think from my experience of Formosa teas they will succeed. Formosa teas, you know, were originally Chinas. They were taken from China, and planted in Formosa where they did amazingly well in the volcanic soil that Formosa possesses. Some time ago I tried the experiment of bringing some of the Formosa teas here, and planting them on my places in Dimbu'a, but there they went back to the old China state, showing it was the Formosa soil alone that improved them. The same thing will happen, I think, with these Indian importations; they will very quickly become like the Chinese indigenous teas, and the idea of using them will be abandoned."

CEYLON V. JAVA AS TEA PRODUCERS.

(By an ex-Merchant-Planter.)

London, Jan. 22.

I thought my letter of the 15th inst. would be the last I should have to trouble you with, on the subject referred to in my three previous ones; but as you transmuted the word "Java" into "Japan," when publishing my letter of the 10th ult., it is necessary to draw your attention to the mistake.

I wrote the word *Java*, and not *Japan* purposely, because the latter is not, and I think never will be, a competitor with Ceylon in the supply of tea to the European markets*; whereas *Java* will most probably in time become a serious rival, especially if it continues to be supported, and encouraged by British protection, as it is at present.

I do not know that *Java* has not as good a climate for the production of tea as *Ceylon*; but I do know that it has a much better soil, a large area of available land, and a good supply of labour.

It is true, the import of *Java* tea into England last year was only seven million of pounds, and that the increase year by year has been comparatively small; but remember the cinchona incident, in which the tortoise beat the hare. It will not be wise for *Ceylon* planters to take a leaf out of the Indian planter's book, and pool-pool the idea of *Java* (where the tea is similar to that of *Ceylon* and made on the same lines) ever becoming a serious adversary.

We all of us recollect how Indian planters jeered at the idea of tea in *Ceylon* ever becoming a permanent and increasing industry. Nay, even now—according to "W. McK."—they say to *Ceylon* men:—"Oh! *Ceylon* may supply the Colonies, America, and the Continent, but we will soon have the English market all to ourselves, and will be content with it." Let us not be too confident. In the battle which is undoubtedly before us, we cannot afford to be generous. Planters may say:—"Oh! we can do very well with exchange at 1s 3d or 1s 4d"; but that you know is not the question. It is, "Can we afford to present our adversaries with 10 to 15 per cent. of the value, to enable them to compete with us?" Is there any call to give them any advantage at all?

* But *Japan* is a great rival in the United States—ED. T. I.

There is a danger, that if the rates of exchange decline a little as they well may, planters will think the storm cones may be lowered, as the storm is passing away; if they think it cannot return, they will find themselves mistaken and may be wrecked before they reach a harbour. Let them remember it has taken years for the wail of the Sugar planters to reach the ears of Government, and when it has reached them they are soothed with a Grand Committee to find out what is patent to the whole world, namely, that they have been ruined by bonnies on the production for export of Beet Sugar.

The mischief I have written to you about, is an insidious one, but on that account is not less real. If exchange on the present system goes back to 1s 2d, as it may some months hence, it will still exist.

Ceylon should endeavour to free itself financially from a Government which for its own purposes will "corner" its currency, as it did when it ceased to mint silver for the public.

I sent my letter to the Secretary of State to Mr. W. E. Thompson Sharpe as being the member for Ceylon and asked him to be good enough to forward it direct to Mr. Chamberlain. I have not yet had an acknowledgment of its receipt.

[About Java is our correspondent not aware that the standard is a gold one there, or at any rate that it is based on gold, although the aetnal currency is silver, the coins being merely tokens as in England. We think, therefore, that Java tea planters can have no advantage over us through Exchange?—Ed T.A.]

By today's mail, we have received the following:—

"Jan. 29.—I enclose copy of Mr. Chamberlain's reply to the letter I wrote to him of which I sent you a copy.

"It is the one I was led to believe I should receive, but as mentioned to you in my letter of the 1st inst., the grievance I asked you to be good enough to ventilate, did not exist when the inquiry took place. The Indian Rates of Exchange were regulated by the market prices of silver, and as long as that was the case, Ceylon had no cause of complaint."

(Copy.) Downing Street, Jan. 28.

C. SHAND, Esq.

SIR,—I am directed by Mr. Secretary Chamberlain to acknowledge receipt of your letter of the 4th inst., relative to the Tea trade of Ceylon, and the Currency system of that Colony.

Mr. Chamberlain has given your letter very careful consideration; but he is unable to see sufficient reason for reopening the question of the Ceylon Currency, which was most fully considered in all its bearings by the Silver Currency Commission, whose report was published in the Colony in 1894.—I am, &c., JOHN BRAMSTON.

TEA CULTIVATION AND TROUBLESOME WEEDS—WORTH DIGGING IN?

[The following has been put at our service by a Colombo mercantile firm.—Ed. T.A.]

February 6, 1897.

From Royal Botanic Gardens, Hakgala.

Dear Mr. ———,—The *Oscalis* that is such a troublesome weed is *O. Violacea*. It belongs to the Geranium family (Geraniaceæ) and therefore cannot be called a trefoil which belongs to the order Leguminosæ, and generally applied to *Trifolium*.

The *Oscalis Violacea* is a native of United States.

(Signed) W. Nock.

Copy. City Analyst's Office, Colombo, Dec. 3, 1896.

Report on a sample of so-called Trefoil leaves, received for analysis, on the 25th November 1896.

The sample of so-called trefoil plants consisted of 3rds by weight of stem and leaves, and 1/3rd roots. The leaves and stems of the so-called trefoil consisted of about 90 per cent moisture, and 10 per cent dry matter.

The roots consisted of about 60 per cent moisture and 40 per cent dry matter.

In 100 parts of the whole plant, there were 20 parts of dry matter, and 80 parts of moisture. The roots, thus, furnished 66.66 per cent of the dry matter, and the stems and leaves furnished 33.33 per cent.

The dry matter of the leaves and stems, and that of the roots, were analysed separately, with a view to ascertain the proportions of the important elements of plant food, taken from the soil by each.

ANALYSIS OF DRY MATTER.

	Stems and Leaves per cent.		Roots per cent.
Nitrogen ..	2.794	..	1.280
Potash ..	2.679	..	.871
Phosphoric Acid ..	.691	..	.417
Lime ..	1.596	..	.352

In order to compare the amount of these constituents removed from the soil by the so-called trefoil and by tea respectively, the following tabular statement will show the amounts of these substances contained in 1,000 lb. of tea, of Trefoil leaves and stems, of Trefoil roots, and of the whole Trefoil plant, all in the dry state.

Tabular statement showing the amounts of important constituents of plant food contained in 1,000 lb. respectively of tea, Trefoil leaves and stems, Trefoil roots, and this whole so-called Trefoil plant dried at 212° F.:—

	Tea.	Trefoil Leaves and Stems.	Trefoil Roots.	Whole Trefoil Plant.
	lb.	lb.	lb.	lb.
Nitrogen ..	46.02	27.04	12.80	17.85
Potash ..	23.61	26.79	8.71	14.74
Phosphoric Acid ..	7.98	6.91	4.17	5.08
Lime ..	5.88	15.96	3.52	7.82

It will be observed that the so-called Trefoil plant contains, weight for weight of dry matter, about 28 parts to the 1,000 in its leaves and stems, as against 46 in the case of tea; but, as the former is a leguminous plant, a portion of this nitrogen must be assumed to be derived from the air, and would, therefore, be a distinct gain to the soil if dug in. The plant seems also to be rather greedy in the matter of Potash and Phosphoric Acid, which, from an agricultural point of view, are the two most important constituents, after Nitrogen, of the tea plant, and which are altogether derived from the soil or from manure. While the so-called Trefoil plant is growing, therefore, it competes with the tea plant, for these elements of plant food as it draws its supplies, however, from near the surface, the advantage to be derived from digging it into the soil as a green manure, might more than compensate for the preliminary abstraction of these elements from the soil, these being again returned in a more readily available state for use by the tea plant.

(Signed) M. COCHRAN, F.C.S., City Analyst.

SILK IN INDIA.—Silk is not likely, says the *Englishman*, to become one of the products of the North-West Provinces, unless great meteorological changes come about. Repeated attempts on the Cawnpore experimental farm to rear silk worms from Assam have proved a failure. The hot temperature is fatal to the worms, which die soon after being received.

Correspondence.

To the Editor.

AGRICULTURAL PROGRESS IN ZANZIBAR

Zanzibar, Jan. 11.

DEAR SIR,—The Government of Zanzibar have decided to appoint a Director of Agriculture and have selected me for the post.

The object in creating the post is to improve, where possible, the methods under which the agriculture of the country is now carried on, and to endeavour, by experiment, to discover some new product that may, to a certain extent, take the place of cloves. The Government desire that the work so admirably begun by Sir John Kirk when he was Consul-General there, and since interrupted, may be continued.

I have taken the liberty of addressing you * in the hope that you will consent to open communication with me, with the view of exchanging information that may be considered of value, and of mutual assistance in obtaining plants and seeds that may be required. It will afford me pleasure if, at any time, I can be of use to you, and I hope you will consider me at your service.

Zanzibar does not as yet issue a Botanical Journal; but, if in the course of time it becomes possible to do so, I shall be glad to send you copies, meanwhile if you will be good enough to supply me with any of your publications I shall be happy to reciprocate your kindness.—I am, dear sir, yours truly,

R. N. LYNE.

TUSSER CULTIVATION.

Weuda, Feb. 6.

DEAR SIR,—The appeal which I made some months ago in your columns for live Tusser cocoons met with no response, but I succeeded in finding some in another district and have got the moths to pair without much difficulty. The next step in their domestication is to get the worms to feed in confinement. It will be probably impossible to feed the worms of the first brood on single leaves, like the mulberry feeding worms but they can easily be reared on small branches of loquat, Kahata (patana oak), avocado pear or veralu, placed in bottles of water. They spin in about 30 days.

These worms will probably do better at higher elevations than this: I have grown very fine cocoons in Dimbula, being somewhat pressed for space, with the Japanese mulberry silkworms and other species, I shall be glad to distribute half of these eggs, gratis, in lots of 50, to any applicants who may care to assist in their domestication.—Yours faithfully, B.

MR. TURING MACKENZIE AND THE CLIMATE OF PERAK.

SIR,—I have just seen in the *Penang Gazette* of January 29th an extract from your paper quoting an interview with Mr. Turing Mackenzie, who is reported to have stated, when referring to coffee planting in Perak and Singapore—"I would chuck up my Sumatra land tomorrow to take up land on the Government terms there, but the climate of Sumatra is very much better at all events than that of Perak—witness the churchyard at Thaiping, which speaks for itself. It is excellently well furnished, mostly with men under 35 years of age, malaria being the great scourge."

For Mr. W. Turing Mackenzie to have made a statement of this nature either shows that he must have a barely bowing acquaintance with the Perak climate or he has been very much misinformed. The

Thaiping churchyard, which has been in existence for 20 years, has at present 38 graves (Europeans). The number includes five children and six women. I am in a position to state that malarial fever caused the death of two, possibly three of the total number, so that the statement about "fever" being the cause of the number of graves in the churchyard is erroneous.

It will be news to the several ex-Sumatra Planters now resident in Perak to learn of the superiority of the Sumatra climate as compared with ours. Speaking from an experience of nearly nine years in Perak, I am able to state that the type of malarial fever met with is comparatively mild, except when there is severe and prolonged exposure, as in the case of those engaged in the Trigonometrical Survey.

I shall, therefore, be much obliged if you will publish this letter to endeavour to do away with any misapprehension that may have been raised through Mr. W. Turing Mackenzie's somewhat rash statement.—I am, &c.,

S. C. G. FOX.

District-Surgeon, Perak.

Thaiping, Perak, February 4th.

MR. MACKENZIE'S REPLY.

Upcountry, Feb. 13.

SIR,—I take off my hat to Dr. Fox, who is a good specimen of the climate of Perak, and as he gives actual figures there is no more to be said.

For myself, I confess to the funks as regards Perak, and during the past year three of my particular friends have been at death's door from fever in Thaiping, two of whom had no connection with the Trigonometrical Survey.

"The climate of Sumatra" is a tall order; but speaking of my own district of Boven Serdang, it is certainly the best lowcountry climate that I know; and my experiences have been many and various.

W. TURING MACKENZIE.

THE COCONUT PALM AND THE SENSITIVE PLANT.

DEAR SIR,—Can any of your scientific readers explain what influence the sensitive plant (*Mimosa pudica*—Sinhalese (*Nidikumba*) has on the growth of the coconut tree (*Cocos nucifera*)? It is asserted that wherever this plant (or weed) grows at the foot of a coconut tree, that tree thrives better than others, and is a more prolific bearer. I heard this a few years ago, and recently when going over a large tract of coconuts at Welikada, I mentioned it to the proprietor and he told me that he was cognizant of the fact, and that he had noticed it on some of his trees: accordingly we visited the spot. I was impressed with what I saw—the trees growing there, taking them as a whole, were not very good specimens. Some looked "jaundiced," the result of hard, bare, cabook soil and quick evaporation of moisture; but those at the foot of which the sensitive plants were growing, certainly looked more robust and their superiority over the rest was at once perceptible. The following theories to my mind bear a certain amount of weight in the solution of the question, viz:—The weed being a surface feeder, it is probable that its roots open out the surface soil, thus making it easy for the coconut to absorb moisture; or it may be that the roots or tubers of the weed contain certain chemical properties favourable to the growth of the coconut, which the spongioles of its rootlets readily imbibe; or that the weed affords a certain amount of succour to the coconuts, by shading its roots from the scorching heat of the fierce rays of the sun.

I pointed out the absurdity of manuring coconuts with husks and dry fronds. No tree thrives on its own refuse; coconut husk takes years to decay and in its damp musty state, is a favourable receptacle for the larvæ of grub,

* As Editor of *Tropical Agriculturist*.

† Local "Timos."

In the property known as "The Moss" at Maradana, which belonged to the late Mr. J. A. Martensz, it was discovered that husks buried at the foot of trees were in a fairly good state of preservation after a lapse of 20 years, and the trees had apparently derived no benefit from them. There was no mistake regarding the period as records showing the dates when each field or plot was "manured" were forthcoming.—Yours truly,
C. A. C.

USEFUL PLANTS AGAINST MALARIA AND INSECT PESTS.

DEAR SIR,—“Householder”'s letter on page 573 is interesting. It is true we do not hear of much that is being done to encourage the cultivation of trees for the object of warding off malaria and insect pests. The trees that have of late years gained the highest repute from a sanitary point of view are most probably various species of *Eucalyptus*, especially the “Blue Gum” (*E. globulus*) and *E. amygdalina*. These are said to have exercised on regions congenial to their growth more hygienic influence than any other arboreal vegetation. They are natives chiefly of Australia and Tasmania and have been introduced into many parts of the world and planted largely in malarial districts, as in the Mediterranean region and parts of Italy, and to some extent at the higher elevations in this country. Species of cinchona also—apart from their yield of quinine, which undoubtedly is the most powerful febrifuge as yet known—are believed by some to have strong deodorant properties. Among the list of febrifugal or sanitary trees, the Ceylon cinnamon, which causes the proverbial spicy breezes of our island, should surely find a prominent place.

It cannot be doubted that the cultivation of some trees more than others, whether by the result of the action of their roots on the soil or by exhalation from the leaves or by both, play an important part in the purifying of the atmosphere in their neighbourhood. Yet one must not be too credulous in regard to plants that are said to afford protection from snakes and mosquitoes, and to be able to drive away rats, &c. Most of us will have heard of the Upas-tree (*Antiaria toxicaria*) of Java which used to be credited with having the power of putting an end to any animal life that came within several yards of the tree, on account of an enormous quantity of carbonic acid gas which it was said to be constantly giving off. A Dutch surgeon wrote about the end of the last century that “criminals condemned to death were given the option of going up the Upas-tree to collect the poison, but not more than two out of every twenty returned.”

Vedaralas tell us with indisputable proofs that no cobra or polonga will venture within some considerable distance of the “Ankenda” (*Acromychia laurifolia*), whilst the possession of a small piece of the root of “Elawara” (*Calotropis gigantea*, var.) is said to be one of the best safeguards against snakebites. We ourselves are well enough used to seeing the “Boy” going over the rooms on an evening carrying a burning lump of the gum-resin of “Malkekuna” (*Canarium zeylanicum*) for the purpose of driving away unwelcome visitors. *Ocimum sanctum*, the Holy Basil of the Hindus, is acknowledged by many people to be a great enemy of the mosquito. Not less important, however, is the root “Vadakkaha” (*Acorus calamus*) said to be: when freshly cut and retaining its full aroma, it is reported to drive away fleas and other insects.
REX.

HOW TO RAISE RHEA PLANTS FROM SEED.

DEAR SIR,—Many enquiries have reached us from India, Straits, Sumatra, &c., as to the best way of treating *Bœhnneria Nivea* (Rhea) seed.

Our experience in raising plants from seed is as follows:—Prepare the nursery in rich soil, place in the top of the nursery about half inch with the following mixture and sow the seed one part rich soil, one part

sand, one part well decayed cowdung manure and one part coir dust, mix well, shade and water once a day in the evening, avoid too much moisture, seeds will begin to germinate in ten days, one lb seed produces over twenty thousand plants.

We find that plants grown by the above mode are a success and a six weeks' old plant has four leaves.—Yours faithfully,
J. P. WILLIAM BROS.

JADOO: A NEW “POTTING” MATERIAL: DOING AWAY WITH SUPPLY BASKETS

Devonshire, Jan'y 27.

DEAR SIR,—It may perhaps be of interest to give your readers some account of a visit I recently had the pleasure, as one of a party of mutual friends, of paying Col. Halford Thompson, the inventor and patentee of a new “potting” or perhaps, I should say, “growing material” for which the “Jadoo” Company has just issued its prospectus; enclosed copy of which will help to fill up the details. The first thing undertaken was an inspection of the various hot-houses and conservatories containing an extensive selection of ferns, shrubs &c., in different stages of growth, all raised and growing solely in Jadoo. Many of the plants were in fine bloom, but what of course attracted my special interest were numerous young Tea seedlings of fairly vigorous growth. That the latter should, with their roots cramped in flower-pots barely of a few cubic inches in contents, show a healthy appearance, forcibly supports the contention that Jadoo supplies in itself an admirable material for nursery purposes. I am convinced that from a nursery formed of good loam with, to the depth of a few inches, an admixture of even only say one-third of Jadoo, the young plants so raised could readily, if not allowed to get beyond a certain size, be removed to the planting field with the material they were grown in still adhering undisturbed to their roots, and so entirely supersede the costly use, and inconvenience of “transplanters.” An important feature is that the substance is extremely light, whilst being of an essentially fibrous nature the pots upon removal invariably disclosed an interwoven mass of roots and jadoo that would tax the ingenuity of a more than ordinarily careless cooly to break up. Knowing too well the immense aggregation of loss to proprietors in the past in time wasted, waste of valuable feed and plants—not to say by permanently injured clearings,—which must have been occasioned by the crude system of planting, till quite recently very generally in vogue, which usually allowed the roots to be bared and exposed; the above would point to qualities in jadoo that may prove of much value and utility. It lightens the soil, especially it is claimed producing a heavy growth of healthy feeding roots; and, not in itself subject to decay, it is a question of some interest, as to whether or not a layer if placed around matured plants (tea, cocoa or coffee) a few inches below the surface (of course to be left undisturbed) might not, from its strongly absorbent qualities, form an excellent permanent medium in economising liquid and other manures of a quickly solvent character, besides encouraging the formation of a mass of fibrous roots which will form in it.

From the Conservatories we proceeded to the factory conveniently situated with a private siding, close to the railway station at Teignmouth. The manufacture consists principally of boiling the peat litter or moss, with the sundry chemicals used, in large boilers—the real secret of the process however—the culminating discovery of over 14 years' patient experimenting by the patentee—lying in the subsequent reactions set up by certain of the latter under fermentation. Jadoo will, I understand, retain its qualities, if kept under cover, for an indefinite time, whilst, on the other hand, it can in use conveniently be “refreshed,” that is to say its fertilising qualities strengthened or replenished when necessary by occasional applications of a concentrated liquid, which forms a second

article of sale the Company anticipate a large demand for. This liquid, I was informed, combines—save the mechanical qualities of the Jadoo fibre—all the valuable properties of the latter as a manure, and can be used independently as such. My visit convinced me that both products, forming as they jointly do the outcome of so long a series of intelligent research and experiment, should wisely be afforded careful trial by horticulturists in the East, generally. Already the fertilised fibre has obtained a sufficiently encouraging recognition abroad to enable Col. Thompson to dispose of the American rights on most advantageous terms to himself, whilst in the West Indies the planting community have been quick to recognise its merits.

C. R.

COFFEE IN NORTH BORNEO.

We notice that the exports of Coffee are shewing an appreciable increase as compared with 12 months ago. The new plantings of the British Borneo Trading and Planting Co. at Segaliud, Kabili, and Sibooaga are looking very promising and part will soon come into bearing, while Mr. Goh Tek Seng's planting at Sibooaga will also soon help to swell the export. From Kudat we hear very good reports of Mr. Henry Walker's Estate at Taritipan, and Mr. E. Walker in making good progress on his new estate. Mr. Stewart Murray (formerly with Mr. Henry Walker) is proceeding to open near to Mr. E. Walker.—*British North Borneo Herald*, Feb. 1.

VARIOUS PLANTING NOTES.

THE INDIAN TEA CROP for 1896-7 is now estimated at 148,250,000 lb., of which 130,500,000 lb. were shipped from Calcutta up to 13th February. The total for India and Ceylon—although the seasons differ—will be as follows:—

India 1896-7	lb. 148,250,000
Ceylon 1896	lb. 108,141,412
				lb. 256,391,412

As regards the Indian Crop,—

The total for 1895-96 was 134½ million lb.

..	1894-95	125½
..	1893-94	123½

so that 148½ for 1896-97 need not astonish us.

The total for both countries in 1897-8 at this rate of progress may equal 275 million lb. : so let would-be planters of tea in new countries beware!

CAUCASIAN TEA.—The firm of Widow J. van der Chijs & Zn. of Delft write to the *Indische Mercur* (in the issue of Jan. 30) as follows (we translate from the Dutch):—

"In continuation of our letters of 19th Dec. last we have now the pleasure of sending you in a separate postal packet, a sample kindly sent to us by Mr. Constantine Popoff of Moscow, of tea grown and prepared on his plantations at Chalon, Kropishoom, and Salibomocouron in the Caucasus by Chinese labourers. We gladly place the same at your disposal." The editor of the *Indische Mercur* adds the following to the above:—"The analysis made by us of the tea is as follows:—Leaf—good black colour with a trace of reddish and a trace of golden tip, in appearance like a Chinese pekoe congou, somewhat small, equal, carefully prepared and moderately well twisted. Taste—clean, without any decided character, most like a Chinese paking, good aroma, but not sufficiently moist for Netherlands consumption; colour of decoction, light and transparent; colour of infusion, very nice-looking, golden yellow, which points to a good quality. Our opinion therefore is, that this first experiment is a very great success, and, although the quality is capable of great improvement, this culture, if it develops, may be expected to become a serious rival to the kinds grown in China."

THE CEYLON TEA CROP IN 1897 :

I. A. ESTIMATE RAISED TO 118 MILLION LB.

We have just learned from Mr. R. E. D'Esterre, Hon. Secretary to the Maturata and Upper Hewaheta Planters' Association, that, through some mistake, the Tea Crop Committee in Kandy omitted to include the Maturata returns in their total estimate for 1897. Consequently, 1,833,400 lb. have to be added, raising the planters' estimate to 119,083,400 lb. What does our pessimistic evening contemporary say to this? The injury *he* has done to tea proprietors in Ceylon, through under-estimating the capacities of the Colony and encouraging tea extensions in Northern and Southern India—everywhere but in this island—of late years, is beyond reckoning.—Since writing the above, our telegram from Kandy has arrived, showing the P.A. has increased its estimate to 119 million lb. or almost exactly the same as Messrs. Forbes & Walker.

COFFEE PLANTING IN MEXICO.

COFFEE LEAF DISEASE IN THE STATE OF CHIAPAS, MEXICO :

(By an ex-Ceylon Planter.)

26th Dec. 1896.

MY DEAR "OBSERVER",—I frequently receive letters from England, United States, as well as elsewhere, making enquiries, and seeking reliable information in regard to coffee planting. I find it very difficult and inconvenient to reply to them : too often the amount of information asked for is not in proportion to the knowledge, which they ought to have of the time at my disposal to reply thereto. Only the other day I received a letter from a gentleman, written from the village where he was born, I suppose : no country was given nor country mentioned in his address. These persons, I have no doubt, wonder why they never receive answers to their letters, and never think their own carelessness is to blame.

This person said he had seen my name mentioned in the *Ceylon Observer*. Accordingly in the hope that he may see this let me tell him to write again—write your name plainly, distinctly, with full address plainly written also. This advice I give to all who care to write to me, and I will endeavour to answer directly or through the columns of the planter's friend—the *Ceylon Observer*.

I do not think this is a good place for

A CEYLON PLANTER

to come to in search of employment as manager of a coffee plantation. Such situations are very scarce, and the wages paid, except only with rare exceptions, are not of such a nature as to induce anyone to embark his fortunes in Latin America.

A Ceylon planter, too, is very much handicapped by other planters resident here—German, French, American, Italian, in fact of every nationality, besides a redundancy of Mexican natives of the country. The first requisite is a good knowledge of Spanish, so as to enable one to do his own business personally, without the services of an interpreter. The methods, too, of doing business in these countries are entirely different to the best way in which we are educated. The Jesuitical doctrine, that the end to be gained justifies the means employed to gain that end, permeates every transaction, and eats into the vitality of every negotiation : accordingly one requires to be very alert, careful, and reserved.

Many persons who come to these countries to teach remain to learn; their lessons too often are very severe. When I first arrived in the neighbouring

REPUBLIC OF GUATEMALA

in the early part of 1883, I thought that the very name of being a Ceylon planter was sufficient to establish me as an authority on such subjects; so it was to a certain extent, but my case was very exceptional and successful. But I readily say that our Ceylon system of coffee planting could never be adopted successfully here, where the same method prevails which is employed in Brazil. The reasons are legion in number and I have written you too frequently regarding them. In a word it is eminently cheaper and simpler, so much so that whatever part of the world I were to go to prosecute the coffee industry I should assuredly work on the lines established in all this continent. Accordingly you see my Ceylon coffee planting education is no use to me. I am one of those who came here to teach and have remained to learn.

Central America stands very high as a large coffee-producing country. It is split up politically into five distinct Republics. The chief of these as a coffee country is the Republic of Guatemala. Last year the harvest reached nearly 900,000 quintals (one quintal is equal to 100 lb. weight.)

It is an accepted fact that

VOLCANIC SOIL

is the very primest for the growth of coffee. Now Guatemala and its immediate neighbour, San Salvador, is nearly altogether of volcanic formation. There are fully 12 distinct volcanoes, ranging in height from 13,500 feet to 15,000 feet above sea level. These volcanoes begin in Mexico, State of Chiapas, and extend in uniform succession throughout the Republic of Guatemala and San Salvador. They are all situated about the same distance from the seashore washed by the Pacific Ocean and not far inland. Their lofty tops look down on the band-like cloud belt, which is often seen to rest more than midway up their sides, like a cotton bandage round a sore finger—scale gigantic. Not a very poetic figure of speech, but that is what I thought one of them looked like the first time I saw it. The upper portions are very rugged and steep; at lower elevations their bases spread out, flatten and broaden and at the usual height above the sea-level a line can be drawn which marks the lower limit of the coffee zone throughout the district of Soconusco, state of Chiapas, thence traversing equidistant from the sea, through Guatemala and San Salvador. From this line reaching upwards is the great coffee belt of Soconusco and Central America.

A PERPETUAL CALM

broods eternally along this gigantic band. The stillness is scarcely ever ruffled even by a gentle breeze. During the rainy season, heavy rain and thunderstorms are the rule nearly every afternoon; but only in the afternoon. During the whole of my sojourn there I scarcely ever remember seeing it rain in the morning. Every morning breaks to display a perfectly cloudless sky, the sun shines with a tropical strength and heat, and to all appearance, were it not for the wet jungle and muddy roads, one would suppose that such a brilliant sky never was darkened by a cloud, or its tranquility disturbed by a storm. After noon, however, the clouds gather with magic rapidity, black and ominous are they, succeeded by heavy rain which pours

down, filling and swelling the rivulets and making everything in the way of a stream an impassable torrent.

This is a true description of the climate which prevails in the Pacific slope of Central America, and differs so very widely from that where I am at present situated that I must describe it also. Today is the 26th December and it is just

EIGHT DAYS SINCE I SAW THE SUN.

Two days ago it rained 27 hours incessantly—never stopped a moment. Today we have no rain, but the whole sky is obscured by dense clouds. How many more days may pass before I shall see the blessed face of the sun I know not; but this I will say: that I am very credibly informed that it not infrequently happens that the sun, is obscured for 15 and 20 days consecutively, particularly at this season of the year. The previous 8 days was entirely the reverse: the sun rose in the morning, unclouded sky, and bright and cheerful was the whole day for 9 consecutive days. Here we seldom have thunder. I cannot say I ever heard any during the 9 months that I have been here. Can anything be more opposite or different than the display of the two climates between this place and the Pacific slope of Central America. Yet there are coffee plantations here which grow and thrive wonderfully. The soil is a very deep rich friable loam of volcanic origin.

When I first went to Guatemala, March 1883, the coffee showed a magnificence and a luxuriance of growth and redundancy of foliage, that I had hitherto been a stranger to. From 8 to 12 pounds of coffee was not unfrequently picked off single trees. But in the early "nineties" I noticed

A GREAT CHANGE

particularly in Soconusco and the district in Guatemala called Tumbador, which immediately adjoins Soconusco. The coffee trees seemed to have lost their great and exuberant vigor. Their luxuriant foliage was decidedly lessened, and in their stead an unhealthy sickly appearance had taken its place; the leaves were more scattered on the ground than on their proper place on the tree; the young wood especially would appear weak, was withered and black-looking from the ends leading toward the trunk. In speaking to a friend of mine, a wealthy planter, he acknowledged the difference, and said it was most marked. "They don't seem to me to have half their former luxuriance of growth," is what he said to me. It is needless to say that I soon found out what the cause was. I noticed what to me was an old and familiar face. The underpart of the leaf I noticed was semi-perforated. They were spotted all over with the same marks. No wonder that I was frightened. I thought I had discovered

HEMILEIA VASTATRIX

beyond all doubt. My fear and anxiety, however, I kept carefully to myself; and to make myself absolutely sure, I collected and prepared botanically a little box of the diseased coffee leaves and despatched them to the Director of the Smithsonian Institution of Sciences, Washington, United States, North America, giving him at the same time a description of the coffee trees, as well as a comparison of what they were years before.

The following is the reply which he sent to my letter, which I feel assured will be read with great interest by all planters as well as all those who have capital invested in Soconusco and Guatemala:—

Smithsonian Institution, United States National Museum, Washington, May 22nd, 1894. Mr. W. J. Forsyth, Chiapas, Mexico.—Dear Sir,—The coffee tree

leaves recently transmitted by you for examination have been referred to the Curator of Botany in the National Museum. He has submitted them to Mr. Ellis of Newfield, New Jersey, who states that the disease, which has affected the trees, is not caused by the fungus *Hemicleia Vastatrix*, but by the growth to which the name of *Stilbum Flavidum* (Cooke) has been given. This, I am told, is quite widespread. Mr. Ellis has in his collection specimens of the same fungoid growth from Costa Rica, Jamaica and Venezuela. Inasmuch as no experiments have been made in this direction no remedies can be suggested.—Yours Respectfully,
G. BROWN GOODE, Assistant Secretary.
(2,683.) (True copy W. J. F.)

A great deal has been written and said about the large profits attending the cultivation of coffee, when all the natural conditions and requirements of the coffee tree unite in certain favored places, and make it produce its greatest and best. This is justly true; but there are many dubious roads, which are said to lead there and pitfalls and precipices where the uncultured can slip and fall. Such a warning I herewith hold out to the unthinking in hope it may lead to some beneficial result. I question if anyone knows that the pest *Stilbum Flavidum* is exercising its powers, and aiding to consummate the extinction of the coffee industry of Soconusco and Guatemala. But it is nevertheless true as the letter I quote amply proves.

This disease is almost entirely confined to the district I have named. Nowhere throughout the state of Oaxaca have I observed any indications of the pest. I have travelled over a large belt of coffee country here and have failed to notice the slightest indications. Considering therefore that there is an absence of the pest in this great and famous state—further that we are removed from the scene of its ravages, fully 150 leagues, with nothing in the way of connecting links to transmit the plague—it accordingly behoves the Government to protect as much as possible the industry here which still remains unblemished in all its vigor and robustness.

I shall now conclude this present paper, wishing you and all my old Ceylon friends a very happy New Year.—Yours truly,

W. J. FORSYTH

THE VENESTA TEA CHEST.

STARTING OF A LOCAL AGENCY.

The Patent Veneer and Metal Case Co., Ltd., of London are introducing their "Venesta" tea chest into the island. Mr. A. S. Penny, a representative of the firm, arrived here by the P. & O. ss. "Sumatra" over a fortnight ago and arrangements have been concluded to turn out chests to supply local requirements, the agents being Messrs. Walker, Sons & Co., Ltd. Mr. Penny gave a demonstration in putting together the tea chests at the office of Messrs. Walker's today, and was good enough to supply information to a representative of the *Observer*. A standard size will be observed in full, half, and quarter chests. The large chests will be 24 by 19 by 19 in outside measurement, 5 cubic feet for freight, and 8,123 cubic inches inside; and on an average of 73.95 cubic inches to a lb. of tea, will hold 110 lb. of tea each. The chest will weigh about 128 lb. with lead, nails, and everything, and 10 chests will go to a ton, shipping. A half-chest will be 20 by 16 by 16 to hold 60 lb. of tea, the weight of the chest being 12 lb.; and quarter chest

will be 13 by 12 by 12, holding 21 lb. tea, and weighing only 6 lb. The method of putting the boxes together is simple, and a box can be built up, lead-lined and ready for packing tea within a few minutes. The four sides of the chests are placed in line, a gauge (wire rod) put between to give a certain space and then fasteners of annealed steel are driven in and the points beaten in. One sheet of lead, the length of the four sides is next placed, wooden batons placed at top and bottom and fastened down. The remaining unfastened side of the chest is then secured. About an inch or so of lead remains above the batons. A sheet for the bottom is placed and folded with the lead already fixed down, and the board is then placed in position and fastened. This, and is made up of three sheets 1-16th of an inch thick each, and pasted together, the grain running transversely, giving the boards great strength with lightness; and an empty chest will bear the weight of a man, the thin plank only bending. The boxes are quite a new idea and only about the end of last year, were introduced into England. The Mariawatta Tea Co., London, are using the "Venesta" chests largely for their Foreign and Colonial trade; and many large estates in India are using the chests, Messrs. Williamson, Magor & Co., being agents at Calcutta. An agency has also been opened in the Persian Gulf, the boxes being used there for the date trade. Agencies are also opened in Australia and New Zealand. Mr. Penny has already secured several orders from upcountry estates, and he will be leaving next Saturday for Mariawatta, East Holyrood, Glenlyon, Waverley and other estates. Mr. Rutherford has placed an order for very nearly 4,000 chests. Machinery has already been put down to turn out 10,000 chests a month, and it is intended to enlarge the work according to requirements.

Besides tea chests "venesta" can also be supplied in large sheets for constructing, lining or partitioning tea factories, stores and bungalows, and being water-proof and an excellent non-conductor of heat, it is believed it can be applied advantageously. In fact it can be put to a variety of uses and we were shown travelling boxes, and hat cases made of the material very strong, light and neat in appearance. In London we are told that small express wagons used by provision dealers are being built, one sheet being used for each large panel. Small bric-a-brac, trays and such like are also turned out with advantage.

The firm is at present experimenting in turning out corrugated roofing and expect to be able to supply roofing for estate stores, etc. Mr. Penny believes that it is likely the Admiralty may use the venesta planks for fittings and light work. A great saving is effected in freight and dock charges, etc., by the venesta chests, because more tea goes home under the same measurement, and the chests being very much lighter than other chests more tea goes home under the same dock scale. A saving is also effected in carriage to estates the shooks measuring and weighing less than others; and there is a saving also in the number of boxes used because 22 venesta boxes contain as much tea as 24 other boxes of same external dimensions. Nails and solder not being required a saving in that direction is likewise effected. During the afternoon today, Mr. Penny gave a demonstration in the stores at Messrs. Walker's before a number of those interested in the tea trade. Mr. Seovell, planter, was one of the visitors.

MARKET MANURES AND THEIR ANALYSES.

We append the Draft of a proposed Ordinance drawn up for us by a legal friend and amended in one or two points by Mr. M. Cochran, Public Analyst, who has added two sub-clauses. In returning the Draft, Mr. Cochran writes:

I do not think it is necessary to introduce the distinction in the Ordinance between soluble and insoluble phosphates. In England, it is very exceptional to use a phosphatic manure which does not contain soluble as well as insoluble phosphate. Here, on the other hand, it is just as exceptional to use a phosphatic manure which does contain soluble phosphate.

We would now urge the Planters' Association to take up the matter and call on their representative to bring the draft measure under the notice of Government in the hope that leave may be given to introduce it into the Legislative Council. It would not be the first time that an unofficial member had (with the leave of the President) introduced and carried through a useful piece of legislation.

Our legal friend's draft as amended is as follows:—

AN ORDINANCE FOR REGULATING THE SALE OF MANURES OR FERTILIZERS OF THE SOIL.

Whereas it is expedient to provide against the adulteration of manures or fertilizers of the soil— It is hereby enacted by the Governor of Ceylon, by and with the advice and consent of the Legislative Council thereof as follows:—

WARRANTY ON SALE OF FERTILIZER: I.—(1) Every person who sells for use as a fertilizer of the soil any article manufactured in Ceylon or imported from abroad shall give to the purchaser an invoice stating the name of the article, and whether it is an artificially compounded article or not, and what is at least the percentage of the nitrogen, phosphates, and potash, if any, contained in the article, and this invoice shall have effect as a warranty by the seller of the statements contained therein.

(2) For the purposes of this section an article shall be deemed to be manufactured, if it has been subjected to any artificial process, or if the seller has declared it to have been manufactured.

(3) This section shall not apply to a sale where the whole amount sold at the same time weighs less than half a hundred-weight.

PENALTIES FOR BREACH OF DUTY BY SELLER. II.—(1) If any person who sells any article for use as a fertilizer of the soil commits any of the following offences, namely:—

(a) Fails without reasonable excuse to give, on or before or as soon as possible after the delivery of the article, the invoice required by this Ordinance or

(b) Causes or permits any invoice or description of the article sold by him to be false in any material particular to the prejudice of the purchaser, he shall, without prejudice to any civil liability, be liable, on summary conviction, for a first offence to a fine not exceeding one hundred rupees, and for any subsequent offence to a fine not exceeding five hundred rupees.

(2) In any proceeding for an offence under the section it shall be no defence to allege that the buyer, having bought only for analysis, was not prejudiced by the sale.

(3) A person alleged to have committed an offence under this section in respect of an article sold by him, shall be entitled to the same rights and remedies, civil or criminal, against the persons from whom he bought the article, as are available to the person who bought the article from him, and any damages recovered by him may, if the circumstances justify it, include the amount of any fine and costs paid by him on conviction under this section, and the costs of and incidental to his defence on such conviction.

APPOINTMENT OF ANALYST. III.—The Governor shall appoint one or more Government Agricultural Analysts for the land, who shall, while holding the Office of Government Agricultural Analyst, not engage in any trade, manufacture or business connected with the sale or importation of articles used for fertilising the soil. Should more than one Agricultural Analyst be appointed, one of them shall be appointed Chief Agricultural Analyst.

POWER OF PURCHASER TO HAVE FERTILIZER ANALYSED. IV.—(1) Every buyer of any article used for fertilising the soil shall, on payment to a Government Agricultural Analyst of the fee sanctioned by the Governor, be entitled, within ten days after delivery of the article to the buyer, or receipt of the invoice by the buyer, whichever is later, to have the article analysed by the Analyst, and to receive from him a certificate of the result of his analysis.

2. Where a buyer of an article desires to have the article analysed in pursuance of this section, he shall, in accordance with regulations hereto appended, take three samples of the article, and shall, in accordance with the said regulations, cause each sample to be marked, sealed, and fastened up and shall deliver or send by post one sample with the invoice or a copy thereof to a Government Agricultural Analyst, and shall give another sample to the seller, and shall retain the third sample for future comparison: Provided that a Government Agricultural Analyst, or some person authorised by him in that behalf with the approval of the Governor shall, on request either by the buyer or by the seller, and on payment of a fee sanctioned by the Governor take the samples on behalf of the buyer.

3. The certificate of the Government Agricultural analyst shall be in such form and contain such particulars as are directed, in the schedule hereto annexed, and every Government Agricultural Analyst shall carefully enter in a Register to be kept for that purpose, the result of any analysis made by him in pursuance of this Ordinance.

(4) At the hearing of any Civil or Criminal proceeding with respect to any article analysed in pursuance of this section, the production of a certificate of a Government Agricultural Analyst shall be sufficient evidence of the facts therein stated, unless the defendant or person charged requires that the Analyst be called as a witness.

(5) The costs of and incidental to the obtaining of any analysis in pursuance of this section shall be borne by the seller or the buyer in accordance with the results of the analysis, and shall be recoverable as a simple contract debt.

(6) In the event of the results obtained by two or more Analysts, who have analysed samples from the same lot of manure, disagreeing to a material extent, the matter may be referred to the Chief Analyst, who shall take steps, either by analysing the sample kept in each case for comparison, or by drawing and analysing a fresh sample, or by both of these methods, as may seem best to him, to determine the true average composition of the manure; and the results obtained by him shall be regarded as representing the true average composition of the manure.

PENALTY FOR TAMPERING.—V.—If any person knowingly and fraudulently—(a) tampers with any parcel or fertilizer so as to procure that any sample of it taken in pursuance of this Ordinance does not correctly represent the contents of the parcel; or (b) tampers with any sample taken under this Ordinance, he shall be liable on conviction to a fine not exceeding five hundred rupees, or to imprisonment for a term not exceeding six months.

APPLICATION.—VI.—This Ordinance shall apply to wholesale as well as retail sale.

COMMENCEMENT OF ORDINANCE.—VII.—This Ordinance shall come into operation on the 1st day of January 1898.

SHORT TITLE.—VIII.—This Ordinance may be cited as the Fertilizers Ordinance, No.— of 189—.

THE PLANTERS' ASSOCIATION AND OUR MATERIAL INTERESTS.

Turning to our staple exports as represented by the Association, it is gratifying, after all we have heard of the decay of cacao on certain estates, to note that the crops go on steadily increasing, and that the current year is likely to excel its predecessors. The case is different with coffee—the old Arabian slowly dying out, although the clearing away of bug by the lady-bird beetle might check the decay, while tea is too prosperous, even now, to allow of anything like due attention being given to Liberian. Cardamoms continue to give a good deal of assistance in certain districts, and we sincerely trust that attention to these several bye-products, as well as to khea—very properly brought forward by the Association—and some others not mentioned,—may steadily increase. We are surprised, for instance, to find no reference to “Rubber,” which ought to grow in importance every year. There is no better repository of information for the practical planter on the outlook for bye-products, than is afforded in our “Planting and Agricultural Review,” prefixed to the Handbook and Directory. The Association has, however, taken a very wise step in calling for a resumption of the advertising of seeds and plants available from time to time, by the Royal Botanic Gardens; and another wise step would be to ask each of the seventeen District Associations in their annual Reports, or in special communications to the parent Committee, to notice what is being done with new products within their bounds. In this way a good deal about “Rubber” might be learned from Kalutara and Sabaragamuwa; on Liberian coffee from Matale, the Kelani Valley, etc.; on Rhea from Kurungala and the lowcountry, and so on. It is encouraging to know that the Association is not to lose sight of the need for legislation to provide a check on the quality of manures sold; and that—in the interests of young planters especially—the Midland Jury lists are to be looked after. We are very pleased to see the reference to our late Postmaster-General in the Report. If ever there was a high-minded, progressive official in the Colony, it was Mr. T. E. B. Skinner: and it is astonishing to us that Sir Arthur Havelock, amid all his professions of esteem, did not, in connection with the opening of the new Colombo Post Office, secure some signal mark of honour for Mr. Skinner, who certainly deserved it quite as much as some others who were not forgotten.

The Labour Supply Question is undoubtedly the most important one before the Association and the Planting community generally. It is not necessary, as we have pointed out, to go beyond the Madras Presidency or a people closely allied to our present coolies in race and language, in order to tap a new and populous district and at the same time relieve distress. We refer to the Udappah, and part of the Arcot, district as worthy of an experiment in recruiting. The mention of Puttalam as the future central port and dépôt for cooly immigration is important. We have long urged such a departure in connection with the railway which must one day run direct from Colombo along our North-west coast, while a branch to Anuradhapura would be a necessary adjunct. With the discussion on Mr. Noel's motion, we shall deal in our next.—The explanation given about the new Roads Ordinance

is very useful: possibly this may account for the delay of the Ambawela Extension road among other things; but we can conceive how much injustice may be done through setting the value of the road to an estate against the land taken up. Is it not the case that a proprietor would often prefer a road to keep outside, rather than to cut through his plantation? All that Mr. Mackenzie tells us of his work in America is of great interest, especially the fact that India has spent as much as Ceylon in the States. As to “advertising,” Mr. Mackenzie has been repeatedly told by us that we do not confine the term to the Press, but interpret the word in the broadest sense and think food-shows, demonstrations and lectures about the very best form of advertising. The “Thirty Committee” again write as if Mr. Rogivue were practically alone working for our teas in Russia. They have surely heard of other big operators—of, for instance, Lipton's House in St. Petersburg sending orders across to London for 2,000 boxes at a time. It is very satisfactory to find the Association taking an interest in the “Arrack” problem—a question, we suspect, which lies at the foundation of the greater part of the serious crime in the island; but is it not rather reversing the usual order to say the Committee will wait for the Commissioner's Report? By the way, how absurd to have a Commission made up of one member? We do not know if this is because Mr. Ellis did not care for associates, like the dissentient jurymen who said that his eleven colleagues were the most obstinate and wrong-headed men he had ever known. Certainly, on this most difficult and complicated Arrack question, there should sit a representative, though carefully picked, body of Commissioners, some of whom should be native gentlemen as most intimately acquainted with the ways and feelings of the people in the principal rural divisions of the island. Perhaps, the Governor only means Mr. Ellis's Report to be regarded as a preliminary one, to indicate the policy as to which a duly-constituted Commission should enquire and take evidence?

PLANTING PRODUCTS.

(Extracts from the Forty-third Annual Report of the Ceylon Planters' Association, held 17th Feb. 1897.)

TEA.

The season generally has been a fair average one. Taking the Chamber of Commerce returns, the increase in crop as against 1895 is 10,201,541 lb. The total exports reaching 108,141,412 lb. of this 11,205,051 lb. were shipped direct from Colombo to ports other than the United Kingdom, or an increase of exports direct to outside markets of 2,018,519 as against 1895, which may be considered very satisfactory, more especially as the Home exports of British grown Teas show an increase of 5 millions on last year—1895. There is also the very satisfactory increase in Home consumption of British grown Teas of 11 millions over last year, which itself showed an increase of 7 millions over the year before. Everything points to increased foreign consumption during 1897, more especially in America and Russia, where your Commissioners (Mr. Mackenzie) in the former, and Mr. Rogivue, in the latter, continue their good work with energy. The average London price was 8½d per lb. as against 8¾d per lb. for 1895; but results, taking the year as a whole, are satisfactory, and confidence in your staple is maintained, while it is generally considered that there is no safer investment than Ceylon Tea property. Extension of planting still con-

tinues in a small way, and the demand of Tea seed is quite as strong as it was in 1895. Labor was short during the busy months—March-May—in some districts, notably where estates lie some distance from the main road. Extension of cart roads is a matter of necessity, and should be pushed on with activity, as not only do coolies dislike the carriage of Tea chests, but transport by coolies takes away a considerable force from the pluckers.

COCOA.—As anticipated in last year's report, crop for 1896 exceeded that of 1895, the figures for the last four years being: 1893—29,775, 1894—22,791, 1895—27,522, 1896 cwt. 33,890, from which figures it may be inferred the crops for 1897 will probably be the largest yet picked, cwt. 35,000 being perhaps a fair estimate. Some anxiety was caused during the past two years by reports received of cocoa trees dying out in rather a wholesale way by the ravages of a small borer beetle, and your Committee considers the matter worthy of the most careful attention. The position of the home market is encouraging, the demand having largely increased whilst the imports have not done so. For the first time for some years the deliveries from London and Havre show more signs of catching up the imports. The following extract from Messrs. Wilson, Smithett & Co.'s circular of recent date gives interesting statistics regarding Imports, Consumption and Stock. (Already given in the *Observer*).

CARDAMOMS.—The forecast of your Committee in last year's report has been borne out—Exports being in 1895 435,090 lb.; in 1896 463,233 lb. The prices realised have also been exceptionally in favour of growers.

ARABIAN COFFEE.—Where this cultivation is maintained there is little encouragement to increase the area by planting up fresh land or keeping up old bushes in first class order.

LIBERIAN COFFEE.—A very small area of this product has been planted, and its success may be hoped for.

RHEA FIBRE has so far only reached the stage of striking, cuttings, nurseries, &c. Kurunegala so far has been the basis of such operations. Keen interest is taken in the matter, and if sufficient evidence is forthcoming of its profitable culture, there are many enterprising planters who will take up land for its cultivation.

CROTON-SEED.—The fine prices ruling two or three months ago made the fortunate possessors of this product pay some attention to the cultivation.

OFFICIAL ESTIMATE OF THE TEA CROP FOR 1897.—Your Committee has decided to estimate the tea crop for 1897 at 119,000,000 lb.

NEW PRODUCTS, FOREST RESERVES.—Your Committee feels that the present prosperity of Ceylon generally affords a favourable opportunity to invite renewed attention to the important question of new products in connection with which a Commission was appointed in 1881 by Government at the instance of your Association. As an Appendix to the Report of the Commissioners (*vide* Book of Proceedings of the Association for the year ending 17th February, 1882) there is printed a memorandum on the part taken by the Royal Botanic Gardens, Peradeniya, in the introduction of useful plants into Ceylon in which the late Dr. Trimen remarked as follows: "Appended to this memorandum is an advertisement from one of the local newspapers of the plants and seeds on sale at the Gardens in June 1881. Such advertisements are now prepared quarterly by the Director, and have, it is believed, considerably tended to the spread of 'new products' in the Colony." Your Committee would bring this matter before Government, and urge that the "advertisement referred to" should again be regularly prepared quarterly and prominently advertised in the "Government Gazette," in the local newspapers, and by printed circulars in the vernacular for distribution widely among cultivators. As regards forest trees, your Committee would remind Government that the late Dr. Thwaites in the year 1879 asked that he should receive instructions to form both at Peradeniya and at Hakgala Gardens, nurseries for supplying at a moderate rate of charge, young plants of suitable kinds for the convenience of

planters who may require them for reservations. Dr. Thwaites further annexed under lists A. B. & C. those species he considered most suitable, both indigenous and exotic, of which seeds could be obtained without any great difficulty at their proper seasons.

Your Committee desires in this report to record the universal regret felt at the untimely death of the late Director of the Royal Botanic Gardens, Peradeniya, and the sense of loss that has been thereby sustained not alone in the departments of learning in which Dr. Trimen was conspicuous, but also among the Planting Community in whose interests he at all times evinced the keenest regard, and for whose progress he laboured in so many ways.

LABOUR LAWS.—Some recent decisions of the Supreme Court have been the subject of consideration and discussion, and while it cannot be said that any remedy has been found for such mistakes, or that a solution of the difficulties that follow has been arrived at, it was unanimously resolved by your Committee that it would be unwise and inexpedient to endeavour to re-open the existing Labour Ordinances, which, on the whole, when reasonably interpreted, afford considerable protection to all interested in the Labor Question.

LABOUR SUPPLY.—Your Committee appends Abstract of the Official returns showing the arrival and departure of coolies for 1896, also for comparison the similar table for 1895.

[Table given already in *Observer*.]

Your Committee is further able, by the courtesy of Government, to invite attention to the following Immigration Returns, compiled by the Master Attendant, Colombo, showing the number of Indian coolies that have come to Ceylon annually for the past five years, 1892-96, *via* North Road and *via* Tuticorin respectively:—

RETURN SHOWING THE NUMBER OF INDIAN ESTATE COOLIES WHO HAVE COME TO CEYLON <i>via</i> THE NORTH ROAD FOR THE PAST FIVE YEARS.			
Year.			Number.
1892	45,687
1893	31,564
1894	39,062
1895	31,448
1896	(up to 30 h November 1896)		29,442

RETURN SHOWING THE NUMBER OF INDIAN ESTATE COOLIES WHO HAVE COME TO CEYLON FROM TUTICORIN AND TONDI FOR THE PAST FIVE YEARS.			
Year.	Men.	Women.	Total.
1892	21,583	7,381	28,964
1893	12,235	3,975	16,210
1894	12,864	3,936	16,800
1895	28,519	9,717	38,236
1896	36,135	11,906	48,041
Year.	Children.	Infants.	Grand total.
1892	4,689	3,655	37,308
1893	2,710	1,455	20,375
1894	3,038	1,257	21,095
1895	9,259	2,687	50,182
1896	9,015	3,412	60,498

SUGGESTIONS FOR INCREASING IMMIGRATION—PASSES TO COOLIES FROM TUTICORIN TO COLOMBO BY STEAMER—THROUGH BOOKING OF COOLIES FROM INDIA TO CEYLON—BLACKMAILING OF COOLIES AT STATIONS ON THE SOUTH INDIA RAILWAY AND ELSEWHERE.—All the above-mentioned subjects have received a large share of the time and attention of your Committee during the past year, and satisfactory results have been attained. In the matter of the alleged Blackmailing of coolies especially, the thanks of the Association are due to both the Ceylon and Madras Governments for the keen and effective interest and action that have been taken with a view to putting a stop to Blackmailing, while interesting and valuable reports have been transmitted for your information and guidance by Government.

QUARANTINE REGULATIONS AT COLOMBO.—In view of the fact that the course of immigration is now being largely diverted from the land to the sea route, it would seem advisable to look to some other port than Colombo for a terminus. During a recent outbreak of cholera on the Mainland quarantine had to

be established at Colombo, and the steamer agents consequently found themselves unable to continue the service of conveying coolies. Such a state of affairs is always liable to recur, but would be disastrous in its results. Your Committee hopes that, on the occasion of the extension of the railway now proposed Northwards, it may be found possible to serve Puttalam, and to establish in that neighbourhood a landing station for coolies, available and safe at all seasons.

ORDINANCE RELATING TO CLAIMS TO FOREST, CHENA, WASTE, AND UNOCCUPIED LANDS.—The above-mentioned Ordinance, which has recently passed the Legislative Council, gave rise to considerable apprehension, and your committee felt that in connection with such Ordinances especially the views of the Planters' Association of Ceylon should have been expressly invited by Government, ample time being given to all interested to consider them. A Sub-Committee was appointed to look into the Draft Proposed Ordinance as it appeared in the *Government Gazette*, and it was resolved to point out that in the opinion of the Sub-Committee Section 19, sub-sections A.B.C., would arbitrarily prejudice many persons in their just proprietary rights, and shake the confidence of investors in all landed property. With regard to the principle of the bill the Sub-Committee was of opinion that the Occupier of Land should under no circumstances be made the claimant, but that if it should be necessary to take action against him, he should be the defendant. Further, that though it is desirable to give legal effect to agreements arrived at between the Government Agent and the occupier, the Government Agent should not be allowed to adjudicate if an agreement cannot be come to, but that the case should go to a properly constituted Court. It was felt that in all cases ample time should be given to claimants for the proper defence of the action, and to safeguard the interests of absentees, and that no Government official that had at any preliminary inquiry been a party should be appointed a special Commissioner. The attention of the Planting Member in Council was drawn to these and to other points when watching the proposed Ordinance at the various readings in the Legislature. Your Committee, while adhering to the views expressed by the Sub-Committee, deem it advisable to annex as an appendix to your Committee's Report for further reference and guidance an extract from the speech recently made by His Excellency the Governor in reply to some observations on the subject submitted to him in an address by the Northern Districts Association.

PRÆDIAL PRODUCTS THEFTS COMMISSION.—The result of the Prædial Products Commission from the standpoint of Government as regards remedial and deterrent action may be summarised thus. In view of provision of Ordinance No. 16 of 1865 the Government does not consider further legislation necessary in respect of the recommendation made in Paragraph 29 of the Report of the Prædial Products Thefts Commission. Paragraph 29 reads,—“We recommend, however, in the present instance, the establishment of special police in the districts which suffer from thefts, the estates which desire such protection and are willing to contribute towards the cost of it. We consider that the reality of any complaints about the prevalence of theft may be fairly gauged by the willingness of those who complain to contribute towards the suppression; and we are therefore of opinion that whenever two-thirds of the owners of estates in any locality are willing to pay for a special police force, this is in itself sufficient to establish the existence of a state of affairs which renders it the duty of Government to pay a moiety of the cost of such police, and we advise that the application of this system should be sanctioned in any district or locality where such police are applied for.”

The Government considered the proposed amendment of section 14 of the Ordinance, recommended in Paragraph 32 of the Report, undesirable. Paragraph 32 reads.—“The system here recommended is, in its general features, already provided for by sections 14 to 22 of the Police Ordinance No. 16 of 1865, and it seems singular that the northern districts, where

thefts are most prevalent, should not have availed themselves hitherto of the provisions of this Ordinance.

“We consider that the Ordinance should be amended by the substitution of five acres for twenty-five acres in section 14, and that in section 15, proprietors should, in addition to giving the number of men, be required to state whether regular or rural police are required, whether they desire police stations or patrols, and whether they would wish the force to consist of local residents or of persons enlisted elsewhere; in other words, they should give a general outline of the scheme they wish to have adopted.”

With regard to the recommendation made in paragraph 34 of the Report, His Excellency the Governor was pleased to order the relaxation of Section 17 of the Rules and Regulations made under Ordinance 32 of 1891, and published in the “Ceylon Government Gazette Extraordinary” No. 5,159 of August 6th, 1892, so far as to leave to the Government Agents the selection of such men as may be employed as special Police in the suppression of thefts of Prædial Products.

NEW MARKETS FOR TEA :

THE THIRTY COMMITTEE.

The Committee's Report is as follows:—

In presenting a short statement of the work of the “Thirty Committee” for the year ended 31st December 1896, it may be useful to remind those interested that the Fund now being employed in pushing and advertising Ceylon tea throughout the world, but of course especially in the United States of America and Russia is the proceeds of the levy of an export duty on tea of 20 cents per 100 lb. under the Ordinance No. 4 of 1894. The money so collected is applied “towards increasing the consumption of Ceylon tea in foreign lands in such manner as may from time to time be determined by the Joint Committee appointed for the purpose by the Planters' Association of Ceylon” and “by the Ceylon Chamber of Commerce,” now known as the “Thirty Committee,” subject to the approval of the Governor in Executive Council. Since the commencement of this arrangement the sum of R453,550.56 have been paid into the Bank for credit of the Ceylon Tea (New Markets) Fund up to the close of the past year. Of this sum according to the accounts kept in Ceylon £16,663 6s 10d equal to R282,847.17 had been drawn for by the present Ceylon Representative in America (Mr. Wm. Mackenzie) exclusive of local payments for tea samples, photographs, &c., while a sum aggregating R25,872.49 has been paid to Mr. M. Rogivue for disbursement in Russia on the lines laid down for this direction.

CEYLON TEA IN AMERICA.—As regards Mr. Mackenzie's work in America the following Report has been received written in the general tone, and which cannot fail to greatly interest all who have watched the progress of the tea campaign in the United States and in Canada. Mr. Mackenzie writes:—“As the day of the annual meeting of the Association is drawing near, it would perhaps be well that I should furnish you with some general notes of what has been done in America with the funds so liberally supplied to me during 1896.

Minute particulars with details of expenditure in a matter of this kind must necessarily be for the Committee only, as it is not advisable to disclose the dealings of any firms of Tea Merchants to every other rival. The Committee knows from my letters and from my accounts, exactly the lines in which I am working, and if they are satisfied, I feel certain the general body of planters have sufficient confidence in them, to allow details in the meantime to be between the Committee and me.

But without touching upon any point in a way to disclose their business, and thus offend any of the firms, energetically working with us, and on our behalf, it may be possible to describe generally what is being done in a way that may be of interest to the subscribers to the Fund, *i.e.* the whole planting community.

It must already be well-known to most Ceylon planters that the Americans are not a tea drinking people. In Britain the consumption of tea is 5½ lb. per head, of coffee, a fraction. In the States, tea is a little over 1 lb. per head, coffee between 8 and 9 lb. This may seem strange to those who still regard the Americans as "flesh of our flesh." That might have been true at one time, say even to fifty years ago. But the immigration of Germans, Austrians, Hungarians, Italians, Poles, and Swedes has been for many years very much greater than that of English, Scotch, and Irish. Last year's statistics of immigration show the number of arrivals of Italians for the year, as 57,000 and of Austrians and Hungarians 57,000. No other nation at all approaches these figures.

Then the descendants of the old English settlers in the east and south are well-known to resemble the French in having very small families. It is stated that two children of European descent are born for one of British in the U.S.

Another reason for the non-use of tea is, that it is generally *so bad* in the States, while coffee is universally better than in Britain. A Tea Merchant told me that when new factories were built in Buffalo some years ago, he did a very good trade *for a year*, with a lot of Irish and Scotch labours who were specially imported to work the factories. During the second year these customers of his dropped tea, and took to coffee and he gave me as the reason that they did not care for American tea (green) and found American coffee a delightful surprise. I have frequently heard it said that a *man* who drank tea was in America called a "Jenny," that is, was effeminate.

The following cases may be regarded as typical of at least four-fifths of the people of the States.

A gentleman who was born in America, of German extraction is agent for an English firm who are pushing our teas vigorously over there. He told me he drank *one cup of tea a week* on Sunday. His wife told me she had never tasted tea until her husband took it up 6 months ago. Since then he had several times made her try to drink a blend of Ceylon and Indian tea, but that she always felt sick when she took a mouthful, and had to give it up.

This gentleman introduced me to one of his travellers, whose duty it was to push the tea. I asked him how he liked our tea. He said that he thought the best way to arrive at an opinion as to its chances with American people was, to try to get his father, mother, sisters, brothers and cousins (twelve in all,) who were tea-drinkers to use it. He took home a packet, carefully attended to directions as to boiling water, quantity of tea, and time of steeping &c. and got all to take a cup. He told them they would not like it at first but induced them to persevere. On the third day the father said "Tom, if it will do you any good, I'll go on drinking this tea, but it is horrible." The mother refused to drink any more of it, whether Tom benefited or not: and the other relations insisted on going back to the old green variety.

Now, those people had an object in trying to drink our tea, but they could not overcome their dislike. What chance have we then with those who have no such object? These cases are not singular, I could give many similar experiences among those whom I gave some tea with directions for making &c.

Among black tea drinkers—a fifth of the population—our progress is easy. But to the majority—the vast majority—green tea and coffee drinkers, a cup of our tea, especially as they make it—putting as much in the pot as they do of weak Japans and allowing it to draw 10 to 20 minutes, is as nauseous as *margosa* oil would be to a Planter! No wonder an American Doctor by whose family I got our tea used for 12 months, told me last month that unless carefully made and drunk within a few minutes it *was poisonous*. We would all think it abominable if we made it, as Americans make their tea.

Any unprejudiced person must see from the above that beyond the region in which black tea is drunk, our progress must be very slow. The question is, if we are to persevere, what is the best method to pursue. A proverb says "you may take the horse

to the water, but how are you to make him drink?" I see one Ceylon Paper repeatedly has advised that the whole Fund should be spent in Press advertising, that is in *letting the horse know the water exists somewhere*.

In America, editors of Journals, A & B, say that the rival Editors of Journals, C & D, believe that when they (the latter) are engaged in sneezing Providence kindly halts. The former Editors admit the halting, but not that it is to Editors of C & D that the consideration is extended! The Press is powerful, but even if it made a few ask for an article advertised, it cannot make merchants interested in a rival article hold it. That is of course, unless the funds at the disposal of the Advertiser are practically unlimited. The matter was settled long ago as far as we are concerned. The Committee may remember that I had a difference of opinion with advertising Agents last year as to the best means of spending our Fund. They naturally said *in the Press through them*. My enquiries elsewhere led me to believe differently. The Agents proposed to leave the matter to be decided by a gentleman known to them, who was acknowledged to be the smartest advertiser of Grocery Articles in New York. This gentleman kindly agreed to judge between us. I allowed the Agents to state the case, which they did quite fairly. The expert's decision was in my favor. He said if your Fund is £100,000 go to the consumer through the Press and otherwise, but with £10,000 only, you must "interest" the Trade.

Since then I see the advice given is "leave all to private enterprise. If you interest part of the Trade, you create jealousy among the others." Those we assist are Firms who do Educational Missionary work in many large towns and even in villages, by having tea stalls in grocers' stores, at Church Fairs, Ladies' Charity Meetings, bazaars etc. by supplying house to house canvassers, distributing samples, circulars, pamphlets, instructions for making &c., and who, when making those efforts in any centre, advertise in the local papers at the same time. It is by such means that every new article of food is introduced in America. Americans are great celebrators. Every local centre has many events which are "celebrated" yearly, and such gatherings afford opportunities for exhibiting our tea, a baking powder, a new cereal product, &c. It would be quite impossible for the two associations to make use of one-tenth of such occasions as are turned to account by our numerous allies.

Last year, 1895, and in the early months of 96 we did a deal of such work, because at that time, our friends were comparatively few. But our efforts, besides being necessarily few, were of much less avail than those of firms because we were not tea-dealers, and could only refer enquirers to their grocers, who nine times out of ten either had none of our tea or sold them some Chinese mixture instead. Large wholesale firms "demonstrating" our tea, can refer enquirers to hundreds of grocers in every large town, where their blends and packets are handled. The girls in charge of these demonstrations teach the people *how to make the tea*, and show them that it is palatable, as made by them. They give away samples &c. The wholesale firms shift these demonstrations from shop to shop. Unless something of this sort is done, grocers will not hold the tea to give it a chance.

Now all this "demonstration" is expensive, and unless we assisted those who undertake it, it would not be done for our tea. The strong firms now working for us, would push the trade in America just the same, but it would naturally be a trade in teas which are generally drunk, which would require little or no demonstration, and which while giving much less trouble, would yield a higher profit. What object would they have in pushing British grown teas at a vast amount of trouble and expense, when an open field is there for them to supply the existing demand for green and unfermented leaf.

I feel certain that if we withdraw aid entirely now, these firms would naturally slip into supplying such teas as the people want. What is there in our

tea that we should expect merchants to lose thousands of pound in pushing it, when they could make a profit by supplying other tea? Many of those helping us, do so because they believe they will eventually recoup their immediate losses, being the first in a trade which they foresee our effort will make, if we persevere. It is not so much because of the amount we can give in aid of their work, as because they know if they do not fall in with us, their rivals will. This is clearly shown by a circular addressed by a leading American firm to their 16,000 grocer customers, in which they say they are obliged to put up a packet of Ceylon and Indian tea because "English packers" assisted by the Association would otherwise get 1-10th of their trade. *That tenth*, they say, is practically all the black tea drunk in America. The balance being green or unfermented teas. The Chairman has copy of this circular.

Jealousy and rivalry are elements of all trade—little would be done were everybody content. I am glad we have created those feelings in America, and I do not believe we have created them in Colombo. True much of the tea sold by our strong London allies may be bought in London, and much of that used by our numerous American friends may be bought in London or New York. It may also be true that Colombo firms would like get to those orders, and that some of them are jealous in consequence. But the tax from which the Fund comes is paid by the growers and is intended to benefit the planters—not the numerous petty Agencies which may exist in Colombo. Agents or Colombo Merchants are so much mixed up with planters as Shareholders and Directors of Companies, that may be difficult to separate their interests. But I feel certain such firms as Messrs. George Stuart & Co., Messrs. Robertson & Co., Bosanquet & Co., Whittall & Co., &c. are not in any way jealous of London or American Houses who, at an expense three to six times greater than our subsidies, do all the educational work now going on in America. If there are Firms "consumed with jealousy," why do they not engage in this work themselves and come in for some crumbs from the fund? At present they only execute orders. Now I take it, our Fund was intended to create a demand—not to subsidize such as merely execute orders.

When the planters see no further use for the "Cess," let them get it withdrawn by all means, but they should not be influenced by insinuations of jealousy. I have entered at length in this phase of the subject, because I notice an effort has been made to create disunion and disaffection. But if it be true as I see in the Colombo papers that the Committee has granted £12,000 for America in 1897, it proves that the gentlemen forming the Committee believe the methods I have pursued to be such as we may expect to produce results. But I shall welcome suggestions reduced to what the Americans call "practical propositions" believing that *definition* would do more good than vague *denunciation*.

As to the results of our work so far it is difficult to speak with confidence as to actual figures. I believe myself that the consumption of our teas in 1896 was double that of 1894 I say *consumption not importation*, because we began 1896 with a large stock in hand in America. The Presidential Election too upset trade in 1896, so much that few Merchants would touch a new article. But during the last three months, I believe it will be found, that the exports to America from London, Calcutta, and Colombo were very large indeed.

Whatever may be results, I can speak confidently of the *great extension of the efforts made in 1896*—especially during the last eight months of the year, to introduce our teas into Stores, to open up new fields for them, and to make them known to consumers in all States East of Chicago. And these efforts have undoubtedly been attended with great success. Some Wholesale firms have now several hundreds of Grocers in each of several large towns, selling our teas. I could tell much more in this direction were it not that I think it better not to publish details of other people's business. But the Committee are in possession of a mass of information bearing on the point,

and a few words from the Chairman will suffice to satisfy the subscribers that their money is not being wasted.

I may give a few instances of what is being done. In one very large Store recently built in New York, six rival firms had stalls for weeks, where our teas were exhibited. That is the girls in de tea, offered it to customers, who entered the store, gave away samples, circulars &c. In another rival store close to this one there were three stalls running last month. In Chicago I found one store with four. In Philadelphia I saw the best exhibit of the kind I met anywhere. One of our strongest allies—an American Firm—had an enormous booth in a Food Show—about a quarter of the immense Hall—beautifully decorated with palms, flags &c. where a lady well known in Ceylon with 14 *girl assistants* welcomed all comers to taste a cup of pure Ceylon or Indian tea. The place was crowded daily.

All towns are not as large as New York, Chicago, or Philadelphia, but in many towns on a scale in proportion to population, this sort of thing is going on constantly. Wherever we can get this kind of work done in a town by two or three whole-sale houses simultaneously, we draw the attention of the public by advertisements in the daily press. We have recently taken up Buffalo and Pittsburg, and are arranging for extending to three other towns at once.

We advertise in 22 leading papers in the Eastern States, besides numerous magazines, and ladies' newspapers.

I may here be allowed to sound a note of warning. Whether it be that *quantity* rather than *quality* is now the aim of most Ceylon planters, or that the teas are really deteriorating, I cannot decide, but no one can deny that compared with teas from India, Ceylon teas are rapidly falling in value. Broken pekoes are no longer in request. Coarser leaf teas are used in blends to bring down the average cost to the blender, while Indian teas supply the point and quality. Ceylon teas are quoted 5d to 6d, dangerously near the price of Chinas.

Our best customer in America has written to me that the largest American Tea Firm—hitherto unapproachable by us, has sent him samples of machine-made China tea as a substitute for Ceylons. He says they are very like Ceylon broken pekoes in style, but fail in cup qualities. He adds they may well "interrupt" the sale of our teas to inexperienced dealers. Everything points to this, that *quality not quantity should be the aim of all in 1897*.

CEYLON TEA IN RUSSIA.—Letters recently published together with statements of accounts, received from Mr. M. Rogivue have already supplied all information possible, and as these papers will be included in the Book of Proceedings of the year it is unnecessary to recapitulate their contents. They afford evidence, however, if evidence were wanted, that vigorous efforts should continue to be made to make known Ceylon tea in the vast Empire of Russia, and that steps should be devised as soon as possible largely to increase the demand for Ceylon tea by that tea drinking nation.

In view of the large area of the country to be worked, and the great value of the trade, if acquired, it may be necessary to supplement Mr. Rogivue's efforts by independent agencies. No one man, however energetic, can cope with trade of the whole empire, and no efforts I should be spared to interest those already engaged in tea in our produce.

CEYLON TEA AT INTERNATIONAL EXHIBITION AT GENEVA.—With a view to following up previous small grants to different applicants who had been pushing the sale of Ceylon tea on Switzerland, and on the recommendation of Mr. Wm. Mackenzie a sum of £200 sterling was paid to Messrs. Tetley & Co., who had represented that the Geneva International Exhibition would afford a most favourable opportunity to push Ceylon tea in Switzerland and the neighbouring countries. It was proposed that Messrs. Tetley & Co. should share with two Swiss firms a chalet to be erected in the grounds. In this chalet they

were to have an attractive tea exhibit and by infusing Ceylon tea to enable all visitors to judge of its superiority over the China tea, most of them had been in the habit of drinking. They stated further that they anticipated so good results that they had made arrangements for appointing agents in all the principal towns in Switzerland, and that they contemplated doing so also in the nearer towns which lie outside the frontier. In acknowledging receipt of the £200 paid to them through the Secretary, the Ceylon Association in London, Messrs. Tetley & Co. intimated that they would furnish full particulars of what they had done for the information of the "Thirty Committee." So far the promised report has not been received, and attention has been drawn to the matter.

CEYLON TEA AT THE EMPIRE OF INDIA AND CEYLON EXHIBITION LONDON, 1896.—At the request of Mr. E. E. Green, it was decided to support him in his application for support in connection with the concession he hoped to secure for a Ceylon tea house at the Empire of India and Ceylon Exhibition 1896; but unfortunately Mr Green had to withdraw his application owing to the action of the Exhibition Directors.

CEYLON TEA IN NORWAY.—During the year a grant was made of 300 lb. of Ceylon tea for free distribution in Norway by Mr. A. Floor at Bergen, while a grant of 200 lb. was also made to Mr. Paliser for free distribution, in various towns and districts in Norway.

CEYLON TEA IN BELGIUM AND HOLLAND.—On the application of Mr. E. R. Templer—who was well recommended—a grant of 1,000 lb. Ceylon tea was made to him on terms together with a sum of £25 sterling to be extended in advertising Ceylon tea in Belgium and Holland.

CEYLON TEA ON THE CONTINENT OF EUROPE: MR. R. V. WEBSTER'S APPLICATION.—In response to Mr. R. V. Webster's offer to distribute samples of Ceylon tea in bulk and packets throughout the Continent of Europe, provided the "Thirty Committee" gave him some support in advertising, a sum of £500 sterling was granted to him for the purpose indicated. Mr. Webster intimating that he will hold details of expenditure at the disposal of the Committee.

CEYLON TEA IN AUSTRIA AND HUNGARY.—During the past year various applications have been received for grants in connection with pushing Ceylon tea in Austria and Hungary, but so far exaction has been referred.

FINANCES.—The usual abstract of accounts for the half-yearly periods ended 30th June 1896, and 31st December 1896, are appended.

Kandy, 31st December 1896.

JADOO AND NITRAGIN.

The Principal of the School of Agriculture writes:—

"I send you a sample of Jadoo Fibre, the new 'growing medium,' which has been well spoken of. The manufacturers in Exeter have been good enough to send me 10 bales for trial, and I shall be glad to supply those interested in jadoo with small quantities for trial on their own account.

"I also send you a specimen bottle of 'nitragin,' or pure cultivation bacteria for leguminous crops, which has been sent me by the manufacturers. The parcel from Germany should have reached me more than a month ago, but through an error, was sent to the Sanitary Officer, with whom it has been for some weeks. The accompanying copy of the 'Agricultural Magazine' contains on page 55 the directions for use of nitragin." Both of these samples can be seen at our office by any one interested. As the instructions referred to are, like all in the useful "Agricultural Magazine," embodied in our *Tropical Agriculturist*, we need not repeat them in the *Observer*.

THE INDIAN AND CEYLON TEA CROPS.

A merchant lately asked us:—

“Is there any ready means of comparing the total grading of Ceylon teas with Indian, for, say, a year? This might give an indication as to which country plucks finest, and possibly accounts for difference in rates.”

The only information we can get is from a tea-dealer who says that the proportion of “fine” Indian teas (Darjeelings, &c.) is ten per cent of the total Indian crop; while the proportion of “fine” Ceylons (Nuwara Eliya, &c.) is only 3 per cent of the Ceylon crop. If this be correct, it certainly explains to some extent the higher average for Indian tea; but would it not be possible to work out the total quantity of Broken Pekoes and Pekoes in the Indian and Ceylon sales for a year in order to offer a further comparison?

While on this subject we may quote the somewhat epigrammatic and contradictory statement of an old resident who follows the local tea industry very closely:—

“ ——— is the exponent of quantity versus quality. If we all did what he does 150,000,000 lb. would be the export of Ceylon tea for 1898. If we go in for quality, the dealers will have us on the hop, and give us ordinary prices for it and then import cheap tea from China to mix with it. It is our common teas that have enabled us to chuck China tea out of consumption.”

INDIA RUBBER FOR CEYLON PLANTERS.

“J. M.’s” letter in another column appears at the right time. We feel that it was a great omission in the Planters’ Association Report that no reference was made to rubber, and, we trust our suggestion as to collecting information on this and other minor products, from the District Associations, will be adopted another year. Meantime, it is of interest to know that very shortly a series of experiments in harvesting rubber is to be undertaken at the Henaratgoda Gardens and that the results are to be carefully noted and published for the guidance and, we trust, encouragement of planters. Every year, too, should make the areas cultivated with rubber under the direction of the Forest Department, more interesting, and it should soon be time to institute tapping experiments, so as to judge year by year, what is the best and most profitable time and mode to harvest the crop. Then if planters, with an appreciable number of rubber trees or creepers and a certain amount of experience in cultivation and harvesting, will but tell us of the same, briefly and to the point, we shall indeed be able to put forward more reliable information as to the present position of Rubber-growing in Ceylon. The importance of the industry as one of the few products, for which there is an ever-growing demand, cannot be over-estimated.

THE CULTIVATION OF RUBBER IN CEYLON.

Kandy, Feb. 2.

DEAR SIR,—It is much to be desired that we should hear more about rubber and its cultivation from all who have information to impart, such as those experimenting in Ceylon and those who are directors of such establishments as the Peradeniya Botanical Gardens. It would indeed be a very appropriate time for Mr. Willis to strike his first note.

Some time ago attention was called in your columns to Mr. Rowland W. Cater’s communi-

cation to *Chamber’s Journal* on *castilloa* rubber and I see in the *Standard* of 29th January an interesting article upon “The Rubber Industry” commencing with the recent discovery of the Germans in their Cameroon possessions, of a prolific rubber yielding tree *Kickxia Africana*. It is said that the value of the export from Lagos was £324 6s 4d in 1894 and £269,893 in 1895 all from this *Kickxia Africana*. In the *Standard* reference is made to efforts of Indian and Ceylon Governments and Ceylon planters to ascertain if the cultivation of rubber can be made profitable and speaks of the experiments of Ceylon planters not being remarkably successful, though finest varieties were introduced, and it states that “it is not uncommon still to hear of coffee planters in Ceylon and others in India laying out their estates in rubber!”

I do not think the introduction of the best varieties was on a large enough scale or has had sufficient time for very complete proof of success over an area of large extent.

The advantage of cultivation in respect to best varieties, accessibility of cheap labour, purity, and careful preparation as opposed to collecting in primeval forests—under disadvantages, that involve destruction of the trees, and after mixing with foreign matter and at much cost,—may be so great as to justify more attention to the matter than has hitherto been given here.

Mr. Cater’s article “Out with the Indian Rubber Gatherers” is valuable for information of various sorts; but when he gives the figure of estimate of a plantation of *castilloa elastica* at Nicaragua with its results in 8 years it makes one wonder whether we have not neglected our opportunities in Ceylon. Having taken his selling basis on 2s a lb. only, calculating his trees planted 15 feet apart, included the premium of 3d per tree paid by the Government, wages of tapping at over 1s 3d per diem, he brings the following result of a 500 acre clearing at Nicaragua:—

	£
Cost of 500 acres of land at 5s p. acre ..	125
Survey and procuring titles thereto ..	100
Clearing land for planting ..	1,000
Collecting seed and planting ..	500
Eight yearly weedings at £200 each ..	1,600
Extras, implements, &c., &c. ..	300
	£3,625

Interest on £3,625 eight years at 5 per cent p. acre ..	1,450
Planters expenses, cost of living &c., per eight year at £200 per annum ..	1,600
Cost of gathering the 8th years crop ..	1,500
	£8,175

But his estimate of profit per acre at the 8th year is as follows:—

Dr.		£	s.	d.
Cost of cultivation eight years 193 trees p. acre ..			7	4
Cost of tapping or harvesting ..			3	0
Balance of profit ..			88	13
			98	18
Cr.				
Government premium ..		£	s.	d.
Yield 965 lb. per tree at 2s ..			2	8
			96	10
			98	18

So that on 500 acres the profit would be £44,337.10.
If this is not satisfactory—go on to the next—the
9th year.

£	£
200 for weeding	Value of crop in 9th year 50,000.
1,500 for harvesting	
500 for planting	
180 for interest	
47,620 profit	

50,000 Profit would be £47,620.

His report of yield of the *castilloa elastica* in Nicaragua is interesting in view of the late Dr. Trimen's somewhat adverse report on the yield in Ceylon.

The trees at Wiharagama, Matale, seeded very freely and it is much to be regretted that on no proper scale has experiment been made with this variety. J. M.

THE COCAINE HABIT.

The increase of inebriety from the use of cocaine is the theme of an article in the *British Medical Journal*. The article points out that the greatest number of victims is to be found among society women and among women who have adopted literature as a profession; and there is no doubt that a considerable proportion of cocaineists have fallen under the dominion of the drug from a desire to stimulate their powers of imagination. Others have acquired that habit quite innocently from taking coca wines fortified with salts of the alkaloid in solution. It is stated that at Manchester, Kentucky, the cocaine habit has recently assumed the proportions of a veritable epidemic, and that thousands of people are suffering from it. The evil commenced with a local druggist, who advertised a popular remedy for catarrh, which was found on investigation to be a mixture of menthol and cocaine. There was a sudden demand for it, and it was taken to such an extent that many of the victims had to be accommodated in the public lunatic asylum. The symptoms experienced by the victims of the cocaine habit are illusions of sight and hearing, neuro-muscular irritability, and localised anaesthesia. After a time insomnia supervenes, and the patient displays a curious hesitancy and an inability to arrive at a decision on even the most trivial matter. In Paris the use of the hypodermic syringe both for the administration of cocaine and morphine is extremely common, and there are establishments to which ladies of fashion resort periodically in order to have the accustomed stimulant administered. According to the authority we have quoted coca wines made from cocaine and cocaine lozenges and tablets should be supplied with the utmost caution.—*H. & C. Mail*.

PLANTING IN NORTH BORNEO IN 1896.

(*B.N. Borneo Herald*, Jan. 16.)

Cultivation (SANDAKAN DISTRICT).—At the Byte Estate about 160 acres are under coffee. Crop for 1896 piculs 532 against 300 during 1895. During the year the B.N.B. Development Corporation extended their coffee planting by 130 acres. They also sold 200 acres to Col. Molloy of which 50 acres have been planted with coffee and 10 acres with coconuts. A Chinaman who has bought land at the Byte has also planted about 30 acres with gambier. Kabeli estate (Coffee).—70 acres. Crop for 1896 piculs 102 against piculs 40.50 for 1895. About 25 acres more has been planted with coffee during the past year. Loong Piasow Syndicate's estate (Coffee)—70 acres. Crop for 1896 piculs 52.73, first bearing.

COCONUTS.—A considerable number have been planted at both Byte and Kabeli estates during the past year. The three year coconuts at the Byte are now in bearing.

MANILA HEMP.—Practically nothing has been done at the above estates with this during the past year, on account of want of skilled workmen. Under this head however, must be noted the 300 acres now being cleared and planted on behalf of the Dawson Syndicate, Glasgow. Despite troublesome or dishonest Chinese contractors, and the usual coolie troubles a large area has been cleared and burned, and the plantation is looking good enough to satisfy the most exigent speculators.

TOBACCO.—As regards the tobacco estates the news from Lahat Datu is very good, there being a large crop and of good quality. On Batu Putih and Bibit the average is 4 piculs. Koyah and Lamag shew a higher production.

KUDAT DISTRICT.—The prosperity of the different cultivations in the Kudat District becomes more and more marked.

THE TOBACCO CROPS have been uniformly heavy and good in quality and search for more tobacco land by companies new to the district is being carried on with energy and success.

COFFEE is receiving attention by the Chinese Hakka settlers, many small acreages having been taken up and planted to the North of Kudat town while the plantations under European management have done well. The areas under cultivation have been extended and new land selected, and it is believed that coffee has become a permanent item of export. The soil is proved to be eminently suited for this cultivation, and there is abundant room for additional ventures.

COCONUT, LIMES AND ORANGES have yielded good crops and coconuts especially are being largely planted.

(Other Estates) **COFFEE.**—In reviewing coffee for the past year the only matter to regret is that operations have not been more extended. This is certainly not owing to lack of confidence of those engaged in coffee but simply the result of limited means at disposal and difficulty of getting outside capital. The new plantings for the year probably do not exceed 3 to 400 acres all told. We should be glad to see our local estates formulate systematic records of their crops, as from personal observation we are convinced that such figures could be shewn as would astonish outsiders.

COCONUTS.—New plantings are not in bearing with the exception of some of the 3 year variety on the Byte Estate. The avidity with which the coconut consignments from Cagayan Sooloo are bought up by our Chinese traders for manufacture of copra, and promises a good local market. The total as planted by Europeans in Sandakan neighbourhood is probably not far short of 800 acres.

TIMBER.—In the earlier part of the year the Hong-kong trade was very encouraging to shippers and led to an extra regular steamer being put on the run. Unfortunately the last quarter shewed stagnation and collapse in prices. The moral is that shippers must not confine themselves to one market. The eagerly looked for era of "the opening up of China" has not yet dawned although we have the preliminary symptoms. There can however be no question as to the opportunity offered for Borneo timber when that does occur.

COFFEE-PLANTING IN NEW HEBRIDES.—We have had a call today from a Jamaica-born Scotsman—for Mr. Girvin's name clearly indicates an Ayrshire origin from Girvan—who has been for three years planting coffee in the New Hebrides, but who is now on his way to Europe with a view eventually to settling down in British Central Africa. Mr. Girvin reports about 2,000 acres of coffee planted in the New Hebrides, chiefly owned by one French and one Anglo-Australian Company; but the chief difficulty is labour, the islanders being very unwilling to do much work.

THE MAZAWATTE TEA COMPANY.

The first general meeting of Mazawatte Tea Company, Limited, was held on Friday, at the Cannon-street Hotel. Mr. John Lane Densham (one of the managing directors) presided.—The Chairman, in moving the adoption of the report, expressed his great pleasure at seeing so large a gathering. The first thing he should like to mention was the pleasing duty the directors had in reporting the continued progress of the business. The expansion of the trade had been evidenced in all parts of the United Kingdom. Their tea was not only drunk in every part of Great Britain and Ireland, but he might say it was taken from Norway and Sweden to South Africa and to Anstralia and West Indies. That year they had been able to pay £15,000 to the vendors, at the rate of 5 per cent on the capital up to some time in July. They had also been to wipe out all expenses for extra advertising. Tea was taken more in agricultural districts than in other places. He looked forward to a very profitable year.—Mr. B. Densham (the other managing director) seconded the report.—Mr. Vickery (a shareholder) suggested that as they were in such a flourishing condition they should send £200 to the Lord Mayor for the Indian Famine Fund. (Hear, hear.) He thought they could afford to be generous. The Chairman mentioned that, owing to there having been a collection in the tea trade, this question had been considered, and it was thought that it would not be a right thing for a company so snbscribe. He and his brother had sent a cheque privately from their own pockets, but he would oppose a company like that giving a donation, no matter how good the object. He felt very strongly on the subject.—Mr. Vickery intimated his intention of moving a resolution on the subject, but it seemed to be the general wish of the meeting that he should not do so, and he resumed his seat.—On the motion of Mr. Vane, seconded by Mr. Duke Dyke, it was agreed that a dividend on the preference shares at the rate of £5 per cent. per annum, and a dividend upon the ordinary shares at the rate of £8 per cent. per annum for the half-year euded December 21 last, be declared.—Other business was transacted, and after a vote of thanks to the chairman the meeting terminated.

NEW COMPANIES REGISTERED.

CEYLON PROPRIETARY TEA ESTATES COMPANY LIMITED.

Registered January 20, by Murray, Hitchins, Stirling, and Murray, 11, Birch-lane, E.C., with a capital of £160,000 in £1 shares. Object, to purchase, take on lease, hire, or otherwise acquire any tea or other estates or lands or hereditaments of any kind in Ceylon or elsewhere, and any machinery, works, stock, and plant, and real or personal, immoveable or moveable estate or property of any kind and wheresoever situate, including concessions or easements of any kind; to hold, use, cultivate, work, manage improve, carry on, and develop the undertaking, lands, and real and personal estate, or property and assets of any kind of the company, or a'y part thereof; to plant, grow, produce, and deal in tea, coffee, cinchona, cocoa, cardamoms, and other plants, trees, and natural products of any kind in Ceylon or elsewhere; to work mines or quarries and to find, win, get, work, crush, smelt manufacturer, and deal with ores, metals, minerals, oils, precious stones, &c. CENTRAL PROVINCE CEYLON TEA COMPANY, LIMITED.

Registered January 20, by Budd & Co., 24, Ausin-friars, E.C., with a capital of £100,000 in £10 shares. Object, to adopt and carry into effect four agreements made respectively between H. P. Powell, S. R. Pryor, and F. M. Mackwood, and the Company; with H. E. Millar and the Company; with E. M. Smith and the Company; and with T. M. Mackwood; and to establish and maintain any mills, factories, or works, or any interest therein, and in particular tea, coffee, and cocoa factories for treating any produce of Ceylon or the East Indies, or any other part of the world; for manufacturing and dealing with the same; as merchants, storekeepers, planters, commission or other agents, manufacturers, shipowners, carriers, warehousemen, wharfingers, underwriters, contractors, and engineers; to acquire and turn to account any oil wells; as miners and smelters, &c. THE DUTY ON TEA AND WAREHOUSE ABUSES.

To the Editor of *The Home and Colonial Mail*.

SIR,—I understand the Indian Tea Association of Calcutta have passed a resolution in favour of the reduction or abolition of the import duty on tea, and have forwarded an earnest appeal to the Association in London to use their best efforts towards the attainment of this end. It is to be hoped the council of our Association may give the matter that independent and through investigation and consideration to which it is entitled, and act for the best interests of the producer and consumer.

Let us consider this important question in some of its bearings. It is sometimes urged that the duty properly acts as a premium on *quality* and that its abolition or further reduction would unduly encourage the production of common and low-class teas. But the changes under discussion could never unfairly discourage the manufacture of the fine teas, because it never can be otherwise than for the benefit of gardens, with the soil and conditions favourable to their production, to aim at the highest quality. On the other hand, abolition or reduction can be no more than fair to gardens wanting in the natural advantages for the growth of prime quality teas, which all over India must always constitute the vast majority. The duty undoubtedly favours the minority with nature on the side of quality, and unfairly handicaps the great majority of concerns only capable, with the utmost skill and care, of turning out teas exquisite make, it may be, but withal of medium quality. This is beyond dispute. To put it plainly, "stand-out" and high-class teas can afford to be watered by duty, so to speak, to an extent that common and medium teas cannot. This is demonstrated by a very simple formula as given below.

Doubtless, abolition or material reduction of duty would unjustly favour the poorer teas from China or Japan. This may not be viewed with apprehension just at present. It would, however, if the China trade should revive, in which case the equitable adjustment (though probably more than need be looked for under our free trade policy) would be continuance of duty in case of repeal, or otherwise differential duty on non-British-grown imports, which is required to compensate the imperial producer to the extent he is handicapped against free silver countries through the operation of existing Indian exchange and currency regulations.

It would seem no more than fair to reduce the tea duty to 2d per lb. as in the case of coffee. This could not fail to prove a boon to the great bulk of the population of these isles, and lead to an increase of consumption, so that the loss to the Exchequer would not be great. It is sometimes asserted that consumption has already reached its limit, but if we reflect what the consumption of an ordinary household with servants (but exclusive of guests) is—probably considerably over double the average consumption per head of the population, making full allowance for the coffee and other beverages used—it would seem reasonable to calculate that if tea were cheaper the consumption per head would soon rise to, or even exceed, that of the Australian colonies at present.

As the duty affects the consumer, the case may be stated, not to go to extremes, as follows:—For *quality* tea 1s 8d, plus duty 4d, equals 2s per lb; on the other hand, for *common* tea 8d, plus duty 4d, equals 1s per lb. In the former case the purchaser has to pay one-sixth of his money, for which he receives no value in tea in the latter one-third of his money goes in that way. Here I, of course, take no account of the profits of the dealer, middleman, or grocer, which may likewise weigh proportionately against the lower-priced teas. It is also well-known that in “stand-out” teas 1d per lb of extra quality often adds 4d to 6d per lb. to the price at public auction. This while in no way benefits the great bulk of producers, is doubtless to some extent fostered by the duty. It may be contended, therefore, that an *ad valorem* duty would be fairest, but its collection would doubtless prove much less convenient for all concerned. In the interest of the great body of producers it is to be hoped, however, that any further material or permanent fall in the retail price of tea is to come from reduction of duty, or it may be of profits on this side.

The strongest objection urged against abolition is the withdrawal of the customs' supervision, and the consequent risk of adulteration and the flooding of the markets with spurious teas. But there is not the same temptation to do this with tea at its present price, as there would have been twenty-five years ago; and many large dealers are of opinion that the Adulteration Acts in force alone afford ample security against adulteration.

But one thing about which there is absolute certainty is, that any advantage, however great from the customs' supervision, is more than counterbalanced by the injury to the tea industry from the objectionable treatment the teas receive in the bonded warehouses. This need not be enlarged upon here, as the subject has formerly been touched upon in these columns, and may, it is to be hoped, be dealt with more fully on some future occasion. All that need be remarked is, that if teas were exposed to the moist atmosphere in bulking, and, worse than this, left unsold by the manufacturer, as is the practice in the warehouses, they would be absolutely ruined, and we cannot with a clean conscience go in for the conquest of new markets boasting of machine manipulation throughout, and entire freedom from objectionable handling, so long as the teas are trampled into the chests by the dock labourer on refilling.

For Imperial considerations, however, abolition would seem a mistake. The duty, though falling upon nearly all, and in some respects, as has been shown, more unfairly than it might, is but little felt. It is almost the only tax paid by abstainers and non-smokers, and it affords Government a means of increasing the revenue in any emergency, without causing dissatisfaction, as was done during the Crimean war. The objection to further reduction is that the net revenue would be unsatisfactory, as the cost of collection would remain the same; but why should this be urged in the case of tea more than coffee, cocoa, or chocolate?

As abolition does not seem desirable on patriotic grounds, and there may not be great hope of material reduction of duty, and whether or not it be decided to agitate for either, justice to the producer and also the consumer demands, without delay, the

most vigorous and persistent efforts on the part of the Association, until the desired reforms be secured in regard to the treatment of our teas in the bonded warehouses, which no one can deny is a discredit as well as an injustice to the British tea industry.

These warehouse abuses have doubtless grown up with and become linked to the Customs' supervision and regulations, and are to some extent due to the London representatives of the industry not having insisted upon certain details that ought to be carried out at the factories being attended to there. But the sooner reforms in those directions are pushed the better for the great body of producers, as the warehouse abuses may be continued (if strenuous and sustained efforts be not made to remove them) even after the repeal of duty and the withdrawal of the Customs' control.—I am, sir, yours, &c.,
PLANTER.

Feb. 3rd 1897.—*H. and C. Mail*, Feb 5.

THE RONDURA VALLEY TEA COMPANY OF CEYLON, LIMITED.

The first General Meeting of this Company was held at the registered office of the Company, No. 6, Prince street, Fort, Colombo, today when Messrs. A. E. Scovell, F. W. Bois and Alfred Scovell were reappointed Directors.

An Extraordinary General Meeting was afterwards held when the following resolutions were carried unanimously.

(1) To consider an offer made by the Yatiyantota Ceylon Tea Company, Limited, to purchase the Company's estates, called and known as Rondura, Broadlands, Yahaide, and Florence, as from 1st January, 1897, the price to be paid, after completion at the expense of the Rondura Valley Tea Company of Ceylon, Limited, of the factory and road, to be £33,230, payable as to £30,000 by the issue to the Rondura Valley Tea Company of Ceylon Limited, or its nominees, of 2,000 ordinary £10 shares of the Yatiyantota Ceylon Tea Company, Limited, at an issue price of £15 per share, the remaining £3,230 being paid in cash at current rate of exchange on date of transfer, for telegraphic remittances from London to Colombo.

That “that the Rondura Valley Tea Company of Ceylon, Limited be wound up voluntarily.” (Should such resolution be passed by the requisite majority, it will be submitted for confirmation at a second Extraordinary Meeting, which will duly convene.” By order of the Board of Directors J. M. ROBERTSON & Co., Agents and Secretaries.

VARIOUS PLANTING NOTES.

IPECACUANHA has been recommended by Father Banlez as a remedy for plague. Dr. Cantlie, in a paper on plague re-published by the Government of India, also recommends an emetic in the early stages of the disease.—*M. Mail*, Feb. 24.

DEAFNESS. An essay describing a really genuine Cure for Deafness, Ringing in Ears, &c., no matter how severe or long-standing, will be sent post free.—Artificial Eardrums and similar appliances entirely superseded. Address THOMAS KEMPE, VICTORIA CHAMBERS, 19, SOUTHAMPTON BUILDINGS, HOLBORN, LONDON.

THE MANURING OF TEA ESTATES : IN CONCLUSION.

The fourth, and final, batch of letters,—from the 36th to the 61st (see pages 619-624)—on the manuring of tea estates, remains to be reviewed in conclusion of the series. The letters are full of information and suggestion, and represent almost every part of the island in which tea is a leading product. Thus, in the first six of them, published on the 5th inst., we have "M." from a "High District," who tells us in a few words that manuring is getting to be general in the island, that about 15 to 20 per cent of the estates use artificial manures, as special facilities are necessary for securing bulky manure; that 2-3rds Castor to 1-3rd Bones is the usual proportion; and that, while he fears a good deal of soil must be washed away by manuring steep slopes, he thinks manuring increases the yield by 150 to 200 lb. per acre. Now, should it not be the endeavour of the careful husbandman, by terracing or otherwise, to reduce risk of the wash to a minimum, since it is the steep slopes that generally most need renewal of soil? "Kelani Valley" confirms "M"'s experience, that more is being done with Castor and Bones mixed in the mills, than with Bulky Manure; that though he commenced the use of artificial manures with misgiving, he is now a staunch advocate of manuring, as it improves the yield and also the appearance of the bushes; but he thinks the quantity of the tea suffers somewhat, and he fears that the water supply is injuriously affected, leading to the greater prevalence of typhoid. This is certainly a matter which demands attention, and if the fear is justified, special care should be taken to protect the water. The opinion that artificial manuring will need to be continued, at intervals, say of three years is shared by many planters, since otherwise the bush deteriorates. But why, if the treatment pays, should it ever be discontinued?

"*Equus in Arduis*," from an "old and medium elevation district," reports that manuring is very general in it, though not throughout the country; while at very high elevations, where transport is difficult, scarcely any manure is applied. The usual mixture is Castor and Bones, though Fish and Nitrates are not unknown. As regards good results, and the necessity of continuing manures when once begun, he agrees with the previous writer; while to the drawback of wash he adds the cost of weeding—a sign, surely, of enrichment of soil. "Manager" from West Matale disclaims experience for a positive opinion, as he has just begun manuring; but so far the results are highly satisfactory, the fields manured with bulk having yielded 950 lb. per acre and with artificial, mixed in Colombo, 1,050 lb. Nor has the price of the tea fallen. "T. Koko" from Wattegame has a similar tale to tell, of yield being doubled and more, by manuring, especially on old coffee land, though he suggests a careful mixture of artificial with bulk with plenty of soil, and he strongly deprecates the burying of prunings "as no tree feeds on its own refuse." We should wish to know how far this opinion is supported by scientific authority and practical experience. On what do forests thrive, but the vegetable mould formed of their own "refuse"—natural, taking the place of artificial, manuring? And are not coconut husks generally regarded as among the best manure for coconut trees? "L. A. W." pleads lack of experience; but he does not doubt the beneficial effects of manures, and fears their

application is too long delayed, especially in the lowcountry, while artificial alone can do little for worn-out estates.

In our issue of the 9th inst. "Z," from Matale reports very good results from the annual application for the last six years of cattle manure on 30 to 50 acres. It is not very clear whether the same field is meant throughout? If so, we suppose the reason for the annual application is that the land is worn out. "A Northern Planter," from Kandy, expresses confidence in manures, whether bulk or artificial, and observes an extension of manuring in the older districts with good results—550 to 600 lb. being harvested from systematically manured fields, against 300 to 350 lb. from unmanured. Last year adverse exchange restricted manuring; and it is doubted whether in a forcing climate, a very high jāt will respond as readily as a hybrid. From Udapussellawa, "Querist" can say nothing from personal experience, but he has been observant of his neighbour's operations, and he would like to see the experience of a period, say four years, recorded. So far, he learns quantity is decidedly increased without sacrificing quality; but he expresses hesitation about adopting artificial manuring "after the deadly effect that Matale manures had on our coffee, but particularly salts of sorts." Now, is there any real proof that our Coffee suffered in the manner indicated? If such disastrous results can be verified and localized, an expert should certainly be consulted regarding similar results with Tea. The tendency of W. J. G.'s verdict is against the manuring of vigorous Tea, giving a satisfactory yield; but in the old and worn-out districts, the benefit derived has been most marked; and yet again, he fears quality suffers from the rapid production of leaf. To manure vigorous plants with artificial manure, he considers tantamount to killing the goose that lays the golden egg.

On the 10th we published four letters—from "I," testifying to the beneficial effects and splendid results obtained by the application of bulky manure, wherever, available, expressing his conviction that manuring must spread, especially in the older districts and that no harm could come of regular applications at fair intervals. "Ouvah" from Badulla can speak, happily, only of the application of well-rooted bulky manure, with most satisfactory results as regards quantity and health of bushes; but he is unable to say anything about quality, and doubts if "artificial" can be applied regularly and then stopped without evil consequences. In a private letter, our correspondent, a planter of large experience and holding a very responsible position, fears that manuring is being done greatly in the dark, and thinks that an Agricultural Chemist might do a great deal of good to the country. Meanwhile, he warmly commends our efforts to collect information and focus results for the benefit of the planting community, and also we may add for the guidance and opinion of experts. "Senex" from Kotagala supports the generally beneficial results we have already noted, but thinks some care should be taken lest large doses of artificial manure, should tell on the flavour of the tea as the natural oils or scents of plants are known to be affected by cultivation; and he instances the wild carrot or celery. This is therefore peculiarly a matter for investigation by an expert, and strengthens our position in favour of an Agricultural Chemist. "B" from the Southern Province gives interesting figures which attest the excellent

increase of yield obtained by manuring, while the bushes and the wood stand out well.

In our issue of the 11th "G. T. R." from Udapussellawa strongly favours Cattle Manure as the best, but in its absence artificial has been applied with good results, and prunings were buried at the same time, and he counsels the practice! The interesting question he propounds is whether the quantity of artificial may not of necessity have to be increased after repeated applications, but will not that depend greatly on the soil? If the soil be worn-out and thin, it would be undoubted gain, to obtain remunerative returns from it, albeit only for a time. "J. B. C." from Kelani Valley supports the verdict in favour of manures on all grounds, and regrets that shortness of labour prevents larger applications. "C. H. B." from Udapussallawa, is also an advocate of manuring, but judiciously, and he especially deprecates over-stimulating. The older and more worn spots show more appreciable results. "S." from Talawakele takes a rather different view, and, pleading the shortness of life, would carry on liberal cultivation everywhere and on all soils, thus securing from 200 to 300 lb. per acre more than at present. This aspiration is controlled by the lack of labour, and, may we add, by the fear of over-production; but the problem he sets forth is one worthy of attention, whether we are not justified in forcing out of the bushes in 30 or 40 years what they will take 55 to 60 years to yield naturally. His advice as to caution, however, will receive more general support, as also the warning against cutting the larger roots. He scoffs at the notion of flavour being affected by a rich soil; but is there not a difference between a naturally rich soil and one artificially stimulated?

The fifty-ninth letter, and a very suggestive one it is, appeared on Saturday last from "C. T." from Ambaganuwa. He strongly advocates bulk, quoting results, and is rather suspicious of artificial manures, which however, is a necessity in most cases. Finally, we come to the 60th and 61st letters which close the series and are by no means the least important. Indeed the "Homo," who signs with a very proper Latin monition, and to whom we owe an apology for not sending him a circular in the first instance, is almost the only one who favours us with tabulated results of experiments carried on, evidently after a fashion that will delight the heart of Mr. John Hughes among others. "Homo" very properly reminds us of the many factors,—some of them apt to be overlooked—that ought to be taken into account, in cultivation; but he and "J. J." agree—like so many more—in giving the preference to "Castor cake and Bones" as, on the whole, yielding the best results.

In concluding this review we owe it to our friends to thank them very heartily for their contributions towards the solution of a very interesting and important problem, with which is intimately wound up the prosperity of the Island. We have another Circular "in pickle"!—indeed it is already in circulation and most valuable information on several points connected with tea cultivation and preparation has already reached us from many leading members of the planting community.

PRODUCE AND PLANTING.

INDIAN AND CEYLON TEAS IN THE UNITED STATES.—We referred last week to the increasing popularity of Indian and Ceylon teas in the United States. A prominent Philadelphia distributor who declined to

handle these teas at one time has recently published the following: "During the year 1896 there has been a most marvellous growth in the consumption and sale of Ceylon and Indian teas, principally, however, in packages under the proprietary brands and under the stimulus of proprietary enterprise. At the same time the sales of bulk India and Ceylon teas have largely increased. This is one of the strongest proofs that can be given of the value of judicious and well-conducted advertising, for had not these teas been advertised as well as they have been during the last year or so the sales probably would have been of an infinitesimal character. Now there is no question in my mind whatever but that the Ceylon teas and the Assam teas have come to stay. Not only are the people buying the teas, but they seem pleased with their aroma, their strength and colour, and their greatly nourishing qualities. In a blend with other teas they are productive of the most marvellous results in producing body, character, and good drawing qualities. The grocer of '97 who does not use to a greater or less extent in his business these machine-made, carefully prepared teas will surely drift to the rear. If the planters' associations keep up their fight for Ceylon and Indian teas they are bound to gain a strong foothold in the United States."

WHITE TEA.—The British Consul at Meshed (Persia) has a note in a recent report on this subject. He states that "white tea" is really nothing but common Pekoe, with a sprinkling of the unfermented sun-dried tips thrown in. Much care is required in preparing these silver tips, and a pound of them would cost perhaps 15 rupees. But even a sprinkling of them is sufficient to impart a very delicate perfume to any tea, and with this the Persians have been greatly taken. The brand sold is poor stuff, with only a slight odour, but the upper classes now use hardly any other, especially during ceremonial visits.

"BEAUTIFUL" CEYLON AND ITS TEA INDUSTRY.—In his lecture before the Society of Arts, referred to elsewhere, Sir Charles Dilke paid a high tribute to the planting enterprise of Ceylon, remarking that Ceylon, which was one of the most beautiful and one of the most interesting portions of the earth's surface, had more than recovered her prosperity through the brilliant enterprise with which the settlers had turned to the planting of a fine tea.

A COSTLY QUARREL.—There is a nice little struggle now in progress in New York between the Sugar Trust and Arbuckle Brothers, a very rich firm of coffee roasters. The New York correspondent of the *Grocer* describes the way it came about. He says: "The Arbuckles bought of the inventor a machiuo which automatically weighs sugar and puts it up into packages, which sugar the Arbuckles sold with their patent glazed coffee, put up in sealed packages, and sold under a proprietary label. For this machine they paid £20,000. They offered to sell it to the Sugar Trust for £50,000, but they refused to purchase. Then the Arbuckles decided to build a refinery, and make themselves independent of foreign or domestic refiners of sugar. In retaliation, parties, in the interest of the Trust, bought out the Woolson Coffee and Spico Mills of Toledo, Ohio, incorporated in 1882 with a capital of £20,000. This company made enormous profits, selling their shares at a price reported at £230. It is said the controlling interest cost the Sugar Trust's agents £252,000. The Arbuckles managed to buy in a secret manner sixty shares of stock (for which, it is said, £20,000 was paid), which move was to give them a position to demand all the knowledge and such rights as stockholders are entitled to receive. Some years ago the Arbuckles adopted a recipe of their mother's for keeping the flavour of coffee, which calls for a coating of the bean with a substance of an albuminous character, giving the coffee a glaze and practically hermetically sealing the bean. The sale increased enormously, and their brands obtained a foothold that no one could dislodge. Some idea of the magnitude of their business may be

gained from the fact that they imported in 1896 a total of 757,091 bags of Brazil coffee alone, or nearly 100,000,000 lb. It is claimed that they roast and distribute over 2,000 bags per day. This has been an enormously profitable business. Thirty years ago the South and West used only green coffee, and it took years to overcome the prejudice which consumers had towards coffee sold ready for use. They believed coffee should be roasted at home, and only as required, if its full aroma was to be retained. The Arbuckles' device insured the aroma, and soon the bulk of the trade. There are now three great roasting concerns. As soon as the Woolson Company changed hands the price of their coffee was reduced, which cut the Arbuckles net. Cut has followed cut, until 2½ cents per pound has been taken off. The fight is between giants, but Napoleon said, 'Heaven is on the side of the heaviest artillery.' The probable outcome will be the formation of a coffee-roasting trust and a compromise and treaty with the Sugar Trust, whereby both interests will go on peacefully and profitably. The Sugar Trust forced the fight from the date of the inception of the Arbuckles' plan for an independent refinery. At present the war is vigorous and costly, and hence is likely to be short-lived.—*H. & C. Mail*, Feb. 5.

TOBACCO—AND CEYLON PLANTERS.

How is it that while the natives—the Tamils especially—in so many districts, Negombo, Chilaw, Jaffna, Trincomalee, Uva and, we suppose, around Dumbura continue to cultivate tobacco profitably, the European planter should have cast it so much on one side? For the coarse native growth, a price equal to 25 cents each big leaf is, we believe, readily paid in the bazaars; and even, therefore, for the supply of the local demand, one would suppose plantation fields of tobacco would, in some places, prove profitable. With the object of getting the opinions on this point of the gentlemen who have had actual experience in our midst, of growing tobacco, we sent some notes of enquiry and the results we are now able to lay before our readers, in the following interesting communications. These were provoked, in the first place by the contributions of an expert, writing from Southern India in our columns some weeks back. His last letter we referred to local authorities and one of these challenged the expert's statement that Ceylon could produce "a very pure and high-class leaf," insisting instead that high-class leaf for cigars could not be produced here. Only on one estate was this ever done in Ceylon, we are assured. Another gentleman with some experience thought "Expert" wrote to the point and that he touched the key of the situation in the following:—

All that is necessary to ensure success is a thorough knowledge of growing and of manufacturing, coupled with businesslike management and the requisite capital.

This "and a railway to Jaffna" he thinks should ensure success to tobacco-growing. Does that mean that Jaffna land would be chosen by European capitalists—or that Jaffna men would be employed as cultivators? Here is how another resident writes:—

I am sorry that I can give you no information with reference to tobacco cultivation. There must surely be some good reason for the cultivation being abandoned by the Ceylon Tobacco Company when they had an experienced Sumatra Tobacco Planter to start and supervise the work. Then if, as was stated at the time, Messrs. Voilar and Gwatkin made such a good thing out of their tobacco, grown near Kandy, why did they not continue its cultivation? Why did Mr. Ingleton

fail to make both the cultivation of tobacco and manufacture of cigars pay?—should be able to give you some reliable information, also—and—who, I remember, was Superintendent of the Tobacco Company when the first crop of tobacco was secured. Where is the land to be got suitable for tobacco cultivation on any large scale? I know of none. I think a dry climate with a good North-East monsoon rainfall would suit it best, as that would dispense with watering and permit of the leaf maturing in dry weather. It has first however to be shown that tobacco can be profitably cultivated in Ceylon by Europeans; if that is once assured I think there would be no lack of men to try their fortune.

Here is the deliverance which Mr. Vollar himself kindly sends us:—

"I do not think the colony can do a big thing in cigar tobacco. There is no doubt we can grow first-rate cigar tobacco, but so far we have failed in the curing of the tobacco, and in the making of the cigars to have them mild enough—which is the thing that is wanted at home. There is no land available in the Central Province, and the soil in the Western is not suitable. Jaffna tobacco is too coarse and rank.

"If tobacco could be grown on the Eastern side and proper care taken in the curing and manufacture, it would, I think, pay well; but it's a very ticklish product to cure and so dependable on weather." Another tobacco authority takes a rather different view, although in the main equally discouraging:—

"I fear good tobacco suitable for the manufacture of cigars for the European taste cannot be produced in Ceylon. It is true Messrs. Vollar and Ingleton grew some fine tobacco in Dumbura eight or ten years ago which took attention at home; but in no other district in Ceylon was ever afterwards such tobacco grown and it had a very fair trial in several other districts as I know only too intimately, but without success. We cannot produce leaf thin enough in texture for the manufacture of cigars and no one will look at ours at home or on the Continent."

There is nothing like having all possible views from different quarters and the next local authority we are going to quote, has entered so fully into the matter that his letter is a little essay in itself:—

You ask me "why tobacco and cigar making don't do in Ceylon." I could reply by telling you why they did not do; but it might get me into hot water, so instead of giving a direct reply I jot down a few notes which may be useful.

There can be no question that under the guidance of capable energetic men, with the necessary skilled experience, and of course backed by sufficient capital and *pluck* to stand a few failures, Ceylon could yet compete successfully in the tobacco markets, though the recent failure of the Tobacco Company would deter many from venturing in the revival.

Stress may be laid on two if not three facts:—
1. Tobacco is a leaf product which, unlike tea, is more like a fruit, in its requiring specially favorable and seasonable weather for ripening, harvesting and handling. 2. That a very large labourforce is indispensable. 3. That freight *has* been a difficulty in the past, and I am not aware if that has been solved yet.

The opinion was expressed long ago that it was not a work for Europeans to engage in, and good reasons were given; but the same was said of coconuts! Nevertheless *no* work requires so much concentrated, constant, intelligent, individual, personal supervision. This may be a piling-up of adjectives, but it's a fact and the tobacco planter must be prepared to forego tennis, cricket, foot-

ball and "Mounted fut" during the busy season. You could not trust native overseers, as tea-makers are—nor your field conductors. Every work must be done as much as possible under your own eye, or a few hours of neglect may cause ruin after months of careful forethought and attention.

Most of the Ceylon (*though not all*) grown tobacco has been too strong and coarse for the English market. More men (*and children*) smoke than ever, and smokers consume more than ever, and want a mild weed, or they would smoke their heads off!

The failure of a Ceylon planter in establishing a demand for Ceylon-made cigars, after prolonged perseverance, deserving a better fate, was owing to (1), Tootightrolling. (2), Leaf too strong and coarse. (3) liquoring down (4) and certain ingredients to improve flavour, his own taste being for "grip" with flavour. The writer has smoked thousands of his cheroots, but found the muster uneven, sometimes only one good box out of four, but that one *was good!* Ten or twelve years ago,—made a beautiful large "Nona" brand, but men grunted at the price which was most unfair, and beating down the price led inevitably to inferior products! 'Tis so with everything now-a-days. It is folly to talk of "cheapness," but fools are plentiful according to Carlyle. Good quality must be supported by good prices. Surely our Tea history proves this. It's waste of time to enlarge upon so palpable a fact, and yet it will take generations more to drive this into men's and women's minds. Most of the Indian fancy work of today is inferior to that of 20 years ago. Brass-ware has not half the weight in it. Cotton goods are coarser. Good linen is a scarce article now. Tools and cutlery are vastly inferior, and as for note paper, it is awful. The ink soaks through and one can only write on one side of a note paper costing R1-25 per 5 quires. (That last gets over me, for you can buy capital note paper at home at 3^d per 5 quires!) The housewife who is always beating down the tradesman does more harm than she imagines to future generations. Who is to blame for so much of the sweating that goes on in Europe? But *revenons à nos moutons*. Good cigars need good baccy grown from selected seed in good land, under favourable circumstances as regards soil (rich in potash and lime and friable) lay, elevation, rainfall, shelter from wind, and suitable aspect, with an ample labour force irregularly employed.

In reply to your query therefore I ask where in Ceylon can these be got? And having grown and cured your tobacco will tea and baccy ship better than tea and apples?

I have shipped several thousands of Ceylon cheroots and also took home some thousands and went to friends in the wholesale trade; but utter failure was the result. To compete with Indian cheroots, they wanted Punchi Nonas at R15 per 1,000 f.o.b.!! Put that in your pipe and smoke it if you can; it made me turn worse than any mal-de-mer!

T. KOKO.

We shall now await with interest, the comments of our Indian tobacco expert on the above expressions of opinion by Ceylon planters.

THE CENTRAL PROVINCE CEYLON TEA COMPANY, LIMITED.

Regarding this Company whose registration we noticed in our last issue the prospectus states that it has been formed principally for the pur-

pose of acquiring, working, and developing the Estates mentioned in the following Report by Mr. Maekwood:—

November 2nd, 1896.

Messrs. Cotesworth & Powell, London.

Dear Sirs,—I engaged Messrs. C. Spearman Armstrong and Thomas Smith (of Dolosbage) to go over and report to me in detail upon the following properties:—

Barnagalla and Dedugalla Estates in Dolosbage district. Goonambil and Eriagastenne and $\frac{1}{2}$ Raxawa in Pangwella district. Wayweitalawa in Ambagamuwa district. Berat in Dickoya district. Castle-milk (including an addition referred to in the prospectus) in Pusilawa district.

I have carefully checked their figures of area, estimates of crops, expenses and profits, and am able from my intimate knowledge of most of the estates, and general knowledge of the others, to confirm their estimates.

The area of the properties is as follows:—

1,545	acres	tea in full bearing.
83 $\frac{1}{2}$	"	" in partial bearing.
110	"	" under 2 years' old.
140	"	" now being prepared for tea.
185	"	" cococa in full bearing.
56 $\frac{1}{2}$	"	" in partial bearing.
1,620	"	forest-Chena and other land, of which 590 acres are virgin jungle—80 acres planted with fuel trees; the greater part of the whole area will grow good tea.

3,740

The estates are in good order, have substantial bungalows, sufficient coolie lines and fully equipped factories, with the exception of Goonambil, where a new factory is in course of erection.

The properties are easily accessible, being all (except one) within a few miles of railway stations, and having high roads passing through or near them. The one estate excepted is within four miles of a high road, and cost of transport from it to the seaport, Colombo, is as cheap as from the other estates.

The labour force on the estates is adequate, the coast advances out amounting to R20,995 as on the 1st July last.

The crops for the past season aggregated 721,826 lb. but of this amount 18,000 lb. from one small place is taken on the statement of the native owner; there were also 520 cwt. cococa.

The crops for season 1st July, 1896 to 30th June, 1897, are estimated at 767,800 lb. tea.

The profits for this period are estimated as follows:—

Tea, 767,800 lb.			R.
to nett (6 $\frac{1}{2}$ d. per lb.)	348,688-00
Cococa, 542 cwt. to nett (45/11 per cwt.)	20,596-00
			<u>Total.. 369,284-00</u>

Less upkeep expenditure, tea and cococa		R.
		238,870-50

Minus profit making outside tea	..	14,880-00
Minus profit making outside tea	..	4,800-00
		<u>19,680-00</u>

19,680-00

219,190-50

Nett Profit..150,093-50

In addition to the above upkeep expenditure, the outlay on capital account for cost of factory, increased machinery, opening 140 acres new land and upkeep young tea is estimated at R56,792-00.

Messrs. Armstrong & Smith, worked their calculations on the basis of exchange of 1s 2 $\frac{1}{2}$ d per

Rupee, at which rate the profit for Season 1896—97 would equal £9,068 3s. I am, Dear Sirs, Yours faithfully,

F. M. MACKWOOD.

The price to be paid by the Company has been fixed by the Vendors at £92,500, leaving £7,500 surplus capital.

The Vendors take payment in £16,500 of Preference Shares and £16,500 of Ordinary Shares, and the balance in cash.

The Company buys the Estates, other than the additional lands at Castlemilk, as from 30th June, 1896, and will pay interest on the purchase money at 5 per cent from that date. The Company will repay the owners with 5 per cent interest, the expenses already incurred on the crop beginning 1st July, 1896, including all sound coast advances, and will be entitled to all profits from that date.

The titles to the proposed addition to the Castlemilk property are now under examination. This property will, if acquired, be taken over as from the date of transfer, and if this purchase be not completed, the surplus capital will be increased by the sum proposed to be paid for its acquisition. The above estimated profit of £9068 shows nearly 10 per cent on the price at which the Company acquires the estates. The surplus capital, it may be hoped will be equally productive, as it will be mostly used in developing the present estates or in further purchases to extend the acreage, several of the estates being in districts where extensions will not be difficult. Estimating the surplus capital to earn 6 per cent, the total profit would exceed £9,500, which, after providing for the Preference Dividend, £3,000, would leave £6,500 available for the formation of a reserve or improvements and payments of dividend on the Ordinary Shares. There should also be some increase in profits as the young tea comes into bearing. Allowing £5 per acre on the 1,620 acres forest, Chena waste and lands planted with fuel trees as well as the 140 acres in preparation for planting, the cost of the 1,980 acres planted, equals £46 1s 2d per acre. Mr. Mackwood is willing to act as the Company's Agent in Colombo.

Messrs. Cotesworth & Powell have, for the commission on sales as previously charged and estimated for in the figures of the Report, agreed to provide management in their offices for a period of 10 years from the 30th June, 1896, and during this period neither the two members of that firm who are Directors, nor Mr. Mackwood while Ceylon Agent, will be entitled to claim any remuneration as Directors. The above estimate of profit is therefore free of further charge for management in London, unless the Company appoint more Directors. The only Directors of the Company at present are the two partners in the firm of Cotesworth & Powell, and Mr. Mackwood, who are the Vendors to the Company of the greater part of the properties proposed to be acquired and they have fixed the purchase price. Intending subscribers for shares are to be treated as having knowledge of these facts and as subscribing on that basis. The Vendors bear all the expenses of the formation of the Company up to the first allotment. Applications for both Preference and Ordinary Shares will be considered before applications for Preferred Shares only. Preference and Ordinary Shares will rank equally for voting purposes. The Articles of Association of the Company restrict the borrowing powers of the Directors, without the consent of a General Meeting, to the amount from time to time paid up or treated as paid up on the Shares for the time being in issue of the Company.

INDIAN PATENTS.

Applications in respect of the undermentioned inventions have been filed, under the provisions of the Inventions and Designs Act of 1883, during the week ending 6th February 1897:—

Apparatus for cooling tea leaf.—No. 37 of 1897.—Nathan William Horatio Sharpe, engineer, of 26th

Perth road, Stroud green, London, for an apparatus for cooling tea leaf to facilitate oxidation or fermentation, and for withering the same.

Improvements in the manufacture of black tea.—No. 42 of 1897.—Samuel Cleland Davidson, merchant, of Sirocco engineering works, Belfast, Ireland, for improvements in the manufacture of black tea from the green tea leaf.

Improvements in apparatus for withering or limping tea leaf.—No. 43 of 1897.—Samuel Cleland Davidson, merchant, of Sirocco engineering works, Belfast, Ireland, for improvements in apparatus for withering or limping tea leaf in the course of its manufacture into black tea.—*Indian and Eastern Engineer.*

THE COCCIDÆ OF CEYLON.*

Fiorinia Fioriniæ, *Targ. Tozz.* Adult male not observed.

Habitat on under surface of leaves of the camellia plant and the coconut palm. Pundloya (September). I have not yet found this insect upon tea, but its presence upon such a closely allied plant as the camellia makes it extremely probable that our staple product may be attacked by this pest. Its presence in large numbers upon coconut leaves must be injurious, the affected leaves turning a sickly yellow colour. The same insect is said to affect the Areca palm. The species is widely distributed, occurring in Europe, America, and Australia. But Mr. Green adds a note this very month:—

Since writing above—this species has turned up upon tea. I have found it firmly established upon a tea plant on an upcountry estate: and also upon Areca palms in the same district.—E. E. G., Feb. 1897. But in regard to identification of course the plates are of most value. Regarding them Mr. Green writes:—

"I very much regret that, owing to an unfortunate mistake between publisher and lithographers, the plates have been printed on smaller paper than the letter press. The difference was not discovered until too late to rectify the mistake. I find too that my publisher has followed the modern plan of issuing the part unstitched, which—however good it may be for the subsequent binding—is not a very convenient form for present use.

"I trust however that, in spite of these and other defects, the work may prove useful.

"I have previously explained that I have been unable to include in this first part the special chapters on Insecticides and General Preventive Measures. These will appear in Part II, upon which I am now at work.

"The book is to be completed, if possible, in four parts: but the number of species to be described is steadily increasing. Since my return to Ceylon I have already added 3 or 4 new species to the list."

It is a small matter about the plates: they can be bound separately from the letterpress, and the great fact is that they are so clearly and so beautifully executed—the lithographing and colouring being perfection.

We feel sure that no District Association or Library worthy of the name should be without this book. Indeed it is one that all Tea Companies and large individual proprietors should at once supply to their Managers for estate use.

THE TONACOMBE ESTATES COMPANY OF CEYLON, LIMITED.

Proceedings of the Third Ordinary General Meeting of shareholders held at Ambewatte House, on Thursday the 25th day of February 1897.

* By Ernest Green, F.E.S., Part I with 33 plates.—London, Dulau & Co.

Present:—Messrs. G. H. Alston, Chairman, and H. Cumberbatch Directors, and by their Attornies Col. H. L. Brooke, Col. E. Corse-Scott, Major A. H. MacNab, Miss A. A. Cumberbatch, Messrs. W. S. Bennett, W. Bowden-Smith, A. Fetherstonhaugh, and T. K. Wright.

The notice convening the meeting was read.

The minutes of the last meeting of the 28th February 1896 were read and confirmed.

Proposed by the Chairman and seconded by Mr. W. S. BENNETT that the report of the Directors as circulated among the shareholders be adopted.—Carried.

Proposed by Col. CORSE-SCOTT, seconded by Mr. T. K. WRIGHT:—"That a dividend of 10 per cent be declared for the year 1896, payable forthwith."—Carried.

Proposed by Col. BROOKE, seconded by Major MACNAB:—"That Mr. J. N. Campbell be re-elected Director of the Company."—Carried.

Proposed by Mr. FETHERSTONHAUGH, seconded by Mr. T. K. WRIGHT that Mr. Hercules J. Scott be re-elected Auditor for 1897.

A vote of thanks to the chair terminated the meeting.

CUMBERBATCH & Co.,
Agents and Secretaries.

REPORT.

ACREAGE.

The acreage of the Company's Estates for the year 1897 is as under:—

	Acres.	Acres.
Tea in bearing	430	
Tea seed bearers	6	
Tea not in bearing	145	581

Coffee		55
Cardamoms in bearing	65	
Do. not in bearing	35	100

Total cultivated acreage		736
Forest and Fuel Plantations		31
Chena and Patna		894

Grand Total .. 1,661

The total quantity of tea secured during the year was 158,919 lb., which has been sold at an average of 51.34 cts. net per lb.

The total cardamoms picked amount to 7,872 lb., which have been sold at an average of R2.22 per lb.

144 29.22nd bushels of coffee have been harvested and realised R2,163.60, or say R15 per bushel.

The total expenditure amounts to R51,489.03. The balance available after providing for depreciation amounts to R37,716.82, and the directors propose to pay a dividend for the year at the rate of 10 per cent absorbing R28,000 to place R9,120.11 to credit of extensions account, bringing the amount at credit of that account up to R17,000, and to carry forward R596.71 to next account.

The wire tramway alluded to in the last report has been erected and is working satisfactorily.

During 1897 it is proposed to plant 20 acres with tea. The crops for 1897 are estimated as follows:—

190,000 lb. Tea
6,000 ,, Cardamoms
225 bushels coffee (Dry cherry)

against an expenditure of R59,863.

The Directors have arranged with the Debenture holders to increase the amount of debentures to £7,000, reducing the interest from 7 per cent to 6 per cent from 1st January, 1897. The loan is fixed for 5 years certain.

Of the Directors Mr. J. N. Campbell retires, but eligible for re-election.

An auditor for 1897 will have to be appointed at this meeting.

INDIAN TEA SALES.

(From *William Moran & Co.'s Market Report.*)

CALCUTTA, Feb. 17.

Virtually the last auction of the season was held on the 11th instant, when 11,978 packages were disposed of.

The quality generally was poor, with the exception of a few Assam invoices.

Colonial buyers took advantage of the lower prices ruling, and a fair quantity was secured for those markets.

Reuter's Telegrams, received since our last report as follows:—

INDIAN TEA:—

February 11th—Auctions.—“Offered 40,000 packages. Sold 34,000 packages. Generally good demand. Common to medium qualities very firm. Average price, 9³/₄d.”

Total Tea passed through Calcutta from 1st April to 15th February.

	1896-97.	1895-96.	1894-95.
Great Britain	131,245,566	120,223,505	114,140,191
Foreign Europe	436,258	276,295	240,254
America	1,926,909	1,030,234	586,187
Asia	4,190,289	4,787,951	3,710,311
Australia	6,263,192	6,581,356	4,766,195
	144,062,214	132,949,341	123,443,138

VARIOUS PLANTING NOTES.

TOBACCO.—In continuation of the discussion as to the growth and preparation of this product in Ceylon, we have to thank “J.M.” for his very useful letter which will appear in our next issue. It is evident that if tea should begin to fail us—say in the older districts—of which there is no sign as yet—we need not consider “tobacco” as quite played out in the hands of planters.

CACAO AND CINNAMON IN THE AMBOINA ISLANDS.—In a paper read at the Colonial Museum at Haarlem on Dec. 12, 1896, and printed in the *Indische Mercur* of Jan. 30, 1897:—

“On the means of restoring prosperity to and developing the Amboina Islands,” the writer, G. W. W. C. Baron van Hoëvell, said (we translate from the Dutch):—“I must draw attention to two other cultures [besides coffee] for Seran, namely cacao and cinnamon. The first, at one time, tried on the little island of Amboina, gave poor results, and a number of extensive cacao gardens there have been destroyed by a disease that caused the fruits to turn mouldy, blacken, and fall off before these were ripe. This disease could now easily be warded off, as a remedy was discovered later on to prevent it: ginger root, planted round the stem, is an excellent trap-plant; and keeps away all diseases from the tree. The case is different in Seran, where I have seen at Awoya in the Elpahpoetih Bay plantations of cacao that were thriving excellently and had nothing to suffer from disease so far. The cultivation of cinnamon can also be recommended. I do not mean that of cassia, the wild variety, which is met with so plentifully in the nplands of Padang, but the true Ceylon cinnamon. I have seen specimens of it in the Amboina residency, which yielded a cinnamon that, according to experts, did not deserve to be classed as inferior to the best Ceylon.”

CLOSETS, Urinals, Night Commodes, Stables, Kennels, &c. should be lightly dredged (after cleansing) with CALVERT'S 15 per cent CARBOLIC POWDER, to destroy bad odours and to kill or keep away insects.—The most effective preparation.—In ½ lb., 1 lb., and 2 lb. dredgers, at 6d., 1s., & 1s. 6d. each, from Chemists and Stores.
F. C. CALVERT & Co., Manchester.

THE AGRICULTURAL MAGAZINE, COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for March:—

Vol. VIII.]

MARCH, 1897.

[No. 9.

SEASON REPORTS FOR JANUARY, 1897.

ESTERN PROVINCE.—Maha paddy harvest has begun. No dry grain cultivation worth noting. Fruits and vegetables scarce generally except in the Colombo district, where the supply was

good and prices moderate. Rainfall light. Harvest prospects may be said to be generally fair.

Central Province.—Maha paddy nearing maturity in most parts, prospects fair. Dry grain crops fair. Indian corn and Kurrakkan cultivation very satisfactory in Walapane. Health of cattle good. Rain fell in most parts excepting Udumwara, fall registered in Matale, 3·95 in.

Northern Province.—Paddy crops being harvested, prospects good. Dry grain crops satisfactory; out-turn in Mannar below average owing to damage by floods. Rain more or less general: in Jaffna, '82 in., in Mannar '72 in. Murrain reported to have broken out at Kalvilan, in Tunukkai division.

Southern Province.—Only a middling paddy harvest is to be expected. Vegetables in Galle district scarce. Rainfall in Galle, 1·56 in.

Eastern Province.—Paddy much damaged by flood in Batticaloa district, in Trincomalee district thriving in nearly all parts. Dry grain crops also suffered from the same cause. Fair prospects of Tobacco in Trincomalee district. Rainfall in Batticaloa 10 in., in Trincomalee 11·16.

North-Western Province.—In the Kurunegala district paddy and dry grain prospects good, health of cattle good, except in Dambadeuni Hatpattu and Katugampola where murrain has been reported. Prospects of grain crops good in Puttalam district. Rainfall in Puttalam 1·20 in. Reaping of maha in Chilaw district where rain has done some damage.

North-Central Province.—Paddy crop in various stages, good harvest expected throughout the

Province. The severe murrain of last year causes great scarcity of buffaloes for agricultural work. Rainfall at Anuradhapura 6·92 in. A few cases of murrain in Kalagampalata.

Province of Uva.—Yala harvest in progress, yield good. Preparations for maha crop going on, but delayed—some fields being abandoned—owing to floods. Indian corn and Kurrakkan ripe and ready for harvest. Fruits and vegetables plentiful and cheap.

Province of Sabargamuwa.—In Ratnapura districts paddy promising, though rain has caused damage in some parts. Fine grain prospects good. Preparations going on for Yala paddy and dry grain. In Kegalle district, maha paddy being harvested and yield very good. Dry grain crops satisfactory. Rainfall registered at Ambanpitiya 2·34 (on three days), at Ruanwella 2·31 (on three days).

Recorded by A. R. JEREMIAN,

THE USE OF THE LACTOMETER.

OCCASIONAL NOTES.

It cannot be denied that the lactometer is a very convenient and handy instrument to use in the testing of milk, but we would impress upon those who pin their faith to it, the necessity for making sure that the instrument they employ is correctly graduated, by verifying its readings, first, by using it with pure water reduced by ice to 60° F., and next with milk cooled down to the same temperature. In the former case the lactometer, if correctly graduated, should stand at the 0 mark, and in the latter at 30 or 1030 as the instrument is marked.

Dr. Wanklyn, the well-known chemist, speaks strongly against the lactometer in his work on milk analysis. He says that in some manuals intended for the guidance of medical officers of health the use of the lactometer is recommended—one of them in particular by Dr. Edward Smith claiming a sort of pseudo-Government sanction for its use, and commending it as being for milk what the hydrometer is for alcoholic fluids. "But," to quote Dr. Wanklyn's own words, "although it is so very popular, and although it has been so implicitly trusted, the lactometer is a most untrustworthy instrument. There hardly ever was an instrument which has so utterly failed as the lactometer. It confounds together milk which is exceptionally rich with milk which has been largely watered." The same writer makes reference to a prison not far from London where the prison authorities are very particular about their supply of milk. They allow no milk to enter the prison unless it comes to the M mark on the lactometer, which the milk purveyor reaches *by skinning the milk*.

Taking the specific gravity of pure milk to be 1030 (which should correctly be written 1.030) at 60° F., an easy way of making the necessary correction for the reading of the lactometer at tropical temperatures is to add 4 to the reading at 85° F. and to add 5 to the reading at 90° F. In Ceylon the lactometer should always be used in conjunction with the thermometer. If the temperature of the milk be found to be 85° and the reading of the lactometer is 1026, the inference would be that the milk is of the best quality since a specific gravity of 1026 at 85° F. is equivalent to 1030 at 60° F. Indeed a lower specific gravity than 1026 at 80° F. need not convey the idea that the milk has been watered, particularly when it is borne in mind how simple a matter it is to raise the specific gravity either by adding foreign matter or by *abstracting* cream. (N.B.—Let it further be remembered that milk abnormally rich in cream shows a specific gravity below the normal.)

But let no believer in the lactometer imagine for a moment that because an instrument is purchased from this or that store, it is therefore correctly graduated. Indeed, it is quite a common experience to find lactometers from whosoever purchased, incorrect by 2 or 3 markings for which due allowance has to be made. Let this error be discovered by testing the lactometer with water at 60° F. We have known the same milk tested in one establishment to show a difference of nearly 10 in specific gravity when tested at another.

It must be gratifying to those connected with the Agricultural College in Madras to find how willing both the Government and the representatives of the public are to help on their work. The late discussion in the Legislative Council there shows that the Agricultural College is not being supported merely because it is a Government institution, but because the Council was convinced of its duty to do all in its power to further the interests of the agricultural classes in the Presidency, and give the greatest possible support to the institution which is working for those interests. Indeed, it would have been a reproach in this XIXth century to even the Government of the "benighted presidency" if it confessed its unwillingness to forward the cause of agricultural education in India.

Those who know the history of agricultural education and reform in England will have some knowledge of the difficult and discouraging nature and the snail-like progress of that work. India is going through the same experience, and she is content to struggle on and persevere in her efforts. Is little Ceylon, then, grandiloquently termed the *first* of Crown Colonies, to be the last in the race for agricultural reform? And it too an eminently agricultural colony?

The spirit in which the discussion in the Madras Council was carried on might well be emulated by any body of senators, for while the subject was thoroughly threshed out for the benefit of those who asked for information, there was no wild talk on the one hand and no tendency to suppression of facts on the other. In the absence of these latter unfortunate circumstances the result of deliberation and discussion was what was to be expected, viz., sound common-sense and truth, and in the end these prevailed.

A planting correspondent in writing to us enquiring where he could get "Homco" manure, and expressing his desire to get two tons of it, says: "It made my cocoa and orange trees *jump*!"

The number of applications for admission into the Colombo School of Agriculture have increased appreciably this year.

The Final Examination of the Forests Students took place on the 15th February and the following days. The results have not been announced as yet.

The Entrance Examination for candidates seeking admission into the Forestry School was held on the same days. Seven candidates presented themselves. The three first who passed were in order of merit—Richard de Silva, Lucas Mendis, and M. A. Fernando.

In November last the highest rainfall for the month (according to the Surveyor-General's return) was that recorded at Digulla, Awisawella viz., 34.80 in., the rainfall at Sogama, Pussellawa, running this close with 34.63. The lowest re-

corded rainfall was at Hambantota, viz., 6.08 in. The heaviest rainfall on any one day was that recorded on Horakelle Estate, Chilaw, viz., 9.15 in.

In December the highest rainfall for the month (according to the Director of Public Works' return) was at Rukam in the Eastern Province, viz., 57.84 in., and the lowest at Tangalla, viz., 5.47 in.; while the heaviest rainfall on any single day was that recorded at Duckwari, in the Central Province, viz., 12.32 in.

JADOO FIBRE.

We are glad to be able to announce the receipt of a quantity of Jadoo fibre, in pressed bales, from Exeter, the headquarters of the Jadoo Company, Limited. In our last issue we expressed our willingness to forward small quantities to those who may wish to give a trial to this new and highly-spoken-of growing medium. The price of the Jadoo fibre per 60 bushels (about one ton) is £5.10. F. O. B. London, Liverpool, or Southampton. The following are some directions for the use of the fibre:—

Always use the Jadoo in a moist condition.

The Sowing of both Tea and Coffee in Jadoo should be carried out exactly the same as in earth; put a small quantity of Jadoo into the trench, making a layer about three inches deep, sow the seed in it, and cover lightly with earth. A three-bushel sack of Jadoo should be sufficient for 450 plants in this way, and can be used again and again for fresh sowings.

For growing "supplies" of Tea or Coffee in baskets—*one-half* Jadoo should be used, and this should be placed at bottom of the basket.

For old Coffee or Tea Plants.—Scrape away carefully about three inches of earth round the tree, and mix the earth so removed with about $\frac{3}{4}$ peck of Jadoo, replace it and cover over with leaves, &c., so as to retain the moisture in the Jadoo. The same treatment should be adopted for Oranges and Mangoes, in every case taking care that there is a sufficient covering of earth or leaves to retain the moisture in the Jadoo. Where Coffee is not grown on the "supplies" system, a very small quantity of Jadoo should be placed in the holes in which the Coffee seedlings are planted. This will bring them to maturity sooner and make the trees healthier.

For Sugar Cane.—A small quantity should be put at the bottom of the holes in which Sugar Cane cuttings are inserted, thus ensuring the striking of the cane, stimulating root action, and retaining moisture around the roots during the dry season. A handful of Jadoo round the cutting is all that is needed, as it is not wanted as a manure, but simply to encourage formation of roots.

Sugar Cane has been rooted strongly in Jadoo in 10 days.

For Indigo.—A very small quantity of Jadoo Fibre, placed at the bottom of the drills in which Indigo is sown, will have a marked effect on the crop.

For Tobacco it will be found invaluable, both for forming beds to sow into, and also when the young plants are transplanted to permanent positions.

For potting foliage and flowering plants Jadoo fibre is highly recommended. The fibre should be pressed tightly round the roots of the plant. As bought, it is said to have sufficient in it to be fit for use, but if it has become dry it should be moistened slightly before using; in any case the plant should be watered directly after potting. Afterwards care should be taken not to over-water. Plants growing in earth can, it is said, be transplanted into Jadoo fibre without much risk. To do this successfully it is recommended that the plants should be kept dry for 24 hours so that the earth will come off easily from the roots which should, after the plant is taken out, be plunged into tepid water and gently moved about until the earth is all washed off. Care should, of course, be taken not to injure the roots. The new pot should be filled to one-third its capacity with the damp fibre, and the roots of the plant to be grown spread out on it, while the rest of the fibre should be pressed down on the top of them so as to completely fill the pot. The plant should be shaded at first and gradually exposed to sun and air.

Jadoo fibre has the advantages of being a *clean* substance, of being able to retain moisture, and supply the plants grown in it with nutriment; and it is further stated of it that it gives a better colour to flowers, and a richer and deeper texture to the foliage, causing the marking on leaves to come out clearer.

We have been supplied with a number of copies of testimonials as to the value of Jadoo fibre in raising coffee, tea, cocoa and orange seedlings. To some of our subscribers interested in the new growing medium, we were able to forward leaflets containing testimonials and other information regarding the fibre, with the last issue of the Agricultural Magazine.

We should conclude this notice by extracting a passage from Col. Halford Thompson's lecture on Jadoo Fibre at the People's Palace, which refers to the manufacture of the substance:—

"The foundation of it is what is known as 'peat moss' which is exceedingly spongy and capable of absorbing into its composition any chemicals into which one may wish to impregnate it. The peat moss is boiled with certain chemicals. The exact nature of these chemicals I will not allude to in this lecture, but it is sufficient to say that in the composition of Jadoo, every chemical element is present that under any circumstances is required for plant food, and to ensure the thorough amalgamation and decomposition of these chemicals the fibre is fermented in a particular way after the boiling process is completed. It is on the careful carrying out of this fermentation, and checking it at a certain point, that the success of Jadoo depends."

We can only hope that those who try the fibre will find that it possesses all the valuable and useful properties claimed for it.

HEPATITIS (LIVER DISEASE) IN CATTLE— (A SO-CALLED OBSCURE DISEASE).

In the January number of the "Agricultural Magazine" a note is published on a little known disease among cattle: it runs: "A curious form of disease about which practically nothing is known occurs among stock in Ceylon. Among the

symptoms are *increased respiration; a darkening of the colour of the coat*, either completely or in patches (while the *hair of the coat at the same time tends to become long*, and in milch cattle *loss of milk*." The above are no doubt some of the principal symptoms that are seen and observed at a glance. However, the writer has had opportunities of examining animals said to be suffering from the complaint noted above and some of the identical animals from which the above particulars have been gathered. In addition to these principal symptoms, one also observes a slight abdominal distention in the affected animals, yellowish tinted mucous membranes, and altered dung. The animal is sluggish and dull and the pulse is very weak. From these and other symptoms it is evident that the animals suffer from a liver complaint and that no other than inflammation of the liver (*Hepatitis*).

The reason of this disease being described as a "new form of disease" is that as liver disease is somewhat rare in cattle, it is only seldom one gets the chance to study it, unless it be in a tropical country. Steele, in his admirable work on the diseases of cattle, writes as follows under *hepatitis*, :—"It is sometimes seen in high-bred animals fed with an excessive amount of highly stimulating food associated with want of exercise. It is most prevalent in hot weather. It is also attributed to changes of temperature and of food, as well as to exposure of various kinds."

Now the Government dairy cows that suffered from this complaint were well-bred animals (comparatively), were fed with a large amount of stimulating food, and had very little exercise; for, the Sind cows that were brought down to the Government Dairy, were in their native land not fed with stimulating food, and, with the cattle breeders of that district, it is the invariable practice to allow their animals a deal of exercise so that they had to cover miles and miles of ground daily in their pastures. It is the same case with the South Indian cows that get affected with the complaint at the Government Dairy. They are bought off a cattle-dealer, who brings them from the interior of Southern India, where there is not plentiful pasturage and where the animals daily have to cover a large area of ground in picking up their food. These are brought to Colombo and the dealer keeps them in his stalls and feeds them up with stimulating food to bring them in condition. We have also the authority of Professor Gamjee to account for numbers of animals getting affected at the same time; the Professor cites instances where hepatitis had assumed almost epizootic forms in hot climates. So far then all the causes that lead to hepatitis were found in this particular instance, and we will also see presently that the symptoms of hepatitis were present in the dairy cows that were affected with this "curious form of disease."

Professor Steele, in describing the symptoms of the disease, says that "*yellowness of the visible mucous membranes and of the skin is considered diagnostic of liver disease but it is not always so*. . . . a certain amount of abdominal distension is observed, the bowels are torpid and faeces dry, scanty and of a chocolate colour, milk is scanty, skin is *harsh staring* and coated with a *yellowish brown* matter, the respiration is some-

what impeded and the pulse is soft, weak and frequent. *Lameness of the right fore limb has not yet been observed in cases of this kind in the ox*. The animal is very dull." Almost all the above symptoms were present in the affected animals. Impeded respiration, darkened coat, hair tending to become long (staring coat), loss of milk, the general symptoms observed by even a casual observer, are symptoms of hepatitis.

Those who are accustomed to a deal of theory without much of its practical application would, no doubt, be disappointed to find two of the so-called patent symptoms in liver disease, yellowness of the visible mucous membranes and the skin, and lameness of the right fore limb, absent in the disease which affected the animals in question, and hence the idea of liver disease might have entirely escaped them, but what does Steele say under the very disease *Hepatitis*: Yellowness of the mucous membranes and of the skin is considered *diagnostic of liver disease, but it is not always so*. *Lameness of the right fore limb has not yet been observed in cases of this kind in the ox*.

So then this curious form of disease was nothing else than hepatitis, and Professor Wallace, with his well-trained practical eye, detected the cause without even being acquainted with the history of the cases.

The writer had no difficulty whatever in pronouncing the cases to be hepatitis on their very first appearance and it well worth testing that opinion by adopting the treatment for the disease in even a few cases. It may be mentioned that such drugs as dilute hydrochloric Acid, Ammonia Chloride, Magnesium Sulphate and Ipecachuana answer well in affections of the liver in domestic animals in warm climates.

W. A. D. S.

THE COCONUT PALM.

In an account of the coconut palm Dr. George Watt gives the following instructions as to its cultivation in his Dictionary of the Economic Products of India:—

SOWING.—Ripe nuts, carefully collected, should alone be employed, and for this purpose they are usually gathered from February to May. Seed from very young or very old trees should be avoided. After having been kept for a month to six weeks they should be planted. This may take place in January to April, or again in August, provided the rains are not heavy. The seed beds should be dug 2 feet deep and the nuts planted 1 foot apart. The nuts should be laid on then, leaving 2 inches of their surface exposed. Ashes, or ashes and salt, should be freely placed in the trenches; these act both as a manure and as a preventative against insects. The seed-bed thus prepared should be kept moist, but not soaked. The germinated seeds may be transplanted when they are in their second to their sixth or even twelfth month. In the Godaveri district they are placed in their permanent positions when three to four years old. In damp localities the transplanting may be done in the hot season, otherwise during the rains.

TRANSPLANTING.—The seedlings should not be put out in the plantation, pits 12 yards apart

having been prepared for them. In rich soils the pits may be small, but in poor soils 1 to 2 yards wide and 2 to 3 feet deep. In cold clay soils these pits should be filled with sand. In marshy land walls should be constructed round them. Ashes are often recommended to be freely mixed with the prepared soil to be put into the pits, as this is supposed to prevent the attacks of the beetles that prove so destructive to the trees. Cultivation of turmeric, arrowroot &c. in the pits, along with coconuts is believed to be beneficial. The soil round the seedlings is also often kept damp by a bed of leaves, particularly such as will not encourage, but rather check, the approach of ants into the prepared soil. If the soil be naturally poor, salt, ashes, paddy-straw, fish manure, goat's dung, and dry manure may be added during the first year.

TREATMENT OF PLANTATION.—By the end of the first year the normal leaves will begin to form, and at this stage the soil around the plants should be dressed and ashes added. Every succeeding year the ground should be opened out and manured about the close of the rains. By the fourth year the stem begins to appear and has about 12 leaves; it is distinctly visible by the fifth year, when the tree has about 24 leaves. The spathes commence to be formed by the sixth year, and the stem is then 1 to 2 feet above the ground, but in exceptionally favourable climates and soils it may be three or four times that height. The first few spathes do not form fruits, but by-and-bye they begin to do so, and in three or four more years the tree is in full bearing. Dr. Shortt says that in good soils and if watered the coconut begins to yield in the fifth year, but in poor soils and if not watered they only commence to yield in the seventh or not till the tenth year. About six months after flowering the fruits set, and by the end of the year they are fully ripe.

Coconut palms may be easily transplanted, and indeed often with advantage. Some of the fibrous roots should be cut away, and manure, together with a little salt, placed in the pit in which it is intended to plant the tree.

As a rule, the coconut throws out a spathe and a leaf every month; each flowering spike yields from 10 to 25 nuts. The produce of a tree in full health and properly tended may be from 50 to 120 and even 200 nuts a year, the yield depending greatly, of course, on the suitability of the climate and soil for coconut cultivation; a safe average would be 100 nuts a year to each tree in full bearing. The coconut will continue to bear for 70 or 80 years.

NOTE ON LAC BY M. RIDLEY, Esq.,
SUPERINTENDENT OF HORTICULTURAL
GARDENS, LUCKNOW.

Regarding the statement commonly made, and as generally believed, that "if lac is not removed from trees it will in time destroy the trees," I have practically demonstrated and proved in the most conclusive way that the above theory is incorrect and entirely at variance with fact. When I first came here, 23 years ago, the matter then came under my notice; many large trees in the

Wingfield Park, Residency Grounds and the station avenues were badly infested with lac, and the plan then in vogue was to sell the lac to contractors, who in collecting it denuded the trees to a most objectionable extent. This led me to think of some way or means of keeping the trees clear of the pest. A Forest officer informed me that this could be done by lopping off all the leading branches and afterwards stripping the branches and stems of all leaves and twigs, the object being to divest the trees of all infected parts and to remove all trees of the lac insect and so prevent its breaking out on and spreading over the trees so treated again.

I adopted this plan with one or two trees in the Wingfield Park, but found it ineffectual, as on the new branches and shoots which were developed lac again appeared as bad as before. This plan proved an entire failure to protect or keep trees clear of lac.

I then decided to stop lac collecting on a few trees, to test and prove the theory about its destroying the trees. The result of this experiment was that after a time the lac all disappeared and the trees in a short period recovered from the effects of the lac and became perfectly clean and healthy again. This is absolute fact, and I can show numerous large peepul and pákar trees which at one time were so infected with lac as to be most unsightly objects, now entirely free from the pest and the trees healthy and vigorous.

On the representation I made to Mr. Boys, when Deputy Commissioner here, he passed an order prohibiting the sale of lac from trees in the station, and since then I believe no lac has been collected from trees on avenues and groves in Lucknow; certainly none has been collected from any of the gardens or other public grounds in my charge, and there has been no loss of trees in consequence.

For some years there has not been much lac on trees in Lucknow, at least on those under my immediate observation; but whether this decrease of lac pest is due to collecting being prohibited or to the seasons not favouring its spread I am not prepared to pronounce an opinion, but the fact remains that it has been much less in evidence for the past five or six years than it was for many preceding years.

I have often been told that the lac gatherers inoculate trees to spread and propagate lac. The results here rather favour that statement. Prohibition may have shown them that they gain nothing by spreading it, and this may have led them to cease inoculating trees; but on this point conclusive and certain evidence is not forthcoming.

I most decidedly do consider that trees are injured by the way lac is generally collected, owing to the removal of such a large portion of the young twiggy growth of the trees.

Near and in towns the object of this free removal of twigs is two-fold: one, to obtain as much lac as possible, the other, to make money by selling the twigs for firewood. If proper and efficient supervision could be provided, lac might be removed to some extent by collecting dead twigs and a small proportion of the finer ones. The trees would not suffer to any appreciable degree if collecting was done in this way; but, as the necessary supervision to ensure this is not available,

prohibition is, in my opinion, the only safe method to follow.

The theory mentioned at the beginning of this note comes no doubt from persons interested in lac and is a purely selfish one.

Others have accepted it from want of evidence to combat it, and so it has come to be very generally accepted as fact. For this reason it would probably be useful to circulate the facts and experience given in this note.

M. RIDLEY,

Superintendent Government Gardens, Lucknow.

6th June 1896.

[In Ceylon we have a number of lac-producing trees, among which are the two mentioned in the above note, viz., Peepul (*Ficus religiosa*), Sin. Bo; Pákar (*Ficus infectoria*) Sin. Kalaha.]—
Ed. A.M.

MILK AND MILK PRODUCTS.

BY MR. JAMES MOLLISON,

Superintendent of Farms, Bombay.

(Continued.)

The butter is now sufficiently washed to be removed from the churn to the butter-worker by means of two wooden scoops. The butter-worker is a simple arrangement, whereby, in a wooden trough, a grooved roller kneads the butter completely free of butter-milk. The butter-milk escapes down the inclined plane which forms the floor of the trough, and runs through a tap hole to a vessel placed to catch it below.

When thoroughly worked, the butter is in a condition to be made up into marketable form. By the use of "Scotch hands" and wooden butter prints or moulds, it can be made up at once into pats for immediate sale. If it is necessary to keep the butter any time, it should be preserved with salt. One per cent. salt is sufficient to preserve butter in good condition for a few weeks, whilst 3 to 4 per cent. will keep it good for months.

Fine table salt should be used. Before it is mixed with the butter it should be powdered very fine with the roller (an empty bottle does very well for the purpose). The salt should be mixed with the butter by thorough working on the butter-worker, a little salt being sprinkled each time the butter is kneaded by the butter-worker. I have proved that butter preserved in this manner, if packed tight in earthenware "crocks" with tight-fitting lids, will, in a comparatively cool place, keep good for months. Moreover, when required for use, the butter could be washed almost free of salt by the free use of pure cold water and of the butter-worker. Improved dairy machinery is designed with the object of making it unnecessary for the dairyman to touch with the hands, either milk, cream or butter, which, in India, is a point of significant importance.

The ordinary method of hastening the ripening of cream is to add to it a little sour milk which, however, must be clean and free from any foreign taint or flavour.

Butter should be made in India in the early morning when the dairy is cool.

Ripe cream before it is churned should be cooled; 55° F. or 60° F. is the proper temperature.

The temperature of cream is lowered by adding

ice or by setting the cream *in its vessel* in cold water. The cooler the cream is churned, the firmer the butter will be. The churn should revolve about 55 times per minute. The best results are got when the butter comes in half an hour. If it comes much sooner it is probable that the cream has been over-ripened. If the cream is not equally ripe, i.e., if during ripening it has not been well stirred and thoroughly exposed *equally* to the air, that at the bottom of the vessel will be less ripe than that at the top, and in the process of churning the ripe or overripe portion of the cream will form into butter granules first. If this occurs, a good deal of cream which has not been converted into butter, will be removed with the butter-milk, and will be lost unless the butter milk is kept for 24 hours, during which period the unchurned cream will rise to the surface of the butter-milk and may be skimmed off. In India a good deal of cream is recovered in this manner during the hot weather. Even under the most careful management some cream will be lost in the butter-milk at this season. The cream from buffalo's milk can be churned at a high temperature than that from cows and yet produce equally firm butter. The feeding of the milch-cattle, as already noted, also influences the temperature at which firm butter can be churned. Colouring matter, if desired, should be added before churning. It is made from 3 oz. annatto seed digested for an hour in 8 oz. pure olive oil and then strained through fine muslin. One tea-spoonful is sufficient for the cream of 40 lbs. buffalo's milk, i.e., for about 4 lbs. of butter. Colouring matter, which is more concentrated, is made as follows: 4 oz. of ground annatto seed is put in a glass flask and just covered with rectified spirit. This mixture is allowed to digest for 7 days. The rectified spirit dissolves the colouring matter from the seed and a pure solution is obtained by straining through muslin. This solution is, however, unsuitable for colouring butter, because the spirit would taint the butter. The mixture is therefore placed in a cooking vessel with 1 lb. of sesamum oil and carefully heated; the spirit is entirely evaporated and the solution is transferred to the oil. The colouring matter thus prepared is placed in a bottle when cool and kept corked to be used as required.

BOTTLING AND CANNING FRUIT.

To preserve fruit in a fresh state it is necessary to raise the temperature above 160 deg. F. to destroy the germs of fungoid growths which promote decay, and to close the receptacles perfectly airtight while at or above the degree of temperature given above. For general use, and to allow a margin on the operator's side, the boiling point 212 deg. F. is usually adopted. The fruit should be sound, firm, ripe—but not "squashy" to the touch. The tin or bottles should be of the size suited to holding enough for one dish for the household, and it must be observed that the fruit will decay if allowed to stand for any length of time after being exposed to the air—for at once on being opened fresh germs fall upon it from the air and set up growths which hasten decomposition. Tins are cheaper than glass jars and therefore are used more, but as they have a tendency to oxidize and become useless in about a couple of seasons, the glass jars are probably

cheapest in the long run. If cans be used the self-closing or patent topped cans are the best, as very few persons care about the trouble of soldering on the tops, and having to cut away the lids when opening for use. The general complaint against the tins is that they often rust on the insides of the lids, and impart their nasty rusty flavour to the fruit. To avert this, small circular discs of greased or oiled paper could be placed over the holes before the lids are forced down, this precaution should also be observed where the patent screw-topped glass jars are used if the tops are made of tin. For cooking the fruit any ordinary stew pan may be used, but an ordinary washing copper if well cleansed acts well.

There are various methods advocated by authorities on the subject, those mostly in vogue are firstly:—Pack the fruit into the jars or cans, boil the syrup in another vessel for ten minutes, stand the jars or cans in a shallow pan with water reaching to within an inch of the top of the cans or jars, cover the pan and bring the water to a boil for several minutes, then pour the boiling syrup over the fruits quite filling the cans or jars. Keep the water round them boiling for a few minutes longer, until no air bubbles rise up through the fruit, then put on the lids and while still hot run a little beeswax or parafine wax around the rims.

The other method, and no doubt the best for small householders, is to place the fruit and prepared syrup into a common washing copper, and stew it until it is of sufficient softness, but yet firm enough to hold its shape when being carefully ladled into the tins or jars while still hot. The jars or cans should then be placed into a shallow vessel or pan, and the water surrounding them brought to a boil until all air bubbles cease to rise among the fruit, then seal down as in the first method. Such little points as putting straw or cloths around the jars to prevent them touching when in the shallow pan; or placing straw or split pieces of deal or wood upon the bottom of the pan to stand the jars upon—to keep them off the bottom, or not allowing the bottles of fruit when very hot to stand in a cold draught, are all well known to every housewife.

It will always be well when cooking to err on the side of under cooking, as the fruit can be stewed a little if necessary when opened for use. The matter of putting syrup or only pure water into the jars is a matter of taste, as it has very little if anything to do with the preservation of the fruit. The authorities on syrups vary from 4 oz. to 1 lb. of sugar to each quart of water, and the times for cooking for various fruits are widely different, but this is a point which must be worked out by the operator according to the ripeness of the fruit under treatment.—*Adelaide Observer.*

RINDERPEST IN THE WANNI AND ADJOINING DISTRICTS.

In concluding my remarks on the prevention and suppression of rinderpest, I cannot do better than give a summary of the rules laid down under this head in Veterinary Major Mills' treatise on Cattle Diseases.

- (1.) Stray animals should be prevented from coming in contact with healthy cattle.
- (2.) All animals which have been recently bought or have been in contact with strange ones should be kept apart from others.

(3.) Whenever an animal shows signs of sickness of any kind he should be kept separate from healthy ones and watched, his food and drinking water being brought to him.

(4.) Cattle suspected of rinderpest should be kept strictly apart from the rest, at a distance of at least 500 yards. All their bedding, gear, dung, &c., should be destroyed by burning. Dogs, crows, &c., must be kept out of the Hospital Pound as much as possible.

(5.) The stall or shed in which a diseased animal has been, should be disinfected by burning sulphur about the place, or by sprinkling a solution of Carbolic acid, Jeye's fluid or some other disinfectant. The floor should be dug up and fresh earth placed, and all walls and wood work whitewashed.

(6.) All animals which have been in contact with a diseased ones should be thoroughly washed with a disinfectant solution and should be kept apart from the healthy.

(7.) The men attending on the sick cattle should not be allowed to approach the healthy animals.

(8.) Animals that recover should be well washed and pastured for at least a month apart from the herd.

(9.) The carcasses of animals that die of rinderpest as well as the litter, dung, &c. of all the infected ones should be burnt.

In order to carry out these rules in the villages of the interior, there ought to be a special Veterinary headman resident in every large cattle village. The present minor headmen are too busy with other work to devote sufficient time and attention to matters connected with the welfare of the cattle. Prompt measures are of the utmost importance in the suppression of the cattle plague. It is hardly of any use to attempt to suppress the disease about the tail end of an outbreak.

Treatment.—When Rinderpest breaks out in Europe it assumes a most virulent form and is not amenable to treatment. Says Professor Williams, "The cattle plague may be classified as one of those diseases in which all methods of medical and hygienic treatment have hitherto proved unsuccessful, and judging from the nature of the malady, always will prove unsuccessful." Professor Steel says: "Numberless receipts have been submitted, tested, and proved worthless. We can name no agent capable of acting as an antidote to rinderpest poison."

These remarks, however, have been made with special reference to the plague as it occurs in most European countries, and do not apply with the same force to the form in which it is often found in Siberia, India and Ceylon. It has been observed that in localities where the disease is enzootic, such as in many Asiatic countries, it often assumes a milder form, and is then amenable to treatment to a certain extent. It is the opinion of the Indian Cattle Plague Commissioners that at least 20 per cent. of animals which would otherwise die may be saved by suitable treatment.

The indications for general treatment are to help nature in getting rid of the virus from the system, to support the strength of the animal by careful nursing, proper diet and stimulant tonic medicines, and to mitigate any urgent symptoms that may arise.

Mr. Thacker's mixture consisting of Campbor, Nitre, Datura, Chiretta and Arrack has been recommended by Veterinary Surgeons Hallen and Pease. I have used this mixture substituting margosa bark for chiretta, and have found it answer well when due attention is paid to the nursing.

The animal should be fed with liquid food such as rice conjee with the boiled rice mixed. Peas (*kadalai*, gruel is recommended by the Indian Plague Commissioners when there is a tendency to excessive purging as it is more astringent and stimulating than rice conjee. Simple water should be very sparingly given, as excessive draughts have been known to increase the diarrhœa and hasten death.

Very mild laxatives are useful in the early stage of the disease when there is constipation; but few villagers make out the disease at this stage. When there is excessive diarrhœa for more than 24 hours, it should be checked by adding some suitable astringents such as catechu or gallnuts to Veterinary Surgeon Thacker's mixture above referred to. Decoction of "beli" fruit may be also added to the mixture if the diarrhœa and dysentery progress.

There are, however, serious obstacles to the treatment of rinderpest in the villages of the interior of Ceylon. The villagers do not care about the nursing of any animal that is attacked with the disease. They do not even think of providing shelter for it, and it is allowed to roam about along with the healthy animals. They seem too lazy to attend to the nursing or housing, and are always ready with their excuses. The utmost they can be persuaded to do of their own accord, is to tie the sick animal to a tree and give it some straw or grass. They are prejudiced against the new method of treatment. In fact, they have no faith in any kind of treatment for rinderpest, and believe that only their deities can either kill or cure the infected animals.

No doubt some specific or heroic remedy that could effect almost a cent per cent cure will carry conviction to their minds and overcome their prejudice. But hitherto veterinary science has not discovered any specific for rinderpest, and nursing has been considered the most important part of the treatment, which, unfortunately, is just what is most neglected.

Under such circumstances, it is with no little eagerness that the veterinary world has been looking forward to the results of the investigations recently carried on by Dr. Koch at the Cape; and the telegram published the other day, to the effect that he claims to have discovered a remedy for rinderpest will be hailed with intense joy by cattle-owners all over India and Ceylon. The exact nature of the discovery has, however, yet to be ascertained, and we must receive the news with caution, lest we meet with disappointment. Let us however trust that it is something more than the hasty conclusion of an impulsive enthusiast, and that Dr. Koch has at last hit upon something that will make him a benefactor to the whole agricultural and veterinary world.

E. T. HOOLE.

Anuradhapura, 20th Feb. 1897.

"NITRAGIN."

We have much pleasure in announcing that we have received some specimens of "Nitragin" (pure cultivation bacteria for leguminous crops) prepared according to Doctors Nobbe's and Hiltner's direction in Höchst-on-the-Main. The Nitragin is contained in bottles inserted in a brown paper case, and has to be kept protected from light and heat. The following are certain facts referring to the material as set forth by the manufacturers:—

The principal food-materials abstracted from the soil by plants, and which therefore require to be replaced in the form of manures, are potash, phosphoric acid, lime and nitrogen.

Respecting the last it has been known that leguminous crops, such as clover, vetches, peas, beans, lupines, etc., do not usually require to be manured with nitrogen (in the form of nitre or ammoniacal compounds), and yet under favourable conditions yield rich harvests, whilst the soil is even enriched with nitrogen.

The reason of this peculiar behaviour for many years remained unexplained, but the onward march of modern science has now demonstrated the ability of leguminous plants to abstract nitrogen from the air—only, however, by the aid of a specific kind of micro-organism, a bacterium that resides in the characteristic nodules on the roots. If these bacteria are not at the disposal of the plant, then it loses its ability to utilise the atmospheric nitrogen, and hence it is found that not every leguminous plant is able to flourish luxuriantly without nitrogenous manure: many remain small and stunted under conditions otherwise favourable, and evidently suffer from the lack of nitrogen.

It is therefore a matter of extreme importance to the farmer to make certain that each field of legumes is supplied with the necessary quantum of bacteria; only then can he expect to obtain full crops from poor sandy soils without nitrogen manures (*i. e.*, without saltpetre, ammonia etc.) and only then will he reap the advantage of a soil enormously enriched with nitrogen.

The wide bearing of this newly-discovered principle has already been taken into practical consideration, and fields are now inoculated, that is to say, strewn with earth in which legumes have already flourished. This method, however, apart from its great cost and the loss of time and labour entailed, also involves the danger of disseminating injurious as well as useful bacteria.

This disadvantage is, however, now completely overcome by the Patent Germ Fertiliser

NITRAGIN

which consists of a pure cultivation of the specific bacteria of legume nodules in a suitable medium.

The inoculation of the seed or of the soil with the Germ Fertiliser, according to the directions given below, possesses the following advantages:—

1. Every single seed is surrounded with bacteria which, after germination, penetrate the root-hairs and commence their rôle as collectors of nitrogen, so that a good crop is secured in the poorest soil without nitrogenous manures.

2. Through the storage of nitrogen by the bacteria, the soil itself becomes richer in nitrogen in an assimilable state, to the advantage of the other crops grain in rotation.

3. The disadvantages of the mode of inoculation previously adopted are avoided.
4. Manuring with nitrogen in the form of saltpetre, ammonium salts, etc., is absolutely unnecessary.

DIRECTIONS FOR USE.

Every bottle contains sufficient for inoculation of 2½ roods.

If the contents of the bottle have already become liquid, they are used as described below for the direct inoculation of the seed. If solid, the contents can be easily liquefied by warming the bottle gently for a few minutes, for instance, in the trousers-pocket, in tepid water, or in a warm room. Exposure to temperatures above the heat of the body, which is ample sufficient to melt, or to direct sunlight must under all circumstances be strictly avoided.

The liquid contents are poured into a vessel containing one to three pints of clean water (carefully washing out the whole contents of the bottle with a little water), and then shaken or stirred until the Fertiliser is equally distributed throughout the vessel and the bacteria are well mixed in the water.

The inoculated water thus prepared is poured over the seed and worked with the hands (or the shovel) until every seed has been moistened. If the quantity of water is insufficient more must be added, but usually for small seed a pint and a half will suffice and for large seeds two or three quarts. The moistened seed is then reduced to a condition suitable for sowing by mixing with some dry sand or fine earth and if necessary allowing it to stand, turning it over from time to time; too great dryness is deleterious. The sowing and turning in is carried out in the manner usually practised. If possible however avoid sowing in glaring sunlight.

Instead of inoculating the seed the same, in some cases, better results are obtained by inoculating the soil by means of inoculated earth. For this purpose for every 2½ roods ½ cwt. earth is inoculated in the above-described manner, using a proportionately larger quantity of water; the inoculated earth is then dried in the air or mixed with dry earth, scattered equally over the field, and worked in 3 or 4 inches deep.

For larger surfaces than 2½ roods a corresponding number of bottles must be used (8 bottles to 5 acres).

At the bacteria are absolutely innocuous, there is no fear of danger from the bottles being left about or employed for other purposes.

Nitragin for the following crops are now obtainable from the Faberwerke Vorm. Meister Lucius and Bruning, at Höchst-on-Main or 6 and 7 Cross Lane, St. Mary's Hill, London, E.C. :—

Common Pea	...	<i>Pisum sativum.</i>
Sand Pea	...	<i>Pisum arvense.</i>
Common Vetch	...	<i>Vicia sativa.</i>
Hairy Vetch	...	<i>Vicia villosa.</i>
Common Field Bean	...	
or Horsebean	...	<i>Vicia faba.</i>
White Lupin	...	<i>Lupinus albus.</i>
Yellow Lupin	...	<i>Lupinus luteus.</i>
Blue Lupin	...	<i>Lupinus angustifolius.</i>
Clover	...	<i>Trifolium pratense.</i>
White Clover	or	
Dutch Clover	...	<i>Trifolium repens.</i>
Alsike Clover	...	<i>Trifolium hybridum.</i>

Carnation Clover	...	<i>Trifolium incarnatum.</i>
or Trifolium.	...	
Bokhara Clover	...	<i>Melilotus alba.</i>
Black Medick	...	<i>Medicago lupulina.</i>
Lucerne	...	<i>Medicago sativa.</i>
Kidney Vetch	...	<i>Anthyllis vulneraria.</i>
Sainfoin	...	<i>Onobrychis sativa.</i>
Serradella	...	<i>Ornithopus sativus.</i>
Wild Everlasting	...	
Pea	...	<i>Lathyrus sylvestris.</i>

ARECANUT CULTIVATION IN INDIA.

The Arecanut is described by Dr. Watt as a native of Cochin China, Malayan Peninsula and Islands. It is cultivated throughout tropical India; in Bengal, Assam, Sylhet; but will not grow in Manipur, and only indifferently in Cachar, Burmah, and Siam; in Western India below and above the Ghauts. It does not grow at any distance from the sea and will not succeed above 3,000 feet in altitude. Most villages in Burma, Bengal and South India have their clumps or avenues of betel palm. The betel palm groves and pepper betel-leaf houses are perhaps the most characteristic features of the river-banks in Sylhet, and from these plantations the inhabitants of Cachar and Manipur obtain their supplies.

MYSORE.—The following facts relative to the cultivation and yield of Arecanuts in Mysore are given in the *Mysore Gazetteer*:—There are two varieties of the Areca in Mysore, the one bearing large and the other small nuts, the produce of both kinds being nearly equal in value and quantity.

The manner of arecanut cultivation is different in different districts of Mysore. The method followed in Channapatna is as follows:—The seed is ripe about the middle of January to February, and is first planted in a nursery. Trenches are dug and half-filled up with sand, on the surface of which is placed a row of the ripe nuts. These are again covered with sand and rich black mould, and are watered once in three days for four months. The young palms are then transplanted to the garden, which had been previously planted with rows of plantain trees at the distance of about four feet. Two young arecas are set in one hole between every two plantain trees.

When there is no rain, the plants are watered every third day. In the rainy season, a trench is dug between every third row of trees to carry off superfluous water, and to bring a supply from the reservoir when wanted. At the end of three years the original plantain trees are removed and a row planted in the middle of each bed and kept up ever afterwards in order to preserve a coolness at the roots of the areca. The trees are five feet high in five years, and begin to produce fruit. The plantation requires no more watering except twice a month during the dry weather.

The methods followed in other parts of Mysore differ in some respects from the one above, but they agree in the essential point, namely, plantain trees are planted with the areca palms, and in most districts trenches are dug to carry off superfluous water. The seedlings, except in one district, are first raised in a nursery and thence transplanted. Manure is used in some districts, but watering is resorted to everywhere. A rich black mould or a black soil containing calcareous nodules is preferred for arecanut cultivation.

The areca plantations in Mysore are interspersed with coconut, lime, jak, and other trees, which add to the shade and to the freshness of the soil.

IN KOLABA.—In Kolaba, the betel palm is grown in large numbers in coconut plantations along the Alibag coast. The nuts are buried two inches deep in loosened and levelled soil. When the seedlings are a year old, they are planted out in July and buried about two feet deep. The soil is then enriched by a mixture of salt and *nachni*, sometimes with the addition of cowdung. Now watering is required at first, but after four months the plant is watered either daily or at intervals of one or two days. If water is not stinted, the betel palm yields nuts in its fifth or sixth year. The tree yields twice or thrice a year about 250 nuts being an average yearly yield.

IN JANJIRA OR SHIVARDHA.—In Janjira, the betel palm is the most important of garden crops. Shivardhan betel-nuts are known over the whole of the Bombay Presidency. The seed-nut is sown in February or March about half-foot deep and is carefully watered. After about four months the plant appears and is watered every second day. When it is four years old it is planted out about two feet and-a-half below the surface, a foot and a quarter of the seedling being buried under the ground, while a round trench of the same depth is left for the water. When the tree is nine or ten years old, it begins to bear fruit, the yearly yield varying from 25 to 400 nuts. This variety fetches, relatively, a much higher price in the market than any of the others.

(To be continued.)

GENERAL ITEMS.

In 1895, it is reported officially, the area under arecanut cultivation in the Kegalla District was 24,680 acres, or more than one-third of all Ceylon. The palms bear best in that district where the yield has at all times been famous, and whence in all historic times there has been a considerable import to Southern India. The area in Three Korales under cultivation is 6,527 acres, with an average yield of 783½ million nuts. The yield per acre on unplanted (i.e. naturally grown) and over-crowded gardens is 120,000 nuts per acre. The nuts are measured by an *amunam* of 24,000 to 26,000 nuts. Therefore, the average weight equals about 5 *amunams*. An *amunam* weighs 2½ cwt. Therefore the average yield per acre represents in weight 12½ cwt. (N.B.—Well-cultivated and scientifically-planted *arabes* yield nearly a ton an acre. Statistics quoted from a small acreage in Madras give nearly two tons.)

To ascertain the weight of cattle, measure the girth close behind the shoulder and the length from the forepart of the shoulder-blade along the back to the bone at the tail which is in a vertical line with the buttock both in feet. Multiply the square of the girth, expressed in feet, by five times the length, and divide the product by 21; the quotient is the weight, nearly, of the four quarters, in imperial stones of 14 lb. avoirdupois. For example, if the girth be 6 ft., and the length 5½ ft., we shall have $6 \times 6 = 36$, and $5\frac{1}{2} \times 5 = 26\frac{1}{2}$; then $36 \times 26\frac{1}{2} = 495$, and this divided by 21 gives 45 stones exactly. It is to

be observed, however, that in very fat cattle the four quarters will be about one twentieth more, while in those in a very lean state they will be one-twentieth less than the weight obtained by the rule.

G. F. Plunkett, who contributes the Poultry Notes to the *Austrian Tropical Agriculturist* for December, advises poultry keepers, if they wish to prevent loss of chickens, (1) to keep their poultry houses clean and free from lice, by regular cleaning out, white-washing and sprinkling the floor with lime; (2) by keeping the chickens off the wet grass in the early morning; (3) by preventing in-breeding by introducing fresh blood into the broods.

The Manning River correspondent of the *Sydney Mail* writes:—At a meeting of the committee of the Agricultural and Horticultural Association, held here recently, Mr. W. Allen, of Danmoresque Island, detailed the result of his experience in the adoption of the treatment of seed oats by immersion in hot water, as recommended by Dr. Jansen. Half of the seed required for sowing was treated for a few minutes with water at a temperature of 145 deg. F.; it was then placed in cold water and sown immediately. The remainder of the seed untreated was also sown afterwards. The two plots of soil used were of the same quality, and every endeavour was made to give the same care and attention to the treatment and cultivation of each seed. The final result proved unquestionably that, although no apparent difference could be noticed in the growth of the two lots of seed, the portion of the seed treated with hot water was absolutely free from any trace of smut or other imperfection. Of the untreated seed it was found that at least 15 per cent. of the heads of oats were destroyed by disease. Much interest has been taken in the district in Mr. Allen's experiment, and arrangements are being made for further trials with scalded seed at various temperatures of water.

On the subject of selection of seeds Dr. Cobb, of the Agricultural Department, New South Wales, says:—"The grading of seeds is almost wholly neglected by farmers in most of the great agricultural countries, and this very fact is one that is sometimes pointed out in defence of not grading the seed. I have heard it said in substance by a well-known teacher of agriculture—a man whose word is respectfully listened to by thousands of farmers—that there could not be much in graded seed, or farmers would not so generally neglect the matter. . . . One might pertinently ask this teacher of agriculture how, if a practice is to be its own sufficient defence, any improvement is ever to take place, and enquire of the advocates of pinched seed why Dame Nature does not provide all her plants with pinched and puny seed, if they are so much better. The truth is that, other things being equal, plump seed is much better than shrivelled seed, and that where the results obtained from shrivelled seed are better than those obtained from plump seed, the result is due to other factors than the quality of the seed. . . . The vitality of seed diminishes with age, hence it is necessary in comparative experiments (except such as are devoted to ascertaining the rate of decrease in vitality due to age) to make sure that the seed used in the different plots and rows is of the same age."

“PIONEERS OF THE PLANTING ENTERPRISE IN CEYLON.” (Second Series.)

GEORGE SMYTTAN DUFF,

BANKER AND PIONEER PROPRIETARY PLANTER.

TIME was when the name of Mr. G. S. Duff was as a “household word” among the Colonists of Ceylon. No more astute nor successful Banker ever came to the East, and no individual capitalist has ever done more right on from the “forties” to develop and sustain the planting enterprise of this Colony. Moreover, Mr. Duff—who is still wonderfully well preserved, although approaching four-score years,—is an evidence of what the tropics may do to prolong a (medically) threatened life and to carry a weak constitution in comfort through early and middle age, until the climate of the United Kingdom—once so inimical—can be faced in safety. There is one case in our experience in Ceylon where a Scottish lawyer condemned by two Doctors as having lungs too far advanced in disease to allow of his living by any possibility, anywhere, beyond two or three years, returned from Ceylon after fifteen years’ residence, to his native Highlands to find the two medicos who had signed his death-warrant, both passed away! Mr. Duff’s case was not quite parallel, but still striking enough as the sequel will show.

Born and educated in the North of Scotland, Mr. Duff’s banking and financial career was early determined on and in 1840 found him in a London Banking office; but having a far from robust constitution, the confinement of office hours and the trying fogs of the City soon told, so that towards the end of 1841, he had fairly broken down, his chest and lungs giving ominous signs of being unable to stand another English winter. Fortunately, the young Banker had good friends: his uncle, Dr. Smytton, had been a College chum of the then Queen’s Physician, Sir James Clarke, and the latter came to attend

Mr. Duff, bringing him daily throughout November-December 1841, all the news of the young Prince (of Wales) born 9th Nov., Sir James being in attendance on Her Majesty. On comparative recovery, Sir James ordered his youthful patient to leave England at once—he must go to Madeira or the Canaries; but learning he would be quite a stranger there, while he had an uncle (another doctor, Dr. Bell) in Bombay, he gave him permission to go there, although he added that Ceylon as being nearer the equator, would be better. The only difference the Queen’s Physician, and his patient had was when the latter began to enquire about the needful fee: “If ever your uncle’s nephew mentions such a thing, we shall have a serious quarrel” was the generous response.

Accordingly, early in 1842, Mr. G. S. Duff sailed from London for Bombay in the ship “Sophia,” Capt. Johns, who had previously belonged to the Indian Navy. Meeting with heavy gales off the Canaries, the ship sustained serious damage, masts and bulwarks being swept away and it was determined to make for Rio de Janeiro to refit. There were 40 lads (mere boys) on board going out for the Indian Navy; but they were kept at the pumps in relays, night and day, and so saved the ship from sinking. After six weeks spent in refitting at Rio, the voyage to Bombay again commenced and Mr. Duff reached that port six months after leaving London. He went to reside with his uncle, Dr. Bell, who had just returned from the Scinde Campaign, having been with Sir Charles Napier in his great defeat of the Amirs at the battle of Meanee. After a time, Mr. Duff’s health not improving, the Doctor sent him to Ceylon for a trip. This occupied two months and on his return he entered the Bank of Western India. In August, 1844, however, promotion came: the Manager in Ceylon, Mr. Smollett Campbell, was transferred to China

and as his successor Mr. G. S. Duff arrived from Bombay.

The Western Bank of India, of which Mr. Duff thus became Manager in Ceylon, had only opened in Colombo and Kandy on the 23rd October 1843. It was preceded by "The Bank of Ceylon" in Colombo on 1st June 1841; in Kandy in 1843. The latter Bank became irretrievably involved in the coffee crash of 1847, £60,000 being ultimately lost and the rival institution now changed to the happier title of "The Oriental Bank Corporation," in return for its Royal Charter, took over the liabilities and business of the Bank of Ceylon. In 1851, the two Banks were formally amalgamated, and the "Oriental" entered, in Ceylon, on that long career of unbroken prosperity which it owed in a very special degree to the shrewd and successful management of Mr. G. S. Duff. Colombo became almost the most important, certainly the most prosperous branch of the Bank in the East, and Mr. Duff continued at his post a Manager from 1844 till 1871, with only one interval of 18 months' furlough in England. So long an occupancy of the management of one Branch has been unprecedented in the history of Banking in the East, nor can a career of such uninterrupted prosperity be paralleled.

We ought to have chronicled before this, however, a circumstance that contributed very much to Mr. Duff's long residence and good health in Ceylon, namely, his happy marriage in September 1847 to Miss Rodney Brown, daughter of Colonel Brown, who, at the time, Commanded the Royal Engineers in Ceylon. Mrs. Duff's mother was a daughter of the Hon. John Rodney, Colonial Secretary of Ceylon from 1815 to 1833, and grand-daughter of the famous Admiral Lord Rodney. When as Colonial Secretary Rodney retired from the Ceylon Civil Service, he owned certain land in the neighbourhood of Colombo, which he pointed out, would undoubtedly be valuable to Government as time rolled on and he offered to exchange it for small annuities in favour of his two daughters. This was agreed to; but the bargain proved a hard one for the Colony, since the lady-annuitants were so long-lived that Mrs. Brown (Mrs. Duff's mother) who drew £60 from 1824, only died on 12th February 1897 at Bath aged 93; while her sister, Miss Rodney, still survives and continues to draw from Ceylon, the annuity of £42 also begun in 1824! Mrs. Duff herself, besides being a very handsome, attractive lady—the leader of Society in Colombo for many years next to Queen's House—was always a picture of health, and, humanly speaking, might have been expected to outlive many years her comparatively delicate husband; but her

death took place very unexpectedly in London during the summer of 1895. Mr. and Mrs. Duff's family consisted of three sons and three daughters: two of the sons being in the Army as Cavalry officers, the third as a private gentleman residing near Folkestone; while the daughters married, one, Capt. Rolfe, 17th Foot and the other two respectively, Mr. Nevett and Mr. P. C. Oswald whose London firm "Nevett, Oswald, & Co." is intimately connected with Ceylon.

But this is hastening too far; for we have now to treat briefly of Mr. Duff's connection with the planting development of Ceylon, by no means the least important division of his career. Of course, as Banker, he was always the judicious upholder of coffee planting in our hill-country, and most of the profits made for his Bank was through the wise as well as liberal encouragement of the planters and the growing business in all departments that necessarily accompanied the spread of the industry. But personally and in his private capacity, Mr. Duff showed his confidence by investments in coffee. His very first venture was in the Tellisagalla estate, Kottmale, with Mr. Crosby, and he also became interested with relatives in Dumbura, by a purchase, which led to the famous Rajawella litigation case. In the Ballacduwa group of estates, Mr. Duff was for some years the partner of Mr. Andrew Nicol; and in conjunction with Mr. J. C. Fowlie he opened Rappahamock estate in Udupussellawa. In Pussellawa and Ramboda he acquired considerable proprietary rights:—Hellebedde which had belonged to the heirs of Colonel Macpherson; while Sanquhar was opened by him, Bluefields and Pallagolla; and Rangbodde purchased from the heirs of General Fraser. In Colombo, Mr. Duff, at one time, owned both Elie House and what is now Mount Lavinia Hotel. On Mr. Lawrence Oliphant selling all the Nuwara Eliya and other Ceylon property belonging to his father, our former Chief Justice Mr. Duff became the purchaser, and from part of the forest land was able to develop Dunsinane estate in the Pundalnoya Valley. When the Messrs. Worms—cousins of the Rothschilds—wished to retire from Ceylon, it was Mr. Duff who arranged the purchase of their properties and so far as this island was concerned, promoted the establishment of "The Ceylon Company, Limited." Then, again, Mr. Duff early became a proprietor and pioneer in the Uva districts. He acquired Gowrakelle, and in partnership with a nephew, the Gonakelle Group as well as Nayabedde in Haputale. Getting alarmed about the dearness of rice and scarcity of labour, Mr. Duff sold the Monsagalla block of land to Mr. C. B. Smith, the same proving, as a coffee plantation, a regular gold mine to the fortunate proprietor. In Haputale, Mr. Duff opened the

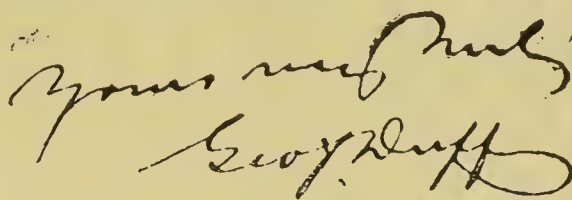

large estate of Wiharegalla* having, as his first manager and part proprietor, Mr. F. F. B. Childers (brother of the well-known Orientalist) since settled in business at Monte Carlo. Afterwards, Mr. Duff opened the fine estates of Dunsinane, Pundalnoya district; West Holyrood, Dimbula; and Culloden in Kalutara district—all since sold to Limited Companies. Few capitalists connected with Ceylon suffered more severely through the coffee crisis—the collapse of a great industry owing to the destruction wrought by a fungus enemy of the leaf—than did Mr. Duff; and that not so much in connection with his own properties or personal investments, as through his good nature in becoming security for old friends. In one such case, the loss at a single stroke, to be made good, was no less than £50,000; but Mr. Duff bravely faced the crisis, sold off his property in the Highlands of Scotland, never lost faith in Ceylon and hopefully entered on the new conditions which led to tea gradually but surely superseding coffee, until now he finds his large group of Ceylon plantations more valuable than ever they were. These now comprise a total of 8,525 acres, of which 3,500 are in tea; while 1,500 more acres are in coffee or other products.

It only remains to be mentioned that in August 1865, during the Administration of Sir Hercules Robinson, Mr. Duff was appointed one of the unofficial members of the Legislative Council, a post which he only vacated on leaving the island in 1871.

We have given a very bare outline of a life of great business activity for 27 years in Ceylon—nor did that activity end with Mr. Duff's retirement to England. He still maintained his interest in business, through connection with "the City" Ceylon Companies—such as the Uva and Spring Valley—as well as through his own extensive estates and ever-developing work as pioneer. Mr. Duff also continued to be the friend and supporter—sometimes, as we have shown, to his own great loss—of many in or connected with Ceylon; while as adviser his counsel was sought in many directions. His faith in the Colony has, however, been amply rewarded by the return of prosperity which tea has brought to all its planting country. From his home in Queen's Gate, Kensington, he continues, through the *Overland Observer*, to watch all that goes on in his old adopted home; while, until recent

* On one of Mr. Duff's visits to Ceylon—in this property was privately declared for sale and the late Mr. C. H. De Soysa offered £80,000 for it. Mr. Duff held out for £85,000; but after he left the island, he changed his mind and telegraphed from Aden to his Agents to sell to Mr. De Soysa. The answer to his continental address was "Too late: Mr. De Soysa has gone in for something else." No loss to Mr. Duff, since Wiharegalla after that year yielded profits aggregating fully the above price, and now in tea is as valuable perhaps as ever it was.

years, he enjoyed his summer residence and shootings in the Highlands, varied by an occasional visit to the Continent, to Egypt or to Ceylon. The great shock of his life came in the summer of 1895 in the unexpected and terribly sudden death of his wife who had always enjoyed good health; but time has enabled Mr. Duff to some degree to overcome the blow and the presence of his daughter and son-in-law (Mr. & Mrs. Oswald) still make his residence "home." When we called to see, and say good-bye to, Mr. Duff, during our recent visit to England, we found him in his library finishing a letter—and the caligraphy of the old gentleman, well on towards 80 years, is as admirably clear and neat with its plain but all-sufficing signature

as was that of the Co'ombo Banker of the "sixties." "In a minute I'll be free," was Mr. Duff's remark as he rapidly completed his letter. rose to a copying press in the corner of the room, secured the duplicate, returned to his seat and laid aside the half-dozen letters he had prepared for the post. "Two or three hours of such work in here daily, keep me alive," was his remark and he then readily entered into reminiscences of early days in Ceylon, imparting confidences, in answer to stray questions, to which we have scarcely ventured to refer in our scanty notice. For, to write adequately of Mr. and Mrs. Duff's life in Ceylon would be to give not only the financial, business and planting, but also the social history of the Colony during one of its most interesting and progressive periods. There were few love matches or marriages of any note among the Colonists of the "fifties" or "sixties" in Ceylon, in which the influential Banker and his hospitable warmhearted wife did not bear a generous part and not a few happy unions, indeed, for which they were very much responsible. That is all of the past; but it is a matter of present and continuous interest that the name of "G. S. Duff" should continue even now as proprietor (individually or in partnership) of such important and widely separated plantations in the island as the following:--

Name	District	Total	Area-acres: cultivated
Helbodde	.. Pussellawa	.. 1,778	.. 735
Rangbodde	.. Ramboda	.. 2,081	.. 922
Wiharegalla	.. Haputale	.. 8,95½	.. 7,99½
Nayabedde	.. "	.. 1,125	.. 867
Gonakelle Group	.. Passara	1,752	.. 995
Gowrakelle	.. Badulla	.. 829	.. 635
Kitulgala	.. Dolasbage	.. 65	.. 50
		Total..8,525	5,008

Long may Mr. GEORGE SMYTTAN DUFF be spared as a typical successful Ceylon Colonist—a model of industry, uprightness and shrewdness as Banker; of enterprise, liberality and confidence as pioneer proprietary planter.

Agricultural Pests :

WITH METHODS OF PREVENTION.

BY MISS E. A. ORMEROD

(LATE CONSULTING ENTOMOLOGIST TO THE
ROYAL AGRICULTURAL SOCIETY OF
ENGLAND).

IV.

BEE TL ES AND WEEVILS INJURIOUS TO FIELD
CROPS AND GARDENS.

The Apple-blossom weevil (*Anthonomus pomorum*) does much harm by laying its eggs in unopened apple-buds, where the maggot feeds, and thus destroys the young forming fruit. This weevil shelters itself during winter under clods of earth and rubbish, and also beneath rough bark on the tree (so that keeping rough ground and bark in order serves much to diminish their numbers); but further, it comes out in the spring, and the females, it is stated, rarely fly, but crawl on the branches, and drop down on being alarmed. By working on this habit of the apple-blossom weevil (and of some other kinds), we may clear many sorts of fruit trees and bush fruit simply by jarring the boughs. Thus the weevil falls, and we only need to use such plans as common sense will teach us, to keep it from getting back again. With the apple weevil, or those that are shaken down from the trees, such methods as putting a rough rope, or a ring of anything they will not cross on the ground, round the trunk, answer well. This may be made of twisted hay (or anything preferred), which has been dipped in spirits of tar, or in tar and coarse oil, so that it may keep wet and sticky or caustic gas-lime may be shovelled round, of course taking care not to hurt the bark.

In Cornwall, where the pitehy-legged Weevils, or other kinds of *Otiorhynchus*, injure the fruit to an extent causing serious loss in the great raspberry gardens, it is found to answer, well for men to go round with freshly tarred boards, place the boards below a bush and shake; the weevils fall on the tar and stick to it. Thus, clearing the weevils and retarring the boards frequently, the weevils are got rid of at a paying rate.

The principle of alarming the weevils, so as to make them fall, may be applied to many kinds of weevil attack, bearing in mind that the weevils commonly fall on the first alarm; and we must give a little attention to their habits, or they may all have dropped down and secured themselves before he have set about frightening them in full form.

Several kinds of weevils feed on peas, beans, and clover leaves, doing thereby most serious harm.

The terribly destructive pea weevils were formerly supposed to feed only by day; then they fall at the vibration of a foot, and bury themselves. There may have been hundreds a minute before, but you will very likely not see one; but beat the ground with a spade and you will most likely see them all struggling up out of the earth again. More recently, however, observations have shown that they may be found at night working at the edges of the leaves, and then it is stated they are not nearly so susceptible of alarm.

Returning now to the ravages of the *Sitones*, commonly known as "pea and bean weevils," these may be told by the semi-circular scoops eaten out of the leaves. We find these attacks the worst to the leafage of young plants, especially when, from weather or other circumstances, the plant is kept back, so that it cannot grow away from them; but the weevils are to be found in legions later in the year, and sweeping these up, as they are to be found in the waggons when clover or peas are being carried, would get rid of some amount of coming attack. The main point we seem to need here is to prevent the settlement of the autumn brood of beetles. These fly well, and have been found to shelter themselves in the top joint of corn stubble, and from this they come out to set on foot attack

in *Trifolium*, or clover, drilled after. Also it has been noticed that where wheat-sheaves stood long in harvest-time, the clover on these spots was free from attack in the following spring, although that on the rest of the field was attacked. Acting on these observations, skimming the surface stubble, so as to get rid of the shelter, has been considered useful; and a good liming, or other chemical dressing, much of which would go into the stubble and make it a very undesirable home for the weevil, would help us. All measures which will push on good growth are valuable preventives in this case; and in gardens it would probably do a deal of good, to lay the drawn and useless haulm along the rows, with any dry rubbish, and burn it. It appears to be the nature of this weevil to come up not to go down, on alarm; and we might thus clear out the parents of the next spring's attack.

The small long-snouted "pear-shaped" clover weevil also does much harm to clover leafage; but in this case the grub lives in the seed-head, and seeds on the young forming seed; and the best known method of prevention is cutting the clover before the flower is fully out. These pear-shaped weevils are so very small that they are hardly observable, but the damage to the leafage, or patches of brownish heads in a field in flower, shows where they are at work.

There is yet one more of the common weevil attack of the bean crops to notice; it is that of a small short-snouted weevil (black with brown hairs and white markings), which is often found inside broad beans, with no signs outside of how it got there. The attack happens thus:—When the bean-pod is still in its very youngest state, even still in the blossom, the beetle lays its egg there; the maggot, which hatches from it, lies in one of the young beans in the pod, but the hole by which the egg was put in, or maggot crept in, is so small that it grows up completely with the growth of the bean. When the beans are ripe and garnered, the maggot is there too. It feeds within; and though it does not prevent the bean sprouting, yet it lessens the size of the seed-leaves, and consequently weakens the first growth, and thus damages the strength of the future plant. Here one good method of prevention is to examine a sample seed, to find whether it is infested. The maggot turns to a beetle within the seed; but before it does this it eats a tunnel to the outside, only just leaving the outer skin at the end. This, having nothing behind it sinks in, as if a knitting-needle had been slightly pressed on it. By this little round dented-in mark you may know infested seed; if, instead of the mark, there is a small round hole, the beetle has completed its work within, and has gone. By these two marks you may judge as to the state of the seed; and, further, if there should be the mark showing the beetle is still within, it is unsafe to sow as attack will follow. The beetles will presently come out, and as soon as the beans in which they were sown have grown, and are in flower, their sometime tenants will mount to the blossoms, and lay eggs to start a new attack. The bean beetles begin to appear in February, and for this reason autumn-sown beans are the most likely to be infested as the beetles are still within.

During the last few years it has been found that dressing infested beans, before sowing, with a mixture of 1 lb. blue vitriol, and 1 pint of McDougall's sewage carbolic to 6 quarts of water, answered well. The above mixture is enough for six bushels of beans.

The cabbage and turnip gall weevils do harm underground. The female lays her egg on the root or the under-ground part of the stem, or in a hole which she forms with her snout; and in consequence of the irritation thus set up the small lumps form, which we know as galls. In each of these the maggot hatched from the egg feeds, until it is full fed. Then it gnaws its way out and forms an earthen case, in which it turns to a pupa, and thence to a weevil.

The maggot does not care for cold. It will mend its earthen case if it is broken; and even if it is buried by the galls on the cabbage stalks being dug in, it appears to thrive as well as if they were still growing. Therefore, it is a great object to get rid of all nurseries of future attack by burning or otherwise destroying old stems with galls, instead of throwing them to a rubbish-heap or digging them in; and a change of crop is useful, by presenting food that they cannot eat, or find useful to lay eggs in, to the gall weevils that may be waiting in the ground.

In many of the weevil attacks which we have been studying, treatment of the surface of the ground is a great point; as, for instance, where they shelter under rubbish, or down stubble, to clear away these shelters, and put on dressings which will be thoroughly obnoxious to the weevils, is good treatment. Where the weevils, or their grubs, are in the ground, it obviously is well to turn them out on the surface, or bury them by trenching so deeply that they cannot come up; and also, so to dig in, or otherwise apply, chemical manures, as to make the soil unpleasant at least to the pest, and so good for the plant that it may grow away from attack.

The turnip flat beetles are well known for their leaping powers. They live during winter under clods, or in dry stone walls, or any convenient shelter and come out with sunshine in spring. Then they feed on any plant of the cabbage kind; charlock is an especial favourite, until the young turnip plants are come up. Presently they lay their eggs (if on turnips) on the under side of the rough leaf, and from these the grub eats its way into the leaf, within which it feeds for about six days. It then comes out, buries itself in the ground, and turns to the chrysalis, from which the beetle appears in about a fortnight, ready to begin a new attack.

The first point in prevention is to take care there is as little winter shelter as possible. Lumps of manure and clods of earth on the field; heaps of stones and rubbish, such as are often allowed to lie in corners of fields; large collections of dead leaves on the borders of woods; and dry dykes or open stone walls—are all winter shelters.

Another point is to let there be as few weeds as possible to keep the "Fly" alive. If it does not find suitable food it will die or remove itself. It has a power of perceiving where its food is; and such plants as charlock, or the white-flowering Jack-by-the-edge, or shepherd's purse, will all help to keep it alive till our turnips are ready. Thus, we may lessen the amount of coming attack; but the great point to depend on for carrying the turnip crop through "fly" attack is judicious preparation of the ground—plentiful supply of enrichment, including a good amount of artificial manure, and liberal supply of seed.

The "fly" does most harm to the turnips whilst they are still in the seed-leaves; therefore, all means should be used to give a good start, and run the plant on in a hearty growth. For this purpose the land should be well prepared beforehand. Where climate allows, autumn cultivation is best. Thus the surface soil is broken down by the winter frosts, and there is a good tilth on the surface, with absence of the clods which shelter "fly" and cause a dry top, instead of the evenly-evaporating surface which suits the young turnips. When thus cultivated beforehand, the land does not require ploughing again in spring; scarifying is enough; and thus the supplies of moisture which have gathered below the surface during the winter remain undisturbed; whereas, if the ploughs are put in, the soil is turned up to a much greater depth, and instead of a mellowed surface with good moisture below, we put with the stores which in a dry season, would have made all the difference of life or death to the crop. The turnip plant is of such a succulent nature, that the point of supplying it with enough moisture is one of the main things in all methods of starting it.

It is advised to let the land remain untouched for a few days before drilling, with a view to the surface not being dried by exposure just before sowing; and the effect of what seems just the opposite treatment

—namely, to sow at once, when partly rotted manure is ploughed in, in spring—is, for the same reason, to secure the moisture. But whenever it may be necessary to work the land, one great point is to secure such a state of under-soil and upper-tilth as will push the plant on; and by no means trust to a mere good tilth, if it is gained, as is sometimes done, by turning the land over in the sunshine and heat until we fairly see the dust rising, and, as it has been well remarked, it is as dry as if we were making hay. Turnip fly delights in heat and drought, and the turnips in just the opposite.

Liberal seeding—3lbs. or more per acre, answers well; for if fly comes there is a good chance of some of the plants escaping, and if it does not the surplus quantity may easily be removed. In either case the large number of plants helps towards a hearty start, as the many small leaves prevent the moisture beneath evaporating, as it would from bare earth, and thus keep a damp air beneath the leaves. Good seed is also very important, so that it may sprout at once, and with vigour.

To gain this hearty and rapid growth through the time of the seed-leaves is one of the reasons of applying artificial manure before sowing, or drilling it together with the seed. A few hundredweights of superphosphate, or other manure suitable to the land, even if there is a good supply of farm manure also, will run the plant on rapidly through the growth of the seed-leaves; and when the rough leaves are come the greatest danger is past.

Where a crop hangs back, the water-cart has been found useful, and also the putting in of the seed with the water-drill; but if the weather should be dry at the time of sowing, there is fear of the small supply of moisture put in by the water-drill causing harm (by the mere temporary effect) rather than permanent growth.

When attack is present, various fertilisers have been found to do good by pushing the plant on; but all applications intending to serve by removing "fly," or killing it, should be used either when the dew is on at night or early morning, or during damp by day.

The turnip fly leaps away when it finds attack coming; but if the dew or slight rain is on it, it cannot leap, because the moisture clogs the hind legs, by means of which it takes its great springs. Therefore, such measures as driving sheep through infested fields, or laying on special dressings, often fail, because they have been done at time when the fly is well able to avoid receiving harm. Turnip fly attack is one of those that it would be well to enter on, if possible, in full detail, as an instance of those which only last for a short time, and which we conquer by methods having, for the most part, very little to do with the insect itself. We know that the turnip is chiefly in danger whilst in the seed-leaves; we know exactly what will suit its growth in this state, and we make ready the ground accordingly; also we clear away weeds which would support the "fly" when the crops are not present for it to feed on.

PROGRESS IN THE PERAK STATE.

In the few remarks which I intend to make on this subject I do not purpose to trouble your readers with statistics, or to say much about the "pig that pays the rent"—the tin mining industry—though up to the present it has run the whole show.

ROADS AND RAILWAYS.

Communications everywhere are the wheels of progress; if they are bad the wheels go slowly round; and if they are good, better, best, the pace is proportionate. At present it may be said that communications in Perak are "good"—that is there is a first-class metalled road from Tuping, where the railway from Port Weld lands you, to Kuala Kangsar on the Perak River, a distance of 23 miles; and from the latter place there is a branch road of 20 miles to Kota Tampan towards Norsh Perak. The continuation of the K. K. road across the Perak River takes you into Kinta, the prin-

cipal tin-producing province (exporting something like 120,000 cwts. annually), where you meet the Kinta Valley Railway at Cheemor, 22 miles from K. K. and 65 miles from Telok Anson—the present outlet of Kinta and Lower Perak on the Straits of Malacca. To take you to the Southern border of Perak and the Northern of Selangor at Tanjong Malim, some 50 miles from Tapah on the K. V. Railway, there is only a bridle-road and indifferent bridges. Such is the state of existing communications, which, taken as a whole, may be called “good”. We will say nothing about the steamers which carry you from Penang to Port Weld and Telok Anson, because they belong to a private firm and are not subsidised. If they were, perhaps they would be more comfortable and the Government of Perak might see more visitors, and secure some of them as investors in the land which is so abundant.

METRE GAUGE RAILWAYS EVERYWHERE.

There is, however, a near prospect of the qualification “good” being converted into “better” as 20 miles of the break between Larut and Kinta in railway communication are under construction, and 25 miles under survey. Between Taiping and Prai, opposite Penang, at about 50 miles’ distance, the railway survey is in progress, as it is between Tapah and Tanjong Malim, another 50 miles. The completion of this through line of railway communication in Perak may be looked for before the year 1900 is ended, for they don’t take up years of time there in talking about their proposed lines and they don’t worry themselves over gauge. They have adopted the metre, and they are content to keep it to the end, as the best suited in cost and capacity for a country of short distances, though with a large traffic in the present, and a still larger in prospect the near future.

What the speedy completion of this “better”—I may say “best” line of communication when Selangor, with 16 miles, links up from Kuala Kubu—may be judged from the small “boom” that set in a year ago in coffee planting, consequent, in a measure, on the steadily-pursued railway policy of the Government of going ahead until their trunk line is an accomplished fact.

THE LABOUR AND ADVANCES ROBBERS.

Prior to the last year or two you could not point to any considerable evidences of the doings of coffee beyond Waterloo (Arabian) and Kamuning estate (Liberian), both the result of European capital and enterprise. Now you can point to recent development of about a thousand acres in coffee in the Kuala Kangsar, and a great deal more in the Kinta district; and a feature in this fresh departure is the investment of Chinese capital. Whichever way it is, from a belief in coffee or a disbelief in mining, the fact remains that the Chinaman is putting his money into coffee, and, when he joins with the European in the race, we can come to no other conclusion than that, for better or worse, there is to be a run on the coffee lands of the Perak State. That it will be for the better all the evidences go to shew; where it may be for the worse I am inclined to say it will be from faults that could be avoided, and not from any drawbacks of soil, climate, labour, or communications. This leads me to speak of the labour problem in Perak. Until within a recent period it was a difficult problem and a deterrent to planting progress, I think it is not so any longer. The Chinese are as apt at most of the planting work as the Tamils, and will do it as cheaply and well. Both these races can now be got in sufficient numbers and without advances, and, so long as tin is at its present price, there need be no fear as regards labour, even should the “boom” to which I have referred extend in volume and make a larger demand than hitherto on the labour supply. We in Perak are, of course, at a disadvantage compared with Ceylon as regards rate of wages, but we have, on the other hand, the advantage in freedom from advances and necessity

of supplying rice. The cooly gets his pay every month regularly, and all that has to be done for him is to provide good lines and give him medicine when necessary; his rice and fish he gets as cheap as in Ceylon, and such things as plantains he gets for nothing or next to it. With all these inducements to the cooly I don’t think the planter in Perak has anything to fear as regards labour any more than he has with regard to the good growth and plentiful cropping of Liberian. I see nothing else to fear that the market, which may become glutted with coffee as it is sometimes in danger of being with tea. Sir Grame Elphinstone last year cleared 500 acres of land, which he planted mostly with Liberian Coffee, and at the beginning of this year he had next to nothing on his books in outstanding advances. I believe this experience of one, which I quote, is the experience of the many in Perak. If it were not so there would not be the advance there has recently been for Chinese would not hang on to a place under advances the same as the Tamils in Ceylon, any more than the Tamils in Perak would do; and there would be much greater loss in recovery, as I had good cause to know in connection with railway work there.

THE TAMILS IN PERAK.

Additional and cheapened facilities in the steam-boat communication between Penang or the Straits and Southern India, coupled, with the increasing popularity of Perak with the India coolie, will bring Tamil free labour over in greater numbers year by year, and the planter there will before long have the advantage of two races competing for his work; and he can look forward to getting more work out of the individual than hitherto. That this will be a blessing to the coolie himself there cannot be a doubt, for it was the short hours and high pay that tended to demoralize the Perak Tamil and make him so inferior in quantity and quality of work to his brother in Ceylon.

YIELD OF LIBERIAN COFFEE.

As already mentioned’ coffee planting in Perak is so much in its infancy that not much can be looked for, so far, in crop results, but what can be mentioned of the yield in 1895 of clean coffee from one estate having 257 acres more or less in full bearing, 6 to 7 years old, is encouraging enough for those later in the field. The acreage mentioned, with something like 400 trees to the acre of Liberian, some of it topped at 6 feet, and some at 10 and 12 feet, gave 6½ cwts. per acre of clean berry, which fetched the highest price in the Singapore market. This result was attained without the aid of any manure; with that aid it is quite likely the crop return might have been increased by fifty per cent.

COCONUTS.

Regarding coconuts I am inclined to think that on a large scale the returns will be much greater than in Ceylon. Going into a native garden where there were some very fine trees, I asked how many nuts were got from a tree in a year, and was told 200. This may be right or wrong, but there is no doubt of the heavy bearing capacities of the trees generally.

I say nothing about Selangor, for I have not been here this time, neither do I say anything about planting Liberian, in imitation of Selangor, on the low, flat, more or less swampy, peaty lands by the sea, for time will tell if the venture be right or wrong.—Local “Times.”

THE WOODS OF SAMOA.

Much has been written about Samoan woods, their beauty, abundance, and variety, but, says the United States Consul-General at Apia, there is but little foundation for the statement that these woods are likely to become a source of marvellous wealth. There can be no question but that the variety of woods is very extensive, and that a limited pro-

Portion may in time become valuable. Most of the Samoan woods are very soft and light, which after becoming well dried, lose not only a great proportion of weight, but become brittle, and of no practical worth to sustain lateral strain. In addition to these, there are several varieties of hard woods, such as the *ifelele*, *talia*, *pau*, *toi*, *nisla*, *tau*, and the *ifi* (*Inocarpus edulis*), which can scarcely be said to be abundant. Several of these are beautiful, very hard, and susceptible of a high polish. One or two varieties grow to a fine size, and are in request among the natives for making kava bowls—wide shallow vessels, hollowed out from cross sections of the butt of the tree, generally from 18 inches to 2 feet in diameter, and some times reaching 3 ft. 6 in. in width. Woods employed for this purpose would doubtless cut into veneers, were there a demand for their peculiar colour and grain by the fancies of fashion. Such, however, does not at present exist, and there is no probability that the mere eccentricity of taste will take a direction to create a demand. A large amount of hard wood is used in making the common canoe of the natives. These are mere logs, hollowed out, and the largest with rare exceptions, would not require a log of more than two or three feet in diameter. These canoes are hollowed laboriously out of the log, on the ground where the tree is felled, being hewn away until the boat is a mere shell of from 1 to 1½ inches in thickness, except at the bow and stern. When thus lightened to a minimum, they are dragged and carried to the water. While large trees are numerous, they are not in proportion to the extent covered by the forest, or to that common in a country of merchantable timber, plentiful, or found close together. The dense character of the tropic forest, the deep shade, moisture, and heat, has naturally, in such a climate, the influence of so thickly crowding the surface with shoots and young trees, that the forest is a mass of slender saplings, overcrowded and dense, all under the stimulus of the need of light and air, towering to reach the open space above. In such a hush, the large trees having attained size on some principles of survival of the fittest, abound in necessarily limited abundance. These large trees, of nearly all varieties, flare out at the butt in ribs or inverted brackets until they cover a space at the surface of from 12 to even 20 feet. The woods are not of straight grain, but are twisted, knotted, gnarled, and contorted in shape, and this bent and knotted quality in the hard and tough varieties produces a most excellent material for knees in small and medium-sized wooden vessels, for which it is much used. In a general sense, it is, perhaps, in this employment that Samoan woods find their greatest value. Much was expected in years gone by from the production of fibres, and an array of plants was cited producing fibres of a merchantable character. The intervening years have allowed the shipments of various samples to Europe for experiment, but the experiments were such that no encouragement or demand followed. The fibre obtained from the covering of the coconut is particularly the only one produce in the Samoan islands. This article is well-known to commerce, and long ago took a place in the manufacture of mats, and to some extent as a substitute for hemp in twines. In all coconut growing countries, it is of course abundant in proportion to the production of mats. In Samoa it is used by the natives in making all the twine and small rope their needs require, and does not enter into export—*Journal of the Society of Arts.*

HASSAN JACK FRUIT.

The Jack-tree of the East Indies (*Artocarpus integrifolia*) is a handsome evergreen tree about 60 feet high, the trunk having a diameter of 30 to 40 inches. Its dome of dark foliage, with the stem burdened with monster fruits, is perhaps one

of the most characteristic features of East Indian village surroundings. The yellow timber is highly valued for carpentry and furniture, and takes a fine polish; it becomes beautifully mottled with time, and then resembles Mahogany. It also yields a yellow dye, little inferior to fustic. The fruit yields a very important article of food to the natives of the East Indies, both when green as well as when ripe. It is closely allied to the Bread-fruit of the Pacific Islands, but usually is not so palatable. Europeans seldom touch it. The oily seeds, when roasted, are eaten, and are said to resemble Chestnuts.

The leaves of the Jack-tree, as the specific name implies, are usually entire. In exceptional cases they are three-lobed; this is specially a characteristic of seedling plants. The lobing of the leaves shows the affinity of the Jack to the Bread-fruit. They both belong to the tribe Artocarpeæ of the N. O. Urticaceæ, as also do the Figs, which yield a similar milky juice. The flowers of the jack, produce on the stem and older branches, are monœcious—that is, they appear on different parts of the same plant. They have a somewhat sweet smell. This is in marked contrast to the strong, unpleasant odour of the ripe fruit. The male flowers are densely crowded on the outside of a fleshy horn-like central receptacle, about 2 to 3 inches long. The individual flowers are very minute, and consist of a single stamen and a two-lobed yellow anther. In a section across the receptacle the male flowers are to be seen radiating in a very regular manner from the circumference of the spongy centre. The female flowers are similarly arranged, but on a much larger receptacle, and are so numerous and thickly crowded as to form an oblong, tuberculated mass of flowers several inches long. Each female flower consists of an oblong, tubular perianth, green and contracted at the mouth. The ovary is provided at the base with a lateral white style passing through the aperture of the perianth. After the ovary is fertilised the mass (or spadix as it might be called) swells in all directions, and forms a tuberculated, compound fleshy fruit, sometimes weighing from 40 to 60 lbs., probably the largest that is known. The central part is the soft, fleshy receptacle; surrounding this, and radiating toward the circumference, are—(1) the succulent parts of the very numerous, linear, abortive florets; and (2) the enlarged perianths of the fertile florets much swollen, and appearing as brownish-yellow succulent masses, 2 or 3 inches long. These two sets of bodies constitute the eatable part of the Jack-fruit. Each seed is completely buried in pulp, and enclosed in a leathery testa. It is usually as large as a Nutmeg; it is destitute of albumen, and composed of two unequal cotyledons.

Good figures of the flowers and fruit are given in the *Botanical Magazine*, tt. 2833 and 2834, from specimens grown in the Botanic Garden at St. Vincent, in the West Indies. A plant is mentioned to have flowered in 1827 in the stove of the Edinburgh Botanic Garden.

The ordinary Jack-fruit above described is familiar in many parts of the tropics, and is widely cultivated in the East, from the Punjab to China, and from the Himalaya to the Moluccas. There are numerous varieties recognised by the natives of India and Ceylon. Although common in the latter country, it has probably been introduced at a remote period from India. It was introduced to Jamaica and St. Vincent by Admiral Rodney in 1782, and thence distributed to other countries in tropical America. The fruit is not esteemed anywhere in the New World; probably the single variety there known is an inferior one.

This year a drawing of a very remarkable Jack-fruit was sent to me by Mr. J. Cameron, F.L.S., Superintendent of the Lal Bagh Gardens, Bangalore, in Mysore. In a letter dated August 29 last he gave the following description of it:—

"About a month ago I sent you a photograph and a water-colour drawing of a remarkable Jack-fruit—

at least remarkable to me, as it is the first of its kind I have ever seen.... The fruit and photograph were sent to me from Hassam, one of our hill districts by Mr. A. Watkinson, a coffee planter. His own letters, with two of my replies enclosed, will afford all the information at my disposal. Would you do me the great favour to say what you think of this fruit?.... With your eastern and western experiences you are, of course, well acquainted with the usual form of this fruit, and can offer a valuable opinion."

Mr Watkinson's account of the tree is as follows:—"There is a peculiar Jack-tree here, the shell which holds the kernel grows on the outside of the fruit... Both planters and natives declare it to be unknown in any other part of the district. The native idea is, it was brought hither by a cobra when young!" On March 23, 1896, Mr. Watkinson sent a specimen of the fruit to Mr. Cameron with the following note: "In October last I wrote you about a curious Jack-fruit, a specimen of which I am sending by bearer. I think you will find that the pericarp is intermixed with the tubercles or spines, and that the peculiarity is not caused by enlarged spines. I am sending a fruit weighing 9½ lb. to Mr. Graham Anderson. I should have sent the larger one to you, but it is already over-ripe, and should be in a state of decomposition by the time it reached you... I could send you another later on, as there are five others on the tree only half-grown." Mr. Watkinson adds, "I can see no difference in the tree itself from the rest of the trees of the wild Jack." The wood-cut (fig. 125) represents the Hassam Jack-fruit one-half the natural size. Its most striking characteristic is the position of the seeds on the outside, instead of being buried, as usual, in copious pulp. There is evidently no swelling either of the receptacle or of the perianth, as in the ordinary Jack-fruit. Hence the Hassam fruit is probably uneatable. The spine-like processes occupying the area between the seeds are the abortive florets.

Sir Joseph Hooker, who has recently completed his great work, *The Flora of British India*, has been good enough to examine the drawing of the Hassam-fruit, and he is of opinion that it is either an abnormal form, or a new species.

Colonel Beddome, F.L.S., who is credited with having found the Jack-tree in a wild state in Southern India, expresses a similar opinion in the following words:—

"The Jack-tree is very common in a wild state in all the moist forests on the western ghâts of the Madras presidency.... Its fruit does not differ from that of the cultivated tree. Your drawing must, I think, represent a quite abnormal form, unless it be a new species. I can only say I never saw anything like it."

Apparently it is not an abnormal form, as the seeds (I learn from Mr. Cameron) are fully developed, and give rise to normally healthy plants. These are now growing in the Bangalore Garden. The matter cannot be carried any further at present, but material is promised of both the leaves and of flowers, the latter in different stages of development. When these arrive it may be possible to come at a more definite conclusion respecting this interesting plant.—D. MORRIS, *Kew*, December 5.—*Gardeners' Chronicle*.

THE COFFEE ENTERPRISE IN SELANGOR.

Judging from the enthusiasm of those directly interested in the cultivation of Liberian coffee in Selangor (writes a correspondent who has been visiting the Native States of the Malay Archipelago) there seems to be a great future in store for the enterprise. In Ceylon you have heard from one source or another, at irregular intervals of the opportunities offered by investments in land in these States, but very little real interest seems to have been taken in the matter. I have had

the privilege of meeting amongst others, Mr. Toynbee, who was engaged in opening out the first estate ever put under cultivation in Selangor, and who naturally is an authority on the subject. He is now one of the largest proprietors in the district. Selangor is the capital of the newly-organized Federated States of which Mr. F. A. Swettenham, C.M.G., is the Resident-General. It is, in extent, 3,000 square miles, or about one-eighth of the size of Ceylon. It lies immediately to the South of Perak, and is well intersected with railways. The climate is much the same as that of Colombo and the lowcountry of Ceylon, and is regarded as being no less healthy than the average Eastern country.

At present there are some sixty estates under cultivation, but many more are likely to be opened out shortly. Possibly Mr. T. N. Christie, Mr. G. A. Talbot, or Mr. W. B. Kingsbury would be the best authorities as to when. In the meantime, however, it is as well to state that at present land may be bought at the rate of the dollar per acre, with a nominal annual ground rent of half that sum. To small capitalists then, the prospect ought to be inviting, because there can be "no doubt, no possible doubt whatever" that the conditions are favourable for the cultivation of the product, and that those who have already invested are anything but dissatisfied with the results of their experiments.

On one point, however, I was solemnly warned. However expert a Ceylon planter may be, he cannot hope to be a successful Selangor planter, until he has, so to speak, served an apprenticeship in the country. First and foremost a knowledge of the Malay language is essential, for although Tamil labour is largely used, it is next to useless in the preliminary work that has to be done, and for which Malays only are utilized. Secondly, it is necessary that the planter should know all about irrigation and the intricacies of drainage—drainage such as is little dreamt of in Ceylon. For instance, a clever prospector will see glorious possibilities in a huge sheet of water, that is a tract of flat ground, covered by two or three feet of water. The first thing to be done, of course, is to drain the water off the ground, and the second to do it in such a way as to prevent a repetition of the flood. This done the estate is ready for planting.

I have said that Tamil coolie labour is largely employed. From what I heard there seems to be no difficulty in the way of procuring this labour. A man is paid twenty-seven cents for a day's work, equal to about forty-five Ceylon cents, while a woman is paid twenty cents. Rain is plentiful, as is necessary for the cultivation of Liberian coffee, the average rainfall being anything between 80 and 180 inches.

What the future of the country may be it is, of course, impossible to say, but at present prospects seem very bright. The Government is doing its best to assist the planters, and fresh capital is continually being imported. To the outsider it would seem that the enterprise has already got beyond the experimental stage, and that the openings for and the probable rewards for small or large capitalists are enticing. It is, however, no place for the uncapitalized Ceylon planter, for, as I said before, the conditions and the nature of the work are very different to those here. Still it is as good a place as any other for the "creeper," and—what a chance for Lipton!—Local "Independent."

CAPE FRUIT.—The ss. "Fantallon Castle" has arrived from the Cape with 728 cases of fruit, consigned as follows:—202 cases of Grapes, to Mr Hudson; 195 cases do., to the Colonial Consignments and Distributing Company (Ltd.); 5 cases to W. R. Sutton & Co.; 86, and 20 cases of Pears, to Messrs. Woodhead, Plant & Co.; 120 cases of Grapes to Mr. E. Hudson; and 100 cases do., to Mr. Nathan. This entire consignment arrived in very good condition.—*Gardeners' Chronicle*.

THE CEYLON PROVINCIAL ESTATES COMPANY, LIMITED.

The second ordinary general meeting of the shareholders of this Company was held at Colombo on the 27th Feb., when the following report was presented and adopted:—

The Directors have the pleasure in submitting their report for the past year, 1896, together with a statement of accounts shewing the results of the Company's work from 1st August to 31st December last.

The accounts now submitted, taken in conjunction with those laid before the meeting held on the 5th September last, cover the Company's operation for the whole of 1896.

The expenses incurred in forming the Company, and the legal and other outlays attendant upon the purchase of the three properties, amount to R9,074.63 altogether, and after providing for that out of revenue the net earnings for the year come to R61,567.99.

On the 5th September last a dividend of 4 per cent was declared, and out of the amount now at credit of the Profit and Loss account the Directors recommend that a further dividend of 5 per cent be paid, in respect of the shares entitled to participate making 9 per cent for the year. The balance after setting apart a sum of R500 to meet remuneration to the Directors they have decided to employ in providing, as far as it will go, for what the Company has spent during 1896 in adding to the cultivated area of the estates.

The Tea extensions in 1896 represent 63 acres altogether (50 on Brownlow and 13 on Glassaugh), and it is in contemplation to clear and plant 30 acres more on Brownlow in 1897.

Since the Shareholders met in September last the purchase of Aadneven Estate has been concluded. The consideration given for it was £6,085 sterling in cash, and 122 shares of the Company taken at a premium of 40 per cent. The area of the property extends to 188 acres altogether, of which 170 acres are under Tea cultivation.

The total Tea Crop harvested in 1896, inclusive of some small sales on the Estates, was 368,367 lb. but in the case of Aadneven the Company got the benefit of 4 months' yield only (September-December). The average selling price of the Tea was about 48.82 cents per lb. and the cost of production 26.80 cents per lb. approximately.

The Estimates for 1897 point to an output of 370,000 lb. of Tea from the three Estates which it is expected will be put on the market for about 27.60 cents.

The following statement shews the area of the Company's properties:—

	Glassaugh and Aadneven.	Brownlow.	Total.
	Acres.	Acres.	Acres.
Tea in full bearing	426	400	826
, in partial "	34	—	34
, not in bearing	28	50	78
Forest	23	62	85
Waste and Grass	21	72	93
Total acres..	532	584	1,116

VOGAN TEA COMPANY, LD.

The annual general meeting of shareholders of the Vogan Tea Company took place at Colombo on the 27th Feb.

The Annual Report was as follows:—

The directors have pleasure in submitting to the shareholders their report and accounts for the year ended 31st December 1896 which they think will be considered satisfactory.

The estimated crop for Vogan and Iddagodde was 265,000 lb., and for Barkindale and Stamford Hill

77,000 lb., i. e., 342,000 lb., and the crop actually secured was as follows:—

	lb.	realising a net average price of cts.	per lb.
Vogan and Iddagodde	275,666	..	41.39
Barkindale and Stamford Hill	87,794	..	53.02

Total.. 363,460 lb., averaging cts. 41.23
The laid down cost in Colombo was for:—

	per lb.
Vogan and Iddagodde	.. cts. 23.06
Barkindale and Stamford Hill	.. cts. 31.35

or an average of cts. 25.06 per lb., which includes a sum spent on manure of R4,636.41, and the cost of making Iddagodde tea in Pantiya Factory for the first five months of the year, and of Barkindale and Stamford Hill teas in Annfield and Ottery Factories respectively for the whole year.

During the year under review 77 acres of tea were opened on Vogan estate, and a further 70 acres of forest were felled and burnt off out of 100 acres to be planted in 1897. For the latter, nurseries of dark-leaved Manipuri Indigenous Seed have been laid down.

At the extraordinary general meetings of the Company held on the 12th and 28th December last, the shareholders authorised the directors to accept the purchase of about 210 acres of land adjoining Vogan and Iddagodde estates, made by their authority from Government, and this addition to the Company's property is a valuable one. At the same time the directors were authorised to issue debentures from time to time as required for the purposes of the Company, the aggregate not to exceed R100,000 at 7 per cent interest or less, on such terms of repayment and for such periods as they may deem expedient.

Up to the 17th of this month Debentures to the extent of R49,000 have been issued bearing interest at 7 per cent, and this rate of interest will be the rate for the balance of the Debentures when issued.

The Acreage of the Company's Estates is as follows:—

	Acres	Tea in bearing
Vogan and Iddagodde	518	
	24½	in partial bearing
	126½	not in bearing
	590	Jungle
	70	(felled)
Barkindale & Stamford Hill	220	Tea in bearing
Total..	1,549	Acres

After writing off R2,731.53, half the amount of preliminary expenses, and setting aside R3,000 for depreciation of Buildings and Machinery, the balance available for distribution amounts to R58,520.09.

Of this sum R28,800 were absorbed by the payment of an interim dividend of 4 per cent for the six months ended 30th June last, and the Directors now recommend a further dividend of 4 per cent for the last six months, making 8 per cent for the year, and the carrying forward of the balance R920.08 to the next account.

As the Share Capital of the Company was not finally called up till about the middle of February, 1896, the Profit is really the result for under eleven months.

The iron work of the new Factory on Stamford Hill is erected and it is hoped that the Company's Tea will be manufactured there from some time in April next.

The estimated Crop for 1897 on Vogan and Iddagodde is 300,000 lb. Tea, and on Barkindale and Stamford Hill 104,000 lb.

In accordance with the Articles of Association all the Directors retire, but, being eligible, offer themselves for re-election.

It will also be necessary to appoint an Auditor for 1897.

By order of the Directors,
LEE, HEDGES & Co.,
Agents & Secretaries.

Colombo, February, 18th 1897.

THE TALGASWELA TEA COMPANY OF CEYLON.

The annual general meeting of shareholders of this Company was held at Colombo on the 27th Feb.

The Annual Report was as follows:—

Teas	..	703 acres
Other products	..	35 "
Forest and chenas..		1,031 "

Total .. 2,039 acres.

The Directors have the pleasure to present to the Shareholders their Annual Ninth Report with a duly audited statement of the Company's affairs as on the 31st December, 1896.

The crop for the year turned out 150,200 lb. of tea against an estimate of 160,000 lb., and was all sold locally at an average of cts. 42.70 per lb. against an average of cts. 47.52 per lb. for the previous year.

After payment of interest on preference shares and writing off the usual amounts for depreciation, there remains a balance of R6,209.78 for disposal and the Directors propose the payment of a dividend on the Ordinary Shares of 3 per cent carrying forward the balance.

During the year, the planting of coconuts, recommended in the last report was proceeded with, and 200 acres have been lined and holed of which 75 acres have been planted. The Directors intend increasing the acreage under this product.

The estimate for 1897, is 170,000 lb. tea. Messrs. S. J. gar and H. VanCuylenburg retire from the board by rotation and are eligible for re-election.

The appointment of Auditor also rests with the meeting, and Mr. Guthrie offers himself for re-election—By order of the Board of Directors,

BAKER & HALL, Agents and Secretaries.

TRAVANCORE TEA ESTATES COMPANY, LIMITED.

Registered February 1, by Murray Hutchius, Stirling and Murray, 11 Birchin-lane, E.C., with a capital of £150,000 in £1 shares, divided into 75,000 referred and 75,000 ordinary. Object, to adopt and carry into effect a certain undetailed agreement for the acquisition by purchase or otherwise for the following tea estates situated at the Peermad district, in Travancore, in Southern India, the same being known respectively as Bon Ami, Mount Nanja, Mully, and Kole Kannam, or any of them, or any parts thereof, and to develop and turn to account the same in such manner as the company shall see fit; and, generally, to carry on business as planters, growers and producers of tea, coffee, cinchona, cocoa, cardamoms, and other plants, trees, and natural products of any kind in India or elsewhere; to prepare for market tea, coffee, rice, and other products; as warehousemen and carriers by land and water; to work mines and quarries, and to find, get win, work, crush, smelt, manufacture, or otherwise deal with ores, metals, minerals, oil, precious and other stones, or deposits or products; to carry on the business of mining in all its branches; to acquire work, and turn to account any patents, patent rights, &c.; to build and work tea factories, coffee-curing mills, factories, tram roads, &c. The signatories are:—

	Shares.

A LESSON IN GARDENING IN CEYLON.

(By a Planter in a Medium District.)

Nallamma, my principal kangani's wife, had, no doubt, many attractive qualifications. In addition to an unusually clear complexion and features that any artist would have been delighted to transfer to canvas, her charm of manner was irresistible: always apparently happy, in spite of domestic cares, bright without effort and jocular without freedom on the one hand or loss of dignity on the other. But her chief attraction in my eyes was her constant love of gardening, and I determined one morning to inspect the kangani's garden, and to do what I could to encourage their cultivation. It had occurred to me, too, that it would be a good plan to give the kangani the greater part of my newest lot of English seeds on the understanding that he should supply me, at moderate prices, with any surplus vegetables he produced. Such things as peas, rhubarb and celery, of which the average Tamil cooly knows nothing, I would continue to cultivate myself, but it seemed probable I should get better results from beans and cabbages, if grown in the kangani's garden than in my own. This idea I should certainly have carried out, but for the fact that I was then only an assistant on the estate, and liable like junior officials to sudden removal by ill-health or promotion.

I had finished my morning's round of work with unusual celerity, and at ten o'clock had ample time to visit the garden on my way back to the bungalow. I found Nallamma not exactly at work, but reaping the fruits of her labours, or rather of her supervision; for, of course, she did not stoop to violent manual effort personally: working by deputy, to those who have that gift, is very pleasant and less conducive than actual physical exertion to rheumatism and back-ache.

I suppose she must have noticed an avaricious look in my eyes, for, she asked me, as soon as I approached the narrow entrance in the fence, what it was I wanted. I told her I merely wished to have a look at her garden, on which she cast a somewhat dubious downward glance at the brinjals and chillies she was carrying in the folds of her cloth.

I crawled sideways through the gap, taking off my broad pith topee, and at once began my examination. I found, just as previous hurried inspections had led me to expect, her garden fully occupied by native vegetables of all sorts, and all of them seemed to be in much better condition than any that my garden could boast of. There were several things too growing in it, which were new to me.

'What is this?' I asked, as we came to a bed of tall plants with showy yellow flowers, apparently a species of *Hibiscus*.

'We eat the leaves in curry,' she replied, 'they are very good but acid.' Nallamma had very fine teeth and I could not help telling her so. 'Ah,' she said, with a pitying air, 'you don't chew betel.'

'You eat these leaves too,' I asked, looking at some slender trees with large, graceful, cream-coloured blossoms. 'Yes, of course,' she replied, 'and the *Agati* flowers too, when not wanted for seed.'

'And these two are edible?' I enquired, pointing to a small bed of foliage plants very like the *Coleus* in my front garden, but with no red or yellow or purple tints in the leaves. 'Yes,' she answered, 'we call them small potatoes: the little tubers are very good, and the plants bear in two or three months' time.' I began to feel that my knowledge of gardening was still capable of expansion.

'Why don't you grow some of our English vegetables,' I suggested rather feebly. 'I would give you seeds or plants.' 'We find these quite enough,' she said: 'yours would take up too much space and they might not be of use in curries.' 'But,' I observed, 'you could make a larger garden and try some of them. At any rate you might cut out some of these useless plantains and grow better things there.'

'The plantains,' she remarked, with a merry laugh, 'are not useless. We get six or eight bunches a year from each always, and the best kinds are

worth a rupee each.' I must confess I felt rather sceptical on this point. I had about a hundred trees growing on two sides of my garden, and got only one bunch from them in about three months.

"Your bungalow servants perhaps take them," she suggested: "every kind is good for cooking if cut before they ripen." This was rather distressing. I had fancied I knew something about plantains and certainly lost no opportunity of pointing out to Ramasamy each flower as it appeared, but I reflected sadly that a great many flowers had borne no fruit for me. I continued my search in hopes of finding some vegetable as to which I might offer hints of improved cultivation, but in vain. Even the onions, of which my cooly had planted several beds at different times, with what I considered good results, were finer and much regular than mine.

"Do you make much flour from your arrowroot plants," I asked, feeling that I might have a chance of telling her how to prepare it. "Not more than you do," she replied with a merry light in her eyes, "but you grow yours in pots in your verandah." "Yes," I assented, "mine are merely ornamental," and I began to explain how the tubers should be cleaned and converted into flour. "I used to make some every year," she said, with a gracious air, "before you came here, but we can get arrowroot and other things from you whenever any of the children are ill. You sometimes give away these things," she added, "to coolies, who are not really ill," and she mentioned two cases in which my charity had recently been evidently carelessly administered.

"Your *bandakai* plants," I observed, "seem to give a large crop: it is a pity they haven't a better flavour." "Oh," she replied, "we like them well enough: the kangani is very fond of them." Perhaps your servant doesn't cook them properly. Different vegetables require different curry-stuffs." This was a point I had never considered; my appu had unlimited curry materials to work with, but there was a sameness about his curries that made them disgustingly monotonous and the dishes often went back to the kitchen almost untasted. I remembered having once suggested that the curry should be given to the fowls, but reflected now that I had never seen the poultry regaling themselves on curry.

"What are these plants," I asked, pointing to some with broad ash-coloured leaves. "Those are a very good kind of yam," she answered: "we eat the stems and the yams too when the porcupines don't destroy them. It was to catch them that my husband borrowed your large rat-traps last month, but they were no use. The porcupines are too clever, and the only plan is to shoot them. But," she added, with an assumed tone of regret, "we caught your horsekeeper's dog, and it is still very lame." The dog had done a good deal of damage in my own garden and I could not conceal my delight.

I failed to find in the garden anything of which either the roots, leaves or fruits were not edible till we came to a couple of low spreading plants with long spikes of red flowers. "This is certainly ornamental," I observed, "but perhaps you use it for curry." "No, for medicine," she replied; "the roots are used in certain cases by Tamil women." I thought it hardly safe to venture further enquiry. I had supposed I knew something of medicine, both European and Oriental, having experimented with many hundreds of sick coolies, usually very successfully, though often, I fear, to our mutual surprise, but this perhaps was a branch of medical lore that I had not yet taken up. Nallamma seemed puzzled at my silence, and I made an effort to continue the conversation by complimenting her on possessing a garden containing nothing useless. "Yes," she remarked, "we do not grow flowers like you do in front of your bungalow; we can get from you all the flowers we want for our temple festivals. I congratulated her on getting so much more produce from a small bit of ground than I could from my larger garden."

"I suppose you get seeds given you by all the other coolies who keep gardens," I suggested. "No,"

she replied, with an air of dainty scorn, "not at all. We give away a great many."

"But how do you manage to get such fine crops," I asked. It occurred to me that perhaps a little of the artificial manure, intended for the coffee trees, was occasionally used, but the suggestion was met by a decisive negative. "We use only cattle manure and ashes," she observed, "and, of course, water the garden regularly." "My garden cooly does the same," I replied, "but nothing seems to grow as well as it ought to. My coolies cost me about twelve rupees a month, and I buy about ten rupees' worth of seeds each season. Ramasami uses the best tools I can get and a very fine watering-can, but even the cabbages don't grow properly and half the seeds don't come up." "I'm afraid," said Nallamma, "you don't look after him sufficiently: you have't time."

This was such an unexpected compliment, and said in such a graceful way that I felt not only pleased but convinced that she was right. "We irrigate our garden from the water course," she added, "and I sprinkle my plants lightly with water from a chatty. Ramasami perhaps sows your seeds in wet weather or does not use the rose of your watering-can except when you are in the garden." And then she continued, with gentle emphasis, "I always sow our seeds myself." I felt that I was acquiring knowledge fast, but did not like to admit it. I argued that my garden-cooly, having no fixed task to do and having generally a fairly easy time, was not likely to shirk such a simple work as watering. "I don't know," she said, "he may be a very good cooly"—her features expressed other disbelief—"but your garden has as good soil as this; I expect it is his fault if your plants don't grow right. His brother has a garden nearly as good as ours. You need not tell him I said so," she observed with a plaintive look. "No, my dear," I answered, with that familiarity which naturally arises from a mutual interest, "I will say nothing, but I will look after him more carefully."

"Do you use these also for curry?" I enquired, pointing to some small plants growing near the entrance, "or are they used for drugs?" "No," she replied gaily, "I have never heard of their being used for either purpose, but the fresh leaves are good for insect bites, and, when rubbed on one's face, remove sun-burn." "Oh!" I exclaimed, looking closely at her clear cheeks, "I can understand why you grow it." She did not seem offended, but advised me to plant in my garden: "Some day," she added, "when you have children, you will find it useful." Apparently she knew something of my matrimonial intentions: my appu had evidently been reading my home-letters, (I did not know he could read English), and the kitchen gossip had reached the cooly-lines.

"I think it is time I went back to breakfast," I remarked. "Yes," she assented "it is late, and you must be feeling hungry." And I wished her "good-morning" with a rather painful consciousness that, instead of having given Nallamma any hints on Gardening, she had instructed me in the first principles of horticulture. And this feeling was certainly not lessened when she sent me, in the evening, by her little son, a collection of seeds, a magnificent cabbage and a dish of beans.

GIPSY JOHN.

JADOO CRITICISED.

"Toda" writes as follows, under date of 13th instant:—

As you published Colonel Halford Thompson's letter, which appeared in the *Madras Mail* of 12th January, criticising a letter of mine *re* Jadoo Fibre, which was inserted in the *Mail* of 19th November 1896, I would ask you in fairness to kindly publish in the next issue of *Planting Opinion*, my reply to Colonel Halford Thompson's letter which you will find in the *Madras Mail* of 4th February, signed "Toda."

We regret we have not sufficient space to quote the letter in full, which occupies a full column of very small print in our contemporary, but we trust "Toda"

will find the omissions in no way impair the weight of his crushing rejoinder.

Colonel Thompson says:—"It is difficult to conceive how £7-10 0 per ton at Madras (now reduced to £7) could by any means swell to R170." Messrs. Parry and Co. tell me they can supply the fibre at R7 per bale of 1 cwt., on rail at Madras. Add another R30 for cost of carriage, (a fair estimate, seeing that the majority of estates are many miles from the Railway Station,) and the present price comes to R170 per ton. In Colonel Thompson's prospectus it was claimed that Jadoo fibre would be useful in two ways, so far as coffee planting was concerned. (i) In the "raising of nursery plants." (ii) In "bringing on supplies," and with these uses I dealt in my original letter. In regard to the first I said "now as to the cost of raising nursery plants." The prospectus states that a 3 bushel sack of Jadoo should be sufficient for "raising 450 (nursery) plants." The ton is said to contain 60 bushels, so that the cost per plant would be about 3 $\frac{1}{3}$ pies. This means an expenditure of—about—R1,650 on the purchase of Jadoo alone, in the case of a nursery, for a 50 acre clearing, planted 5' x 5'. Colonel Thompson says this calculation is wrong because I "have taken the quantity of Jadoo required for a seed bed large enough to raise 450 seedlings at a time"—it will be observed that Colonel Thompson admits the quantity given in the prospectus, a three bushel sack for 450 seedlings is correct—(but which could be used again and again so that 20,000 seedlings could be raised from it) as the basis of a calculation based upon the original 450 seedlings being the whole quantity that could be raised out of that amount of Jadoo." The circular says nothing about the possibility of using a given quantity of Jadoo "again and again," but this does not affect my calculation in the smallest degree. If it takes a 3 bushel sack to raise 450 seedlings (as Colonel Thompson admits) then, with the price of a ton at R170, each seedling would cost 3 $\frac{1}{3}$ pies, and a nursery for a 50 acre clearing planted 5' x 5' would entail an expenditure of R1,650. Colonel Thompson draws an alluring picture. You buy your 3 bushel sack of Jadoo, and raise your 450 seedlings by its aid every year for the term of your natural life. Then you leave it to your successors as an heirloom, who do the same, and so on to the crack of doom. The only drawback is that as a 50 acre clearing would require a nursery of 90,000 plants as a minimum, and as you can only raise a nursery once a year, it would, at the rate of 450 plants per annum, take about 200 years to plant the clearing up. The new light that Colonel Thompson throws on Jadoo, viz., that it can be used for a series of years as it does not lose its efficacy, would of course reduce the cost of a nursery in subsequent years, so far as the purchase of Jadoo is concerned. Before I leave this question, I would add that it is "difficult" for one not in the know "to conceive" how Jadoo can be used again and again. The testimonials printed with the prospectus, and those given in the *Madras Mail* of the 9th December, imply that, when Jadoo is used in a nursery, it encourages root growth in a wonderful way, and that, when the seedlings are large enough to be put out in the field, the fibre is a mass of fibrous roots. How then is the fibre to be retained for future use, without serious injury to these fibrous roots? I trust Colonel Thompson will make this point clear. With regard to the second use I said (I quote from my original letter), "But these figures pale into insignificance before the cost of 'bringing on supplies.' The prospectus gives $\frac{3}{4}$ peck as the quantity each supply should receive.

= 3 16 bushel,
or, say, 1 bushel for 5 plants,
= 1 ton for 300 plants,
= 9 ans. per plant"

On this head Colonel Thompson says "the amount of Jadoo required for raising seedlings in beds to supply 50 acres would be certainly not more than 5 cwt. and would cost therefore R12.8 instead of R1,650 as calculated by Toda." Every word of this sentence is inaccurate, and it is here that Colonel

Thompson gets into a state of more "hopeless confusion" than anywhere else in his letter. In the first place I never said that "the cost of raising seedlings in beds to supply 50 acres would be R1,650." The calculation in which those figures were given had reference solely to cost of a nursery for planting up a 50 acre opening. Colonel Thompson is evidently unable to distinguish between planting up a new clearing, and supplying an old estate. (Query. Has he ever seen a coffee estate?). Further the large quantity of Jadoo— $\frac{3}{4}$ peck—given in the prospectus as the amount necessary for each supply, shows clearly that the prospectus did not contemplate the "raising of seedlings in beds" as supplies. It meant that that amount of Jadoo should be applied to each supply in the field. Again, it is not in the power of Colonel Thompson or anyone else to say that the amount of Jadoo required for "raising seedlings in beds to supply 50 acres would be certainly not more than 5 cwt." or any fixed amount, for the simple reason that "supplying" is a variable quantity. Granting that $\frac{3}{4}$ peck is the right amount of Jadoo for each supply (and Colonel Thompson does not deny it), how many plants would 5 cwt.—the amount fixed by Colonel Thompson as sufficient for a 50 acre clearing—cover? The ton contains 60 bushels, so 5 cwt. would contain $\frac{1}{4}$ of this or 15 bushels. At 1 bushel for 5 plants, this would mean (5 by 15)=75 supplies. Well A's 50 acre clearing (lucky dog!) might need only 75 supplies, while B's clearing of a similar extent might need 7,500. What then becomes of Colonel Thompson's fixed price of R12.8 for supplying 50 acres? On the lines marked out by Colonel Thompson, it is impossible to arrive at any definite conclusion as to cost of supplying. My calculation is the correct one, viz. that if it takes $\frac{3}{4}$ peck per supply, then it costs 9 ans. per plant, with Jadoo at R170 per ton. One thing is obvious from Colonel Thompson's letter that, however great his theoretical knowledge of the merits of Jadoo may be, he knows absolutely nothing about its practical application to coffee. The figures given in the Jadoo prospectus are either right or wrong (and Colonel Thompson in his letter implies they are right). These figures are a 3 bushel sack of Jadoo for 450 plants in the case of a nursery, and $\frac{3}{4}$ peck for each supply (to be applied of course in the field). If these quantities are right, my calculations are right, in spite of the tissue of nonsense contained in Colonel Thompson's letter. If they are wrong, the sooner Messrs. Parry and Co. (who have a practical knowledge of coffee planting) correct them, the better for everyone interested in the question of Jadoo bre.—*Planting Opinion*, Feb. 20.

LECTURE ON RHEA.

An interesting and instructive lecture entitled "Rhea—its History and Prospects" was delivered at a meeting of St. Andrews' Guild on the evening of the 12th by Mr. J. Melrose Arnot, F.C.S. There was a large attendance. The Hon. Sir John Woodburn (President) presided and introduced the lecturer.

The lecturer dealt with the subject in detail. At the outset a description of the plant was given, showing its essential features by means of diagrams and growing plants. Then the history of the plant was passed in review, and the lecturer stated that the fisherfolks of India, China, and the South Sea Islands were probably the first people to make use of the fibre and to cultivate the plant, which he said they still continue to do. He then handed round samples of the hand-cleaned fibre which had been obtained from the fishers of Dinapore at a cost of R2 per seer. The methods of cultivation and propagation followed in Asia and China were described, and it was pointed out that a rich sandy loam in a warm and equable climate with a good rainfall, well distributed throughout the year, is the most favourable circumstance for the production of good crops, which may be gathered four or five times per year. The lecturer then insisted upon the necessity for liberal manuring and careful cultivation, enforcing the point by means

of tables showing composition of plant and soil, and remarking that although one part of Bengal seemed to suit the plant fairly well in common with other crops, it suffers severely from long drought. The primitive modes of preparing the fibre were described, and then the various modern processes were reviewed, special attention being devoted to the Gomess process, the Macdonald-Boyle process, and the process of Mr. J. S. Brown, Bally Paper Mills, a working experimental model and complete drawings of whose machines were exhibited. The lecturer then said all fibres have this in common, that they are elongated cells, but they vary greatly as to length, thickness, form of section, shape of ends, hardness, softness, elasticity, flexibility, lustre, and strength. All fibres of one class however have characteristics in common, that is to say, that all fibres obtained from one natural order or family of plants so closely resemble one another as to be only with difficulty distinguished. In the textile industries, for instance, we have a wide range of easily recognisable fibres, as cotton and jute, hemp and flax, wool and silk; but the various varieties of cotton can only be distinguished by an expert, and same may be said of hemp and of the animal fibres, wool and silk, although they are not cellulose. In the paper industry we have a much wider range of fibres, and many of them so closely alike that we have to depend on the appearance of some invariable complement to the fibre, such as the cells of the pith or the leaf-hair of grasses to identify them. I have here prepared a table to show the chief physical characteristics of the most important commercial fibres, and you will see that for length, strength, and lustre, rhea far transcends all the other vegetable fibres. And besides all this it combines with its rare whiteness an affinity for colouring matters which is not approached by any other normal cellulose. Jute dyes excellently, but jute is a very pronounced tigno-cellulose, and the colours, when dyed, lack the purity of tone which they show so admirably on rhea. Chemically considered rhea is a pecto-cellulose like all the other finest textiles, as linen, hemp, and cotton. When we consider what may be the future for rhea, we must be careful to bear in mind that none of the people to whose lot it will fall to make a success of it have any experience yet. That the fibre can be extracted so successfully as to leave little to be desired is, I think, beyond a doubt; but the growers are only experimenting yet, and so we have no good supply of regular qualities of fibre, and consequently the spinner has to work upon an uneven material whose qualities he has not yet mastered. Cultivation and frequent cropping improve both the strength and fineness of the fibre, and when the plant is produced largely and steadily, we may expect to see a great advance in every direction. The fibre combines well with silk, flax, and wool, and, when alone, it rivals the more ordinary sort of silk. Moreover, it enjoys an advantage which silk has not—it may be converted into the most excellent paper after it has become useless for any other purpose. When a sufficient supply is forthcoming, machinery will be modified so as to obtain the best result. Much has been said about rhea as a substitute for jute; but jute is more easily cultivated, and the rayat would, I fear, fail to give rhea the manuring and attention which it demands during the greater part of the year, so that most likely rhea would not be widely cultivated in the jute districts, and the jute business would still continue. The whole future of rhea now depends, on the cultivator, and there is every reason to believe that in many districts it may be grown at a profit. I have heard that the company which is working the Gomess patents can manufacture rhea *filasse* as cheaply as cotton is produced, but as the raw material is not sufficiently abundant that would not continue to be the case in the event of a largely increased demand arising soon. At present they are producing about two tons weekly. But the rhea fibre is more likely to become a serious rival to flax and wool than to jute. Jute is indeed among textiles, as like newspapers in another

sphere, often used for nobb ends, but, as a rule, doing the drudgery of the world and cast aside when it has accomplished its more immediate purpose.

The President congratulated the lecturer on his successful lecture and demonstration, and in opening a discussion on the subject of rhea, said that Lord Mayo's Government in offering a reward of £5,000 for the best process for preparing rhea had begun at the wrong end. The principal problem which had alone to be solved was the difficulty of getting the material in sufficient quantity in India. It had been shown that the climate of Bengal was not suited to its cultivation; it required a moist and equable climate, otherwise interruptions occurred in the fibre which was fatal to its utilisation. He understood that a keen controversy was going on among botanists as to whether the mistake had not been made of growing the tropical species of rhea in semi-tropical regions and the semi-tropical in regions similarly unsuited to them. Surgeon-Major Prain followed and confirmed what Sir John Woodburn had said with regard to the confusion which existed with regard to the species of rhea most suited for manufacturing purposes. There was little doubt that the tropical species was the one which Dr. Roxburgh had originally introduced from Sumatra, and was therefore not suited to India generally. He said that Dr. George Watt had lately proceeded to Assam with the object partly of ascertaining which species is the true rhea. Mr. John Gemmell, in the course of a few remarks, said that the plant had been tried as an experiment in several tea gardens in Assam with some success, but that the cost of cultivation had acted as a deterrent to its extended introduction. Messrs. George S. Sykes, James Luke, and G. W. MacMinn also contributed to the discussion.—*Indian and Eastern Engineer*, Feb. 20.

“TEA AND MANURING.”

A young planter who has been interested in the discussion on the above subject wants to know whether, as a matter of fact, tea has ever been known to be killed through manuring; and, secondly, whether tea, once manured, and improved in yield, has ever been known to go back to less than the original crop per acre? We are not so sure about the second; but surely a negative is the only answer to the first question?

An old and practical planter writes on another controverted point:—

“As regards ‘cultivation’ in previous correspondence, the ‘opinion’ of some that returning green prunings to the trees poisons them, my *experience* in tropical cultivation of over 30 years is that under proper conditions this gives some of the very best results!”

UDUGAMA TEA AND TIMBER COMPANY LIMITED.

At the annual general meeting held on 1st March 1897, the following Report was submitted:—

The directors submit to the shareholders the accounts for the year ending 30th September 1896.

The yield for the Saumarez, Uduagama and Homadolla amounted to 144,359 lb., an increase of 17,065 lb. on the previous year. This comes to 238 lb. per acre all round.

For the present year ending 30th September 1897 the estimated crop is 155,000 lb.

Of the cleared land in Maminadola 144 acres planted in 1895 have come on very well and should be in bearing next year; 85 acres were planted last year and are looking very healthy, and 81 acres are now felled and are ready for planting. It is estimated that when all these clearings are in bearing they should yield 150,000 lb.

been applied over about 20 acres, the total area manured since the Company acquired the property being computed at 414 acres.

The Company's Property consists of:—

476 acres Tea under leaf. Yield in 1896= 426 lb. Tea per acre.
50 „ Forest.

Total. . 526 acres.

About 4 acres are to be brought into cultivation during the year.

The estimated crop for 1897 is 190,000 lb. Tea.

It will be seen that the property representing Capital stands in the balance sheet at approximately R501 per acre cultivated, as compared with about R508 in the previous year's account; and that the profit per acre is about R68.00, as compared with R84.00 in the previous year.

Mr. John Albert Martin retires from the Board by rotation, and is eligible for re-election.

The Shareholders will be requested to elect an Auditor for the current year.—By order of the Directors,
B. G. L. BREMNER, Secretary.

Colombo, 24th Feb. 1897.

THE BOGAWANTALAWA DISTRICT TEA COMPANY.

The Bogawantalawa District Tea Company Ltd., has been registered with a capital of £250,000 in £10 shares of which 12,500 are preference, and 12,500 are ordinary. Object to adopt and carry into effect an agreement expressed to be made between this Company and C. Fetherstonhaugh, Sir George William Campbell, K.C.M.G., A. Tabor, and J. C. Fort for the acquisition, by purchase, lease or otherwise, of any land and buildings in Ceylon or elsewhere, and any estate of interest in or any rights connected with any such lands and buildings, and in particular the Kirkoswald, Bridwell, Elbedde, and Bogawane estate, Dikoya, Ceylon, or any of them, and, generally, to develop the resources of, and turn to account the said properties by clearing, planting, cultivating, farming, grazing, mining, and building thereon. The signatories are:—

	Share.
C. Fetherstonhaugh	1
A. Tabor	1
J. C. Fort	1
H. Bois	1
C. M. Robertson	1
J. G. Forster	1
E. Bois	1

The directors shall not be less than three, nor more than five; the first are the first four subscribers. Qualification £1,000. Remuneration, £500 per annum with a percentage of the profits divisible. Registered Office, Fenchurch Street, E. C.

THE YATADERIA TEA CO. OF CEYLON LIMITED.

The annual meeting was held on 5th March.

The Directors' report is as follows:—

The Directors have the pleasure to submit the Balance Sheet and Profit and Loss Account for the year ending 31st December, 1896, duly audited.

The balance of Profit (including R10,120.84 brought forward from last year, after crediting Reserve Fund with R15,000 as voted at the last General Meeting; and after writing off for Depreciation of Buildings and Machinery as shown by the accounts) is R74,329.43. Of this sum R23,750 has been absorbed in paying an Interim Dividend at the rate of 12½ per cent; and the Directors propose that a further Dividend of 12½ per cent, and a bonus of 7½ per cent absorbing R38,000 be declared and made payable on the 8th March; that R5,000 be transferred to the Reserve Fund account and that the remainder of R6,329.43 (after paying R1,250 special fee voted to the Directors at the General Meeting in 1895) be carried forward.

It will be seen that the property representing capital stands in the Balance Sheet at approximately R204 per acre cultivated, as compared with about R255 in the previous year's accounts, and that the profit per acre is R87.

The Factory extensions referred to last year have been nearly completed; and a new turbine and sifters have been erected.

The total Tea crop was 541,159 lb. or 82,341 lb. less than estimated in the last report, rather finer plucking having been adopted with a view of improving prices, which as far as can be judged was successful. The plucking area was 768 acres. The total quantity of Tea for disposal was 545,393 lb. including 1,234 lb. made from purchased leaf, of which 12,988 lb. were sold locally averaging 27.28 cents per lb.; and 532,405 were shipped to London, of which 102,160 lb. had still to be accounted for; but the average obtained for the 430,245 lb. as yet accounted for is 33.24 cents per lb. The cost of the Tea delivered to buyers or put on board ship, including all charges and Depreciation of Buildings and Machinery, was 20.59 cents per lb. (being .08 of a cent more than in 1895). The net value realised from sales (a portion being estimated) was 32.34 cents per lb. (being 4.83 cents less than for the previous crop). The sum written off for depreciation represents .71 cents per lb. of the cost.

The Company's property (including 96 acres purchased during the year) consisted on the 31st Dec. 1896, of:—

Acres.	Tea plan-	Yield in			
	ted in.	1896.	lb.	tea per	acre
172	1885	793	lb.	tea per	acre
208	1887	730	„	„	„
100	1888	723	„	„	„
42	1889	792	„	„	„
6	1890	811	„	„	„
52	1891	939	„	„	„
120	1892	757	„	„	„
68	1894	160	„	„	„
37	1895	not in bearing.	„	„	„
75	1896	„	„	„	„
22	Cocoa and Factory site.				
255	Forest, &c.				

1,157 acres as per last report.

96 „ purchased from Crown and Natives.

1,253 Total acres.

The Directors propose an extension of about 35 acres Tea in 1897, which has been cleared.

The estimated crop for 1897 is 537,600 lb. Tea.

Mr. John H. Starey retires from the Board, in terms of the Articles of Association, and being eligible, offers for re-election. Mr. David Fairweather resigned his seat at the Board on leaving the Island, and the Directors elected Mr. Charles Minto Gwatkin in his stead.

The Shareholders will be requested to elect an Auditor for the current year.—By order of the Directors,
B. G. L. BREMNER.

Secretary.

Colombo, 24th Feb. 1897.

INDIAN TEA CROP.—The Indian Tea Association publish the following figures showing the actual outturn of the Indian tea crop of 1896:—Assam, 59,655,793 lb.; Cachar, 20,401,487 lb.; Sylhet, 25,099,486 lb.; Darjeeling, 7,817,495 lb.; Terai, 3,738,927 lb.; Dooars, 22,073,781 lb.; Chittagong, 1,030,125 lb.; Chota Nagpore, 220,322 lb.; Kangra, 2,180,000 lb.; Dehra Doon and Kumaon (Estimate), 2,000,000 lb.; Private and Native Gardens (Estimate) 4,000,000 lb.; total, 148,217,416 lb. The total shipments to all places from 1st April to 31st January 1897 are 138,171,829 lb. The exports to the Colonies and other ports, together with local consumption, are not likely to exceed 16 millions, which will leave about 131½ million pounds for export to Great Britain.

THE EILA TEA COMPANY OF CEYLON, LIMITED.

At the meeting of the Eila Tea Company of Ceylon, Ltd., held at the offices of Messrs. J. M. Robertson & Co., on the 6th March 1897, the following report of the directors was presented and adopted:—

The directors have the pleasure to submit their report and accounts for the year ending 30th June, 1896. The crop on Eila estate has slightly exceeded the estimate, but the crop from Kanangama was a little under that estimated. The total crops from the two estates amounted to 358,066 lb. against an estimate of 360,000 lb. The price realized for the tea was not altogether satisfactory and the net average of the tea sold from the two estates was 37.97 cts. against 42.83 cts. last year. The net profit for the year, after allowing R6,100.49 for depreciation, is R44,657.11 (equal to nearly 15 per cent on the capital of the Company) to which must be added the balance brought forward (after payment of the dividend for 1894-95) of R2,095.13 together aggregating R46,752.24. Out of this an interim dividend of 4 per cent has been paid leaving R34,752.24 available for distribution. The directors recommend that this be disposed of as follows, viz:—That a final dividend of 9 per cent be declared on the share capital of R300,000, making

13 per cent for the year.. ..	R27,000 00
That a sum be carried to Reserve Fund of	R6,000 00
Leaving to be carried forward to next account	R1,752.24
	R34,752 24

The estates on 30th June, 1896, consisted of Eila, 410 acres tea, 5 years old and upwards; 50 acres tea, 2 years old and upwards; 105 acres tea, 1 year old and upwards; 62 acres tea, under one year; 330 acres forest, total 957 acres.

Kanangama, 20 acres tea, 5 years old and upwards; 15 acres tea, 4 years old; 108 acres forest, total 323 acres.

Mr. H. Tarrant retires in accordance with the articles of Association, but being eligible offers himself for re-election. The shareholders will also have to elect an auditor for season 1896-97.

THE RATWATTA COCOA COMPANY, LIMITED.

An ordinary general meeting of the shareholders of this Company was held at the Company's Offices at No. 20 Baillie Street on the 6th March 1897.

The following is the report of the directors:—

The Directors have the pleasure to submit their fourth annual report, together with a statement of accounts for the year ending December 31st, 1896. The accounts show that the Company's property stands at a nett cost of R120,941.27. For this capital outlay the shareholders have a property consisting of 789 acres. The definition of the estate as at present constituted is as follows:—

	3 Years old.	2 Years.	1 Year.	Total.
Tea and Cocoa	86 acs.	9 acs.	—	95 acs.
Cocoa	66 "	109 "	81 acs.	256 "
Liberian coffee and tea	15 "	9 "	—	24 "
Liberian coffee	—	—	11 "	11 "
Grass	—	—	—	3 "
Coconuts planted	—	2,000	4,000	389 "
Forest—normally	—	—	—	400 "
				Total .. 789 "

Besides opening and planting this land, a substantial Superintendent's bungalow has been built of bricks, tiles and sawn timber. A cocoa store, of brick and iron roof, is nearly completed, and the necessary cooly lines. In view of the low prices obtained for cocoa in late years, and the success of

tea in the Matale district, your Directors called a general meeting of shareholders to discuss the subject; when it was resolved that only the best fields of cocoa (about 200 acres) should be retained as cocoa, and that the cultivations of teas be extended as fast as possible, thus not rendering the Company dependant on only one product. The capital of the Company was raised from R150,000 to R200,000 to allow of this programme being carried out. With this double cultivation, the Directors look forward to the future with confidence. Valuing the reserve forest at R50 per acre, it will be seen that the cost per acre of cultivated land is R285 per acre, a figure which must be considered moderate, remembering that the land is all young and coming into bearing. When the whole estate of nearly 800 acres is under cultivation (which it is hoped it will be in 1,900), the Company will have a very valuable property, as it is now known from the statistics of an adjoining estate, that the district grows tea equal to the best in the Island for quantity. Work of 1897—100 acres of forest will be cleared and planted with tea, and as much of the exposed cocoa land as can be done. Directors—Mr. E. Jeffries retires from the Board, but is eligible for re-election. An Auditor will also have to be elected.

THE UPPER MASKELIYA ESTATES COMPANY, LIMITED.

The annual ordinary general meeting of the above Company was held at the Company's Offices, No. 7, Queen Street, Fort, Colombo, on the 6th March 1897.

The directors' report was as follows:—

ACREAGE 31ST DECEMBER, 1896.

	Brunswick & Bloomfield.	Caskieben.	Total.
Tea in full bearing	446	200	646
Grass, Timber Trees, &c.	72	7	79
	518	207	725

The Directors have now the pleasure to submit to the Shareholders the Accounts of the Company for the past year.

The yield of tea from Brunswick and Bloomfield has been well maintained, the crop for the year having been 229,238 lb as against 227,359 lb in 1895, while the prices obtained may be considered satisfactory, in view of the course of the Tea market and of exchange, the net average for 1896 having been 45.60 cents per lb as against 48½ cents in 1895.

The profits and receipts from sources other than sales of Tea amounted to R5,610.16 against an estimate of R8,800, the shortfall being almost entirely due to the purchase by the Company of Caskieben Estate.

At Extraordinary General Meetings held on 5th September and 10th October, 1896, Special Resolutions were passed increasing the Authorized Capital of the Company to R350,000 to provide for the purchase of Caskieben Estate. The 160 shares of the second issue have all been taken up by holders of those of the first issue, and Caskieben has been duly conveyed to the Company.

The purchase of Caskieben dated from 30th May, from which date to 31st December 46,225 lb. Tea were secured and sold on the Company's account at a net average of 44.25 cents per lb. The outlay on the Estate for the same period amounted to R12,636.29, equal to 27.33 cents per lb. on the crop secured. From the profit thus realised falls to be deducted R3,715.75 interests paid to the Vendor from 30th May to 30th October, which is duly shewn in the Accounts.

The Capital Account outlay for 1896 amounted to R1,468.44 under the head of "Buildings," for the New Caddies and Rice Store referred to in the last Annual Report, and also R3,849.49 under the head of "Machinery" for Rapid Roller, &c., which it was found desirable to provide. Against the latter sum has been placed the receipt of R900 by the sale of an old Roller.

After making adequate provision for depreciation of Buildings and Machinery, as also for Commission due to the Superintendent on the year's working, a balance of R87,654.20 is shewn at the Credit of Profit and Loss Account. This sum includes R40,000 premium on the second issue of Shares, and R6,997.60 brought forward from the previous year's accounts. The Directors recommend that in terms of their Circular to the Shareholders dated 21st August last, the sum of R45,000 be applied towards the purchase of Caskieben, and placed to credit of an "Extension Fund" account. The Profit and Loss would thus be reduced to R42,654.20, out of which an interim dividend of 6 per cent. on the original Capital of R270,000 was paid on the 8th August, absorbing R16,200. The Directors recommend a final dividend of 9 per cent on the original Capital of R270,000, making 15 per cent for the year, and a dividend of 2½ per cent as provided for in their Circular of 12th October, 1896, on the second issue of shares of R80,000. These final dividends will amount to R26,300, leaving a balance of R154.20 to be carried forward.

The crops estimated for 1897 from the Company's estates amount to 323,000 lb. Tea against an estimated outlay of R90,206. The estimated profit from Rents and other sources is R2,500. In addition to the above expenditure the sum of R4,000 is allowed in the estimates for New Machinery, Lines, &c.

Mr. W. D. Gibbon having retired from the post of Inspector of the Company's Estates as from 1st January, 1897, Mr. A. E. Wright has been appointed to that office.

Mr. G. W. Carlyon having retired from the Board on his departure for England the remaining Directors elected Mr. Alex. Thomson to fill the vacancy. Mr. C. A. Leechman having also retired from the Board, Mr. A. E. Wright has been similarly appointed to the Directorate. In terms of the Articles of Association Mr. A. E. Wright now retires by rotation from the post of Director and is eligible for re-election.

Mr. R. L. M. Brown having resigned the post of Auditor to the Company, the Directors, under the Company's Article No. 92, appointed Mr. Hercules J. Scott to fill the vacancy thus occasioned. The appointment of an Auditor for the current year rests with the meeting.

By Order of the Directors,

WHITTALL & Co.,

Agents and Secretaries.

Colombo, February 20th, 1897.

THE RUANWELLA TEA COMPANY, LIMITED.

The annual ordinary general meeting of the above Company was held at the Company's Offices, No. 7, Queen Street, Fort, Colombo, 6th March, 1897.

The following is the directors' report:—

ACREAGE:

Tea in full bearing	313	acres.
" " partial bearing.. .. .	25	"
" not in bearing	36	"
Jungle and Waste land	199	"
Total	573	acres.

The Directors beg to place before the Shareholders the Accounts of the Company for the past year.

The total crop secured was 153,828 lb., being 6,172 lb. less than was estimated. This was equal to 491 lb. per acre, and it was produced at a cost of R34,768.82 on working account, being at the rate of 22.60 cents per lb., which is slightly under the estimate. It sold for a net of R51,514.56, an average of 35.43 cents per lb.

A sum of R1,776.09 expended in manuring during November and December has been brought forward to this year's working account. The capital expenditure during the year has been R19,165.81 for new

clearing, factory extension and new steam engine and boiler, against which has been credited R1,938 for proceeds of plants and old machinery sold.

After providing for Colombo administration expenses, Superintendent's Commission and writing off R2,000 for depreciation of buildings and machinery, as also R254.87 the balance of preliminary expenses, a net sum of R13,707.84 equal to 5.17 per cent on the total paid-up capital of the Company remains at the credit of profit and loss account, out of which the Directors recommend that a dividend at the rate of 5 per cent be declared, leaving R457.84 to be carried forward.

This disappointing result is mainly due to the low prices obtained for the Company's Tea, attributed to the insufficient Factory accommodation, the additions to which occupied an unexpectedly long time in completion. The desired accommodation has now been provided and ample machinery arranged for, and the Directors will not be satisfied unless a marked relative improvement in the prices obtained is manifest during this year.

This year's crop is estimated at 180,000 lb., equal to an average of 530 lb. per acre, costing 24 cents per lb. on working account, including R2,000 for manuring and a capital outlay of R8,160 on clearing and machinery is anticipated.

For the information of the Shareholders the Directors issue with this Report a copy of Mr. W. R. G. Hickey's last visiting report.

The Directors all retire from office in terms of the Articles of Association, and Mr. Eric S. Anderson, being about to leave the Colony, does not offer himself for re-election.

The appointment of an Auditor for the current year rests with the meeting.—By order of the Directors,

WHITTALL & Co.,

Agents and Secretaries.

Colombo, 12th February, 1897.

PERAK PRICES OF COFFEE AND GUTTA FOR FEBRUARY.

Coffee, \$30 to \$30.50 per pikul.

Gutta Percha, First quality, \$130 to \$180 per pikul.

Gutta Percha, Second quality, \$50 to \$110 per pikul.

White Gutta \$50 to \$60 per pikul.

India Rubber, \$120 to \$130 per pikul.—*Perak Government Press.*

NOTES FROM THE METROPOLIS.

February 12.

The lecture delivered one evening this week before the Society of Arts by Mr. David Crole on

"THE CHEMISTRY OF TEA"

was clearly not intended for general consumption, but rather for the instruction of probationers in chemistry. Mr. Crole is an Assamite, and the Indian element in his audience predominated as a matter of course. The lecturer began by deploring the fact that chemistry and kindred sciences had not bestowed as much attention on tea as on other products. With tea, he said, the advancement of knowledge had been chiefly made along practical lines, and science had been, till (broadly speaking) the present decade, very little requisitioned to help in the evolution of a more perfect system of cultivation and manufacture. His present object was to direct more general attention towards and stimulating research in this direction. These introductory sentences will serve to show the scope of Mr. Crole's paper. The audience were soon called upon to wrestle with passages of most elaborate and ear-splitting chemical definitions and descriptions, delivered with the ease of an expert by Mr. Crole, who also showed intimate acquaintance with the names of nume

rous products—"phloroglucin" and "para-di-hydroxybenzene," and many other sneeze-words which your correspondent confesses, he does not know how to spell. Indian and Ceylon teas, it was explained later on, possess more of both tannin and theine than China teas, but it would be wrong to infer from that fact that the consumer imbibed more tannin and theine with a cup of British-grown tea, for a larger quantity of China tea had to be put into the pot. China tea, said Mr. Crole, was lowest in theine, Japanese had a little more, and then came Java, Ceylon and Indian (in the order mentioned). Sir E. Stewart Bayley presided, and among the audience were Mr. G. W. Christison and Mr. A. G. Stanton. Though the tone of the lecture was severely scientific, a lively contributor to the *Daily Telegraph* manages to weave plenty of fun into a half-column report of the meeting. After romping about among the poets who have made verses out of tea, he winds up with the remark that it is bad enough to be frightened with "There is death in the pot", but it is worse to be intimidated with "There is 'cheesiness' in the chest"—from which it will be inferred that the lecturer had something to say as to the advantage of steel tea chests.

Among new Companies floated this week is THE CEYLON PROPRIETARY TEA ESTATES COMPANY, LD.,

with a share capital of £160,000, divided into 40,000 £5 per cent cumulated preference shares of £1 each, and 120,000 ordinary of £1; 150 £5 per cent first mortgage debentures of £100 each have already been subscribed for. The directors are Mr. H. K. Rutherford, Mr. G. A. Talbot, Mr. R. A. Cameron and Mr. F. H. Wiggin (late Chairman, Beaumont Tea Company of Ceylon). Sir Wm. Johnston, Bart., is the Secretary. "The Company is formed," says the prospectus, "with the object primarily of acquiring as going concerns the following tea estates in Ceylon: the Beaumont Group (Pusselawa District), the Forbes and Warburton estates (Maskeliya), the Summerville estate (Dikoya), the Troy estate (Kelani), the Radella estate, seven-eighth shares (Dimbula). It is estimated the 2,113 acres under tea will yield at the rate of 400 lb. per acre, or 845,000 lb. per annum, when all the acreage is in bearing. This, at 3½ per lb. profit, will give a return of £11,000 per annum, which is sufficient to pay the debenture and preference interest and a good dividend on the ordinary capital." The price to be paid to the vendors for the properties (subject as to the Beaumont Group, Forbes and Warburton to £15,000 debentures or Beaumont Tea Coy. of Ceylon, Ltd.) is £95,480, payable £71,376 in shares and £24,104 in cash.

CLUB ECHOES AND TEA LEAVES.

(By an ex-Upcountry Resident.)

LONDON, February 12.

Last night, having failed to get a seat at Nansen's great meeting the evening before, I consoled myself with attending a lecture delivered at the Society of Arts, John street, by Mr. David Crole. The subject was

THE CHEMISTRY OF TEA,

and I have no doubt whatever that the lecturer himself understood all the jaw-breaking words and technical terms he used in the course of his address, but honesty compels me to admit they

were far beyond *me*. I am the less ashamed of this confession, humiliating as it may appear, because at the close of the lecture one old planting hand after another stood up to acknowledge the same identical thing. The very Chairman—a K.C.S.I. no less—confessed himself baffled, and one experienced tea planter, whom I met afterwards, succinctly expressed the performance as the "most awful heathenish jargon" he had ever heard in all his days. The Latin inscription which Littleton of dictionary fame, composed for the Monument and which included the names of seven Lord Mayors in one word, was nothing to it. This was all the more to be regretted that Mr. Crole has evidently accumulated a vast amount of scientific information on the subject. In fact what this distinguished specialist does not know about tea, I should say is not much worth knowing, and if he had only had a little mercy on the less highly trained brains of his audience, all would have been well. A lecturer on any subject must cultivate a popular style if he wishes to be enjoyed by the man in the street.

But enough of criticism. Passing over the purely technical part of Mr. Crole's remarks, the outcome of his lecture was pretty much as follows: He altogether deprecated the rule of thumb system in tea planting and advocated more general attention to the scientific side of the matter. Much, he said, has yet to be discovered about what goes on in plant-life, and therefore details, which might be useful to the tea planter are as yet lost to him. (A table of analysis which Mr. Crole had borrowed from his own textbook on the subject of tea hung on the wall behind the lecturer and was frequently referred to. The list of substances displayed on it was truly formidable to an unscientific mind!) Bohea tannic acid, the chief form of tannic found in black tea belongs, the lecturer said, to the *non-greening* variety, "tea" tannic the characteristic form of the acid in *green* tea on the other hand being of the *non-blueing* class. When tea liquor remains in contact with the air for some days, the cloudiness that is apparent is due to a reaction between the tannic acid and the legumin, and the consequent formation of an obscure and insoluble compound, the astringency being decreased to a marked extent. This reaction accounts somewhat for the "mellowing" of tea that is kept for a time. Teas freshly manufactured produce unpleasant symptoms when drunk, therefore they should be mellowed for at least six months. *Thickness of liquor* or *creaming*, that quality so highly esteemed by tea tasters and buyers depends on the amount of mucilage present in the tea, and also in the action of tannin on *theine*. The amount of essential oil, *theol* in tea is variable, but it is a very important constituent, as its presence determines the greater part of the flavour aroma. Being volatile it is apt to be lost if the tea is exposed too long to the air. It is developed during the process of withering, and in the first stage of firing, but irrational firing may drive off a good deal of it by the steam generated in the firing. If proper attention, said Mr. Crole, were given to this part of the subject, he had no doubt the percentage of essential oil in tea might be greatly increased, and the quality of the tea consequently improved. It could be extracted from refuse tea, etc. by distillation by steam, but the great barrier is the seeming impossibility in keeping it, as it so readily resinizes in contact with the air. The more resin, the less essential

oil and the resins in tea being insoluble in water have no effect on the strength of the liquor.

In the manufacture of tea Mr. Crole spoke of the various mistakes that might be made by inexperience such as allowing the concentration of the sap in withering to go too far, which would prevent the cells bursting, impair the colour in fermentation and so forth; the bruising of the fresh leaf which gave the air access to the sap during withering, causing consequently inferior quality and appearance of the tea; the exposing of the tea to the direct rays of the sun, or to excessive temperature otherwise; the allowing the rolled tea to lie about heaped up for any length of time, inducing a secondary fermentation, which last he ascribes to a living germ similar to that in the yeast plant, and desirable in the extreme to arrest at the very outset, its action being deleterious to the quality of the tea. Four points he laid great stress on—1st, the leaf when withered and rolled, should be sieved to sort out the fine leaf from the coarse, as it is impossible to obtain an even fermentation if the two kinds are not separately dealt with.

2. A clean cement floor on which the leaf may be spread out evenly, not too thickly, and kept moist.

3. A dark cool airy room with a moist draught of air if possible.

4. The temperature of the leaf should be kept under 85° F. if possible.

After which Mr. Crole explained his theory that tea should be fermented under such reduced temperature as can only be obtained in a tea factory by the artificial use of a refrigerator, and added somewhat ruefully that having circulated this idea rather rashly a year ago, a machine had since been brought out forestalling his own invention on these lines. He has, however, gone on with his own and considers it embodies all the points his practical experience and scientific knowledge have suggested.

The disagreeable cheesy smell occasionally perceptible on opening tea chests, arrived at the docks, he attributed neither to the lead lining round the tea solely, nor to the green wood used in the boxes, but to both conjointly, and that some emanation of the green wood corrodes the lead, and then either itself, or its compound with lead, acts on some constituent of the tea. In steel chests, the remedy might be found, although of course that was merely a surmise. The foregoing is a summary of the more practical points in the lecture. What my boiling down of it loses in scientific language, I hope will be forgiven for the sake of everyday English which is perhaps more intelligible to the world in general.

In matters specially connected with Ceylon, perhaps the most noteworthy item of the week is the issuing of the prospectus of the new

TEA COMPANY.

The Company style themselves the Ceylon Proprietary Tea Estates Company, Limited, with a share capital of £160,000, divided into 40,000 £5 per cent preference shares, and 120,000 ordinary shares of £1 each. The Directors are: H. K. Rutherford, G. A. Talbot, of the Ceylon Tea Plantation Company, Limited, and R. A. Cameron, (Director, Eastern Produce and Estates Company, Limited), and F. H. Wiggin (late Chairman, Beaumont Tea Company of Ceylon, Limited). The Bankers are the Commercial Bank of Scotland; and the offices of the new Company are in 21 Mining Lane, E.C. The Company is formed with the objects of buying and working the Beau-

mont Group of estates in Pussellawa, the Forbes and Warpurton estates in Maskeliya, the Summer-ville estate, Dikoya, the Troy estate, Kelani, and the Radella estate, seven light shares, Dimbula.

THE CHEMISTRY OF TEA.

(From the *H. & C. Mail*, Feb. 12.)

An interesting but highly technical paper on "The Chemistry of Tea" was read by Mr. David Crole at the Society of Arts on Wednesday evening. Sir Stewart Bayley was in the chair and in introducing the lecturer stated that besides being an expert chemist he had also been a tea planter in Assam.

Mr. Crole began by describing the various chemical constituents within the tea-plant and their action there so far as that action was yet known. The chemical constituents of tea make a list of most portentous names—tannic, gallic, and boheic acids; benzene, phloroglucin, oxyhydro-quinone. Meat tea, said the lecturer, was a horrible mad, dear though it was to the hearts of certain English folk, because the tannin of tea then taken into the system in conjunction with albuminoid matter was converted into a leathery compound which took all the time of a powerful digestion to tackle. In fact, the meat tea meant dyspepsia. Besides theine the other alkaloids found in tea were theopylin, theobromine, assumin, quercitrin, and some other undertermined ones, which the lecturer thought should be investigated.

Mr. Crole, after dealing at length with the chemistry of tea and its organic constituents, came to the question of the chemistry of the process of manufacture. He said:—

Whilst the leaf is withering little chemical change takes place, beyond an incipient oxidation of some of the constituents of the sap. Withering is brought about by the evaporation of a certain variable amount of moisture, but generally about one-quarter of the original weight of the freshly-plucked leaf. This loss of moisture occasions a concentration of the sap: if this proceeds too far, however, (1) the cells will not burst in rolling; (2) some of the constituents of the sap will no longer remain in solution; and (3) the colour during fermentation will be uneven, owing to there being insufficient sap to spread over the whole surface of the rolled leaf.

If the fresh leaf is bruised the air gains access to the sap during the withering process, and the tea is, in consequence, inferior both in quality of liquor and also in appearance, owing to decomposition and premature oxidation having set in.

If the leaf is exposed to a temperature which is excessive under the circumstances—as, for instance, exposure to the direct rays of the sun—an untimely oxidation will set in which will spoil the leaf for manufacture.

The object of rolling is to give a twist or roll to the leaf, and also to break the cells of the leaf and thus liberate the juices they contain, so that they may be further acted on during the next process, and also that they may be more capable of extraction with water.

On the cells being broken the sap escapes, and during the continuance of the rolling is spread all over the surface of the rolled leaf, where it is in a very favourable position for the oxygen to act on it during the next stage of manufacture—viz., fermentation. Some of this exuded sap is acted on by the hot air contained within the box of the rolling-machine, and in consequence a portion of the organic acids (chiefly the tannin) undergo partial oxidation. Some of the tannin combines with the oxygen to form phlobaphene (Bamber), and also glucose and gallic acid, assuming a dark insoluble form during the process, while part also combines with some of the albuminoid matter, an insoluble, leather-like substance resulting. These two last reactions are only incipient at this stage, but are more fully developed during the next process (fermentation).

The next process, viz., fermentation, is the most important one from our present point of view—*i.e.*, the chemical aspect of the subject. Strictly speaking, it ought to be confined to a primary fermentation process (probably due to an oxidising enzyme); for if fermentation is further encouraged (by allowing the rolled leaf to lie about heaped up for any length of time, for instance) the tea manufactured from such leaf will be spoilt. In my opinion, this species of secondary fermentation and decomposition always begins to set in after the primary fermentation, or oxidation pure and simple, has proceeded far towards completion, and it is to forestall the secondary fermentation, more especially as well as to fix the primary fermentation, that the first stage of firing is mainly intended.

Mr. Bamber, who wrote on the chemistry of tea asserts that there is no fermentation at all during the process which popularly bears that name in the industry, and he bases his theory on several experiments in which he failed to discover any micro-organisms; but recent research has shown that enzymes usually possess an oxidation action; and again, if the process is only an oxidation one, why is it of such extreme importance to "fix" it by the first stage of firing at the exact moment when the climax is reached? For the firing would not fix oxidation, by any means, but would strongly tend towards hastening and increasing it. Therefore, I think that there is every reason to conclude that the technical term "fermentation" is quite correct.

My theory is that the process commonly known as fermentation in the tea industry is, during a greater part of the time, at any rate, mainly an oxidation one, but that later on (it takes a little time for the microorganisms to develop and get to work), a fermentation due to an organism manifested by the peculiar rancid odour produced by overfermentation of a butyric nature begins to be set up, which it is desirable in the extreme to arrest at the very outset, since its action is deleterious to the quality of the tea.

Fermentation may be described as the splitting up of complex organic substances into simpler bodies, by means of either (1) living organisms, or (2) natural ferments or enzymes.

Living germs (micro-organisms) are responsible for such fermentative processes as are carried on by the yeast plant, or in sour milk, rancid butter, or when nitrogenous matter acts on sugar to produce gum.

The natural ferments or enzymes are named diastase (in malt), emulsin (in almonds), inverting (in yeast), pepsin, ptyalin, and trypsin (the active principles respectively of gastric, salivary, and pancreatic juices).

The primary fermentation that I have described as being the only one to be encouraged in tea, is due to one of the second class (*i.e.*, a non-living ferment), whereas the secondary fermentation, which is the one to be discouraged, and arrested by firing, can with a good deal of certainty be ascribed to a living germ or organised ferment.

For the oxidation process to be accomplished properly the following points should be observed:—

(1) The leaf should be sufficiently withered and rolled, and then should be sieved to sort out the fine leaf from the coarse, as it is impossible to obtain an even fermentation if the two kinds are not dealt with separately.

(2) A clean, smooth cement floor on which the leaf should be evenly spread, not too thickly, and the leaf should be kept moist.

(3) A dark, cool, airy room, with a moist draught of air if possible.

(4) The temperature of the leaf should be kept below 85 deg. F. if possible.

As regards the temperature at which tea should be kept during the oxidation stage, I have given what I consider is a minimum temperature obtainable under ordinary circumstances in a tea-house in the plains; but I hold that a maximum of coolness during the operation, so as to protract it as long as possible (without, of course, reaching the point when the secondary fermentation is in active force), ought to

be the aim in view, for reasons that will have been noted when reading the remarks on the formation and decomposition of various substances during the processes of manufacture. In fact, it would be well worth while to ferment teas under such reduced temperature as can only be obtained in a tea factory by the artificial aid of a refrigerator. I made this suggestion in my MS. of "Tea" over a year ago, but I was misguided enough to circulate it. Since commencing to write this paper I was apprised of the fact that a machine had been brought out somewhat on these lines; but as it did not altogether carry out my ideas I determined, without delay, on bringing out a machine myself embodying all the points that I found from a very extensive practical experience of and a large number of experiments with the fermentation of tea, were requisite.

One of the most important chemical changes at this stage is an increased formation of essential oil, which it has been an aim in my machine to encourage.

The astringency of the tea is reduced by a further conversion of part of the tannin, to which this quality is mainly due, by a combination of part of the tanno-acids with some of the albuminoid matter, into a leathery substance which imparts the characteristic tough feeling to the leaf at this stage. These two last reactions usually commence during the rolling process.

A small quantity of the tannin is changed into gallic acid and glucose, and it would be a great advantage if more of it underwent this change, since gallic acid is not nearly so injurious to the human economy, when taken with albuminoid food, as tannin.

The pleasant aroma and nutty flavour of the leaf, so markedly developed during this process, are due to the formation of several volatile oils. If the process be too long continued, however, acids very similar to those present in rancid butter are formed, viz., butyric acid, &c. Prolonged firing will, of course, rid the tea of this disagreeable feature, but only at the expense of the greater part of the essential oil as well. This acidity, due to butyric fermentation, causes the coagulation of some of the albuminoid matter, which is chiefly present in the form of vegetable casein (legumin), which is an alkaline albumen resembling the casein of milk. This coagulation is unfortunate, as it converts a valuable food material (which tea is very largely provided with) into an insoluble form, with the result that a large supply of nutriment is rendered useless. However, were it not already coagulated by the tannin, it would soon become so by the heat to which it would be subjected in the firing.

During the first stage of firing an increased amount of essential oil is freed by the bursting of the cells, and a further quantity is also formed by chemical action.

Another action of this operation is to arrest the secondary fermentation—by which I mean that fermentation which, as I have already explained, begins to set in when the oxidation has about reached its critical point. It also removes about 40 to 50 per cent of the moisture from the half-manufactured tea.

Special attention should be paid to avoid most of the important volatile constituents being carried away and lost owing to the employment of too high temperatures and draughts of too great a force.

The concluding operation that tea undergoes in the factories where it is manufactured is, of course, packing; and with regard to this, I may mention that it not infrequently happens that when a wooden chest is opened, on its arrival in the docks, the tea is found to possess a very nasty, cheesy smell, which takes some time to completely pass off. For some time the only explanation for this rather disagreeable feature that was forthcoming was that the tea, under certain extraordinary circumstances, acted on the lead lining enveloping it. But although experiments were tried to produce this state of things artificially, no such action could be got to occur; and then a new theory was started, placing the whole

the boxes, the exudation from which has a corrosive action on the lead between the wood and the tea. However, this has not been actually established yet as the cause of "cheesiness." I have little doubt, in my own mind, that both reactions conjointly produce this objectionable occurrence, and that some emanation of the green wood corrodes the lead, and then either itself, or its compound with lead, acts on some constituent of the tea. Anyway this is a point that naturally turns one's attention towards the several kinds of steel tea chests that are now being exploited—*H. & C. Mail*, Feb 19.

In our last issue we gave a verbatim report of that portion of Mr. Crole's paper read before the Society of Arts which referred to the chemistry of the process of manufacture. It was the first portion of his paper which was especially technical. In dealing with this part of the subject Mr. Crole said that gallic or dioxysalicylic acid did not possess the deleterious property of precipitating albumen, gelatine, or starch, as tannin did, and since it was just as capable of imparting pungency to tea, it would seem a pity that a great deal more of the tannin was not reconverted into it. He would suggest that experiments be made in tea factories as to the effect of careful regulation of access of air and amount of heat applied during the operation of "firing" the tea, and that means should be tried to regulate the conversion and re-conversion of gallic and tannic acids during the fermentation stage of manufacture. To tannin the pungency of tea was largely due—a valuable property from the commercial point of view. The origin of tannin in the plant was somewhat difficult to account for, but it would seem that it arose, at any rate in part, from gallic acid, though it must be mentioned that during the manufacture of tea some of it was oxidised back again into gallic acid and glucose by the action of a particular enzyme (pectase). From this last reaction it would be seen that tannin was a glucoside. When tea liquor remained in contact with air for some days a cloudiness was apparent which was due to a reaction between the tannic acid and the legumin, and the consequent formation of an insoluble and obscure compound, the astringency of the infusion being of course at the same time decreased to a marked extent. The reaction accounted in some measure for the "mellowing" of tea that was kept for a time. Freshly manufactured teas produced unpleasant symptoms when drunk, therefore, they should always be allowed to mellow for at least six months. A deleterious property of tannin was what it precipitated gelatine, and formed with albuminoid matter compounds closely related to leather. When the tannin of tea (or any of the tanno-acids) was taken into the system apart from albuminoid material it was quickly converted during digestion into glucose and gallic acid, the former being a useful food substance, and the latter at any rate less injurious than the original tannin. The amount of essential (volatile) oil in tea was variable. It was of great importance, as, though present in such small quantities, yet its odour was so strong that it imparted a major share of the aroma and a certain amount of the flavour to tea. Owing to those volatile properties tea loses its characteristic delicate aroma if exposed to the air for any length of time. This constituent was developed to a certain extent during withering, and also during the first stage of firing. Through irrational firing, however, a good deal of it was driven off mechanically by the steam generated in the firing, or may be in part oxidised into resin. He was rather inclined to think that more than one representative of this class of compounds (viz., volatile oils) was present in tea. He had little doubt that, if proper attention were given to the subject, a very considerable increase in the percentage of essential oil would result, and the tea consequently be greatly improved in quality. It could be extracted from refuse tea, &c., by distillation with steam; but the great difficulty in the way was the seeming impossibility in keeping it, as it so readily resinised in contact with air. Coming to the nitrogenous bodies found in tea, the lecturer said that various alkaloids had been discovered, and he was persuaded that yet more

would be revealed by future analysis. On account of the refreshing properties due to theine, all the plants in various parts of the world that elaborated it were used for making beverages. No doubt the value of a tea should be in direct proportion to the theine it contained, but Dr. Driver found, as a result of his analysis of twenty-eight samples, varying in price from 7d to 7s, practically no more theine in high-priced teas than in common ones; for instance, in a sample of *strong* (in the technical acceptance) tea he found 4.43 per cent of theine, and in a sample of *weak* tea, 4.35 per cent. The amount of chlorophyll present would seem to be actually a reliable index of the quality of black tea since it varied from 3 per cent in good to 1 per cent in common teas. What the consumer liked in tea was strength, body, and delicacy of flavour, but he carried what amount of theine he got, for he had no ready means of estimating the proportion present; yet, if he drank tea on account of its refreshing properties, he would do well to see that he got a maximum of the alkaloid which possessed this important characteristic. Plants which were able to elaborate certain alkaloids in one part of the world, either entirely failed to do so when transplanted to another part, or else only did so to a limited extent. The cocoa plant was a good instance in point. And it seemed that for this reason Chinese tea contained less theine than Indian teas. Chinese contained the least, Japanese slightly more, then Java, Ceylon, and Indian, in the order mentioned. It was popularly supposed that tannin was present in tea in inverse ratio to the amount of theine, but that was not borne out by analysis. Indian tea possessed more of both tannin and theine than Chinese teas, but it must not be inferred from that fact that the consumer imbibed more tannin in the one case than in the other, for in household use more China tea had to be put into the pot than was the case with Indian tea.

DISCUSSION.

The following is the discussion which took place on Mr. Crole's paper, read before the Society of Arts, of which we gave a report a day or two ago:—

Mr. A. K. Donald desired to elicit the views of Mr. Crole as to the infusion of tea. He wished to know whether, if tea had water poured over it quickly, and the tea was then taken away, one would get a considerable proportion of theine and very little tannic acid, or whether, if it was infused for a long time, the proportion of tannic acid would not be increased, as compared with the theine. Further, he would inquire what effect carbonate of soda had if put into the water; did not that extract more tannic acid? It certainly produced a very peculiar flavour; and it has been stated in some books (particularly in Professor Johnston's "Chemistry of Common Life") that putting in carbonate of soda had the effect of getting out some albuminoids, and consequently making the tea more nutritious. It would be interesting to know whether Mr. Crole had any theory upon this point.

Mr. H. E. Bristow, referring to the statement of Mr. Crole that for the fermentation of tea a temperature of 85 deg. or less should be maintained, remarked that no mention was made as to the length of time of fermentation. He would like to know whether there was any method of fixing the proper time for the fermentation process to last; was it to be determined in any other way than by the colour of the tea?

Mr. T. W. Davies said the reader of the paper had spoken of the principle of tea as an essential oil. He would like to know whether Mr. Crole had had a sufficient quantity of that essential oil to test it so as to know whether it was really an essential oil containing an hydrocarbon; might it not be a volatile alkaloid after the character of, for instance, nicotine.

Mr. D. M. Stewart asked if Mr. Crole's attention had been called to the differences of the teas of different districts. The remarks in the paper as to the cool temperature in which the fermentation should be

blame of the mischief on to using green wood for carried out led him (Mr. Stewart) to think of the difference there was between Darjeeling and almost all the Plains gardens in the matter of flavour. He had himself noticed, when in Darjeeling, that if a cool blast of air, such as was produced by a mist cloud coming down, went over a garden as the leaf was being plucked, as a rule the flavour was very much increased; that was what was known as the Darjeeling flavour. Mr. Crole did not seem to think that much change could take place while the leaf was growing, but this fact seemed to point in the other direction—that some change might take place whilst the leaf was growing, if there was a sudden change of temperature.

Mr. Crole, in reply, said that when tea is infused the theine is extracted very much more rapidly than the tannin. For that reason tea should only be infused for three or four minutes, in order to get the maximum of theine and the minimum of tannin; the tea-leaves should not be in the water more than four minutes. With regard to carbonate of soda, its action was, in the first place, to soften the water, thus allowing more of the flavouring matter to be extracted. Another prominent action was to diminish the astringency of the tea by neutralising, and even preventing, the solution of the tannin. He did not think it had any other action on the constituents of tea. He did not know what ruled the time of fermentation. In one garden it might be that eight hours' fermentation would be required, while the next, separated by only a fence, would not want more than two hours. The difference was probably due to soil and jāt of tea. But he thought that teas should always be fermented according to their colour and smell, and not by any time method, unless, of course, they were fermented in a refrigerator. What the effect would be of a cold cloud while the leaf was being plucked he could not say; but undoubtedly a certain amount of cold during the process of fermentation was a great advantage. It was inexplicable to him that, while the tea was growing or being plucked, a cold cloud or cold blast should bring out the flavour, but he could understand that that might be the fact. Mr. Davies had spoken with regard to the essential oil in tea. There was little doubt that it was absolutely an essential oil; but there were other alkaloids, of course, in tea, and some of them had not been determined. He was himself working at the determination of one of them—not associated with the essential oil of tea, but with what was called boheic acid—and he thought he would be able to get an alkaloid from that. As he stated in the paper, boheic acid was probably not a single organic acid, but a compound of assamic acid either with another acid or with an alkaloid.

The Chairman, in moving a vote of thanks to Mr. Crole, said he was not capable of judging of the excellence of the paper from the technical and scientific point of view, but it contained some advice which he was quite sure was most useful and valuable, and which he hoped would be taken to heart. It was impossible to doubt, as was stated in the paper, that so long as the tea manufacture and similar manufactures were worked by mere rule of thumb, so long would the manufacturers fail to get the best that was to be got out of their products. Their experiment was tried in Assam, for a short time, of having a chemist to help the planters generally in the process of manufacture. He had not heard what became of the experiment, but he believed it had not lasted for any length of time. It was one which, of course, could not succeed unless kept up for a number of years together; and it required an expert who should be well paid, and who would confine his whole time and labour to the study of chemical questions. He was sure that, both in the manufacture of tea and in the manufacture of indigo, such an experiment would pay the planting community over and over again. With regard to the remarks made in the last paragraph of the paper as to the cheesy smell of tea on arrival at the docks, that was an old question in Assam. He remembered

that years ago there were endeavours to get rid of it by changes of boxes or by inquiries as to the chemical action on the lead, but nothing effectual had come of them. Concluding, the chairman said he was only expressing the unanimous feeling of those who had heard the paper in offering Mr. Crole their very best thanks.

Mr. Christison said: As the chairman had done him the honour of calling upon him to contribute to the discussion, it might seem ungracious on the part of one who had been so long connected with the production and manufacture of tea, unless he stated that it was not the want of interest in the subject or of will that made him diffident in rising. He thoroughly agreed with the chairman as to the vast importance to the tea-planting industry of having scientific assistance. So important an industry ought to employ scientific experts continuously; but great care must be taken to engage those most suitable and competent for the necessary investigations. He felt that as the paper was of so technical a nature he was not competent to express any opinion as to its merits. In reference to the least scientific portion of it, which treats of the chemistry of the process of manufacture, if the opinions expressed on the more practical points are deductions from Mr. Crole's independent scientific investigations, all that he could say was that, so far as they go, they tend to confirm the commonly approved practice in the tea districts, and what has been that practice for a very long time. Though on the technical points he was not in a position to speak, he had no hesitation in saying that thanks were due to Mr. Crole for devoting himself to scientific research on a subject too little studied or even thought about. The publication of this paper could not fail to lead to further discussion and research with good results.

The resolution was carried unanimously and Mr. Crole having briefly responded, the meeting terminated.—*H. and C Mail*, Feb. 19.

VARIOUS PLANTING NOTES.

TEA DUTY IN DENMARK. —A merchant writes: —“Can you tell me what the duty is on tea in Denmark. I have applied to the Danish Consul, and he doesn't know.” In our Handbook and Directory for 1895-6, we gave a list of countries with the duty levied on tea in each. In that list Denmark is down for “3d”; but we believe there has been an increase since; for we find the Danish duty given at 4d in a London authority for this year.

HANDBOOK OF THE FLORA OF CEYLON.—This great task, which Dr. Trimen set himself to elaborate, was to have been completed in four volumes, the third of which was issued in 1895. It was to complete the fourth volume that the late lamented Dr. Trimen went back to Ceylon, in spite of the shattered state of his health. Sad to say, he was unable to accomplish this before the end came. When he was no longer able to sit up to work, the indefatigable botanist did so lying on his back. Of the 3,000 species native to the island, about 800 still remain to be tackled. They consist chiefly of grasses and Orchids. It is believed in Ceylon that the completion of the fourth volume may take place at Kew under the direction of Dr. Thistleton Dyer. Dr. Trimen had a good many years' local experience before he commenced his *Flora*, and it is much to be regretted that he did not live to complete it. His name will, however, be always identified with the botany of Ceylon. Mr. Willis, the new director will have his hands full with the duties of his office for some time.—*Gardening World*, Feb. 13.

TEA PLANTING AS A PROFESSION.

This is the age of competitive examinations, and year by year the standard of knowledge required to pass them successfully becomes higher. They are the door through which most professions are entered, and, says *Hearth and Home*, the tendency is to introduce them in many where formerly totally different methods prevailed. Year by year it becomes harder to provide for boys who have no taste for brain-work, and who, although in full possession of their faculties, cannot attain the high standard of learning wherewith we must now be fortified to pass even the simplest of tests. In England itself there are very few openings in which headwork is not required. India and the Colonies offer a larger field, which unluckily is daily becoming a smaller one. In most colonies such work is of an arduous nature, only fitted to be undertaken by the most robust, who have to work harder than day-labourers at home; but in the East, where the menial work is done by natives, there is less toil, combined with a greater degree of comfort, and good health, although an important point, need not be of the powerful order which is imperative for the settler "out West," or in the newer settlements of Australia. Of openings in the East, tea-planting perhaps offers the greatest inducements and best prospects to boys who like an outdoor life and cannot pass the examinations necessary for appointments in Government service. "But isn't the profession terribly overcrowded?" parents ask. Of course it is, but so is every other desirable profession under the sun. Planters (who do not at the moment require pupils) will tell you that it is terribly so, and that the prospects of tea are distinctly bad; but this statement must be taken with a grain of salt; it is only comparative, and nine men out of ten will tell you their own particular profession is in the most hopeless state of any.

The prospect of a successful career as tea planter is, it must be allowed, not very good, if the boy has to make his way on his merits alone, unbacked by capital. In this case he will rarely attain a greater eminence than the position of manager (and this is not to be despised), but if after his period of probation, when he has thoroughly mastered the intricacies of tea planting, he can command a sum to invest in a small estate, or to buy a partnership, it completely alters the matter. Statistics tell us that the consumption of tea, despite doctors, is greatly on the increase, although planters no longer amass the fortunes of former days a very fair competence may still be made in their trade, and a very comfortable life may be led. Most planters take pupils, thereby adding a considerable sum to their incomes, and at present this is the only school in which the would-be planter can graduate. The greatest caution must be exercised in selecting a person with whom to place the pupil. The choice of a place, too, is another very important matter, as the climatic and social conditions of the various tea districts vary greatly. Ceylon certainly takes the lead of tea-growing districts in point of desirability, its balmy atmosphere and beautiful scenery making it an ideal residence (it is one of the three sites of the Garden of Eden), while its luxuriant vegetation makes the cultivation of all manner of crops an easy matter. A planter's life is by no means an idle one, passed in lazily enjoying the profits of black labour, as the pupil soon discovers.

Work, hard and continual work, albeit there is no actual manual labour, from early morning till short, tropical twilight, gives place to night, is the secret of successfully conducting of tea plantation. Before sunrise, after an early cup of coffee, the owner is up and making a tour of inspection around the estate, seeing that the Tamil coolies, men and women, are at their work among the sweet-smelling tea shrubs and slender white-flowered cinchona trees. Constant supervision is required wherever Oriental labour is employed. In the heat of the day, travelling over the sunny, trodden paths, even when protected by a solar tope, is trying.

Then the accounts of the estate have to be carefully kept, the state of the markets studied, and a vast amount of correspondence to be got through. Shrewdness and the power of calculation are highly necessary qualities, for the success of the crops in a great measure depends upon a thorough knowledge of the weather and the conditions of the soil. When the pupil has finished his novitiate in tea planting he will, if he has capital, buy a share in some estate, possibly the one whereon he has lived; but if not possessed of money he will have to content himself with the position of manager or overseer. The pay given to these varies considerably, according to the size of the estate, but a very usual rate is from R300 to R500 per mensem, with a bungalow included. It will be seen from this that the pay is not high but living is cheap, and the axiom that "Man wants but little here below" is realised in the tea districts of Ceylon.—*H. and C. Mail*, Feb. 12.

IMPORTATION OF DUTIABLE GOODS IN PACKAGES OF TEA.

The Treasury Department has information to the effect that a practice prevails among foreign shippers of tea, intended for this country, of placing dutiable goods in the same packages with tea, such as paper bags, chinaware, transparencies, etc., which are to be used as gifts to retail purchasers.

The above practice is held to be unlawful under the tariff laws, inasmuch as it prevents a proper examination of the goods and facilitates frauds upon the revenue.

Instructions regarding such importations have been issued to the Collector of Customs at all ports of entry, ordering the retention of all packages of tea containing other merchandise. The original order was as follows;—

Treasury Department, Office of the Secretary,
Washington, D.C., Aug 21, 1896.
Collector of Customs, Port Townsend, Wash:

Sir,—The Department has received your letter of the 4th inst., inclosing a communication from your deputy at Tacoma, in which he calls attention to an objectionable practice which is in vogue among certain importers of tea. The practice he describes is the placing in each chest or box of tea of a piece of porcelain ware, intended, as he presumes, as a gift to the purchaser.

Although this mode of packing is not expressly interdicted by the law, it is fraught with such danger to the revenue and such labor to the customs officers as make it inadmissible. The Secretary of the Treasury has, under the Statutes (R.S. 2949), authority to make rules and regulations, not inconsistent with law, to secure a just, faithful and impartial appraisal of all merchandise imported into the United States.

You are therefore instructed to retain possession of packages of tea containing other merchandise, as above described, and to notify all persons concerned that no such packages will be admitted to entry except for immediate exportation.

You further call attention to the new method of putting the contents of boxes of tea into small papers, and you point out the difficulty of deciding upon the nature of teas so put up, unless every package shall be opened and examined.

The practice last described is not held to be fraught with danger to the revenue, and therefore is not forbidden. You are advised, however, that a thorough scrutiny of tea so packed should be made, even if it sometimes necessitates the opening of every paper package in a chest.—Respectfully yours,

CHARLES S. HAMLIN,
Acting Secretary.

—*American Grocer*, Feb. 3.

THE SOUTH WANARAJAH TEA ESTATES, LIMITED.

A copy of the prospectus of this Company has just reached us. The share capital is £100,000, divided into 5,000 cumulative six per cent. preference shares of £10 each and 5,000 ordinary shares of £10 each.

The Directors are Matthew P. Evens, Director of the London Commercial Sale Rooms, Limited, Chairman. Hamilton A. Hancock (Hancock Brothers & Co.), 28, Mincing Lane, E.C. Thomas J. Lawrance, Director of the Ceylon and Oriental Estates Company, Limited. Oswald C. Magniac, Hay's Wharf, Tooley Street, S.E. Managing Director in Ceylon.—W. Reeve Tatham, South Wanarajah Estate. Being interested as the Vendor, will not vote as a Director until after the completion of the sale. Solicitors.—Harwood and Stephenson, 31, Lombard Street, London, E.C. F. J. and R. F. de Saram, Colombo. Bankers.—The National Bank of Scotland, Limited, 37, Nicholas Lane, E.C. Head office in Edinburgh, and Branches in Scotland, the Chartered Bank of India, Australia, and China, Colombo. Auditors.—Fuller and Wise, Chartered Accountants, Portland House, Basinghall Street, E.C. Secretary (*pro. tem.*) and Offices.—P. E. Harvey, 39, Lime Street, E.C.

This Company has been formed to acquire as going concerns the two tea estates known as South Wanarajah and Dartry, situated in Ceylon, and to acquire, carry on, and purchase other estates in Ceylon as favourable opportunities occur, the unissued capital being available for that purpose.

The total area of the two estates is 713 acres, viz. :—

467	acres tea in full bearing,
46	“ “ in partial bearing.
29	“ “ 2 to 3 years old.
17	“ “ 1 to 2 “
21	“ “ under 1 year old.
<hr/>	
580	
41	“ cocoa and coffee.
71	“ grass and timber.
21	available for tea.

Total. .713 acres.

It is intended to acquire the Dartry Estate as from 1st January last, and the South Wanarajah as from 1st July next.

Taking a full year's estimated revenue, the profit derivable from both properties should be considerable, as shown herein, and after providing for the interest on the present issue of Debentures and the Dividend on the present issue of Preference Shares the balance should be sufficient to afford a handsome return upon the Ordinary Shares.

As 46 acres are still only in partial bearing, and 67 acres are still too young to pluck at all, it will be seen that the output of made tea should considerably increase without further extensions, and, therefore, it is confidently believed that there will be a very considerable addition to the profits of the Company in two to three years.

South Wanarajah is situated in the Dikoya district, 4 miles from Hatton Railway Station, and has the Government cart road through the property. The buildings, which are sufficient for all the requirements of the estate, include a well-built bungalow, ample line accommodation for the coolies, and a new and substantially-built brick factory, equipped with all necessary machinery of the latest type for the present and future requirements of the estate. The motor power is a turbine fed by an abundant supply of water from the river Dikoya.

The Dartry Estate is situated in the District of Gampola, and is only 1½ miles from the Gampola Railway Station, and has a private cart-road from the factory to the Government road, which facilitates and cheapens transport operations. This estate enjoying as it does a perfect climate for tea, and the command of ample labour supply from the villages adjoining, may be said to possess great advantages which cannot be too highly estimated. The property has moreover been opened in a most liberal manner, and

planted with Tea of the best jat. The buildings are substantial, consisting of a manager's bungalow, two conductors' bungalows, and sufficient line accommodation for the coolies. The factory is well equipped with machinery for all the present requirements of the estate. The motors are a turbine and an oil engine, the latter being used when the water runs short, as it usually does during one or two months of the year.

The Vendor's estimates of crop from the estates for the present season, say from 1st January to 31st December, 1897, are as follows:—

Tea, 3,000,000 lb. at the low price of 6½d. per lb. nett (as against 6¼d. per lb. for last season)	£7812
Tea Seed, &c	800
	<hr/>
	8612

Ceylon working expenditure	£5000
Depreciation of machinery, London charges, Directors' and Auditors' Fees &c.	462
	<hr/>
	5462
	<hr/>
	3150

Deducting—	
Debenture Interest..	900
Preference Share Dividend ..	60
	<hr/>
	960

A balance of £2190 is left available for Dividend on the present issue of Ordinary Capital of £18,000.

The price to be paid by the Company for the purchase of the estates and properties including all the dead and live stock (except the furniture and personal effects), free from incumbrances, except as to a mortgage on the South Wanarajah Estate for Rupees 55,000, or say at 1s. 3d. exchange £3437 10s. 0d., has been fixed by the Vendor at £33,000, payable as to £23,000 in cash, and as to £10,000 by the allotment of 1000 fully-paid Ordinary Shares of £10 each, which will rank for dividend as from 1st July next. Taking the price of the uncultivated and reforested land at £10 per acre, the price of the land under Tea, Cocoa and Coffee, including all the buildings factories, and machinery thereon, is about £57 per acre.

Mr. W. R. Tatham the Vendor, who has had a long experience as a Ceylon Planter, has agreed to act as Managing director during the term of ten years.

The Vendor will pay all the expenses of and incidental to the formation and registration of the Company up to the first general allotment of Shares, and will convey the estates to the Company free of expense.

PLANTING AND PRODUCE.

THE TEA DUTY QUESTION.—In a letter which appeared in our last issue a correspondent, "Planter," drew attention to the question of the reduction or abolition of the duty on tea. In our opinion the advantages of such a fiscal step are obvious. It would benefit all who are concerned in the industry. The producer would gain by it on account of the increase of consumption which would inevitably follow, and also because it would strike an effective blow at the evils that attend the Customs' supervision of tea imports in the bonded warehouses. The contention that duties keep up the quality of teas is, we believe, a fallacy. It is the character of the soil and natural conditions and surroundings that determine quality. It cannot be doubted that the consumer would hail the advent of abolition with great satisfaction. Nothing was more popular with the masses than the reduction of the tea duty effected by Mr. Goschen when he was Chancellor of the Exchequer in the first Unionist Administration. In fact, so gratifying was that policy from an electioneering point of view that it is probable the present Ministry, should they someday find it necessary to appeal to the country, will resort to a similar expedient to revive their apparently waning popularity with the labouring classes, as evidenced by the recent bye-elections. In-

direct taxation is distasteful to the public, particularly when it affects anything in the shape of feed or drink. Much sympathy was evoked at the Romford and Walthamstow elections by Opposition orators pointing out how much more useful it would have been to have taken off the duty on tea and similar articles of universal consumption than to have drawn on the national exchequer for the relief of agricultural rates.

UNFAIR INCIDENCE OF THE DUTY.—Another aspect of the question which weighs with the public is the unfair incidence of the duty. As "Planter" points out, on quality teas the duty is just half as much as it is on common teas, which is a manifest hardship to the average consumer. Tea planters unacquainted with the ins and outs of home politics have no idea of the large part that this question of taxing tea plays in rural politics and in the political discussions always going on in the poorer urban districts. "Planter" has patriotic compunctions as to the advisability of abolishing the duty altogether on the ground that in the event of war it might be expedient to rise the revenue by increasing the tea duty. But as it is generally admitted by both parties in the State that the burdens of taxation should be imposed on the persons best able to bear them, no Government would be likely to put a tax on food or kindred substances, that falls most heavily on the masses, while there was an income tax to screw up, which mainly falls on the well-to-do minority. As to putting differential—much as Indian and Ceylon planters may desire it—duties on China teas, that proposition, however plausible in theory, is not within the range of practical politics. No Chancellor of the Exchequer would entertain the idea at present; Sir Michael Hicks-Beach, who is one of the staunchest of Free Traders, least of all. British enterprise and the hold British-grown teas have on the community are the best safeguards against China competition. We do not believe ourselves that the consumption of tea has reached its limit, as some aver. The tendency of the times in all ranks of society is to eschew the cup that inebriates and to drink more and more tea. This tendency, if it be condemned by the medical faculty occasionally, is still growing, for all classes of the community are fond of tea, and believe that, in spite of the evils of dyspepsia which are supposed to wait on those who drink too much, there is nothing yet known which compares with tea as a comforting and invigorating drink.

TEA PLANTING AND MATRIMONY.—The columns of *Truth* are usually open to grievances of all kinds, either at home or from India and the Colonies, but there are some problems rather too wide and deep even for *Truth*. We recently touched upon the subject of planters and matrimony, admitting, however, that it was rather a large order. The editor of *Truth* evidently thinks so too, for he says: I am desired by an Indian tea-planter to help in correcting the mistaken notion which prevails in many quarters at home respecting the class of young men who are required in the tea industry. The idea seems to be that any ne'er-do well or noodle will be good enough for a berth on a tea garden in India or Ceylon, and owing to the foolish complaisance of directors of companies and owners of estates in yielding to the influence of relatives and friends, such youths are often sent out. The business is really one, however, in which a special scientific training is demanded, and directors who foist on to an estate incompetent young fellows with no knowledge or aptitude for the work do themselves and their shareholders a very bad turn."

THE LABOUR QUESTION.—*Truth* touches upon another matter affecting tea planters, for in the same issue as the above the editor says: "A new phase of the coolie recruiting question is brought out in a letter that I have had from a tea planter at Sibsagah, in Assam. He frankly admits that under the system of

so-called 'free emigration' from Chota Nagpur, coolies are brought and sold like cattle. Nor does he deny that atrocious cruelty is practised in connection with the traffic; but he says that these iniquities occur in the recruiting districts, where the planters are powerless to stop them, and that once the coolies get to the tea gardens they are well treated. The special point of view from which he writes, however, is the high price which employers in Assam now have to pay for these "free emigrants." Formerly a planter could send forth one of his own garden sirdars as a recruiter, and rely upon his bringing back twenty or thirty or more adults, at a cost of from R35 to R50. Now the supply of such labour from Bengal is almost wholly in the hands of coolie contractors, and these middlemen make the planters pay from R100 to R150 for each adult delivered in Assam. One result of the high prices is that a strong inducement can be held out to men to abscond and enlist over and over again, the dealer in coolies making a good profit for himself each time. My correspondent's proposed remedy for a state of things which he plaintively declares is becoming unbearable seems to be a combination among owners of tea estates to boycott the coolie contractors, and run the recruiting business on their own account, though under the supervision of a Government officer. This would be a very good move for the planters, but whether it would be sufficient to put an end to the abominable abuses which exist in the recruiting districts is exceedingly doubtful. What is wanted is a root-and-branch reform, if not the abolition of the whole system, which at present is nothing less than a legalised slave trade."

THE CHEMISTRY OF TEA.—Mr. David Crole, whose book on "Tea: a Text-book of its Cultivation and Manufacture," will be published shortly, read a paper on "The Chemistry of Tea" at the Society of Arts on Wednesday. The paper, a portion of which we publish in another column, was a very technical one, and as there were few among the audience who had made a special study of the chemistry of tea the discussion on the paper was necessarily brief, although the chairman called on Mr. Christison and other gentlemen who have had practical experience of tea manufacture to take part in it. We have not space to reproduce Mr. Crole's elaborate and carefully prepared exposition of the chemical constituents of tea, but we reproduce the more practical portion of his paper dealing with the chemistry of the process of manufacture. As the chairman of the meeting stated, the whole subject of the chemistry of tea requires investigation, and Mr. Crole's paper should help to stir up interest in the subject.

RATHER TOO POPULAR.—At a time when there are complaints that the "creeper" system is overdone, and that tea planting as an occupation for young men in search of employment and adventure is overstocked, the appearance of articles in family papers on the popularity of tea planting are not so welcome as they otherwise might be. We reproduce elsewhere an article on "Tea Planting as a Profession" from the pages of *Hearth and Home*. It is not a highly-coloured picture of the prospect, but it is calculated perhaps to entice young men with a desire to go tea planting before they have ascertained the difficulties which are pretty certain to overtake them in the pursuit of a likely opening. Unless a young man has first passed some time in an engineer's shop and mastered the rudiments at least of mechanical engineering, to say nothing of agricultural chemistry, and has rendered himself fit for the tea garden, he is of no practical use, and has everything to learn. If he has done all this he has still to find a vacant berth where his rudimentary knowledge will find scope for expansion. Under these circumstances the choice of climate and the attraction of the life need not fill too large a place in his mind. Of young men on the look out for billets on tea gardens there are enough and to spare; therefore, unless new comers are physically and mentally fit and speci-

ally qualified generally there is no room for them in India or Ceylon, and they will do better by staying at home. We quite admit that the question what to do with young men whose education has been costly and who aspire to any kind of life which takes them abroad is one of the problems of the day. Even for the stay-at-home studious youth it is perplexing. All the professions are overstocked, and it is only the young man with remarkable qualities and indomitable pluck and perseverance who is likely to succeed in any walk of life unless it be by a fluke. But tea planting, as we have said, is also overcrowded, and therefore it offers no field for candidates from home who are not specially qualified. It is not sufficient that the aspirant for a tea planter's career should have free and easy manners, no special love for work, and no particular fitness for anything but routine life. India and Ceylon are intensely like other places in that these human products are not necessary to the welfare of the regions. Waiving the question of the outlook, even to a qualified young man, with tea planting offers if he have not capital behind him, it is clear that the market for tea assistants is over supplied, and that rose-coloured views on the subject of the prospect offered are doomed to disappointment.—*H. & C Mail*, Feb. 12.

ON THE RIGHT TRACK.—The importance of opening up and supporting new market for Indian and Ceylon tea has now become generally recognised. For some time past we have repeatedly drawn attention to the matter, and it will be remembered that at nearly all the general meetings of the tea companies last summer this fact was specially emphasised. In turning to the results that have already been achieved it is gratifying to note that, so far as North America is concerned, the quantity of British-grown tea taken during 1896 shows a considerable increase on previous years. From statistics compiled by Messrs. Gow, Wilson, & Stanton, we find that the quantity of Indian tea was 5,202,405 lb, compared with 4,059,595 lb. in 1895, and 2,428,230 lb in 1894. The figures for Ceylon tea are as follows: 1896, 4,268,614 lb; 1895, 3,735,590 lb; 1894, 2,295,140 lb. "Well begun is half done," and it must be admitted that these results are highly satisfactory, and should prove a great stimulus to future efforts. It must, however, be borne in mind that the task is by no means complete, and that it is only by united action on the part of the Indian and Ceylon planters in supplementing the efforts of Mr. Blechynden and Mr. Mackenzie by raising as large a levy as possible, and other means, that it can be accomplished.—*H. & C Mail*, Feb. 19.

TEA PACKING.

Necessity is the mother of invention. We note that the prolonged depression in the Welsh tin-plate trade has caused those interested in that industry to seek fresh fields of enterprise for the disposal of their produce. The Tin-plate Manufacturers' Association of South Wales have awakened to a sense of the wide field which Indian and Ceylon might afford for the utilisation of tin-plate for tea packing purposes. Several meetings have been held in the district to discuss the project. At these meetings the fact was pointed out that only 2 per cent of the tea imported into this country is packed in metal cases, and a determined effort was expressed to win the remaining 98 per cent for the trade of the Principality. Voluminous correspondence has appeared on the subject in the Welsh newspapers. Large dealers in the metropolis and elsewhere have been consulted, and an expert was invited to read a paper on the question by the Association.

The objections of some tea importers to tin as compared with wooden chests were, of course, trotted out at the meeting referred to. One ridiculous objection was that tin fatally debarred any sort of ventilation, and led to the following correspondence in a local newspaper: A correspondent signing himself "A Well-known Local Grocer" wrote: "Tin will never do. You know that they when stacked often causes sufficient heat to cause a blaze. Well,

unless some outlet for the damp contained in tea is provided it will all go wrong. Of course the air cannot get to it to give it sufficient oxygen for a fire, but the result with air-tight tin boxes will be that the tea will get heated, then mildewed, and spoilt. Under the present arrangement the leadfoiling of the wooden boxes, not being hermetically sealed, allows the hot air to get away through the wood, and the tea arrives here quite sound and wholesome. It is my firm belief that it would not do so were it to be packed in sealed tin boxes."

The foregoing epistle elicited the appended reply from a leading Cardiff business man, who had for fifteen years been a tea planter in one of the most prosperous districts in India: "I read with astonishment the opinion of 'A Well-known Local Grocer.' I should like to know this man, as such ignorance of a subject in which one would naturally suppose a grocer to know a little is deplorable, and I would be loth to accept him as a representative of his trade. Tea is and must be packed in hermetically-sealed chests, otherwise (considering the extraordinary power of absorbing moisture which tea possesses) 'the sea will get heated, and then mildew and spoil.' 'A Well-known Local Grocer' will be surprised to hear that before the tea is packed it is refired, and every particle of moisture withdrawn; it is put into the chests hot, and immediately the lead is soldered down and hermetically sealed. Great care is also taken by the planter in nailing on the wood top, in case even a nail should be driven carelessly and perforate the lead, and thus spoil the air-tight case in which the tea is enclosed." According to the value opinion of Mr. Christison, whose paper on tea planting read before the Society of Arts dealt with this subject, unsoldered cases as received by grocers and warehouse methods have something to answer for.

As to the superiority or inferiority of tin cases to lead-lined wooden boxes for tea packing purposes, we must leave that controversial point to be settled by planters, contenting ourselves with drawing attention to the activity which is being displayed in the tin centres of South Wales to meet the requirements of the tea industry.—*H. & C. Mail*, Feb. 19.

CEYLON PROPRIETARY TEA ESTATES COMPANY, LIMITED.

From the prospectus of this Company which we mentioned had been formed with a capital of £160,000, we quote as follows:—

This Company is formed with the object primarily of acquiring as going concerns the following tea estates in Ceylon:

The Beaumont Group (Pussellawa District); the Forres and Warburton Estates (Maskeliya); the Summerville Estate (Dikoya); the Troy Estate (Kelani); the Radella Estate, seven-eighth shares (Dimbula), and of purchasing other properties when favourable opportunities offer.

The following are the total acreages of the properties (subject to the reduction of one-eighth, in the case of Radella estate, for the purchase of which negotiations are in progress.

Estates.	Approximate Mean Elevation. Feet.	Tea in bearing. Acres.	Tea in partial bearing. Acres.	Reserve and Waste. Acres.	Total Acreage.
Beaumont Group	3,000	608	189	393	1,190
Forres and Warburton	.. 5,000	380	—	9	389
Summerville	.. 3,800	200	—	37	237
Troy	.. 300	326	—	145	471
Radella	.. 5,000	410	—	186	596
Total Acres ..		1,924	189	770	2,883

The properties are freehold, with the exception of 75 acres of tea and 5½ acres of uncultivated land on

the Beaumont Group, held on lease, under which there is an option of purchase for part of the acreage.

It is estimated the 2,113 acres under tea will yield at the rate of 400 lb. per acre or 845,000 lb. per annum, when all the acreage is in bearing. This, at 3½d per lb. profit, will give a return of £11,000 per annum, which is sufficient (after allowing for the one-eighth share in Radella estate not yet acquired), to pay the Debenture and Preference interest and a good Dividend on the Ordinary Capital.

The estates are intended to be taken over as and from the 1st day of January last, and the price to be paid to the Vendors for the properties (subject as to the Beaumont Group, Forres and Warburton to £15,000 Debentures of the Beaumont Tea Company of Ceylon, Limited, hereinafter referred to) is £95,480, payable as to £71,376 fully paid Ordinary Shares, and 20,000 fully paid Preference Shares, and as to the balance, in cash.

Allowing £5 per acre for the value of the uncultivated land, the purchase price of the land planted with tea, including buildings, factories, machinery, &c., is at the rate of £51 13/- per acre,

After payment of purchase money the present issue of Shares will provide £6,520 available for preliminary expenses and working Capital, and also for the proposed additional purchase of land.

The Preference Shares will be entitled to Cumulative Dividend of five per cent per annum, and will take priority both as regards Dividend and Capital over the Ordinary Shares.

The £15,000 Debentures will be secured by a First Mortgage in favour of Trustees on the Beaumont Group, Forres and Warburton Estates, and are intended to replace an equal amount of Debentures of the Beaumont Tea Company of Ceylon, Limited, which are charged on the same Estates, and which the Ceylon Proprietary Tea Estates Company, Limited, is to get in and cancel.

The terms of purchase of the Beaumont Group of Estates and Forres and Warburton Estates are contained in a letter from the Directors of the Beaumont Tea Company of Ceylon, Limited, to H. K. Rutherford and R. A. Cameron, dated 31st December, 1896, and telegrams dated 18th, 22nd and 24th January, 1897.

The terms of purchase of Summerville and Troy Estates are contained in an agreement made the 5th February, 1897, between Mary Elizabeth Evelyn Elwes, Violet Lucy Elwes and Arthur H. L. Elwes of the one part, and the Ceylon Proprietary Tea Estates, Company, Limited, of the other part.

The terms of purchase of seven-eighths of Radella Estate are contained in letters from Francis Holme Wiggin to R. A. Cameron, dated 1st, 7th, 15th, 23rd and 31st December, 1896, and telegrams of 18th, 22nd and 24th January, 1897.

ASSAM AND INDIAN RUBBER.

Those who know Assam believe that nearly everything can be produced there. The exceptional demand for rubber at the present time lends additional interest to the accounts of the rubber output from Assam. This amounts annually to about 3,500 mounds (about 128 tons) worth in Calcutta R3,50,000 (£35,000). This includes, beside the rubber produced in the province, in the plantations and reserves, the "foreign" rubber collected and brought from the interior by the natives. It is estimated that, from the latter source, a supply to the extent of 900 to 1,000 maunds per annum may be kept up for five or six years, by which time the trees will have been exhausted, and supplies will have to be brought from a greater distance at increased cost—that is, assuming the rubber plants to exist in the remoter regions. The total area of the plantations already established is estimated at about 2,400 acres, but many parts are not fully stocked, great difficulty having been experienced to preserving the trees from illicit tapping by the

natives, even in the reserves. The present position of the rubber industry in Assam is very fully discussed in a "Note on an Inspection of Certain Forests in Assam," by Mr. H. C. Hill, officiating inspector-general, forests, dated March 31, 1896, from which the following is taken:—

"The illicit tapping of trees in reserves, sparsely scattered over miles of almost impenetrable evergreen forest, with an undergrowth of cane, is easily explained. The roughly-collected impure rubber sells at a rupee a seer, and to obtain a number of seers, which are interchangeable for twelve times their weight of rice at the nearest Koya's shop, a man has only to make his way to a tree, make cuts in the roots, and, returning three days later, collect his spoil. No system of inspection, paths, or staff of patrols, would render protection effective over a block of forest of 200 square miles, such as the Balipara and Charduar reserves, with, perhaps, ten or twenty trees to the square mile in the richest parts, even if men could be got to stay in the forest in the rainy season. Under existing arrangements, the tapper works in the rains, when all guards are withdrawn. The northern boundary is uninhabited and trackless except for wild elephant paths; therefore, the rubber, once collected, is easily carried across the line, to be reimported as foreign produce. The result is the continued destruction of the trees in reserves, as well as in unclassified forests, and if this is the state of things within the inner line it may be safely concluded that the trees are being generally killed off across the line. The only prospect of assuring a continuous rubber supply seems to be in the direction of artificial plantations, where the trees can be concentrated on a limited area, the effective protection and exploitation of which will be possible. Can these plantations be expected to become a profitable investment? The Government of India decided in 1894 that the further extension of the plantation was not advisable, because a considerable amount of expense would be incurred, and there was a great doubt whether the expenditure would prove remunerative, and further, because, even if it were remunerative, many years must elapse before any profits could be obtained. In any opinion, the cost of establishing a plantation where open lands are planted, as in 1892-3, may be estimated at R30 per acre; the existing plantation has cost R50, but, with the experience gained, there can be little doubt that operations will be cheaper in the future. The prospective yield of the plantation has been discussed at length, but it would seem that some assumptions have been made too unfavourable to the plantation. Trees have been put out seventeen or eighteen to the acre, and it has been assumed that half would disappear and seven or eight remain per acre but I think it may reasonably be held that more than eight trees will be permanently maintained. Admitting that an acre with eight trees or more will yield 40 seers at a tapping, which may be repeated every five years, the net value of the rubber being R80 per maund, the return per acre per annum becomes R16. If R40 be taken as the initial outlay per acre, and calculated at 3½ per cent, compound interest, it amounts to R220, and interest being paid on this at 3½ per cent., out of the R16 there would still be a net return of R8 per acre per annum. If these views are accepted, there would seem to be a good case for extending the plantation by 250 acres a year, at a cost of R10,000, for the next twelve years at least. By that time it would cover an area of 5,000 acres, the prospective yield of which would add a net income of at least R80,000 to the forest revenues of the province."—*H. & C. Mail*, Feb. 19.

THE SUGAR COMMISSION IN BRITISH GUIANA.

GEORGETOWN, BRITISH GUIANA, FEB. 4.

The Royal Commissioners, Sir Henry Norman, Sir David Barbour, and Sir Edward Grey, arrived in this colony by Royal Mail steamer a week

ago and in the interval they have examined some thirty witnesses representing all classes and interests in the community, and have visited two large and representative sugar estates. The amount of evidence taken is extensive and probably entirely exhaustive of the subject of the sugar industry and the large part which it fills in the commercial, social, and industrial life of the colony. Of such a mass of information it is impossible to give more than an outline, and it is sufficient to say that without exception the trend of the evidence has gone to show the identity of the interests of the colony with the fortunes of its staple industry. The expression used more than once has been "the sugar industry of the colony." In a previous letter I gave a few figures showing the predominant position of the trade of sugar growing and exporting in British Guiana, and it is not necessary to labour the point by repetition. It is, however, important to note that a great majority of the witnesses give it as their opinion that the sugar-cane is the only product that can be grown with any degree of success on the alluvial soils of Demerara. A considerable volume of evidence has been taken as to the practicability of alternative industries to sugar, but very little really satisfactory information is to be obtained. For years past the subject of "minor industries," as they are called here, has been *en l'air*, but wherever attempts have been made to raise anything besides cane or "ground provisions"—*i.e.*, plantains, cassava, yams, and so forth—failure has been the rule. The heavy salt soil is quite unsuited to cocoa, which is so successfully grown in Venezuela, and local labour conditions would render coffee unprofitable as an export commodity. The cultivation of rice is becoming general amongst the time-expired coolies who remain in the colony, and when proper machinery is introduced, it is probable that sufficient rice will be grown to meet local demands; but British Guiana can never hope to compete with India as a rice-exporting country so long as labour in the one country cannot be had under 1s a day—the irreducible *minimum*—and in the other may readily be obtained for 1½d. The conclusion to which one seems to be forced after studying the evidence given is that sugar, and sugar alone, can be successfully cultivated for export purposes on the coast lands of the colony. At present colonists are turning wistful eyes towards the interior, which, until the discovery of gold some twelve years ago, was allowed to remain a sealed book to the generality of the public. The development of the interior, however, cannot be adequately undertaken by a Government whose revenue is falling as steadily as its expenditure is increasing, and there is a lamentable dearth of private capital for such a purpose. The gold industry even, according to more than one witness, has not been an unmixed blessing, for it has absorbed thousands of pounds of local capital, only a small proportion of which has proved productive. What is chiefly needed is the introduction of foreign capital for the development of the goldfields, but until the boundary of the colony is finally adjusted that is hardly to be expected.

The Commissioners have devoted considerable attention in the examination of witnesses to colonial expenditure, and particularly to the cost of immigration, which constitutes a large drain upon the exchequer. Since the year 1878 the Government has borne one-third of the total cost of immigration, but, in view of the serious de-

pression of the sugar trade, during the last financial year the Government share was increased to two-thirds. In addition the presence of thousands of indentured labourers on the estates necessitates the maintenance of an extensive medical service, the whole cost of which falls upon the colony. It was suggested by Sir David Barbour that this public expenditure on immigration is equivalent to a bounty to the planters, and the reply elicited was that the introduction of so many immigrants must benefit a revenue largely derived from the taxation of foodstuffs and clothing, and it was further stated that had it not been for East Indian immigration the population would have steadily decreased during the past 30 years. Other witnesses, however, have contended that from the point of view of the settlement of the country and the formation of a wealth-creating peasantry, the introduction of the coolie has proved a marked failure. Another very costly item which has figured in the investigations of the Commission is the payment of return passages, for which the colony is at present liable to the extent of £1,000,000. As it is, a considerable proportion of the coolies elect to remain in the colony on the expiration of their agreed term of service and residence, but the number is not satisfactory, and it is difficult to devise a means of increasing it without involving the colony in an expenditure on small bonuses equal to the cost of the return passages. The Commissioners remarked the fact that while the sugar industry is declining immigration is still maintained (2,425 coolies were imported during the year 1895-96), but the planters contend that a ready supply of indentured labour is absolutely essential to the carrying on of their industry, as no reliance can be placed upon the negro and the free coolie.

With regard to efficiency and economy in the cultivation and manufacture of sugar, expert and scientific evidence given before the Commission entirely bears out the statement which I made in my last letter upon this subject—namely, that the cost of production has been reduced to a *minimum* and the methods adopted are thoroughly up to date. It has been stated in the evidence given that the German manufacturers can show no process of production which might be considered an improvement upon those employed in Demerara, and the yield of the cane has been increased to a point beyond which it is practically impossible to go. And yet in spite of all his efforts the Demerara planter is unable to make headway against the brute force of bounties. During the past six years nearly 13,000 acres previously under cane have gone out of cultivation, and it is only due to the happy circumstance that the past season has been exceptionally favourable that the whole of the existing plantations are still being carried on. One estate, indeed, has been abandoned and is now on the market, and another large plantation is in process of being "cropped." With two or three more equally favourable seasons there need be no immediate fear of a wholesale abandonment of estates—that is, provided that sugar does not fall lower in price than at present, and colonists are somewhat less inclined to regard their position as desperate than they were two or three months ago. One conclusion seems to be general, and that is that considerable economy must be exercised in the public expenditure of the colony.

The Commissioners sail on Saturday next for Trinidad.—*London Times*, Feb. 19.

LADY-BIRDS AND BUG.

Sir,—Your correspondent "Black Bug" in his letter to you of the 28th January, (this was written before receipt of our last issue.—Ed.) which appeared in your issue of the 6th instant brings up a point in connection with Lady-birds (*Coccinellidæ*) which has more than once occurred to me. So many estates in S. India are more or less heavily shaded that the fact of Lady-birds living or not living under shade may become a serious question. I have watched the habits of *Coccinellidæ* very carefully during the past year and a half and have found them under shade. That they are sun-loving insect is only too true, but I am inclined to think that as I have found them to do they will not hesitate to attack their prey under shade, although they will return to the unshaded and sunny tree on the estate to live and breed. From what I can gather I believe that the coffee in Hawaii was not to any extent shaded, and where large trees did occur they were citrons and as much infested with coccidæ as the coffee. Mr. E. E. Green's opinion on this point would be interesting.

I am not a Collector and have not studied *Coleoptera* in general; but I fancy I could find more than five varieties of *coccinellidæ* on the coffee in this district. Would "Black Bug" care to have specimens and would he identify them for me? If so I shall be glad to correspond.

I quite agree with "Black Bug" that it is improbable that many varieties of Lady-birds would forsake their natural food to blunt their teeth on Black Bug (presumably "Black Bug" means *Lecanium Coffee* and not *Lecanium nigrum*), but this wont hold good with green bug (*Lecanium viride*) which is a soft shelled scale and would probably not only be a more plentiful but an easier prey for the Lady-birds where it is to be found.

With regard to your "occasional note" in same issue on Black Bug.

I shall be very much surprised to hear that *Chilocorus Nigrinus* have been found preying on Black Bug (*Lecanium Coffee*). It is quite likely that another variety of *coccinellidæ* may be at work, though. I hope the Kotagiri planter will have given you the details you ask for in your next issue. Would he also kindly send some specimens?

I have just had my attention drawn to a letter of Mr. E. E. Green's in the *Ceylon Observer* of the 6th instant. In this letter Mr. Green suggests that the reason of the slow increase in numbers of *Chilocorus Nigrinus* is due to its natural enemies in this country and suggests an exchange of the different specimens of Ladybirds with Ceylon with the view of experimenting with them in countries where their own parasite may not be found.

This is, I think, an admirable suggestion, and I shall be most happy to exchange some of our *coccinellidæ*. Just at present unfortunately both the Green Bug and the Lady-birds are dormant, but in another month specimens should be fairly easily obtained.

I am only afraid that Ceylon and S. India are too nearly allied to make it impossible that parasites may be found in both countries or at any rate that the specimens one exchanges may be so nearly allied that the parasites will not hesitate in transferring their attention from the exported to the imported Ladybirds.

However, as Mr. Green says the experiment would be inexpensive and easily carried out, and I think (and hope) may result in practical mutual benefit.

Pillavaly Estate, HOWARD NEWPORT,
Hon. Sec., L. P. P. A., Dindigul.

—Planting Opinion, March 6.

TEA IN THE FUTURE.—A tea proprietor writes:—"What do you think of present prices for tea properties; are they likely to last another year or two? Over-production and low prices rather alarm one." And with some reason: it is very difficult to say what the next year or two may produce!

THE MAHA UVA ESTATE COMPANY, LIMITED.

The annual ordinary general meeting of the above Company was held at the Company's Offices, No. 7, Queen Street, Fort, Colombo, on the 13th March.

The following is the Report:—

ACREAGE.	
Tea in full bearing	- 299 Acres.
" " partial bearing	- 200 "
" not in bearing	- 118 "
Coffee amongst Tea (130 acres)	
Cardamoms	- 80 "
Grass	- 15 "
Total Cultivated	- 712 "
Jungle and Waste land	- 211 "
Total of Estate	- 923 Acres.

The Directors have pleasure in submitting to the Shareholders the Accounts of the Company for the past year.

The following are particulars of the Crops and prices secured in 1896, as compared with 1895:—

Crop.	1896.		1895.	
	lb.	Net average price. R. c.	lb.	Net average price. R. c.
Tea	- 155,020	— 49	105,472	— 52
	bus.		bus.	
Coffee	- 369	16 12	2,453	16 80
	lb.		lb.	
Cardamoms	- 502	1 60	615	1 18

The increase in the yield of Tea is very satisfactory, being 18,020 lb. in excess of the estimate for last year. 275 acres of the oldest Tea, which extent cannot yet be considered as in full bearing, gave an average yield of 463 lb. per acre.

In the last Annual Report it was mentioned that the Directors proposed, during the past year, to issue the balance of the authorized Capital of the Company, viz., 30 Shares of the nominal value of R500 each. This was done in June last at a premium of R400 per share, and the amount so realized appears at credit of the 1896 Profit and Loss Account, which shows an available balance of R43,156.06. The Directors recommend that the Share Premium referred to, viz., R12,000, be transferred to Depreciation Account. An interim dividend of 4 per cent on the Capital at 1st January last, viz., R285,000 was declared on 8th August last, absorbing R11,400. In terms of the Directors' circular of 26th March last the Shares issued in June are to rank for Dividend at the rate of one half of the total dividend for the year. The Directors now recommend that a final dividend of 5 per cent be paid on the Capital as at 1st January last, viz., R285,000 making 9 per cent for the year, and that a dividend of 4½ per cent be payable on the last issue of shares, viz., R15,000. After payment of these dividends a balance of R4,831.06 will remain to be carried forward to the current year's account.

The Capital account outlay during the past year amounted to R14,746.55, being for cost of acres 14.3.22 land added to the acreage of the Estate, for additions to Buildings and Machinery and for outlay on young and new clearings.

During the current year about 200 acres planted with tea in 1893 will give some crop. The Crops estimated for 1897 are 170,000 lb. Tea, 300 bushels Coffee (a preliminary estimate), and 1,000 lb. Cardamoms against an expenditure of R51,323 for delivery of same into Colombo. The outlay on Capital account is estimated at R8,360, mainly for upkeep of the acreage not yet in bearing, and additional line accommodation.

On the departure from the Island of Messrs. C. Young and G. W. Carlyon, Messrs. E. J. Young and A. Thomson were respectively appointed to the vacancies in the Directorate thus occasioned. In terms of the Articles of Association Mr. A. Thomson now retires by rotation but is eligible for re-election.

Mr. R. L. M. Brown having resigned the post of Auditor to the Company, the Directors, under the Company's Article No. 92, appointed Mr. T. J. Stephen to fill the vacancy thus occasioned.

The appointment of an Auditor for the current year rests with the Meeting.

By Order of the Directors,

WHITFALL & Co.

Colombo, 2nd March. 1897.

Agents and Secretaries.

THE DRAYTON (CEYLON) ESTATES CO., LIMITED.

A general meeting was held on March 13th at 11, Baillie Street, Fort.

The Directors' report is as follows:—

The Directors beg to submit the Annual Balance Sheet and Profit and Loss Account for the year ending 31 December, 1896.

After providing for depreciation of buildings and machinery, the balance of profit available is R25,815.91. The Directors propose that a dividend of three per cent. be declared, making, with the interim dividend of eight per cent, eleven per cent for the year, and the balance R4,365.91 be carried forward to next year's account.

The crop of tea secured from the Company's estates including 27,755 lb. tea made from Cwm leaf was 386,776 lb., against an estimate of 400,000 lb.

The total cost of the 386,776 lb. tea was 27.99 per lb. including Cwm rent, but exclusive of depreciation, and estimating that the tea unsold will fetch 47 cent per lb. the nett value realised for the whole crop will be 50.92 cent, showing a profit of 22.93 cent per lb.

The Company's properties consist of Drayton:—

Tea Bearing	..	685	acres.
Young Tea	..	84	"
Grass Land	..	18	"
Timber	..	10	"
Forest	..	17	"
Waste Roads, &c.	..	69	"
Yuillefield:—			
Tea in Bearing	..	207	"
Young Tea	..	11	"
Forest and Timber	..	7	"
Waste	..	8	"

1,116 acres.

The estimated crop for 1897 is 405,000 lb. to cost 27½ cent F.O.B. Adding rent of Cwm R4,500 the cost will be rather over 28½ cent.

Estimate allows of 2¼ cents per lb. being spent on manuring.

Mr. A. R. Wilson-Wood resigned his seat at the Board on his departure from the island, the Directors elected Mr. Harry Whitham a Director in his stead.

In terms of the articles of Association, Mr. Harry Whitham retires from the Board by rotation.

Mr. A. R. Wilson-Wood having since returned to the island offers himself for re-election as a Director.

The Shareholders will be requested to appoint an Auditor for the current year.—By order of the Board of Directors,

HARRY WHITHAM, Secretary.

Colombo, 2nd March, 1897.

TEA "OXIDIZER."

Mr. Nathan Sharpe, the well-known Patentee of Tea Packing and other Machines in connection with Messrs. Richard Moreland & Sons, is at present on a visit to Ceylon. The first of his "Oxidizers" is on the way out and is to be erected on Bandarapolla estate. Mr. Sharpe is sanguine about its good work and great saving of space: he will remain six weeks in the island.

Mr. Sharpe got the idea of his machine from remarks in the lecture by Mr. Christison before the Society of Arts where we also were present and spoke. We read of the machine:—

THE "SIMPLEX" COOL OXIDIZER.—Various systems now prevail in the tea districts, especially in the plains,

for the purpose of keeping rolled tea leaf in as cool a condition as possible whilst undergoing the important chemical change of Oxidation, more commonly expressed and termed "Fermentation." The Inventor of this machine thought that a great deal of room, labour, etc., could be saved by bringing the leaf under treatment into a more economical space and applying a cheap and efficient method of cooling the air, which would come into closer contact with the leaf, and perform a perfect cool oxidization of the leaf throughout the process. Methods of cooling air have (and still are, in other manufactures) been somewhat costly items, and we might say that a great deal of thought and attention has been bestowed on this machine, to enable us to present it to the notice of the Planting Community as it now stands, simplicity itself, therefore reasonable in cost.

LEAF SURFACE.—The machine consists of series of racks which support 144 leaf trays, 3 feet long by 2 feet wide, which gives 864 square feet of leaf surface, in a ground space of 12 feet by 6 feet, therefore the machine, when fully charged, will hold 36 Rolls or about 11,000 lb. of rolled tea leaf.

THE ANKANDE ESTATE COMPANY OF CEYLON, (LIMITED.)

The first ordinary general meeting of Shareholders of the Ankande Estate Company of Ceylon, Limited, was held at the Company's Registered Office, 22, Baillie Street, on the 13th March.

The report is as follows:—

The directors have pleasure in presenting to the shareholders their first annual report with a duly audited statement of the Company's affairs as at December 31st, 1896.

The Company took possession on January 1st, 1896, as a going concern of three estates constituting the Company's property, consisting of, and at the prices below stated:—

	Aukande.	Glenury.	Altwood.	Total.
	R	R	R	R
Price Paid.	60,700.	14,789.	30,221.17.	105,710.17
Acreage Tea..	91 acres	18 acres	7 acres	116 acres
	in full bearing	in full bearing	1 to 5 years	
Do Cocoa & Liberian Coffee ..	60 acres in full bearing	114 Cocoa and Liberian Coffee.
Do Cocoa..	17 acres under 2 years	37 acres in full bearing	..	
Do Cardamoms..	93 bearing	93 Cardamoms
Do Unopened (heavy Chcu)	262 acres	22 acres	2 acres	286 unopened

Total Acreage 430 acres 77 acres 102 acres 609 acres

The various crops gathered during the year exceeded the estimates in every case, and the prices obtained were well up to market averages.

After writing of preliminary expenses, paying interest on R23,510.17, part of purchase money outstanding on loan from vendors and placing R2,500 (returned by vendors, as working capital as arranged with them) to reserve, there remains an available balance of R7,877.28, out of which the directors propose paying a dividend on vendors' shares (R82,200) at the rate of 4 per cent per annum, and carrying forward the balance of R4,589.28 to 1897.

The estimates of ordinary expenditure and revenue for 1897 are as follows:—

	R. Ankande.	R. Glenury.	R. Altwood.	Total.
	R.	R.	R.	R.
Expenditure	15,450	2,035	3,560	21,045
Revenue	21,250	2,975	8,400	32,625
Balance	5,800	940	4,840	11,580

for 1897. Total estimated profit.

The directors propose to increase the cultivated area of Ankandé by clearing up and planting in tea during the S. W. monsoon 50 acres and during the N. E. monsoon further 50 acres, total 100 of the unopened heavy chena land there.

According to the articles of Association the whole of the directors retire, but being eligible offer themselves for re-election.

The appointment of Auditor also rests with the meeting.

LEWIS BROWN & Co., Agents and Secretaries.

PROSPECTS OF "TEA" IN LONDON.

Several letters from "the City" by this mail are marked by quite a cheery tone as to the prospects of tea and Tea Companies. One gentleman, who pays close attention to "tea," thinks it is going to take the place of "gold" in the esteem of provincial investors throughout the United Kingdom, in view of the great loss sustained of late through "gold mining shares" in Western Australia and even in South Africa. We quote as follows:—

The public are looking with increased interest after tea shares, since they have suffered so much in gold mines without a prospect of getting any return from many of them. There are buyers from all parts of the Kingdom and I believe we shall see a considerable expansion of business this year and the number of new companies coming out will form wider field for investors.

"The unsettled political outlook has a very serious effect upon general business just now, for people do not know what may be the result of the bellicose Greek and unless the Powers are united as to what is to be done serious consequences may still further develop."

From another City authority we have the following:—

"Mr. James Sinclair has returned from Ceylon, very favourably impressed with the appearance of the properties owned by the Dimbula Valley Tea Co., and the satisfactory future that lies before it. Quarantine regulations prevented his landing at Brindisi or Marseilles, as the authorities at these ports absolutely prohibit the landing of any passengers from the East, except under the most galling restriction, and a delay which renders the voyage round to Plymouth much preferable in every respect."

"The feature of the last few weeks has been the strong position of the Indian tea market, owing to the short supplies. Ceylon teas have shown some improvement and the market is stronger, but prices compare very unfavourably with those obtained the Indian teas."

"There is a lull in the production of Tea Companies. Owners are asking very high prices, whilst the unsettled state of the political horizon render investors very cautious with their moves."

THE KNAVESMIRE TEA ESTATES COMPANY LIMITED.

The first ordinary general meeting of the Knavesmire Tea Estates Company, Limited, was held on the 13th March, at the Registered Office of the Company, No. 14, Queen Street.

The Directors' Report is as follows:—

DIRECTORS:—H. O. Hoseason, Esq., A. G. L. Dupuis, Esq.

Your Directors have now to submit their Report and Accounts for season ended 31st December, 1896.

The accounts cover the first twelve months of the Company's work, and shew a balance at credit of "Profit and Loss" of R19,799.69, out of which the Directors recommend payment of a Dividend at the rate of 7 per cent per annum. A Dividend at that rate will absorb R17,717.67, and leave a sum of R2,082.02 available to cover Directors' fees, and to liquidate in part the expenses connected with the formation of the Company, and transfer of the Estate.

The past season's Tea Crop amounted to 250,940lb. upon an estimate of 250,000 lb., and the Directors are confident that a materially larger yield would have been secured, had the labor force been on a satisfactory footing all through the year.

The Labor question is still a source of anxiety to the Directors, but in some respects the position has improved of late, and the efforts of all concerned are being directed to bring about such an increase of the force as will admit of the property being cropped up to its full capacity in the future.

For 1897 the Directors have decided to fix the Crop Estimate at 300,000 lb., a figure which they regard as well as within the mark, assuming an adequate Labor force. The cost of producing the above Crop and placing it in Colombo is estimated at R63,930.

In terms of the Articles of Association all the Directors retire on this occasion, but are eligible for re-election.

GEO. STEUART & Co., Agents & Secretaries.

THE KIRKLEES ESTATE COMPANY, LIMITED.

The annual ordinary general meeting of the above Company was held at the Company's offices No. 7, Queen Street, Fort, Colombo, on the 13th March.

The following is the Report:—

ACREAGE OF KIRKLEES ESTATE.			
Tea in bearing	..	280	acres.
" " partial bearing	..	32	"
" not in bearing	..	80	"
Total Tea 392 acres.			
Cardamoms	..	20	"
" and Timber	..	4	"
Timber	..	56	"
Uncultivated Land	..	245	"
Total 717 acres.			

The Directors have pleasure in submitting to the Shareholders the Accounts of the Company for the past year.

The Crops secured in the year were 88,597 lbs. Tea, 86 bushels coffee and 736 lbs cardamoms. The average net prices realized were 54½ cents per lb. for the tea, R16.65 per bushel for the coffee and R1.35 per lb. for the cardamoms.

After making ample provision for depreciation of Buildings and Machinery the net profit for the year amounted to R13,117.11, to which has to be added the balance brought forward from 1895, R1,541.57, making a total of R14,658.68 available for dividend, equal to about 14¼ per cent. on the Capital of the Company. An Interim Dividend of 5 per cent was paid on the 6th August last, and the Directors now recommend a final dividend of 8 per cent, making 13 per cent for the year, leaving a balance of R1,658.68 to be carried forward to the current season's account.

The estimates for this year are 95,000 lbs tea, 50 bushels coffee and 1,000 lbs, cardamoms, on an expenditure of R33,680.

The estimate of expenditure on capital account is R12,300, which provides for the upkeep of the tea not yet in bearing, additions to Machinery and Buildings and a survey of the Estate.

During the year Mr. G. W. Carlyon resigned his seat on the Board, and Mr. A. Thomson was invited to take his place. In terms of the Articles of Association Mr. G. H. Alston retires by rotation from the office of Director, but is eligible for re-election.

The appointment of an Auditor for the current year will rest with the meeting.

By order of the Directors, WHITTALL & Co. Colombo, Feb. 27th, 1897. Agents & Secretaries.

PLANTING AND PRODUCE.

(From the *H. and C. Mail*, Feb. 26.)

PUSHING TEA.—The pushing of tea by retailers goes along merrily. We notice that a Glasgow store gives "sugar for nothing" in the proportion of half a pound to each quarter-pound of tea at 4½d. We trust that the day will never arrive when tea will be given away with something else. It is an age of over-production and consequent low prices, but tea is an exceptional position, at least in some respects. It cannot as yet be grown even on bounty terms in Europe, and the Chinese and Japanese have not yet started on their threatened raid on the markets of the world.

THE SUGAR COMMISSION.—From an account of the first sitting in Demerara of the Royal Commissioners, which we give in another column, it will be seen that the evidence of planters, Government officials, magistrates, merchants, chemists, engineers, and others has been taken. The opinion generally expressed appears to have been that all has been done that can be done to make the sugar industry of British Guiana profitable, and it is claimed that the one thing needful is fair competition, on a natural basis. The Commissioners intend visiting the islands of the West Indies. Apropos of the sugar supply and the Sugar Commission, Lord Stanmore presided on Monday night at the Imperial Institute at a lecture on "The Past, Present, and Future of the Sugar Supply of the British Empire," by Mr. C. A. Barber. The subject was treated in a comprehensive manner, and was illustrated by a large number of views on the screen. After referring to the enormous growth of the consumption of sugar at different periods, Mr. Barber said that in 1895 the total consumption in Great Britain was 1,566,000 tons. Fifty years ago cane produced nearly all the sugar, but there had been a factory established for the manufacture from beet at the beginning of the century. He referred to the large quantity sent here by France and Germany, and to the unfair system of bounties; and, in concluding his lecture, remarked that the future of sugar was full of interest. Beet was going to stay whether bounties continued or not. The British colonies were in a very bad way, there was no doubt about that, and many proprietors would be ruined. He believed, however, that coarse sugar could be produced so well and cheaply in the islands that ultimately they would emerge from the trial. The question was how many of the present race would see the triumph? The Commission that had gone out to the West Indies would find that they had other things to contend with besides bounties.

TEA IN RUSSIA.

Mr. Wm. B. Steveni, who claims to have been the very first to have given a start to Ceylon Tea in Russia—immediately after our meeting him at Vichy in France, in Sept. 1887—writes as follows by the mail delayed through the "Orotava":—

St. Petersburg, 22nd Jan. 1897. Add: 15 Admiralty Canal.—Some weeks ago I wrote a long letter* advising you to have some articles written in the leading Russian papers *re* the excellent qualities of Ceylon tea. As I cannot write Russian myself *i.e.* well enough for the press, I, personally, should reap no advantage from these articles being written; but I cannot help but think that the planters—if they are wise—would make use of this offer. I also hope they will not forget the man who first conceived the idea of introducing Ceylon tea into Russia and paved the way for Rogivue and his assistants. I really do not care what form the testimonial takes; but I think if the tea planters are men of fine feeling they will not forget me. I suffered so much ridicule and even loss in this attempt, that I should like to have something to show for it—even if it were only a tea-caddy! You, I am sure, can understand this

* Not received.—ED. T.A.

feeling. I find Ceylon tea is now being sold here. It is however making slow headway. The taste does not suit the public and perhaps the quality is not quite as good as it might be. I know I bought ½ a lb. not long ago; but the quality is so poor that I cannot finish it. *It costs Rs 2.20 per lb.*

We leave the P. A. Committee or rather the Committee of Thirty, to say whether they feel inclined to send Mr. Barnes-Steveni an "Oriental tea-caddy" as a memento to the first man who stood up for Ceylon tea in Russia? And in addition to empower him to spend £5 or £10 on a series of articles in the Russian press on the goodness of our Ceylon teas.

PLANTING PRODUCTS.

(Extracts from the *Forty-third Annual Report of the Ceylon Planters' Association, held 17th March, 1897.*)

TEA.—The estimate as furnished by our Hon. Secretary at the instance of the Parent Body is 2,800,000 lb. made tea. Further large acreages have been planted under tea during the year now under review, the weather for such operation being exceptionally favourable. The further lowering of prices for our teas, and the upward tendency of exchange during the latter portion of the year will doubtless suggest to members the great importance of exercising all judgment and caution in the future selecting of tea land, as the old cry of "overproduction" is now being raised, and we may have to face smaller profits in consequence. The high favour in which Tea Companies in Uva are viewed by the public, as attested by the Colombo share lists, goes to prove how eminently suitable our soil and climate are to the tea bush. The north-east monsoon rains were severe and continuous, thereby seriously retarding our flushes during those rainy months. For the sake of record, your Committee think it interesting to commit to writing the fact that in the month of December the flood water touched the Badulla bridge!

COFFEE.—Your Committee feel it unnecessary to allude to this products (Arabian) at any length. Age (in many instances), green bug, and leaf disease are steadily performing their mission of destruction, and it is now pretty well allowed as hopeless to successfully cultivate this product. The *Liberian* variety has received considerable attention in the Mooneragalla district, with varied results. Crops generally have been very short indeed.

COCOA.—Much new land has been planted under this product, especially in the Mooneragalla district, where it is so thoroughly established and grows luxuriantly. Beyond a little "*Helopeltis*" to be observed here and there, this industry so far may be said to be free of pests, and requiring, as it does, so small a labour force, it is peculiarly adapted to these days scarce of labour.

NEW INDUSTRIES IN THE KURUNEGALA DISTRICTS.

(From our Correspondent.)

I.—COCONUT MANUFACTORY, COCONUT OIL, FIBRE, AND DESICCATING MILLS.

The name of J. H. Vavasour & Co. will ever remain intimately connected with the introduction into Ceylon of an industry which, in point of importance in the labour it employs, the capital it involves, the prominence into which the island is brought by it in various parts of the world, promises to be second to none of the other industries here—namely coconut desiccating. Desiccated coconut already forms a principal article of export and one of the most popular shapes in which the product of the coconut palm is sent out of the island. Mr. John Ciovis de Silva, the well-known merchant, with commendable zeal foresight and enterprize, has added to our provincial industries this useful branch, and in the space of a month

or so, Kurunegala will boast of a coconut manufactory, coconut oil, fibre and desiccating mill in full working swing. In a coconut district such as this is, the usefulness and importance of a manufactory of this kind cannot be overestimated. Rather than allow the principal agricultural product to leave the district and be diverted into various channels outside its borders it will attract and utilize the trade, offer a ready market to the district owners of coconut, and open out a never-failing field of work to the labouring classes. Such a public benefactor deserves well of his countrymen, and in giving the following description of the mills, which will probably commence operations in April or May next, we wish Messrs. J. C. de Silva & Co. of which firm, Mr. John Clovis de Silva is the chief partner and moving spirit, every success in his new venture.

THE MILLS.

The main building is one of the most imposing structures in Kurunegala. It stands on a plot of ground, about 10 acres in extent, on the Circular road, South, in the hamlet Vilgoda, and is about a mile from the Jail Corner. The roof is of zinc, and the wall of red brick, pointed with cement, while the doors and windows are painted chocolate. A 6 ft. brick wall with massive gates runs along the road frontage. The *tout ensemble* is picturesque in the extreme.

The main building is 203 ft. long and 86 ft. wide, and occupies the central portion of the land. For purposes of internal economy and arrangement the building is divided into three portions to serve three departments.

(1) THE DESICCATING DEPARTMENT

which takes the right hand side of the building, and occupies the largest space, 153 ft. by 86 ft. Then this space is again subdivided into (a) the packing room and (b) the desiccating room. There is accommodation for eleven desiccators, but only three have been fitted up for the present, and are similar to those used in the tea factories.—Brown's patent single desiccators, manufactured by the Colombo Commercial Company. The desiccators occupy the entire length of the room on the southern side, the engine room being at the extreme end on the east. The engine is 8' by 13½' by 20" compound tandem condensing engine, with 9' 0" by 5' 0" type D cylindrical multitubular boiler by Ruston Proctor & Co., Lincoln. It is the first of its kind imported into the island. Another imported, after it, has lately been fitted up at the New Ice Mills, Colombo. The enormous amount of time and labour and expense saved by the use of a compound as against a simple condenser, is too well-known to be repeated. The boiler in question will develop 12 nominal and 50 indicated horsepower.

The other machines to be used in this department are the slicing, grating, and stripping machines. The grating machines are from the Commercial Company, Colombo, and the slicing machines from C. A. Hutson & Co., Colombo. The shelling of the coconuts will be done by axes, and the shaving by spoke shaves used manually, chiefly by women and boys.

There are also one hot water tank to boil coconuts in and a washing tank in which the nuts are washed.

THE OIL DEPARTMENT

is just in front of the ground taken up by the fibre department, and occupies a space 90 ft. by 25. This department is not to be worked just at present, and will commence operations probably some time after the other two branches are sufficiently well developed and all in proper working trim. When this department begins work, Richard's occupation at Gangoda will be gone. Gangoda is a hamlet in Kurunegala, where the native oil mills (*chekkus*) do a small trade, which at one time flourished. The chief residents are Tamil chetties, who were one time well-to-do men but strange to say, not one ever succeeded in keeping the money, (and in days of yore it was not such a rare

commodity as it now is), he piled up. There is not a single man now at Gangoda among the oil-mongers who is above want.

"Something ails it now
The place is curst."

THE FIBRE DEPARTMENT

is just behind the oil room and covers a space 54 feet by 86 feet. Ten fibre drums have been set up along the southern length of the hall, and will be worked by the same shaft as the other machines.

Then there are the crushers to crush the husk, the winnowers to shift the fibre, while the most interesting branch of the department is the "heckling shed," where the fibre is combed and dressed. It is said that young women are as a rule employed for this kind of work and perhaps with much reason for a gay pert damsel would "do up" the fibre as she would her own hair, which you could not expect from the sere and yellow leaf! So there will be an excellent opening for Miss Kurunegala at the Mills, when work is in full swing. Then, again, there are the balloting presses. We next come to the tanks which are right behind the fibre room and are two in number. They measure 25 ft. by 23 ft. each. These tanks are used for soaking the husks, and are fed by the well adjoining it, which was constructed by contract for a sum of R750.

THE SUPERINTENDENT'S BUNGALOW

stands on the right and a little distance away from the main building. It is to be an upstairs building with two bed rooms and a hall at the top, and two rooms, a dining hall, and office with outhouses, etc., below.

BUILDING MATERIAL.

With the exception of fire-bricks imported from J. and M. Craig, Kilmarnock, the rest of the bricks used was supplied locally, principally by the well known kiln at Malpitiya, three miles from Kurunegala—which has won quite a reputation for the superiority of its bricks. Locally manufactured bricks were largely used in the construction of bridges and culverts on the Kurunegala branch of the railway, and Mr. Waring wrote in his final report:—"The bricks used for the most part were made at brick fields on and near the work, the remainder having been made at Colombo. The locally made bricks were, I think, fully equal to those from Colombo." In this connection it would be interesting to know whether fire bricks were ever made in Ceylon. Is not fire-clay to be met with in the island? If fire-bricks have not been made, perhaps it is due to the fact that they do not command a market here, and that it is cheaper to get the imported article.

The zinc roof was supplied by Messrs. Hutson & Co. and the timber bought locally, while the workmanship so far as the wood work goes was contributed by Moratuwa carpenters, the masons being men of the place.

THE STAFF.

Mr. R. C. Dickson, a competent practical Engineer, supervised the setting up of the machinery and to some extent the fixing up of the roof, on a special agreement. Mr. Dickson was at one time residing at Kurunegala, and daily visiting the manufactory, but as the work progressed, he changed his residence to Kandy and now pays periodical visits. It will interest the friends of Mr. Sydney Morse, whose memory is bound to live long in musical circles, that Mr. Dickson as well as his brother served the same apprenticeship as Mr. Morse and his brother did in Scotland, in qualifying themselves as practical Engineers, and that they all passed out at the same time. Nothing surprised Mr. Dickson more than on suddenly coming face to face with his quondam fellow-apprentice in the streets of Kandy! Mr. Dickson is a nephew of Dr. Cochran, the City Analyst. Mr. Dickson's trusty lieutenant is Mr. Henry de Silva who has had ten years' experience in the desiccating mills of Messrs. Vavasseur in Colombo, also at the Kelaniya Mills, and who will be the Superintendent of the Machinery when the work starts. Mr. Silva is busy in carrying out the work, according to the instructions laid down. For most

of the particulars contained in this account and for the exceptionally kind and obliging manner in which everything of importance and interest at the work was explained and shown, the writer is gratefully indebted to Mr. Silva and to Mr. Mendis, the able and energetic agent of Messrs. J. C. de Silva & Co.

THE COST OF THE WORKS

we can only give a guess at. If they cost a cent they have cost their proprietor certainly R40,000, inclusive of machinery, which he is sure to recoup, and we trust with handsome profits before long. It is his intention at present to commence work with about 20,000 coconuts per diem. There are mills which use up as many as 60,000 per diem. At the modest rate at which Mr. Silva proposes to make his start, there will be a never-ceasing demand for coconuts in every part of the district. Mr. Silva already owns thousands of acres in the Kurunegala district, and he has the lease of extensive plantations; nevertheless he will have to place lands other than his own, under contribution to meet the daily demands of his mills.

THE POPULARITY OF DESICCATED COCONUT

is widespread, but the writer never could understand why there is such a halo of secrecy around desiccating manufactories as to prohibit the entrance of visitors into the charmed places where the desiccating goes on. Is it the risk run by the secrets of the trade being found out, or the chance of some spy getting a tip or a wrinkle which may be only known to the charmed circle, that the desiccating rooms are so jealously guarded and watched, or can it be that the entrance into these rooms means so much diminution of the manufactured article which is the greatest temptation to the visitor to resist the tasting of?

PACKETS OF DESICCATED COCONUT.

Talking of the high favour in which desiccated coconut is held by "strangers within our gates," Mr. Silva mentioned to the writer that it was as much as he could do to keep off the inquisitive and itching fingers especially of the fair visitors to the mills he had worked in, from picking at the scrapings, on the invariable plea of "just to have a taste only of the nice stuff." At times, on weighing the desiccated coconut at the close of the day's work, as much as 20 and 30 lbs. were found short, the result of the visitors gratifying their taste. With a view of preventing this gratuitous and of "admittance except on business," Mr. Silva proposes to have little packets made up of desiccated coconut, with printed labels containing instructions as to the way in which the contents may be turned into pudding etc., and to sell the packets at a nominal rate. This idea will certainly have the desired effect of checking "shortage and intrusion." The packet will doubtless be a boon and a blessing.

THE THIRTY COMMITTEE.

Minutes of Proceedings of a meeting of the "Thirty Committee" held at Kandy on Saturday the 13th day of March 1897 at half past seven o'clock in the morning.

Present:—Messrs. J. N. Campbell (Chairman), A. Philip (Secretary), R. S. Duff Tytler, F. C. Gubbins, A. A. Bowie, J. P. E. Ryan, Gordon Pyper, H. V. Masfield, H. Cumberbatch, C. E. Wellton, E. Rosling, F. G. A. Lane, Oliver Collett.

The notice calling the meeting was read. The minutes of proceedings of a meeting of the "Thirty Committee" held at Kandy on Monday the 1st day of February 1897 were submitted for confirmation.

Read letter from Mr. J. H. Renton regretting his inability to be present.

Read letter from the Secretary, Ceylon Chamber of Commerce, notifying that the following members were recently elected to represent the Chamber on the "Thirty Committee,"—Messrs. Gordon Frazer, J. H. Renton, C. W. Horsfall, H. Cumberbatch, P. Bois, while Mr. F. M. Mackwood as Chairman of the Chamber will continue to be on the Committee.

Read letter from the Manager, National Bank of India, Limited.

Read letter from Government acknowledging receipt of copy of the minutes of proceedings of a meeting of the "Thirty Committee" held at Kandy on the 16th January 1897.

REPRESENTATIVE IN AMERICA.

Read letter from Mr. Mackenzie to Mr. Sackville dated London 10th January 1897; also the accompanying enclosures.

Read letter from Mr. Mackenzie to Mr. Philip dated London 14th January with statement of expenditure on account of the Committee to 8th January 1897, 19th January, 27th January 1897. Resolved:—"That the sum of £3,000 sterling applied for be placed at Mr. W. Mackenzie's credit at London by wire for the American campaign.

Read letter from the Secretary, the Ceylon Association in London, forwarding the following resolution passed by the Tea and Produce Committee of the Association at a meeting held on the 18th January.—"That the Secretary be requested to ask the Committee of Thirty on what general principles the amount raised in Ceylon by the taxation of tea is spent.

"What amount is expended in America—and to ask that an account of expenditure for the year 1896 (without details that it may be considered injudicious to publish) be sent to this Committee."

Read cablegram from Mr. Wm. Martin Leake, dated 1st February 1897, reading "Mackenzie sailing Saturday; please telegraph credit £1,000."

Intimated that the request had been complied with. Resolved:—"With reference to the resolution forwarded by the Ceylon Association in London, that in terms of his letter to the Secretary dated London 19th January 1897, Mr. Mackenzie be requested to give the Committee of the Ceylon Association in London such details and particulars regarding the disposal of the funds granted to him for pushing and advertising Ceylon tea in America as may appear to him judicious."

Resolved (II):—"That in answer to the specific questions the Ceylon Association in London be informed, (a) on what general principles the amount raised in Ceylon by the taxation of tea is spent?"

The general principles are advertisements and demonstrations in localities which are being specially worked, and by assisting those who are spending their own money in pushing Ceylon tea.

(b) WHAT AMOUNT IS EXPENDED IN AMERICA.

The amount expended in America up to say 31st December 1896, as per Mr. Mackenzie's accounts is £17,090 9s 8d. (Seventeen thousand and ninety pounds nine shillings, and eight pence.)

(c) That an account of expenditure for the year 1896 (without details that it may be considered injudicious to publish) be sent to this Committee.

That Mr. Mackenzie will be requested to give the Committee of the Ceylon Association in London such information as he may deem judicious.

CEYLON TEA IN RUSSIA.

Resolved:—"That with the object of further pushing Ceylon tea in Russia Mr. T. N. Christie be asked to visit Russia during the year 1897 and to report to the Committee as to the best means of securing this end; (2) that the sanction of Government be asked to an expenditure of a sum not exceeding £200 to cover all expenses Mr. Christie may be put to, during his visit to Russia in connection with the mission referred to in the above resolution."

CEYLON TEA ON THE CONTINENT OF EUROPE.

Read letter from Mr. K. V. Webster by his Attorney Mr. J. H. Renton acknowledging receipt of cheque for R7,852.76 being the equivalent of £500 sterling granted to Mr. Webster for the purpose of pushing and advertising Ceylon tea on the Continent of Europe.

CEYLON TEA IN BELGIUM AND HOLLAND.

Read letters from Mr. E. R. Templer on the subject of his offer to push and advertise Ceylon tea in Belgium and Holland, and regarding the 1,000 lb. tea

sent to him with draft for £35 sterling, and stating that the tea was of such good quality that he had no hesitation in saying better or perhaps such good teas have never been sent to Belgium or Holland.

Resolved:—"That Mr. Templer be informed that the 1,000 lb. of Ceylon tea already sent to him may be considered by him as a free grant, the proceeds to be used for further pushing the sale of and advertising Ceylon Tea, but that in future any business arrangements for additional supplies must be made to the Ceylon Tea Company Limited, direct or to any other firm. The Committee trusts that Mr. Templer will see the importance of continuing to keep stocks of Ceylon Tea through the ordinary Trade Channels; the Committee will be glad to have reports—as promised—from time to time of the progress made, and would add that any future grant will depend on the attendant results.

CEYLON TEA IN AUSTRIA AND HUNGARY.

Read letter from Messrs. Darley, Butler & Co. making an application for a grant of 500 lbs. of Ceylon Tea for distribution in Austria and Hungary on behalf of a correspondent in Vienna.

Resolved:—"That a grant of 500 lbs. of Ceylon Tea be made to Messrs. Darley Butler & Co. for the purpose indicated in their letter."

CEYLON TEA IN GERMANY.

Read letter from Mr. Chas. A. Bohringer asking for a grant of £50 sterling to be spent in advertising and paid over on production of vouchers showing how the money has been spent.

Resolved:—"That a sum of £50 sterling be granted to Mr. Bohringer on the terms stated in his letter."

CEYLON TEA IN SWEDEN AND NORWAY.

Read letter from Messrs. Akt. Bolg. Maren & Co., Stockholm a king for a contribution towards expenses to be incurred in introducing and pushing Ceylon Tea in Sweden and Norway.

Read letter from Mr. A. G. Seton recommending the application, and expressing the opinion that it affords a good opportunity for making Ceylon Tea known throughout the Scandinavian Continent.

Resolved:—"That a grant of £250 sterling be made to Messrs. Akt. Bolg. Maren & Co. for advertising and pushing Ceylon Tea in Sweden and Norway, and that they be informed that the Committee will be inclined to give them further support if they are able to open in other localities. The Committee will be glad if Messrs. Maren & Co. will send some particulars showing the places in which the advertising is chiefly done, and the approximate amount apportioned to each town.

Report and accounts for the year ended 31st December 1896.

Submitted and laid on the table Report of the "Thirty Committee" for the year ended 31st December 1896 together with the Abstract of Accounts of the Ceylon Tea (New Markets Fund) for the like period.

The "Thirty Committee" then adjourned.

A. PHILIP,
Secretary to the "Thirty Committee."

THE KELANI TEA GARDEN COMPANY. LIMITED.

A general meeting of shareholders of the Kelani Tea Garden Co., Ltd., was held at the offices of Messrs. Carson and Co., on the 13th March

The Report was as follows:—

ACREAGE.	
282 acres	Tea in full bearing
52 "	" planted 1896
30 "	Felled
224 "	Reserve
<hr/>	
588 acres	

The Directors have pleasure in submitting to the Shareholders the accounts of the Company for the year ending 31st December, 1896.

The crop secured amounted to 166,056 lb. of male Tea realizing R67,056.77, or an average price of cents 40.38 per lb., as against an expenditure (exclusive of

items under Capital Account) of R39,505.83, or an average cost of cents 23.79 per lb.

The balance at credit of Profit and Loss Account after making provision for

Depreciation on Buildings and Machinery	R5,369	11
Stationary and Postages	5	00
Auditor's Fee and Management Expenses	3,050	00
	<hr/>	
	8,424	11

Less Transfer Fees	R22	00
Interest on Bank Account	205	51
	<hr/>	
	227	51
	<hr/>	
	R8,196	60

amounts to R19,351.34, and with the balance brought forward from previous year of R3,255.84, a total of R22,610.18.

This the Directors recommend being dealt with as follows:—

A dividend of 5 per cent for the year absorbing R15,000, and the balance R7,610.18, to next account.

The Directors are endeavouring to negotiate the purchase of about 160 acres land which adjoins the 52-acre clearing opened last year.

Mr. J. W. Bamforth, for many years Superintendent of Chesterford estate, will take charge from the 15th March, 1897.

It is hoped that the returns for the current season will be more satisfactory than for the past year.

The estimated crop for 1897 is 185,000 lb.

Mr. H. Creasy has retired from the Board of Directors, and it is suggested that Mr. Chas. L. Davis be elected to fill the vacancy.

The appointment of an Auditor rests with the meeting.

CARSON & Co., Agents and Secretaries
Colombo, 30th January, 1897.

THE UDABAGE COMPANY, LIMITED.

A general meeting of shareholders of this Co., was held at the offices of Messrs. Carson & Co.

The following is the report:—

ACREAGE:

Originally purchased by Company	.. 355 acres.
Lately purchased very suitable for Tea	785 "
	<hr/>
	1,140 acres.

Tea full bearing	.. 210 acres.
" planted 1894	.. 6 "
" " 1895	.. 2 "
" " 1896	.. 82 "
	<hr/>
	300 acres.

Reserve .. 840 "

1,140 acres.

The Directors have pleasure in submitting to the Shareholders the accounts for the year ending 31st December, 1896. The crop secured amounted to 123,385 lb. made Tea realizing R42,376.26, or an average price of cents 34.34 per lb., as against an expenditure of (exclusive of items under Capital Account) R31,317.01, or an average cost of cents 25.38 per lb.

The balance at credit of Profit and Loss Account after making provision for

Stationery and Printing	R. c.
Balance preliminary expenses	10 00
Interests	314 88
Directors' fees and Visiting Agent	1,907 40
Auditor's fee	1,450 00
Agents and Secretaries	50 00
Depreciation on Buildings and Machinery	750 00
Legal Expenses	2,535 13
		<hr/>
		1,586 00

88,603 41
Less transfer fees .. 13 00

R8,590 41

amounts to R2,468.81, and with the balance brought forward from previous year of R1,221.74, a total of R3,690.55. This the Directors recommend being carried forward to next account.

As regards the working of the Estate, the Company has been under a disadvantage owing to changes of superintendence. The Directors have now secured the services of Mr. A. F. Barn-Smeaton, under whose management considerably better results may be looked for.

During the past year, the valuable land in the vicinity of Udabage being rapidly acquired by others, the Directors deemed it advisable to secure three fine blocks aggregating 781 acres. In order to pay for this, and the cost of the opening, Debentures bearing interest at the rate of 7 per cent. were issued, but only R53,000 have been taken up, and the Company is indebted to its Bankers in the sum of R15,821.48 on which interest at current rates is running.

The Directors, therefore, propose entering into negotiations at home for the raising of a Sterling loan secured by a primary mortgage on the Company's property upon more reasonable rates than can be obtained locally, and which will permit of their paying off the Debentures and debts, and provide sufficient funds for further extensions.

The estimate for the current season is 125,000 of made Tea, and up to 250 acres are being felled and planted up.

Mr. J. N. CAMPBELL retires in terms of the Articles of Association, but is eligible for re-election.

The appointment of an Auditor rests with the meeting. *CARSON & Co.*
Colombo, 23rd January, 1897. *Agents and Secretaries.*

PLANTING NOTES.

I see an outcry has been raised against the products of a tree being applied to it as

MANURE

in connection with disease in turnips at home. As usual in such cases the outcry is being re-echoed here, and people declaim against burying tea-prunings which are wrongly called "refuse." I consider that word a misnomer and would call it a product of the tree. There is no analogy between the refuse of the animal creation and the leaves, fruit or branches of trees or plants. In the one instance, the refuse is that portion of the food, which is refused by the system after it has extracted from it all that is necessary for its sustenance. According to this definition trees and plants have no "refuse" or excreta. Old agriculturists believed that plants passed through their roots what was not necessary for their sustenance, and that this "refuse" was harmful to that order of trees and plants, and that after a time, they refused to grow on the same land. This was the beginning of rotation of crops. This is an instance of right conclusions being drawn from wrong premises. The practice that observation led agriculturists to adopt, scientific research has pronounced to be the right one, but for different reasons. The soil is deprived temporarily of certain constituents by one order of plants, but another order not requiring the same constituents thrive well enough on the same soil. As you very pertinently remarked, forest soils are improved by the dropping of leaves.

Old coffee planters used always to bury prunings when the labour was available and

PULP

never went to waste, but was a valuable ingredient of compost heaps. Sabonadiere, an acknowledged authority in coffee planting, wrote:—"Pulp is a very useful manure. I have found pulp most beneficial, mixed in equal proportions with cattle manure, the effects seem to be equal to cattle manure alone." Of prunings, he writes:—"Prunings make a very good vegetable manure, they should be buried in trenches when still green." George Wall, another acknowledged authority, and who had besides a scientific knowledge of agriculture, wrote:—"Prunings are a very useful manure." It might be urged

that this application of the "refuse" of the coffee tree to it was one of the causes, if not the cause of leaf disease. I leave that question for scientists to answer.

"C. A. C." in your columns, who affects to write with authority, says, that he pointed out to ignorant native agriculturists the folly of applying to coconut trees their "refuse" in the shape of husks and branches. He instances the "Moss," belonging to the late Mr. Maartensz, where husks when dug out after being buried for a large number of years was found to be undecayed. It does not seem to have struck this authority that the soil of the "Moss" is sandy, and sand is a preservative agent when dry and what little decay of vegetable matter takes place in sandy soil is when it is damp and this only in wet weather. I buried husks in a clayey soil, and when I dug the spot three years after there were traces only of the husks, and the soil where they were buried was a dark-coloured loam, *Moral*.—It is not safe to generalize on insufficient data.

My observation goes to show that not only does sandy soil dry up quickly, but vegetable substances on it seem to have the moisture in them extracted by such soil. Dry coconut branches heaped up on sandy soil become quite dry and crisp when a few days of dry weather follow a season of wet weather, while those heaped on more retentive soil, get quite decayed and crumble into pieces after wet weather. "C. A. C." may be interested to learn that another authority and as eminent as he, recommends the burial both of branches and husks of coconuts. I refer to the veteran and experienced coconut planter Mr. W. B. Lamont, whom perhaps the infirmities of age have made to rest his facile pen. He and Mr. Jardine could attest to the value of nuts as an application to coconut trees.

TOBACCO PLANTING

for Europeans as an industry is again being discussed. It is a garden cultivation and as such is very expensive if carried on with paid labor and will not yield adequate returns to Europeans. I believe the system adopted in the Straits is for each Chinese coolie to be given a certain number of plants to tend, and payment is made according to the number of plants successfully tended, i.e., payment is by results. If I mistake not, Messrs. Don VanCuylenberg and Mark Maxfield were both engaged in tobacco cultivation—the Straits and Sumatra—and they would be able to speak with authority on the style of the cultivation, cost and results. On the Western and North-Western Provinces the system adopted is for the tobacco fields, usually sandy tracts, to be manured with cattle and movable pens. The droppings are not turned in at once but lie exposed on the surface to our tropical sun and rain. The former must dissipate a good deal of the ammonia and the latter, especially in the North-East rains like those we had at the end of last year when the tobacco lands became quite swampy, wash it out of the not very retentive soil. Well, after months of exposure to the sun and rain, the manure is ploughed in with native plough or dug in with mamoties, and the land is prepared for planting. It is lined and little holes are dug out for the plants, and these are put out and shaded. The real hard work commences now, the plants are watered morning and evening, vacancies are supplied, the ground, which becomes hard and pressed down by the constant action of the feet, is now at frequent intervals and is weeded, "poochies" are removed from the leaves, and the plants are manured with well-rotten cattle manure, and otherwise tended till they are fit for topping. Then the work becomes more laborious as suckers have to be constantly removed. In fact, the attention required is unremitting till curing commences. When the plants are fit to be cut for curing they are sold at prices varying from R50 to R75.

I shall, when time permits, give you my experience as a grower of Tobacco for light cigars and for native chewing.

INDIAN PATENTS.

No 81 of 1897.—Amended application. See No. 6 of 1897. Specifications of the undermentioned inventions have been filed under the provisions of the Inventions and Designs Act of 1888 :—

Improvements in apparatus for drying tea.—No. 345 of 1896.—William Alfred Gibbs, gentleman, of Gilwell park, Chingford, England, and Gilbert William Suttou, Civil Engineer, of Rothmans, Great Baddow, Chelmsford, England, for improvements in apparatus for drying tea and other substances. (Specification filed 17th February 1897.)

Machine for Drying Tea and analogous Substances.—No. 390 of 1896 :—Henry George Hills, Tea Planter, Silcoorie Tea Estate, Cachar, for a machine for drying tea and analogous substances. (Specification filed 22nd February 1897.)—*Indian and Eastern Engineer*, March 13.

GUTTA PERCHA IN DUTCH GUIANA.

The Foreign Office has recently issued a Report by Consul Churchill on the Balata industry of the colony of Netherlands Guiana, which is of interest to Forest officers in India, as it shows that the list of trees which yield gutta-percha or indiarubber is by no means complete.

Balata is a kind of gutta-percha obtained from the milky juice of the bark of the bully or bullet-tree, *Mimusops Balata*, a large forest tree belonging to the order *Sapotacea*, which ranges from Jamaica, and Trinidad to Venezuela and French Guiana. Although the tree has been known for years past, and its wood, which is very hard, largely used for sugar-mill rollers, machinery and building purposes, the collection of the juice for the manufacture of gutta-percha is of quite recent origin, and it is to this point that we wish to draw attention, as there are probably a number of trees indigenous to India which are capable of yielding gutta-percha in paying quantities. The matter is worth the attention of Forest officers, especially of them in charge of evergreen forests in the Southern Provinces. In connection with this, we would invite a reference to a letter from Mr. Lushington, printed in this month's issue, and to the general mentioned by him would add *Isouandra*, which also belongs to the order *Sapotaceae*.

We reproduce below some extracts from the report in question :—

'The bullet-tree is found in (Netherlands Guiana) in greater abundance in the low-lying zone of flavio-marine deposit. It is also found in the higher lands of the interior, but in a less abundant and more scattered condition. On the bullet-tree bearing grounds in forest, where they are plentiful, the observer may see from 20 to 30 trees of a thickness of 12 to 30 inches within a radius of 100 feet around him, where this tree is less plentiful, the observer will only see two or three trees within the same area. The bleeder usually looks over his head and discovers the tree by its foliage. He also knows that the bullet-tree must be near when he comes upon certain kinds of bush. Above a trunk thickness of about 30 inches the tree is usually not worth bleeding.'

'The tree often grows in zones or belts, on which it prevails in excess of all other trees. The limits of these zones or belts being crossed, the forest may be traversed for hours without a single bullet-tree being met with, after which perhaps another zone is run into.'

'Regarding the character of balata, Mr. Jenman quotes Dr. Hugo Müller, F.R.S., as follows :—

"Although my own opinion about balata, derived from personal experience, of its practical application in a few instances was entirely favourable, I thought it desirable to avail myself of an opportunity of obtaining further opinion direct from an indiarubber manufacturer, considering that this would be much more to your purpose than anything I could say on my own account, hence the delay in my answering your letter.

"It seems, then, that balata is by no means neglected, and, in fact, it would find ready purchasers if more of it came to the market. As it is, the supply is very limited, and generally it comes only once a year. It commands a higher price than gutta-percha, and this in itself is a proof of its usefulness. It is used almost in all cases in which gutta-percha is used, but on account of its higher price only for superior purposes.

"It seems that balata is treated by the manufacturers simply as a superior kind of gutta-percha, and, therefore, its name disappears when manufactured."

"Nevertheless, balata is distinctly different from gutta-percha, and this is especially manifested in some of its physical characters, for instance, it is somewhat softer at ordinary temperature, and not so rigid in the cold."

"The chemical composition, however, is probably quite identical with that of gutta-percha and of caoutchouc."

"In one respect balata shows a very marked and important difference from gutta-percha, and that is in its behaviour under the influence of the atmosphere, whilst gutta-percha when exposed to light and air soon becomes altered on the surface and changed into a brittle resinous substance, into which the whole of the mass is gradually converted, in the course of time balata, on the other hand, is but slowly acted upon under the circumstances."

"I inclose a piece of balata tissue which has now been in my possession quite six years, and although it shows a peculiar mealy efflorescence due to chemical change, it is still supple and coherent. A similar tissue of gutta-percha would have long before now become entirely converted into a brittle resin."

"The electrical insulating quality of balata is said to be quite equal to that of gutta-percha, and altogether there seems to be no question about the valuable properties of balata. All that is wanted is a sufficient and constant supply and a somewhat lower price. But even at its present price, I think, it would find a ready market if it came in large quantities, and thus enabled manufacturers to use it for applications on a large scale. As far as I could make out, it is used by itself and not mixed with gutta-percha."

'The balata industry of this colony is in its infancy. In Surinam the forests which have been bled are abandoned, and new lands are sought for and exploited up to date. Only those areas where an abundance of trees is to be found have been selected. On areas where 100 trees are found it sometimes happens that about 75 per cent only give milk at the particular period when the bleeder visits them, and that at some later period the remaining trees will also run; but as the bleeders have gone beyond that particular section, it is not profitable to come back and bleed the remaining trees just at the special time when they are ripe for it.'

'The forests are all the property of the Crown, and are leased by the Colonial Government at a rental of 10c (1d) per hectare per annum for the exploitation of balata only, and that in conformity with the Balata Ordinance of the colony.'

'There is no export duty whatever.'

'The bleeder receives advances from his employers against which he contracts to deliver balata. For his balata he receives from 50 to 55c. (10d to 11d) per lb., delivered on the concession. An average bleeder will gather about four gallons per day. A very successful bleeder may get as much as 10 gallons during the same period. In Surinam a bleeder will gather an average of 1 gallon per tree, bleeding from the base of the tree up to a height of 20 feet and scarifying the back to half its circumference only, further sacrifice being illegal. A gallon of milk will dry to about 4 lbs. of balata.'

'The bleeders are mostly recruited from Berbice, in British Guiana, and about 1,000 men are at present employed in this colony in the industry.'

'The hot and very wet seasons are not good for balata bleeding. The trees blossom in August, and the seed drops about the month of November, when the new leaf shoots out. By the end of January the

milk obtains the condition when it runs most plentifully. The leaves of the old trees, the milk which is not easily getable are dark-brown on the lower side and green above, the younger trees are light green on both sides. During the flowering season the milk does not flow to any paying extent. The leaves of the young trees are thick, and, when broken, the milk issues freely from the wounds. After the month of August to the middle of January no work is done, this leaves about eight working months.

'Balata cannot be purchased in the market in Paramaribo. It is only gathered for those who employ balata bleeders, therefore, no quotation as to its price can be given, although it will be seen from the statistics of the exportation of this commodity, which the Colonial Government have very kindly placed at my disposal, that for statistical purposes a valuation is given. The only certain thing that is known is, that the bleeder receives from some employers 50 and from others 55c. per lb. for the balata which he produces on the concession. Beyond this, however, there are other expenses which must be added, such as commissions to foremen, loss by runaway bleeders, deaths, thefts, loss by capsizing of boats, cost of transportation, surveying of concessions on occasions of dispute as to boundaries, assistance of pilots, Indian trackers, &c.'

COFFEE PLANTING IN HONDURAS.

We have before us an interesting little *brochure* of 24 pages on the above subject, in which there is a strange omission of the date of publication by the American Company that published it. There is no reason to believe that it is of earlier date than last year, though the latest date of the documents from which it quotes is 1894. It is a publication put forth by the Honduras Planting and Trading Company, with the object of setting forth the attractions generally of Honduras as a spot for the investment of capital, and specially the qualifications of the Company as a guide to those seeking investments. Though the Company counsels large investments, and would almost seem to discourage small capitalists—whether through its own dicta or through the opinion of Consul Peterson whom it quotes—it does not profess to have, or to have had, the command of unlimited capital. Thus, while we find on page 10 that no one should "attempt to do a paying business in Coffee-raising in Honduras" on less than \$25,000 to have a plantation of 125,000 trees, and "double that amount would bring in much better returns"; the Company itself was incorporated with a capital of but \$100,000, and it owns "a coffee farm of only 100,000 trees"; and it is the experience gained from these which has induced it to invite others to join them in plucking the golden fruit. From the mention of trees as a prime element in the calculation, our readers will infer that the system of planting which finds favour in Hon-

duras is different from that which obtained here, and even yet obtains in the remnants of the industry which once represented the wealth of the country. Such inference would be correct; but before we proceed to discuss differences in the system of planting, we must point out that the Honduras treated of in the booklet is not the British Possession, which represents only about 7,000 to 8,000 square miles, but the extensive Central American territory, out of which that slice had been carved just 99 years ago. Here is a description of the territory on page 13 of the pamphlet:—

If the reader, looking over a map of North America, will pause at a point just south of Mexico where the continent begins to narrow down preparatory to forming itself into the Isthmus of Panama, he will notice five small divisions, each having a different color denoting one or other of the five Central American Republics. The largest of these patches of color, running from the Caribbean Sea on the Atlantic side to the Gulf of Fonseca on the Pacific, represents the Republic of Honduras. Its two sister Republics, Guatemala and Nicaragua, are on either side, while sandwiched in, and looking as if they had each pre-empted a piece of ground from the others, are the two smaller countries of Salvador and Costa Rica.

And if any reader feels any doubt after its perusal that the Company is an American one, the following from page 14 (apart from the single *l* in traveller) should place the matter beyond all doubt:—

The name Honduras, meaning "land of heights and depths," is so aptly applied that it is almost the first thought forced upon the traveler's attention as he makes his way into the interior. Quoting the same author again, we find him commenting upon this fact in these words: "When the greater part of all the earth of a country stands on edge in the air, it would be invidious to designate any one particular hill or chain of hills. A Honduranian Deputy once crumpled up a page of letter paper in his hand and dropped it on the desk before him. 'That,' he said, 'is an outline map of Honduras.'" These mountains, ranging in height from 1,000 feet to 6,000 feet, and the deep valleys between them, afford climatic conditions varying from the tropical to the most temperate where wheat can be successfully grown. It is between these extremes that the best Coffee lands are found—lands where the climate is neither too hot nor too cool, and capable of producing such Coffee as to draw the following expression of opinion from the same traveler whom we have already twice quoted: "The Coffee was always excellent, as it should have been, for the Honduranian Coffee is as fine as any grown in Central America, and we never had too much of it."

Looking to the physical and climatic conditions above described, one need feel no surprise on reading of the luxuriance of the coffee grown in that region; but the Company evidently recognizes the fact that the climate and physical features of a country cannot alone attract investors, and that agricultural enterprise takes count of something more than cheap labour and facilities of transport besides. A settled Government is a most important factor in the calculation; and the difficulty arising from the tendency to unrest and revolution in the numerous Republics of the West, is sought to be met by an extract from the *La Voz del Pueblo*, which is described as one of the Government official organs. In its issue of 12th May 1894, this combination of the voice both of the people and of the Government, after warmly welcoming immigrants to its hospitable shores, thus indicates, in its sharp reference to others, the suspicious which investors might feel:—

"These men from the cities, the indefatigable

workers, who look to mother earth for the well being of their families, and through that for the general welfare of those nations where they plant their smiling and cheerful homes of work and peace, and for whom there is an increasing welcome affection and friendship in Honduras, are the opposites of those who, in a fraudulent and pretended harmony with some administrations, like that which preceded the present one, join our ranks in order to make an iniquitous bargain and disturb us with the sole ambition of filling their purses without giving a penny in return for the protection afforded them; who, the day after a social revolution, sneer at their former protectors and speak of them sarcastically, attempting all along with palpable hypocrisy to ingratiate themselves with the new power. This they cannot do with the eminently liberal Government of today. Fortunately, the few emigrants of the latter class are well known—too well known by the Hondurians, and, as experience has shown, their worst enemies are their own more honorable compatriots, who have joined themselves to the sons of this country in honor, loyalty, honesty and work which knows neither stint nor limit."

To turn now to matters strictly agricultural, we do not find any description of the particular species of coffee which is grown in Honduras; but if "the fleshy part of the berries" can be washed off in running water, without any previous immersion in cisterns, the pulp must be of a particularly accommodating consistency. Perhaps, it was not intended that the curing process should be described with fullness and accuracy; only that the cost of bringing land into cultivation should be correctly set forth, and its profits estimated with reasonable approximation. The seedlings are transplanted when 2 years old into what is called a grove—so that shade is probably preserved—and are put down 500 to the acre—about the same as Liberian—as against 1,200 to 1,700 for Arabian Coffee. Against our 3 feet for Arabian, Honduras Coffee is topped at 5½ to 6 feet which is rather higher than the Liberian variety is cut down to; and the effect of the pruning is said to raise the yield from 1 or 1½ lb. per tree to 4 lb. on an average. But surely the trees, two years when put down, should begin to bear before the fourth year of planting out, but we are told that it is only in the fifth year the bearing:—

Generally averages from ¾ to 1 pound. From this on, the yield is doubled each year *i.e.*, in the sixth year the return will average about 1 pound; 2 pounds in the seventh year, and 4 pounds in the eighth to tenth year, after which the trees will continue in full bearing for at least 30 years.

That, "under proper conditions of soil and climate" coffee has "few if any natural enemies," reads almost like fiction after our terrible experience; but it was not till the end of the "seventies" that we began to think much of our enemies. The estimated yield per acre, 2,000 lb. off trees 5 to 6 feet high, planted well apart in "rich, black loamy earth" on which virgin forests had flourished, is by no means outside the range of probability for a limited acreage well cared for; but the expectation of 100 to 300 per cent profit can scarcely be realized on large ventures. This, however, is what Consul Peterson, late of Honduras, says in the United States Consular Reports for 1894:—

The soil, climate and conditions in Honduras are equal in every respect to those of Guatemala, Nicaragua, or Costa Rica, where the Coffee industry has already reached large proportions. The only drawback in Honduras is lack of means of transportation and facilities for shipment to the coast. At present, there is practically no exportation from Honduras, the product of the plantations being

readily sold at home. I have known the price of coffee, even in time of peace, to reach the sum of forty (40) cents (gold) per pound and in time of war as much as seventy-five (75) cents, notwithstanding the splendid adaptation of the country to its production. The Honduran Coffee is equal in every respect to the Mexican, Guatemalan, or Costa Rican product, and is well-known to be of a superior quality, commanding a price in the great markets of from twenty (20) to twenty-five (25) cents per lb. A new plantation of coffee will commence to produce a profit by the end of the fourth year after planting, and after the seventh year a profit of from 100 to 300 per cent. on the capital invested may be expected. The average cost of the production of coffee, after the plantation is well started and five years old, will not exceed seven (7) cents per pound. The preparation of the land for a coffee plantation will consist only of clearing it off well and keeping it clean. The young trees are to be secured from a nursery, and cost from \$10 to \$20 per thousand. Nurseries, of course, are maintained on every plantation. The young trees are planted from twelve to fifteen feet apart, in regular rows, like an orchard in the United States, and the holes are dug about one foot square and fifteen inches deep.

Then the Consul proceeds:—

The following extract, taken from the *Two Republics*, of Mexico, applies so exactly to the conditions in Honduras, that, with some slight changes, I reproduce it here: "All expenses of cost and planting 1,000 trees are estimated at \$100; their keeping and attendance during the three following years, or until they reach the bearing age, at from \$80 to \$100 per 1,000 trees. During the third year, the plantation produces sufficient coffee to pay expenses. The outlay for every 100 pounds of coffee prepared ready for market does not exceed \$7 as a maximum price, the market price of which is, at the present time, \$20 to \$22 per 100 pounds. The value of coffee plantations in full bearing is calculated at the rate of \$1 per grown tree, a single acre producing from 400 to 500 trees, which price only serves as a basis of purchase, as it includes, besides the land and buildings, cattle, implements and machinery. Much of the labor required for the cultivation and preparation of Coffee is performed by women and children, which largely increases the labor supply and reduces the cost, the average being thirty (30) cents per day. The season for planting commences in April and ends in November, but plants raised from seed require eight months to mature before they are ready for transplanting to the field in which they are finally to grow. "The altitude best suited for Coffee culture is from 1,000 to 4,000 feet above sea level, that is, up to what is termed the frost line. If the soil be rich and deep, 500 trees to the acre is a sufficient number. Results have been found more satisfactory with this number than with a greater or less number of trees per acre. The Coffee districts are also among the healthiest in the country, and the climate suitable for Coffee-growing is adapted also for persons accustomed to living in a temperate zone. "The soil and climate suitable for Coffee-growing are also adapted for the cultivation of tobacco, corn, beans, bananas and oranges, and in the lower-lying districts for sugar cane, rice, and most tropical and subtropical fruits, the growing of which is made accessory to Coffee culture. The pineapple is the least expensive and the most profitable, especially where the planter has close and cheap transportation to the gulf ports." To the last paragraph of the above extract might be added the fact that a rubber-tree can be placed in the centre of each square of twelve feet, which, in the course of a few years, would vastly augment the income and profits of the plantation.

We do not apprehend the desertion of our Tea enterprise as a result of the publication of these figures; but it is well to know how people are impelled by great expectations. We may mark for extract in another issue the experiences of the Company itself as told in these pages.

PLUCKING, PRUNING AND PREPARATION OF TEA.

Just as we were printing off our Circular, making inquiries under the above heading, the following letter came to hand :—

“The Back Woods,” Feb. 6, 1897.

The Editor “Tropical Agriculturist.”

DEAR SIR,—As the manure campaign is now over, I should like to introduce another, and equally important matter of culture, viz: Pruning Tea Bushes, and to get your and other opinions thereon.

With the usual system of pruning, that is leaving a spur of two or three inches of the young wood, from which the young flushing shoots spring, though much can be done, and is done by careful cultivators to keep the bushes from getting too high or too lumpy by the healing up of many pruning cuts, still there are cases, when it becomes advisable to cut down into the old wood, and from it, to get a new bearing surface.

This is done, as a rule, with much greater moderation than it was some years ago; but on some estates, there is still to be seen the ruthless cutting down or hacking in almost to the collar, and cussions enough, I never yet met with any of those who practise this: what we sometimes hear called—heroic cutting down. Who could give a substantial and intelligent reason for it. Some of the evil results, in my opinion, are these:—the bushes are reduced to a much narrower surface, and, in most instances, they never regain their former condition; unless possibly in strong rich virgin soil, or if heavily manured with bulk, and even then doubtful.

The shock to the bushes is so great that some of them die outright—other parts, a side or a quarter, more or less as the case may be. The dead or dried and stunted stumps are—especially in the lowcountry—the prey of white ants.

There is greater waste of material in the quantity cut away, loss of time, and of course of returns, before the bush is in bearing order again; add to this, that months pass before the tea is equal to its former quality.

With these evils and others that might be mentioned, is it not remarkable that this harmful system finds favour with some good heads, even yet. Were tea not a more than ordinarily hardy shrub, there would have been less to say now about over-production.—Yours faithfully,

ARBOREAL.

The questions in the Editor's Circular run as follows :—

Would you kindly—as briefly as you please—give us your opinion on the causes which have brought down the average prices for Ceylon teas of recent years in the London and Colombo markets?

(1) Would you say how far you think Coarser Plucking of Leaf may have had to do with?

(2) Or the more prevalent attention to Manuring Tea?

(3) Or severe Pruning—cutting the bushes too far down?

(4) Or less attention to care Preparation in the Factory?

[Some say good tea is made in the field; but we suppose careless or inadequate factory work may spoil the most carefully plucked leaf?]

(5) How far Shortness of Labour Supply has affected your work in field or factory?

(6) Any other cause that strikes you—apart from

(7) Overproduction and Increased Supply in Competition at the Sales?

We now begin to give the answers which embody a great variety of useful opinions and information from some of the best-known planters in the island :—

No. I.

The country generally.

Answering your questions briefly, I do not think coarser plucking is being adopted over any extensive area, nor do I think manuring has any thing whatever to do with lowering prices.

Severe pruning deteriorates quality no doubt for a time, but how are we to get a low jât bush to flush at all, at medium elevation (3 to 4,000 feet) without, at intervals of 3 to 4 years, cutting down.

We all know that fine leaf makes fine tea, and I certainly do not think that less care is being given to manufacture now than in previous years. What are undoubtedly defective on many estates are withering arrangements—these on many properties that I know are most faulty and quite inadequate to cope with quantity of leaf coming in. I am glad to say there are signs all over the country that this is being recognized. I visited several estates lately where the superintendents had leaf spread 1 foot deep in the rooms of the bungalow!

In my opinion we must mainly attribute to increasing supply, the lower prices of the past 2 years. When stocks run down in London and demand gets brisker, we shall not hear so much of “poor quality and little flavour!”

R. A. B.

No. II.

No. 1.—Planters, who have failed to get good or leading prices, may have gone in for a system of plucking to get quantity, and thus to some extent have helped to bring down the average prices for Ceylon teas.

No. 2.—I do not think that manuring has had any influence whatever in reducing the rates.

No. 3.—Heavy pruning, I am inclined to say, does interfere with the quality of our teas for 6 to 10 months after cutting down or until such time as the bushes get on a full cover again.

No. 4.—Managers are all keen on getting the best prices they can, and, with the additional experience which has come with recent years, they endeavour to make the best of the leaf that the estate produces. I cannot say that I have observed or heard of less attention being given to careful manufacture than used to be when the majority of estates were getting lighter averages.

No. 5.—Shortness of Labour does to a great extent interfere with good and careful plucking as well as manufacture; but so far I have never myself had cause for complaint under this heading.

No. 6.—Increased production has doubtless more to do with the downfall of prices than all the other factors put together. It is now some 12 to 15 years since tea planting was commenced on a large scale in this and other coffee districts, and at that time we were under the impression that about 300 to 350 to 400 lb. would be outside returns per acre per annum to expect. It is true some poor old fields only give the lower average, whereas the better and manured fields yield double.

MID DIMBOOLA.

No. III.

THE FALL IN THE AVERAGE OF CEYLON TEAS AND ITS CAUSE.

(1) May possibly affect individual average; but I think the plucking, generally speaking, is finer than it was say 5 years ago.

(2) Not much, if any.

(3) Do. do.

(4) With more commodious factory and greater knowledge, I think the work in factories generally is more carefully done today than ever it was.

(5) When an estate finds itself short of labour part is generally abandoned and the rest plucked as usual, so I do not think that this affects the average.

(7) Overproduction is, I think, the only cause that is worth considering, and that this exists, so far as the London market is concerned, is proved by our having to find fresh outlets for our produce every year.

Of course individual exceptions go to prove the general rule.—Yours truly,

DIMBULDANDA OYA.

No IV.

High District.

(1) Not much; plucking is about same as it used to be.

(2) Not manuring certainly; witness (Hautville) prices in Agrapatna; Dewetrai in Low Country.)

(3) Pruning could be more scientifically done than it is in many cases, and both yield and quality of crop improved.

(4) This is where we are weak, and even the Java planters have in conjunction with Government a scientific chemist helping them, their prices are going up, ours down !!

(5) Not much.

(6) Overproduction is at the bottom of lower prices and things will be worse yet. "N."

No. V.

Ramboda.

1. I think Coarser Plucking has had something, but not much to do with it.

2. I do not think that Manuring has injured the teas.

3. Severe Pruning is periodically necessary, say once in 10 years, and I think there cannot be any doubt about the teas being weaker for a considerable period after heavy Pruning;—for the first 8 or 10 years of our tea industry heavy Pruning was not required.

4. I think more attention is now given in the Factory than formerly.

5. We have always had sufficient Labor here.

6. I think the chief cause of the fall of prices is, that the taste of buyers has changed of late.—L.

No. VI.

Medium District.

1. I do not think Coarser Plucking has anything to do with the bringing down of the average price.

3. I believe severe Pruning is a good deal to blame for inferior quality of leaf.

4. And I am perfectly sure if more care was given to Preparation in the Factory the average would keep up. Many estates cannot make good tea for want of accommodation. Tea is made in the factory, very little in the field.

5. Shortness of Labor Supply has not affected field or factory work. V.

No. VII.

Dimbula, Feb. 15.

In reply to your circular the fall in prices is due mainly, in my opinion, to Overproduction.

1. At the same time from exigencies of labour Plucking has a tendency to be less carefully done than a few years ago.

Theoretic Plucking is also done (as a rule) much less finely than a few years ago, and the extra

yield fully compensates up to this date for any diminution in the quality and price of the resulting tea.

2. *Manure* does not (to my mind) injure prices to any great extent, although it does affect flavour in individual fields for a few months especially in wet weather.

3. *Pruning*.—Severe pruning—I have no established opinion on this point, but am inclined to think that severe pruning would affect prices much as manuring does for a few months. I do not think pruning generally is in any way responsible for the present drop in prices.

4. *Factory Preparation*.—It is impossible for any factory staff to handle a heavy crop as carefully as a light one—a certain percentage of leaf *must* be underwithered and overwithered, and indifferently fermented (in spite of every care being taken by the teamaker) if the crop is a heavy one harvested in damp weather.

5. Up till now, shortness of labour has not affected me personally, but has undeniably done harm generally—the shortness being rather in field than factory.

6. Seasons vary considerably, and I consider that the crop of 1896, following on the heavy crop of 1895, and being in itself large, can hardly be expected to produce so good a price as was realised in 1895, following upon the short crop of 1894. A certain measure of exhaustion of the finer principles of tea must result in the second of two heavy flushing years, and continuous and monotonous work makes the whole staff have a tendency to get "stale." BOHEA.

No. VIII.

Ambaganuwa.

Answers.

(1) The chief of the causes.

(2) No.

(3) Yes, to a great extent, but we *must* prune hard.

(4) No.

(5) During April and May, a great deal of rubbish is made on account of strained resources, both as regards field and also factory work. If flush be left too long and the planter gets behind with his rounds, then the leaf that comes in makes bad tea. So also in the factory, when the factory arrangements are unable to cope with the great rush of flush. Night work means, as a rule, inferior tea. But all this lasts but two months.

(6) Played out land, poor soil, general state of the money market and trade in general.

(7) Increased production and congested sales causing unfair competition.

We would have better prices *if*—we had rich alluvial soil, more decided seasons, rest and harvest, abundance of labour, more extended markets, less congested sales. Our harvest is, like the poor, always with us, and our other works are carried out at the same time. If we had harvest time for a short busy season, when all operators were concentrated on manufacture—and then a long easy season when pruning, and manuring could be leisurely proceeded with then we might do better. 1897.

No. IX.

Talawakele, Feb. 15.

DEAR SIR,—With regard to your questions:

(1) I am certain that coarser plucking has nothing to do with it. Plucking on the whole is much finer than it was five, six and seven years ago.

(2) It may be that manuring has caused some little deterioration; but I doubt it, as manuring has certainly not been generally overdone and it gives a vigorous bush, and a vigorous bush gives tea with quality.

(3) I am certain that "severe pruning,"—but I do not say that the severe pruning may not in most cases be necessary,—has everything to do with this fall, except what is accounted for by your 7th heading and, perhaps, under your 6th heading, by competition with increased prices in plucking in India.

(4) I believe that as much care is used in the manufacture as formerly with more knowledge and better machinery.

I fear there is nothing to be done *here* except to make the best of a still very passably good job.

Tea must sooner or later be heavily pruned and afterwards the results are never quite so good in quality as previously. B.

— — —
No. X.

Dimbula, Feb. 15.

1. Coarse Plucking will undoubtedly lower the quality of tea; but careful plucking is now the rule and the bud and two leaves plucked.

2. Having no experience in manuring, I cannot say if quality is affected by it or not.

3. Cutting bushes too far down may affect quality for a long time as even after the usual pruning leaving 2 or 3 inches of young wood above last pruning, it takes six months before quality and strength are in the leaf.

4. I am of opinion that preparation in the Factory is more careful now than it used to be, owing to increased withering accommodation and more machinery. Certainly you must have good leaf to work upon, and the best leaf may easily be spoiled by carelessness or want of withering space and machinery.

5. Shortness of labour soon tells on quality and quantity. Regular and systematic plucking gives the best tea, and if from want of labour your 8 to 10 day round takes 15 to 20 days, the quality of leaf soon is spoiled and the quantity is lessened.

6. Perhaps a too general publication of the cost of production of tea may tend to keep down prices. JAY.

— — —
No. XI.

High District, Feb. 15.

Dear Sir,—Formerly the bulk of our tea came from old coffee estates at above 2,500 feet; but, of late, a very large proportion of low country tea at low prices has reduced the average. Large yields of coarse leaf, where quality is not obtainable, of course, glut the market with low-priced trash. Factory supervision is of more importance than field supervision as the former checks the latter as far as plucking is concerned. Where shortness of labour means borrowing from neighbours and Sunday plucking, the quality is bound to suffer.—Yours faithfully,
N. C. D.

No. XII.

High District.

Factory has accommodation for $\frac{1}{2}$ million lb.

1895 318,000 lb. sold for 1s 0 $\frac{1}{2}$ d

1896 340,000 " " " 1s 1 $\frac{1}{2}$ d

No change in system of plucking.

(1) This can be ascertained by a comparison of grades.

(2 & 3) Does not affect quality as far as I know.

(4) Preparation in the Factory is MOST important and I scarcely know of a building which has *always* sufficient withering space and machinery.

(5) Overstocked with coolies.

(6) Starvation wages paid to Superintendents and the mistaken idea that anyone can make tea. B.

— — —
THE PLUCKING, PRUNING AND
PREPARATION OF TEA:

REVIEW OF LETTERS I TO XII.

If the questions contained in the first circular we sent out, bearing on our great staple, may be said to be suggestive of the dictum, that good tea is made in the field, the second set of questions circulated by us may be interpreted to favour the theory that the factory is responsible for the quality of the tea that bears the estate mark. We must disclaim either theory as our creed, as also all intention of drawing a sharp line between cultivation and manufacture. Indeed, the remark between parentheses in our second circular, between questions 4 and 5, would indicate our recognition of the interdependence of field and factory work; while, it will be observed, that more than one question in the second circular has reference to field operations. The fact is that neither field nor factory alone can produce good tea, and our chief concern is with the tea industry as a whole, and the object of our inquiries is to elicit information which will be helpful to planters in their endeavours, while securing from their estates the highest possible yield without injury to the bush, to maintain a high level of excellence for the tea they produce—in other words, to obtain the best possible prices. The effect of the mass of interesting matter which the first circular brought to a focus, from districts varying in every possible way—in soil, climate, elevation and fertility—is to establish that the outturn of the acreage already planted can be appreciably increased—say to the extent of 25 per cent at least—by liberal cultivation and manuring, and without any injury to the quality of our teas—always assuming there is labour enough to apply the manure, to pick the increased crops and to carry on the manufacture. The case for quantity has thus been made clear. We have to deal now in the letters before us principally with quality and price, as influenced by a variety of considerations. The second set of questions is, if anything, more searching than the first, and the answers to them are even more interesting than those which the first circular produced.

As will have been seen from the letter of "Arboreal" the need for the second circular was recognised even before it was issued, as pruning is rightly considered a very important factor in tea production, influencing, as it does, both quantity and quality. It is curious that, while, at the outset of the Tea enterprise, Planters were half-afraid to prune their bushes, and erred generally on the side of under-pruning until Mr. William Cameron (? Campbell) about 15 years ago brought his Indian experience to bear on the numerous estates he was asked to supervise, the error now seems to be in the direction of over-pruning—hacking almost down to the collar. Of course this is done—where it is done—at long intervals of live to six years; but we know, as a matter of fact,

that a certain percentage of bushes die under the treatment; while we can quite understand that it permanently injures the weaker bushes which are seldom or never what they were before, in symmetry or plucking surface. Indeed, there seems to be a consensus of opinion that many months ensue, after such severe pruning, before the quality or flavour of the tea is what it was. This, then, is one of the causes which have led to the lowering of our average prices. "R.A.D." leans to this view; but he regards cutting down at intervals of 3 to 4 years absolutely necessary for the production of flush in bushes of low jät at medium elevations. He does not believe that manuring has contributed towards low prices, or that coarser plucking is very generally adopted; nor does he think that less care is bestowed on manufacture than formerly. Inadequate and faulty withering arrangements, he considers responsible for much of the deterioration in quality, while he notes some attempts at improved arrangements; but the chief explanation of lower prices is to be found in the growth of production. Few will dispute this last conclusion; but should not the very fact of an increasing supply suggest the need of greater care in preparation! It is not enough to say, there has been no falling-off in care. With greater experience and improved machinery we should be able to produce tea of better quality; but how is this to be done with leaf laid out a foot deep, and even the bungalow rooms utilized for withering?

"Mid Dimbula" regards coarse plucking as a result, rather than as a cause, of lower prices which he refers principally to increased production. When men find that the same quantity of tea brings them in a diminished income, they naturally try to increase the quantity, so as to improve their income! Neither manuring, nor inattention to manufacture, in the opinion of this correspondent, explains the fall; but shortness of labour, as interfering with careful plucking, has contributed towards it, as also heavy pruning, for from 6 to 10 months after the cutting down. And a point generally lost sight of is that, whereas 12 to 15 years ago, 300 to 350 or 400 lbs was considered an outside figure for most estates; many now yield double that, and have a corresponding lack of appliances and labour to deal with it. That, we should say, points to a form of insufficient attention to manufacture. "Dimbulanda-oya," on the other hand, while holding that coarser plucking explains the falling-off in prices in individual cases, thinks that, generally speaking, the plucking is finer now than it was five years ago. Exonerating as he does both manuring and heavy pruning from responsibility to any appreciable degree for the fall, and holding that wider experience and bigger factories contribute to more careful manufacture, he regards overproduction as the principal, almost the only, cause of poorer prices—especially as shortness of labour, he says, leads to the abandonment of flush that cannot be overtaken, and the plucking as usual of what can be plucked. "N," too, thinks plucking is much as usual, and that manuring certainly has not told on prices—in proof of which, he refers to Harteville in Agrapatana, and Dewatnrai in the lowcountry. More scientific pruning, whereby both quality and yield might be bettered, is possible; the scarcity of labour has not told much on prices, but over-production has, and will tell yet more; while, in his view, the Factory is the weak point in our system. Our correspondent does not content himself with

merely condemning preparation; he puts his finger on the lack of scientific knowledge as the blot, and refers to the upward tendency of Java tea, in the preparation of which a qualified chemist helps, while our teas are going down in price. "L" from Ramboda admits the evil influence on prices of coarse plucking, while acquitting manure of all blame. He also admits the weakening of the tea produced for many months after severe pruning which, however, he regards necessary at least once in 10 years, after bushes have attained a certain age. With greater attention than before paid in the Factory, and with no deficiency of labour in his district, the chief cause, in L's opinion, of the fall in price is a change in the taste of buyers. But would not that tell on their purchases? They do not neglect our teas. They buy more than ever they did before; but they value the teas at less. It seems obvious that they could not do this, if we produced less and the competition were keener—whether their taste was changed or not; but the question is, Is the tea the same as it was? Can we do nothing to command the better prices of Indian sorts? "V" differs from "L" as regards coarser plucking; he blames severe pruning; he acquits short labour, and holds the Factory responsible. More care and more accommodation are necessary; and very little depends on the field, if the Factory does its duty.

"Bohea" from Dimbulla admits that labour exigencies lead to faulty plucking; that manure does tell on flavour and price, but only for a short time, and in rainy weather; so also with heavy pruning; that heavy cropping in one year (as in 1896) following a large crop (as in 1895), does tend to exhaust the finer principles of tea—and even the buoyant energies of the stall through continuous and monotonous work. But, with all this, over-production, he regards, as the main cause of the fall. "Bohea" puts his case well, especially when he emphasizes the difficulty of handling a heavy crop in damp weather, and the influence of under-withered and over-withered leaf on the total outturn. "1897" puts down coarser plucking as the chief cause of lower prices, while heavy pruning, which is inevitable, also tells; but he acquits manuring of all responsibility and denies that less attention is paid in the Factory than before, though when there is a rush and night work becomes necessary, the resulting tea is bad. The poverty of the soil, the state of the money market, increased production, congested sales, and continuous plucking without decided seasons, have all contributed towards the fall.

Of the four letters "B" from Talawakele, "Jay" from Dimbulla, and "B" deny coarser plucking; while the last-mentioned in one word establishes the importance of adequate Factory accommodation. His Factory is equal to $\frac{1}{2}$ million lb.; in 1895 he turned out 318,000 lb. which sold at 1s 0 $\frac{1}{2}$ d.; in 1896 the outturn was 340,000 lb. and the price was 1s 1 $\frac{1}{4}$ d.! The plucking was the same, the yield was larger, the prices higher. We agree that starvation wages to Superintendents should not be the reward for results even approaching this. "N.C.D." admits coarser plucking, and thinks the increase of low country estates tells on the average. In other respects, these correspondents do not differ. They admit the importance of care in the Factory, but realize the evil influence of shortness of labour and irregular plucking. Manuring is not condemned; but the deteriorating effects of "cutting down" are admitted. Heavy pruning, however, is regarded as

a necessary evil; but may not manuring restore strength to the leaf of hard-pruned bushes, as it imparts vigour to the bushes themselves?

(Letters Continued.)

No. XIII.

Hantane District, Feb. 15.

DEAR SIR,—In reply to your circular for the reasons why prices of Ceylon tea have fallen.

(1) I don't think Coarser Plucking is the secret. Here we have steadily gone in for medium plucking, never changed it, but the prices have gone down.

(2) Manuring tea is not so general as to affect the whole production, nor do I believe that manuring does aught else than good.

(3) Severe Pruning I have no experience of. I don't prune severely but often, every twelve-month or so. The estate is old, the soil is poor, but it is liberally manured and pruners are kept steadily at work all the year. The result as far as I can yet judge has been wholly beneficial: no falling-off in the teas, and good plucking averages, all the year round.

(4) That "good tea is made in the field" is only a half-truth. Nobody can make good tea from hard or over-grown leaf, but any one can spoil good leaf in the factory. To insure good tea requires care all round, just as to work an estate well, means attention to every detail. Plenty of withering space, and the ability to wither is a great deal.

(5) Have had no reason to complain of shortness of Labour Supply affecting either my work in field or factory. Have been stuck up with leaf that would not wither and been bothered that way, which is bad enough.

(6) Haven't an idea to offer since you prescribe "Increased supply."—Yours truly

HANTANE.

No. XIV.

Feb. 15.

DEAR SIR,—In reply to your Circular of 12th:—For many years past the race has been for biggest yield per acre. With increasing estimates, Superintendents have had no choice and quality has been sacrificed for quantity.

2. Application of artificial manure has reduced price often by about 1d. per lb. Your correspondent "W. H. M." on this subject is right in saying that manure gives a more fibrous leaf, but this result is not confined to tea grown on best land. Dry tea is lighter—bulk for bulk—and outturn from green leaf reduced.

3. Low to medium elevation, yearly pruning, well cut down, gives best quality without reducing yield.

4. No, there is more care and attention bestowed on manufacture now than previously. Bad tea is made in the field—good tea in the Factory. With bad leaf good tea is impossible, field therefore responsible, in other words made the tea. Best of leaf is easily spoilt in Factory—therefore good tea means tea made in Factory.

5. Not seriously.

6. Mixed jat gives better quality of made tea than any one jat only. Better jats give bigger yields, and this added to increased and increasing acreage, manuring and coarser plucking, have enabled us to oust John Chinaman (pro tem!) and almost swamp ourselves, for, during past ten years our London average has fallen from 1s. 3d. to 8d. with only about 1d. difference in exchange.—Yours truly,

X. RAYS.

No. XV.

Medium District.

SIR,—My reply to your questions relative to the causes which have brought down the average prices for Ceylon teas would be as follows:—

1. Coarser Plucking accountable only when caused by flush running ahead, owing to scarcity of labour. Little Coarse plucking is done on upcountry estates now.

2. Certainly not due to manuring.

3. Here we have undoubtedly the chief cause. In olden days, on coffee estates, Pruning was made a *study*. Even such shining lights as G. W., A. S. (of Hunasgeriya), Fred K. and the well-known and respected brothers F. R. and W. S. gave their minds to it. Essays, long treatises dealing with every phase of the subject were written, it was the staple of argument between Proprietors, Agents and Visiting Agents and of conversation wherever planters most did congregate and whose assistants listened and learnt. Did not the great I. G. say when he first saw Haputale (referring to pruning) that nature had done everything and science nothing for that splendid district? and is not the epigram of another well-known authority and prince of real good fellows still with us "the knife is the best manure"? Yes, to go through a coffee estate in the sixties and seventies was to see cultivation, but for the poor tea tree! Crammed in everywhere, in every soil and every climate, not even spared in its tender youth, as Virgil so beautifully describes it:—

*Ac dum prima novis adolescit frondibus ætas
Parcendum teneris * * * **

Ante reformidant ferrum.

("They dread the knife" indeed!) Mocked, tormented, sawn asunder, anything is good enough! "Cut it straight across" says one; "cut it down to 8 inches" says another; "all this (pointing to the whole stem of the tree) is no good, cut it out" says a third; "this should all be in the factory" says a fourth, pointing to the leaf left above the fish leaf. "I have found the best results from leaving only one leaf after pruning" says a fifth; and so on. Anything is good enough for the poor tea tree, which has saved Ceylon and made so many rich. Cut away, gentlemen, cut away! get your yield! force your poor trees to push out every leaf they can in their attempts to save themselves from asphyxiation, and then strip it all off—they must give you more or die! but don't expect high prices, don't imagine that the poor half-strangled, unhealthy, sapless wood will yield you the same luscious leaf, rich in the same components, which will be produced by the vigorous unharassed four-year-old tree. This is what has brought down the Ceylon average, Sir, and made people say, Ceylon Estates will only produce fine tea when they are young.

4. Not perhaps to inattention, but to change in method of factory work. A few years ago we rolled for 20 minutes to half an hour: the leaf never got heated and was exposed, only a couple of inches deep on cool tables till it was properly oxidized. Now we roll twice, sometimes three times—the whole operation, with sifting, taking from two and half to three hours, and notwithstanding every care to keep the leaf cool, fermentation begins after the first half, or three quarters of an hour, and goes on, to some extent, all the time. A little delay, a little want of smartness in getting the leaf into the driers and over-fermentation takes place. A soft flavourless liquor and a "mixed infused leaf" is

the result. "Some leaves good colour, wanting brightness—very little flavour" is the broker's report. Good tea is made *everywhere*. In pruning, in plucking and in factory—work must be good all round to make good tea—even then you can only *keep* flavour if it is there; you cannot make it.

5. Shortness of Labour has no doubt had its effect. It prevents pruning being done well, and at the right time, prevents leaf being plucked exactly when it is ready; and when you are behind your flush, makes it impossible to get the plucking done as carefully as it should be. An adequate supply of labour would, I believe, raise the price of Ceylon tea 1d per lb.

CUSTOS PAUPERIS HORTI.

XVI.

(1) I don't think, as a rule, planters do pluck coarser! I should rather say finer.

(2) I think it a mistake on any estate to manure good tea for the sake of additional yield; old land can often only be made to pay by manure; good land does not require it. Cattle manure, I do not think, deteriorates leaf; though artificial may.

(3) From what I do, and what I see my neighbours do, tea is not nearly so severely pruned as it was a few years ago.

(4) More attention is paid than ever before to manufacture; but a great many estates have absolutely inadequate withering accommodation and also rolling power! Things are done too much on the cheap by the proprietors of estates and they lose thereby.

(5) Shortness of labour would not affect Factory work, but in plucking; short labour means coarse plucking and coarse leaf.

(6) There is no wintering of the bush as in India, and any tree that has no rest must deteriorate, whether it produces leaf or fruit. Indian teas are stronger, though not of so good flavour; and strength is what seems to be wanted at present.—Yours faithfully,

W. I. G.

No. XVII.

MEDIUM ELEVATION DISTRICT.

DEAR SIR,—First and foremost the chief cause is that the present production is above the present requirements. Taking your questions in order.

1. I don't consider that such coarse plucking is now in vogue as previously.

2. Though manuring myself one-third of the estate yearly, I cannot see there is any falling-off in quality. I am continuing the same system as I did 6 years ago, both in plucking and manufacturing.

3. Tea occasionally require a heavy pruning, but this is often very much overdone. No doubt the leaf plucked from this is inferior to tea taken from tea pruned higher.

4. There is very little doubt that a quantity of the tea now manufactured has not the efficient supervision, and machinery that it should have; even given good leaf it is not treated properly.

5. Labour Supply has no doubt something to do with the quality of the leaf, as if a flush once gets behind, the tea thus made is inferior to a tea made from a flush taken at the proper time.

INCOG.

No. XVIII.

Udappussellawa, Feb. 16.

SIR,—A non-teamaking neighbour has handed me your circular and asked me to answer the questions.

1. I do think Coarser Plucking has deteriorated the quality, and No. II is more closely con-

nected with No. I than appears at first, because manured tea flushes quicker, and the flush is over-grown on the manured field if taken in regular routine as it generally is, especially now-a-days when few estates have sufficient labour to keep the flush in hand always and the effect is more noticeable in the busy months. I don't believe that manured tea really gives a worse quality of leaf *if* the flush can be plucked when it is ready, and the same rule applies to severe pruning, as the flush comes quicker, and too often we are not able to put coolies on the day it is ready, and, of course, a quick growing field suffers more through being left a few days, and the effect of this becomes more noticeable every year, as when only half the estate was in bearing, the whole labour force was available to pluck.

IV. I don't think the teamakers are any worse now, than they were; but many factories are more crowded than they should be, to do full justice to the leaf.

V. This question seems to strike at the root of the trouble. With a plentiful supply of labour and plenty of room in our factories, I believe, as good teas are made now as were ever made, but in the majority of cases, we have to do the best we *can*, not the best possible and do indirectly. I believe the application of manure does affect the price of tea.—Yours faithfully,

J. A. O.

NO. XIX.

Uva side, Feb. 15th.

DEAR SIR,—Overproduction, or rather I should say ample production, is the first and chief cause of the fall in prices, as it always is and must be in the case of all products. There can hardly be said to be *overproduction* of tea yet, as, I believe, stocks in hand are not increasing.

Always excepting above reasons I will answer your questions seriatim.

1. Yes; Coarser plucking has certainly a great deal to do with it in two ways: a larger quantity is thrown on the market, and what is gathered makes weaker and inferior tea, and too often a greater quantity comes into the factory than there is room to give to it for withering properly and manufacturing carefully. This coarser plucking has been forced upon those who were at first unwilling to go in for it. The hunger after big profits by proprietors resident in England, or in the case of Companies by the shareholders, forces the resident managers to pluck coarse whether they like it or no; prices once brought low by this cause, others found their profits diminishing, and took to coarse plucking for their own protection.

2. Manuring gives larger yields, and throws more leaf on the market, and often puts more leaf into the factory than the latter has proper capacity for. It may also cause a greater rush of leaf in the heavy flushing months than there is labour enough to pluck, and the coarser leaf resulting is seldom thrown away.

But manure may be directly injurious to the outturn of the tea, if it is done with indiscretion. Manuring with artificial often destroys the flavour and this opens another question which it would be of service to thoroughly thrash out, *i.e.*, what kinds of manure tend to destroy flavour and the reason of it. I do not think that bulky manure destroys flavour. Too forcing a manure tends to make the resulting tea weak, but there is

no reason why any manure should do so, if not applied in too forcing doses. Perhaps, the loss of flavour may be traced to the same cause.

3. Yes, I have been often told by those who have had experience that flavour is greatly lost by cutting down old bushes to 12 or 15 inches after they have reached too great a height after successive prunings; I have never heard that such bushes ever regain their original flavour. Besides this, too severe a pruning is likely to act in the same way, though in a lesser degree and from the effect of which bushes would be more likely to recover. With insufficient young wood left above the previous cut, the new shoots are less likely to be healthy and robust.

4. I believe that attention to careful preparation in the factory is as great as ever it has been, if not more so, and there is better machinery. There is no doubt that different modes of manufacture will give better results than others, but there have always been different ideas and different methods of manufacture, and this has little to do with the fall in prices. Yes, good tea is undoubtedly made in the field, but not more so than in the factory. There cannot be said to be any one work in connection with field or factory which is immaterial to the outturn of good tea. Neglect in the field will neutralize care in the factory, and *vice versa*.

5. Shortness of labour need not have any effect on prices, because runaway flush often makes the best tea, provided the coarse leaves are thrown away; but very few estates can afford to do this, and the result of course is a weak and pointless liquor. In my own case, I have not hitherto been too short of labour.

6. The more leaf which is left on the bushes, the better the flavour and quality generally, but the less the yield. Many estates now keep their bushes as low as possible for the purpose of forcing the yield, which invariably results in a loss of flavour and strength; they may get a higher yield and perhaps bigger profits, but the tea made is not so good. G. H. G.

XX.

So far as the Matale West district is concerned, I think most of us have plucked coarse, because we found it pay best. I doubt whether any one in the West Matale district plucks fine. The reason is, I think, that we find we can get quantity by coarse plucking, which gives us a very satisfactory profit. Were we to pluck fine, owing to want of flavor, our prices would, in my opinion, increase very little, but our yield would go down very largely. At present the places in the Matale valley are giving from 700 to 1000 lb. per acre, and I have very little doubt, that if we plucked finer, we should make less profits. A very well-known planter and proprietor, some years ago, was advised by his brokers to try and copy Hoolankanda teas, which at that time topped the market. He wrote back that he would be very glad to do so, if the brokers could show him, that it would pay him better to get 2s. for his tea, than 7½d. This appears to me to hit at the chief reason of the fall in price as compared with India. I am inclined to think that most low-country estates have tried more for quantity than quality, because it gave the most satisfactory results. I certainly think that more careful plucking would raise our prices, but I do not believe it would compensate for the loss in yield. T.

THE PLUCKING, PRUNING AND PREPARATION OF TEA :

REVIEW OF LETTERS XIII TO XX.

It will have been seen from our summary and review of the first twelve letters on the above subject, that Planters from all districts are agreed that attention to all the three P's which appear in our heading are as essential to the manufacture of good tea, and the maintenance of our reputation in the market, as are the historical three P's of our late Governor, to success in life, or at any rate to the character of a businessman. Without proper pruning, the quantity and even the quality of flush is prejudicially affected; bad plucking, whether through carelessness or lack of labour, is fatal to the turning out of good tea; and the most scientific pruning and intelligent plucking will be thrown away, unless the Factory does justice to the produce of the field. And how much is included in the word preparation or manufacture! Everything from the weighing in of the green leaf to the weighing out and taring of the chests—including withering, rolling, sifting, firing, re-firing, re-sifting and packing; can all these things be possibly accomplished by rule of thumb? Where all the conditions are normal—the leaf having been well plucked in good time, the withering accommodation being sufficient, the weather being favourable for even withering, and all the machinery in good order—no higher intelligence than that of the Factory kangany may be necessary to turn out a good break. But one or other of these conditions constantly varies; and more than ordinary intelligence and powers of observation are necessary to meet varying conditions; and "N's" reflection, that in Java science is available in the Factory, and is followed by better and improving prices, deserves some attention. We have ourselves always favoured the employment of an Agricultural Chemist, and we are confirmed in our opinion by the notes which have reached us of Mr. Crole's Lecture at the Society of Arts, in which it is not difficult to discover in an abundance of technical and high-sounding words and phrases, observations and counsel of the widest practical importance. They tend to establish, what all practical Planters believe—though they may not be able always to practise what they believe or to explain what they wish to practise—that the dictum that good tea is made in the field is true only in the sense that the best equipped Factory cannot make high class teas from sapless and badly plucked leaves. The Factory is of importance, not alone as a repository for the many and delicate processes necessary for the manufacture of tea, but also as a check on bad work in the field—that is, on bad plucking. It is helpless, however, to do aught in respect of leaf deficient in the principles essential to good tea; and it is there that science should come in—to tell us if the flavourless and sapless leaf can be improved, and if so, how. We refuse to believe that science cannot help us in restoring to the soil what has been drawn out of it, so that the leaf may be reclothed with the properties which produced good Tea from the young and unexhausted bush.

So much by way of preface to our notice of the letters 13 to 20 of the series, which we published last week. "Hantane" repudiates coarse plucking, and, like many another, claims an improvement in plucking; he does not believe in deterioration through manuring; he has not been short-handed; he does not practise severe

pruning, but prunes once a year; and though the estate is old and the soil poor, there is no falling-off in the teas, while the plucking average remains satisfactory. How is it then prices have gone down? Over-production is hinted at as the main cause; but our correspondent recognises the need of ample withering space; and his one trouble has been with delay in withering. That only a half-truth is expressed, in the legend that "good tea is made in the field," is very forcibly and clearly pointed out. "X. Rays" takes a different view on plucking, and holds that the race for big yields has studied quantity at the expense of quality; while on manuring he differs yet more from Hantane," holding it responsible to the extent of 1d a lb. in the fall, as inducing a fibrous leaf and one which yields less dry tea. Now these are points which science and experience combined should help to elucidate; for one would think that if the bush is used up and the leaf is destitute of sap, it is manure which should restore vigour to the bush and juice to the leaf—the "mucilage," which Mr. Crole says, gives thickness and cream which Tea tasters value so highly, to the liquor. "Yearly pruning, well cut down," is the prescription for maintaining both quality and quantity; and he combines belief in greater care in preparation than of old with the conviction that bad tea is made in the field, good tea in the Factory. His reason for this last proposition is rather unsatisfying; for he admits that with bad leaf good tea is impossible, while the best of leaf may be spoilt in the Factory. True; but when good tea is made out of "the best of leaf," why should not the field share the credit for it? Though the better jâts give higher yields, a mixture of jâts is desiderated for a better quality of made tea; but big yields, manuring and coarse plucking have increased exports at the cost of price.

"*Custos pauperis horti*" cannot plead poverty of ideas, nor can his "wattie" be a particularly poor place, if his flush runs ahead, and his coarser plucking be due to that cause. While absolving manuring of all blame, he is strongly of opinion that unscientific, savage pruning is responsible for the deterioration of tea. There can be no question that the pruning of coffee is not comparable for severity with tea-pruning; while the manner of harvesting crop—divesting a bush of its tender leaves as they appear—must be injurious to its vigour and even its very life, were it not that tea is one of the hardiest of shrubs. To carry methods which are inevitably harsh and unnatural to their extremes, and over-pluck and over-prune, must, therefore, be suicidal; and our correspondent expresses his condemnation of these excesses in terms which will, we trust, leave a deep impression. He notes the same tendency, to overdoing in the Factory, where heavier rolling (oftener and more prolonged) beats the leaf, induces early fermentation, and affects quality. "Work must be good all round—in pruning, in plucking, in the Factory—to make tea." That is a truth worth remembering by those who think that the manager's absence from his charge at frequent intervals, cannot tell; and these processes are, of course, affected by short labour, which is held to account for the loss of 1d in the lb. "W. J. G." desires coarser plucking thinks manuring good land merely to increase the yield a mistake, notes less severity in pruning now, and greater care in manufacture—though lack of withering space is a hindrance, as also

insufficient rolling power. These last, and short labour (leading to coarse and careless plucking, coupled with the absence of a wintering season) explain the deterioration. "Incog," from a medium elevation district, denies coarser plucking; and herein he differs from J. A. O. of Udapussellawa, who holds that manuring, by hastening flush, is responsible for coarse leaf, as also from G. H. G. from the Uva side, and T. from Matale West—all of whom admit coarse plucking and explain it by the larger profits it yields. Incog. finds that manuring one-third of the estate each year does not affect the quality of the yield as a whole; while the heavy pruning, which is occasionally necessary, does. The growing quantity turned out of the Factory renders close supervision difficult, if not impossible, and with a scanty labour supply which delays plucking, quality suffers. J. A. O. generally agrees with these views, and holds short labour and crowded Factories specially responsible for mischief. G. H. G.'s dictum that artificial manures destroy flavour will find smaller support than his suggestion that inquiry should be instituted as to what manures affect flavour, and how. It is probable that too forcing a manure makes the tea weak, while the other reflections on excessive pruning, the need of all round attention, short labour, and greedy plucking, merit attention. T's demonstration of the greater remunerativeness of coarse plucking will be generally accepted, and the conclusion is obvious, that over-production must generally follow the methods which rather tell on quality. The fall is then only natural!

(Letters Continued.)

No. XXI.

Madulkelle, Feb. 16.

DEAR SIR,—In reply to your circular of 12th inst., I beg to state that

1. Better leaf is now plucked in Ceylon than ever before, in fact as far as I can see, every year sees more careful plucking the rule.

2. Manuring, I am inclined to think, has certainly a slight prejudicial effect on quality, but not nearly so much as some people aver. The reason for poorer quality and prices will, I think, be found in

3. The severe pruning now more or less prevalent in the tea districts. The call for quantity from agents and owners as well as the endeavour to put our teas f. o. b. for the lowest figure possible, and which can only be achieved by securing quantity, is forcing Superintendents much against their will sometimes, to prune oftener and severer than they otherwise might.

4. Good tea is made in the field. Your parenthetical remark goes without saying.

5. Not as yet has shortness of labour done any harm. For a month or so I may be forced to pluck a little coarser, but that should only affect the prices of a break or so.

6. I would place the reasons for reduced prices in order of merit so:—

3. Manuring—possibly.

2. Heavy and frequent pruning—probably.

1. Over-production—undoubtedly.

NORTH OF KANDY.

No. XXII.

1. "Coarser plucking" has nothing to do with it. It is the endeavour of every Superintendent, who takes an interest in his work, to harvest fair leaf all the year round; but the style of plucking is ruled by the weather and state of

the labour market. In heavy flushing weather it takes twelve or more days to get round—in slack times the round is completed in 7 or 8 days when very fine leaf is the result. In fact plucking is generally carried on now as it has been conducted any time during the last ten years.

2. In my opinion manured tea lacks strength as well as flavour.

3. Can have no possible effect on general prices. Pruning is being carried on in twenty different ways every month in the year on one-twentieth of the total average of tea.

4. No.

5. Shortness of labour supply has never affected work in any Factory as far as I know. It can never fit in perfectly with flush demand.

6. I can think of no other possible cause but over-production. N. A.

No. XXIII.

Prices have fallen but it does not follow that quality has deteriorated. In fact one of the annual Brokers' Circulars recently issued states that quality has, if anything improved. If in particular instances quality has not been maintained it is probably due to (a) Coarser Plucking with the object of an increased yield; (b) irregular plucking from want of labour; (c) machinery and withering space not being kept up to requirements. Our knowledge of tea making is empirical; but is always increasing and Planters are always ready to spread the latest tip. Though Superintendents may not spend as much time in the factory as formerly, they have well-trained tea-makers who are competent under supervision to attend to the details of manufacture. O. Y. A.

No. XXIV.

I do not think the cause lies in the tea itself; but in the increased supply, say over-production.

The leaf plucked is no coarser than it was.

Manuring has not become so general as to be responsible for it, nor severe Pruning.

If anything, the manufacture receives more attention than it ever did, though this cannot overcome bad plucking.

Shortness of labour is felt more in field-work than crop, though it leads to some coarser leaf. The market holds the real reason. W.

No. XXV.

The Country Generally, Feb. 16.

1. From what I have seen the plucking is *finer* in all districts than a few years ago.

In reply to your queries from Nos. 2 to 6 the soil alone is to blame for the loss of the Ceylon flavour which brought the teas from this island into favour. Few planters will agree with me, perhaps, but the above is my conviction, the bushes get no tropical winter such as they have in India and there is no recuperation—no rest! I fear *manure* will not bring back the flavour. "H."

No. XXVI.

Passara, Feb. 16.

1. So far as I am concerned, I pluck the same now as I did 3 years ago.

2. Very little tea is yet manured in Uva, but I should think manuring extensively would affect the quality of the tea detrimentally: the flushes would be heavier, come on more quickly and consequently the leaves and shoots would be more sappy and succulent.

3. The same applies to severe pruning.

4. Here I think we touch the spot. I am convinced were we to follow more closely India in this respect and have more continuous European supervision in our factories, our prices would improve. Far too much is left to native supervision. There is little doubt that the best and most carefully plucked leaf is often spoiled in the manufacture, or at least not done justice to.

5. This has not much to do with our poor prices I consider. P.

No. XXVII.

The Country Generally, Feb. 16.

Causes which have brought down the average prices for Ceylon teas:—

1. What is called 'coarser plucking' which is really sensible plucking. Had it been possible to send 100 millions lb. of the same tea as once was supplied by Rookwood, Hooloo and Agar's Land, prices would have fallen to the same level. Fine plucking produces only a fancy article insipid and unsuited to the taste of the million.

2. Manuring has only to do with quantity not quality.

3. Neither does severe pruning affect the quality—only shortens the life of the bush.

4. Oh, yes. Preparation has much to do with it and the quantity of red leaf and muck sent to Colombo sales is a scandal. I quite endorse, by the way, all that Mr. Green writes *re* "small breaks." Those brokers are enough to break the records of small proprietors.

5. Shortness of labour may affect the quantity; but no judicious Superintendent would allow it to affect the quality. Ergo in that case, prices ought to go up.

6. Production—I do not say over-production yet. S.

No. XXVIII.

Pussellawa.

(1) Coarse plucking is a curse causing over-production &c. and undoubtedly spoiling our market.

(2) I don't think manuring has been general enough or carried on long enough, as a rule, to much affect bulk of Ceylon teas as yet, although my impression is that it gives quantity at expense of quality.

(3) We always found in old days that a severe pruning spoilt our teas for the season. I fancy nearly as many men prune light now-a-days as heavy, *i.e.* go to the other extreme and merely slash across.

(4) With present large quantities turned out of factories I fear the preparation is not so careful, and more is done by rule of thumb than before. (Good tea is made by attention to detail in *every* process connected with manufacture.)

(5) Shortness of labour should not affect the manufacture much. It pays better to abandon a field for months than to struggle round the plucking in 15 days or so and get bad leaf.

(6) Not particularly.

I.

XXIX.

Maskeliya, Feb. 13.

1. I do not think planters as a rule are plucking coarser than before.

2. Manuring certainly affects the tea to a certain extent, but when bad *jât* is manured, the leaf improves in softness and by getting a better leaf to manipulate in the factory, I think a great deal of, or all, the evil effects of manure, are done away with.

3. The severe pruning done on a lot of estates is no doubt accounting for lower prices.

4. 75 per cent of Ceylon factories have insufficient withering space: as this is the most important item in manufacture greater attention should be paid to it. The tea is certainly made in the field to a large extent. An estate with bad climate, jât and soil can never compete, however fine the plucking, with an upcountry estate.

5. Shortness of labour no doubt greatly affects prices, as planters cannot keep up with their flushes. My conviction is that should labour be short, planters should let part of the estate run and only pluck the fields they can go round within 8-12 days, according to the climate.

7. Overproduction and increased supply are however the main causes.—Yours faithfully,
PLANTER.

XXX.

Dikoya, Feb. 17.

1. There can be but little doubt of late years most estates have studied the question of yield per acre, and instead of vying with each other with regard to prices, it has been more a question whether A gets a better yield per acre than B, and I consider that this has simply solved itself into coarser leaf having been accepted as a result.

2. The only way manuring might have affected prices is in the case of an insufficient labour force to cope with the extra leaf; but given an adequate labor force with careful manuring; and prices, in my opinion, would be improved.

3. The question of drastic pruning should not affect the point in question at all materially, as it is a work that *has* to be done sooner or later, and most estates would probably arrange to do only a small proportion of their acreage in the year, and in that way prices for the year would not be materially affected.

4. This question of probable carelessness in Factory affecting prices should in a general sense, I think, be put aside, as a manager who neglected the supervision of his Factory would probably neglect the work outside as well, and in that case would not remain long where he was. I do think, however, there is a good deal of follow-my-leader business about tea manufacture in general which might be remedied; but the secret of bad prices in 9 cases out of 10 is *insufficient withering accommodation*. How many factories are really properly equipped in this respect? Estates have yearly increased their crops and yet have the same accommodation as they had when they were getting probably 25-30 per cent less.

5. In many cases shortness of labor has meant bad leaf and bad prices, but this state of things would probably not last very long and so on most estates should not account for the general fall.

6. The whole thing will work itself out in my opinion; men *must* pluck finer to improve prices; those that do will get attention in the market, and those who continue for yield only will probably get lower and lower till they realise that it is not paying them.

It has paid of late years quantity as against quality; but the time has come when quality must have its innings and the sooner it is realised the better for the name of Ceylon tea.

E. H. R.

No. XXXI.

17th Feb.

SIR,—In reply to yours of 12th, I do not think planters are going in for coarser plucking now

on this side of the country than they were a year or two ago. Little manuring has been done so far.

Severe pruning undoubtedly affects the quality of the tea made, at least for some months after pruning.

I am certain much better teas could be made in some factories, were more attention paid to the work in both field and factory. I believe in careful, *not fine*, plucking and adequate supervision in the factory. Given the above almost any estate in Uva over 3,000 ft. elevation should show averages at least 1d per lb. above the London prices for the year, and in the dry weather June-Sept., there should be a much greater difference. Many men scarcely look at the leaf in the baskets, and certainly do not over-burden the factory with their presence, and when their teas fetch lower prices than their neighbours', lay the blame everywhere but in the right quarter.

During the busy months, March, April and May, few men have sufficient labor to get round in 8 to 10 days and the teas made from a flush 12-16 days old are bound to be inferior. Increased supply is, however, in my opinion, the main cause of the lower prices ruling of late years.—Yours,
J.

XXXII.

1. I do not consider that coarser plucking is responsible for the falling-off in quality.

2. Nor do I think it's attributable to manuring.

3. Not low and frequent pruning—to secure quality—is the chief factor in the depreciated quality.

4. Careless work in the factory and inadequate machinery will depreciate the value of tea; but tea is made in the field and not only is careful plucking necessary, but, to secure flavour, the trees must be pruned high and pruned at long intervals. N.B.—The fine teas from St. Leonards were procured in this way. When working the Kandapola group of estates and making some 50,000 lb. of tea a month, I secured some of my best prices and teas, from leaf that, because of inadequate accommodation, had been only a quarter withered.

5. Short labour spoils the quality of leaf as the plucking is not performed in its proper rotation and the result is* a large amount of "bhanji" leaf is formed (and cannot easily be got rid of for months after) which will ruin the quality in any tea.
D.

No. XXXIII.

Dimbula, Feb. 17.

1. I have no doubt that coarser plucking of leaf has very much to do with it, as well as trying to get a much greater yield per acre. V.A. says this field must (observe the word) give 450 or 500 lb. per acre.

2. No! manuring tea has not done it. The more healthy the bushes, the better leaf.

3. I am against severe pruning; medium is what I do, cutting down once in 6 years or so. Less severe pruning is done now than formerly.

4. No, more attention. Good tea is neither made in the field nor in the factory: it's the combination of both. It's more easily spoiled in the factory than in the field. It must be remembered that if flavour and strength are not in the leaf no manufacturing can put it there, though it can be very easily thrown away in the factory.

* This is, of course, *besides* the immediate result of coarse leaf harvested.

Careful factory work is a great essential in making tea.

5. Shortness of labour has made your tea run away; consequently, coarser tea is plucked, as no person likes to throw away leaf.

6. I know no other cause except over-production.
J. J.

—
No. XXXIV.

Teldeniya, Feb. 18.

1. I fancy plucking is very much what it always was, and has nothing to do with the fall in prices.

2. Can (judicious!?) manuring do harm to any cultivation or crop? I do not think so. If new soil or manuring upsets quality and flavour, let us rush for old exhausted land.

3. There is no doubt severe pruning (cutting down to a foot) does away with quality and flavour of tea for fully 12 months.

4. I do not think less attention is given to factory work. On the other hand, too much fuss and interference with the tea-maker is apt to upset the regular routine of work. Of course, "tea is made in the field"—good or bad—but it takes some trying to spoil fine leaf.

5. Glad to say, I have never been short-handed, but I can quite believe a short labour supply would upset the plucking a good deal and so spoil the quality of the leaf.

6-7. It is not possible to make the same tea all through the year, weather and pruning having a great effect on quality and make, and prices are therefore bound to rise and fall. The tea of today is as good as ever it was. Increased supply should bear the blame of fall in the market value—here we make our best teas in the south-west months, I suppose from the check the bushes receive from the wind—our poorest teas in March and April, when the great rush of leaf is on.

I add our 3 wants as a rule:—Want of withering space, want of power, and want of coolies.

What say you? Do you think Naseby teas of today are not as good as those when fine prices were being realized some time back? What puzzles one is, where all the poor teas sold in the Colombo market comes from, or how it is plucked and made—but it was always so, it is no new thing.
R. B.

—
No. XXXV.

February 18.

1. I do not think men, as a rule, pluck coarser than formerly.

2. Manuring may, at first application, give you a leaf lighter than the trees yielded before they were manured, but as manuring, in the course of three or four months, improves *the wood*, the leaf must naturally be better from manured trees.

3. Severe pruning is only resorted to when the trees, say after three prunings are, what is called, pruned down.

4. Tea manufacture, as a rule, is as much attended to as formerly.

5. If an estate is short of labour, naturally too long time elapses between each plucking, and liquor suffers.

6. I think production is getting ahead, gradually, of consumption—hence the gradual fall in price.
V. A.

—
No. XXXVI.

February 18, 1897.

(1). Considering that a large number of estates had been formed into Companies it is a difficult

matter to say whether coarse plucking is the principle cause for low prices. I think Superintendents pay more attention to plucking than they did a few years ago. Pro. planters who work their own estates, are generally fond of coarse plucking, doing great harm to their own interests in bringing down the average prices for Ceylon teas.

(2). Having had little or no experience in manuring tea, I am not in a position to answer this question.

(3). Severe pruning is bound to bring down the average prices for Ceylon teas, unless estates adopt a proper system of pruning $\frac{1}{3}$ rd of estate every year. A great number of lowcountry places are pruned once in 12 or 18 months, and these (estates) cannot possibly send good teas to the market. Estates at high elevation are pruned once in three years, but the time is not far distant when we shall have to follow the example of lowcountry planters of pruning tea once in 18 months.

(4). I do not think careful attention is paid to the manufacturing of tea. Native tea-makers are often very careless, and Superintendents should pay three or four visits to the factory every day.

(5). I have never been short of labour, but those who have not a sufficient labour force on the estate to pluck once in 12 days, cannot expect to make good tea.

(6). Careful *plucking*, *manufacture*, and proper system of *pruning*, may keep up Ceylon prices, but as far as my experience goes, as the tea gets older, Ceylon is bound to produce a poorer quality of teas.

(7). Over-production has a great deal to do with the low prices, but this sort of thing cannot go on for any length of time, for the day will come, when estates at low elevations will gradually become worthless, giving a chance to estates at high elevation to realize good prices.
W. N.

—
THE PLUCKING, PRUNING AND
PREPARATION OF TEA:

REVIEW OF LETTERS XXI TO XXXVI.

Resuming our remarks on the letters on the above subject, from No. 21, we note a continuance of the divergence of opinion already recorded on the subject of coarse plucking. It is rather a difference of testimony on a matter of fact; for, if there is coarser or finer plucking now than before, the statement regarding the change would scarcely be reckoned an opinion, about which practical men of experience would differ. Either there is coarser plucking now, or there is not. How is it, then that some writers distinctly affirm coarser plucking, and either justify it as more remunerative, or condemn it as leading to the fall in prices which is loudly deplored, while other writers as confidently report an improvement in plucking, but equally lament the lower prices, which they refer to other causes than the system of plucking? The explanation seems to us simple, and one which reflects on the accuracy neither of observation nor of statement of the writers. Each refers to matters within his personal knowledge and observation without the least idea of misleading. The system of plucking differs in different districts, and even on different estates. Roughly speaking, estates in the lowcountry, or of medium elevation, prefer quantity to quality, seeing that their teas cannot command the prices which those of the higher districts fetch;

while proprietors, who own plantations in districts of highest elevation, are naturally ambitious of maintaining the prices which have given their places prominence. Of course, there may be exceptions in lowcountry estates plucking fine, and high estates going in for quantity; but, as a rule, a hot steamy climate favours quantity, and the rarer air of the highlands imparts a delicate flavour to tea. We are unable to illustrate this explanation by reference to particular letters, as some of our correspondents, no doubt for good cause, prefer not to mention the district from which they write, or to indicate the estate or estates whose system they record; but, we think, it will be found that the apparent discrepancy in the evidence of the witnesses, who have favoured us with replies, is explicable by the different standpoints from which they write. The same explanation applies, though not to the same extent, to the varying answers to some of the other questions.

But to proceed, "North of Kandy" from Madulkelle reports, not only better plucking than ever before, but an improvement in plucking every year. "O. Y. A." on the other hand, in our issue of the 11th, admits that, if quality has not been maintained in particular instances, it is probably due to coarser plucking, whose object is a higher yield, or irregular plucking through lack of labour; while "N. A." thinks that coarser plucking has nothing to do with the fall in prices. He avers that it is the endeavour of every superintendent who takes an interest in his work to harvest fair leaf all the year round, but the style of plucking is affected by the weather and the labour supply, though generally the system has remained the same for the past ten years. "W." agrees that the leaf plucked is no coarser than it used to be, though he is silent on the different results which must follow from making the round of an estate in 7 or 8 days, and from inability to get through the fields before 10 to 12 days, if not more. Of these four correspondents, two hold manuring, and severe pruning to maintain yield, responsible for deterioration; while a third is silent on these operations, and the fourth denies that they are general enough to supply the explanation. Over-production is the cause which strikes all; and while one dismisses the suggestion of the need of greater care in the factory with the dictum that good tea is made in the field, another denies it laconically, a third holds a trained teamaker an ample equivalent for less time in the factory by the superintendent, and the fourth reports that manufacture receives more attention than ever before!

Two of the four letters in our issue of the 13th instant are dated from "The Country Generally"! They should be useful as illustrating how opinions differ throughout the country generally, and establishing that there are two faces in a shield. "H" declares that plucking is finer in all the districts he has seen, than it was a few years ago; but "S" is convinced that what is called coarser plucking is really sensible plucking, and that, if 100 million lb. of the same tea had been exported as once distinguished Rookwood, Hooloo and Agar's Land, the fall in price would have been the same as now. Fine plucking, in his view, produces only a fancy article, insipid and unsuited to the taste of the million. Here, it seems clear to us, is a radical difference of opinion on paper, as to what constitutes fine plucking; and we should not be surprised if, in practice, "H" and "S" agree as to what constitutes fair and sensible plucking. "P."

from Passara plucks the same as he did three years ago; neither manuring nor heavy pruning is practised extensively in Uva, so that they cannot be held responsible for deterioration, if such is the effect of these two operations; but what does tell on prices, he considers, is the absence of sufficiently close supervision in the factory. In India, he says, the practice is different; but too much is left here to the native subordinate, whose intelligence and knowledge are less than his master's, and who would naturally follow his master in taking things easy in the factory. "I." from Pussellawa differs from the three correspondents, who have preceded him, in regarding coarse plucking, not only as a fact, but as a curse too in its effect on the market. Here, then, are four planters, each of whom takes a different view of plucking—one insists that it is finer, wherever he has been, than it was a few years ago; the second, that he himself plucks the same as he did three years ago, and he evidently knows no change in others; the third lauds what people call coarse plucking as sensible plucking; while the fourth spells coarse plucking curse! Then as to the causes of the fall in prices, we have seen that "P" holds the lack of supervision in the factory responsible. "H." thinks the secret is in the soil which, without the recuperation of wintering, is helpless to produce the same leaf it did when the bushes were young, while manure cannot bring back the flavour; "S." exonerates manures, which affect only quantity, and severe pruning which tells only on the life of the bush, but blames preparation, and the quantity of red leaf and muck sent into the Colombo market; "I" too, fears that the increased quantities put out of the factories now-a-days, render care difficult, if not impossible, in the factory, though he holds both manuring and hard pruning prejudicial to quality. With regard to red leaf and muck, it is really a question for the producer whether they leave any profit at all, and, even if they do, whether they would not be more profitable directly as manure, and indirectly by reducing the quantity of low grade teas thrown on the market

THE KOLA NUT.—Most of our readers are familiar with the name of this product, and we have done our best to arouse a practical interest in its cultivation by distribution of seed and diligently publishing all the information we could collect concerning it. Briefly, it will grow anywhere where Liberian coffee will grow, but the hotter and moister the climate the better. The trees planted from are ten to twenty feet apart. The returns compare favourably with even the best of coffee land. The chief difficulty hitherto experienced in India was the enormous price demanded for the seed by the few firms from whom it was obtainable. We are glad to announce that the great colonial seedsman, Mr. Thos. Christy, states in reply to a query, that he can deliver a basket of about 100 lb. f.o.b. London for about £6. As perhaps ten nuts go to the pound, this counting freight, makes the cost per hundred about £12-8-0 on the estate. Allowing 400 trees per acre, and the liberal margin of twenty-five per cent for failures in germination, the initial cost in seed runs to about sixty rupees per acre. If half a dozen men clubbed together, it would probably come a greater deal cheaper. We have an idea that the kola plants might be first put out tentatively as a species of shade tree among the coffee itself, say at the rate of 100 trees per acre.—*Planting Opinion*, March 6.

KANDYAN HILLS COMPANY, LD.

A general meeting of shareholders of the Kandyan Hills Company, Ltd., was held at the offices of Messrs. Carson & Co., 21, Baillie Street, on the 19th March.

The report was as follows :—

ACREAGE :	
Originally purchased ..	1.190 acres.
Since acquired ..	100 "
	1.290 "
Tea in bearing ..	320 "
New clearing 26 planted ..	32 "
In process of clearing ..	50 "
	402 "
Reserve land ..	790 "
Cocoa ..	100 "
	1,292 "

The Directors have pleasure in submitting the accounts for the past year ending 31st Dec., 1896.

The crop secured amounted to 128,625 lb. made tea realised R49,251.74 and 103 cwt. 1 qr. 24 lb. cocoa realizing R3,508.12. The average cost (exclusive of expenditure of items under capital account, profit and loss and sundries) of made tea was 28.27 cents per lb., and the average price realised 38.27 cents per lb. This includes R3,126.76 spent on manuring 110 acres.

The average cost per cwt. of cocoa was R28.27. The average price realised R33.90 per cwt.

The balance at debit of profit and loss account after making provision for

	R.	c.
Stationery and postages ..	50	00
Preliminary expenses in the formation of the Company, including commission to Mr. Grigson ..	5,241	65
Interest at 7 per cent on £4,500 mortgage ..	5,976	92
Directors' fees Visiting Agent ..	1,300	09
Agents and Secretaries ..	750	00
Auditor's fees ..	50	00
	R13,368	57

amounts to R566.71, which the Directors propose to carry forward to next account.

The result is disappointing, and is accounted for by low prices ruling for medium teas last year, and the low prices of cocoa.

The Company was also unfortunate in losing the services of Mr. E. S. Grigson, and subsequently Mr. G. F. Traill, who was acting as visiting agent during the former's absence at home.

Every effort is being made to improve the quality and the manufacture of the teas.

Only 26 acres having been planted last year, it is proposed that up to 74 acres be opened this year, making the 100 acres as contemplated in the prospectus.

The mortgage for £4,500 bearing interest at 7 per cent per annum, is being replaced by one for a similar amount, bearing interest at the rate of 5 per cent per annum.

The appointment of an auditor will rest with the meeting.—By order of the directors,
CARSON & Co., Agents and Secretaries.

THE ROEBERRY TEA COMPANY OF CEYLON, LIMITED.

The first annual ordinary general meeting of the shareholders of this Company was held at the offices of Messrs. Bois Brothers & Co. on the 22nd March.

The Report was as follows :—

ACREAGE.	
407 acres	4 years old and upward.
135 "	3 do do
127½ "	Just planted
669½ acres of Tea	
4½ "	Cardamoms just planted
23 "	Grevilleas
696½ acres	
336½ "	Uncultivated
Total. 1,033 acres	

The Directors have now the pleasure to submit their first annual report and accounts being those for the year ending 31st December last. The yield of Tea during the period has been 127,840 lb. costing cts. 38.52 per lb. and realizing cts. 45.47 per lb.

On a reference to the accounts it will be seen that the nett profit amounts to R6,753.69, after writing off the whole of the preliminary expenses, and the Directors recommend that this balance should be carried forward to the next account.

The result of the year's working is not so satisfactory as the Directors at one time hoped, and this to a great extent has been caused by the delay in the completion of the Factory which necessitated the tea being manufactured for a considerable period at the nearest available Factory, involving a heavy expenditure for transport of green leaf for a distance of some 14 miles, besides the additional cost of manufacture.

The Factory is now in satisfactory working order, and it is hoped that the consequent improvement in the quality of the tea made there since its completion in September will be maintained.

During the year 127 acres of tea have been planted and large nurseries established, which will be found adequate for any further extensions that may be decided upon in the immediate future.

Mr. Mason visited the estates on the 12th and 13th February and reports that the general appearance and condition of the property is "distinctly good; the Roeberry division in particular shews a very thick cover almost throughout the entire estate."

The out-turn of crop for last year was as follows :—

	Bushels	lbs. Tea.
	284	127,840
as against an estimate of ..	280	115,500

The estimate for the current year is 174,000 lb of Tea against an expenditure of R57,790, which sum, however, includes the cost of up-keep of all young tea.

Mr. Mason reports that the planting of the new. Clearing was all finished in January and that the work has been most carefully done, the vacancies at present appearing being almost nil.

The old tea, viz., 190 acres, 5 years of age and upwards, gave an average return of 466 lb. per acre, and there is no reason to suppose that the younger tea will not give equally satisfactory results when it arrives at maturity.

In terms of the Articles of Association all the Directors now retire but are eligible for re-election. The appointment of an Auditor for the current year will rest with the meeting.

THE PALMERSTON TEA COMPANY OF CEYLON, LIMITED.

At a meeting of the Shareholders of the Palmerston Tea Company of Ceylon, Limited, held at the registered office, No. 11, Queen's Street, Colombo, on the 22nd March.

The report is as follows :—

ACREAGE.	
403 acres	over 5 years
69 "	" 3 "
472	
21 "	Forest, Grass and Timber Trees
Total. 493 Acres,	

The Directors have now the pleasure to submit their first annual report and accounts, being those for the year ending 31st December last. The yield of Tea during the period has been 176,410 lb. costing 29'66 cts. and realizing 55'85 cts. per lb.

As will be seen from the accounts the nett profits for the year amount to R33,348'58, after writing off one-third of the preliminary expenses. An interim dividend of 4 per cent was declared on the 14th August, absorbing R16,400'00, and the Directors recommend a final dividend of 4 per cent making 8 per cent for the year. The sum of R548'58 will then be left to be carried forward to the current year's account.

The Estimate for 1897 is 190,000 lb. Tea against an expenditure on working account of R55,605'50.

In terms of the Articles of Association all the Directors now retire but are eligible for re-election.

The appointment of an Auditor for the current year will rest with the meeting.

THE HIGH FORESTS ESTATES COMPANY LIMITED.

The annual ordinary general meeting of the above Company was held at the Company's Offices, No. 7, Queen Street, Fort, Colombo, at 3 p.m. on Monday, 22nd March.

The Report is as follows:

ACREAGE.	
Tea in bearing ..	432 acres.
„ in partial bearing 103 „	
„ not in bearing ..	53 „
„ planted in 1896 ..	246 „
	834 acres.
Forest and Patna ..	798 „
Total ..	1,632

The Directors have pleasure in submitting to the Shareholders the Account of the Company for the past year.

The total crops secured were 146,861 lb. tea, which realized a net average of 53 cents per lb. and 5,513 lb. Cinchona bark at a cost of R48,287'47 on working account.

After making ample provision for depreciation of Buildings and Machinery the result of the year's working shows a profit of R25,942'90, from which falls to be deducted the balance at debit (R3,608'54) brought forward from 1895. This leaves a sum of R22,334'36 available, and the Directors now recommend the payment of a dividend of 2½ per cent, which will absorb R20,000 and leave a balance of R2,334'36 to be carried forward to the current year's accounts.

For the information of Shareholders a copy of Mr. Megginson's report on the Estate, dated 6th March, 1897, is issued with this report. The reasons for the shortfall in the crop are fully given therein. The Directors have every confidence that the current year's working will show more satisfactory results.

During 1896 a sum of R43,886'50 was expended on the opening of the 246 acres and on nurseries, R26,139'17 on buildings, and R19,563'67 on machinery. The expenditure on Capital Account during 1897 is estimated at R58,977, viz: R14,750 on completing the extension of the Factory, Bungalow, Lines, etc., R4,250 on new machinery, and R39,977 on the upkeep of the young tea and in opening up a further 215 acres. To meet this Capital expenditure the Directors in September last gave notice of a call, payable on 1st Jan., 1897, of R150 per share on the part-paid shares, which call has been fully met.

The yield of tea in 1897 is estimated at 200,000 lb. against an expenditure of R64,090.

During the past year Mr. G. W. Carlyon resigned his seat on the Board and Mr. C. A. Leechman was appointed to the vacancy. Subsequently Mr. C. A. Leechman resigned and Mr. F. W. Bois, on the invitation of the other Directors, accepted the vacant seat.

Under the articles of Association all the Directors now retire from office but are eligible for re-election.

The appointment of an Auditor for the current year will rest with the meeting.

By order of the Directors, WHITTALL & Co., Agents and Secretaries.

Colombo, 11th March, 1897.

COLOMBO COMMERCIAL COMPANY, LIMITED.

The following is a copy of the Directors' report, which was presented at the second ordinary general meeting held in London on the 16th inst.

The Directors now present the following annual accounts to shareholders, viz:—

Profit and loss account for the year ending 30th September, 1896.

Balance sheet made up to 30th September, 1896.

The year's operations have resulted satisfactorily, and the Directors are able to recommend the payment of the following dividends free of Income Tax:—

Dividend in full on the 6 per cent.	
Preference shares for the year	£
ending 30th September, 1896 ..	1,091 2 0
Dividend of 8 per cent. on the Ordinary shares for the same period ..	5,600 0 0
	6,691 2 0

After payment of these Dividends there will remain the sum of £415 15s. 3d. to be carried forward to next account.

During the year the six per cent. Debentures have been converted into debentures bearing four and a half per cent. interest, and an additional sum of £4,000 has been issued at this rate. It is the present intention of the Board to pay off £4,000 of five per cent. debentures, maturing on 30th September, 1897.

The Liquid Assets in Ceylon appears in the Company's accounts at an exchange of 1s. 1d. per rupee the present value of the rupee being about 1s. 3d.

It will be seen by the profit and loss account that the sum of £2,007 8s. 4d. has been transferred to exchange reserve against capital expenditure. The board are glad to report that they have been enabled to make such a substantial addition to this account during the year; inclusive of this sum the amount appearing under this heading is now £19,000.

Braybrooke Lodge, a property adjoining the Company's mills at Colombo, was in the market, and in view of the extension of the Company's business the Directors considered it advisable to secure it. The purchase has been completed, and the cost has been written off in the accounts now presented.

Mr. Brown went to Ceylon last November, and is expected to return in time to take the Chair at the forthcoming meeting.

The Directors are glad to report that the prospects of the Company are favourable, and they also have much pleasure in acknowledging the valuable services rendered by the Company's Manager and staff in Ceylon during the past twelve months.

On the retirement of Mr. H. H. Potts from the Board through ill health, the Directors elected Mr. P. C. Oswald to the vacancy. Under clause No. 95 of the Articles of Association, Mr. Oswald retires from the Board on this occasion, and, being eligible, offers himself for re-election.

Messrs. Deloitte, Dever, Griffiths & Co., the Auditors, also offer themselves for re-election.

By order, J. ALEC ROBERTS,

Secretary

London, March 5th, 1897.

COLLUM'S PATENT "ACME" TEA SORTING MACHINE AND SELF-ACTING MESH CLEANER.

Last week we were invited to attend the offices of Mr. James Melling, consulting engineer, Dashwood House, E.C., to witness a demonstration of a working model of the above-mentioned machine. Mr. Collum, the inventor and patentee, was present and explained the working and the advantages he claims for his invention. It is a neat, compact machine about 10 ft. in length, 2 ft. 6 in. wide, and 1 ft. 6 in. high. The longitudinal frames are of strong angle iron, strengthened at the corners by cheek plates being rivetted to the frames, and are held rigidly together by traverse steel rods.

Upon this structure two long trays are suspended, in which the interchangeable sliding mesh frames are placed. The upper tray has a slight fall from right to left, the under tray from left to right. This fall can be increased or lessened according to wish. An ingenious and simple arrangement is fitted to the two trays, and is connected to a crank shaft having its supports and bearings at the left hand end of the framework. The crank shaft is also fitted with a small fly-wheel and a split pulley. When the motive-power is applied the crank shaft and connecting rod impart to the trays a rapid backward and forward motion, so arranged that a counter-balancing action is obtained, thus ensuring absolute steadiness. A $\frac{1}{2}$ -h.p. engine is sufficient to drive a full size machine.

Mr. Collum has recently added a "mesh cleaner," a very useful addition. When the meshes become choked, by simply pressing a lever downwards the "mesh cleaner" is put into action, and the whole sifting surfaces become at once quite free. This is accomplished while the machine is running at full speed, a great saving of time. This invention, it is claimed, will sort five, three, or two grades at one operation, and we were informed that a full-size machine has sorted 1,000 lb. of tea in one hour.

The model certainly worked admirably. A pound and a half to two pounds of tea was placed in the top tray (when in motion), and in a very short time all had passed through the different sorting spouts into separate receptacles, completing the operation in a most satisfactory manner.—*H. and C. Mail*, March 5.

THE INDIAN TEA ASSOCIATION, LONDON.

The following is the interim report of the American and Foreign Tea Committee:—

In presenting their interim report the committee have the pleasure to state that, in response to the appeal made in March, 1896, subscription to the fund for introducing Indian teas to the American market amounted to the sum of R103,674-8-0 say (£6,500) as against R92,575 collected in 1895. This included, as in the previous year, a generous contribution from the planters of Southern India.

Mr. Blechynden, the representative of the association in America, has, under the direction and supervision of your committee, continued to co-operate with Mr. Mackenzie, representing Ceylon, in the work of bringing the teas of both India and Ceylon to the notice of the American public. Your committee are therefore satisfied that everything possible is being done to awaken interest in our teas by carefully arranged advertisements and articles in the press, as well as judicious aid given to traders in taking up our teas in competition with those of China and Japan.

Advertisements of Indian and Ceylon teas appear in large type, followed by the advertisements of traders who have the tea for sale, in leading journals circulating in the following towns, viz.: New York, Brooklyn, Philadelphia, Boston, Detroit, Buffalo, New Haven, New Bedford, Paterson, Pittsburg, Malome, Massina, and Chatiangay.

The committee beg to refer to the extracts from Mr. Blechynden's report on his work for 1896, which are annexed, as affording strong evidence of the value of the work done and of the necessity of continuing the campaign.

The progress made in the use of Indian and Ceylon teas in North America is distinctly encouraging, as the following figures, which have been carefully revised by Messrs. Gow, Wilson, and Stanton, will show: Indian and Ceylon tea taken by North America during each of the last six years. Indian: 1896, 5,205,405; 1895, 4,050,595; 1894, 2,423,230; 1893, 2,111,247; 1892, 1,586,426; 1891, 1,342,321 lb. Ceylon: 1896, 4,268,614; 1895, 3,735,590; 1894, 2,295,140; 1893, 1,870,590; 1892, 1,489,474; 1891, 991,981 lb. Total: 1896, 9,474,019; 1895, 7,792,185; 1894, 4,723,370; 1893, 3,981,837; 1892, 3,075,900; 1891, 2,334,302 lb.

Foreign markets absorbed 42 million lbs of British-grown tea in 1896. There is no possibility of exactly gauging the benefit to prices thereby obtained, but some indication may be gathered from the following figures: The importations of all teas into the United Kingdom increased from 1890 to 1896 by 42 million lb., and the price of British-grown tea fell 2d per lb. in that period. It may be fairly assumed that if the 42 million lb. of tea absorbed by foreign markets had come to this market in 1896 prices would have been reduced by a further 2d per lb., which would mean a loss not less than a million pounds sterling to the Indian tea producers only.

Looking at these facts, and considering that this year's crops from both India and Ceylon are likely to show a substantial increase, your committee are strongly of opinion that there should be no relaxation made at present in the effort to win the American market, and they therefore recommend another levy on the same basis as last year, to be collected, as before, in Calcutta.

Arthur Bryans, Robert Lyell, R. B. Magor, James Riddell, R. G. Shaw, A. G. Stanton, J. N. Stuart, John Stewart, W. H. Verner, C. W. Wallace, members of committee; Earnest Tye, secretary. Feb. 18, 1897.—*H. and C. Mail*, March 5.

PRODUCE AND PLANTING.

THE ANTI-TEA CRUSADE.—Mr. Crole's reference in his lecture read before the Society of Arts to the digestive difficulties of a meat tea has given the opponents of tea an opportunity. These good people occasionally lash themselves into frenzy about the awful consequences of tea drinking, and therefore the smallest indication of support from a lecturer on tea gives them a much-desired opening. Under the head of "The Terrors of the Teapot" the *Daily Graphic* prints the following effusion from a correspondent: "Tea is so daily—nay, hourly—a beverage that Mr. David Crole, whose lecture at the Society of Arts you recently reported, renders service to humanity by exposing its horrors and the risks people incur by imbibing freely of a poisonous effusion. The portentous names are perplexing, but who does not fear an attack of indigestion as pointed out by Mr. David Crole in his able lecture? He omits to speak of the meat breakfast. It is easier to digest than the meat tea, and might it not be helpful to analyse the assimilation of the contents of the terrible teapot in conjunction with, say, bacon, sausages, kidneys, cutlets, and other breakfast dishes, to say nothing of various cold meats on the side table? The demon teapot has so firm a hold that his worshippers will not easily lose faith in their idol. Practical suggestions of a less injurious beverage would benefit the community. Have we nothing to fall back on our breakfast but the small beer of the good old days when the horrible teapot and its deadliness were unknown?" It is rather rough on Mr. Crole that his lecture on tea should have been made a peg whereon to hang a hatful of abuse against tea, and an excuse for launching such demi-"cuss" words as "terrible," "horrible," and "demon" at an inoffensive teapot.

NEW JOINT STOCK ENTERPRISE DURING FEBRUARY.—The amount of new capital offered for public subscription during February amounted to £5,659,000. Of this amount £98,000 was asked for in connection with tea. During the first two months of this year the capital asked on behalf of new tea projects amounted to £203,000.

SAMPLING TEAS IN BOND.—In the course of a letter on this subject a correspondent writes: "Recently I received a parcel of tea, and the first three chests which were opened each contained from one pound to two pound samples worth 8d per lb. less than the original tea. This is the latest instance of many similar cases which have come under my own observation, and it is high time that this kind of thing was discontinued. There is something seriously wrong in a warehousing system of this kind."

GUATEMALA COFFEE.—Mr. Audley Gosling, Her Majesty's Minister at Guatemala, points out, with reference to the season's coffee crop, which he estimates will yield 600,000 quintals, value about £1,800,000 that Guatemala coffee continues to maintain its high price and reputation, nor has the fall in "Santos" (Brazilian) affected it. It is believed that even should over-production ensue, due to the extraordinary extension of the industry throughout Central America and Mexico, Guatemala coffee, owing to its excellent flavour and quality, will still find ready buyers. Where the cultivation of the berry is carefully conducted the trees suffer little deterioration. In Guatemala it is hand-picked, berry by berry, and not, as in Brazil, torn from the branches. The competition which Central and South American producers chiefly fear is that of the West Coast of Africa, where coffee-growing is fast superseding the palm-oil industry.

CINNAMON.—The demand for cinnamon is fully equal to the supply, and the tending of prices is in an upward direction. At the quarterly sales last week there was a brisk competition, and nearly the whole of 1,250 bales and 43 parcels Ceylon realised full rates current by private contract, to an advance of ½d per lb, especially for the commoner qualities. There was no material rise as compared with the prices established in November last. The general range of quotations was as follows: First quality cinnamon, low at 7½d to 9½d, ordinary to good at 10½d to 1s 1d, fine and superior garden growth at 1s 3d to 1s 6d; seconds, very inferior at 7d to 9d, common to finest at 10d to 1s 2d, choice plantation at 1s 4d to 1s 5d; thirds coarse at 8d to 9d, middling to fine 9½ to 1s 1d, best mark at 1s 3d to 1s 4d; fourths and fifths from 6½d up to 1s, extra fine 1s 1d, and a few broken (in boxes) at 9d to 10d per lb.

THE ADULTERATION OF PRODUCE.—A deputation representing the Produce Sectional Committee of the Manchester Chamber of Commerce recently waited upon Mr. T. W. Russell, Parliamentary Secretary to the Local Government Board, to urge the necessity for prompt legislation to amend the Adulteration of Food and Drugs Act in a number of points, the principal of which were the establishment of a Board of Reference for standards and a change of the law with respect to warranty. After hearing views of the deputation, Mr. Russell said his view was that without a properly constituted Board of Reference all legislation on this question must fail. It was very unjust to allow standards all purity to be fixed by analysts in different ways over the country, and it was absolutely necessary for the safety of the consumer as well as of the trader that such a Board should be set up to settle standards of purity that would be binding upon the whole community. A Bill based in the main on the recommendations of the Select Committee had been prepared, and the Departments would lose

no opportunity of pressing on the Cabinet the necessity for legislation. By the way, a Birmingham grocer who was fined the other day for selling coffee adulterated with 60 per cent. of chicory pleaded that he did not know he was doing wrong. Perhaps he thought his customers had a playful way of asking for coffee when they really wanted chicory.—*H. & C. Mail*, March 5.

VARIOUS PLANTING NOTES.

TOBACCO LEAF SALES.—We are obliged to Mr. Philip for supplying the information asked for by a correspondent in a recent issue. The result, in R25 per cwt. or about 23 cents a lb. cannot be considered very encouraging; but Mr. Philip had special difficulties to contend with and that he overcame these so well, says much for his tact and good management.

THE GLASGOW ESTATES CO.—A home shareholder writing to us by this mail, says:—"I have just seen the Glasgow Estates Report. I see nothing about the Small Reserve Fund, which was created some time ago; it seems to have been put to an account called the Extension Fund Account. At least if that is not the case, where is it? There is no mention of a Reserve Fund in the Director's Report, and they ought to have said that it had been merged in the Extension Fund." Our correspondent is in error in stating that a Reserve Fund was ever opened. The sums set aside from profits (over and above the usual provision for depreciation of buildings and machinery) have always been put to credit of the Extension Fund account, which was opened at the first annual general meeting of the Company.

PLANTING AND AGRICULTURE IN THE STRAITS SETTLEMENTS.—From the Report for 1896 of Mr. Berkeley, on Kuala Kangsar district:—

On the Kamuning and Waterloo estates the area under cultivation is greatly increased. On Heawood a big clearing has been planted up, and at Gapis the coffee, coconuts and pepper all look well. Syed Muse's pepper estate has become the property of Government by purchase, and Cicely has reverted to us on the expiration of the last lease. These two latter are still on our hands, but I hope tenants will soon be forthcoming. A large area of coffee has been planted on the Kinta road at Chegor Galah, Manura, Lerik, and elsewhere, and some of the older native pepper gardens look well.

Towards the end of the year there was great distress in many parts at Bota, Lambor, Kruh, Pulau Buaya, and elsewhere. This is accounted for—first, by the people not having been allowed *ladangs*—secondly, by their improvident habits, and thirdly—by the awful cattle plague which raged all through the district. They sell their rice in advance to traders for a very low price, often for clothes and jewellery. The Government came to their rescue, and rice was given to starving families, either free, in payment of work done, or on advance. It is to be hoped that they will take advantage of the lesson and cultivate more *bandang*, as they now know that no *ladangs* will be allowed. The best means the Government could adopt to prevent this recurring would be to stop the export of rice by a big export duty, and by charging heavy licenses to buy rice.

At the Bruas a good deal of land has been taken up, and much timber exported. It is to be hoped that the Timber Farm will not be renewed after 1897. We suffered for six months from a severe drought, followed by one of the highest and certainly the longest lasting flood on record, which, by ruining a great deal of *padi*, added to the distress referred to above.

Correspondence.

To the Editor.

CEYLON TEA IN AMERICA.

London, 1st Feb. 1897.

DEAR SIR,—In your leader (see page 545) on the interview "Brown Paterson" had with me, you say I am inconsistent in depreciating newspaper advertising, while praising the firm which advertises Ceylon tea in over 300 papers.

The difference lies in the fact that the latter is in Canada—a tea-drinking country; whereas "Brown Paterson" was referring to the United States—a coffee-drinking country. There, mere advertising, unless on a scale far beyond our means, would be quite useless, unless we first induced dealers to hold our teas. A strong friend of Ceylon tea writes "I am taking up a new town now, but will not advertise till I get 50 grocers to hold my teas." I send a cutting from the *American Grocer* showing the imports of tea into the United States from 1880 to 1896 [already given in *Observer*.—Ed. C.O.] You will see that the consumption *per head* has decreased, although the average cost per lb. has fallen from 27 cts. (1s 1½d) to 13½ cts (6½d). This, of course, arises from the great immigration from coffee drinking countries, chiefly Italy, Austria and Germany about which, see enclosed cutting from *Globe*. I enclose another reference to the Japan tea organizer with Mr. Larkin's reply to what he says on behalf of Japan tea.—Yours faithfully,

WM. MACKENZIE.

PLANTING AND THE AUSTRALIAN NEW
HEBRIDES COMPANY, LTD.

10 Bridge Street, Sydney, Feb. 5.

To the Editor, *Tropical Agriculturist*, Colombo.

SIR,—We give you some particulars hereunder regarding the New Hebrides which we think will be of interest to many of your readers.

The New Hebrides are situated 1,460 miles North-East of Sydney, and consist of some 20 fertile Islands, some of which are 60 miles in length. They are connected with Australia by a three-weekly steam service from Sydney (a time-table of which we enclose herewith) by a steamer of 1,200 tons @ 12 knots speed. The Capital of the New Hebrides Islands is Port Villa situated on the Island of Sandwich. The Sydney steamer here connects with the Inter-Island steamer of 400 tons register.

Our idea in bringing the New Hebrides under your notice is on account of the many advantages it affords for the "Tropical Agriculturist." Coffee, Cocoa, Vanilla, and Bananas are cultivated.

COFFEE was introduced some five or six years ago and although cultivated in a primitive way the export last year amounted to some 250 to 300 tons. The bulk is sold in Sydney realizing from 7d to 10d per lb. Both the climate and soil are well suited to its cultivation. The Islands are hilly and covered with vegetation and abundance of shade for young coffee may be left when clearing the land for Plantation purposes.

BANANAS are now grown in large quantities, the steamer on her last trip bringing 15,000 bunches the fruit is far superior than that of Queensland and Fiji.

CACAO AND VANILLA.—It is only during the last twelve months that these have been introduced, and the young plants are looking remarkably well.

There is but little doubt that the New Hebrides afford fine fields for the Coffee and Tea Planter, large tracts of choicest land may be purchased or

rented at nominal cost. Labor may be had in abundance from the local labor recruiting vessels who bring the labour from Islands other than the one upon the Planter who requires the boys is settled. The recruiting Fees for good strong labourers average from £6 to £8 per head. The laborers come to the Planter under an engagement of three years and as a rule renew the engagement for an additional three years. The wages paid amount to £10 each per annum with Food, principally Rice, Yams, Taro and Bananas.

Our Company, we might mention, was formed for the encouragement of British interests in New Hebrides and we have large tracts of land that may be purchased or leased at nominal figures by intending Planters.

We enclose herewith some copies of a pamphlet regarding settlement, also under other cover we send you sample of coffee grown.

We shall thank you to give the above a paragraph in your valuable Journal as we feel sure that many of your readers will be much interested in it.

Any further particulars may be had by applying to the undersigned.—Yours very truly,

P. THE AUSTRALIAN NEW HEBRIDES
COMPANY, LIMITED,

JOSEPH MITCHELL.

[Copies of circulars with the fuller information can be had at our office by any one interested.—Ed. T.A.]

LOCAL FRUIT AND VEGETABLES.

Kandy, Feb. 23.

DEAR SIR,—Can any of your readers explain what part in the economy of nature the "Siamese Twin" plantains, to be found on every bunch of the fruit, play?

While on the subject of fruit, I feel certain our new Director of Gardens would earn the gratitude of the community, native as well as European, if he should turn his attention to improve the quality of the several descriptions of fruit and vegetables we possess in the island, many of the former are of fair flavour, but producing very little pulp. Cultivation has rectified this defect in many instances in Europe, and surely a like success may be looked for from efforts in the same direction out here. If I may, I would suggest that a plot of ground in the Peradeniya Gardens be devoted to the object I refer to.

PALAM.

TOBACCO IN CEYLON.

Feb. 26th.

DEAR SIR,—In reference to your very interesting article upon the subject of Tobacco and enquire as to the causes of its cultivation not being taken up by Europeans, may I venture to make a few observations. It appears that Mr. Vollar in his opinion that first rate cigar tobacco can be grown in Ceylon must be correct. The Sumatra experts, who commenced the business of the Tobacco Company, were attracted by what Mr. Vollar had grown and they showed their belief in it by becoming purchasers to a considerable extent, and as they were men of experience it seems clear that it was not any defect in growth that brought about the ultimate abandonment of the enterprise; but the curing of it was another matter. Still even that had been seen to by their experienced manager and prior to that Mr. Vollar and others had had a measure of success; but there were many other difficulties arose. Land could not be acquired in large blocks and it was necessary to get it on scattered pieces, hence we saw Dumbara, Katugastota, Wattedagama, Ukuwela, Matale and Kurunegala all furnishing lands and these acquired slowly and no doubt expensively, for though the

land might be acquired at a low rate per acre, it necessitated being done by a highly paid staff of Agents and Managers, local and expert, and others negotiating with natives and arranging titles. Besides all this, tobacco is far and away the most delicate and most dangerous cultivation. The greatest possible attention is required at every step. There is nothing to equal it in any Ceylon produce—the nurseries and insect attacks; the planting requiring an enormous force of labour at almost a moment's notice; and when caterpillars come as they must and will very frequently a similarly large force is needed. Subject to all sorts of danger from vicissitudes of climate and weather and quite open to destruction from a day or two of strong breezes it is difficult to find a district that would be really safe and nothing but a splendid market and a successful crop season could possibly repay the toil and failures of others. I believe, however, that the Sumatra experts were anything but satisfied that their tobacco did find full justice in the market, and probably the trade would hardly accept at fair value even good tobacco from a new source. We are not wanting in precedents for such treatment. I have not forgotten the efforts made by the late Mr. A. M. Ferguson in favour of Ceylon Tea in Australia against the interests vested in China—a thing of this sort requires years of opposition. You are correct in assuming that tobacco is still grown profitably by natives in Dnmbara, and I may tell you that at Katugastota in the native gardens a good deal of money has been made there last year, and no doubt this has been done with the seed and with the experience picked up from the Tobacco Company's former buildings. J. M.

THE TOBACCO LEAF SALES OF THE CEYLON TOBACCO COMPANY.

Kandy, Ceylon, 27th Feb. 1897.

SIR,—With reference to the paragraph in the *Ceylon Observer* of Friday the 26th instant under the heading "Tobacco" the net total amount realized by Tobacco Leaf Sales, after the Ceylon Tobacco Company, Ltd., went into Liquidation was *R11,307.64*.

The average price was a little over *R.25* per cwt. all round, while there is no doubt that there was a ring of dealers to endeavour to keep the prices down as on more than one occasion I declined to accept bids with the result that a moderately good price was ultimately obtained all round.—I am, sir, yours faithfully,

A. PHILIP.

PRODUCE QUOTATIONS: LIBERIAN COFFEE.

DEAR SIR,—I notice in your issue of 25th March, the Chamber of Commerce Price Current of 23rd gives Liberian parchment "per bushel *RS.25* very scarce;" but Mr. A. M. Chittambalan in his local market list printed in same issue of 25th gives the price as *R12.50* per bushel (nominal.)

Do such quotations as *RS.25* when the produce is scarce, compared to *R12.50* its price a year ago, when it was not scarce, denote that we have now, or are more to find this cultivation a delusion, and let it lapse into abandonment? Can you throw any light upon this sudden collapse? Are the Singapore merchants getting all the European

and American orders or are there other sources and our crops too insignificant to count, or are our buyers so few as to afford no real market at all?

I have some fears that the cultivation is not greatly progressing as it is, but with such prices at *RS.25* I presume it would be altogether discouraged.
COFFEE.

TEA PRUNING, PLUCKING AND PREPARATION.

March 3.

DEAR SIR,—I cannot refrain from an exclamation of supreme surprise on reading the first replies to your queries *re* fall in prices. What on earth are V. A.'s made of, if they must needs wade through oceans of leaf on their way to their virtuous couches?

Give us practical men who can see an inch beyond their noses as our "Guides, philosophers and friends" or we'll continue to flood the market with inferior broken teas the cause of which is evidently hob-nailed boots!—Yours faithfully,
FARMER.

[But let "Farmer" oblige us by sending his own answers to the circular-questions and so show how they ought to be dealt with. We have begun publishing the replies in the order of receipt and not by any process of selection.—*ED. T.A.*]

QUERIES ABOUT TEA.

MATALE WEST, March 4.

DEAR SIR,—Geo. White & Co.'s memorandum No. 157 dated Feb. 3rd is interesting. Take No. 1 with outlets, Nanuoya and Talawakelle, altitude of estates from 3,500 to 6,500 feet, the highest price obtained was $1\frac{1}{2}$ d and the lowest $6\frac{1}{2}$ d. How do you account for a difference of 8d. Surely coarse plucking alone; or that combined with careless manufacture cannot account for this? Have aspect and soil anything to do with high prices? or is it that one was cultivated for a long number of years before being planted with tea? This will not hold good in all cases; as there are estates in most districts that secure top-prices although planted with coffee for a long time, while others planted in forest or chena get two prices.

Do some estates deteriorate faster than others? I can call to mind 2 estates that secured top-prices some years ago for 4 or 5 years in succession. The prices went lower and lower, till at last estates adjoining one of these secured higher prices, though formerly these was such a difference as 8d. and 9d. per lb. between them. How is it the Northern Districts get such low prices? One estate alone gets as much as 8d. though the elevation of some are 3,000 feet and more. Surely all the Planters of the Districts are not incapable men and a good many estates pluck rather fine. In Maskeliya, Dikoya and Bogawantalawa with outlet-Hatton—the highest price was 1/1 and the lowest $6\frac{1}{2}$ d.

In Lower Dikoya, Kotmale &c., outlet-Wat'awella and Nawalapitiya—elevation 1,500 to 4,500 there is not much difference in price, highest $1\frac{1}{2}$ d, lowest $5\frac{1}{2}$ d. and only 3 estates secured prices from 8d. to 8 $\frac{1}{2}$ d. Why does Dnmbula get higher prices than Dikoya? Is it owing to the lower rainfall and does a very high rainfall, *e.g.*, Matale District lower the price of tea.

A large number of estates all over the island at good elevation and with healthy bushes secure low prices. Superintendents and Conductors known to make good tea, are put on these. New and expensive machinery are put on. The price still remained low. How do you account for this?—Yours,
PLANTER.

COARSE AND FINE LUCKING OF TEA.

Nawalapitiya, March 8.

DEAR SIR,—Now that the discussion in your columns re coarse plucking and rubbishy tea, with over-production—the inevitable results of such a method being adopted—is being freely ventilated, will not the figures given below be a poser to our V.A.'s and Directors of our Ceylon Tea Companies as to this suicidal policy which hereafter means death to the shareholders and other proprietors of tea!

Take for example the Celestial Empire: heavenly John's fate was sealed when Ceylon stepped in with a tea equal to any in the world and by miles superior to that being heaped on the market by John Chinaman & Co. What followed we all know. With this recent knowledge well before us, if we are to go on glutting our already overstocked market with tea that John was wont to supply when he had it all to himself, can we doubt the results? "Give a dog a bad name, &c." has been veritably proved in the case of John Chinaman, and if we persist in our mad career that such will be our experience in the near future is not a mere nightmare. To obtain a sound reputation takes tons of gold, but to secure a bad one you need hardly spend a brass farthing. "To be forewarned is to be forearmed." Let us therefore in 1897 rise to the occasion ere the death-knell is sounded over Ceylon's spicy teas. There is this frivolous exense which some are always ready to advance.—"If we drop in our exports, others will rise up. Let them! All I say is those countries which will flood the markets with rubbishy teas will soon find their doom; whilst we in Ceylon, if we *now* strike the happy medium and keep to it steadily, shall and will have the sweet comfort of knowing that our teas are an established staple for years to come.

Now for my table produced by humble efforts:—"Quality vs. Quantity"—which will also do away with the clamour for laborers, a grand reduction of the labor force being an undoubted outcome.

Estate supposed to yield, say 100,000 lb. tea annually; coarse plucking.

Average 6d. a lb. = £2,500-0-0. Same estate 80,000 lb.; fair plucking; average 7d. = £2,333-6-8. Difference = £166-13-4.

Cost of extra 20,000 lb. tea at, say 4d.

Will land you in £333 6 8

Profit on coarse leaf 166 13 4

Difference in expenditure 166 13 4

80,000 lb. tea at 7d. £2,333 6 8

Difference in expenditure 166 13 4

£2,500 0 0

Put that in your pipe and smoke it, ye croakers of "quantity pays"! What about wear and tear of machinery, &c., &c., saved? C. T.

P.S.—Whether I produce 100,000 or 80,000 I can safely do both at 4d. a lb. Difference in plucking won't affect it: it may the first 2 months or so till Menatchie gets up to the new style of plucking; and ever after your averages are precisely the same as if you were plucking an extra leaf or even ½ a leaf.

[Has "C. T." observed that a great many of the letters in answer to our circular, deny that the plucking is any coarser than it has been all along?—ED. T.A.]

HOW TO DEAL WITH UNPROFITABLE LOWCOUNTRY TEA.

Matale West, March 11.

DEAR SIR,—I was looking over the prospectus of the Talgaswella Tea Company and the Estimate (made if I am not mistaken by Mr. T. C. Owen) for opening 500 acres in tea. It showed at the end of 3½ years, a profit of 22½ per cent. How has this been fulfilled?

Waterholing should be tried in dry districts, where the land has been drained properly, and where it is not too steep.

I had a very poor piece of tea where I tried this. The cost was about R7 to R8 per acre and the yield was doubled, and the field has continued to give double for the last 5 years. Might not this be tried on Talgaswella where the climate is hot and the evaporation consequently great; especially as some of the land is said to be sandy. All the rainfall, or nearly all, will be absorbed and the tea will flush well during the drought. Again should shade not be tried? I do not know if Grevilleas grow well in the low-country, but Dadap and Albizzia Mollucana do. They might be planted originally 10' x 10' and after 2 years or so when the trees grow, they should be thinned out and the distance might be 20' x 20' or more. Leguminous plants enrich the soil and the experiment if tried will not cost much, and cannot in any case do damage.—Yours truly,
PLANTER.

ENEMIES OF TEA.

Maligatenne Estate, Veyangoda, March 15.

DEAR SIR,—Enclosed in a match box you will receive by post a worm or a grub which attacks tea trees. It was found under the following circumstances. Observing a small collection of what appeared as a heap of saw dust at the foot of a tea tree of two years' growth, I examined the tree and found a small hole at the foot of the tree about 1-8th of an inch from the ground. I probed it and found the hole to take an upward direction. I cut down the tree and laid it open, and found the grub about 8 inches from the hole up the tree. As the above information may be of some use to tea planters, I thought it right to send it to you.—Yours truly,
C. L. H. DIAS BANDARANAYAKA.

[The "grub" is the larva of the Borer, *zeuzera coffea*, described in Mr. E. E. Green's 'Insect pests,' page 8. It is an old enemy of coffee, though never a widespread one in Ceylon. It is also found in tea, but not in such numbers as to need any special efforts to check them.—ED. T.A.]

APPOINTMENT OF A SPECIALIST TO INVESTIGATE CACAO DISEASE.

SIR,—Cacao growers will be gratified to hear that the Government intends to have the cause and nature of the pest which has in some places done so much damage to the red variety of cacao investigated, and I believe, the services of a competent specialist will be secured. Our thanks are due to H. E. the Governor for having promptly interested himself in the matter.—Yours faithfully,
THOS. NORTH CHRISTIE,

St. Andrews, Maskeliya, March 22nd,

TEA CHESTS

In the multitude of counsellors there is safety. And apart from the local supply of timber for tea boxes—very limited, we fear—and the supply from Japan, which, some people think, may any day be restricted, it is a comfort to think that so much is being done in this direction, both in Europe and America. At the head of the home list in importance must be placed, the Glasgow Acme Steel Chest Company, which has already got so great a hold on Indian tea planters, that its Directors have felt justified in securing and erecting special works for their operations, and are about to increase the capital of the Company. They have got a most energetic capable Manager in an Aberdonian gentleman, who was trained as an Analytical Chemist; but whose keen business habits had attracted attention. Still, in his first year he was able, as Chemist, to show his Directors, how they could save £500 a year in their manipulation of the steel plates; and we may expect the "Acme" people to go on improving their style of chest which they hope ere long to turn out at the rate of a million a year.

A tea box owned by a London Syndicate, and in the invention of which, an old Ceylon planter, Mr. J. C. Roberts, was prominent, is specially praised for the equal tares, it is likely to secure, as well as for its lightness and cheapness. A special celluloid preparation is used, tucked by very thin steel, and the steel and cardboard make the chests very flexible. Cut across in two, these are readily convertible into half-chests. Dawson's Baltic timber box for tea is said to be both cheap and good; and so is a Canadian tea-chest, which it is hoped to supply largely to India and Ceylon. And lastly we have in our midst, as lately announced in full detail, the "Venesta" tea chest. We have heard remarks made as to a recent testing of these chests, on a Dimbula estate, that it is a pity that the rival boxes were not filled with precisely the same quantities, or rather weights, of say, dust tea, and that then the test applied could not prove otherwise than equal and fair.

The time is, no doubt, approaching—say at the next Agri-Horticultural Show in Colombo—when not only Tea Machinery of all descriptions, but all the varieties of tea chests can be shown and even tested, to some extent, simultaneously. Meantime, it is satisfactory to know that there is no chance of a failure of supply, nor yet of a monopoly in any one direction, in this important item of a tea producer's stock-in-trade.

THE KALUTARA COMPANY, LIMITED.

The annual ordinary general meeting of the above Company was held at the Company's Offices, No. 7 Queen Street, Fort, Colombo, on the 18th March.

The following is the report:—

	ACREAGE.	
Tea in bearing	425 Acres
Tea not in bearing	153 "
Arecauts, Grass, &c.	7 "
		585
Forest	499
		1084
	Total	.. 1084

The Directors have now the pleasure to submit to the Shareholders the Accounts for the period from 1st April to 31st December, 1896

The Crop during that period was 153,477 lb. Tea, which realized a net average of 39½ cents per lb.

After making ample provision for depreciation of Buildings and Machinery, there is a balance at credit of Profit and Loss Account on the nine months working of Rs21,053'40, equal to 7 per cent per annum on the Capital of the Company. After writing off the whole of the preliminary expenses (Rs3,995'99), the balance available amounts to Rs17,057'41. The Directors now recommend the payment of a Dividend of 4 per cent, which will absorb Rs16,000 and leave a balance of Rs1,057'41 to be carried forward to the current season.

The estimate for this year is 195,000 lb. Tea from the 425 acres in bearing on an expenditure of Rs17,653'58, which includes a sum of Rs6,000 to be expended in manuring 120 acres.

The estimated expenditure on Capital Account is Rs32,350'11, which provides for the upkeep of the 153 acres not in bearing, the planting up of additional clearings, in extent 82 acres, and the cost of a new withering shed.

Mr. C. A. Leechman having retired from the Board, Mr. J. G. Wardrop was nominated to the vacancy thus occasioned.

In terms of the Articles of Association all the Directors now retire, but are eligible for re-election.

The appointment of an Auditor for the current year will rest with the Meeting.—By order of the Directors.

WHITTALL & Co.
Colombo, 5th March 1897. *Agents and Secretaries.*

INDIAN PATENTS.

The fees prescribed have been paid for the continuance of exclusive privilege in respect of the undermentioned inventions for the periods shown against each:—

IMPROVED HULLER FOR RICE, COFFEE, AND GRAIN.—No. 73 of 1892.—Edward Lennon Cantwell, civil engineer and patent agent, of 5, Old Post Office street Calcutta, for an improved huller for rice, coffee, and grain, and for scouring and cleaning rice, wheat, and every description of grain. (From 1st March 1897 to 1st March 1898.)

IMPROVEMENTS IN THE METHOD OF, AND APPARATUS FOR, DRYING TEA LEAF AND THE LIKE.—No. 152 of 1892.—Henry Thompson, engineer, of Ipswich, in the county of Suffolk, for improvements in the method of, and apparatus for, drying tea leaf and the like. (From 10th March 1897 to 10th March 1898.)—*Indian and Eastern Engineer*, March 20.

MANURING TEA WITH BULKY MANURES.—An experienced planter, now at home, writes:—"By the way didn't I once mention to you that when planters were manuring with bulky manures, that great care should be taken not to cut the side roots. I have seen a great deal of careless work done that way, and I can't think in a case of that sort the manure is likely to benefit the tree, when its feeding roots are cut. Coolies are excessively careless when holing, and are certain to cut large numbers of roots unless strictly prohibited from doing so. A kind of special hoe should be used with blunted edge, to draw the earth back from the stem of the tree where it enters the ground, not to cut a hole to deposit the manure in, for if the hole is cut with a sharp holing mamotie, such as is used in cutting roads or drains, the large side roots are almost certain to be cut through."

DEAFNESS. An essay describing a really genuine Cure for Deafness, Ringing in Ears &c., no matter how severe or long-standing, will be sent post free.—Artificial Ear-drums and similar appliances entirely superseded. Address THOMAS KEMPE, VICTORIA CHAMBERS, 19, SOUTHAMPTON BUILDINGS, HOLBORN, LONDON.

BOWSTRING HEMP.

The plant which yields this fibre is known botanically as *Sansevieria Zeylanica*, and to the Natives of Ceylon as "Niyanda." The fibre is largely used by the Kandyan people in the making of fine coloured whips and mats, and for such purposes the work of extraction is done by manual labour. Some attempts have been made to grow the plant commercially and for export, and notably by Mr. C. Shand who, in the time of coffee depression, worked up *Sansevieria* among other fibres but could not get it to give a profitable yield of clean fibre. It should be mentioned, however, that Mr. Shand used a self-made and comparatively crude machine for extraction and that this fact may account for his failure to grow the plant remuneratively.

Sansevieria is once more brought to the notice of tropical planters and this time as a second or catch crop on tea-land, to be grown on those portions of estates not required and not suitable for tea. In this connection it forms the subject of a bulletin, issued by the Government of India, as one of their useful Agricultural Ledger series of publications. It is universally admitted, says the bulletin, that such a crop is much needed, and considerable attention has, of late, been given to the subject, with the result that Bowstring Hemp may possibly come to be so cultivated. Rhea fibre has also been spoken of as a secondary crop to tea, but Dr. Watt, Reporter on Economic Products to the Government of India, states that there is room for both fibres, that some districts might find Bowstring Hemp more convenient and equally profitable to rhea, and that these are fibres which will meet independent demands and can never enter into competition.

On samples of Indian *Sansevieria* fibre being submitted last year to Mr. T. H. Christy, he valued the stuff at £15 to £17 per ton, but added that had the colour been bright white instead of yellow he would have put down the value at £20 per ton. "This fibre," he remarks, "will sell easily." Mr. C. E. Collyer, Reporter on fibres to the Imperial Institute, states that with the present low market for fibres Bowstring Hemp equal to the Indian samples will not fetch more than £20 per ton in London, but when more carefully prepared and of the usual good strength and colour the value will probably be £25 and upwards. In a subsequent report, Mr. Collyer adds that the quality of the fibre will be much improved by the use of suitable decorticating machines and so far as any fibre has come to market the best results have been from the improved "W. E. Death" machine which turns out about 6 cwt. per day at a cost at least as small as by any other system. Another important remark made by Mr. Collyer is to the effect that soil and climate have much to do with the quality of the fibre as also does the choice of the right variety of *Sansevieria*.

As regards cultivation a note by a West Indian planter is the only information which the bulletin under review records. It appears that the plant grows best in moderate shade in black soil; the propagation is easy from either cutting from stems or from roots; the plants should be about 18" apart, and 18" between the rows; the soil should be moist but not wet; growth is much more rapid under shade than in the hot sun, and the quality of the fibre is better. The plants are said to be ready for cutting in from 9 to 12 months and may be cut at any season, except after a long drought when the

fibre is apt to be harsh and tender. The plants attain nearly double the height in black soil and shade compared with red soil and in the sun and the fibre of the freely growing plants is naturally much superior. Authorities, however, would seem to differ as to the time when the first crop could be taken, some being of opinion that the first crop should not be taken till after 3 years, while others give 12 months as the time. In a communication to the Kew Bulletin, 3,000 plants per acre is given as the rate of planting, that is planting 3' by 3', making allowance for roads, &c. The estimates of crop also naturally differ to some extent. Some authorities say that 40 lb. of fresh leaves 3½ to 4 ft. long give 1 lb. of clean fibre or over 1,600 lb. per acre per crop—two crops being got in a year. Roxburgh estimates the crop obtainable for one acre at 1,613 lb. and that two such crops could be got in a year from good soil in favourable seasons and with plants of the proper age, that is 1½ ton per acre per annum at the end of 3 or 3½ years.

Sansevieria Zeylanica grows luxuriantly in a wild condition in many of the forests in Ceylon from whence it is collected by the natives for such local manufactures as those already referred to. A trial with the plant on stiff soil in the Matale district proved a failure, nor did experiments with this and other varieties of *Sansevieria* on sandy soil and in the open succeed on the premises of the Agricultural School in Colombo—results which go to support the opinion of the West Indian planter recorded above, that the plant affects shady localities and vegetable soils, (conditions which are present in forest lands). The Superintendent of the Agricultural School in 1895 had some rope made out of fibre extracted from *Sansevieria* which was obtained from the Kurunegala district, and submitted a sample for an expert opinion through the Crown Agents for Ceylon. The report of Mr. Thomas Briggs (which was published in the *T. A.* of Oct. 1895) was to the following effect:—"The ropes or better called lines look very well and would sell here as they are if snipped in coils. All these, Nos. 1 and 2 (*Sansevieria Zeylanica* and *Pourroya Gigantea*) are worth about £20 per ton delivered in London."

We have no doubt that some of our enterprising planters will be inclined to give a fair trial to *Sansevieria* as "second fiddle" to tea, after having satisfied themselves by reference to the Director of the Peradeniya Gardens as to the best variety of the plant, from an economic point of view, for cultivation in the lower tea districts.

WYNAAD PLANTERS' ASSOCIATION.

We extract the following from the minutes of a general meeting held at Meppadi Club on March, 3rd:—

COFFEE PASSES.—Read semi-official from the Superintendent of Police Malabar, pointing out how very important it is that passes should be always accurately made out, as the system of passes is a factor in the prevention of Coffee stealing on the road, which planters would do well to make the most of. At present many are inaccurate. Sometimes the signature, sometimes the date or some other important particular is omitted which makes the pass valueless.

OUTTURN OF COFFEE.—Read letter from Capt. Curslake R. N. The Honorary Secretary was instructed to thank Capt. Curslake for his letter, and to point out that Europeans are employed to check the measurement of coffee in the curing yards; and that seamless bags are obtainable through the agents

but the Association think that it is practically impossible to arrive at any fixed standard of moisture in coffee applicable to Wynaad, the Coast and London.

THE QUEEN'S JUBILEE.—Read circular proposing the presentation of an address to Her Majesty by the U. P. A. S. I. & draft of the same. Cordially approved.

COFFEE ASSOCIATION.—Read circular on the proposed formation of an Association to promote the sale of coffee. Recorded.

NEW MEMBER.—Mr. J. W. Handiy was elected a member of the Association.

THE UNION ESTATES COMPANY OF CEYLON, LIMITED.

The annual ordinary general meeting of the above Company was held at the Company's Offices, No. 7 Queen Street, Fort, Colombo, at 1 p.m. on Saturday, 27th March, 1897.

The Directors' report was as follows:—

		ACREAGE.					
		Tea in partial bearing.	Tea in full bearing.	Tea not in bearing.	Cocoa.	Total Cultivated.	Grass, Jungle & Waste land.
Hayes and Gongalla	508	9	8	—	525	1,254	1,779
Dea Ella	189	50	—	70	309	177	486
	697	59	8	70	834	2,431	1,265

(On Dea Ella 260 acres of tea are interspersed with coconuts.)

The Directors have now the pleasure to submit to the shareholders the accounts of the Company for the past year.

The tea crops considerably exceeded expectations, having amounted to 305,092 lb. against the estimate of 265,000 lb. At date accounts have still to be received from London in connection with the sale of 33,545 lb. Hayes Estate Tea upon which a reasonable estimate of value has been placed. The 271,547 lb. for which account sales have been rendered have realized a net average of 37½ cents per lb.

The cocoa crop amounted to cwt. 52.0 18, which realized only a net average price of R31.82 per cwt.

The cost of delivering the crops into Colombo amounted to R89,820.30 against the estimate of R87,065. The excess of expenditure over estimate, is fully accounted for by the additional crop secured.

After making ample provision for depreciation of Buildings and Machinery, the result of the year's working, including a small balance from 1895, shews a sum available for distribution of R23,014.09. The Directors recommend a dividend of 7 per cent for the year, which will absorb R22,400, and leave a balance of R614.09 to be carried forward.

The question of improving the transport facilities to and from the Estates has engaged much of the attention of the Directors. Work on the Grant-in-Aid road from Denyaya to Anningkaude is progressing, and it is hoped that this section will be finished about June. The Directors have joined in an application to further extend this road from Anning-

CHAFED SKIN, PILES, SCALDS, BRUISES, CUTS, STINGS, NEURALGIC and RHEUMATIC PAINS, SORE EYES, EAR-ACHE, THROAT COLDS, and SKIN AILMENTS quickly relieved by use of **CALVERT'S CARBOLIC OINTMENT.** Large Pots 13½d. each (English rate). Sold at Chemists, Stores, &c.

F. C. CALVERT & CO., Manchester.

kande to Hayes Factory, and it is hoped that work on this section will soon be commenced. So far the application made for the improvement of the Dea Ella outlet has not been acceded to, but the matter has again been brought to the notice of Government.

The crops estimated for 1897 are 307,550 lb. tea and 70 cwt. cocoa, and the expenditure on working account is estimated at R93,388, which includes cost of manufacturing 26,000 lb. tea for a neighbouring estate. The outlay on capital account is not yet estimated, as it depends largely on the continuation of the road to Hayes.

Mr. G. W. Carlyon having resigned his seat on the Board on leaving the Island, Mr. Alex. Thomson was appointed to fill the vacancy. Mr. W. D. Gibbon retires by rotation and is eligible for re-election. Mr. Chas. Young has retired from the Board, which vacancy it rests with the meeting to deal with.

An Auditor has to be appointed for the current year.—By order of the Directors.

WHITTALL & Co.,
Agents & Secretaries.

Colombo, 15th March, 1897.

GOW, WILSON & STANTON'S INDIAN AND CEYLON TEA SHARE REPORT.

London, E.C., 10th March, 1897.

The uneasiness generally felt in regard to European politics naturally tends to curtail investment business, and inquiries for shares have consequently been limited. Holders, however, have shown but little desire to part with their securities except at previous quotations, but in cases where prices were slightly reduced, investors have generally come forward to absorb anything offered.

The Indian market has been very strong during the past fortnight, and owing to the scarcity of low price grades, considerably better rates have been obtainable for these, while the good useful quality of the autumn crop is proving a source of revenue to the tea gardens, owing to the high prices ruling for this class of tea. Not much of the season's crop now remains to be disposed of, and the recognition of this fact has no doubt assisted to raise quotations in the market.

The Ceylon tea market has shown an advance during the fortnight, and the average price has recently somewhat improved. All the lower grades of whole leaf tea are in strong demand at improved quotations.

Dividends.—Associated Tea Estates Co., an Interim of 3 per cent on both preference and ordinary. The Leesh River Co. have declared a dividend of 6 per cent for the year, 1896.

PLANTING IN NYASSALAND.—We are indebted to Mr. J. W. Moir, a well-known pioneer planter on the Shire Highlands, B. C. Africa, for the following corrections and interesting information; the Map referred to is the one appended to the latest Report of Commissioner Johnston and which we reviewed in the T.A. Mr. Moir writes:—

"It is pleasant to know you take so much interest in our districts. There are some very funny things about Sir H. Johnston's Map. Five of my estates are missed out altogether of 14,000 or 13,000 acres. One (surveyed) is at Chiromo, and so perhaps more or less out of the Map, one is certainly not surveyed yet. But two that were surveyed at the very same time as several others which are mapped, are not in. And the Pioneer estate, opened by H. Brown is likewise left out; why, I cannot say.

"I daresay you would see that some of our coffee (mine) fetched up to 10s 6d for peas; and 9s for flats; but this was rather overdried, as I found on making careful experiments and weighings in London lately. So it had lost a little colour. We shall do better yet. Things promise better for the future."

COLOMBO PRICE CURRENT.

(Furnished by the Chamber of Commerce).

Colombo, Mar. 30th, 1897.

EXCHANGE ON LONDON: CLOSING RATES, Bank Selling Rates:—On demand 1/3 1-16; 4 months' sight 1/3 3-32; 6 months' sight 1/3 1/4. Bank Buying Rates:—Credits 3 months' sight 1/3 1/4; 6 months' sight 1/3 5-16. Deots 3 months' sight 1/3 9-32; 6 months' sight 1/3 11-32.

THE AGRICULTURAL MAGAZINE, COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for April:—

Vol. VIII.]

APRIL, 1897.

[No. 10.]

SEASON REPORTS FOR FEBRUARY.

WESTERN PROVINCE.—Paddy. Maha harvest over, and preparations going on for Yala sowing. Fruits scarce, vegetable supply good except in Negombo district. Rainfall light. Maha crops good.

Central Province.—Paddy. Maha crop being harvested or nearing maturity, except in Uda Hewabeta and Walapane, where cultivation has just commenced. Prospects good except in Uda Bulatgama. Dry grain crops good or fair, but not satisfactory in Matale owing to damage by rain.

Northern Province.—Paddy. Kalapokam 1897 harvested, crop good in Mannar, somewhat damaged by rain in Jaffna and Mullaittivu. Cattle murrain still prevailing in Tunnkkai.

Southern Province.—Paddy. Maha harvest on, and preparations going on for yala, crops fair. Fruits and vegetables scarce.

Eastern Province.—Paddy. Munmari crops harvested, outturn good except in some places where damage was done by floods of the previous months.

North-Western Province.—Paddy. Maha crop in various stages but harvested in many parts, yield and prospects generally good.

North-Central Province.—Paddy. Crop in various stages, but a good harvest is anticipated. A few occasional cases of murrain in Kalagam palata.

Province of Uva.—Paddy. Yala crop gathered, yield good. Cultivation for maha commenced. Fruits and vegetables plentiful and cheap. A few cases of cattle murrain in Kendagolla village.

Province of Sabaragamuwa.—Paddy. Maha harvest good both in the Ratnapura and Kegalle districts. Dry grain crops satisfactory except in Kadawata and Meda Korales owing to drought.

GREEN MANURING AND MIXED CROPPING.

Mr. Ewart of Atchencoil, Shencotta, in writing to us says:—"It may interest you to know that Dadap loppings have been tried as green manure, and the result has been an increase of some 30 per cent in paddy." This is the *Erythrina lithosperma* used together with *E. indica* (erabadu) as shade for

cocoa in Ceylon plantations. We have heard of the foliage of the latter—a common native hedge plant—being used for green manure in parts of the Island, as well as the leaves of Keppitiya (*Croton lacciferum*), *Tephrosia tinctoria* (pila), *Callicarpa lanata* (illa) and other trees. In India, plants that contain a milky juice such as *Calotropis gigantea* (wara) and the milk hedge (*Euphorbia tirucalli*) are specially preferred by the ryot, but besides these various other plants are favourite manures. The following are among those which are most generally employed in India, or are supposed by the natives to have some special manurial value: *Adhatoda vasica* (Adathoda), *Calotropis gigantea* (wara), *Cassia auriculata* (Ranawara), species of *Datura*, *Dodonaea viscosa* (Eta werala), *Indigofera paucifolia*, *Jatropha curcas* (Rata endaru), *Melia azadirach*, *Mirabilis jalapa* (Sendrika), *Ocimum sanctum* (Maduru Tala), *Pongamia glabra* (magul karunda). In parts of India *Adhatoda vasica* is largely used as a vegetable manure for paddy-fields, and it is believed to possess the property of destroying low forms of aquatic vegetation as well as of protecting crops against insect attack. It would appear that a number of the so-called green leaf manures in use are selected for certain properties they possess which are inimical to insect life. Apart from their action as fertilizers, green crop manures are valuable agents in improving the mechanical condition of both clayey and sandy soils, and we believe that by a judicious selection of green crops and leaves, the village cultivator will be in a position to materially improve his land and increase the yield of his crops. The reference to the result of green leaf manure with which this note opens only goes to prove this latter fact. In the light of our present knowledge of the mode of nutrition of leguminous crops, we would advisedly look for our green crop fertilizers among the members of this order of plants—to which erabadu, dadap, illa, pila, indigo, ranawara, and magul karunda (the plants already referred as being commonly used for the purpose) belong. So far the cultivator has had to base his choice on his own experience and that of previous generations. He will now be able to add to his list of green leaf manures by further additions from the leguminosæ.

In this connection we would make reference to the benefits of mixed cropping, not carried out in the slip-shod manner which we find our cultivators adopting in their chenas, but regularly and in order, as it should be. The Superintendent of the Poona Farm has been experimenting with Dhall (*Cajanus indicus*) as a nursing and foraging plant for cereal and fodder crops. It is advised that dhall should be planted four feet apart and the principal crop grown in rows between it. Dhall occupies the land about eight months; it has enormous root development and resists drought in a remarkable degree. Its long tap roots penetrate the soil and collect plant food there. All the leaves fall as the crop ripens, and these litter enriches the surface soil, while the roots enrich the soil with nitrogen got from the atmosphere. These characters place Dhall in the forefront as a rotation crop and as one of the plants that should be chosen for mixed cropping, par-

ticularly in cereal cultivation, whether for grain or fodder. The *Indian Agriculturist*, referring to the Poona experiments, truly remarks that leguminous crops of the papilionaceous sub-order are the best to rotate with cereals, because through the influence of bacteria existing in the tubercles on the roots of these pulse crops, free nitrogen is taken from the atmosphere and converted into an organic compound of nitrogen. This combined or organic nitrogen becomes available as plant-food as the root residues of leguminous crops decay in the soil. "The growth of leguminous crops with cereals in rotation, or, as is more common in India, as a mixed crop", says our Indian contemporary, "has probably done more to raise the fertility of Indian soils than any other cause." It is a fact that many of the papilionaceæ are not only useful as rotation or mixed crops, but also provide excellent green fodder for milch or other cattle.

We believe that much good can be done by teaching cultivators how to make use of green leaf and crop manures, to the best advantage and persuade them to adopt an approved system of mixed cropping in their chenas, using such a fertilizing crop as dhall, which, at the same time, will add materially to the poor stock of food at the disposal of the villager in the remoter parts of the Island.

OCCASIONAL NOTES.

Mr. Menon, of the College of Agriculture, Saldapet, and at one time connected with the Colombo School of Agriculture, paid us a visit last month on his way back from England to India. Mr. Menon has been spending some two years at the principal agricultural centres in Great Britain and on the Continent, and has derived a deal of valuable experience thereby.

The students composing the new Forestry class are Messrs. Fontyn, Karunaratne, H. S. Dias, R. de Silva, L. Mendis and M. A. Fernando. The work of the class commenced on the 1st prox.

Preparations are in progress for a trial with imported varieties of Indian paddies. The ploughing which is now going on is being done with a light iron plough made locally.

The "Green Bank" dairy in Jail Road which was started a month ago on a small scale is, we hear, being gradually extended. The increase in the number of better class dairies goes to prove that there is a rising demand for good milk in the city, and also that dairying if intelligently carried on is a remunerative industry.

DR. KOCH'S INVESTIGATIONS INTO THE CAUSE OF RINDERPEST.

INTRODUCTORY.

The Agricultural and Veterinary Journals are largely occupied with the subject of rinderpest which has been once again brought prominently into notice by the devastation that the plague has caused in South Africa. It will be remem-

bered that the Cape Government engaged the services of Dr. Koch, the eminent Berlin scientist, to study the plague on the spot with a view to discovering a preventative and cure for the disease. Dr. Koch established his laboratory and experimental station at Kimberley, and his two preliminary reports have already been published in full. With us, outbreaks of rinderpest are a common experience, and every year sees large numbers of cattle carried away, so that the position of the native cultivator becomes more or more difficult, and he is not merely left poorer by the loss of his stock, but also by the crippling of his resources in the cultivation of his land: for how often may not the remark of the Government Agent of the North-Central Province in the January Season Reports be repeated as to other parts of the Island: "The severe murrain of last year causes great scarcity of buffaloes for agricultural work"? And yet, what has been done in the way of dealing with the scourge? Where is the activity that should characterize the efforts to cope with the plague? Any enquiry into the possibility of discovering a preventative and cure for rinderpest is of such importance and so nearly concerns us, that we make no apology for suppressing a good deal of the matter that should have occupied the pages of the present number, and devoting a great part of this issue of the Magazine to the reports on the investigations referred to: and we have no doubt that most of our readers will be thankful for the information which we are able to afford them. It is said that the Royal Society has also taken up the enquiry, so that there will be no lack of talent among the scientific workers who will be associated in the search for a remedy for the plague. We must, however, not forget to give the credit that is due to those who have already done so much good work within the last few years in examining into the cause of rinderpest, viz. Dr. Edington, Veterinary Surgeon Hutcheon, and Dr. Simpson, the Health Officer of Calcutta. We should mention that we are indebted to the official Agricultural Journal of Cape Town for the text of Dr. Koch's reports.

DR. KOCH'S FIRST REPORT.

Dr. Koch's first report, dated Kimberley, December 9th, 1896, is of a preliminary character and does not deal with his own investigations. He states there that he put himself in communication with Doctors Turner and Edington and Veterinary Surgeon Hutcheon, and refers to his visit to the research station of Dr. Edington situated at Taungs. The following is his description of his experience in his own words:—

"Having arrived there on the morning of the 6th (December 1896), I visited the laboratory and saw the arrangements made, its experimental animals, prepared specimens and cultivations. Of the animals, one had died during the night of 5th to 6th, according to Dr. Edington's statement 23 days after having contracted rinderpest, and two more were sick. The autopsy which was made soon afterwards by Mr. Robertson showed that it had succumbed most probably to a secondary infection, starting in the tonsils.

A short time after this *post-mortem* examination was finished, at 12-30 p.m., one of the two animals that were sick died. This one was also immediately dissected by Mr. Robertson. This

examination revealed the characteristic lesions of rinderpest in a comparatively early stage. Of both these animals dissected blood, mucus, and pieces of the internal organs were collected and preserved, partly moist and partly dry. In the afternoon we inspected five head of cattle, which in the meantime were brought from Kafir kraals lying westward from the railway-station at Taungs. One of these appeared to be recently attacked. After having purchased the same we withdrew from its left jugular vein a fair amount of blood for experimental purposes.

On the 7th inst. I drove with my companions to the town of Taungs, where I was told I would find a large number of diseased cattle. However, I did not see one beast in the town, as all the cattle were driven by the inhabitants into the mountains. Government Veterinary Surgeon Soga informed me that the people living in Taungs had lost already 20,000 head of cattle from the pest, and thought to save the remainder best by driving them far away. I consequently returned at once to Dr. Edington's experimental station. The animal which we had brought the day before was then killed and dissected. The organs showed the characteristic appearances of rinderpest. From this animal material for examination and infective purposes was likewise taken. After having seen some more cases in an advanced state of rinderpest, and having obtained mucus from a newly-diseased animal, I returned during the night from the 7th to the 8th to Kimberley, accompanied by Drs. Turner and Kohlstock, and Mr. Henning.

Twenty head of cattle, twenty sheep, and twenty goats were in the meantime purchased. Of this number eight head of cattle were infected with the material brought from Taungs in such a manner that small sponges soaked in infected liquid were put into the nostrils, and then also the muzzle was painted over with the same sponge. To watch the animals and to superintend the persons employed in connection with the animals, Mr. Henning remained in the compound, and will continue to stay there for the time being.

From what I have seen till now of the cattle plague in the Cape Colony, I have no hesitation to say that the disease is the genuine rinderpest. With reference to the micro-organisms found and cultivated by Dr. Edington, I could hitherto not arrive at any definite conclusion. The infection trials performed with these cultivations appear to me not demonstrative, and I must consequently reserve my opinion concerning them until I have personally carried out experiments with them."

DR. KOCH'S SECOND REPORT.

The 2nd report, dated Kimberly, January 3rd, 1897, after detailing the arrangements made for laboratory work and microscopical examination, proceeds:

"Of the small experimental animals, sheep and goats are sheltered underneath the verandah along the stables, and two dogs are tied to poles underneath the verandah along the rear wall of the house. Birds, rabbits, mice, guinea pigs and pigs are housed in cages standing partly alongside the stable walls, and partly in open sheds. In the latter is also fastened a donkey and a mule, of which the former is only used for ex-

periments, while the latter serves at the same time for drawing the trucks and the trolley, upon which the dung and the carcasses of animals are carried away."

The report here goes on to indicate the precautionary measures enforced to keep all animals which have recovered from rinderpest quite apart from those to be operated on and those which are being experimented with, so as to avoid the possibility of spontaneous infection. The method of work in taking temperatures and other details are carried out in such a way that "we consider any chance of transferring the pest impossible."

On the 22nd December Dr. Koch visited Tafel Kop Farm, in the Orange Free State, where he saw 23 out of a herd of 120 animals in various stages of rinderpest. From the diseased animals he gathered mucus which was dripping from the nose and mouth, and also some bile and blood from two which were previously slaughtered. In addition to this, specimens of organs were collected for microscopical examination and inoculation purposes.

On the 29th another visit was paid to two farms, at one of which 33 out of a herd of 66 had already succumbed, and at another where 40 out of a herd of 140 had been carried off. At both places the living cattle showed in various stages of the disease. From a beast which had shortly before expired, specimens of blood were taken for examination. "Besides the materials for scientific research, both these visits afforded an interesting study of the nature, manner of spreading, and course of rinderpest."

"Our inoculation experiments performed hitherto had so far chiefly the object in view to discover an efficient method of transmitting the scourge of healthy animals, as the modes formerly in vogue cannot be considered satisfactory in this respect. They consisted in rubbing into the nostrils or bringing into the subcutis by means of setoning needles excretions from the diseased animal's body, such as slime running from the nose, the watery discharges from the eyes, and even evacuations from the intestinal canal. In doing so, the result was either uncertain in its consequences or the disease was from the start complicated with sepsis through being introduced into the system septic matter. The correctness of this assumption was also corroborated in my own experiments. As mentioned already in my previous report, we at first put the infective material in the nose and upon the mucus membrane of the mouth. The effect of this was that of eight animals treated in this way with material from Taungs, only one, that afterwards became the starting point for a whole series of experiments, contracted the disease. Of the second batch of animals, three in number, infected with slime from Tafel Kop, likewise only one took the pest. Taking into consideration the experience gathered in former epidemic outbreaks of rinderpest, it occurred to me that a *modus operandi* superior in every respect would be to inject blood hypodermically. For when blood is taken during the earlier stages of rinderpest, it does not contain any septic matter, but simply the contagion of rinderpest. This supposition has as yet shown itself perfectly justifiable. We have inoculated in the dewlap five animals with defibrinated

blood, and they contracted the disease without exception after a period of incubation lasting from three to five days. Four of these animals have already succumbed, showing at the autopsy all appearances of rinderpest. One of them recovered after having been very ill, and will be utilised for immunisation experiments.

I purpose in making such successive injections of blood from one animal to another to get a series of infections, which will always supply me with fresh materials for examination. We think it best to have two such series, viz., one with material from Taungs, and another one with such brought from Tafel Kop. To make these experiments not too expensive we shall in each series only infect one animal at a time.

Experiments were also made with bile, which was taken from animals that had succumbed to rinderpest, and which we injected in the subcutaneous tissue. The motive for so doing was because a mixture of bile with blood or other liquids was said to be sometimes used by Free State farmers, and also the circumstance that in the bile of most of the cases examined I have found in pure cultivation a bacterium, which according to the description published is conformable with the microbe discovered by Dr. Simpson in Calcutta, and declared to be the cause of rinderpest. All these experiments with bile, however, had negative results.

We are consequently justified in saying that bile does not contain the contagion of rinderpest, and that Simpson's bacteria cannot be considered to be the microbe of rinderpest. All efforts to find by means of the microscope, as well as through cultivation, a specific micro-organism in the blood, have as yet proved fruitless. I also did not succeed in finding any specific micro-organism amongst the microbes which the mucus from the nose, the secretions from other mucus membranes, and the contents of the intestines naturally contain in large numbers. My examinations having the discovery of the origin of rinderpest in view, will naturally be continued, but the greatest stress must be put upon finding a process by which we are able so to attenuate the virus of rinderpest that we may use it as a preventive. With this object in view, we have inoculated other animals less susceptible to rinderpest, first of all sheep and goats. This was done on the 14th December when one Cape sheep, one Merino sheep, one Angora, and one Cape goat were inoculated with rinderpest blood. These animals did not show any marked symptoms afterwards, but they all suffered after a period of incubation extending two or three days from a rise of temperature identical with that of rinderpest. A second inoculation made on the 7th December with one goat, one Angora, one Merino, and one Cape sheep, had the same effect. Having thus proved that by injecting rinderpest blood a sort of mitigated rinderpest can be produced in the animals mentioned, we infected in second generation on the 24th of December two more goats, Angoras, Merinos, and Cape sheep. The rise of temperature seen also in these animals demonstrates that it is possible to propagate this attenuated rinderpest within the system of sheep and goats. After one or two further generations I shall try to re-transfer this attenuated rinder-

pest contagion to healthy cattle. Similar experiments we are just making, or intend soon to carry out, on antelopes, pigs, asses, mules and dogs.

I further propose to study the susceptibility for rinderpest of as many animals as possible that are suspected in this country to contract the disease or to assist in spreading it. I would in this respect recommend that camels also should be procured, in order to definitely decide upon their immunity against rinderpest or otherwise. Apart from all this, we shall further try if by some other means, viz., through chemical or physical influences, rinderpest blood cannot be rendered useful for preventive measures, that is to say, may be turned into a vaccine.

An opportunity to test carefully the remedies and modes of inoculation in vogue in South Africa against the disease has not yet offered itself, but I shall after a time inoculate with a virulent material those animals which were first treated with bile, in order to see if rinderpest bile has any protective properties or not.

On one of our visits to the Free State I observed that all animals on the farm were inoculated as a preventive with garlic or "knoflook" into the dewlap, but this procedure had evidently no beneficial result. On another farm the owner had drenched his cattle with a mixture of carbolic and petroleum, but this likewise proved futile.

On the other hand, however, every one who had the opportunity of becoming acquainted with the state of affairs along the Free State border in the district of Kimberley, will not hesitate in asserting that the restrictions enforced along this line have fulfilled their purpose. On one side of the boundary there have been for weeks several farms badly visited by rinderpest, and yet the Colonial one is still entirely free from the scourge.

With reference to the rinderpest microbe found by Dr. Edington, I beg to report to you that Dr. Edington has handed to me on the 28th ultimo a cultivation grown in bouillon, from which he inoculated in my presence two test tubes containing the same medium. Having convinced myself that the culture had been growing in the latter pure and opulent, I inoculated on the 31st ultimo with either of these cultivations one healthy beast, and shall report to you in due time what effect this operation had upon these animals.

I would further like to direct your attention to the circumstance that one of the three animals, the autopsy of which was made in Tamngs, was suffering from Texas fever, as we found on the next day when examining the blood. In order to avoid, when making such experiments, any errors that could happen through the disease being combined with Texas fever, we make it a point to examine microscopically the blood of all animals which we use for infective purposes. Potter.

Concerning our South African rinderpest, we have noticed that the symptoms in some respects differ somewhat from the descriptions given by other observers. We have, for instance, found that the escaethema and diphtheritic-like changes on the mucous membrane of the mouth and on the palate are but little marked, whilst the early pathological lesions in the intestines are rather considerable. Thus we have seen thrice amongst ten *post-mortem* examinations fibrinous bloody excretions of the walls of the intestinal tube.

The latter has produced coherent masses about a yard long, which formed a sausage-like complete cast of the walls of the intestines, and surrounded a small canal filled with excrement of a thin fluid nature. The masses mentioned consisted of detached epithelium of the digestive tract, a firm fibrine-like substance and blood.

What may be the reason of this difference, whether climatic influence or the peculiar breed of cattle, I am at present unable to decide. In all other points, however, the symptoms of the disease do so completely agree with the genuine rinderpest that their identity cannot be doubted.

The observations made during the last English epidemic by Burdon-Sanderson, viz., that the beginning of the pest can be recognised by an elevation of temperature several days before other symptoms are manifest, we could confirm in every single case that came under our notice at the Experimental Station. This is a fact of utmost importance not only for experimental research but also for practice, as thus the advent of the disease can be detected already at such a time when no infectious discharges are evacuated and the animal is not yet able to spread the pest."

ARECANUT CULTIVATION IN INDIA.

(Continued.)

IN THANA.—The betel-nut is grown largely in Thana, Bombay. The best nuts are carefully selected in October and dried in the sun; unhusked nuts are considered best for seed. They are planted in a well-ploughed plot of land in pits three inches wide and three inches deep, and at a distance apart of from six inches to a foot. For the first three months the young palm is watered at least every fourth day and afterwards every third day. When the plants are a year or a year and a half old they are fit for planting out.

The selling price of young plants varies from 6 pies to 1 anna.

The betel palm usually grows in red soil, but it flourishes best in sandy soil that remains moist for some time after the rains. Before planting the young palm, the ground is ploughed, levelled, and weeded, and a water channel is dug six inches deep and a foot and a half wide. Then pits nine inches deep and two feet wide are dug at least four feet apart, nearly full of earth, but not quite full, so that water may lie in them where the soil allows; plantains are grown in the beds to shade the young palms. Except during the rainy season, when water is not wanted, the young trees are watered every second day for the first five years and after that every third or fourth day. During the rains manure is sometimes given.

The cost of betel-nut cultivation in Thana is calculated as follows: An acre entirely given to betel palms would, it is estimated, hold 1,000 trees. The total cost of rearing 1,000 betel palms for five years—that is, until they begin to yield—is about £127 13s., including compound interest at 9 per cent. After 5 years a thousand trees are estimated to yield about £50 a year, from which, after taking £18 4s. for watering assessment and wages and £11 9s. 11½d. as interest at the rate of 9 per cent on £127 13s., there remains a net estimated profit of £19 16s. 3½d. or 15·52 per cent.

IN BENGAL.—The supari or betel-nut is common in Eastern Bengal, especially in Tipperah, Backergunge, and Dacca; and its cultivation is very profitable to proprietors of land. It bears fruit in the eighth year, and is most productive from that time to the sixteenth year, when the produce falls off. The nuts are gathered in November.

Betel-nut cultivation is very extensive, especially in the Police circles of Tubkibagara and Hajiganj. A considerable trade in this article is carried on with Dacca, Narainganj, and Calcutta. The cultivators of the palm usually own a large piece of ground, slightly raised above the level of the surrounding country, and surrounded by ditches. In the centre of this they build their dwellings, and all round then they plant betel-nut trees. An acre of land will obtain about 3,000 trees. When first planted the betel-nut requires to be protected from the sun; for this purpose rows of madar trees are planted between the lines of betel-nut trees, and the growth of jungle is encouraged. When the betel-nut trees have grown strong, and no longer require the shade, the cultivators are too lazy and thoughtless to remove the jungle; and the result is that whole parganas which were once fully cultivated are now covered with dense jungle, in which even the betel-nut trees cannot grow; while thousands of the inhabitants have been swept away by cholera and malarious fever of a very virulent type. The unhealthiness of the neighbourhood of betel-nut plantations is variously attributed to the dense jungle and undergrowth above-mentioned, to the exhalations from the trees, and to the malarious gases generated by decomposing vegetable matter in the ditches surrounding the plantations. The betel-nut trees grow to a height of about 60 feet; and in some parganas they are cultivated to such an extent as to almost entirely exclude rice cultivation.

THE RELATION OF MODERN SCIENCE TO AGRICULTURE.

This is the subject of a brilliant address delivered at the University of Aberdeen by Professor Hendrick. The professor, says an English exchange, "clearly set forth the ground on which he stands as a teacher of science related to agriculture, and no one can possibly disagree with the claims urged on behalf of scientific teaching. He has not claimed too much, nor yet has he claimed too little." The address, which has been fully reported, is far too long to be quoted in our limited columns, but we cannot forbear making copious extracts from it, in the hope that it might bring conviction, as regards the importance and usefulness of modern agricultural teaching, to the minds of the conservative and sceptical who are always ready to sneer at technical education in agriculture and to cripple its power for good.

Professor Hendrick's opening remarks were as follows:—

"In coming for the first time publicly before an Aberdeen audience, and as—I think I am right in saying—the first lecturer in agricultural chemistry in this ancient university, it seemed to methat

there are many subjects on which I might address you. But when I reflected that there are, unfortunately, still in our country those—and they are not confined to agriculture—who look upon science as essentially opposed to practice and on what is scientific, and as it is often sneeringly called *theoretical*, as by its very nature opposed to what is practical, it seemed to me that I could not do better than come forward at once and treat the general question of the relations of modern science to agriculture. This university, in common with most of the universities and university colleges of Britain, has recently made a new departure in organising in her faculty of science a department of agriculture. All over the country we have been hearing a cry, voiced with greater or less wisdom and enlightenment, for agricultural teaching of all grades—from that of elementary schools to that of universities. I hope to show you, if you will bear with me so long, that there is only too good justification for this cry, and that our universities and colleges are not a moment too soon in responding to it. Indeed, I may at the very outset state to you my main contention. Science has in this nineteenth century already revolutionised agriculture, and brought about an unprecedented state of affairs for that most ancient industry. And I maintain that it is not only important, but of fundamental importance, that the rising generation in agriculture who are going forward to face the twentieth century should be equipped with all the weapons which our science, which our modern knowledge can give them. I also maintain that it is our duty to raise up a body of trained agricultural investigators to extend and improve our knowledge, and to provide a suitable field and means of inquiry for these.

It is not my place to deal with economic questions relating to the altered state of agriculture. I am not here to deal with systems of land tenure or their improvement, with land banks and improved systems of agricultural credit, with improvements in carrying and marketing systems, or with any of the other instruments for adjusting ourselves to altered conditions brought about and rendered possible by the advance of knowledge. But below all these, of greater and more fundamental importance than any of them, is the advance of that knowledge, the increase and spread of that science, which has not only altered all the relations of agriculture, but has revolutionised all industry, and, indeed, changed the whole outward appearance of modern society. With this it is my duty to deal. If, gentlemen, I had the presumption on this my first appearance before you to preach you a sermon, ancient wisdom would readily supply me with a text. I might preach to modern agriculture what Solomon preached long ago:—"There is gold and a multitude of rubies; but the lips of knowledge are a precious jewel.

Some three or four centuries ago philosophers began to leave the medieval method of basing all their knowledge on ancient authority, and boldly set out to examine and question Nature for themselves. For long most of the knowledge gained was what the practical man would call useless. Fortunately, however, when very little so-called practical results were gained, there were always men with sufficient enthusiasm to pursue knowledge for its own sake. So, through long years,

knowledge was added to knowledge, and theory to theory, till modern science, which had been slowly growing for two centuries, burst into full bloom, and that fruit-bearing from which we are profiting in this century was made possible. We know more than our ancestors, and ancient wisdom tells us that it is the part of the wise man, and, I may add, of the wise nation, to increase knowledge and understanding."

* * * *

"I have roughly sketched, then, the altered conditions in which the progress of the world has placed agriculture. The new conditions require, of course, new methods. It is useless to fight a modern army with spears and bows, no matter how skilful we may be."

* * * *

"Science has armed the farmer with weapons of precision which place him as much ahead of his predecessors as the soldier of today is in his equipment ahead of the soldier of Waterloo.

It is not enough to put in the hands of a body, even of the most able and intelligent men, modern weapons to make them a modern army.

They must have organized training in the principles of their use. They must be organised and drilled, and beyond them there must be specialists who are constantly active in increasing all knowledge which can add to the effectiveness of their methods of offence and defence. So it is in the army of our agricultural industry. We are in the midst of a great struggle. In the twentieth century they will command the market who are not only good men with good weapons, but who are well educated and well organised, and who have a good scientific staff behind them to constantly improve their knowledge and their weapons. We cannot yet set any limit to the fierce competition for our markets, because we cannot yet set any limit to the development of new countries, to the development of improved machinery and methods, and to the development of the carrying industries of the world."

Professor Hendrick then went on to refer to Technical Education, and what the various Governments are doing in equipping the people from the armoury of science, and in promoting and increasing that purely theoretical knowledge which supplies the raw material to make new weapons; a work in which every country which claims modern civilization—from Germany to Japan and round the world home again by way of the United States and Canada—is engaged, by organizing the education of the agriculturist.

He proceeds next to refer to the cry for something which is 'practical,' and remarks "but I am not quite sure that what we call practical does not very often consist in making the roof before we have laid the foundations."

* * * *

"The demand is all for something practical, which the practical man can understand. That means for the demonstration and development of principles already so well established that they are fit to be brought into relation with practical life. This is extremely useful work, and you will mistake my meaning if you suppose I am questioning its usefulness. But it is not the highest work.

Really new knowledge cannot, on account of its very newness, be known to, or, in most cases, appreciated by, those engaged in practical life until it has been so established and its relations with other knowledge so determined that it is fit to be brought into relations with practical life. This always means the work of years, often of a lifetime. Still, such knowledge is the very source and mainspring of advance. It is the highest kind of knowledge. It is the knowledge which research stations and our highest teaching institutions, our universities, ought to increase and spread. It is the foundation on which our whole system of technical education should rest. This is accepted as past the need of demonstration in Germany and France. Tyndal preached it eloquently in America a quarter of a century ago. America has been acting on his advice."

"Gentlemen, I fear I am risking your displeasure in speaking in this way before practical men, but I have almost got to hate the very words 'technical and practical education,' on account of the utterly wrong idea so often bound up in them in this country. By all means let us have technical education—let us have agricultural education; but let them be really practical. Let them begin by teaching principles and theories on which the practice rests, and leave alone that which can be better trained in practice to practice. 'What is the use of chemistry?' says the practical man. 'I have no time to waste with that. I want something practical.' So we constantly get students who want to come directly to learn agricultural chemistry before they have learned anything of the principles of chemistry itself. They want to learn the applications of a science before they have mastered its elements. I am not here to teach practical agriculture, but I am here to teach the principles, the theories as applied to agriculture of one of the sciences which lie at the foundation of agriculture and of all industry. The difference between the new and the old education is not that, whereas a boy once learnt agriculture on a farm, now he will learn it in a school or college. Not at all! Modern conditions require that we should arm our agriculturists, and especially those who occupy any position of leading in agriculture, with knowledge of the scientific principles which underlie their art, but that does not excuse them from the necessity of learning their art even as their forefathers did. There is something added on. Modern conditions give a man a greater productive power, but they also demand of him a greater training. Education cannot make a practical man, and knowledge cannot make a wise man. But, to the practical man and to the wise man knowledge of principles and the trained mind are an inestimable advantage."

"I am afraid the mere use of the words science and scientific produces a prejudice in many minds against those things in connection with which they are used. Still more dreadful is it to use those awful words theory and theoretical, which are supposed to denote the very opposite of what is good and useful. It is very unfortunate that, like so many words, these words have various meanings which, though connected with one another, express very different things. The words science and scientific I need not defend. Though there is much science, falsely so-called, science

means merely exact knowledge—knowledge reduced to a system. But what have I to say for theory? Well, what is a theory? The word, unfortunately, has a loose and degraded meaning—a bad meaning—as well as the strict and good meaning in which it is used in science. In its bad meaning, which is not very definite, but has various shades of badness, it stands for a useless or groundless speculation which leads nowhere, and which is not tested by facts or practice. But that is not the sense in which we use it in science. I am inclined to think in this sense the non-scientific man is a greater theorist than the scientific. This is the very antithesis of what is scientific. The very first lesson of science is never to theorise in this sense.

So soon as we have accumulated a mass of facts in any branch of knowledge, the mind naturally seeks an explanation of them. It seeks to group them together, to systematise them by some great common circumstance or cause which produces them. In fact, it forms a theory. It may be a wrong theory, but at least it is based on facts, which it attempts to explain.

But all the history of science shows that a wrong theory is often an approximation to the truth, or contains some germs of truth in it. A scientific theory, then, must not only be an explanation of fact, but it must not be inconsistent with any known fact. It must be able to fit in with and explain everything known which is connected with it. If it does not, it must be modified or rejected. Scientific theory is therefore a most useful thing. It is a most practical thing. Not only does the clashing of rival theories when we are at the stage before we have arrived at an accepted theory—always lead to investigation and inquiry on the part of their advocates, each anxious to discover everything which can favour his point of view and hence lead to great extension of knowledge, but when we have arrived at a correct theory we are placed in a position of great advantage. We now have an explanation of certain facts of Nature. Hence we are so far in a position to use and control Nature for our benefit, because we now understand her working. But further, and still more important, we never arrive at a true theory without it leading to developments, often in the most unexpected directions. We can never arrive at the explanation of any one set of facts without it throwing light on a host of others. There is no department of natural study so small and mean that the acquisition of a true theory regarding it will not improve the outlook of all human knowledge. Some of you may know how beautifully Tennyson put this thought in the poetical words:—"Flower in the crannied wall, I pluck you out of the crannies; I hold you here, root and all, in my hand, little flower—but if I could understand what you are, root and all, and all in all, I should know what God and man is." We see, then, that a real theory is the most practical of things. It grows from facts; it explains facts; it increases known facts; it never loses its hold on facts. I am not ashamed to proclaim myself a teacher of theory."

In concluding his able address Professor Hendrick said:—

"Now, gentlemen, I must not try your patience any longer, but endeavour to come to a close.

But just let me ask—What is the use of this agricultural department? This is for you to determine. I have endeavoured to the best of my ability to point out to you the crying need there is to bring our highest training and research, which, I presume, should be found in our universities, into touch with our industries. In this district, as in many others even in our manufacturing and commercial Britain, agriculture is the great industry. It should be the duty of this department, then, to form a centre of scientific knowledge and a centre for the dissemination of such knowledge in the agriculture of the district. We cannot do this without your sympathy and support. Our modern agriculture needs to have scientific specialists placed at her disposal, brought into the closest possible relations with her, not merely as analysts and commercial scientists, but as teachers and advisers, centres for the creation and spread of knowledge. The modern agriculturist, be he landlord, factor, farmer, or be he a manure merchant or manufacturer, or other follower of a business depending on agriculture, needs to know a great deal of the sciences connected with agriculture. Therefore, he needs to be taught. From these classes, therefore, and from the teachers who are to carry the information on to other grades of society, we ought to draw students. If we do not, we are not doing our duty, or you are not using your privileges. Already in Germany no man need apply for any agricultural post of importance who has not a college training in the sciences, as well as a field training in the practice of agriculture. Are we going to fall further behind? It is an ignoble thing to be spurred on merely by fear of the foreigner; but, if you will not move from higher motives, let that move you. Then, even when our men are taught, they cannot know everything. They cannot become encyclopædias, carrying all the information of all the specialists who have taught them. Therefore we need means, such as are supplied by the universities and research stations abroad, to bring our specialists and their knowledge freely to the use of agriculture. We are here to be used. No, gentlemen, the world has changed, and we must change with it or be crushed out. If the days are gone when we can get 5 per cent., we must be content with 2½. If the days are gone when it was enough to take pains with our hands and our feet, we must take pains with our heads as well. We must call to our aid that force which has changed the world or it will destroy us. I appeal to the twentieth century for my justification."

INSECT PESTS.

[Being selections from the Report of the Government Entomologist, Cape Town.]

In an entirely normal state of nature, the relations between plant-feeding insects and their enemies remain practically the same during a series of years. These enemies are predaceous animals, such as snakes, toads and birds, and predaceous and parasitic insects. The first class, that is the predaceous animals, and a part of the second feed with little discrimination on a great variety of insects, and hence their influence on a particu-

lar species is largely in direct relation to that insect's abundance. Most of the enemies of the second class, however, confine their attention to one species or to a few closely-allied species, and hence the abundance of a particular species of insect is greatly influenced by the abundance of these enemies. For a few years these enemies may keep an injurious insect in an almost complete state of subjection; but, becoming over numerous, they perish for want of food, and the injurious insect is left to multiply in peace, which it quickly does. But its climax is soon reached, for the few enemies peculiar to the species which have survived the famine again find the land abounding in plenty, and, responding to the conditions, they in turn multiply and soon again subject the plant-feeder. Thus in a series of years, in spite of the marvellous fecundity with which Nature has provided insects, their numbers remain approximately the same. The limits in time of this "rise and fall" varies widely with respect to different insects. With some, as with many aphides, only a single season is required; with others, as with many locusts, several years are required. But always Nature tends to preserve a balance, and under strictly natural conditions no insect long remains superabundant.

Man, however, upsets these fine adjustments of Nature. He devotes immense areas of territory to the same food-stuff, he cultivates the plants, rendering them more luxuriant, more tender and succulent. Thus he favours the plant-feeding insect. Nature had designed it to meet with privations, for less nourishing food and less bountiful provision. Under its new conditions the insect simply luxuriates. To effect its perpetuation it had been endowed with wonderful powers of multiplication, and these are now used to their fullest extent. Food is now plenty; there is room for their increase. Many birds and other small animals are not tolerated by the farmer among his crops, and thus no small degree of the check which Nature had provided to prevent an undue superabundance of the plant-feeding insect is removed. The parasitic and predaceous insect enemies remain, it is true, but these alone can wage only an unequal war, with the balance always much in favour of the plant-feeder. For these reasons the farmer must wage eternal war against plant-feeding insects.

Comparatively few persons realize what an immense variety of forms is displayed in insect life. To the average Colonial farmer there are a few species of locusts, a few different kinds of caterpillars, some flies, a dozen or so "bugs" and perhaps as many beetles. Knowing so few insects, he fails to appreciate the difficulties in the study of entomology, and why, with all the entomologists, so little can often be told him regarding a particular insect.

In number of species, insects far outnumber all other classes of animals combined. Dr. C. V. Riley, late entomologist to the United States Department of Agriculture, published the statement in 1892 that *ten millions* would in his judgment be a moderate estimate of the number of different species of insects! The vast majority of these remain undescribed and unnamed. In the United States about twenty-five thousand species have been named and described, and of these Dr. J. A.

Lintner, the New York State Entomologist, estimates that at least fifteen thousand are injurious, and that about half of this number, or between seven and eight thousand, may justly be regarded as pests.

(To be Continued.)

REMEDIAL VALUE OF VEGETABLES AND FRUIT.

Asparagus is used to induce perspiration.

Apples are useful in nervous dyspepsia; they are nutritious, medicinal, and vitalizing; they aid digestion, clear the voice, correct the acidity of the stomach, are valuable in rheumatism, insomnia, and liver troubles. An apple contains as much nutriment as a potato, in a pleasanter and more wholesome form.

Bananas are useful as a food for those suffering from chronic diarrhoea.

Blackberries as a tonic. Useful in all forms of diarrhoea.

Cranberries for erysipelas are used externally as well as internally.

Carrots for sufferers from asthma.

Celery is valuable as a food for those suffering from any form of rheumatism, for diseases of the nerves, and nervous dyspepsia.

Figs are aperient and wholesome. They are said to be valuable as a food for those suffering from cancer; they are used externally as well as internally.

Fresh ripe fruits are excellent for purifying the blood and toning up the system. As specific remedies, oranges are aperient. Sour oranges are highly recommended for rheumatism.

Grapes dilute thick blood, send the circulation to the surface, remove obstructions from liver and lungs, and bring the stomach to a healthy condition.

Lemons for feverish thirst in sickness, for biliousness, low fevers, rheumatism, colds, coughs, liver complaint, etc.

Lettuce is useful to those suffering from insomnia.

Onions are almost the best nervine known. No medicine is so useful in cases of nervous prostration, and there is nothing else that will so quickly relieve and tone up a worn-out system. Onions are useful in all cases of coughs, colds, and influenza; in consumption, insomnia, hydropobia, scurvy, gravel, and kindred liver complaints. Eaten every other day they soon have a clearing and whitening effect on the complexion.

Pineapple juice will cut the membrane from the throat of a diphtheria patient when nothing else will.

Peanuts for indigestion; they are especially recommended for corpulent diabetes. Peanuts are made into a wholesome and nutritious soup, are browned and used as coffee, are eaten as a relish, simply baked, or are prepared and served as salted almonds.

Pie plant is wholesome and aperient, is excellent for rheumatic sufferers, and useful for purifying the blood.

Spinach is useful to those suffering with gravel.

Turnips for nervous disorders and for scurvy.

Tomatoes are a powerful aperient for the liver, a sovereign remedy for dyspepsia and indigestion.

Watercress is a remedy for scurvy.

Watermelon for epilepsy and for yellow fever.

GENERAL ITEMS.

A correspondent to the *Scottish Farmer* referring to ticks, says:—Having had considerable experience with ticks in South Africa, I may say that I never found them injure much healthy fat cattle. Principal Williams recommends tar and linseed oil. I have found lard and flowers of sulphur superior to anything else.

There is great rejoicing in Denmark by Dr. Bang's discovery of the bacterium which causes abortion. It remains now to discover the best way of destroying the germ, but meanwhile it has been demonstrated that a bull used for service on a cow that has aborted may infect any cow he serves afterwards.

In New Zealand the aeration of milk is made compulsory by law. Every supplier of milk has to pass his milk through an aerator, or, at all events, remove the animal odour from it immediately it is drawn from the cow. The "refrigerator" which also aerates milk is too expensive for common use, but now more than one cheap aerators has been patented. The latest on the market is the "Anstral," which is said to be very satisfactory and cost only 12s. 6d.

The latest device for preserving eggs is to rub them over with the white of egg and pack in flour. By this method both the yolk and whites are said to remain marvellously fresh and sweet.

JOHN BROWN.

“PIONEERS OF THE PLANTING ENTERPRISE IN CEYLON.”

(Second Series.)

JOHN BROWN, ENGINEER AND PLANTER.

THE late Mr. John Brown was born at Udney, Aberdeenshire, on 17th October, 1826. He was educated as a Civil Engineer and served first on the staff of Mr. Gibbs of the Aberdeen Railway, and afterwards on the Railway Survey and Construction staff of Mr. John Miller of Edinburgh.

In the year 1848 he sailed for the East via the Cape to take up an appointment on an Indian Railway under Government. The vessel made a fast voyage, and on reaching Point-de-Galle, and finding that he had ample time, before his due date, Mr. Brown determined to visit Colombo and Kandy and see something of the Ceylon planting districts, before proceeding to India. This was probably very much owing to the fact that Mr. and Mrs. R. B. Tytler were passengers in the same vessel,—Mr. Tytler returning after having gone home to get married; and all he had to say about coffee in Ceylon no doubt influenced the young Engineer. Be that as it may, life and prospects in Ceylon proved so attractive, and there was such evident scope for the exercise of his own profession among the planters, that Mr. Brown determined to abandon his Indian engagement and to remain in the island. For some years Mr. Brown was very busy over engineering work in connection with the coffee enterprise, chiefly in Pussellawa. His first engagement was to under-

take the planning and erection of extensive works for coffee preparation on Rothschild, the property of the Messrs. Worms, which he brought to a successful conclusion. Mr. Brown's next and his largest undertaking was in connection with the late Mr. R. B. Tytler's giant coffee irrigation scheme, commonly known as the Rajawella Waterworks. On this Mr. Brown was occupied for six years, and the large turbine and pumping machinery erected at the side of the Mahaweliganga, in Dumbara, were, finally, a complete engineering success. Water in large volume was forced up to the top of the hill on the property; but the difficulty in distributing it over a sufficient area of the planted coffee, prevented the scheme from turning out eventually, the financial success anticipated for it. As this was one of the most notable engineering works ever undertaken in connection with the coffee enterprise of Ceylon, or indeed with tropical planting anywhere in the world, we extract from several issues of the *Ceylon Observer* of the "fifties" and "sixties", accounts of the progress and opening of the Waterworks:—

IRRIGATION APPLIED TO COFFEE PLANTING.

SOME of our readers travelling by the Colombo and Kandy coach may have observed lately sundry carts along the road laden with massive iron pipes, about nine feet long and of diameters varying from six to ten inches. These pipes form part of the Machinery intended for raising water to irrigate the portion of the Rajawelle Estate belonging to Messrs. Morton and Tytler; and as considerable public interest and curiosity have been excited on the subject of these contemplated Water-works, we proceed to give some general account of them.

The Rajawelle Estate, situated in the lower Doombera valley, is known to lie within the line of country in which the S. W. Monsoon occasionally fails, and the result is that this Estate, which in moist seasons bears very heavy crops, loses in a very dry season from one-third to one-half of the crop on the trees. There are only two or three small streams in the property, and even these in very dry years occasionally cease to flow; but the Mahavilla Ganga forms the boundary of Rajawelle on the south-side, and as the Mahavilla affords at all seasons an abundant volume and fall of water, the idea occurred to the proprietors of the Estate, to make that river itself subservient to the purposes of irrigation. The problem practically was a serious and difficult one. The old Estate lies a mile and a half from the river in a straight line, and is divided from the new Estate by a ridge ascertained by actual survey to be 460 feet in vertical height. The power requisite for raising even a moderate quantity of water to this high elevation by a single lift, is very great; yet the necessity for employing a single lift could not be avoided except by substituting still more costly Machinery, such as a powerful Steam Engine half way up the hill. To this there were many practical objections. Accordingly it was resolved to throw up the whole quantity of water required, by means of the power obtainable from the river alone: and after consulting practical Engineers in England and Scotland, it was resolved to employ as the motive power *Whitelaw's Horizontal Water-wheel*. This Wheel, with the Pumps and connecting Machinery, has been accordingly manufactured by Messrs. Whitelaw at Glasgow, and the whole are on their way to Ceylon in the 'Coromandel.' The iron-piping (of the length of 6,250 feet and weighing 212) Tons intended for the conveyance of the water over the ridge was brought out by the 'Armais' some weeks ago; and we believe a great part has been forwarded to Rajawelle. The works at the latter place are in rapid progress. The great sluice, for supplying the water to the Wheel, is nearly cut. This sluice, which will be a small Canal when completed, is to be nearly three quarters of a mile in length, and eighteen feet broad by three feet deep,—discharging at least half a million of gallons of water per minute. As there are several rapids in this part of the Mahavilla Ganga (indicating of course a great declination in the bed of the river) a comparatively short extent of sluice gives a great fall;—consequently it is found that the three-quarters of a mile give a fall of some 24 feet. The large body of water supplied by this canal, with the fall of 24 feet, produces a very large amount of motive power; in fact it is calculated to be equal to a Steam Engine of about 200 Horse-power. We believe that a Steam Engine of this size would have cost more than the whole expense of the intended works,—independently of the objection that its working would have been very costly, whilst the Water-wheel is self-acting.

The Wheel will be quite a curiosity in its way. The Diameter is only 14 feet,—a size which would be considered small for any of the Water-wheels used on Coffee Estates for working Pulpers and Clerihew fans. We believe that the ordinary overshot Wheels used on Estates are about 16 feet in diameter; but the resulting power is seldom more than from 8 to 12 Horse-power. An overshot Wheel of 200 Horse-power, would require to be at least *sixty feet* in diameter; and a Wheel of such an unwieldy size would have required to be very favorably placed, as regards the supply of water and other circumstances, to be worked effectively. We remember seeing a sketch, in the *Illustrated News* last year, of a gigantic wheel of this description, lately erected at some Mines in Wales, but although the diameter was four or five times as great as that of the Rajawelle Water-wheel, the effective power was less. Mr. Whitelaw himself, in a letter published in the *Mechanic's Magazine* of May 6th 1854, speaking of this very Rajawelle Wheel, describes it as

"A Water-wheel of 200 Horse-power, which I am making for Messrs. Gwynne & Co., Engineers, London, which is to work six single-acting pumps of 20 inches stroke and 8½ inches diameter, to raise

"water to a height of 460 feet for irrigating an Estate. When finished I believe, *no water-wheel in the world will be of greater power than this*; but be this as it may, it will be a large one."

The principle of Whitelaw's Wheel is peculiar and not very generally known. It is placed horizontally, and as a central opening for the ingress of the water from the sluice, which is supplied by a large induction pipe. The diameter of the pipe for supplying the Rajawelle Wheel is 76 inches, so that a tall man with his hat on might stand upright in it! This pipe will be always full; and even persons practically unacquainted with Hydro-dynamics, can readily understand that an enormous force must be exerted by a perpetual column of water six feet four inches in diameter and twenty-two feet in vertical height. The principle of action is somewhat complex in theory, though extremely simple in practice and result. It has been described as "centrifugal"; and so it is to a certain extent. The arms of the Wheel are curved and have orifices at the extremities; and the water, forced in through the central opening, rushes through these curved arms and out of the orifices; and Mr. Whitelaw describes the action as communicated by the water pressing on the sides of the arms as it rushes through and by the centrifugal force as it rushes out. But as we observe from the drawing which has been sent to us, that the diameter of the central opening in the Wheel is very much less than the diameter of the large supply pipe, we fancy that the action is greatly aided by the operation of another: valuable hydro-dynamical principle, viz. *that a force exerted upon a certain surface of water is multiplied when communicated through the water to a smaller surface*. The increase is in a known ratio, viz. inversely as the squares of the surfaces. This is the principle of the hydraulic press. It was by the application of this principle that Mr. Robert Stephenson raised the vast tubes of the Britannia Bridge. On a small scale, the action of a common "syringe" is precisely the same; and this perhaps is the humblest illustration of the principle.

The Rajawelle Wheel is to work three or more Pumps, which are upon the ordinary principle, and no further remarkable than for their size and strength. These pumps will deliver their water into the conduit or long iron piping laid over the ridge; and Messrs. Gwynne & Co. have guaranteed that the Machinery shall deliver 500 gallons of water per minute at the top of the ridge, which, as mentioned above is 460 feet in perpendicular height. To give an idea of the strength of the valves required in these pumps, it may be mentioned that the actual weight of the water in the conduit pipe when full, will be, in round numbers, over *seventy tons*; but as the pressure exerted by a column of water is proportionated only to its vertical height, the effective weight may be taken at one-tenth of that figure. A continual pressure however of even 7 or 8 tons upon pump-valves, calls for both stout material and good workmanship.

How much of the Rajawelle Estate can be watered efficiently by the amount of water above stated (500 gallons per minute) is a question which actual experiment alone can solve. Much difference of opinion exists on the subject. Some of Messrs. Tytler and Morton's friends are kind enough to assure them that the whole thing will be an utter failure! The Estate consists of 700 acres or thereabouts, of which 200 Acres (the old Estate) lie over the ridge, and 500 Acres (the new Estate) between the ridge and the river. Taking 600 trees to the acre on the old Estate, and 1,200 trees to the acre on the new the total number of trees may be set down at 720,000; and this happens to be exactly the number of gallons of water per 24 hours at the rate of 500 gallons per minute. In other words, if the whole Estate is to be watered at once, the quantity received by each tree would be only *one gallon* in the 24 hours; and this without allowing for loss by evaporation, &c. But we believe the intention is to water only 50 or 100 acres at a time; and it is calculated that in about a *month*, the greater part of the Estate would have received a supply equal to a heavy shower of rain. In 1853 the drought at Rajawelle lasted nearly

five months; and experience is said to have shown that it is only when the trees have been more than a month or so without any supply of moisture that they begin to suffer materially. In June and July 1853, in the height of the drought we learn that Mr. Tytler tried the experiment of leading a small stream of water among a few acres of the old Coffee, and that the experiment was perfectly successful, though the stream itself had dried up before the drought was quite over. The watered trees filled their cherries, just as in a moist year, while the unwatered trees in the adjoining squares had fully half their berries light. And with regard to the supply of water, it should be mentioned that Gwynne & Co.'s engagement is that the quantity guaranteed shall be delivered at the top of the ridge. The conduit piping has stop-cocks at various intervals, and as a much greater quantity of water can be delivered by the same power at lower levels, the greater part of the new Estate can be supplied far more abundantly than on the above calculation. However actual experience will be the best test; and we learn that the works are expected to be in actual operation before the end of the present year. Mr. John Brown, formerly in the service of Messrs. Worms, is the Engineer employed on the spot; and under his efficient supervision the works are proceeding rapidly and satisfactorily.

THE RAJAWELLA WATER WORKS.

We are rejoiced to hear that the great irrigation works at the Rajawella estate were successfully tested on Saturday the 7th instant, the water being forced to the top of the hill, some 460 feet above the level of the Mahavilla ganga. We hope the unwonted elevation will not turn the old River's head. We heartily congratulate those concerned on the successful completion of what has been an anxious and costly work, and a great experiment. Its successful issue is of great importance to the future of Ceylon.

Later on, however, some of the machinery first erected was found unsuitable, for in the *Observer*, January 1859, we find the following:—

THE RAJAWELLA IRRIGATION WORKS.

"*Immense Hydraulic Engine.*—Messrs. Abernethy have just finished, at their works at Ferryhill, Aberdeen, a hydraulic engine of very great power. It is intended for an East India plantation, and its object is to pump water, for purposes of irrigation, on both sides of a hill whose altitude is 500 feet. It consists of twelve pumps, which act in sets, and will be driven by a water-wheel of 200 horse-power. The engine is calculated to lift water at the rate of 1,000 gallons a-minute. It is of massive construction and admirably finished workmanship. We (*Aberdeen Journal*) are not aware that any hydraulic engine of nearly equal power has yet been constructed in this country."

We have no doubt this is the machinery for Rajawella now on its way round the Cape. Mr. Brown, the Engineer, (who went home mainly with reference to this machinery) is already in the Island.

THE RAJAWELLA IRRIGATION MACHINERY.

The great pumps—probably the most powerful in the world—intended to force up water to the highest point of the Rajawella property—have arrived at Colombo in the *Ellon Castle*, and with the connected pipes and machinery are being landed and sent on to their destination under the superintendence of Mr. Brown, the Engineer. Some idea of the pumps may be formed from the fact that there is a pressure of 8 tons on each piston. It is expected that they will send water up to a height of some 450 feet—the highest point, above the river, of the fine estate for which they are intended. For the

sake of the continued and extended success of the Coffee enterprise in Ceylon, as well as out of regard for the spirited proprietors of the Rajawella property, we trust the experiment will be largely successful. The effects of full success can scarcely be estimated. On one estate it is calculated that in a year of drought it would make all the difference between an unremunerative gathering of light husky Coffee, and a bumper crop of full, bright, solid berries, yielding a profit of £10,000. For this year we are glad to hope that the Dumbara and many of the other lower estates are safe—long continued heat having been succeeded by copious showers of rain and occasionally hail—the latter being light and harmless. All that is wanted is moderate weather in June. By next year the great irrigation works will be in full play, placing, let us trust, the owners of the particular property beyond the reach of anxiety, and opening up a new era for Coffee Planting in Ceylon.

THE RAJAWELLA WATERWORKS.

It affords us much pleasure in announcing the final completion and success of this costly and spirited undertaking. By force-pumps of an ingenious construction, moved by a Turbine of 200 horse-power, water is raised along a pipe of a mile and a quarter in length, to a height of five hundred feet, sufficient in quantity to serve for the irrigation of eight hundred acres of Coffee. In the bold conception of the original idea, the patient perseverance in carrying it out, the overcoming of engineering difficulties as to the most suitable machinery and the erection of the ponderous pieces, and in the fortitude and faith which sunk thousand after thousand of pounds in an improved experiment, too much credit cannot be given to all parties concerned. It is an honor to the Island to have such a work to exhibit. We are assured there is no room any longer to doubt of its final success. The Pumps originally supplied by Gwynne & Co. were a failure, but another set, supplied by Abernethy & Co., of Aberdeen, work with a precision and ease comparable to clock work, and though the replacement cost £3,000, and the former contents of the pumping house lie a scattered heap of worthless iron, there is more than equivalent for all in the great fact that the property is independent of drought. The present season's very heavy crop is mature, and the beans that are picked are of well-filled quality, equal to the produce from any estate of the same elevation. The effect of the water applied in irrigation is plainly and immediately perceptible upon the drooping trees. They are kept fresh in aspect and the crop is sustained by circulation of the sap, which would stagnate in the absence of the moisture at the roots. It appears to us that the value of these works is not confined alone to the watering of the trees, most important though that view of their object be, but that in the carrying out of liquid manure, coupled with the digging of the soil, in such a warm district as Dumbara, not only would there be a saving of labor in manuring, but it would be impossible to predicate to what extent the quantity of produce might be increased.

Mr. Brown's skill and perseverance in overcoming the difficulties, incidental to so novel and trying an engineering enterprise, greatly impressed those who watched him. His quiet, resolute determination combined with great ability, carried him through where other men would have failed and established his reputation in Ceylon as a reliable, sagacious Engineer and a valuable colonist of the right type for a young plantation country.

The time had now come, indeed, for the young Engineer-planter, to begin planting on his own account, and accordingly Mr. Brown, who had now seen a good deal of the country, took up land for coffee planting in partnership and conjunction with Messrs. Norman Stewart and J. B. MacIntyre. Stewart, Brown and MacIntyre—as the partnership ran—opened and planted a group of estates in the Badulla district, the principal of which was known as Glen Alpine, and which, after yielding rich crops for several years, were sold in 1864 to a London Limited Company, entitled the Ouvah Coffee Company. This Company proved successful, and Mr. Brown was induced to join the Board as Managing Director. Under his care the Ouvah Coffee Company, as also the Spring Valley Coffee Company—in whose formation by the purchase of the famous Spring Valley Coffee plantation from Mr. Baunatyne, Mr. Brown had assisted—became very prosperous and paid large dividends for many years. To these was afterwards added the Hunasgeriya Estate Company; and in the year 1877, Mr. Brown and some friends started the Colombo Commercial Company, Ltd., which though intended mainly at first to act as Colombo Agents for the Coffee-growing Companies, has developed into an engineering and contracting as well as mercantile and planting concern of an importance far beyond Mr. Brown's original conception, thanks very much to the judicious management of this Colombo Company and to the impetus given by the prosperity of "tea"!

The latter portion of Mr. Brown's life was almost entirely devoted to the management of the several Companies, with which his name was identified, and the fact of his having successfully piloted them through the difficult times that followed the collapse of the coffee enterprise in the "eighties," and restored them to prosperity in tea, is sufficient evidence of the care and enterprise of his management. We believe that only one other Coffee Company succeeded in passing through the crisis brought about by the coffee fungus, *Hemileia vastatrix*, which practically ruined a great planting enterprise in Ceylon.

Mr. Brown had a decided faculty for invention, and, as a practical Engineer, he early found room for its application in a young planting colony just developing a new enterprise. He was responsible for many of the improvements made in Coffee-pulping machinery, his own Coffee Crusher and Pulper not being the least noticeable—and when attention passed from coffee to tea he introduced two more well-known machines in "the Desiccator"—a splendid tea-drying machine also used to prepare desiccated coconuts—and his "Triple Action Tea Roller." Both these machines have been warmly commended and have proved most successful, and considerably over

500 Desiccators were in use in Ceylon alone at the date of Mr. Brown's death. The Triple Action Tea Roller—highly praised for its work by planters best acquainted with it,—was unfortunate in being the cause of an action at law for infringement of patent taken by Mr. Wm. Jackson against Mr. Alfred Brown and the Colombo Commercial Company, the Agents for the machine. The case was carried to the Privy Council, when Mr. Jackson was unable to sustain his charge of infringement; but it must always be regretted that the Privy Council judgment was not pronounced until after Mr. John Brown's death.

Mr. Brown died from the result of an illness contracted in Ceylon in the early part of 1894. He left Colombo for England in poor health, accompanied by his eldest son, and contrary to all expectations he did not get benefit from the sea air, but gradually lost strength and died after reaching Alexandria, where he was landed from the steamer in order to secure experienced medical advice. He died at the Deaconesses' Hospital, and lies buried under an Aberdeen granite tomb in the Alexandria Cemetery:—

"Mr. J. Brown was born on 17th October 1826, married for the first time to Elizabeth Hall, 7th September 1858 and again to Elizabeth Wylie Abernethy on 18th June 1892. Died 18th March 1894. He left seven children, all by his first wife."

The subject of our Memoir cannot be described as having been a brilliant man; but the quality of his mind was solid and thoroughly practical. His success in life was mainly due to hard work, thoroughness and sincerity of purpose. Once having made up his mind as to the proper course to pursue—that so-and-so was the right thing to do or the right way to do it,—no one could turn him from his purpose, or persuade him to the contrary. In private life, Mr. Brown was most worthy. In respect of both the Coffee and Tea Planting Enterprises of Ceylon—in a connection extending over some 45 years—few men have left more practical or useful evidence of their presence than Mr. Brown. As an Engineer, an Inventor, a Proprietary Planter, a Managing Director, and Chairman of Companies, Mr. Brown took a prominent and successful position, and his name ought long to be remembered in the annals of the Planting, Engineering and Commercial development of Ceylon.

COFFEE IN PORTO RICO.—A New York exchange authority says:—"The Porto Rico coffee crop will, this season, according to advices received by leading merchants doing business with that island, fall short all of 66 2-3 per cent over the amount exported last season. This shortage will not in any way be felt in this market, as the importations are comparatively light from Porto Rico, their markets being those of France, Italy and England."

Agricultural Pests :

WITH METHODS OF PREVENTION.

BY MISS E. A. ORMEROD,

(LATE CONSULTING ENTOMOLOGIST TO THE
ROYAL AGRICULTURAL SOCIETY OF
ENGLAND).

IV.

INJURIOUS MOTHS—METHODS OF PREVENTION.

In the case of the white cabbage butterflies, the caterpillars of which often do serious mischief in gardens, they have been found not to do so much harm in proportion to field cabbage, because the caterpillars choose a dry, well-sheltered place to chauge in. For this they crawl away from their food-plants, and hang themselves by a silken band under eaves, palings, or the like shelter, out of doors, or in any neglected corners in garden-sheds, where they are allowed accommodation, and much may be done to lessen amount of attack simply by tidiness. The collections of old brooms, bits of wood, and dry rubbish of every kind in which they shelter, are much better away, whether indoors or out; and a brush taken along angles and in corners and under stairs, ladders, beams, &c., in garden-sheds, will sometimes clear the chrysalids out by the handful. A search of this kind between the time of the first and second brood in summer, and some time between November and March, would do much good.

It is an excellent principle to keep down the effect of insect-attack by broad measures of agricultural treatment which will carry the plant well on away from the power of the insect; but at the same time it should not be forgotten that when there are a great number of large caterpillars or chrysalids plainly to be seen, and easily to be laid hold of—whether with fingers or by other means—the best thing to do is, forthwith, to lay hold of them.

There are not many kinds of butterfly caterpillars which are hurtful to crops in England; but amongst the hosts of different kinds of moth caterpillars that cause great loss, about the very largest of all, which is that of the death's head moth, is best got rid of by hand-picking. This sometimes does much harm to potatoes by feeding on the leafage.

The caterpillar usually hides by day, and feeds in the evening or at night; therefore, when great harm is found to be going on (either in this case or others like it) from an unseen enemy, it is well for some trustworthy person to watch at dusk or dawn for what is going forward, and with large creatures like these caterpillars a very small quantity of light will be enough to see them by as they gently move the leafage in feeding. When full-fed the caterpillar goes down into the ground to change; therefore, turning up the chrysalids is an easy measure of prevention with this potato-feeder.

The various kinds of attacks of moth caterpillars are so many, and the injuries they cause so great, that in whatever point we may select now for study, it seems at the cost of leaving out something else of importance; but in these short details. I have tried to draw attention to some four or five principles of preventing or remedying attack:—

One is taking away shelter (as in the case of cabbage caterpillars). Another, the possibility of hand-picking, shaking down, gathering, or whatever term we use for it, being so managed as to be a practicable and paying operation, instead of a ridiculous loss of time. Another is prevention of egg-laying on fruit bushes, by keeping them so properly pruned that there is no attraction of cracks and crevices. We have also noticed that the caterpillars may be smoked or poisoned in their burrows—a simple piece of knowledge, but yet one which, some few years ago, would have been of great service in saving coffee shrubs in one of our colonies. Further, we have noticed that, with webbing caterpillars, it is decidedly well, before we pay our visit, to see if the family are at home.

With the great increase of the fruit industry, we have now areas of thousands of trees where formerly these were counted by hundreds, and we have a consequent increase in amount of the attendant fruit-tree insect vermin. Where there is a large extent of plant growth of any kind, orchard trees or otherwise, affording food in their feeding condition, and shelter in their other stages, to special kinds of insects all the year round, and for successive years, there these insects are sure to be present. This has been the case in such a marked and increased degree during the past few years, and in some of our fruit-growing localities, as to necessitate the adoption of some special measures of prevention suitable to the special habits of some of the kinds of caterpillars, and also of remedial applications suitable for sweeping them all off and destroying them together (whatever their other habits may be), when broadscale ravage on the leafage calls for broadscale clearance.

One very important division of caterpillars to which measures of prevention can be applied, is that of the "looper" caterpillars of various kinds of moths, of which the females are either totally wingless, or the wings are abortive to such a degree as to prevent them being of service in flying. Of these, two of the most hurtful kinds are the mottled umber (*Hybernia defoliaria*), and the too well-known winter moth, sometimes called the Evesham moth.

The method of life of both the above kinds is for the caterpillar to hatch in the spring, on the orchard trees on which the eggs have been laid, and feed on, or possibly fairly ravage, the leafage and all the soft growths, during a period which may be from about the end of March until the end of June. Then the caterpillars leave the trees, and go through the change to chrysalis state beneath them. This may be just about the surface of the ground, or a little below. From these the moths begin to come out in October or November, and the wingless female moths creep up the trees and deposit their eggs. This habit, if the moths only went up the trees during a special period, would put means of prevention at once in our hands. But even as it is, the infestation may be greatly reduced by putting bands of sticky material round the trunks, such as will either deter the moths from trying to go up, or hold them firm if they try to cross. This plan catches the moths by hundreds on each tree, but care must be taken lest the mixture applied should injure the bark. On the rugged, thick bark of old trees, where the out-side is a mere dry dead coating, it is possible that even tar may be applied without doing harm, though not without risk.

But with young trees there is very great danger of serious injury, and sometimes great losses have taken place consequent on tar or grease being applied direct to the bark. The application soaks into the tissues, and the tree in such case perishes.

The safest way is to begin by passing a band of tough grease-proof paper, such as may be procured at very small cost from grocers, round the tree. This may be about seven inches wide, but the wider the better; the ends should overlap, and the paper be secured in its place by a piece of string being tied round near the upper and lower edges. On this the grease may be smeared. A flat bit of wood, like a paper-knife, is a convenient implement for spreading it with, and common cart-grease answers well as a cheap and effective application. Even, however, where the tree is protected, some care must be exercised in the choice of the "sticky" mixture selected, as some of the materials sold under the name of "axle-grease" contain petroleum residue, animal grease, or other components, which, like tar, would have very undesirable effects if (as I have myself seen to happen) they should soak through the supposed grease-proof paper to the bark.

The above treatment does much good, but does not answer perfectly, for the following reason. Though the great body of these moths come out from the middle of October to December, this period by no means includes the whole appearance. We find them still at the end of January, and the later brood may be found coming up towards the end of winter; and at the end of March another kind of moth, with wingless females, namely, the *Anisopteryx ascularia*,

or March moth, which lays its eggs in bands embedded in down on the twigs, is (or very likely is) also present.

These various moths, including besides what may be called those of common habits, such, that is, as moths which come on the wing to the tree, and of which the caterpillars, after feeding, spin up on the bark, or in any convenient shelter, may be counteracted in some degree by measures based on knowledge of their habits. The webs of those that make nests may be cut off and destroyed with the caterpillars, or (in the case of the small ermine moth) the chrysalids, within them. Cocoons covered with eggs, as in the case of the common vapourer moth, may be searched for and destroyed; and, similarly, the rings of eggs of the March moth and of the lackey moth, which resemble them in being laid in a band on twigs, may be got rid of in some degree by careful search, and pruning off the infested twigs where they can be reached. But for the most part these and various other means of prevention or remedy have to be applied, not as broad measures of treatment, but as special measures for each special attack, involving necessarily special outlay. For these reasons, that is, the pressing need which has long been felt of having some kind of application at hand which is cheap and sure in its action, and which can be brought to bear at once, when required, on any or all sorts of moth-caterpillars together (whatever their various natures or previous histories may have been), and will kill the whole collection of ravaging hordes at once, without damaging the leafage, the experiments have been made, which have resulted, in some of our fruit-growing districts, in the successful introduction of the method of spraying caterpillar-infested leafage with Paris-green, which has long been found serviceable in the United States and Canada.

Another very important division (taken agriculturally) is that of the surface caterpillars, so-called from their injurious operations being for the most part carried on near the surface of the ground.

The family of moths to which these belong is termed *Noctuidæ*, from the circumstance of many of them flying chiefly at night or in the dusk. The heart and dark moth, the caterpillar of which is almost as often found at turnip bulbs as that of the turnip moth; cabbage moth, the great yellow underwing, and some other kinds, the caterpillars of which more or less frequent the surface of the ground, do infinite harm, both in field and garden. In some cases, like the turnip moth caterpillars, they feed at, or below, the ground-level on almost every common root crop, or corn crop, they can reach; and when the weather is too severe in winter for them to continue feeding in the turnip bulbs, they simply go down deeper for a time, and, after coming up again to feed, turn to chrysalids in the ground in the following spring or early summer. Others, like the caterpillars of the cabbage moth, feed in the hearted cabbage, and turn to chrysalids in, or on, the surface of the ground before winter. But, whatever slight difference there may be in the habits of these various kinds of thick fleshy caterpillars, about an inch and a half long, which we only too often find either at the roots or on the leaves of the cabbage and turnip, this special point of their usually passing the winter under ground puts them very much in our power.

Before the caterpillar turns to the chrysalis, it makes a cell in the earth, in which it is protected from wet and sudden changes of temperature, or it seeks or prepares a safe resting-place for its change, or for a time; and so long as the caterpillars are thus protected no amount of cold to which they are here exposed will, as far as we know, do them the least harm. But if they are thrown out of these shelters to the influence of drying winds or hot sunshine, or to lie soddening helplessly on the surface in moist or muddy ground, or to being frozen in these states, then their constitution will not bear it.

If the caterpillars are turned up too soon, that is, either before they are torpid, or before they have changed to the chrysalis, they will simply go down

again. If the soil is turned up when they are gone down very deep, they will not be the worse for what has been done above them. Each worker must look a little for himself, for dates and habits differ with climate and other things; but a little careful observation made by tuning over the earth, so as to see where the creatures are, will be well repaid. They are quite large enough to be easily seen, if they are in numbers to need attention. This principle may be worked both in winter and summer—with caterpillars that turn to chrysalids under ground or in cocoons above ground, and with those that frequent leafage of trees or roots of grass, as well as those we have spoken of.

The common cabbage and turnip surface caterpillars will be found thus (or when time has elapsed for their change to take place), in chrysalis state, on or in the ground near where they fed.

The beet and mangold moth (silver Y moth) caterpillar spins a cocoon on, or not very far from, the plants it infested; and in all those cases, and scores of others, much good may be done by turning up the chrysalids, destroying the weeds they harbour in, and using all other methods of treatment, which a moment's thought will suggest, to destroy the pests.

Clearing all weeds that attract the moths is one method of preventing increase. The constantly increasing amount of insect attack is in part because of the constantly wider spread of cultivated land. There is a much greater amount of special crops, such as special insects feed on; and instead of there being, as in wild districts, perhaps, one plant in a hundred that may suit the caterpillar, there are districts all through the country where nine-tenths of the growth are its chosen food. If, therefore, in addition to the crop food, we let weed food collect in our borders, we add most needlessly to our troubles; and by clearing and burning these patches round garden and fields we may do a deal of good.

When attack is bad, the chief thing to trust to is fertilising dressing; but sometimes dressings of gas-lime on the land, and on the plants, will check attack to a serviceable extent. This has been found useful in the attack of caterpillar to hearted cabbage in the autumn. The gas-lime falls down among the leaves, and thus fills the parts where the caterpillars shelter by day, with what, to a certain extent, keeps them out, and is not pleasing to them.

It was formerly difficult to apply this knowledge practically; but now, looking at the variety of implements which have been recently introduced into this country, suitable for spraying or washing either orchard tree leafage or that of field crops, there would be no difficulty in experimenting, at least on orchard foliage, as to the effects of cold water in clearing off caterpillar presence.

The treatment for prevention of surface caterpillars may be shortly described thus:—Turn them up by cultivation where land is known to have been infested; and where catch-cropping is practised let the field be cleared of all food at least a fortnight before a new crop is put in; keep up the strength of the crop, but use remedies if you can—if they will be sure to destroy the grubs.

In a very large number of attacks, it is the worst possible practice to try to work directly on the grubs; you must counteract their mischief, rather than try to get (literally) hold of them; but with the large moth grubs, which are often one, instead of a score of hundreds, to a plant, the case is different.

For the same reason, birds help us much with some kinds of moth caterpillars. They can bore down, and draw out these large grubs, without the broadcast destruction which often follows on their services in searching for wireworm.

The crow, raven, jackdaw, rook, and partridge, are all said to be of use in clearing away the caterpillars of the turnip moth; and in the case of some of the swarms of small caterpillars which attack forest trees, especially the small green oak-leaf roller (*Tortrix viridana*), the flocks of birds which collect when great attack is going forward are our only helpers.

MR. J. B. FERGUSON ON COFFEE IN BRITISH CENTRAL AFRICA.

Mr. Ferguson, the coffee expert in the service of the African Lakes Corporation has paid a visit to Zomba and the neighbouring plantations, and has been kind enough to give us some notes on the subject of the impressions he has gained in British Central Africa.

Mr. Ferguson was unwilling to give a final opinion as to the future prospects of this Protectorate in the matter of coffee growing, on the ground that he had not yet completed his tour of the plantations, and also considers a longer residence in the country necessary. He has, however, visited most of those belonging to the African Lakes Corporation, both in the Shire Highlands and in Angouland; the estates of Messrs. Buchanan Brothers, and also those of the principal traders and missionaries, and so far as he has gone his opinion is a favourable one, if shade and manure be supplied to the coffee.

He states that there is not a trace of coffee leaf disease in the country, and he does not attach much importance to the minor ills to which coffee is subject here. He mentioned three things however as worthy of attention, *viz.*, the Borer Grub, want of Manuring, and Drought.

Mr. Ferguson informs us that, the British Central African borer is different from the Indian, inasmuch as the former ultimately becomes a beetle, the latter a fly. The presence of borer may be detected in several ways: dust from the holes is scattered on the ground round the base of the tree, and at the time of blossoming, after a shower of rain, the flowers open up immediately in the case of healthy trees, whereas in the case of trees affected with borer the blossoming "hangs fire."

Planters in this country simply employ boys to pull out the grubs with a piece of wire. Mr. Ferguson does not think this plan effective. He tried it on some trees at Mandala, but after having extracted the grub, he cut down the tree, divided it into sections, and found several other borers still in it in different stages of maturity. A tree that is bored is not in a healthy state, and probably some of the light berries may be produced from this cause. Mr. Ferguson, therefore, recommends that a tree with borers should be dug out at once and burnt, so that all the borers may be destroyed, otherwise the tree becomes a nursery of borers. The matured insect, in the form of a beetle, is said to appear generally at the beginning of the rains, therefore, the proper time to get rid of borers is during the dry season before the beetle appears, otherwise a fresh series of eggs will be deposited under the bark of the coffee tree and a new progeny established.

Drought, Mr. Ferguson thinks, might be successfully counteracted by efficient shade. He states that there is not so long a drought in Ceylon and India, as in B. C. A., as between wet season and wet season there are what are called "blossom showers," often amounting to several inches of rain; whereas, in most parts of British Central Africa there is very little rain between the wet seasons. Mr. Ferguson tells us that the principal shade trees grown in Ceylon and India are different varieties of the ficus, the best of which are of the Banyan species. There are about eleven different varieties of Ficus, some of them natives of British Central Africa, but all of them different from the Indian species. Good specimen may be seen in the Residency garden, Zomba. The banyan tree is of this species, and Mr. Ferguson was very emphatic in recommending it for shade purposes. He says it is very generally used in India, and the most valuable estates in Coorg are those shaded with it. The reason why this tree is a favourite is that the wood it is composed of contains a great amount of moisture, and has thus a cooling effect on its surroundings: again, the leaves fall off during the cool season, when shade is not required, and it is thus a source of manure, while, on the other hand, during the hot season it is always in full foliage and affords perfect shade,

and the peculiar formation of the branches prevent "drip," and tends to carry the rain falling on the tree down the main stem to the ground.

As to manuring, the manure generally applied in India and Ceylon is that obtained from cattle sheds and stables, also bone meal and poonac (oil cake). A small pit is dug near the tree, the manure placed in it, and then covered up again.

In a few cases recently where young planters have opened up estates in B. C. A., they have collected a great deal of the brushwood and branches together and burned them. The ashes have then been scattered on the plantations in small patches round each coffee tree, thrown on the surface. Mr. Ferguson condemns this practice. Ashes he considers a good manure when mixed with other manures into a compost, or when applied alone, but it should not be scattered on the surface of the ground, but in a pit near the tree, and then covered up or dug into the soil. If thrown about loosely the wind carries it away altogether, or it may be carried entirely off the plantation by a heavy shower, especially if the land is on slope,

Mr. Ferguson attaches great importance to shade. He says that not only does shade counteract long spells of drought, but, as in Coorg, it is a certain preventive of coffee leaf disease. He considers that there are trees indigenous to British Central Africa which might do for shade, but thinks it would be well to introduce seed of trees which have been found by experience to give admirable shade, such as the banyan tree from India.

Note:—As there appears to be some doubt as to the generally understood meaning of the word "Banyan" Tree, we have asked Mr. Alexander Whyte for information on this point, and he has been good enough to give us the following note:—"It is quite customary, both in India and Ceylon, to apply the term Banyan to other members of the genus of Ficus as well as to Ficus Indica, the true "banyan" tree. It is perhaps a loose way of speaking, yet I have seen it frequently in print and it has been used by distinguished authorities, e. g. Sir Emmerson Tennant, if I mistake not, while referring to Ficus Religiosa, speaks of it as the 'Sacred Banyan Tree,' though it has two other names well-known in India and Ceylon—'Pippul' Tree, or 'Booh' Tree. There is one word of caution I should like to give with regard to the opinions of coffee experts who come from other coffee growing countries to the Shire Highlands. It is impossible to suppose or expect that one who is new to this country, although with very large experience in coffee, can definitely say at once that what is good in India or Ceylon for coffee may be equally good in this country. Innumerable valuable hints and suggestions can be had from an experienced coffee grower from an outside country, but, at the same time, as the conditions may be so different, it is well not to adopt in too great a hurry the course which is taken in such other countries, as possibly further experience here might show that they require modification."

DISTRICT OF THE ARUWIMI, CENTRAL AFRICA.

This district is really an annex of that of the Stanley Falls. All that I have said of the one might be applied to the other. The portion between Bena-Kamba and Basoko, along the Lomami consists of sandy plains unsuitable for planting, so also with the banks of the lower Aruwimi, and here there are rapids also.....It would not do to cultivate coffee for export beyond the rapids or in the Nellé district. According to what is told us of this country, it is to the north of the grand forest what the Manyéma (grass region) is in the South:—Savannahs, very populous, well-cultivated by the natives, who belong to strong races and are susceptible of great improvement.

Here and there along the river between the Lomami tributary and the eastern frontier of the

district cultivation might be attempted in well-chosen spots. The numerous ant-hills point to the existence of clay at least in the subsoil.....

At Basoko there are also some plantations, the importance of which rivals that of Stanley Falls. They are on the borders of a stream in clayey and alluvial soil. In spots, however, which the natives had cleared to grow manioc, and had abandoned, the coffee plants looked stunted, proving that the soil was not originally very fertile. At Basoko I saw 800 coffee bushes, 4 to 6 years old, 3 to 3½ metres high and nearly 2 metres wide; 270 cacao trees 4 to 5 years old and 3 to 3½ yards high, 3½ yards apart, and bearing abundantly. There were many more plants recently put out and also in nursery. From one of the coffee bushes planted in 1890 I saw the blacks who accompanied me, gather 23 Kilo (69½ lb.s) of ripe berries and 5 of unripe ones. That was on the 23th January, and in December M. Hénan, the planter at the station had gathered 7 kilos.....

Some figures as to the cost of planting and cultivating may be interesting: it is difficult to estimate the cost of clearing as much of that was done by members of the staff (soldiers) in spare hours. At Basoko and at Coquilhatville, the clearing and preparing of the soil took 1,000 days, which I value at ¼ franc each, i.e., frs. 250. For the maintenance of 100 hectares (250 acres) 250 men or women will be necessary, say 300 × 25 = 750 days per hectare, (2½ acres) that is an annual outlay of 200 francs per hectare.

Including all these expenses, then, each kilogramme (2¼ lb.) of coffee harvested in Upper Congo will have cost at most 20 centimes (about 2d.) for labour. I reckon it will have cost for expenses of administration, and direction, over-sight and other contingencies 2½ more. As for the cost of transport from Stanley Falls to Antwerp, when the railway is finished, they will not be quite 4½, say 4d. The kilo of coffee arrived Antwerp will have cost nearly 1 frs. and can be sold for 2 to 2.20 francs, and we know that a plantation of 100 hectares would produce from the 6th year at least 150,000 kilos, of coffee. This is an ideal that it is possible to attain in many parts in the Congo.

I have also collected some figures upon Cacao. On one tree five years old, cultivated at Basoko, I counted 34 fruits, some fully, some half grown. Ten of these ripe ones contained 427 seeds in a dry state. The 34 fruits would have given about 1,200 grammes (2½ lb.) of dry seed. The kilo of Congo cacao is valued at fr. 1.20; at that price a hectare (2½ acres) of cacao trees planted 9 ft. apart, would bring in 1 kg. 200 × 800 = 960 kilo. worth 1,152 frs. from the 5th year. It is decidedly less profitable than an equal area of coffee. As for the expenses of cultivation they are the same. If one takes into consideration the inherent difficulties in the cultivation of cacao (rich soil and sheltered situation needed, delicate seeds, difficulty of transplanting) it will be agreed that cacao is not so suitable for the Congo as the Liberian Coffee.

There is one other tree frequent in the sandy forests of the Aruwimi, that is the tree that gives the copal gum, the *Trachylobium*. It belongs to the Leguminosæ, has bifoliate leaves, irregular petals and is of coriaceous texture. The tree is freely found on the borders of streams and attains a height of about 30 ft. The station of Asoko buys on an average 600 kilos. of copal gum per month. Its value in Europe is very variable. The district could probably produce 20 tons a year, probably more.

During 1895, the district sent about 100 tons of Rubber, and the quantity might be doubled or trebled. Oil Palms are very frequent on the left bank of the river. "Raphia" and "panza" are also very abundant. Basoko station has also been well planted with fruit trees—citrou, mango, papua &c.,

DISTRICT OF THE BANGALAS.

This district also presents vast sandy surfaces alternating with slimy and more fertile soils, but the clearing of the forest has disastrous effects, so that in 3 or 4 years, the good soil has often disappeared and white sand only remains..... But at Um-

anghi an agricultural station has rightly been planted, for there we find a clayey soil and many ant-hills. 5,000 coffee plants and 2,000 cacao are planted, and as the forest had been thoroughly cleared, plantains are planted for shade; the vigour of those bears witness to the fertility of the soil.....

The best shade for coffee is certainly secured by the partial clearing of the forest... Hence they have started a small plantation 2½ miles from Makolo quite in the forest... But hitherto the labourers have had to walk there and back from Makolo, this, is a waste of time... To keep the field clean, 3 women were set apart for every 2½ acres and had no other work; they even sweep up the dead leaves—an unnecessary work; I rather think it would be better to fork up the weeds and not to destroy them; on sloping land the washaway would be prevented....

The plantations altogether in this station comprised 230 acres of cleared land, 28 of which were at Makolo; 123 were planted with coffee and 25 with cacao. But many plants had been put out with only 2 leaves and should have remained longer in the nursery. An apparatus for cleaning the coffee by John Gordon & Co. has been sent here, but is not yet working.

Among the products cultivated by natives I notice the ground nut, sugar-cane, rice, manioc and beans.

The district produces 400 tons of Rubber annually. The forests are rich in oil-palms (*élaïs*) *panza* and *raphia*, and there are also copal-producing trees.....

—*British Central Africa Gazette.*

CRETE AND ITS PRODUCTS.

It has been placed to the credit of the late Emperor of Brazil that on being shown the fly-wheel of a certain steam-engine, and informed that it made over 300 revolutions per minute, he remarked that it was far ahead of his country, for they could only muster that number of Revolutions in a year; and so of Greece it may be remarked that many have been the Revolutions during the past hundred years, especially in Crete—one of those—

"Isles of Greece,

Where burning Sappho loved and sung"

and to-day the whole of Europe and Great Britain is exceedingly perplexed as to what is to be the order of things in Crete, and in Greece itself, in the days to come. We can only express the hope that freedom and prosperity may be the outgrowth of the present imbroglio, for then horticulture and agriculture will flourish on this borderland of the East. As to the resources which these two are capable of yielding in freedom and peace it were difficult to say. The island lacks proper cultivation, is thinly populated, its exports are limited in value and number—olive oil, wine, raisins, soap, Locust-beans. Valonia, Almonds (shelled), and some Oranges. Of the products now shipped from the various Cretan ports, a fair proportion finds its way to this country—in the shape of olive-oil, raisins, Locust-beans, Valonia.—*Gardeners' Chronicle.*

ANOTHER BIG BRAZIL COFFEE SYNDICATE.—

In a London paper dated April 10th, by the French mail, we find the following important paragraph. It would look as if "coffee" were going to be overdone as much as "tea":—

A large and extensive group of coffee plantations, situated in the San Manuel district of the State of San Paulo, have been sold to a Dutch syndicate for the purpose, it is believed, of flotation as a company on the European markets. The purchase price is stated to be £500,000. It is understood that negotiations are in progress for the purchase of other coffee estates in the same province by various syndicates, both English and Continental. The flotation of the Dumont Coffee Estates on the London market in the early autumn of last year has encouraged the undertaking of similar business in other quarters, and more than one flotation is expected at an early date.

THE REPORT ON THE CAWNPORE EXPERIMENTAL FARM

for 1895-96 has reached us. The Farm is under the immediate charge of the Principal of the Agricultural School at Cawnpore, who must be highly gratified with the praise bestowed on the farm by no less an authority than Dr. Voelcker; for the latter, in his report on the "Improvements in Indian Agriculture," records the following opinion:—"In fact, I was much pleased with the Cawnpore Farm, and was not prepared to find in India anything which so nearly came up to my idea of what an experimental station should be."

Among other matters which occupy the attention of the farm authorities is the distribution of implements, of which we read that there was a remarkable increase in the number distributed during the year. This is said to be due chiefly to the efforts of the representatives of the department in bringing the improved implements into prominence at the Agricultural Shows. We note that the implements were either sold or given out on hire, or for trial. Under the head of "Distribution of Seed," we find that between 20,000 and 30,000 lb. of seed were distributed during the year under report from the seed-store attached to the Farm; while under the head of Cattle, we have a note on the Veterinary Hospital, where the number of patients treated was 72, and the cases cured 70. The results in the latter case are naturally considered to have been encouraging. Among other interesting experiments are those with reference to Cotton Cultivation, and the various systems of conserving Cattle Manures, which are said to be likely in time to lead to some results of economic value.

We have only been able to refer to a few of the striking features in this Report, but our perusal of the document leaves us no room for surprise that so eminent an authority as Dr. Voelcker should have spoken in high terms of the Cawnpore Farm. When may we expect to see a like institution in Ceylon? Not while the Government do not provide a vote for such important work as the distribution of seeds and implements, and for the carrying out of useful experiments in connection with their Agricultural School. In this connection we would emphasise the importance of a Veterinary Hospital such as that referred to in the Report (worked, if possible, in connection with the Society for the Prevention of Cruelty to Animals, as in Bombay) seeing that the Government have a highly-paid Veterinary Surgeon, who is apparently not over-burdened with work or responsibilities. A veterinary hospital would not only be the means of popularizing European veterinary treatment, but would also afford a training ground for students of the Veterinary School whose opportunities for acquiring a practical training in the veterinary art must be very small. It is a matter for regret that the Government of Ceylon did not think of inviting an expert, such as Dr. Voelcker, to draw up a scheme of work for the Ceylon Agricultural School at the same time that he was reporting on the "Improvements in Indian Agriculture."

THE ESTATES COMPANY OF UVA, LIMITED.

The annual ordinary general meeting of the above Company was held at the Company's Offices, No. 7 Queen Street, Fort, Colombo, at 12-30 p.m., on Saturday, 27th March, 1897.

The directors' report was as follows:—
ACREAGE.

	Tea in full bearing.	Tea in partial bearing.	Tea not in bearing.	Total Tea.
Dammeria Group ..	436	29	110	575
Battawatte and Forest Hill ..	209	167	211	587
Gampaha ..	332	20	119	471
	977	216	440	1,633
	Other Products.	Timber Trees and Grass.	Forest and Wasta land.	Total.
Dammeria Group ..	43	23	502	1,118
Battawatte and Forest Hill ..	5	14	141	747
Gampaha ..	81	82	232	866
	129	119	875	2,756

(Some coffee also remains amongst tea and timber trees on Gampaha and Battawatte Estates.)

The Directors have now the pleasure of submitting to the Shareholders the accounts for the past year.

The tea crop, which was estimated at 350,000 lb. amounted to 350,102 lb in addition to which 32,025 lb. were made from purchased leaf. Of the total quantity, viz: 382,127 lb. 372,818 lb. have been sold at a net average of about 48½ cents per lb. A reasonable valuation has been placed on the unsold portion of the crop, viz: 9,309 lb. The receipts for manufacturing tea for other estates amounted to R5,679.32.

The Coffee crop was slightly under the estimate of 970 bushels, having amounted only to 918 bushels, as against 3,070 bushels in 1895. As will be seen from the Working Account, the Cocoa and Cardamom crops slightly exceeded the estimates of 50 cwt and 500 lb respectively.

The expenditure on Working Account amounted to R148,451.80, which included the whole of the Salaries and Establishment charges on each of the Estates.

During the past year the Tea acreage was increased from 1,574 to 1,633 acres, partly by the planting up of land under other products and partly by opening up new land. A small addition of Acres. 12.3.18 has been made to the Dammeria Group by purchase of that extent of Crown land. The cost of these extensions, as also upkeep of the Tea fields not in bearing, amounting to R26,854.17, is added to the cost of the Estates. The cost of additions to Buildings and Machinery during the year amounted respectively to R10,307.60 and R10,530.80.

An issue of 99 shares of R500 each was made in terms of the Directors' Circular letter of 26th March last, these shares being taken up by the holders of the then existing shares at a premium of R100 per share. The paid up Capital of the Company is thus increased to R700,000 and a sum of R9,900, the premium on the new issue, is placed to credit of Profit and Loss account. The Directors recommend that this premium be transferred to Depreciation Account.

After making provision for ordinary depreciation of Buildings and Machinery a sum of R58,867.38 is available for distribution, which will be reduced to R48,967.38 by the transfer of the share premium as above referred to. The Directors recommend that a dividend of 7 per cent for the year be declared on the Capital as at 1st January, 1896, viz., R650,500. and that, in terms of the issue, a dividend of 3½ per cent be declared on the Capital last issued, v.z., R49,500. The payment of these dividends will absorb R47,267.50 and leave R1,699.88 to be carried forward to the current year's accounts.

The question of improved outlets for both Battawatte and Gampaha has been engaging much of the attention of the Directors. An extension of the Madulsima road through Battawatte and Forest Hill, as a Grant-in-Aid road, is likely to be undertaken at an early date, while the Directors hope in a short time to have matters ripe for an application being sent in to Government for the very necessary extension of the Uda-Pussellawa road.

The crops estimated for the current year are 415,000 lb. Tea, 590 bushels Coffee, 60 cwts. Cocoa, and 600 lb. Cardamoms, while the estimated expenditure on Working Account, viz., Rs. 150,554, provides for the manufacture of 40,000 lb. Tea for another estate.

The outlay on Capital account, which is estimated at Rs. 13,922, will be for upkeep of the Tea fields giving no return and extension of the area under Tea, as also for additional coolie lines &c.

An extension of the Gampaha Factory is also in contemplation but for this no estimate is yet framed, while the cost of providing improved outlets for both Gampaha and Battawatte will probably have to be met

Messrs. Carlyon, Figg and Chas. Young having resigned their seats on the Board on leaving the Island, Messrs. A. Thomson, G. H. Alston and W.D. Gibbon were duly appointed to fill the respective vacancies. Mr. C. A. Leechman having also retired from the Board, Mr. E. J. Young was appointed in his stead, and that gentleman now retires by rotation.

The appointment of an Auditor rests with the meeting.—By order of the Directors,

WHITTALL & Co., Agents & Secretaries.

Colombo, 17th March, 1897.

CINNAMON SALES IN LONDON.

The particulars of the last quarterly sales of cinnamon, held in London on the 22nd ultimo, which we published in our last issue, afford gratifying evidence of the correctness of the anticipations in which we had indulged, of a permanent improvement in the value of, perhaps, the oldest of our staple exports. After a period of long, and almost ruinous, depression, our historical spice began looking up a year or two ago; and although it was feared, from the suddenness and extravagance of the first considerable rise, that the upward tendency was artificial—as indeed it was on that particular occasion—and would be only temporary, the prices which then ruled have been fairly well maintained. The speculative prices which certain medium marks secured, have of course not been realized since; but there has been no general drop. On the contrary, almost every sale since then has proved satisfactory to the producer; and the confidence we expressed, that it is a better demand, and not speculative operations, which first provoked keener competition, seems fully justified. The main reasons which point to this conclusion are that almost all the cinnamon brought to the hammer, is knocked down in the auction rooms, the balance finding ready buyers immediately after, at current or improved rates; and secondly, that the demand is pretty evenly distributed, and all sorts find buyers. Not only so, and not only that unsold lots scarcely ever have to be reserved for the next quarterly sales, as happened pretty frequently a few years ago, but the difference in price between fine and medium bark is not as pronounced as it used to be. For many years, and until about two years ago, fine pale cinnamon of the best known brands fetched quite double the prices of medium marks; and often even

more. Thus, we have known C. H. De S. (the De Soysa brand) realising for its firsts only 7d. to 8d., while Golua Pokuna would fetch 1s. 6d. to 1s. 7d. at the same sale. All this is now changed, and the relation of prices for barks which are pure and unadulterated, though they may differ greatly in thickness of quill and but little in quality of the spice, is more reasonable. Fancy prices for fancy makes are getting out of date; and the spice fetches about what it is really worth, with a reasonable allowance for more attractive appearance and the higher wages which have to be paid for the manufacture of fine quills. Thus, at the February sales the difference in price for Firsts ranged from 1s to 1s 6d; for Seconds from 11½d to 1s 5d; Thirds from 10½d to 1s 4d; and Fourths from 10d to 1s 1d. Fine bark may be said roughly to have fetched about half as much again as ordinary quills, instead of double or more. Then, the grading of ordinary bark showing a very inappreciable difference, the difference in price, too, was correspondingly small—from 10d for Fourths to 1s for Firsts; while in finely quilled cinnamon, the difference being more appreciable, the prices ranged from 1s 1d to 1s 6d. Again, the “unworked” cinnamon, which is sold as it is landed, without any manipulation in the Docks or Warehouses, and which the trade would not look at some years ago, was all competed for and sold at prices which approximated to those of ordinary bark, after they had undergone expensive unbalancing, brushing-up and re-baling. From this last mentioned circumstance alone, we are justified in deducing a real demand, as the London monopolists were very strong some years ago in resisting the claim of exporters to have more frequent sales, and sales on samples drawn from one bale of each quality, instead of having every bale undone. So long as the demand was slack, producers were unable to enforce the last demand; but now unworked cinnamon seems to provoke as keen competition as worked spice; and what is more, prices have risen in face of infrequent sales. Our great staple tea has receded in price despite weekly auctions, while cinnamon, which had to abandon even monthly sales in deference to a ring in London, has risen. The fact is of importance in connection with the discussion on the fall of prices which tea has experienced, as it points to the supreme importance of the relation between supply and demand in regulating the market.

Turning to the catalogue we find that the old marks maintained their old pre-eminence, Golua Pokuna leading as usual, closely followed by Wester Seaton, Kimbulapitiya, and Mudaliyar Rajepakse's Kadirane properties. A. & Co. (Messrs De Mel's Ekelle property), G. De C. (the late Mr. Gabriel De Croos' brand) come next, and then the great “unworked,” led by the C. H. De S. marks. Of 1,248 bales offered, nearly 1,200 bales found buyers in the room; and it would be a mistake to suppose that the offerings were small. Although the quantity was short of that which was brought to the hammer in February last year, the catalogue of February 1896, it must be remarked, was exceptionally large. The February sales are generally light; and in 1895 they received only 766 bales or nearly 500 bales less than was sold last month. Since the sales, a firmer tone seems to prevail, so that the outlook is decidedly cheering, and proprietors have to be congratulated on the returning prosperity for which they had long to wait.

The following is the report on the last sales from one of the leading firms in the trade in London:—

London, 25th Feb. '97.

CINNAMON.—The first auctions of the year were held on Monday last the 22nd instant when 1,248 bales Ceylon offered against 1,792 bales at the February 1896 sales. There was a good demand and about 1,200 bales were cleared in the room with capital competition. Ordinary to medium qualities of quill sold steadily at par to 1/2 per lb. advance and the finer brands maintained the good advance established in November except a few bales of first and fourth sorts which sold at 1/2 to 1d. per lb. cheaper. Fine "worked" Ceylon sold: Firsts good to fine 1/ at 1/6; seconds 11d. at 1/5; Thirds 10½d. at 1/4, and Fourths 10d. at 1/1.

The "unworked" spice sold (as landed) about 1,000 bales. Firsts ordinary to good 10½d. at 1/; Seconds 11d. at 11d; Thirds 10d. at 11½d., and Fourths inferior to good 7½d. at 10d. per lb.

CHIPS & C.—48 bags sold at 3½d. and about 50 bags quillings & c., at 8d. at 10d. per lb.

1896. 1895. 1894.

Stock of Ceylon 2,453 bales against 4,583 3,885. 3,515
The next sales are fixed for the 31st May.

LIVING ON COCONUTS.

The value of the coconut as food is shown in a story from Pemba, Africa. One coconut, night and morning, kept a man alive for seven months under most cruel and trying circumstances. The man was a slave named Muftah, who ran away from his master an Arab, named Ali Bin Abdullah. His master recaptured him, then treated him with horrible cruelty. He was put in irons, which were welded on his flesh near the ankles, and the irons were attached by a bar to a cleft tree. For seven months was Muftah kept in this position, exposed to all changes of weather, enduring noon-day heat and evening chill the torments of insects and semi starvation. A coconut, night and morning, was his only food and drink. He was eventually rescued by H.M.'s Consul at Pemba, Dr. O' Sullivan, who had him sent to Zanzibar. That he lived so long under such conditions is a matter of surprise, and speaks well for the food value of the coconut.—*Produce World*.

PRODUCE AND PLANTING.

TEA BLENDING.—The development of tea planting has led to a similar growth in the business of tea dealing, especially in that department of it in which blending is made a conspicuous feature. While many of the old firms of tea dealers still maintain their trade and position, several comparatively new firms have entered into competition, making a great point of the art of judicious blending which they cultivate. The *Grocer*, recently describing the new premises of one of these firms which it states by the way, were only established quite recently, says:—"The floors are fireproof, and the different departments are admirably suited to the purposes for which they are intended. Goods delivered from the bonded warehouses are at once lifted by means of a crane fitted with the 'friction jigger' to the top or third floor, designated the receiving room. Here the teas are fed into cutters, which reduce the leaves to a uniform length and free them from extraneous matter. From these machines they pass through to the 'hopper' on the second floor. The capacity of the drum is about twelve chests, or some 1,200 lb, and this is directly connected with the mixing machine (of equal capacity) on the first floor by means of a capacious funnel. Thus it will be seen that as soon as the 'mixer' is cleared another parcel can be introduced in a few

moments, and a very large quantity of tea can be dealt with in a brief period. The ground floor forms the delivery department, and it is to this room that teas packed on the different floors and ready for delivery are conveyed in the powerful hydraulic lift. At the time of our visit the building was not out of the contractors' hands, but large numbers of employes were engaged on the various floors in the various processes involved in preparing the firm's packet and loose teas for the market. In the basement a six-horse-power nominal Crossley gas engine has been erected, and here also a circular saw is to be laid down in order to facilitate the work of chest making. Special arrangements have been made for keeping the rooms free from dust, and for drying labels rapidly by the provision of powerful fans, and the ventilation has been carried out on scientific principles." The firm referred to, it appears, "offer every facility to retailers to adopt the 'own name and label' system of trading, and they supply photographs of tea plantations for window display. The care they devote to blending is indicated by the fact that samples of the drinking-water used in almost all parts of the country are kept on the premises."

JUST ROMANTIC ENOUGH.—It is not surprising that the British youth yearns after a tea planter's life as he reads the glowing accounts given of it in some of the light literature of the day. Even the globe trotters are impressed with the glimpses they get. In a book called "Romantic India," just published by Mr. Heineemann, we find the author, a Frenchman, M. Andre Chevrillon, indulging in a glowing sketch of a Ceylon tea garden proprietor. We knew that all tea garden proprietors in Ceylon are not "fat, gentle, pale," and that sitting in *chaises longues* with cigarette and book is not the lot of the "creeper," but the following description reads well:—"Yesterday," says M. Chevrillon, on the railway, returning from the interior of the island, I met a Hollander; fat gentle, pale, peaceful of gesture, scanty of speech. Of the Dutch temperament there is left only the phlegm and softness; the sanguine flesh tint has disappeared under the heat. After five minutes he asked me my address that he might send me some flowers; for my pockets overflowing with roses, jasmines, mimosas, my admiration for the very great size of the floral display on every side had surprised him. After a time I learned that my man is a native of Ceylon, that he has tea plantations in the mountain, and lives with his family at Colombo. To-day I dine with him. His bungalow, situated in the cinamon gardens, is like a villa of some rich old Roman, deliciously bright and cool, immense halls separated by partitions of fragrant woods, carved and cut in fretwork, great wicker *chaises longues*, where one may recline all day with cigarette or book. The children pretty, but singularly pallid, a translucent, waxen tint, fined down and enfeebled by the climate; a household of servants, who seem very much beloved. Parents and children speak Cingalese to them."

THE BOARD OF TRADE RETURNS AND PRODUCE.—The striking feature of the Board of Trade returns of our foreign and colonial trade during February is that the declared value of the imports into the United Kingdom again shows an increase (£1,768,428), and the declared value of our exports of British and Irish produce and manufactures a decrease (£1,839,413) for the month. Striking increases are found under the head of duty-free and dutiable articles of food and drink, and represent *inter alia* increased imports of wheat from the United States and Turkey, flour from France, maize from Argentina, coffee from all sources of supply except Ceylon and Brazil, and tea from Ceylon and India.

COOLIE LABOUR IN THE WEST INDIES.—The official report referring to Jamaica is interesting alike for its statistics and its reference to the East Indian coolies there. There is a decline in the value of the exports from the figures of former years, the difference compared with 1894-95 amounting to £48,317

Coffee, bananas, sugar, rum, and cocoa are the chief items that have declined, whilst the exports of oranges, grape fruit, ginger, lime juice, and pimento have expanded. It may be interesting to state as regards oranges that the total export in 1895-96 was 97,025,398, of the estimated value of £169,794 these figures exceeding the sum of the exports in the four preceding years by 12,062,751 in number and £44,319 in value. The island is thus continuing to reap the result of the misfortune which befell Florida in 1894. It appears that the East Indian population thrive in spite of the depression in the sugar industry, which has little if any effect on their average wages, the greater number being now employed on fruit-growing properties. One high-caste East Indian, formerly an immigrant, is now the possessor of over 2,800 acres of land, and has been elected a member of the parochial board of Trelawny. Over three hundred coolie adults with their families left for Calcutta in the Government vessel on May 18, 1895. Ninety-nine adults who had claimed and were entitled to free passages did not present themselves, and the ships had to be despatched short of the full complement. The amount of £3,139 was taken away in Treasury bills by eighty-nine families. A further instance of the prosperity and thrift of the East Indian population is shown in the increase of savings' bank depositors compared with 1894 of from 793 to 1,029, and of deposits from £13,958 to £22,680, notwithstanding the closing of several accounts by coolies.

A NEW CONSTITUENT OF INDIAN HEMP.—The hemp plant, *Cannabis saliva*, grown in temperate countries, produces a valuable fibre; but in India the fibre produced is of little use in the arts, and the plant appears to devote its energies mainly to the production of a resinous secretion, which, owing to its soporific properties, is a very valuable medicinal agent. The resin exudes from the plants, and is collected by men walking through the fields with long leathern gaiters, to which it sticks; it is known as "charas," while the tops of the plants collected with the resin on them, and matted together by pressure, form "hashish." Very many attempts have been made, says the *Imperial Institute Journal*, by chemists to isolate, from the various Indian hemp products, the principle to which their medicinal activity is due, with the result that many and very different substances have been from time to time regarded as the active principle. The most recent investigation of Indian hemp is that of Messrs. Wood, Spivey, and Easterfield (*Journal Chem. Society*, May, 1896), who obtained by fractional distillation of "charas" under a very low pressure a resinous substance to which they gave the name "Cannabinol." At ordinary temperatures "Cannabinol" is a viscous resin, melting to a thick oily liquid when the containing vessel is placed in warm water. The therapeutic action of this substance has been examined by Mr. Marshall, M.B., assistant to the Downing Professor of Medicine at Cambridge University (*Lancet*, Jan. 23, 1897). Mr. Marshall made two experiments with the drug upon himself, taking on the first occasion from 1 to 15 gram., and on the second a smaller quantity. The first dose did not cause sleep, but induced a peculiar state of delirium, accompanied by complete loss of memory and all sense of the passage of time. This state of delirium alternated with perfectly lucid intervals. On the second occasion the small dose taken produced similar effects in a milder form and for a shorter time, being followed by sleep, during which a series of visions were seen, usually of a grotesque character. The use of the drug seems quite unattended by any unpleasant after-effects such as are experienced with some other narcotics. It was tried on one patient suffering from insomnia with very good results. The terpenes obtained as a first fraction in the preparation of "Cannabinol" were also purified by Messrs. Wood, Spivey and Easterfield, and sent to Mr. Marshall for therapeutical experiment. They were found to act exactly like ordinary terpenes, so that they are not connected with the characteristic action of the hemp products.

PRODUCE FROM THE GOLD COAST COLONY.—The Gold Coast Colony is in a flourishing condition notwithstanding the general unrest in the colony during the year 1895, owing to the Ashantee expedition; the total value of trade increased by £146,166, or roughly at the rate of 9 per cent., the total of exports and imports for the year being £1,809,340, contrasted with £1,663,173 in 1894. In 1895 the quantity of rubber exported from the Gold Coast increased by 1,000,000 lb, a total of 4,022,385 lb comparing with 3,027,527 lb, the values being £322,070 and £232,550 respectively. The year's output was the highest on record. Cacao, coffee, and kola nuts were imported in larger quantities.—*H. and C. Mail*, March 12.

TAMIL COOLIES AND LABOUR SUPPLY.

To the Editor, *British North Borneo Herald*.

Sir,—In the issue of January 1st there is an article about the Indian labourer *i.e.* the Tamil cooly. You scarcely give him fair play when you say he is physically unable to perform heavy work, while towards the end of your article you say he is by no means a bad road maker and can cut drains; also you recommend him for earth works. These works are usually considered the heaviest you can put a cooly to perform. Evidently the writer of the article knows nothing whatever about the Tamil cooly. I have had several years experience with Tamil labour and have always found them capable of doing the heaviest work with ease and neatness which the Malay lacks.

Secondly, you talk of obtaining Tamil coolies through Agents. This would be a most unsatisfactory way, as planters in Ceylon always send their Kanganies to get the coolies who know which men are suitable to work on estates and not an agent who will pick up any coolies for the sake of his commission. I should suggest sending someone to Ceylon and from there taking a Kangany with him to the Indian Coast to pick the coolies. After the Tamils have once got a footing and find they are well treated others will follow, by sending a trustworthy Kangany back to fetch more each year as required.

The Dusun cannot be put on the same footing as the Cinghalese for felling and clearing; the latter is much quicker, lops better, and works steadier.—Yours, etc. E. WALKER.

Manpakad Estate, 27th January, 1897.

[The writer of the article had had long experience of each form of labour, Tamil, Chinese and Malay, and still maintains that individually the Tamil cannot or will not do as much earth cutting as a Malay. In other words it takes three Tamils to do the work performed by two Chinese or Malays. Coffee, hemp and rhea were specially excepted. Our correspondent overlooks the fact that as regards most of the estates and clearings there are no kanganies to send to India and neither tobacco planters nor woodcutters have as yet cared to employ Tamil labour. The "Agency" question is easily solved by the rejection of unfit coolies at the Agent's expense. Dusuns may be worse than Cinghalese as woodcutters but the men mostly employed on the East Coast are Sooloos, Javanese, Banjerese, &c. We should be glad if Mr. Walker would state whether he considers Tamils equal *man for man* to the Chinese. They are doubtless cheaper per head and bring wives and children who can also work. But experience in the Malay Peninsula shows that owing to their much greater laziness, liability to sickness, and less strong physique there is no appreciable saving by employing them. We are nevertheless glad that Mr. Walker has written as the Labour question in North Borneo cannot be too thoroughly discussed.—Ed.]

PROGRESS IN NORTH BORNEO.—A correspondent writes:—"The mail brought out word that one of our principal Tobacco Companies was sending a manager out to open a coffee estate on one of their blocks of land. A Syndicate are about to bore for mineral oil on Province Dent."

UPPER DIMBULA: ITS VEGETATION
AND SCENIC BEAUTY:
VARIETIES OF TIMBER-TREES; INCREASE
OF BIRDS.

In the early days of coffee planting, Dimbula was divided into "Upper" and "Lower." In reality there was not much difference between the elevation above sea-level of the plantations in each division—Union and Bogahawatte ran as high as Louisa and Radella; but the approach to the one was from Kotmale, while the others had their outlet via Nuwara Eliya. There is no question now, however, as to the estates which run over 4,500 to 5,500 feet meriting for their district, the distinction of Upper Dimbula. We refer especially to those between Great Western and Nannoya, above or on each side of the railway line; and the plantations along the headwaters or crowning the slopes between the Nannoya and the Agraoya until we come under the shadow of Kirigalpotta or touch the far-extending Bopatalawa patanas.

It, on the one hand, the railway has done inestimable service in enabling lowcountry residents and visitors to enjoy some of our finest mountain scenery, how much is lost from the inclination to hurry through each district and to be contented with a glance at the general outline? The old Gampola and Ramboda and still more the Ramboda and Nuwara Eliya coaches were tedious and trying in many ways; but what enjoyment they afforded in the details of mountain, stream and valley scenery, now seldom or never seen by the ordinary visitor or traveller. In the same way we may say, after a brief sojourn within its limits, how little is known of the attractions and scenic beauty of Upper Dimbula from a mere trip by the railway along the one side of it. To see and appreciate Dimbula (as well as the adjacent districts) nothing but a driving or riding (or to a less extent a bicycle) trip covering every mile of its "pucka" roads can suffice. In any case, let no one say they know anything of the district, until they have travelled by the Agraoya, up as far as the Agras road will take them; and from Lindula alongside the Dambagastalawoaya past Kowlahena and Henfold, Maria and Lippakelle, Maedull and Cymru right into what Wm. Smith used to call "Molesworth's Railway Gorge" at the foot of Elgin estate; and yet again until they have traversed the road between Matakelle and Lamiliere and along a series of plantations the Dimbuldanda-oya till they enter the fine avenue shaded by grevilleas or eucalypts on Lorne and Abbotsford and pass on to the Longden Road *en route* for Nuwara Eliya. This is becoming a favorite route for bicyclists who think nothing of running from the Sanatarium to Talawakele or as far as Hatton (a Colombo visitor and Rangoon friend did the 32 miles 2,000 feet down, in 4 hours the other day); but who, though they enjoy a shady avenue for several miles, are far too much occupied in engineering sharp turns—of which unfortunately there are too many—or in giving "ample room and verge enough" to bullock bandies—to find proper opportunity of looking at the scenery, much less studying the vegetation. And yet there is a great deal in both worthy of note. We think it a pity that in his recent visit to Dikoya and Maskeliya, His Excellency the Governor did not drive down the Longden Road through Dimbula to Hatton, rather than travel by rail. Very likely,

the drive is only reserved until the Dimbula district is properly honoured with a viceregal visit, on which occasion, we trust, all the main roads we have named will be traversed, and the district thereby properly appreciated. In some respects, there is no more delightful upcountry drive in the island than the one from Talawakele to Nuwara Eliya, or *vice versa*. There is mountain and river scenery—big falls, tumbling cataracts, smooth pools, and long reaches of shady stream—with diversified vegetation from the clumps of shrubby, yellow or giant bamboos, to the shady grevilleas, graceful acacias, and the towering gum trees—all breaking the monotony of tea fields dotted over, however, with cinchonas, and by the wayside with not a few coffee bushes, singly or in limited groves. Cultivated native fashion, but with the trees neatly trimmed, it has been quite a treat to see an appreciable number of coffee trees—not acres—on some of the plantations in blossom, bringing back recollections of the beautiful fields of snowy jessamine-like flower, to be succeeded by the plentiful ruddy cherries of "auld lang syne." Our higher districts, as a whole, are becoming wonderfully well-wooded—(an advantage which many estates short of firewood sadly need)—and this is especially the case in Upper Dimbula.

We suppose the experienced Manager of Mount Vernon is as favourable as ever he was to the grevilleas (the Queensland silky oak) dotted over his tea fields on account of the great benefit which their litter of leaves confers on the tea bushes, while the big trees in no other way do harm. The fertilizing material is indeed abundant, if we may judge by the roadside gatherings on Lorne and adjacent estates, where we were repeatedly reminded of Milton's line:—

"Thick as autumnal leaves that strew the brooks
In Vallambrosa."

The bamboos have no such beneficial effect; but they are confined chiefly to clumps on the riverside, though some fine collections are found higher up in the ravines. The timber offers compensation for the sometimes troublesome litter:—the smaller bamboos split up making useful palings or garden fences; the larger ones a capital substitute for spouting, with many other means of turning the different sizes to use. Nothing, however, can be more picturesque in early morning or afternoon sun, than the glancing yellow Ceylon, Nilgiris or Himalayas, or the dark dark green Java, bamboos by the riverside in contrast with the prevailing plantation cultivation. All four kinds of bamboo are found on Abbotsford, and we suppose, we may say without any exaggeration that Abbotsford—thanks to the enterprise and enthusiasm of our relative and chief, the late A. M. Ferguson—is the best "timbered" or "wooded" tea plantation in the island? There are, as we said, some coffee bushes left and a very appreciable quantity dotted over the tea fields, of cinchona trees—alas, of no value unless the demand and prices increase and justify continued cultivation and bark-harvesting;—but these are nothing to the number and variety of timber trees. No census has ever been taken; but the experienced Manager, Mr. Fraser—himself an arboreal enthusiast—thinks there cannot be fewer than a score of varieties of Eucalypts, from the gigantic *Pauciflora*, running to 100 feet high and 8 to 9 feet in circumference, to the jarrah and red gum or the

handsome swamp mahogany. Then among many other introductions, especially on Lower Abbotsford—there is a difference of about 1,500 feet altitude between the top and lowest part of the estate—there are notable, magnificent specimens of *Albizzia moluccana*, umbrageous, lofty, massive, like so many grand beech or elm trees, and although not more than 15 years old, yet measuring up to 9 or 10 feet in circumference. The contrast between the cockscomb-like yellow grevillea flowers and the feathery white flower of the albizzia is very delightful. Of other trees we may mention several varieties of casuarina, pinus, cryptomeia, toons and allies, and acacia, the *Melanoxylon* especially, of which there are also fine belts on Deasford estate. Of individual ornamental trees there is enough for a botanic garden. Then, again, in garden cultivation, we believe the esteemed Superintendent of Hakgala Gardens sometime ago would not credit what he was told was to be seen on Abbotsford in the shape of Palm trees. And it is certainly very interesting to see, at 5,000 feet altitude, palm trees (albeit Australian in habitat) which might be taken at first sight for palmyras, 50 to 60 or 70 feet high, flourishing so freely that their reproductiveness in young palms from the dropping seed is likely to become a nuisance to the gardener or planter!

Nor have we mentioned all the advantages which have been secured in Dimbula and adjacent districts from the planting of timber, fuel or ornamental trees amidst the tea, in the gardens or in separate groves. "The songsters of the grove" have, as might be expected, very freely availed themselves of the cover and homes provided for them. "The singing of birds is again heard in the land"—heard over the 50,000 acres of primeval forest originally cleared to the last tree for coffee, cinchona or tea in this immense district. Not only so; but more bird visitors are finding their way up from the low country—attracted, no doubt, by the genial climate, garden-like culture, comfortable groves, and abundance of food. And here comes in the economic use of birds in destroying insect among other enemies of the planter and his staples. It has been an unusual and delightful treat to us at 5,000 feet to be wakened at sunrise by the multitudinous singing of birds outside our windows and away on the tree-tops, recalling the home cry in "Cymbeline":—

"Hark, hark! the lark at Heaven's gate sings,

And Phœbus 'gins arise."

For lark, read blackbird, as the chief favourite in Upper Dimbula and indeed in all our higher regions up to and within Nuwara Eliya itself. Indeed, the tree and garden cultivation in the higher districts have brought the birds—for who ever saw or heard them in the Dimbula jungle?—or even in the higher jungles now. The lowcountry sparrow is even now found in Dimbula. We trust the process of establishing groves of timber or fuel trees, or of dotting these over the landscape and of introducing ornamental trees into the gardens and around the bungalows, in our planting districts—both high and medium and in its own way even in low districts,—may continue and extend more and more; and then we may be sure that the risk of any serious enemy to our tea or other products, springing up, will be greatly lessened.

Meantime, we commend to all visitors and travellers—not to speak of residents who move about from time to time—the advantage of be-

coming acquainted with the scenic and other beauties of our higher planting districts—Dimbula, Dikoya, and Maskeliya, not to speak of Udapussellawa—even as seen from the first-class roads which traverse so many of them in different directions.

ENEMIES OF CACAO.

We call attention to an interesting letter from Mr. Vander Poorten, who has had prolonged experience now as a cultivator of cacao. He refers to the letter in which Mr. Christie announced that the Governor had considerably agreed to call in a Specialist to report on the pest affecting the red species of cacao. No intimation is given as to where this Specialist is to be sought, and whether he is to be an Entomologist or Fungologist? We do not know, indeed, whether there has been a preliminary local enquiry, and whether such special talent and training as we may have in our midst has been consulted—or whether the Governor is acting, or has acted, simply on the request of the Planters' Association Committee, or of Mr. Christie as spokesman for a number of cacao planters? We ask these questions, because apart from the letter we publish today—the writer of which shows practical and scientific knowledge—we cannot find that Mr. E. E. Green of Pundaluoya has been consulted as to the "Specialist" required for "the cacao pest." Now, we know, a prophet is not without honour save in his own country; but seeing that Mr. Green has made for himself no undistinguished position among scientists at home, and remembering further that we have had in the course of the past thirty years, "specialists" come out to this colony, who proved decidedly bad bargains,—we should certainly have liked to see Mr. Green, as well as the Director of the Botanic Gardens, consulted as to the wise and proper course to be taken in the matter. Mr. Green himself, being the most modest of scientists, will deprecate what we have written; for, in answer to our enquiry, as to his knowledge of cacao enemies, he writes as follows:—

"From Mr. T. N. Christie's letter it appears that the specialist is required to investigate some one particular pest affecting the red variety of the cocoa. I am not quite sure to what disease he is referring. But if, as I suspect, it is of a fungoid nature, the services of a specialist (a cryptogamist) would certainly be necessary. I am certainly not qualified to advise in such a case. My particular studies have been entirely in the entomological line. Some few weeks ago Mr. Chas. Gibbon sent me some sections of diseased cocoa steens, together with some small boring beetles which he supposed to be the cause of the trouble. But an examination of the material showed me that the beetles were not accountable for the disease, but had been attracted by the decaying wood. The whole sap of the tree was diseased. I was unable to say whether the inquiry was due to unsuitable soil or to some fungoid disease; but it was certainly not caused by any insect enemy.

"Many thanks for your kind expressions of opinion upon my qualifications as an economic entomologist. It is a subject that has always interested me, and I have endeavoured to keep myself abreast of the progress and work done in this direction in other countries. But it is difficult for a private individual, unsupported by either funds or authority, to conduct the necessary experiments. Many of these—though expensive—must be unremunerative. We have very much to learn about the action of various insecticides and there can be no progress without many failures, for which a large margin should be allowed."

We most heartily agree in the need of economic experiments in reference to the enemies of more than one of our staples, and we cannot at all understand why, before importing a Specialist (even though a Cryptogamist or Fungologist) advantage should not be taken by Government of Mr. Green's special qualifications to get him to visit the different cacao districts or estates afflicted with enemies and to report on the same. Mr. Green can be depended on to give an honest, as well as useful Report, and in the case of "Tomici perforans" as described by Mr. Vander Poorten, it is possible an enemy has to be dealt with that is peculiarly within the scope of Mr. Green's department, and yet which apparently produces results as serious as any arising from a fungoid enemy? It must be understood that we are not in the least opposed to a "Specialist" being got to deal with any disease outside the scope of Mr. Green's training after the necessity for the same is clearly shown; but we cannot help thinking an inspection and Report from the latter to Government ought to precede the importation—such Report probably indicating with scientific exactness what was really expected of the newcomer.

Still more, we have to point out for the information of Government that if a fungoid enemy is the trouble of the planters of red cacao, the proper course is, first, to send specimens of the fungus to the leading European authorities to identify, describe and possibly to tell us all that is known of its work elsewhere. We are able to assure the Government that this is what was done by the late Dr. Thwaites in reference to the coffee fungus: at the very outset he sent specimens to Messrs. Berkley and Cooke, the greatest living fungologists, who pronounced our great coffee enemy to be new to science, named it *Hemileia vastatrix* and recommended that its life history should be worked out. It was only then, that Professor Marshall Ward was got out as a Specialist, to study the fungus in its habitat and frame its life history, as he so successfully accomplished. Surely the same course is the wise one to follow now? It is, moreover, very unlikely that the cacao fungus should prove "new to science" and more probable that we should be told a great deal about it if specimens were sent to the proper quarter; for this reason, among others, that Dutch and German scientists have been investigating the "Enemies of Cacao" for many years with reference both to Java and Dutch Guiana.

LIBERIAN COFFEE IN SUMATRA.

We are glad to learn that Mr. Turing Mackenzie has returned to Sumatra with sufficient support from Ceylon to enable him to develop his valuable land concession for Liberian coffee, etc.

INDIARUBBER VS. GUTTAPERCHA.

As is well-known, both India rubber (in small quantities) and Gutta percha (largely, are produced in B. N. Borneo, and those products are amongst the most important of the districts which the new railway is designed to tap. Apropos of this the following definitions of the difference between the two gums may be of interest:—"India rubber is of a soft, gummy nature, not very tenacious, astonishingly elastic. Gutta percha is fibrous, extremely tenacious, and without much elasticity or flexibility. India rubber

once reduced to a liquid state by heat, appears like tar, and is unfit for further use. Gutta-percha may be melted and cooled any number of times without injury for future manufacture. India-rubber coming in contact with oily or fatty substances is soon decomposed and ruined. Gutta-percha is not decomposed by coming in contact with oily or fatty substances. India-rubber is ruined by coming in contact with sulphuric, muriatic, and other acids. Gutta-percha resists the action of these and nearly all acids. India-rubber is a conductor of heat, cold and electricity. Gutta-percha is a nonconductor of heat, cold, and electricity."—*N. B. Herald*.

PLANTING IN THE WYNAAD.

WE call attention to a rather important advertisement (p. 499) sent us by a well-known experienced Wynaad planter, whose testimonials, as to practical ability and reputation, are of the most satisfactory description. Mr. Ryan not only reports first-class land to be freely and very cheaply available on leases of 12, 24, 48, or 99 years, and low Government assessments (not exceeding two rupees per annum on the cultivated acre); but he adds that "labour is cheap and plentiful"; and also an abundant supply of manure. All this should induce a rush of commissions to Mr. Ryan, and it indicates the prospect of Wynaad becoming an important competitor in respect of medium and common teas. But it will take some years yet, before it can come to the front to a serious extent.

AGRICULTURE IN CEYLON AND THE NUWARA ELIYA AGRICULTURAL SHOW.

We direct attention to a discriminating notice of the recent Show, from a competent hand on another page. To say that such Exhibitions are of no use to natives as well as colonists—as a contemporary seems to have done—is to our mind, the very acmé of blind prejudice or obstinate unbelief in the progress which every year witnesses around us. This action is on a par with quoting Mr. Coomaraswamy of all men as an authority on native agriculture! We suppose the same writer, if he lived in the "twenties" or "thirties," would have said it was of no use introducing potatoes into our hill-country, since the natives would never grow them. Or, no use for Mr. Nock to show his new vegetables at successive Shows, during the past twelve years, as nobody cared about them—while the fact is that natives by hundreds, if not thousands, have profited by his recent introductions from the West Indies, brought before many of them first as exhibits at Shows; while as regards "potatoes," "cabbages," and other ordinary English vegetables, who can say how much benefit has been conferred on the natives of Uva, Udapussellawa, Matnrata, Ramboda, and other districts and the Tamil coolies throughout the planting region—by their gradual introduction from the "twenties" downwards. No better way again can be devised of bringing any new, or specially improved vegetable, fruit or other agricultural introduction before the general public—natives especially—than in Agri-Horticultural Shows. Not simply "society," or the well-dressed crowd of all classes, who pay for admission, take note of the exhibits. They are the talk of the bazaar, of the *hoi poolloi*, who

crowd around the enclosure to get in at the end, of the many coolies who take an interest in master's "exhibits," prizes or misfortune, and altogether it is difficult to tell even in this somnolent land, how far the benefit of such Shows may extend among the people around us. Of course, we plead, in regard to more strictly native rural districts, for Exhibitions on a less imposing scale and more suited to the condition of the people.

In this connection we may refer again to the practical address of His Excellency the Governor at the Nuwara Eliya Show. We have generally been accused of giving too much attention to planting and agriculture in one form or other, and the series of volumes of our *Tropical Agriculturist* are evidence that we have not failed to do our duty by the land we live in or indeed by tropical lands generally. The *Agricultural School Magazine*, issued independently, as well as bound up with our monthly, deals more particularly with practical subjects within the scope of native readers, and let it never be forgotten that the Ceylonese are far and away in advance of Indian Agriculturists in their knowledge of English. We have again and again found native gentlemen making experiments with new products, or in improving old, through the guidance afforded them by their English reading in local or other publications. It is rather extraordinary to us that the Governor should be puzzled about the usefulness of an Agricultural School or College in Ceylon, seeing that His Excellency must know how highly favoured such institutions are by the Governments and experienced officials in India, where, there cannot be more scope or intelligence among the people that is freely available in Ceylon. Surely this island can afford and ought to have an Agricultural College as much as Madras? Here then is what is doing over the way according to the latest Madras papers:—

THE AGRICULTURAL COLLEGE.—The practical examination in Veterinary Science, Botany, Agriculture, Surveying and Levelling commenced on Friday, and was continued till Saturday. The examinations will be resumed on the 15th and be continued up to the 20th proximo, and will be followed up with the Theoretical examinations in the same subjects up to the end of April next, when the College will close for the summer recess.

If Sir West Ridgeway is therefore in any doubt as to how the local School or College should be conducted, can His Excellency do better than compare what has been done here with the course pursued in Madras? We earnestly desire that Conferences could be arranged between Indian and Ceylon officers in many departments of the public service—in the Police, Railway, the Postal-Telegraph, the Survey, P. W. D., Botanic Gardens, Technical and Agricultural Schools, to name only a few, and even without troubling the Revenue and Judicial branches. Only good could result from meeting for a fortnight or month once in two or three years to compare modes of working and results. That would certainly be a most practical way of improving local administration. In the meantime let us see what the Governor's Commission on the Agricultural School, is to bring forth. Who are its members and whom are they to examine? Should not one of the Commissioners be sent over to watch the present examinations, and generally to study the Madras Agricultural establishment and procedure?

COOLIES—COOLIES—COOLIES!

Is likely to be a cry often heard in the present and coming two months. Mr. Ingramcotton, it will be observed, gives the Planters' Association exactly the information and advice we tendered sometime ago, namely that Bellary, Cuddapah and North Arcot (among Tamils and Telugus) are the only promising districts for an extra supply of coolies. The Immigration Agent should, at once, be deputed by Government to visit and report on these districts.

In our own planting districts, matters are rapidly coming to a head. A careful planter, not 100 miles from Kotagala, writes:—

"Crimping is of daily occurrence: kanganis go about and find out where they can get the highest advances and then give notice."

A merchant again sends us evidence of the extraordinary rates per head, leading proprietary planters, are prepared to pay for coolies: not far off R100 a head apparently. We are aware that planters who have never before been troubled about tunds, are worried this season. But how is it, on the other hand, that there *are* estates (in the older districts especially) on which advances have never been given or asked for? Is it on account of garden and other special privileges? If so should not something be done in this direction in other districts to keep Ramasami more "at home" and contented: how would it do to multiply boutiques—so that kanganis and coolies need not wander to the big central bazaars to hear all "the scandal" and to get tempted?

DOGS AND JACKALS.

On a coconut plantation near Hanwella are two ordinary village watch-dogs. They are fond of hunting on their own account and have been known more than once to bring down and kill a jackal, probably when it was prowling about their master's fowlyard. Is this unusual?

VARIOUS PLANTING NOTES.

CEYLON TEA EXPORTS.—We learn on the usual authority that the total shipments for March from Colombo equalled 9,125,000 lb; while the estimate for April is 9½ to 10 millions lb.

CINCHONA PROSPECTS.—We referred to these the other day as so poor that few planters in Ceylon cared even to allow their old trees to continue in existence. But here is a rather more reassuring report from the latest London *Chemist and Druggist*:—

Cinchona.—Since the last Amsterdam auctions several parcels have been sold privately at full prices. There has also been more demand for *Druggist* quill. In the Amsterdam market the opinions about cinchona bark are very conflicting, but the majority believe in a lasting improvement on account of the decreased receipts from Java, which, they maintain, will continue to dwindle. On the other hand there is also a party who say that the shipments are only kept down for a time, and that we shall be swamped again shortly; this, however is the minority, and the feeling generally has improved of late. The April auction will be a large one, about 6,000 bales, but still, if the March shipments are small (and this will be made known before the sale), a good result is expected. It is said that the German factories are working day and night to keep pace with the orders in hand, which clashes with the supposed existence of enormous stocks in their hands, about which they are always talking. At all events the consumption of quinine seems to have been enormous,

COCONUT PLANTING AT VETTUKKADU, JAFFNA.

Vettukkadu is a village of the Division of Punaryn, which is one of the Maniagarships into which the District of Jaffna is divided. It is about 12 miles by sea from Jaffna. About fifteen years ago, Dr. Candiah of the Civil Medical Department, now a pensioner, bought a piece of Crown land and planted it with coconuts with the result that he now gets a fair return for the money and labour expended. The example thus set has induced other Jaffnese to take to coconut planting in and about Vettukkadu. Some years ago, Mr. Casipillai of the local Bar, purchased an extent of Crown land, larger, I believe, than Dr. Candiah's and commenced planting. The estate formed is now under careful and systematic cultivation. It will come into full bearing a few years hence and there is every prospect of its proving to be a profitable investment. More recently, about 600 acres were purchased by a number of Jaffnese, who have already cleared about two-thirds of the extent. The planting of a portion of this extent, undertaken only last year, promises well, judging from the appearance of the plants. Reference was made in your columns some time last year to the land bought by Mr. Bastiampillai of the Fiscal's office, Batticaloa, who had the pluck and sagacity to send a gang of Moormen under Mohammadu Ibrahim Kandu of Eravur. The Moorman, who took the work on contract, fulfilled it to the satisfaction of Mr. Bastiampillai, who now finds that he has had to spend less for clearing than the owners of adjoining lands.

It may be of interest to state what I have observed on a recent visit to Vettukkadu, that there is a considerable acreage of crown land to the south, east and west of the new clearings, quite as good, if not better, for purposes of coconut planting. The water is good, being found within a depth of 7 feet from the surface, even in the driest season—a point of great importance to the cultivator of the coconut which requires regular watering for a number of years.

The soil of Vettukkadu is regarded as specially adapted for coconut cultivation. The proximity of the village to Jaffna and the facility of communication by sea between the two places are recommendations which cannot be overlooked. The carriage of produce by carts from the estates along the central road as far as Elephant Pass is expensive. Vettukkadu is easily reached by boats and the transmission of produce from there must be comparatively cheap. Just as I am writing, a friend furnishes me with the information, which he avers to be true, that applications have been made by natives of Jaffna for about 200 acres of land to the south of the new clearings. I, for one, will not be surprised, if before long, the whole of that neck-shaped stretch of land known as Vettukkadu becomes one vast expanse of coconut groves.—*Cor.*, "Jaffna Catholic Guardian," March 27.

COCONUT OIL IN AMERICA: DUTY DEMANDED.

The Eldorado Linseed Oil Works of San Francisco have filed a protest with the Committee, urging that a tariff of 2 cents per pound be imposed on coconut oil as follows:—"As we are conducting a prominent industry, which is of great importance to the Pacific coast, and for which we seek protection under the proposed tariff bill, we write you. We are engaged largely in the manufacture of coconut oil, and our factory is situated in West Berkeley, on the shores of the bay, where we give employment to a number of hands. This oil, under the present tariff, is free of duty, and is largely imported from India and the East Indies into the ports of the Atlantic seaboard. The raw material from which this oil is expressed is the coconut grown

in the South Sea Islands and brought here in a dried state, commonly known as copra. This business in which we are engaged is capable of great expansion were it not for the severe competition which we were obliged to meet from the imported oil, made by Indian labor. Under the early tariffs a duty of 10 per cent was imposed on the imported oil, but subsequently this duty was removed, the oil being classified as a nut oil, and entered free of duty. The oil is largely used in the manufacture of soap throughout the United States, and were sufficient protection afforded the industry we could make enough to supply the United States, and this protection would simply counteract the additional freight which we are obliged to pay for transportation to the Eastern markets. In fostering this industry you would be building up the commerce of the Pacific coast, inasmuch as the South Sea Island would furnish us with copra, taking, to a great extent our products in exchange, a trade which is now going to Germany, and which could thus be diverted to our shores. We address you this merely as preliminary, and would like your suggestions as to what steps should be taken, or, if you are willing to interest yourself in the matter, we will furnish you with sufficient data to fortify the position and make your demands appear reasonable. We believe that a duty of at least 2 cents per pound should be imposed on this article."—*New York Oil Reporter*, March 1.

BRAZIL COFFEE NOTES.

We are glad to hear that the coffee plantations in Jujuy are giving splendid results, and so next year the fruit will be cultivated on a large scale in the northern provinces.—*Sport and Pastime*, Buenos Aires.

Some of the prominent planters in the northern districts of Sao Paulo, those served by the Paulista and Mogyana railways, will be much diminished. The reports from the new districts in the southern part of the state, those served by the Sorocabana railway, are still highly favorable.—*Rio News*.

ARNTULLY ESTATE, JAMAICA.

This was the property of the late Mr. Wm. Sabonadiere. We now read in the *Colonies and India* :—

The future resident of Arntully Estate, Jamaica will be Mr. Hubert E. Eves, a son of Mr. C. Washington Eves, C.M.G., who recently left England, accompanied by his wife and family, for their new home. This is a further instance of the interest which Mr. Washington Eves takes in the island, and it is hoped that the property which Mr. Hubert Eves is now taking over may prove in every way successful, and become one of the best coffee estates in the island.

RUBBER PLANTATIONS.

The cycling world will soon look with interest to "the Major's" advent at Lagos as a stimulus to increase rubber production. Surely the Straits might make a big move in this direction. A home paper says:—

The marvellously quick development of the india-rubber industry at Lagos will, no doubt, incite other tropical portions of the Empire to emulation. In the course of a single year the exports of this commodity from Lagos increased from 5,867 lb. to 5,069,576 lb., a growth of trade probably without parallel. But the natives who obtain the rubber in the forests employ such wasteful and destructive methods of "tapping" that the supply is sure to dwindle away, as has hap-

pened through the same cause on the upper waters of the Amazon. If, then, this young and most profitable industry is to become a permanent source for wealth, whether at Lagos or elsewhere, some methods of insuring constancy of supply must be adopted. There are no ways by which that might be accomplished. The rubber-producing forests could be leased on such conditions as would give the lessee personal interest in preventing destructive "tapping." Or, better still, as not confiscating native rights of free search, plantations might be established at suitable places. Once the trees reached maturity, they would continue to yield the precious juice for many years, if properly treated. Before science turned its attention to the matter, the invariable practice was to bleed a tree to death, and it is that barbarous method which still obtains at Lagos. But by a new and improved process, sufficient vitality is left in a "tapped" tree for complete recovery and future fruitfulness. There seems to be no reason, then, why rubber plantations should not make as profitable investments as tea or cinchona gardens.—*S. F. Press*, March 22.

EXTENSIVE PURCHASE OF GALLNUTS.

The Government Agent of the Province of Uva, Badulla, notified that he would receive offers for the purchase of 20,000 bushels, more or less first class aralu nuts on or before April 15th. We quote as follows from a paper by Mr. J. W. Modder, in the latest *Ceylon Forester* :—

The tree is most familiarly known all over the Island by its Sinhalese name of "Aralu-gaha." In Tamil it is called the "Kadaki-maram."

In commerce they are known as Chebulic myrobalans and are largely exported to Europe from India and even Ceylon. In the Southern Circle of Bombay the Forest Department is said to clear annually a nett profit of a lakh of Rupees by the sale of these fruits alone. The average annual export from Ceylon is valued at about R22,700 and very nearly the whole of this quantity is gathered in the Province of Uva. It is said that the Ceylon nuts are equal to the best Indian Myrobalans.

Uses of the fruits: The fruits are used for dyeing, tanning and medicine. Mixed with alum they give a yellow dye, and with iron clay a superior kind of ink. An oil is extracted from the kernel. Fruits which are over burnt or badly eaten by white ants and unfit for any other purpose when pounded and mixed with mortar strengthens the latter immensely. This addition is generally made to the mortar used for the foundations of large and valuable buildings.

Gall nuts bring the largest revenue under the head of "minor Forest produce" to the Department and there is no reason why the receipts under this head should not be still further increased by judicious treatment of these Forests departmentally with a view to improving the condition of the existing trees and assisting reproduction. The renters pay R3,500 on an average a year for the right to gather the nuts and make a large profit over the transaction, and there is no reason why the Department should not work the Gall Nut Forest profitably. Areas which yield gall nuts in the Uva, Eastern and Sabaragamuwa Provinces can be reserved and worked by a special staff.

PRODUCE AND PLANTING.

IN PRAISE OF ASSAM.—In the last *La Revue de Paris* Prince Henri of Orleans describes the final stage of his Mekong exploration, and in doing so he records some interesting facts concerning Assam tea-growing. He points out to his countrymen that there were three years ago close on 300,000 acres covered with tea-plants. This enormous tract of land was divided into 823 estates, employing regularly 300,000 labourers, as well as a floating population of 100,000 who are called in when necessary. The French Prince was

exceedingly struck by the prosperity of Assam. He visited a number of tea plantations, and pays a tribute to the sense and good management with which they were conducted. He points out, and we hope that he is correct, that each superintendent is paid somewhat over a thousand a year, and two coolies are supposed to be able to look after one acre while the plant is actually growing. He goes on to say that the gathering of the leaves takes place during six months of the year—from March to September—and in good years an acre can yield as much as nine hundred pounds of tea in twelve months. He warns those who are thinking of turning their attention to Assam tea planting that a considerable capital is required, for a tea plantation can only be said really to pay after three or four years of incessant labour. With reference to the labour questions which seem to have puzzled Prince Henry a little, he points out that the existing state of things in Assam seems to suit the people, and he dwells on, the advantages of the hospitals and schools.

USEFUL KNOWLEDGE.—Mr. Christison is doing very useful work in the interests of tea by continuing his lectures on Indian tea and its manufacturer in various parts of the country. Lecturing at Watford last week Mr. Christison gave his audience some interesting facts about Indian tea cultivation. He said in India there were in 1894 423,000 acres under tea cultivation, as against 305,000 in 1895 in Ceylon; and there were in other parts of the British Empire small pieces, bringing up the total area under cultivation in the Empire at the present time to probably 770,000 acres.

MAKING THE MOST OF IT.—In a handbill issued by a Glasgow firm of tea dealers the advertisers endeavour to score off the tea duty question. They say :—"It should be kept in mind that every pound weight of tea is charged with an Imperial tax (or duty) of 4d. Therefore, if you buy a pound of tea for 1s, you are paying 8d for tea, whilst the remaining 4d goes to the Imperial Government. If you pay 2s for your pound of tea, your contribution in the form of taxation is still only 4d, and you will get, if you deal with an honest firm, the full value of the remaining 1s 8d in tea of fine quality. We sell pure common tea at 1s per lb. (wonderful value for the money), because some people will have it, but we advise our customers to go in for quality, which is, after all, the true test of cheapness."

COFFEE CULTIVATION.—An effort is being made in India to stir up increasing interest in coffee cultivation, and the coffee planters of Southern India are urged to form an association at home for pushing the sale of coffee, and, in fact, to follow the example of those who represent the Indian and Ceylon tea industry. We have in previous issues pointed out the course which, in our opinion, would be likely to prove useful if a special move is to be made in Indian coffee, and we have also endeavoured to show some of the main difficulties in the way. Meantime, coffee cultivation generally is on the increase, and in British Central Africa alone rapid strides are being made. In 1891 the first few sacks were sent to the London market, and favourably reported on. In 1895 nearly 170 tons were exported, last year the total rose to 300 tons, and this year it is expected that there will be at least 600 tons. It is estimated that at the end of the century the export of coffee from the Shire highlands will amount to 2,000 tons, and the planters are agitating for the construction of a railway from Chiromo to Blantyre, in order to obviate the present difficulties of transport.

THE POSITION OF COCOA.—The advance in the price of cocoa from the lowest point in November last to the present date in Miucing Lane quotations has been about 6s to 10s per cwt., chiefly on the common and middling qualities of Jamaica, Grenada, Trinidad, other British West India, African, and San Domingo,

Excepting those of Ceylon and Caracas, few or none of the finest growths now show any improvement in value, and cocoa between 54s and 61s remains at nearly the old level of depression. Before the recent rise took place, says the *Grocer*, cocoa was cheaper than it had been for five-and-twenty years previously, and though it may not become still dearer in a hurry, it is the generally received opinion that it can hardly undergo the severe depreciation it did in the past year. Descriptions which were next to unsaleable at from 35s to 45s per cwt are now worth 41s to 52s, and low defective grades that were disposable only at 25s to 32s have recently fetched 36s to 42s. The advancing market which has been witnessed this year so far is mainly accounted for by the constantly active demand for exportation to Germany, where the consumption has increased by 50 per cent, within the last year or two. The Germans prefer cocoa to coffee, esteeming the former to be the more nutritious article for their use, and as the commoner qualities have been best suited to their requirements, anything below a certain figure has been sure of finding a ready sale. Our export trade in cocoa with Germany has therefore been materially enlarged, and though no detailed official statistics are published, it may be calculated that the amount of cocoa shipped from the United Kingdom to that country is now twice what it was in 1896. Another favourable feature for holders is that the landings of cocoa in London since the opening of 1897 have been lighter than in 1896, comprising no more than 48,300 bags, in lieu of 50,600 bags; while the stock in the bonded warehouses, instead of being excessive, as hitherto, is 14,800 bags less than that in the former year.

THE RUBBER FORESTS OF UPPER BURMA.—The Assistant Conservator of Forests in Burma, Mr. H. N. Thompson, devotes a section of his last report to the rubber production of Upper Burma. It appears that in the Hukong valley the rubber tree is not a gregarious one; sometimes a family group of four or five trees may be seen, but as a rule a mature tree is found every 200 or 300 yards in the richer forests. When the tree is surrounded by dense shade it grows to enormous heights in order to get at the light, and some of those examined by Mr. Thompson were the largest trees of any species he had ever seen. In the thick forest he found no seedling in the ground; they were invariably growing at a great height on other trees and sending their roots down towards the ground, so that the roots finally formed great supports on which the main trunk rested, while the original tree on which the seedling was a parasite was destroyed. The difficulties of transport from the Hukong valley is increasing as the more accessible trees are being worked out. A Chinese has a practical monopoly of the trade here. The rubber is taken to Mogauug, a route across the mountains to Myitkina having been abandoned owing to the exactions of the Sana Kachins. The forests at the head of the Namkong are rich in rubber, and the tree attains a height of 200 ft., with an enormous girth. The Kachins go from far and near to collect the rubber in the dry season, and the chiefs levy toll on the produce as it passes down the rivers. The Chinese control the trade, selling provisions and cloth to the Kachins, who pay in rubber. The produce of the forests within the drainage area of the Tarou River goes to Assam, across the passes of the Patkoi mountains. The Nagas, having got in their crops in December, set off for the rubber forests, where they know every tree, the knowledge being in many cases passed on from father to son. Rubber in this district is said to be growing scarcer, and it often takes a man forty days to collect a coolie load, although the Singpho villages levy a tax on each collector. When first collected the rubber is very pure, but the Nagas have acquired the trick of adulterating it with earth and stones, so that Assam rubber is not regarded with favour in the Calcutta market. The rubber that goes to Rangoon is also adulterated, the Chinese

being adepts in the art of concealing stones in it. Mr. Thompson thinks it useless to apply legislative protection and regulation to these rubber forests, unless the districts were taken over and administered directly, for the Singphos are extremely independent and own no masters while some of the chiefs told him they could not enforce rules or interfere with the collectors. But the protection of the trees growing within our own administrative sphere would be possible, though Kachin opposition would have to be dealt with.—*H. and C. Mail*, March 14.

B. CENTRAL AFRICAN CURRENT CHAT.

A good waggon road is in course of construction from Zomba to the Upper River. To be a good level road it is necessary to keep lower down than the old Domasi road. It will probably pass close to Songani plantation which will give this district a road all the way to Blantyre, that is allowing it is kept clean. It is little good making a road in this country, if it is allowed to take care of itself for the future.

A curious coincidence happened on Deer, 30th at Mr. Lloyds plantation. In 40 minutes it rained 41 of an inch when there was a pause. The rain then came on again for another 40 minutes the gauge registering exactly 41.

The question of growing coffee profitably in Natal is again being revived. A correspondent of the *Natal Farmers Magazine* remarks that trees which were diseased are now by proper treatment, healthy and full of fruit. Shelter seems to be the main point to consider.

We hear of some record planting at Gala estate, Namadsi, 130 acres has already been planted, and other 70 which was cleared last year is now being pitted. *Gravillia Robusta* will probably be planted as a shade tree.

We deeply regret to hear of the death of Mr. John L. Nicoll from dysentery.

It will interest our readers to hear that the Rev. Mr. Murray who was so severely wounded by a leopard at the station in Agoniland in the beginning of last year is at present in South Africa lecturing on Nyasaland Missions. He had to go to England to get his eye properly attended to and is not even yet in the most robust health. He and his wife may be expected back in April.

A syndicate has been formed in Southern Hungary for the purpose of laying down large castor-oil plantations.

Lemou and Lime trees make excellent hedges and are recommended by the Queensland Department of Agriculture.

Belgium sends 600,000 cwts. of chicory to France yearly.—*Central African Planter*, Feb. 1.

NYASA NEWS.

Mr. C. C. Bowering has given us the following notes of a recent journey up Lake Nyasa:—

"Going through Lake Malombe in the beginning of November, there was not a hippo to be seen. Returning in the end of December, however, there were literally dozens at the south end, near Mvera. They appeared to be mostly young animals, and showed no fear of our barge. Two or three repeatedly rose within thirty or forty yards of us.

On Christmas, Capt. Rhodes and the staff of the naval department gave a dinner at the naval depot, Fort Johnston. The "Adventure," "Itala," "Domira," and "Monteith" had left only a day or two before, or we should have been over thirty in number. Capt. Beddoes, who sailed down in the dhow from Fort Maguire, took only 22 hours on the passage. The dinner was followed by fireworks and a native dance, which was continued late in the following day.

At Kotakota a football match was played between the Universities' Mission and the gunboat "Pioneer." The Mission team gained an easy victory. Several Europeans played on each side, but the best player was undoubtedly one of the Mission teachers, who had been a prominent member of the native team at

Zanzibar, where he had frequently played against crews of the various men-of-war.

On the north-east shore of Lake Nyasa the high mountains come down sheer into the lake, which is here very deep, no bottom being found at 300 fathoms.

The German station at Langenburg is a very smart looking fort. It is built of brick, and is painted white. When we were there the garrison had just returned from an expedition against the Wahehe which had been very successfully carried out. The garrisons of the various stations had, at a given date, advanced on the Wahehe from different directions. They captured large quantities of cattle, sheep, and goats.

Fort Hill, the recently formed Administration station, is situated about seven miles from Mwiniwanda's stockaded village on the road. It has a good boma, and is pleasantly situated at a height of about 4,300 feet above the sea-level. Coffee has been planted, but it is too early yet to say how it will succeed. Coffee which was planted, however, some ten years ago at Chirenje Mission station, the site of which is within a few miles of Fort Hill, promised well, I am told, up to the time it was abandoned.

Ranyara, the B.S.A.Co.'s station is just over the boundary. While I was there we sat down six to dinner on St. Andrew's Night. Mr. Forbes had just returned from a trip round the Chambezi, where he had secured some fine heads of puku and roan antelope. Mr. Young had also arrived at the station, having been to Senga, where he was hospitably treated by the Arabs.—*Central Africa Gazette*, February, 1, 1897.

CATERPILLARS AND TEA.

A Darjeeling correspondent writes us:—The caterpillar plague is fast spreading. On one garden here in about a week they caught and destroyed nearly 100,000. On one garden in Assam about 1,000 coolies are daily employed in destroying these pests. The weather here is now perfect. The March winds have died down, and we are having beautiful cloudless skies.—*Indian Planters' Gazette*, March 20.

NUWARA ELIYA AGRI-HORTICULTURAL SHOW.

(By one present, and competent to criticise.)

March 31, 1897.

Few people who have visited the Show at Nuwara Eliya can conscientiously deny that it was in almost every respect a great success, and that in some points it would have put many a European Show of the kind well to the shade. All the more redounds to the credit of its promoters, when it is considered the paucity of such undertakings in the island, and hence the difficulty in getting exhibitors generally to take as keen an interest in it as they otherwise would, everything as it were, being out of gear in the long lapse of time between these Shows. Still the number of entries was large, many having to be put down as "extra" when these could not conveniently come under the classes in the schedule. Yet it is somewhat surprising to hear, in a land-like ours, where agriculture is the mainstay of the population, some amongst us—Europeans they are also—express a feeling of general dissatisfaction if not disappointment at the whole concern; even one of our leading newspapers is pessimistic enough to contend that such Shows cannot have any beneficent effect on the agricultural instincts of the natives. But that is an argument which will not receive the favour of many of us. There are some people, it must be admitted, in Ceylon as everywhere else, who would find their tastes

more gratified at a *tableau vivant* or a boxing saloon than at a charming Exhibition of the most valuable and beautiful members of the vegetable kingdom, collected and brought together from different parts of the country:

"To me the meanest flower that blows can give Thoughts that do often lie too deep for tears."

Such Exhibitions are, as a rule, the only opportunity many of us have of gaining any idea of what has been done, is being done, and yet remains to be done, by the agency of man in the way of *improving* fruits, flowers, and vegetables, as well as the livestock of the farm. It is impossible to realise the wonderful variety, the interest, the potentialities of new developments which still lie hidden in our soils, and nothing is better calculated to bring these out than the honest, open competition afforded by Shows to agriculturists and horticulturists alike, be they professional or amateur.

We have heard it remarked that the best feature of the Show at Nuwara Eliya was the unusually large number of exhibits in the (European) vegetable class; although vegetables, as well as fruits and flowers, indigenous to our own clime, were rather poorly represented. In the way of tropical fruits, a very interesting collection was that exhibited by the Royal Botanic Gardens, to which also the Show was indebted for a magnificent group of plants, covering an area of about 100 feet square, artistically arranged by Messrs. Nock and Macmillan, the gorgeous flowering plants therein being from Hakgalla Gardens, and the palms and foliage plants mainly from Peradeniya Gardens; but these, of course, were not for competition. The former Garden also sent for exhibition a choice selection of cut-flowers, as well as a selection of potato tubers, grown from seed imported from Sutton & Co., which were in themselves a worthy illustration of what can be done with good sorts by proper cultivation, even in a climate where spring eternal reigns.

In viewing the schedule and the exhibits generally, we were inclined to think that a few improvements in the arrangement of things were desired, and this, no doubt, will be considered on a future occasion. For instance, some of the judges, who really ought not to have seen the inside of the Show before the judging commenced, had actually to arrange the exhibits. All the judges had their work well cut out for them; but those in classes I to VIII, viz., Messrs. Willis, Nock, and Macmillan, had more than their share, being hard at it almost without a halt from 9 a.m. to 5 30 p.m.

RAMIE: HOW TO START A PLANTATION.

Those desirous of starting plantations of this valuable fibre-plant, so often alluded to in our columns, will find the following of interest. The Boyle Fibre Syndicate of London has obtained a concession of 5,000 acres from the Sultan of Johore. The soil is a loamy alluvial, clay sub-soil, the annual rainfall is 97 inches spread over the whole year. A sketch of the system adopted will be of value:—

The method of cultivation is also a point upon which something requires to be said. The Government of France has expended much money upon the cultivation of ramie in Algeria, but while the production has been fairly satisfactory, it has been found necessary to reap the plants simultaneously over the whole area cultivated. In other words, the plants are treated as a crop. The prolific character of the plant, however, lends itself to a different treatment. By obtaining an estate of a suitable

size and laying it out on a definite plan, much better results can be obtained. If it be assumed that an estate of 1,200 acres be cleared—preferably near a navigable river for obvious reasons—at least 900 can be put under cultivation, the remainder being needed for roads and access paths. Dividing this into suitably sized blocks, they can be filled with young plants. These blocks are arranged and the plants propagated in continuous succession, so that by the time the last block is ready, the plants in the first are ready for cutting. When they are 18 in. high no further cultivation is needed, and the plants will continue to grow for an indefinite period if occasionally thinned out. The advantage of this course over the crop system is that, by the latter, ripe, overripe, and immature stalks are cut indiscriminately, thus preventing any possibility of uniformity in the stalks or fibre. By the block system, on the contrary, only the plants which have attained a given maturity are cut, so that it is reasonable to expect a more uniform quality of fibre, in addition to which the machinery required is less, as it is constantly working on a regular supply, instead of at periods, owing to the intermittance of the supply.

The fibre which it is desired to obtain is embedded in the green stalk in a mass of gum or viscous sap, which is surrounded by the bark. Hitherto it has been the custom to strip the dried stalks by hand and ship the material to this and other countries in the form of ribbons. When so dried there is surrounding the fibre a brittle bark and a quantity of dried gum or resinous matter, which is insoluble in water. Both these substances require removal, and it is this which has hitherto been the fatal stumbling block. The ramie which comes from China, and bears the name of "China grass," is partially prepared by hand, the bark having been removed and the gum to some extent. Although the amount of cleansing needed is reduced, there is still some wanted, as the adherent gum must be all removed before the material can be successfully worked.

From what has been said, it is clear that there are two substances requiring removal, the bark and gum. Although attempts have been made to effect the cleansing in one operation, the experience of the past, and with other fibres, shows that a division of the process gives the best result. Just as in the case of flax the operations of retting and scutching are necessary to its perfect cleansing, so with ramie the double operation is the most effective. The difficulty has been to determine two points, namely, how to deal with the stems, and the character of the machine which can effect the operation. It has been shown that in drying the loss of weight is very great, and in addition to that the hardening of the gum renders it more difficult to remove. By the time the fibre is extracted not more than 5 per cent. of the green weight is obtained. It is not, therefore, surprising that attempts have been made to deal with the stalks in a green state, which is at once the most rational and economical plan. Many decorticators have tried, and we have, from time to time, described them; but the matter is one which requires more than the invention of a machine—it needs an organisation to use the machine to the best advantage. Such a machine has, it is claimed, been invented by Mr. J. M. Macdonald, and an inspection of it proves it to be simple, easily handled, and capable of ready repair—three points which are of supreme importance when it is desired to deal with the material at its place of growth.

The system, it is proposed to adopt, is to lay the land out on the block system, as described, and to place in the centre of each large block a set of decorticators of the Macdonald type, one of which is sufficient to treat the produce of five acres. Tramways are arranged to take the product to the decorticators, and not more than 250 yards will have to be traversed by the coolie after cutting the stems before reaching the tramway. From 50 to 60 tons per acre of stems can be grown in a year, and each coolie can easily cut 6 cwt. of stems per day. It is intended that daily cuttings shall be made, so that only matured stems will be treated, thus ensuring a uniformity of material, which is at present absent. As the block at-

tended to by each coolie is two acres in extent, the amount cut from it can be easily checked which will ensure each decorticator having sufficient work.

It is intended to treat the stems in their green state, first by decortication and then by immediately degumming. The advantage of this is two-fold. First, all the bark and stalks can be returned to the field in the form of ashes, as when dried they will be used for fuel. In this way the mineral nutrients are returned to the land, which, as we have seen, so freely gives them up. Second, the degumming takes place at a time when the gum is soft and fluid, thus enabling it to be removed by solvents of a weaker kind than are necessary when the stalks have dried. This is so obviously the right thing that it only requires saying that the risk of damage to the fibre will be much reduced. In the third place, the fibre will be shipped as cleaned filasse ready for use by the spinner at this side. Freight will thus be saved, the spinner will save the cost of preparation, and the land be enriched by those materials which are so beneficial to it and so useless to the manufacturer. It is estimated that the material in the form of degummed filasse will be placed in this country at a cost not exceeding £45 per ton, which leave a good profit to the grower.

The ideas on manuring are a little crude, *i.e.*, burning the waste products so as to return the minerals. In the same circular from which we have quoted, it is stated that an annual crop of 4 cwts. removes the following huge amounts of plant food:

	370lb. of which Bark	Contains per cent	Stalks per cent	Leaves per cent
Nitrogen	X Fibre	15	29	55
Potash	252lb. „ „	10	60	95
Ph. Acid	156lb. „ „
Lime	758lb. „ „	3	10	87

There is no doubt that the methods to be employed save a great deal of loss in mineral, but the *burning* will cause a total loss of the far more valuable and expensive nitrogen.

An analysis given of the ash of green plants revealed that Lime was present to the extent of 30.82 parts in every hundred, Potash 11.8 and Phosphoric Acid 7.29.

We may add that Mr. J. M. Macdonald, the Managing Director of the Syndicate, with whom we are in communication, intends to remain in the Straits until the first hundred tons of filasse (fibre ready for spinning) are dispatched to England. Mr. Macdonald has further very kindly stated that he is ready to send us information of the progress of the estate in due course for the benefit of our readers. His present address is "Poste Restante," Singapore.—*British North Borneo Herald*, March 1.

HIGH-GROWN TEA IN CEYLON IN 1887-1896.

The following report by Mr. John Hughes, Agricultural Analyst, on a packet of Ceylon tea from a high-elevation garden, the tea of which he had analyzed ten years previously, ought to be interesting to planters:—

"I have been examining the tea you were so kind as to bring me the last time you called and have compared the results with the Pekoe Souchong sent in 1887:—

	1887.	1896.
Water lost at 212° F	7.30	3.60
Soluble extract	37.90	37.40
Mineral matters or ash	5.43	4.76
Nitrogen	4.40	4.51

The water is much less in 1896, the tea probably having been much more perfectly dried. The amount of extract as the result of infusion with boiling water, which was allowed to stand 10 minutes, is remarkably similar to that of 1887 tea as also is the percentage of nitrogen. The quantity of ash, however, is notably less about .75 in round numbers, and it is of a white appearance, rather than of the more usual *darker* color. I imagine, but I have not

tested it analytically, that the percentage of potash and phosphates in this white ash is rather less and, if so, it would suggest exhaustion of the soil in these ingredients. Anyhow it would be of advantage to institute some comparative determinations of the proportions of potash and phosphates in tea made at different times of the year with a view of ascertaining the variation caused by atmospheric influences and soil exhaustion.

"From the specimens of leaves opened by hot water, it would appear that the plucking of 1896 is decidedly *coarser*, and the flavour of the tea is, in my opinion, as a consequence, not equal to that of 1887."

This report indicates a direction in which the Analytical Chemist should be able to help the planter as to the constituents wanting in his soil which would ensure a tea approved in the market.

CEYLON TEA, COFFEE AND COCONUT OIL IN AMERICA.

AMERICAN papers by this mail have a good deal that is of interest to Ceylon producers. In the first place, the *New York Grocer* of the 3rd March extends the following cordial welcome to our Commissioner and hearty congratulations on the increased business in Ceylon teas:—

Mr. William Mackenzie, the Ceylon Tea Commissioner, arrived from London by the steamer "Lucania" a week ago, and is exceedingly gratified at the great—in fact, wonderful—increase in the sale of Ceylon and Indian teas in this country. Direct shipments from the island of Ceylon for 1897 are three times as great as in 1896. The work of Messrs. Mackenzie and Blochydeu in bringing machine-made teas to the notice of the American public has been so wisely directed and persistently pushed that we do not wonder that these teas are becoming popular all over the United States, especially in the Eastern and Middle States.

Next we may give the weekly report on tea as follows:—

Invoice business continues to be very slow, and the general tone of the market is rather easy than otherwise. There has been a marked increase in the direct shipments of tea from India and Ceylon to the United States. The exports from Ceylon to America from January 1st to January 26th were 64,866 pounds, against 10,415 pounds for same time in 1896.

The imports of tea for the calendar year 1896 were 83,965,317 pounds, valued at \$10,749,889, against in 1895, 97,883,061 pounds, valued at \$13,319,334. It came from the following countries:

	1895—lb.	1896—lb.
United Kingdom ..	3,696,192	3,784,299
British North America ..	574,427	564,354
China	51,458,868	46,176,355
East Indies	1,007,675	1,448,808
Japan	39,914,508	29,793,133
Other Asia and Oceanica ..	1,206,712	2,143,374
Other countries	21,669	54,494
Total.	97,883,051	83,965,317

Today at noon the Montgomery Auction and Commission Company will sell 5,023 packages, including 263 packages India and Ceylon Pekoc—an unusually attractive assortment.

Then in the same paper we find a curious outburst affecting coffee:—

"WICKED JOURNALISM."—In the last issue of the *American Grocer* attention was called to the extreme sensationalism of certain newspapers. Since then we have had a glaring example of false—yes, deliberately wicked—statements calculated to foster prejudice, excite hatred, disrupt society, and destroy the integrity and power of its units. The *New*

York Journal of Saturday last makes the following statement:—

Coffee.

Total output of coffee (lb.).....	650,000,000
Amount controlled by Coffee Trust (comprising the Arbuckle Company, of this city; the McLaughlin Mills, of Chicago, and the Woolson Spice Company, before the latter company was "acquired" by the Havemeyers) (lb.).....	495,000,000
Profit of the Trust every year (at Mr. Arbuckle's figures of 1 cent a pound)....	\$4,950,000
Profit of the Trust every year (at Mr. Havemeyer's figures of 3 cents a pound)....	\$14,850,000

The above is evidently the work of one, whose estimates have for a purpose been made deliberately false.

COFFEE.—There never have been a Coffee Trust. The Arbuckles have been protected by United States patents and trade marks. Their distribution has not exceeded, if it has reached, 2,000 bags per day, or 95,000,000 pounds a year. Their importations at New York in 1896 were 757,091 bags. The total imports in 1896 were 630,000,000 pounds, and 642,000,000 pounds in 1895. This coffee is imported in a raw condition and loses about 16 per cent. in roasting, bringing the average yearly distribution for two years down to 534,000,000 pounds, distributed by 2,500 wholesale grocers and 220,000 retail store-keepers. A profit of 1 or 3 cents per pound is not extravagant, especially when it is a fact that coffee has been declining in price for two years, and has fallen 4 cents per pound within one year.

If the *Journal* believes that trusts are against public policy it will do better service for their overthrow by telling the truth, and thereby commanding respect for its statements.

And finally in an Oil Trade Journal there is a paragraph in connection with "Tariff Revision" which indicates a possible change that may affect our great native staple:—

COCONUT OIL.—R. Percy Keese, Brooklyn; "I do not know if your attention has been called to the article of coconut oil as one upon which a moderate duty could be well placed. At present it is free. There are about 10,000 tons per annum imported. It is used in the manufacture of white soap, taking the place of our domestic oils and greases, for the reason that it has the capacity for holding more water in the manufacture. It is a low-priced article, being only about 5 cents per pound, and a duty of ½ cent per pound would practically yield \$100,000 per year. It would not curtail the importation be particle, and therefore, the amount would nets a gain to the revenue, and it would work no domestic upon any one, but would protect our hardship greases to some extent. I assume, of course, there will be a duty imposed on tallow."

ECHOES OF SCIENCE.

Chestnuts are an important article of food in France, more especially in the departments of Archdèche, Corsica, and Sardinia. The largest come from the Pyrenees. Roast chestnuts still hold 40 per cent of water, and boiled chestnuts 70 per cent, but dried chestnuts only 12 to 15 per cent. These contain as much nitrogen as wheat, and M. Balland, in a communication to the Académie des Sciences, Paris, think they might be used as a food for the Army,

A horticulturist of Southern France states that he can grow black and white grapes from the same vine. His method is to take two "sarments," or branches, one giving white, the other black, grapes, and rub the two ends together, then bind them lightly, before planting them in the ground. If this is carefully done, the vine will bear white and black, and even piebald grapes (half white, half-black) at the same time.—*Globe*,

JAVA COFFEE, TEA, RICE AND SPICES.

A general statement has been issued by the Rotterdam brokers concerning coffee tea, rice and spices during 1887 to 1896. This statement affords many interesting particulars. The world's production of coffee fluctuated in the last ten years between 7 and 12½ million bags of 60 kilos. Of this quantity Java (Government and private cultivation together) delivered from 0.4 to 1.1 million, to which about 100,000 bags are to be added from Padang and Celebes. The Palembang coffee, which is usually shipped to Singapore, is certainly taken up under the head of British East India coffee. It may thus be stated that the Dutch East Indies provide for about ten per cent of the wants of the world's consumption. It is striking that the Java production does not increase. The decrease of the Government's cultivation is a known fact, but it is another case as it concerns the private cultivation. In view of the numerous concessions granted a doubling of the production might have been expected. This has, however, not occurred, as the production of 1895-96 was nearly equal to that of 1886-87. The disease of the leaves must be regarded as a great factor in the small outturn. The imports of rice in Holland varied from 1887 to 1897 between 100,000 to 130,000 bags, of which Java had about the tenth part. The import of tea in Holland increased considerably, being in 1887-91 140,000 chests of 40 kilos., against 170,000 chests in 1892-96. In the former period Java tea represented the smallest portion, but in the latter this kind predominated. In 1896 there were against 68,300 chests China tea 102,000 chests Java tea. A considerable portion was again exported; but the consumption in 1896 amounted to respectively 41,500 and 30,200 chests. The consumption of China tea decreased gradually in this country, and Java tea increased. Five years ago the consumption was 50,300 and 15,500 chests respectively. This proves that the Java tea is more and more liked on the Dutch market and has, in fact, a good future.—*L. and C. Express*, March 12.

PLANTING IN MYSORE.

From the Proceedings (just received) of the Annual General Meeting of the South Mysore Planters' Association we quote the following:—

FAMINE.—In this province I rejoice to say that grain crops have on the whole been better than could at one time have been reasonably hoped for, an exceptionally heavy fall of rain in late November having saved a considerable portion of the dry crops.

THE PLAGUE.—If this terrible pestilence should make its way into this province and into Mangalore and its neighbourhood, our labour supply will be very seriously affected. I trust the authorities in the latter place, bearing in mind the large quantities of coolies that come up to Mysore from S. Canara, will take such measures as are possible to prevent the spread of the disease.

LABOUR.—The supply has been more plentiful than for some years past, and I agree with the gentlemen who wrote from North Mysore that an opportunity is occurring to check the upward tendency of advances. Ghauts especially have come up in increasing numbers, but Tamil labour having proved generally unsatisfactory and untrustworthy, has been less employed.

RAILWAYS.—It is gratifying to observe the forward policy of the Dewan with regard to Railways. He is fully aware of the immense advantages accruing from opening up the country, and is encouraged in his views by the increasing returns on the lines already existing in the province. The branch line from Shimoga to Birur is being made, and the Durbar have expressed a wish to construct a line between Arsikiri and Hassan at their own expense

and have submitted proposals to the Government of India regarding it.

CARDAMOMS.—Crops this season were very short and high prices have ruled. The Revenue Supt. has not as yet issued his report regarding the re-assessment, though it is now more than a year since he was deputed to make the enquiry.

"Coffee-stealing" is still a great grievance with our Mysore neighbours.

THE TEA TRADE OF CHINA.

One of our Chinese tea buyers made the somewhat astonishing statement (in Ceylon) that the use of machinery made no alteration whatever in the flavour of China tea. Experiments in this direction have so far been too limited to justify such a dictum, and the interviewed one was probably unaware that only a few years ago, with some simple machinery, a China tea was—by Mr Pinches, an Indian planter on a visit to China—prepared in the Indian way, sent to Calcutta to be reported upon, and there valued by the brokers, who knew not whence it came, as a very high grade Indian tea. In more recent days the Foochow Tea Improvement Company (a small company with a high-sounding title, but with earnest men connected with it) have shown that, if desirable, the China flavour, once so dear to English palates, can be eliminated, and this before they have erected machinery of any kind, and merely by making some trifling alteration in the manipulation of the leaf in its earliest stages of fermentation—in fact, without any amended cultivation and without any patent rolling and firing machines. Until far more extended experiments have been made in China as to what can and what cannot be done with altered methods of cultivation and the introduction of machinery the "Times of Ceylon" is a little adrift in stating that under no circumstances can Ceylon-flavoured tea be produced in China. It is true that some of the existing tea districts in China are worn out and incapable of producing either a good or profitable tea under any circumstances, but at the same time it must be borne in mind that China is a large country, and that she probably contains as many square miles of suitable virgin tea lands as there are square acres of such in Ceylon. That, in the present benighted state of affairs, China can continue her tea trade at all is an open question. With liking and duty on their present scale it is more than doubtful that she can do so. With these two factors eliminated, in ten years she would probably be the sole tea-producing country in the world, as she once was even in the memory of man, and our good friends in Ceylon would do well to bear this in mind. There are many changes being wrought in China: those who guide her destinies may, even sooner than is generally anticipated, assist rather than thwart what ought to be her really most important industry, and then let other tea-producing countries look to themselves. If the Chinese Government saw fit to treat the tea industry of China as the British Government treats the tea industry of India and Ceylon she would actually collect more revenue; and by bringing money and imports into what are now semi-starved or half-depopulated districts, check the seeds of a rebellion that will result in her elimination as an Empire. China's statesmen are alive to the fact at last, and they may possibly take such prompt measure to save her tea trade as will give the "Times of Ceylon" something more to think of than the detail fact as to whether the precise flavour that they obtain on their teas in Ceylon can be imitated in China. Experts would probably advise China not to alter the flavour of her teas in imitation of Ceylon—the product of that island is doing for England what absinthe has done for France, so far as the health and physique of the population is concerned: pure China tea always was and always will be a wholesome beverage. No one can advance the same in reference to Ceylons. The point that China has to look to is that Ceylon tea is a cheap beverage, and China tea a comparatively dear one. Take off duty, liking,

abolish steamer conferences, allow free use of machinery, fix a modest price for Government lands, and China will put a better and cheaper tea in London than ever Ceylon has done, and also her population will be the richer and increase their import buying power by very many millions of taels.—*China Mail*, March 25.

MINOR PRODUCTS.

It may at first sight seem inopportune to discuss minor agricultural products or at any rate to press them on the attention of capitalists and investors, at a time when tea is doing so much for the Colony, and when our own columns testify to efforts to further develop the great industry with which the prosperity of the island is closely interwoven. It has, however, been our endeavour always to discourage the setting of all our eggs in one basket; and this for reasons not wholly confined to the paramount consideration of supply and demand. The cry of over-production almost always follows large profits derived from any great enterprise, and not least from any great agricultural enterprise; but it is not the sensitiveness of the market alone which should influence producers. The greater liability to disease of large expanses of one cultivation—and, if not the greater susceptibility to attack, the greater facility with which any pest, whether insect or fungoid, must spread without intervening cultivation to arrest the devastation—is a consideration which should always be kept in view. And among the noteworthy services rendered by the lamented Dr. Frimén to the island, must be reckoned the annual warnings he uttered against the increasing rush into tea, and the counsel that other products should receive encouragement even in *pukka* tea districts. We cannot recall a single Administration Report of our late Director of the Royal Botanic Gardens, which did not insist on the absolute necessity of avoiding sole dependence on one product, if the welfare of the individual proprietor, as well as the progress in prosperity of the island generally, be considered. It is not on these grounds alone that we press attention at this particular time to new products. We have in view other than the tea proprietary—though we, by no means, desire to exclude it; and we do not lose sight of the fact that, in coconuts and cinnamon in the low-country, and in cacao, cardamoms (even cinchona and coffee, such as they are) upcountry, we have products which represent an immense capital and whose combined influence on the trade and commerce of the island cannot be mistaken or gainsaid. What we contend is that our resources are by no means exhausted in connection with the staples we have named. The soil and climate of the island are suited for other products; and capitalists—whether those engaged in the enterprises we have already enumerated, who may be anxious about a second string to their bow, or others whom local considerations and financial training may have deterred from the old products—may find remunerative employment for themselves and their money in the minor products we suggest.

The one which specially occurred to us, in connection with the rather sombre report of the Spinning and Weaving Company, is cotton. Why should not the island produce all the cotton it needs, within its own borders? At any rate, why should it not be independent of imports for the

raw material which is necessary to keep our solitary mill at work? The matter has been urged with great persistency by "Rambler" in our columns; and the following, from a planter who does not confine his energies to one product, and who has some knowledge of the Northern districts, is the text on which we should wish to say a few words today:—

"There are thousands of acres in the arid districts which are beyond the reach of the great irrigation works, but which, reasoning from analogy, should grow cotton splendidly. It would be a grand public service to bring these tracts into remunerative cultivation; and, as a first step, why should not the best of the dismissed Agricultural Instructors be encouraged, by free grants of land (and even of money under strict business conditions), to pioneer cotton, and set the example to the peasantry of making its cultivation pay?"

The suggestion is one which deserves the attention of the Governor who, we are glad to think, is fully convinced of the importance of official encouragement to agriculture, and whose little speech at the Agri-Horticultural Show at Nuwara Eliya indicated the practical bent of his mind. We have not lost sight of the failures and the successes connected with cotton cultivation in the year that the Spinning and Weaving Company started operations. The Directors imported seed from India, Egypt, and even America, we believe, and distributed small quantities for experimental purposes. We can recall very encouraging reports of yield and staple from the late Mr. Blackett, as the result of experiments in Dolobage, from Dr. Stork at Heneratgoda, from more than one planter in Dumbura, as also from Ceylonese landowners in other parts of the country. But, so far as we know, no one experimented with the seed on fresh land or on an extensive scale, and, as a result, few, if any, repeated the experiment. The seed was put down for a catch crop, with tea or coconuts, or in some unoccupied corner of a large plantation. The experiment brought to light the destructiveness of the insect enemies with which cotton has to contend, the susceptibility of the plant, and especially the boll, to moisture, and the care that is necessary in harvesting and preparing the crop for transport. It is not surprising that the remunerativeness of the principal products overshadowed the subsidiary stranger. The profits were not dazzling; and men did not care to burden themselves with the petty details and worries of a product which did not yield better returns than the industries in which they were engaged. They did not care to be diverted from their large investments. The game was not worth the candle.

The case would, however, be different, if fresh ground were to be broken for the product; and if the Northern Railway is to be undertaken, it would be to the direct and immediate interest of the Government to provide against the running of empty trucks. The idea of utilizing the service of the youths who have been trained to agriculture in the Agricultural School, strikes us as a good one; but why should concession be confined to them? Let tenders be invited for the purchase of suitable blocks of land on easy terms of payment, on condition that a defined proportion of the land should be devoted to cotton cultivation. If the conditions be faithfully fulfilled, the last instalment might be remitted; or if an acreage in excess of the stipulated extent be devoted to cotton, a free grant of such

excess might be offered. Let an impulse be given to the cultivation by such means and by accepting delivery of the cotton, on behalf of the Spinning and Weaving Company at the nearest Kachcheri, till there is a railway to Anuradhapura; and we are sure the Government will not be a loser by a liberal far-seeing policy. Both directly in the recovery of taxes, and indirectly in a larger revenue from imported food stuffs and in smaller expenditure on Hospitals and Dispensaries, it will reap a certain reward. And may the credit for its initiation be Governor Ridgeway's!

PRODUCE IN GERMAN EAST AFRICA.

The Germans appear to be endeavouring to make the most of their possessions in East and West Africa, and appeals are consequently being made from time to time in Berlin for capital for new companies intended to carry on the work of afforestation and coffee and tobacco planting. The most of the money raised hitherto appears to have been allocated to the coffee industry, and to have been raised fairly easily. For example, a company to work the plantations in Victoria (Camereroons) was recently floated in Germany, and the capital of 2,500,000 marks was over-subscribed by 700,000 marks. Other companies of a similar sort floated during the last three years have also been generally over-subscribed, capital only now being required for the plantations of Sakarra.

In German East Africa the Government has inaugurated a number of nurseries and experimental plantations of various descriptions. Coffee culture is considered to have prospered beyond the experimental stage, the last crop at Usamberre, for instance, having sold for an extraordinarily high price. The coffee bean is, therefore, excluded from the scheme of the experimental plantations, four of which have been established in the neighbourhood of Dar-es-Salaam, a coast town a little to the south of the Island of Zanzibar. Professor Woltmann, of Bonn, some time ago analysed specimens of soil taken from near Dar-es-Salaam, and found the ground unsuitable for the cultivation of many tropical plants; but, on the other hand, in the experimental plantation, located in the immediate neighbourhood of this place, vegetables are grown which find a ready sale, and young eucalytus and palms are reared, which are subsequently removed and planted in the public thoroughfares of Dar-es-Salaam, or distributed among the other coast and interior stations, whither have also been sent consignments of seeds and young trees which, it is hoped, the local authorities will endeavour to carefully cultivate. The Karazini nurseries comprise 45 hectares of ground, mostly given over to the cultivation of cotton. At Msimbari Schamba coconut palms have been planted, one to the hectare, although this seems giving a great deal more ground to the tree than it really requires. These should begin to produce in their seventh year, and will continue to do so for from thirty to fifty years. During that period a net annual profit should result of three-quarters of a rupee per tree. A coconut palm plantation has also been established in close proximity to the powder magazine at Dar-es-Salaam; but the primary function of this appears to be the protection of the magazine from bush fires, which have hitherto been somewhat frequent in the locality. Mulberry planting, which had been tried in different parts of the colony, has now been discontinued in view of the unsatisfactory experience of planters in India.

More important than any of the above enterprises, however, are the Government plantations at Mohorro, situated south of the delta formed by the Rufidji River, and chiefly devoted to tobacco. The soil appears to be of a highly favourable character, and two Sumatra planters whose opinion is prominently quoted in the official return consider the tobacco

plants of Mohorro of a very high quality. The small quantity of plants, however—there were 27,000 in 1895—has not allowed of fermentation, and it has, therefore, not been possible to estimate the value of the crop. Indeed, it does not quite seem as though the tobacco would ferment successfully at all; for it is spoken of by Dr. Paul Neubaur, of Berlin, as a "non-fermentative." The same authority, however, states that many German tobacco merchants of consequence, whose names he mentions, are unanimous in the belief that the Mohorro tobacco has a very good future before it from a trade point of view. The soil in which it grows is good, plain, heavy, and eminently suitable. There is plenty of cheap timber easily accessible, and the plantation is at no great distance from the sea. These conditions, co-operating, with the fairly healthy climate, should make the working of the plantation a task of some promise. Last year's plants showed a fine and thin leaf of light colour, which, if it could only be brought to properly ferment, would, in the opinion of the Sumatra planters already referred to, be equal to a good Sumatra leaf. It must be admitted, however, that the most unsatisfactory experience gained in connection with the plantations at Lewa has considerably shaken confidence in tobacco culture in German East Africa. To re-establish this confidence is probably the reason why the Government is devoting itself with unusual ardour to the cultivation of the plant at Mohorro.

The skilled work appears to be in the hands of Chinese, 33 of whom were recently imported from Singapore, the more mechanical labour being performed by negroes, whose daily wages average about 16 pesas. The needs of the Chinese are being studied with a generosity which verges upon the lavish. A large house has been erected for their accommodation, and Mozambique pigs, Bombay ducks, and European chickens have been introduced into the settlement, apparently for their special benefit. Other structures which have recently made their appearance at Mohorro embrace stables, stores, and a large building intended to be devoted to the process of fermentation. Medical men consider the climate relatively good: but it is stated that one Chinaman has already died of fever, and that most of his fellow immigrants since their arrival have suffered from maladies of various sorts. The German officials, however, contrive to keep in fairly good health, and are now occupying themselves with planting experiments of divers description. Vanilla, gutta-percha, and coffee and among the products which it is being sought to place under cultivation; and for all of these the Government believes there is a profitable future. Meanwhile, it does not appear that individual enterprise is being encouraged to any extent, and with the exception of one or two sanguine persons, mostly of British nationality, traders continue to leave German East Africa severely alone.—*H. & C. Mail*, March 19.

NEW METHOD OF TREATING THE VANILLA POD.—A communication, dated 22nd May last, has been received at the Foreign Office from Mr. Courtenay Bennett, Her Majesty's Consul at Reunion, inclosing extracts from the *Independent Crocle* of Reunion, containing a paper read by M. Dolabartz, Manager in Reunion of the Credit Foncier Colonial, at a recent meeting of the Reunion Syndicate Agricole upon a new process of treating the vanilla pod:—According to M. Dolabartz the operation consists of drying the vanilla in an hermetically closed vessel by means of chloride of calcium in the proportion of about one kilog, for every kilog, of dried vanilla obtained. The chloride of calcium is not lost, as it can be easily regenerated by heating it in an iron or copper receptacle; one lot of chloride of calcium is thus sufficient for several processes if kept, after regeneration, in an hermetically closed vessel. According to information received, 2,981 kilogs. of raw vanilla will produce about a kilog, of prepared vanilla. It can be easily understood that vanilla dried in an air-tight vessel must lose much less vanilline than when dried by the ordinary process, by which it is exposed in the open air for several weeks. (*Board of Trade Journal*, August—*Kew Bulletin*, 1896.)

INDIARUBBER IN GERMAN AFRICA.

In an official report on "The Products of the German Colonies and their Industrial Value," Dr. O. Warburg writes: In the export of caoutchouc only three of the German colonies of tropical Africa are of importance. Caoutchouc is the chief article of export from Cameroon and German East Africa. Although in tropical Africa a few other plants (*Picus* and lately *Kickxia*) have furnished serviceable caoutchouc, in our colonies, rubber has been gained almost exclusively from the *Landolphia*s, especially *L. Kirkii* and *L. Petersiana*, in East Africa, and *L. Comorensis var. florida*, in the Coast colonies. In the northern part of the Cameroon district only the milky juice of an unidentified tree is turned to account. The exports were:

TOGOLAND.

		Pounds.	Value.
In 1892	..	81,400	\$33,500
In 1893	..	63,800	24,750
In 1894	..	68,200	29,000
In 1895 (excluding first quarter)	..	41,000	

[It must be taken into consideration that only a portion of the caoutchouc obtained in Togo is exported to German ports and that therefore the figures as given here are too low by half.]

CAMEROON.

In 1892	..	710,600	\$256,000
In 1893	..	910,800	356,750
In 1894	..	880,000	326,000

GERMAN EAST AFRICA.

In 1891	..	521,000	\$240,000
In 1892	..	686,000	282,000
In 1893	..	500,000	233,000
In 1894	..	415,000	247,000

That this enormous quantity of 1,363,200 pounds to the value of \$602,000 can only be obtained by the destruction of countless caoutchouc trees, is plain, as no method excepting the cutting off of the trunks has as yet been discovered, and this indicates that before long the export must decrease unless heroic measures are adopted to check this wholesale destruction.

To obtain caoutchouc advantageously from plantations has so far proved a failure. The many experiments in other countries have found their followers here. In Togo the d'Almeida Brothers, last year, planted 1,500 Ceara rubber-trees, for shading their coffee-plants. The Kpeme Plantation Co. contemplate making a caoutchouc plantation in the vicinity of Togo. Experiments with these plants as shade trees in Cameroon (Victoria) had to be abandoned as they were damaging the coffee trees. The Para caoutchouc-tree is now being experimented with. In German East Africa Perrot planted, on the Mkulumuzi plantation, owned by the West German Trading and Plantation Co. 10,000 Ceara caoutchouc-trees, and the v. St. Paul plantation have put out 30,000 caoutchouc-plants.

* * *

From other sources the exports of India-rubber from German East Africa are found to have been for 1894, as follows:

To—	Pounds.	Rupees.
Germany	.. 156,115	181,905
Great Britain	.. 17,600	25,766
Zanzibar	.. 339,665	475,589
Total..	513,380	6 80,260

Converting the rupee at par this valuation would be equal to \$341,630, or at the present value in the United States currency, only \$157,833.—*India Rubber World*, March 10.

RUBBER RESOURCES OF SIERRA LEONE.

The India-rubber resources of the British protectorate of Sierra Leone, West Africa, received special attention from the colonial governor, Colonel Frederic Cardew, c.m.g., during his recent prolonged tour in the interior, an account of which has been presented to the legislative council and printed in the *Sierra Leone Weekly News*. It was the third tour undertaken by the governor within three years,

each over a different route, and involving in all same 1875 miles of travel. As a result, the extent and direction of the water-courses are now much better understood, and the extent of the forests more accurately known, especially in the valley of the Mano river, forming the boundary between Sierra Leone and Liberia. Much of the governor's latest route was through territory never before visited by white men.

"Though the indigenous products of the protectorate may not be superabundant," writes the governor, "still, I believe, partly from want of cheap means of transport, a lack of enterprise on the part of the traders, the ignorance of the natives in the methods of gathering and preparing their products, such as India-rubber, and palm-oil, and their paucity of wants, not nearly half the products of the country are ever brought to the markets. There are large tracts of forests with abundance of rubber and valuable timber awaiting exportation. They have been in no sense explored, and they only require intelligent and systematic methods for gathering the rubber to yield their wealth to the first comer who has the necessary enterprise."

Referring to a certain district traversed during his late tour, he says that the extent of forest land within it may be computed at not less than 600 square miles. Along the greater portion of his route the forest is of some eight to ten years' growth, the former cultivators of the soil having disappeared on account of the activity of slave-raiders at one time. But in many parts of the district virgin forests still exist. It is of particular interest, however, to learn that "even in the forests of recent growth there is an abundance of rubber. This is contrary to the accepted view that the permanent disappearance of the African rubber creepers is the inevitable result of the felling of the virgin forests. This was the opinion expressed by G. F. Scott Elliot, whose official report on the botany of Sierra Leone was reviewed in the *India Rubber World* of November 10, 1894.

Unfortunately Governor Cardew's enumeration of rubber-bearing species does not render their identification possible. He does not even quote the same local names as those given by Mr. Elliott, whose observations were made in a different district. The report continues:

"Three kinds of such [rubber] plants were pointed out to me. Two were vines called, respectively, in the Timni language 'lilibue' and 'nofe,' and the third a tree called in the same language 'kewatia.' The 'lilibue' yields the choicest rubber in the protectorate. In gathering it, incisions are made in the bark of the vine, which is not, however, always cut down. In the case of the 'nofe' vine, it is invariably cut up into small pieces of about six inches in length, and thus completely destroyed. The 'kewatia,' i. e., the rubber tree, appears to grow rapidly, and in eight or ten years to attain a girth of from two to three feet, but the tree, however, like the 'nofe,' is also destroyed in the process of gathering its rubber; it is felled and the bark ringed at intervals of about six inches along the trunk. The rubber appears to be treated in a different way to that of the vines; the latter is coagulated with lime juice, but the rubber which exudes from the rings cut in the tree is placed in hot water, on the surface of which it coagulates, and is then cut into strips, which are formed into balls for the market."

The governor considers it absurd that large trees should be destroyed for a paltry few ounces, or even pounds, of rubber, and urges that steps be taken to instruct the natives in better methods of rubber gathering, before greater damage has been done to the forests. An account of the methods of preparing Para rubber for market was published at the recent agricultural exhibition at Sierra Leone, and the authorities have since drawn up "an account of other processes which may be suitable to the rubber industry of this colony." The natives of some of the districts appear to be ignorant not only of methods of rubber gathering, but also

of the value of rubber. "If the traders," says the governor, "who purchase the rubber and other indigenous products would inform the government in what direction they consider reforms should be introduced in the prevailing systems of gathering such produce, the government would, I feel sure, lend an attentive ear to their suggestions."

Sierra Leone rubber has long figured in the English market, and is regularly quoted in New York, although Sierra Leone grades have entered less into consumption in the United States, proportionately, than Accra and some other African sorts. Kramrisch & Co. (Liverpool) have supplied The India Rubber World with the following statement of the imports into Great Britain of Sierra Leone rubber for six years past, though it may be said that not all the rubber thus classified is the product of the Sierra Leone protectorate. The figures given are somewhat greater than the amounts credited to Sierra Leone in the British official trade reports:

Pounds.		Pounds.	
In 1891....	2,275,840In 1894....	1,944,320
In 1892....	2,076,480In 1895....	2,222,080
In 1893....	2,352,000In 1896....	1,944,320

Kramrisch & Co. further report: "Rubber from Sierra Leone played an important role during the past year. The rubber coming from that district found increasing favor among manufacturers, but contrary to expectations the receipts from Sierra Leone decreased, causing a considerable advance in price. The arrivals of Sierra Leone rubber [in England] during the first six months of 1896 averaged about 110 tons per month, of which quantity a goodly proportion was of the "red" unsoaked kind. The average arrivals during the latter six months were only about 35 tons per month, of which only a trifling quantity consisted of that red quality most in demand. Prices for the latter have therefore steadily advanced, 2s 4½d. being the highest price paid."

In comparison with the figures given in the last paragraph, it may be added that for several years past the average monthly arrivals in England of Sierra Leone sorts have been 106 tons during the first half of the year, and 44 1/3 tons during the latter half.—*India Rubber World*, March 10.

NEW PRODUCTS FOR JAFFNA.

The raising of Tomatoes for sale by two farmers living in the Pt. Pedro district has suggested the question whether it would not be desirable to encourage the introduction of new products into our peninsula. It seems that for a year or two past the missionary living at Pt. Pedro has started a quantity of young tomato plants and distributed them to different men in the district, to experiment with. As a result this fruit has been plenty in the vicinity of Pt. Pedro for two years. The plants were set out in good soil and duly cared for, and with January fruit was gathered and sold, especially to Europeans, at ten cents a pound. What the yield has been this year we do not know, but during the past month about one hundred pounds have been bought at Udupiddi. A still larger amount must have been sold during January and February when the fruit was at its prime. With the hot weather the vines die off, or, if they survive, produce very small fruit.

This is only one new product. Others will suggest themselves to our readers. New fruits and vegetables might well be introduced into our peninsula, and with profit. There is no question but that better varieties of many of our vegetables might be cultivated to the advantage of all concerned. There are new kinds of Brinjals, Squashes and Beans that might well be tried, and that would be an improvement on the present varieties. Certain kinds of vegetables that grow in the temperate zone, might, in favourable localities, do fairly well; such as are now raised at the Kachcheri and in one or two other places.

Then as to fruit, we see no reason why the Florida or Sicily oranges should not be grown in Jaffna. Why should not the Mangosteen be raised here? Why should we not have a better

variety of the Pine apple and the Guava? And surely more can be done with the Grape than is being done at present. We believe there are several varieties of grape that might well be introduced into our peninsula.

It needs a little enterprise of course. Nothing can be done without some labor and cost, and undoubtedly the gains would be small at first. But in time it would be seen that Jaffna had been greatly benefited by the introduction of these new kinds.

Again, the Government should encourage the farmers to experiment with new things, as is done in civilized countries. Seeds and plants should be distributed free for a year or two, or until it was seen that the farmers were really taking an interest in the growing of the new varieties. Prizes might well be offered for the best display of the new vegetables and fruits, at some public gathering. It would be a good idea to have an annual fair, or at least have one once in two or three years. It would, in our opinion, act as a stimulant and encourage the people to go out of the beaten track of the dead centuries. Progress would be the watchword instead of custom.—"Jaffna Morning Star," April 1.

LIBELS ON B. C. AFRICA.

PLANTING EXPERIENCE.

Our attention has been drawn to another of those malicious libels on B. C. A. which we regret to say have been so frequent of late. This one which disgraces two pages of the 7th November issue of "The Field" and is written by some worthy under the non-desplume of "Falcon" is one of the worst it has been our misfortune to peruse as "Falcon" as might be expected is one of those would-be Nimrods who come rushing up the river determined on slaughter, and after staying a month or so principally at Chiromo and Mlanje, get a slight touch of fever and then clear for dear life. After getting over their fright, (if this is ever possible) they consider themselves in the light of renowned travellers and quite in a position to criticise anything and everything pertaining to British Central Africa, although it is 100 to 1 that they have never been outside a radius of 30 miles.

"Falcon" after attracting the readers attention by explaining that he wishes to tell them the "plain unvarnished truth," (which by the way would be quite impossible for him to do considering his length of residence in the country) goes on to give his opinion on B. C. A. Coffee. "As a matter of fact," says the all-wise "Falcon," the slopes of the Mlanje range of mountains, once covered with heavy overgreen forest, have long since been denuded of them by the Mangauja tribe, who have for ages carried on the very wasteful system of cultivation known in India as koomree. The forest has been felled and burnt, as fast as it renewed itself, and a crop of Indian corn, or sorghum obtained from the soil at intervals of from six to ten years. The humus and more valuable soil has in this manner been removed, and washed away by the annual rains, leaving behind nothing but a *very indifferent subsoil*. It is in such soil as this that many of the planters have planted coffee, and the *wretched appearance of the plants* is sufficient proof of the worthlessness of the land. But even elsewhere the appearance of the coffee, under the most favourable conditions, and in good soil, is such as to convince anyone who has had practical experience of coffee in other lands, that in British Central Africa it has not found a congenial home. In some plantations borers are excessively bad, more than 50 per cent of the trees having been destroyed by them; in others the primaries die back from the cold winds that blow in winter.—With the development of mining enterprises must rise, and sooner or later leaf disease, which is rampant in the coffee estates in Usambara, will make its appearance."

Such is a sample of the kind of twaddle indulged in by this wiseacre, and from it our readers will be best able to judge how much the writer knows about coffee in B. C. A. Then comes the usual tirade on Blackwater fever and the cruel slaughter of game

in B. C. A. but as usual a hundred times exaggerated. As his remarks mainly apply to Mlanje (probably he never visited any other district) we would draw his attention to one Mlanje plantation which last year yielded a crop of 30 tons, and other plantations gave good crops according to acreage, which does not look like "very indifferent sub-soil." Among our Planting community we have now a good few men who have had that "practical experience of coffee in other lands" which the writer talks about, and have come to the conclusion that coffee has found a "congenial home" in B. C. A. These men are not fools and would not have embarked on planting in this country unless they were firmly convinced of its great future.

But the proof of the pudding is in the eating of it, and the high prices realised for Nyasaland Coffee which we publish today gives the lie direct to "Falcon" and all his kind. "It is singular," say the London Brokers of the Zambesi Industrial Mission, "that although every effort is being made *all over the world* in coffee growing districts to produce fine quality, it is quite the exception that such a result as yours is obtained." The foregoing does not entirely correspond with "Falcon's" remark that in B. C. A. coffee has not found a congenial home.

The supremely ridiculous statement that in some plantations borers have destroyed 50 per cent of the trees, we can only put down to the fact that some naughty Planter must have been having his little joke at the expense of this innocent abroad. As for the cold winds we only wish there was a chance of them coming our way.

We cannot do better however than again quote our remarks which appeared in our August number in answer to Mr. Morgan's criticisms on B.C.A.—The only point which is really serious is the menace to our labour supply should gold be discovered. It is not however likely to be found in B.C.A. and should it be discovered in payable quantities in the B.S.A. Co.'s territory, a wise Administration could easily frame such regulations as would prevent the disorganization of our labour supply. The B.S.A. Territory, unlike the Rand, has a native population of millions to draw from so that it would not be necessary to recruit labourers in B.C.A. Such criticisms as Mr. Morgan's may do some good in keeping the wrong sort of man out of the country for B.C.A. is no place for "armchair" planters. Under a wise and beneficent government there can be no doubt that B.C.A. will become one of the foremost states in Africa. We have a unique geographical position, the country is at such an elevation as to make it fairly healthy and development will make it healthier still: we have high plateaus suitable for sanatoriums within easy reach of nearly every part of the protectorate; we have already got telegraphic communication and a railway is certain within the next three years. All that is required is capital and energy, the one without the other will not suffice, but the prospects for the two combined are of the best. In saying "all that is required" we are assuming that we have a government suited to the country. This however is at present by no means the case and the sooner the present provisional form of government is changed for a more permanent one with a properly organised civil service the better for the country.—*Central African Planter* Feb. 1.

STEAM PLOUGHING IN INDIA !

We observe from an official list of agricultural implements tried during the year 1893 that a steam cultivator costing R4,000 was in use in Sarun District. A local indigo-planter reports that he saw it tried in very dirty lands which had not been cultivated for two years, and it brought out all the weeds and grass by the roots and thoroughly broke up the land. He also reports that he saw it tried on land in which there was no apparent moisture, and within 10 days of its use the moisture was at the surface.—*M. Mail*, April 6.

HILL TRAMWAYS COMMISSION.

We call attention to the letters from Government and the Report appended thereto of the above Commission. We have read the latter, and have only space and time to ask what practical good is to be served by such hastily got-up, imperfect and in some respects misleading documents. We have never in the whole history of Railway Commissions in Ceylon seen a State paper of a more uncertain if not perplexing character than the Report before us. This is, of course, owing to the wide scope of its Commission and the limited space of time afforded for inquiry and examination. That time would not be enough in our opinion, to do justice to any *one* of some half-dozen lines of tramway discussed and more or less reported on. The only line in fact, on which a useful Report might have been drawn up is that from Nanuoya to Nuwara Eliya and Kandapola, and here any practical result, it seems to us, is rendered impossible through the absence of an Engineer with experience in Electric Railways. The indenting for such an Engineer ought surely to have preceded the Commission. Both Mr. Mackintosh and Mr. Christie discuss questions connected with electric lines; but neither gentleman, we suppose, has had actual experience, and every year is witnessing great improvements on Electric lines. Then again the Hewaheta-Maturata line is thrown out of court as unworthy of consideration; while we should have considered a line from Peradeniya on the Deltota road towards Hewaheta a scheme which ought to be both possible and promising. But then the fact is that not one of the schemes named in this Report can be said to be fully or exhaustively treated. The Commission have apparently galloped over the country on paper and presented a Report which must be considered both cursory and imperfect, or very preliminary indeed.—Mr. Saunders signs the Report: how many meetings did he attend, and did he visit any of the districts concerned?

"RAMASAMI": OUR LABOUR SUPPLY.

(Communicated.)

We have so often been accustomed to the cry of wolf in the labour market that we have hitherto hesitated to credit the very serious reports which reach us from the various districts of the island as to the actual scarcity of coolies. Very many estates, it seems, could now profitably employ double the number they can muster, while not a few are striving to keep the estate in cultivation and overtake plucking with one-third the necessary force.

We have long prided ourselves on our usually ample supply of cheap labour and could afford to smile at the attempts of less favoured tropical colonies to compete with us in our special products; but a sad change has come over our prospects in this respect during the past two years.

"Ramasami," from being one of the most docile and industrious of men—the Scot of the East—has, in too many cases, degenerated into a thriftless, unstable vagrant, wandering from district to district in order to dodge his creditors and obtain fresh loans. The actual number of coolies in Ceylon is not so much short of requirements as that the muster of honest workers is out of all proportion to the number of idle loafers in the lines and bazaars.

Now the cure for this seems simple enough, viz.—Make it illegal to lend or rather to recover from an estate more than, say, R10 or R20 and the thing is done. But we are not sanguine that the Government will be very ready to move in the matter, though certain enough that legislation in this direction would prove a boon to the planting interests and a much-needed protection to poor misguided Ramasami himself.

There are, however, other interests at stake which pull in a different direction, but we would fain hope that these—as described to us by an up-country correspondent—are somewhat exaggerated. “These vagrant kanganyis,” he says, “are a fruitful source of profit to proctors, around whose doors crowds may daily be seen—seeking and obtaining advice how to act.”

Certain it seems that the good understanding which was wont to exist between the coolies and their doray now, as a rule, no longer exists, and until we can manage to deal with, and protect the labour force already in the country, it seems needless to talk of tapping new sources of supply.

It is against this growing demoralization that we would earnestly raise our voice. The cause is palpable enough. How best to counteract it is the question. Money, as usual, is at the root of the evil, facilities for borrowing, reckless spending, ruinous and unscrupulous usury.

What are called estate advances seem to have risen from an average of R20 a head two years ago to R50 at the present moment, and there seems every likelihood of this sum being doubled in a few months.

In former times, these advances were given by Superintendents for the express purpose of procuring labour from the Coast, and any breach of this understanding would have been treated as a case of obtaining money under false pretences. Now, alas! the Coast is seldom thought of, it is simply a case of “Show me your tundu.”

The Toolakan Jew is master of the situation, and it is at his instance that the ever-recurring move is made. The estate manager is helpless. At his wit's end to save the flush, he pays the exorbitant demands and staves off the evil day for a few months, till the Toolakan's interest again accumulates—when pastures new must, at all hazards, be sought. It is not the debt to the estate only, but the native money-lender that has to be reckoned with. The amount on the “tundu” may be only R1,000, but, as a rule, R500 “adium” is demanded.

PERAK NOTES.

(Perak Pioneer.)

In February a Malay was killed by a tiger while working in his garden at Kota Stia.

Mr. Curtis, the tea planter from India, is anxious to acquire 5,000 acres of land for planting purposes in Perak.

Mr. J. J. Tait has planted 75 acres of coffee since October last at Tanjore Malim. He intends to put in a few acres of tobacco as an experiment.

Mr. A. T. D. Berrington, the Senior Magistrate, leaves for home via America tomorrow on long leave. Mr. C. Wray will probably act for him on the return of Mr. R. D. Hewett from leave until our new S.G. has been appointed when Mr. Watson will take up the acting appointment.

We regret to hear that owing to the Medical Adviser to the Colonial Office having declared Dr. Wheeler to be unfit for further service in the Equatorial region, he has been compelled to retire on pension.

MINOR PRODUCTS.

CINCHONA.—The monthly London cinchona-auctions held on Tuesday were of small extent. Five brokers offered bark, their catalogues containing the following quantities:—

	Packages	Packages
Ceylon cinchona ..	46 of which	46 were sold
East Indian cinchona ..	259 ”	259 ”
West African cinchona ..	198 ”	198 ”
Java cinchona ..	200 ”	200 ”
	703	703

It will be seen that every package was disposed of; indeed, a much large quantity would probably have found buyers, for the tone was one of unusual animation, and an average advance of 10 per cent. on the last public-sale rates was readily paid. The best lots realised a unit of 3d per lb., but the general run of the parcels scarcely reached that figure. The following are the quantities of bark purchased by the principal buyers:—

American factories	44,407
Messrs. Howards & Sons	42,966
Auerbach factory	18,955
Imperial Quinine-works	11,720
Brunswick factory	6,536
Frankfort-on-M. and Stuttgart works	3,661
Various druggists and others	4,331

Total .. 132,576

CROTON-SEED.—A small parcel has been sold to arrive at 85s per cwt., the same figure as that paid at the last auctions. At auction 9 bags rather dark mixed seed were bought in 30s per cwt. being the highest bid forthcoming but the lot has since been sold privately at 75s per cwt.

KOLA.—The arrivals have been considerable lately, especially from the West coast of Africa, and a parcel of no fewer than 211 bags has been entered from Hamburg by the “Lapland.” There was a large supply at today's sales, but no business was done except in 3 packages common water-damaged rubbish, which sold without reserve at 1½d per lb. For good *West Indian* 8d per lb. is asked—*Chemist & Druggist*, March 20.

A NEW CEYLON PLANTATION COMPANY.

The latest venture is the Oodoowerre Estates Company of Ceylon, Limited., the memorandum as well as articles of Association of which appears in the *Gazette*. The objects for which the Company is established are, among others, to purchase or otherwise acquire the Oodoowerre estate in the district of Badulla, or any part or parts thereof. To establish and maintain in the United Kingdom, in Ceylon, or elsewhere, stores, shops, places for the sale of tea, coffee, cocoa, and other articles of food, drink, or refreshment wholesale or retail, and to establish in any part or parts of the world agencies for carrying on or developing the business of the Company or any branch thereof. The nominal capital of the Company is R500,000, divided into 1,000 shares of R500 each, with power to increase or reduce the capital. The signatories are Herbert Tarrant, Katharine Tarrant., Jas. A. Henderson, A. O'Dell Figg, R. Huyshe Eliot, Annie Buckland Eliot and John C. Popham.

DISEASE OF NUTMEG TREES.—The Dutch-Indian Government—says the London *Chemist*—have under consideration the advisability of sending Dr. J. M. Janse, of the Java Botanic Gardens, to Menado and the Banda Islands to inquire into the disease that is affecting the nutmeg-trees, and into one which appears to be threatening the “cocoa” plantations.—We are not clear whether “coconut” or “cacao” plantations are here meant: we know Dutch scientists have been investigating disease in the cacao tree,

MICA.

The Mica Manufacturing Company, Limited, has been formed with a capital of £80,000 in shares of £1 each, to acquire all the mineral rights of the Lake Girard Group of Mica properties, comprising about 1,700 acres, situated in the provinces of Ontario and Quebec, Canada. There has been spent about £70,000 in selecting, acquiring, opening up the properties, and establishing the business, and there has been sold, either in rough or prepared form, mica to the value of £40,000. The purchase price has been fixed at £63,000, of which £3,000 is payable in cash, and the balance in shares, or partly in shares and partly in cash, leaving 17,000 shares available for issue for the provision of working capital.—*Indian Planters' Gazette*, March 27.

THE RESULT OF THE DISAPPEARANCE OF FORESTS IN TRINIDAD.

It is pointed out in the *Bulletin of Miscellaneous Information* of the Royal Botanic Gardens, Trinidad, that the rainfall for that island is slowly but surely decreasing. The average rainfall for the decade 1862-71 was 66.715 inches; for the next decade (1872-81) it was 65.993, and for the third decade (1882-91) it was 65.037. The decrease indicated by the first and third values is 1.678 inches or 2.51 per cent during the thirty years from 1862 to 1891. Presuming that the same rate of decrease runs on for the next sixty years, Trinidad will then suffer from a rainfall diminished by about 8 inches. Mr. Hart points out that a rainfall decreasing at such a rate is alarming; and if the inference is carried on, it follows within that, a measurable distance of time Trinidad must become an arid desert as barren as the Great Sahara. The cause of the decrease is said to be the disappearance of the forests.—*Nature*.

[We doubt the inference altogether: perhaps the next 30 years may prove the "wet" cycle for Trinidad. Forests in Ceylon have been far more cleared than in Trinidad with no falling-off in total rain.—Ed. T.A.]

VARIOUS PLANTING NOTES.

PROGRESS IN TEA.—Apart from the large clearings in the Balangoda district of Messrs. Finlay, Muir & Co. (1,000 acres), Mr. Leaf (300 acres) and others, it is said that there are 2,000 acres ready to plant in the Kelani Valley this season.

CASTILLOA ELASTICA IN TRINIDAD.—Mr. J. H. Hart, F.L.S. Superintendent of the Botanic Gardens at Trinidad, writes:—"We have raised and sold some 10,000 *Castilloa* this year, and we have a plantation in Tobago, and one here ready for bleeding."—*Kew Bulletin*.

A SOUTHERN planter from Wynaad, writing about Mr. James Ochterlony, and his command of capital, says:—"The standing monument of enterprise is the grand old Ochterlony Valley with its thousands of acres of coffee, tea and cinchona." The well known standing monument of another Ochterlony in Calcutta is a high tower—considerably less useful!—*Madras Times*, April 9.

A WELL-KNOWN FOCHOW TEA PLANTER, Mr. Sing Put, has lately been travelling through Ceylon, garnering up-to-date information about tea growing, picking, and curing. The tea industry in the Fochow country has been seriously affected during the past few years by the enterprise of the Ceylon and Assam planters, and the Chinese are now apparently trying to pull themselves together to make headway again.—*London Echo*, March 18.

THE TEA CROP.—There seems an unusual area of tea pruned (lightly) this season upcountry; but the recent alternate showers and great heat will bring on all such very quickly, and, indeed, planters generally will be very busy with "flush" during April. We hear the old estates of the Gallaha Company in Nilambe and Hantane very highly spoken of, by impartial authorities, for their fine cover and jât of tea as well as the good crops promised. Gallaha Factory is one of the largest and most complete in the island.

THE RICE CROP PROSPECTS in the 14 chief rice-producing districts of Lower Burma is as follows:—The area under crop has decreased by 10,408 acres from the area reported last month. The area reported from Akyab is less by 31,154 acres than that of last month, while the area in Thatôn has increased by 38,078 acres, and there are small changes in several districts. The anna estimate in Prome has been raised to 14½ annas; in other districts the estimates are unchanged. The estimate of the exportable surplus is the same as that of last month.—*M. Mail*, April 7.

KAPOK has not been received in this country on a very large scale. It is not, however, quite unknown here. The following particulars have been received from a well-known firm in the City:—Messrs. Ide and Christie to Royal Gardens, Kew, 72, Mark Lane, London, E. C., September 28, 1896. Sir, In reply to your letter of the 24th instant, Kapok is coming here regularly to the extent of 100 bales a month from India and Ceylon. Today's value is 2½d. to 4d. per lb. The trade is not large, but may grow. Yours, &c. (Signed) Ide and Christie. Dr. Morris, C.E.G., Assistant Director, Royal Gardens, Kew.—*Kew Bulletin*

"COFFEE GROWING"—is the subject of a brief paper in the *Agricultural Gazette* of New South Wales by an old Ceylon planter, Mr. C. Skelton. Mr. Skelton was pleased with a sample of coffee grown on the Clarence river; but said it would not pay unless 6 cwt. an acre could be got and even then be dreaded frosts. He gives practical advice to intending planters, and names "John Walker & Co." as the firm to supply all necessary machinery.—In Northern Queensland, rather than in New South Wales, we should expect to find a suitable region for coffee.

AFRICAN COFFEE.—Of late years the production of coffee in British Central Africa has considerably increased. In 1891, the first few sacks were sent to the London market, and favourably reported on. In 1895, nearly 170 tons were exported, last year the total rose to 300 tons, and this year it is expected that there will be at least 600 tons. It is estimated that at the end of the century the export of coffee from the Shire highlands will amount to 2,000 tons, and the planters are agitating for the construction of a railway from Chiromo to Blantyre, in order to obviate the present difficulties of transport.—*Daily Chronicle*, March 16.

CACAO DISEASE.—We are pleased to learn from Mr. R. S. Fraser of Warriapolla that the precaution of sending diseased parts of the attacked cacao trees in advance to high fungoid authorities is not to be lost sight of. The Director of Botanic Gardens will see to this—if he has not already done so, and doubtless on the resulting report, will depend the decision as to a Cryptogamist or other specialist coming out to Ceylon. It is very mysterious at present how the "red" cacao suffers—decaying as individuals or in clumps; while the extraordinary thing is that a diseased tree if cut at the neck, very quickly throws up perfectly healthy shoots,

OUR LABOUR SUPPLY.—The Planters' Association has sent round a Circular calling for information as to the wants of planters in respect of coolies—how many additional men, women and children would be taken on if made available. Meanwhile Colombo Agents and others have been getting a Circular from a firm at Patna offering to supply "good coolie labour" to Ceylon—no doubt on the same terms plus carriage as to Sylhet, Cachar, &c. !

GAMBIER, COCONUTS, &C., IN THE STRAITS.—From the Report on the Coast District for the year 1896 by Mr. C. D. Bowen, we quote :—

The increase in the number of small settlers in the vicinity of Port Dickson has been very marked, especially along the Lukut road; a great many of these people are Japanese, who are about the best class of agricultural settlers. There was a very fair increase in the export of gambier, but a slight decrease in the export of pepper and tapioca. A block of 300 acres was alienated for the cultivation of coconuts and more land for this kind of cultivation is likely to be applied for during 1897. So much of the land along the coast has been taken up in former days for gambier that very little land for the cultivation of coconuts remains.

"**ALBIZZIA MOLUCCANA.**"—We are reminded that the first seed of this valuable tree introduced into Ceylon came from Mr. Mundt, Director of Botanic Gardens, Java, to Mr. Neate of Pussellawa—then of Nawalapitiya. Mr. Wm. Money of the Indian Civil Service—brother of Col. Money—and the clever author of "How to Govern a Colony," first recommended Mr. Neate to get this seed and assured him if he planted up one or two hundred acres, there was "a fortune in it." Unfortunately for himself, Mr. Neate merely grew a few trees at Nawalapitiya and distributed the rest of the seed. The timber of his oldest trees—some of them giants—was tested for tea boxes and found to be very suitable. The tree is one that grows readily at a variety of elevations.

THE OODOOWERE COMPANY.—So the old and almost classical property of Oodoowere is at length to give its name to a Limited Company. It was one of the earliest of Badulla Coffee estates opened. In 1858 Sir Henry Ward reported "the finest piece of young coffee I have seen in the whole island is on Mr. Berlin's Oodoowere estate." In 1865 after reporting Sir Hercules Robinson's first, and Major Skinner's farewell, visit to Haputale, we rode up the Pass from Haldummulla, through the first clearing of Gonamatava and on past Bandara-wela down to Oodoowere where we passed the night in Mr. James Irvine's hospitable bungalow. Everything was flourishing then; but Oodoowere had a big rest before it was put into tea and there are promising reserves.

A FINE SPECIMEN OF COFFEE grown from Guatemala seed, was received at this office, says the Hilo "Tribune," from Mr. J. M. Horner's plantation at Kukaiau, from a four year old tree, which had upon the one primary received nearly 900 well developed coffee cherries, and there were forty such primaries on the same tree, fully three-quarters of a pound to the primary. Some of these primaries Mr. Horner informs us had 1,000 cherries, and says he will have twenty-five tons of coffee this year, and where all his trees from Guatemala seed he would have sixty tons from his plantation instead of about thirty tons. That is the way he replies to the difference and selection of seed. Side by side the Guatemala and wild coffee trees are growing, and the former produces eight times the amount of the latter. The growth of wood is in favour of Guatemala by long odds.—"Planters' Monthly."

A FAMOUS CACAO PLANTATION.—Yattawatte has long been known as a leading "cacao walk" as they say in the West Indies, and Mr. Jas. Martin has been identified with it for the past seventeen years or so. We recall it when the property of Messrs. R. B. Downall and Col. Young in 1896. Mr. Motague Kirkward (of Japan) writes :— "My visit to the Yattawatte cocoa estate was very instructive, interesting, and delightful with such a good host as Mr. James Martin."

COTTON GROWING IN THE NORTH.—With reference to our editorial deliverance on minor products and the prospects of cotton succeeding in the Northern districts, we learn that there is a large expanse of fine forestland from opposite Dutch Bay northwards. The "black cotton soil" of Mannar (identical with that in Tinnevely) has always been famous. In fact the conditions here, as elsewhere, point to cultivation and civilisation advancing inland from the coast and there is far greater encouragement for settlement from Chilaw right on to Mannar and onwards from Puttalam to Anuradhapura, than there is in the miserably forbidding country North of Kurunegala.

OUR LONDON TEA REPORT.—We ought to have drawn special attention to the exceptionally interesting Report dated March 19th from Messrs. Gow, Wilson & Stanton. They give a most encouraging account of the re-exports of Ceylon tea from the United Kingdom, more especially to Holland, Denmark, South America, and South Africa. Their table shows that the total of the re-exports compare as follows :—

CEYLON.				lb.
Total	1896	8,496,663
"	1895	7,147,071
"	1894	5,166,029
"	1893	4,112,232
"	1892	3,448,058

—while the total of Indian tea re-exported in 1896 was only 4,339,640 lb. We must refer to the "blue sheet" for details. The increase in 1896 over 1895 in the case of North America is not quite 400,000 lb. In the case of "Russia and Germany," taken together, we get an increase of over 600,000 lb. in the same period.

RUSSIA AND INDIAN TEA.—Commenting upon the prohibition of the importation of Indian tea at Batoum, by the Russian authorities, the Calcutta *Englishman* of the 24th inst. says :—If we may go by precedent this pernicious example will not improbably be followed by many other countries. Of course we have the assurance that Great Britain, the largest market for Indian tea, will remain open, but nevertheless should the Indian product be interdicted by other European Governments the effect would infallibly be to seriously retard its expansion in other parts of the world. This is a matter which the Government of India cannot afford to ignore. Representations should be made by the British Foreign Office to the Tsar's Government against what looks not so much like a sanitary precaution as an attempt to inflict a serious commercial injury upon India. If we submit tamely to treatment of this kind there is no saying where Russia may stop. We call upon Government to take steps to combat this mischievous regulation, not even pausing at hinting its willingness to retaliate if it is persisted in. Russia is certainly vulnerable in regard to her enormous petroleum trade with India.

THE DUTY ON TEA.—We have now arrived at that period of the year when Budget anticipations are the order of the day. Sanguine experts conjecture that the surplus will reach the highly satisfactory figure of two millions. If this calculation should prove to be accurate, those interested in the tea industry may fairly claim a remission of the impost which now presses so heavily on their produce. Tea yields a revenue of nearly four millions a year. It is generally looked upon as being one of the prime necessities of life. The bulk of the tea consumed is a British product. As we have reiterated pointed out, the duty is regarded by "the man in the street" as a tax on food, and nothing would be more popular at home than for the Ministry to take the line we have advocated of reducing or abolishing the impost. Anything that would benefit India at the present juncture now that she is the victim of plague and famine and consequent depression in business would be ungrudgingly allowed even by the many financial interests that always scramble for the crumbs which fall from the table of the Chancellor of the Exchequer in surplus years.

CEMENT FLOORS.—A novel kind of flooring has been provided in the power station of the Edison Electric Illuminating Company of Paterson, N.J., U.S.A. This floor consists of a huge casting of cement forming the undivided floor of the entire station. The floor proper is 4 inches in thickness, but at intervals of 15 feet there is cast on the back or underside of this 4 inch web a beam 18 inches in depth and 9 inches in width, running crosswise of the station and resting upon the supporting piers of brick. The floor is further stiffened by longitudinal ribs 14 inches in depth, and tapering from 4 inches to 6 inches in width, placed 3 feet 6 inches apart, running between the heavier crosswise beams lengthwise of the station. These stiffening projections are a part of the main casting, so that the floor is virtually one immense casting of cement, with stiffening ribs on its underside, supported upon brick piers. The floor is completely fireproof, and is said to cost less by one-third than a floor involving the use of iron beams, while it affords a firm foothold, and presents a surface sufficiently smooth to be easily kept clean. It will be interesting to learn what effect oil will have upon it.—*Engineer.*

A STANDARD OF TEAS.—We read in the *American Grocer*, of March 10th that the recent Act of Congress, regulating the importation of tea, provides for a Board of Experts, whose duty will be to establish standards of grades:

We (*Grocer*) trust that this may prove a success, but our experience in having tea experts fix a standard has not been encouraging. A sample of fancy Formosa Oolong, examined by four of the best experts in the trade, was differently valued by each, there being a difference of twenty and in one instance, forty cents per pound. Tastes vary, one estimating a certain flavour of great value, that another expert does not regard desirable. It is practically out of the question to fix standards by chemical analyses. Geisler, whose analyses of tea are reliable and extensive, says: "A strict relation between the chemical composition of the tea and the commercial value of the same, is therefore scarcely to be looked for, although the former would disclose at once that tea which is physiologically the best." There is very great variation in the amount of ash, particularly ash insoluble in acid, the soluble ash in one lot of green teas varied from 2.02 to 5.019; Congou from 2.88 to 3.52; while the ash insoluble in acid varied from .32 to 1.31. It is the character of the infusion which concerns the consumer, and not the composition or style of the leaf, and yet these go a great way toward fixing price. Expert tea tasters are governed by strength, body, flavour, aroma and quality of the infusion in fixing value. To adjust standards will require the highest qualifications on the part of members of the Boards of Experts. Unfortunately the tea trade is not over-supplied with high class experts, therefore the Secretary of the Treasury needs to exercise great care in the selection of the seven men who will constitute the Board.

PLANTING IN UGANDA.—It is only seven years since Dr. Peters, the German explorer and agent, found Uganda destroyed by rival factions, and he sought to bring it within the German sphere. It became British, however, and is making astonishing progress. Even since 1894 the imports into the chief town have been more than quadrupled; and the exports have been advancing at a corresponding rate. As the natives of the Uganda kingdom are an advanced race they are offering an ever-widening market for manufactured articles in textiles and metals, including agricultural implements and industrial tools. Uganda is going to be a cotton, tea, tobacco, and coffee growing country.—*H. and C. Mail.*, March 26.

DATES.—In reference to the notes on Date Cultivation in Australia (*Kew Bulletin*, 1895, pp. 161-2) and Antigua (1896, pp. 26-28) the following brief account of what may be considered the normal growth of the tree will be useful for comparison:—Extract from the Report for the year 1894-95 on the Trade of the Kerman Consular District, Persian Beluchistan (F.O. 1896, Annual Series, No. 1671, p. 7). Dates grow to great perfection in many parts of the country, notably at Pahrāj and Fanooh. The output could be easily doubled by planting fresh palm groves. Date palms begin to yield at three years, and reach their prime at 30. A good crop for a single tree would be from 80 to 100 lb. They are fertilised by hand, one male tree supplying pollen for perhaps 40 female plants. The dates used for export are those that grow at the summit of the tree. From the action of the sun they become hard and dry, thus being easily packed. The lower branches remain soft, and are kept for local consumption.—*Kew Bulletin.*

THE GOLD COAST.—The general fiscal condition of the Gold Coast Colony, as described in a report just published by the Colonial Office, "was not only satisfactory but flourishing" during the last financial year. Revenue and trade increased, although there is no other colony in the Empire so lightly taxed. In the last six years about a million monkeys have been slaughtered on the Gold Coast for the sake of their skins; but the trade is decreasing, because the traders have to go further into the interior to find the monkeys they require. Last year over 99,000 skins, worth over £14,000, were exported. The land in the colony is not generally cultivated, though the soil is naturally rich and will produce almost any commodity. It abounds in the oil palm, mahogany, rubber, and kola trees, and many other valuable woods; but, chiefly on account of the absence of proper roads and the general ignorance of the natives, products which require a careful preparation of the soil and supervision have not been cultivated systematically. On the subject of communications, a passage from an address of the Governor to the Legislative Council is quoted:—"The conditions under which bulky produce is transported from the interior to the coast are such that, beyond a certain distance inland, products have no commercial value; a new producing sphere could be tapped if a railway of 50 or 60 miles in length were constructed, and trade could be further developed by the gradual extension of the line; it is therefore desirable to carry a railway inland from the place best adapted for development as a harbour. What that place shall be is the matter now under consideration." Trade roads also are being constructed and extended. The report concludes as follows:—"The colony has within it all the essentials for prosperity. Rich in gold, in valuable timber, in soil which will produce almost any commodity of trade value, it is already attracting the attention of capitalists, and with finances and trade in a satisfactory state there is no reason why it should not advance in material prosperity and bring wealth to English merchants and native producers and workers."—*London Times.*

PLUCKING, PRUNING AND PREPARATION OF TEA.

(Continued from page 712.)

No. XXXVII.

Dikoya, Feb. 18.

I think all teas after a certain age lose flavour, and, unless there are young clearings coming on, the old flavour which younger estates have, cannot be maintained, except in very "stand-out" estates.

1. In this district labour is plentiful as a rule. I don't think plucking is coarse, but medium.

2. I do not think manuring injures flavour—the fact that the bushes are vigorous ought to give the reverse result.

3. This is rarely resorted to: one case I know, when this was done, gave very beneficial results, both as regards yield, and at the same time quality was maintained.

4. I do not consider attention to manufacture has been less careful—but the reverse.

Plucking is very important, and coarse and hard leaf should be carefully kept out of factory; but plenty of withering room is one of the great points of good manufacture.

5. We have been very well off for labour all the year.

6. I consider the last line of your query, *underlined*, is the chief cause of bad prices; they know we can't keep teas, and must sell, and won't bid more than they can help. L.

No. XXXVIII.

Baldarawela, Feb. 19.

1. There is, I think, no doubt but coarser plucking has had a good deal to do with fall in prices, the craze in some instances being for a large yield per acre; this combined with supply exceeding demand, is to my mind greatly responsible for the fall in price.

2. I do not think manuring has anything to do with it. A number of estates that never saw manure in any shape or form shows no stand-out prices against those we know that are manured.

3. All teas for some months after pruning are thin poor liquor, whether the pruning has been severe or otherwise. I have not noticed any worse results from heavy pruning in this direction, than when medium pruning was resorted to. Where pruning is very light my experience is the bush throws out an abnormal quantity of bangy leaf, from which good tea cannot be made.

4. My experience is that preparation in the factory receives as much attention as it ever did. No doubt, careless or inadequate factory work would spoil the most carefully plucked leaf; this I consider seldom happens where withering accommodation and machinery is sufficient for requirements.

5. Shortness of labour has not, as far as I know, affected factory work in any way, as all the factories I know of are well equipped with machinery of the latest and most approved type, I have no hesitation in saying labour difficulties have to a great extent affected quality of leaf. Sunday plucking in the busy months has to be resorted to the quality of Sunday work, no matter how close the supervision may be, is not, as a rule, of a very high order.

6. Over-production and an absence of fresh markets for the increased supply is largely responsible for fall in prices; in a rising market we never hear of inferior quality. B.

No. XXXIX.

Matule, Feb. 18.

I am of opinion that the fall in price of Ceylon teas may be attributed to the supply being in excess of demand, and that growers have found it pays them better to meet the demand for ordinary teas than to produce the finest teas for which so little has been paid in the London and the Colombo markets.

1. Planters have tried to meet the requirements of the buyers, judging these requirements by the prices they offered for the teas.

2. I am of opinion that manuring improves the quality as well as the yield of the tea, judging by the appearance of the leaf, both before and after it is manufactured, and therefore do not think that manure has anything to do with the fall in price. Though not an expert in tea tasting, I believe our ordinary teas are of as good value now as they were in 1892, only that the buyers won't give the price, as the stocks are larger, and they have no fear of the supply not being equal to the demand.

3. Nothing whatever to do with the fall in price. Severe pruning has frequently been found very beneficial to the tea bushes.

4. Sometimes, want of sufficient withering accommodation has been the cause of our teas not being quite so good as they would have been, had more withering space been available, but on the whole, I do not think less care is bestowed on the manufacture of our teas.

Enlarged and better equipped factories enable the Superintendents to exercise greater care, and produce with less trouble and certainly greater cleanliness, the teas of the present day, when compared with that of the past.

To your within-brackets query, I reply that the most careful attention in the factory, with the finest machinery available, be the individual in charge teamaker or European Manager, good tea cannot be made from poor or coarse leaf; therefore the first step in the manufacture is careful plucking, and if the leaf be good, the climate and elevation suitable, the manufacture of good tea in most factories is assured.

5. Frequently short labor supply has prevented my getting round the estate with my pluckers in time to pluck the flush at the stage I should have liked to have it; the consequence is, the leaf was larger and did not give the same percentage of the finer teas. I have no doubt had I had more coolies, I would have gone more largely into the manuring question with the proprietors, and almost doubled the yield, but what is the use of producing leaf if you have to abandon the plucking of fields as have been done in this district for want of labor, on more occasions than one? For the present, I think, you have enough of the

TRUTH.

No. XL

Teldeniya, Feb. 19.

I should have answered your first letter on manuring dated 26th December, and now I have yours of 12th inst. My views are—

1st. Manuring: I would not advocate it.

2nd. My experience in manuring tea is only confined to the last 6 months of 1896.

3rd. The field I manured never gave more than 260 lb. per acre before manuring. Although good work is being done in America and Russia, the supply is increasing much faster than the demand.

Your letter of 12th inst. :—

In my opinion the teas turned out now are much better than formerly. People have more experience and all the coolies and tea-makers are thoroughly trained. My opinion is that most of the people pluck finer than they did a few years ago.

Severe pruning—cutting low down—adds to the yield but *not* to the *quality* of tea; the tea made from low pruned bushes is not in my opinion so good for a considerable time as tea made from bushes with a good *tap* on them.

I manured 50 acres; it was pruned in January and February and I commenced to apply the manure on 1st July and finished by 15th August: for the year from 1st January to 31st December, it gave 467 lb. per acre for the year, and from 1st July to 31st December, the date on which I commenced to apply the manure to the end of the year, the yield was 279 lb. per acre for the 6 months: 10 year old tea on old coffee land. This was the first trial of manuring tea on the estate: this is the result of a carefully kept record.

Now if you advocate manuring of tea with markets as these are at present I should say it would be a case of looking for a millstone to put round one's neck. I would say take what can be got *without* manuring until the demand exceeds the supply and any fields of old tea are falling off in yield. If people all go in for manuring—in place of 119,000,000 the output will soon reach 140 or 150 million—then the question will be the outlet for the extra quantity; there will be more demands for coolies, advances will reach R100 per head and prices will fall still lower.

There is no fault in the factory, the appliances are much better than they were some years ago, and the people in the Factory have more experience. If the leaf is fairly good and *well withered* there is little chance of its being spoiled in after work: the fault is not in the factory.

My shortness of labour supply, as far as my experience goes, has not affected the work either in field or factory. The last, and, I believe, the main cause of falling prices is neither more nor less than *over-production*. 1878.

NO. XLI.

Maskeliya.

The market is glutted with tea. Overproduction is the cause of the fall in prices. Were the output to drop fifty per cent, up would go the prices again!

1. Plucking receives as much attention as ever it did. The leaf is no coarser than 8 or 10 years ago. I am sure this cannot be blamed for low prices.

2. Manuring has little if anything to do with it, *if* the leaf is plucked in time.

3. Severe pruning—that is cutting the bushes down to a foot or so—is only done once in 8 or 9 years. The quality of tea made from recently pruned tea is always inferior for 6 months after the pruning, but I can't say that leaf from *cut-down* fields is worse in this respect than from the ordinary pruning.

4. Manufacture is as carefully done as ever it was. Coolies get expert at this work and take an interest in it. Most factories are now very well equipped with machinery, and the withering accommodation, as a rule, is ample.

5. Shortness of labour does not affect the work in the factory, although it does so pretty often in the field during the heavy flushing months; for few estates are so well supplied with labour that an additional force of 30 to 50

coolies would not be welcome in April-May and November-December.

TRAMWAY.

No. XLII.

North of Kandy.

1. Coarse plucking is too palpable a cause in many cases to be disputed; and as this obtains largely in the lowcountry, the proportion of tea from which districts is increasing, the average for the whole island is naturally affected; where hard practical men find it pays, it is ridiculous for erities to condemn!

2. Not enough manuring has been done to affect injuriously the island's average.

3. Severe pruning in the majority of cases is only adopted where thought absolutely necessary—and it affects quality for a year or so after—so that it may *partially* account for fall in prices.

4. A good deal may be debited to half-trained, and badly trained tea-makers, who are far too common. "Ramasamy" well trained often proves more trustworthy; because he'll carry out master's orders and not *think*!

With regard to your parenthetical query here, good tea begins farther back than the field—for jât of seed is important too. But it's like tobacco, care must be exercised right through from seed nurseries to packing and shipment (ex apples!)

5. Not affected here by short labor.

9. a. Insufficient withering space when rushes of leaf come in.

b. Too rapid firing.

c. Night work and over-heated factories.

d. Varieties of jât and consequent uneven withering through different textures in leaf.

e. The *packet trade* at home; no one so far has remarked on this cutting down business.

N.B.—Much of the Broken Pekoe of today is Broken Pek. Sou. Ask the brokers about this?

T. KOKO.

P.S.—We have yet to discover what special element in the soil gives flavor and point. Many have noticed in tasting at their factories that leaf from young tea in new land has more flavor than that from old (? or young) tea in old land.

If estates, with new clearings in forest or old chena, would manufacture a separate break from this young tea fields, I feel sure above would be found correct almost universally. Then let the chemist find out what manure will restore the best element to old lands, and let the machinery inventors perfect a cool fermenting chamber, and quality will improve. Saith the cynic: "And the *quantity* of good teas will increase . . . and prices will *not* increase proportionately! So it's supply and demand after all!!"—T.K.

XLIII.

1. Coarser plucking on the part of many at medium and lower elevations particularly, I think, have probably reduced prices and on these estates it is said to pay best.

2. I think it is generally admitted that manuring increases the yield without adding flavor to the teas and perhaps in some cases is thought to reduce the flavor.

3. If trees are cut down low they are forced into heavy flush at the expense of flavor.

4. Every care should be taken with the manufacture of tea in the factory, but coarse or indifferent leaf cannot be made into fine teas,

but works, field and factory require constant attention to secure good results.

5. Perhaps in some cases shortness of labor no doubt has affected work in field and factory, but this could be made to affect quality or quantity, whichever was deemed desirable by those concerned.

6 & 7. I think perhaps coarse plucking and overproduction has affected the market.

TEA BUSH.

No. XLIV.

Nebada.

The three things named, *coarse plucking, style of pruning and manuring*, tending as they may all do to the production of large yields, must certainly open a wide door for the bringing in of low quality of tea. There can be no doubt that the object aimed at has been large yields. And there is also no doubt that it is only in favoured estates that such yields are consistent with high quality. The temptation of large production is, therefore, at the root of low average prices, because although large crops of poor teas *may* cause overproduction and bring prices to a ruinous level, the fact is that hitherto such crops have been profitable. All other considerations refer to minor points well within the control, and most efficiently controlled, by the generally good management existing in estates, aided by the supervision of competent visiting agents. There is always a high average for high class tea, and the average price in London is but the outcome of the planter's efforts to combine quantity with quality to the best advantage possible in the land he happens to be cultivating. That is what he will always do still, and we must stand or fall by the consequences.

M.

No. XLV.

Feb. 20.

1. Coarse plucking is not more general than formerly—rather the reverse, since more estates manufacture their own leaf in place of selling it.

2. Overstimulating manures have detracted greatly from quality of some 5 per cent of Ceylon estates.

3. Severe low pruning (necessitated by too close plucking and injudicious modes of pruning) has much to do with a falling off of quality.

4. There is, if anything, more intelligent attention to factory work than formerly.

5. Shortness of labour has caused inferior leaf to be brought in during the busy seasons on half the estates in Ceylon.

6. The market being better supplied is more critical of quality. The numbers of factories are not equal to their increased output. Demand is running on the stronger liquoring teas of India. The estates with worn-out soil do not produce as good a quality as when the tea was younger. This applies to a large area of the oldest coffee districts and the parts that have the heaviest rainfall.

M.

No. XLVI.

1. I think, as many, of the large tracts of tea in the lowcountry have gradually and year by year come into full bearing, the yield has been increased, throwing into the markets a large proportion of lowcountry leafed teas than were shipped when only a few estates commenced manufacturing. At times, too, say April-May

heavy flushes come on, and then the labour supply is inadequate, and *volens volens* coarse plucking has to be adopted.

2. I don't like manuring and I don't think it tends to improved quality; rather the reverse; in an indirect manner, for, if you have not sufficient labour to compete with the increased yield, you had much better leave manure alone.

3. Very possible; severe pruning is very much in vogue, and at the same time the roots are attacked with the mamoty, to say the least, heroic treatment.

4. Without doubt, not enough time is given to factory. Of course, good teas can be, so to speak, made in the field, but these, on the other hand, can be spoilt by want of attention in the factory: more attention wanted, too, to sorting and grading.

5. Personally I have always been well-off for labour, but this is going to be a greater trouble yet.

DIKOYA.

No. XLVII.

Feb. 20.

1, 2, and 3. All these mean a certain loss of strength and flavour, especially when combined.

1. Coarser plucking undoubtedly lowers the price by giving a large percentage of lower grade teas and lowering the price of higher grades through mixing in rolling.

2. Manuring tends to weaken the flavour and lessen the strength.

3. This affects prices similarly to No. 2, for say, 6 to 9 months from date of pruning.

4. This, in my opinion, has perhaps most to do with lower average prices.

Yes; careless or inadequate factory work will spoil the most carefully plucked leaf.

5. I do not think it has affected the price of my teas or factory work, but it has thrown field works back very prejudicially—such works as pruning, weeding, roading, draining etc.

6. Of course, overproduction and increased supply has also largely to do with falling-off in price.

D.

No. XLVIII.

Kandapola, Feb. 22, 1897.

I think the deeper the tap roots get into the sub-soil, thereby deriving inferior nourishment, the poorer the quality of leaf may become. This is only a surmise.

1. There is no doubt that plucking an estate once in 7 or 10 days is productive of a better quality of tea, than if rounds were allowed to run to 12 or 15 days. Coarser plucking may have something to say to the fall in price of Ceylon teas of late years.

2. I do not think manure, if applied once every three years, should affect the quality of tea.

3. I believe that a high bush gives a better quality of tea than a bush pruned down low.

4. Tea is practically made in the field in my opinion, but inadequate withering space or careless work may spoil the best leaf. I do not consider less attention to careful preparation in the factory has anything to do with the lower prices of Ceylon teas.

5. Shortness of labour, on the other hand, I do think may have, and probably has accounted for inferior quality of teas produced, therefore for lower prices.

6. Increased supply in competition at the sales very probably also accounts for the fall in price of Ceylon Teas.

G.

PRUNING, PLUCKING AND PREPARATION OF TEA :

REVIEW OF LETTERS XXIX TO XXXVI.

The number of letters which have reached us on the above subject, and the necessity of publishing them as fast as the exigencies of space permit, impose on us the obligation of passing them in review before they become stale, and emphasizing the points in them which merit attention. We now come to the letters commencing from No. 29. Of the letters which appeared on the former date, three deny coarser plucking and its responsibility for the fall in price—"Planter" from Maskeliya, "J." and "D"; but they admit that shortness of labour tells on the quality of the leaf plucked, and thereby on the tea manufactured with the result that prices are affected. But does not coarse plucking become a necessity when an estate can be compassed only once in 12 to 16 days instead of 7 to 8? There seems to be a consensus of opinion in favour of letting part of an estate go unplucked when labour is scarce, rather than delay plucking and damage the outturn of tea; but practice seems to differ from precept, if not invariably, in the majority of cases; for wherever shortness of labour is felt, it supplies an explanation of delayed plucking and inferior outturn. The fourth correspondent—"E.H.R." from Dikoya—expressly admits coarser plucking, and finds the explanation for it in the tendency of most estates to study the yield per acre, rather than the price per lb. But what is meant by yield? Is it gross yield in lb. of tea manufactured? Or net yield in profits? If the latter, our correspondence columns show that doubt is felt by experienced planters if the larger gross yield means a larger income. If it does not, and if it means even only the same income—the advantage of more restricted plucking is obvious on the ground of a lessened demand for labour, and smaller exports which might induce keener competition and better prices.

On the question of manuring there is no appreciable difference of opinion between the above-named for correspondents. "Planter," while holding that manuring does affect the tea to a certain extent, believes that the leaf of bad jât is improved in softness; and the evil effects of manure are neutralized by the production of a better leaf for manipulation. "E. H. R." believes that manuring can do harm only if there is not labour enough to an estate to cope with the heavier flush it induces. Given the labour, improved prices should follow increased crops. "J." has little experience of manuring; and "D." denies that manuring does harm; but frequent pruning, the last-mentioned concedes, the chief factor in deterioration. "J." shares that view to a certain extent, as it is months before the effects of heavy pruning wear away; and so does "Planter;" but "E.H.R." does not quite concede the evil. It is an operation which becomes necessary sooner or later, and matters can be so arranged that only a small part of the estate need be subjected to drastic pruning in one year. The bulk of the leaf would thus be unaffected; but if the weak and insipid leaf of the heavily pruned bushes are not manufactured apart, they must even to a small extent, affect the bulk. All four correspondents are agreed on the delicacies of the Factory, whether as regards accommodation for withering, or attention to details. "J." feels certain that better teas could be turned out with more attention, as some planters "scarcely

look at the leaf in the baskets, and certainly do not overburden the factory with their presence." The duties and responsibilities of a tea planter who really seeks to do his best are far from light; but the temptation to leave too much to subordinates, and afterwards to believe that it can do no harm, should be resisted. "E.H.R." while asserting the scanty withering accommodation in most factories puts aside insufficient supervision, as the man who neglects indoor work will neglect outdoor work as well, and will not keep his place long. But is Nemesis always unerring? And until the evil is remedied, is not the mischief widespread? "Planter" asserts that in 75 per cent of factories, withering space is insufficient, and although bad jât, climate and soil cannot compete with good, justice cannot be done to the best leaf without the needful accommodation. The feeling seems very strong and very general that it is a false economy which denies withering space to factories.

The subsequent letters show similar divergence of statement on plucking; for, whereas "R.B." from Teldeniya and "V.A." deny that there is much, if any, change in plucking, or that it explains lower prices, "J.J." from Dimbula has no doubt that coarser plucking has much to do with lower prices, and "W.N." generally agrees with him. The leaning is towards record yields per acre; and when the Visiting Agent says a certain field must give so many lb. per acre, the Superintendent ceases to be a free agent. The last-mentioned correspondent regards proprietary planters the chief offenders, as they fancy coarse plucking, while superintendents generally pay greater attention to plucking than before. Having had no experience of manuring, he cannot speak of its effects; but the three other writers acquit it of all blame. "J. J." justifies his verdict by the dictum that the healthier a bush is, the better should be its leaf; "R. B." asks pertinently whether judicious manuring can do harm to any cultivation or crop, and whether an answer in the affirmative would not be tantamount to upholding the superiority of exhausted soils; while "V. A.," conceding that manuring may at first give lighter leaf, holds that with the improvement in wood, the leaf must improve in three or four months. Severe pruning is unequivocally condemned by three of the writers, and the fourth says that it is resorted to only after three prunings or so. There is, of course, a difference in practice between up and low country estates—the intervals on the former being three years, while the latter prune every year or eighteen months. On the question of preparation, too, the difference is as three to one. Three of the correspondents deny less attention in the factory, and plead the helplessness of the factory to produce good tea from weak sapless leaf, but the fourth questions due care and attention on the part of superintendents, who leave too much to tea-makers who get slack in the absence of frequent visits. The evil influence of shortness of labour in inducing irregular plucking, is admitted even by those whose labour force is sufficient for all wants; but overproduction is regarded as the principal factor by men who may differ on other points. Some hold that teas vary with the seasons and a uniform quality is impossible throughout the year; others believe that age and absence of rest account for much of the deterioration which is inevitable. *Quere.*—Can science do nothing to check this deterioration?

(Letters continued.)

XLIX.

Agrapatana, Feb. 22.

DEAR SIR,—It would need an essay to deal fully with your questions regarding tea prices, the fall in which is probably due to many causes in combination and seldom to one alone.

In the first place, the fall of the Ceylon average is probably due largely to the increasing quantity of low grade teas produced in proportion to the high grade ones.

The estates celebrated for producing high-priced teas have not, I think, lost much in their averages in the London market during the last two years. A slight fall there is certainly, but not a great one, and that fall, I consider, due to general over-production, the supply during the last 12 months being all along rather ahead of the demand.

There is a tendency towards coarse plucking stimulated by the proprietors and their Visiting Agents who are anxious to see increasing yields and by Managers who wish to brag of their great returns per acre; but after all the chief consideration is which method gives the greatest profit and that is frequently a matter of very nice calculation. I am myself convinced that the high-lying estates which have got flavour will pay best by giving most attention to the development of that characteristic and leaving the quantity to take care of itself.

I do not think manuring has affected prices one way or the other. Severe pruning has undoubtedly the greatest possible effect upon quality and I have known several estates at one time celebrated for their high prices lose all the quality which gained them those prices at one blow by pruning down the whole of the tea at once, and the market once lost is not easily regained.

The dominant factors in the production of tea of the best quality that each estate can procure are:—

1. Attention to the constitution of the bush by careful cultivation and plucking.
2. The care given to the kind of leaf plucked.
3. The withering of that leaf evenly and quickly.

If these points are attended to, all the rest of the factory work comes easy and falls into its natural place, and as far as I have seen there is no want of attention in Ceylon factories.

Shortness of labour has probably prevented many estates from carrying out the conditions necessary to secure the best results and few superintendents, I expect, have the nerve to abandon for a time so much of their acreage as they are unable to deal with properly for the sake of maintaining their quality.—Yours faithfully,
B.

No. L.

Central Province, Feb. 22.

DEAR SIR,—In reply to your circular dated the 12th instant I should say:—

(1) The fall in the price of tea during the past 2 years is not due to coarser plucking. The fall previous to this may have been and was, in my opinion, largely due to a change in this direction in several districts where selective plucking did not give the equivalent in price that was lost in yield.

(2) Manuring unless when applied to add quantity to an already over-succulent growth, has not adversely affected quality. When the needs of the bush have been duly considered and allowed for in the manure, there has been a distinct improvement.

(3) I should think there are not two opinions in regard to this. Severe pruning seriously affects the quality of the tea. I cannot say, however, that this is more prevalent now than in previous years. Fields of hide-bound bushes here and there are yearly being treated in this fashion; old coffee-land tea gets more frequent touches of this treatment as the growth generally is more mangy of this class of tea, and more subject to the growth of lichens and other pests.

(4) There is certainly not less attention paid to careful preparation in the factory if anything it is more methodical. There is considerable doubt yet, I believe, as to the best methods of manufacture for any particular estate, and leaf, the many varying conditions of climate, factory position, &c., necessitating variety in the factory methods, apart altogether from the constantly varying claims upon us to meet the needs of consumers. There is a good deal of insufficient factory accommodation especially as regards withering space, and this to the extent prevalent does affect the quality of the tea. Without good leaf fine quality tea cannot be made; on the other hand there is much fine leaf that by no known process of manufacture can be turned into fine quality tea, climate and soil being largely responsible.

(5) Shortness of labour, I should think, does affect the quality of the tea during the rush in April and May; but beyond that taken as a whole there has been no very serious harm from this cause.

(6) In the older coffee districts, the absence of the necessary fertility is a main cause of the inferiority in the tea, and I should imagine it is having its effect in the lowcountry where a forcing climate would naturally tend to draw on the available supply too closely of a soil that is only ordinary in many instances, and produce flushes wanting in some of the essential elements, a most interesting question for the agricultural chemists. Long spells of very wet weather adversely affects tea, being probably destructive of nitrate-forming microbes so useful to all plants whose dominant element is nitrogen.

D.

No. LI.

Lowcountry, Feb. 19.

I think shortness of labour has a good deal to do with fall in price, and incompetent and *unreliable* teamakers; also the desire of big out-turns.

Upcountry estates at fairly *high* elevations 4,000 to 6,000 ft., I don't think show much decrease in price, provided they have a good supply of labour, and can gather the flush regularly and systematically. Severe pruning gives weak tea *for a time*.
C.

No. LII.

Dikoya Lower, Feb. 19.

1. I don't think that plucking is quite so coarse as formerly, on the whole.

2. Careful experiments lead me to believe that judicious manuring does not injure quality of liquor.

3. I know numerous cases where prices have gone down without any low cutting or hard pruning.

4. Men never were more anxious than now to produce good teas in their factories; and, on the whole, there never was more pains taken. Of course, the best leaf may be spoiled in factory; but no manufacture can *give* flavour.

5. Shortness of labour has affected work considerably on some estates.

6 and 7. I believe that the chief reason of fall in average prices is greater competition, caused by increased supply. This has been demonstrated in some markets, where the price of fine broken pekoes has gone down to that of pekoe. D. K.

PRUNING, PLUCKING AND PRE-
PARATION OF TEA :
REVIEW OF LETTERS XXXVII TO
XLIV.

In the batch of letters on the above subject commencing from No. 37, "L" from Dikoya, while claiming that the plucking in his district is medium, not coarse, labour being plentiful, ventures on the statement that all teas after a certain age lose flavour, and that unless young clearings maintain the reputation of the island, the old prestige cannot be sustained except in very "stand-out estates." If this contention, which move than one writer has put forth, be well founded—and it is explained by the absence of any wintering, without which the bush can obtain no rest from the unnatural treatment involved in continual plucking, varied by more or less severe pruning—the outlook for the tea enterprise would be very serious. But the apprehension of steady deterioration of our tea, year by year, is not justified by facts. There are teas, not of one or two estates, but of numbers, which have maintained their position for many years, whose prices have either fallen off but slightly in correspondence with over-production, or been maintained and advanced in the face of diminished competition. If, however, the fear be well-founded, that there must be general deterioration, as the age of the bushes increases, then the question of manuring assumes double importance. Primarily, the object of applying manurial substances to the soil, is to maintain or increase the yield; but if tea—are we not right in saying, unlike other vegetable products?—loses its flavour, too, in the course of time, surely the Agricultural Chemist should at once be applied to, to see if the decadence cannot be arrested and the flavour maintained or renewed. "B" from Bandarawela, on the contrary, feels no doubt that coarse plucking, in pursuance of the craze for a large yield per acre, has contributed to the fall in prices; and "Truth" from Matale leans to the same view, when he says that growers have found it pays them better to make ordinary teas than to produce the finest teas for which the prices are not attractive, while "1878" from Teldeniya insists not only that there is much finer plucking than ever before, but that the teas turned out are also much better, as a result of the larger experience in all branches of the industry which every one has from the cooly upwards. The main cause of the falling-off in price, in the opinion of this correspondent, one need not be surprised to learn, is over-production. He admits, however, that severe pruning spoils the quality, while adding to the yield, but the factory appliances he considers much better than before, and the experience of them the greater. He would assign no blame there, but he strongly condemns manuring, as tending to lower prices by increasing the sup-

ply and the need for more labour. But, surely, the advantage of manuring is not merely to increase the yield. The health, and even the very life, of the bush, must depend in many places on the renewal of the soil; and as for labour, would it not require more to open up and maintain new places if the old fail to maintain the supply and to respond to the demand? But beyond that, "Truth" is not singular in his belief that as manuring improves the leaf, it improves the quality of the tea as well; and "L" shares that view; while "B" cannot see that it damages the quality.

"L" holds that very severe pruning is seldom resorted to, and when it becomes necessary the result is wholesome; "B" shares this view to a great extent; and, while admitting that thin liquor follows pruning, whether medium or severe, for some months, has observed that the effect of light pruning is an abnormal quantity of bangy leaf. "Truth" acquits severe pruning of responsibility for bad prices, and "1878," like most planters, admits that the poor quality is only a temporary result. We have seen that the last-mentioned has no fault to find with the factory; "L" denies less care in the factory, and claims that it is greater; "B" is of much the same opinion, provided the accommodation and machinery are adequate to the wants of the estate; and "Truth" follows to the same effect, while insisting that the best machinery and the closest attention cannot produce good tea from indifferent leaf. Bad leaf may be due to weak bushes, but it is often explained by shortness of labour, which prevents "Truth" from asking for manure; for, as it is, he cannot get round the estate even with the flush.

"Tramway" from Maskeliya denies coarser plucking, or carelessness either in the field or the factory: he acquits manuring of responsibility for the fall in prices, where there is labour enough to meet the rush of leaf; severe pruning, down to a foot or so, he considers necessary only once in 8 or 9 years, and its evil effects on quality are transient; but he lays all the blame on over-production. Reduce the output, he says, to 50 per cent, and the prices will go up. It would seem to follow that, in his view, extension alone explains the excessive supplies he deplures. This view is not shared by "T. Koko," from the North of Kandy, who declares that coarse plucking, especially in the lowcountry, is too palpable a cause of low prices to be disputed; and if it pays it is not likely to be abandoned. Its remuneration is precisely the point about which practical men differ—the *non placets* asserting that the extra cost of labour, the withdrawal of labour from cultivation, wear and tear of machinery, cost of packing and transport, and the prospect of higher prices for better tea and smaller supplies, do not enter fully into the calculation. Manuring and severe pruning (except temporarily) are held free from blame; but half-trained and badly-trained tea-makers are held accountable for bad tea; while bad jât, insufficient withering space, too rapid firing, uneven withering from mixture of jâts and heated factories contribute to the fall. The responsibility of the packet trade for the fall is not easy to understand. Is its immediate effect not to promote consumption? And an enhanced demand should add prices; but that the Chemist should find out what gives pungency and flavour to the tea, is a suggestion which has our ap-

proval; for, we cannot believe that science cannot restore to a plant, through its food, the qualities it loses through exhaustion of the soil. "M" from Neboda and "Tea Bush" regard coarse plucking at medium and low elevations, and the ambition for large yields of tea per acre, responsible for low prices; but the practice is claimed to be profitable. If it is found to be so, it is unreasonable to expect its abandonment; for, it is on the real remunerativeness of the industry, and not on the reputation alone of the teas, that its continuance and development depend. If "Tea Bush" is correct in his opinion that manuring increases the yield, without adding to the flavour of the teas, and indeed while affecting it prejudicially, the necessity is all the more urgent of ascertaining whether the drawback cannot be remedied. If it cannot, the deterioration must continue, and the factory can do but little to improve teas if substance is lacking in the leaf. On the need of the utmost care in the supervision of the factory, there is as little divergence of opinion, as on the need of ample withering space and cool surroundings. Even those who assert that coarse plucking and large yields find favour because they pay, admit the probability that they may cease to be remunerative; and if quality becomes an object, the reform must begin with the soil, and it is not too early to start the investigation of the influence of soils and manures on the strength and flavour of the liquor.

(Letters continued.)

No. LIII.

DEAR SIR,—With reference to your queries as to the causes which have brought down the average prices of Ceylon teas:—

(1). That coarse plucking is one of the causes cannot be gainsaid. We see by the Colombo tea sales lists, lots of stuff sold at 8 cents and 9 cents—that proves coarse, if not careless, plucking. A greater cause of the low average, however, is, in my opinion, the much greater proportion of lowcountry, and, of course, inferior quality coming into the market.

(2). Manuring, if we know what to apply, ought to improve quality and thus raise the average. It is a well-known fact that the flavour of fruits is much improved by scientific culture, (for instance, the grape or pine-apple), and if fruits, why not leaf?

(3). Excessive cutting down (a pernicious system fortunately fast dying out) though it reduces the quantity, also reduces the quality for many months, and must contribute to lower the average.

(4). There is not, as a rule, the same watchful care over manufacture that was years ago. There are too many meets now to prepare for and attend. Large rollers do not make such good teas, nor so fine in appearance, as the smaller ones; but as this bears on fine and coarse alike, I do not see that the average should be much affected. There is much truth in the saying, that good tea is made in the field, but unequal withering or over-fermenting will turn out low grade teas, however fine the leaf.

(5). I have no personal experience of shortness of labour.

(6) and (7). That rubbishy stuff that goes in Colombo sales at 8 cents and 9 cents (largely the result of careless plucking though sometimes of shortness of labour) should be consigned to

the manure heap, or the boiler furnace, instead of going to depress our already very low average.
—Yours &c.,
M. D.

Extract from a letter written a good many years ago:—On many estates pruning seems to have developed into a ruthless hacking down of the bushes which only their natural hardiness, their still being young, their strong deep feeding roots together with the finest of climates, enable most of them to survive and rally in spite of this execrable treatment erroneously called pruning. In the lowcountry I have seen beautiful fields of tea made very patchy in one year by this fashionable cutting down. Many bushes were killed outright. The half-dried stumps of many more, never regained their former luxuriance. This sort of hacking down is even more common in the hill country, though, attended with fewer fatal results.

At this present time you would not have far to go in some of the finest districts without seeing beautiful fields of four feet across tea bushes, being ruthlessly cut down with knife and saw to a few thick sticks, representing nine or twelve inches breadth instead of four feet. When you take into consideration the enormous quantity of material in excess of what is necessary thus cut down and thrown to waste, the shock to the bushes, likely to kill a number and render many others stunted and feeble, the time that must elapse before these thick leafless sticks can grow to a fair-sized plucking bush again, and the draft on the soil to make up the waste,—tell me if you can, good Messrs. Editors, *C. O.* and *T. A.*, a single good and justifiable reason for such cutting down as that alluded to? Also tell me how many hardwooded bushes you know in the vegetable kingdom that would live and thrive under it?

As tea gets older this wholesale, wasteful and destructive system will become more transparent and those who practice it now will discover their error with regret some day, or I am no.—ARBORICULTURIST.

[In pruning, as in most other matters there is, we suppose, a *via media*. We know that years ago Indian visitors strongly denounced the Ceylon system of pruning, on the grounds now stated. But somehow the system has been successful. In the case of jat approaching China, wonderful results have been obtained from low pruning and where high jat bushes have been plucked for a long period, or have run into seed and become scrubby, careful and experienced planters will act on the principle that to enable such trees to recover they must cut low,—down to a foot, say, instead of the orthodox eighteen inches. Will some of those who believe in and practise low pruning favour us with the philosophy of their system?—ED. *T.A.*]

From an Indian paper we quote:—

There are many who still use a murderous looking weapon, more like a billhook than a pruning knife, both for light and heavy pruning, but I think there is little doubt that the yield of their gardens would be increased by the introduction of small knives and careful pruning.

To begin, taking my own experience in three districts with new and old cultivation, and in a fourth with old cultivation only.

I have left the plants to grow till three feet high, and then plucked all above that height, and then the season after that pruned them down below every branch, in no case leaving more than 10 inches above the ground. The plucking over the 3 feet tends to thicken out the stem and strengthen the roots; while the cutting down so low forces the plant to throw up a number of stems from its roots while these are young; later on they will not sprout so readily.

The next year it will be found that there is already some breadth on the bush, and cutting 6 or 9 inches above the first year's cut and leaving 3 inches of new growth in succeeding years the bushes will both grow and yield well. I have always found those cut down lowest in the first year make

the best bushes in the end. Being by habit a tree, the most of the strength goes to the original stem if left long.

This style of pruning must be supplemented by very careful plucking at the beginning of the season, so that in the 3 inch new wood left there will not be a "plucking knot," this being the fatal thing to leave in a bush.

Now all this looks very simple, and the men using big knives and slashing across the bushes at a particular height for all of them, will argue that they cannot go wrong if they use a measuring stick, and cut to that every year, but not being great little tin gods, we cannot insist on each bush growing to order, nor can we be absolutely certain that every one has been correctly plucked, neither can we be sure that in the slashing a little too much or a good deal too little wood may be cut.

Year by year the bushes alter their character, though apparently having the same treatment. Now comes in the necessity for small knives and discriminating pruning.

This pruning can best be done by the women, and indeed they have the most interest in it as soon as they are got to understand that on their good work depends the amount of leaf got in the season. On my garden I have certain lines called by certain women's names, that have been pruned badly by the women. These lines are kept as "büksis" for them in the plucking season, and they don't like it at all.

The aim of the light pruning is to leave only straight wood, and not too much of that, taking out all plucking knots and crow's feet. The small *banjis* inside may be left alone; if they are taken out, the bushes will be just as full of them the next season, showing that some of the strength of the bush has been wasted in reforming them, and besides they form a protection to the bark from the sun. Neither should the leaves be taken off as they (with the small *banjis*) are the lungs of the plant, and stripping the bush only renders it more liable to disease. Pruning and plucking give shocks enough, without any necessity for emphasizing them.

LIV.

Dimbula, Feb. 24.

(1) Would you say how far you think Coarser Plucking of Leaf may have had to do with it?—More care is taken to secure good leaf now than was formerly the case, so this is not one of the reasons.

(2) Or the more prevalent attention to manuring tea?

In my opinion artificial manure does destroy "quality" in tea, while increasing quantity; but it has not been universally used. Many estates which have had none, and on which the management and style of manufacture remain unchanged, have nevertheless had their prices drop of late; so in addition to manuring there is some other agency at work.

(3) Or severe pruning—cutting the bushes too far down?

Severe or constant pruning is, in my humble opinion, a fatal error, and has possibly done as much to bring down prices as anything outside the factory.

(4) Or less attention to careful preparation in the factory?

No. The tendency seems to be to give manufacture a good deal more attention than it formerly got, but yet a large amount of poorly made teas is constantly put on the market, and the reason for this will be found among the following:—

I.—Want of sufficient factory room on machinery or both.

II.—Stinginess of Proprietor or Agent in not allowing sufficient funds to secure a suitable tea-maker.

III.—*Cheap* and therefore inefficient management, and cheap and nasty work to suit estimates framed by, say, Messrs. Jabez Barabas & Co., who want to show their "friends" how *economically* everything is done on Pitchi Kadu Tottum.

IV.—Inability on the part of the V. A. or Boss to give the young Superintendent a practical lesson in teamaking or show him his errors and how to make the most of his tea.

V.—Want of encouragement to Superintendents.

It seems strange at first sight that proprietors should be willing to let their tea suffer from any of the above-mentioned and easily preventable causes, but still many do so and the result is as might be expected. One can only suppose that absence from Ceylon or ignorance of the conditions necessary for producing a high-class tea prevent their grasping the true situation.

The day cannot be far distant now when it will be recognized as it should be, that the manufacture of high-class tea is, like brewing, work for an expert and that an estate Inspector is *worse* than useless unless he be a practical planter of wide and real experience—a trained taster and tea expert, and possessing a thorough knowledge of all machinery.

5. I should say a shortness of labor would affect prices to some extent, but not so much as shortness of factory room for instance.

6. A favorite complaint of some Agents is that tea "though well made, is not suited for the market," and if this is the case, agents should keep their Superintendents well posted up in what is wanted and so secure teas suited for the market and maximum prices for proprietors.

To sum up:—I think the deterioration of our teas arises from various causes, viz:—

Age.—We cannot make such a good article from bushes over 12 years as under. *Manure* as I have stated. *Severe pruning.* *Bad manufacture* from the causes mentioned.

No. LV.

Balangoda, Feb., 25, 1897.

I do not think that either common plucking, manuring or pruning has much to do with lower averages. I think the chief reason is the larger area of low-grown tea now coming in, as compared with previous years, also the much larger quantities that have to be passed through small factories without sufficient power or machinery, and in consequence less carefully made. Rush of leaf and insufficient labor also all tend to lower averages.

Good leaf can most certainly be spoilt in factory.

— — —
No. LVI.

Central Province, Feb. 25.

DEAR SIR,—In my opinion the recent falling off in quality and consequently price of Ceylon tea is greatly due to insufficiently equipped factories, so far as both machinery and withering accommodation are concerned, especially the latter.

Very many estates in Ceylon have of late years been manured and in many cases the yield has increased from 350 lb. per acre to 500-600 lb.

This large increase has been manufactured in the existing factories, which, although when built were ample for the requirements of the estate are now quite unequal to dealing with the greater quantity of leaf.

Although I am convinced that superintendence in the field is very necessary, I am equally sure that were more time spent in the factory, and the responsibility of manufacture not left so entirely in the hands of underpaid native tea-makers, the Ceylon average would not long remain at its present low level.—Yours, etc!
G.B.K.

PLÜCKING, PRUNING AND PREPARATION OF TEA.

REVIEW OF LETTERS XLV TO LII.

The letters, commencing from No. 45 disclose similar differences of statement on the question of coarse plucking to those already noted. "M" denies that coarse plucking is more general now than formerly—thereby implying that it has always been prevalent to a considerable extent; and he inclines to the view that plucking is finer now, and grounds his belief on the circumstance that more estates manufacture their own leaf, in place of selling it. But he admits that shortness of labour results in the plucking of inferior leaf, especially in busy seasons, on quite half the estates. "Dickoya" believes that lowcountry extensions, which are coming into full bearing year after year, have thrown into the market larger quantities than ever of coarse teas; and when heavy flashes come on, about April and May, an inadequate labour force compels coarser plucking. "D" asserts the combination of coarse plucking, manuring and heavy pruning, as tending to deterioration; while coarse plucking by itself accounts for a larger percentage of low-grade teas, and the lowering of the price of the higher grade, through mixing in rolling? "G." from Kandapola, while admitting coarser plucking, and the evil influence of longer intervals than 7 to 10 days between pluckings, advances the theory that the deeper the tap root gets into the subsoil, the poorer the nourishment it provides the bush with; and that tells on the quality of the leaf. But do not the principal feeding roots radiate from the stem, and should not manuring, judiciously applied, counteract the evil effects of an aging bush and inferior subsoil? By judicious application, we do not mean only the provision of such constituents as the bush needs, with reference both to the treatment it undergoes and the character of the soil, but also the manner of applying the manure without needless injury to the roots which would aggravate the shock caused by continuous plucking. "G." disbelieves in any injurious effect on flavour, caused by manures, if applied once in three years. "D." on the contrary holds that "manuring tends to weaken the flavour, and lessen the strength of teas; but no reasons are alleged for this opinion, and we fail to see how treatment which is calculated to give tone and strength to the bush, can weaken the liquor drawn from the leaf. Injury to the flavour, by making it coarse and unpalatable, is intelligible, though it remains to be established that this result follows necessarily from the application of manures, whatever their constituents, and if it does follow that it is not transient. "M." and "Dickoya"

believe in such deterioration, but we should prefer to suspend our judgment until chemical tests have supplied data on which one could safely proceed; but manuring, as tending to produce leaf beyond the competency of pluckers, is quite another matter, and the experience on all estates cannot be the same. Severe pruning is condemned by all four writers, as tending injuriously on quality, while two expressly state that a high bush gives better tea than a low pruned one. "M." asserts more intelligent attention to factory work than before; "Dickoya" holds quite the opposite view—that not enough time is given to factory work—and he is supported by "M." who thinks less attention to preparation has perhaps most to do with disappointing prices; but "G." denies this, while holding inadequate withering space responsible for much harm. And there follow some suggestive letters—notably those by "B." from Agrapatana, and "D." from the Central Province. The former recognises the increasing proportion of low-grade teas, as one of the many causes that have contributed to the decline in prices, which, he affirms, is very slight in the higher priced teas. His contention supports our refusal in our last article to accept the theory of a natural deterioration of our teas from the age of the bushes; for, not only does he appeal to figures in proof that the fall in good teas is but slight, but he points out that that fall is easily explicable on the ground of over-production. While saying thus much, he has observed a tendency to over-plucking, stimulated by proprietors and Visiting Agents, anxious to see increasing yields, and by Managers who boast of returns per acre. "D," on the other hand, denies coarser plucking, though it operated at one time in places where selective plucking did not make up in profits for loss in yield. As "B." says, it is often a matter of nice calculation, whether coarse or fine plucking pays better; and we agree with him that high-lying estates should not sacrifice flavour to yield. "C." ranges himself with "B." in the view that the fall in price in teas from high elevations is slight, when labour is not scarce. Scarcity of labour, he thinks, has a good deal to answer for, and so with "incompetent and unreliable tea-makers," and the desire for big outturns; while severe pruning gives weak tea only for a time. "D.K." agrees with the previous writer on the evil influence of short labour, and so do "D." and "B."—the last-mentioned adverting to the courage necessary in a superintendent to abandon plucking on a certain acreage, in order to maintain quality. Clearly, that is a matter in which the responsibility should rest on the Visiting Agent or the proprietor himself; but, then, the superintendent would be relieved of the responsibility of maintaining an adequate labour force. With the alternatives before him of a deficiency in the estimated yield and a falling-off in quality, the superintendent will more fully recognise the need of exercising the greatest tact and judgment in keeping together his labour force without encouraging reckless advances.

On the question of manuring, "B." denies that it has told on prices; while severe pruning, to his knowledge, when carried out too freely over an estate, has so affected quality, as to render recovery of the old reputation difficult. "D." holds the same view on manuring, except when over-succulent growth has been further sought to be stimulated. When the needs of a

bush have been duly considered, there has been a distinct improvement in quality; and careful experiments by "D.K." have led him to the conclusion that manuring does not spoil quality. "B." summarises effectively the requirements of the day, in (1) attention to the constitution of the bush by careful cultivation and plucking; (2) care as to what leaf is plucked; and (3) even and quick withering. If these are attended to, factory work is rendered easy; and he has observed no want of attention in factories. "D." agrees in this; but thinks the requirements suited to varying conditions of climate, position of factory and the needs of consumers, are little understood; while insufficient accommodation is a considerable grievance. "D.K." too, testifies to the attention bestowed in factories. The views expressed by "D." on the absence of fertility in old worn-out soils, and the forcing climate of the low country, render authoritative advice on manuring, such as Mr. John Hughes tenders on the next page all the more urgent.

(Letters Continued.)

No. LVII.

Maskeliya Feb. 13.

(1) Coarser plucking *does not* affect the drop in prices; for all grades, coarse and fine, have gone down equally—indeed, if anything, the finer grades most.

(2) Neither does manuring affect prices so far as can judge and I've done a good deal.

(3) This, in my opinion, does so. Low severe cutting down especially so, and *too frequent* prunings. This is an easy and simple method of *increasing* your yield; but it is long ere the *wood matures* sufficient to give a good class of tea.

(4) Far better and more elaborate machinery is now used in factories and much more (may I call it) scientific tea making brought to bear on the manufacturer now than of old: so I can't see well, how it could be from less care, speaking *as a whole*, that prices are affected. Of course, well-plucked leaf *may* be spoiled in factory, but this would apply to isolated cases only. Given a reduced output all over the world, prices would jump at once.

5 This last remarks under No. 4 applies twice.

6. Overproduction and the usual law of supply and demand are the factors.

See Kandapola tea and prices; as a rule, they allow the bushes to run as long as *3 years unpruned*. The wood is old and well matured, and produces good liquor. I don't say this is possible everywhere—unfortunately, it is not so.

W. A.

No. LVIII.

Agrapata, Feb. 27.

1. On some estates at lower elevations there is no doubt that coarser plucking has influenced the prices of tea, but I do not consider that at higher elevations the tendency has been to pluck coarser, but in many cases, the reverse.

2. I have never found manuring affect the quality of tea at this elevation, but that it rather improves it, if properly and judiciously done, though, of course, in certain soils and climates indiscriminate manuring may give yield only and reduce quality.

3. I believe severe pruning to be less prevalent than formerly and that, on the whole, more care is taken in this work.

4. I consider there is room for improvement in manufacture and, in some cases, want of more machinery to prevent night-work or more room for withering. With the rapid increase in acreage opened for tea, there has been corresponding increase in number of factories, and the necessary experience has been often missing to keep up with all this. Good tea is made both in field and factory and to show good results, and give good profits there should always be experienced management in the field and supervision by those who know how to make the most of this in the factory and direct those there.

5. At certain times of the year when the "rushes" come on, shortness of labor would, of course, affect the work in field and factory. It has not been so in my case, as I have always had sufficient supply of labor. But I know, that in some cases with all this increased tea coming on of late years, this has seriously affected the quality of the tea, but to what extent generally, I cannot say. As a matter of fact, I do not believe that the tea, made of recent years, has been worse than previously, in any well-ordered factory. I believe that I make better teas than ever I did and yet get lower prices. This is corroborated both by local and home reports on the teas, and I have no doubt very many others have found this to be the case. Is it not a fact that actual profits on estates per acre have been larger on most estates with increased yields, &c., than when highest prices ruled, and would it not be so now if exchange had not risen, and allowing for increased prices paid for estates, and it is for each one to find out what gives best profits per acre, allowing liberally in factory for all machinery and manufacture to secure best prices for leaf received there, and in field, for proper cultivation to keep up quality of leaf on trees. W. B. J.

No. LIX.

North Matale, Feb. 27.

- (1) Overproduction more than anything.
- (2) Have no experience in manuring tea—so did not answer first letter.
- (3) Would not think so.
- (4) Do (agreed).
- (5) In a rush of leaf, the tea cannot be so good as generally we are then short-handed.
- (6) No. M.

No. LX.

Rangala Feb. 16.

Manuring in this (medium) district very little; and only this year is one estate doing a good deal with artificial.

Re yours of 12th instant.—(1) I think bad and coarse plucking is one of the primary causes of Ceylon teas being so low in price. (2) and (3). With careful work, this has little to do with it. (Manuring may take off flavour, this I'll be better able to judge 12 months hence.) (4) *Manufacture*.—Want of care and attention has a great deal to do with poor teas.

Many factories are left to the charge of some cooly or teamaker, who is equally ignorant of the first principles of manufacture of tea. Green leaf comes to factory from fields and in a few days it is manufactured by rule of thumb into so-called tea and soon despatched. How some I have seen, finds a sale, I can't think. Such is the history of tea manufacture in a few factories I know!! S.

THE MANURING OF TEA ESTATES.

We have much pleasure in laying before our readers the following valuable review by Mr. John Hughes of the series of letters on Manuring of Tea which recently appeared in our columns. Mr. Hughes complains in a private note that many of the replies we received to our questions are rather vague and general, no details being given of actual results and cost as compared with increased yield. Such figures are absolutely necessary to the formation of a practical opinion for future guidance. However, Mr. Hughes enters very carefully into the whole question and his facts and figures, as well as practical counsel, cannot fail to be of much service to all careful and thoughtful tea planters in Ceylon and elsewhere. The Report is as follows:—

By the last mail the writer received a request from the Editor of the *Tropical Agriculturist* to review the 61 interesting communications that had been forwarded in reply to the Circular issued, asking for detailed information respecting the extent to which Manure had been applied to tea.

The general character of these replies appears to indicate that manuring is becoming much more general upon old estates, where tea has been substituted for coffee, but that upon really good soil and upon new estates, it has not yet been resorted to. This is quite what should be expected, and also shows the importance of considering the quality or chemical composition of the soil before incurring unnecessary expense.

In this country as recently as last summer in the potato experiments at Reading on Messrs. Sutton's trial plots, we had an illustration of the folly of applying certain manures to soils already fully supplied with phosphoric acid and potash. The increase in yield did not pay for the increase in the cost of production, and consequently was unremunerative. Therefore, before commencing any expensive system of manuring tea estates, it is essential to ascertain in what respect the soil needs assistance whether in regard to nitrogen, potash or phosphoric acid; for, in regard to Lime, we need not trouble to make inquiry as it is not specially required for tea.

Many of the writers of the replies state in a very positive manner that they would not think of manuring tea on good soil, and they are quite right both *practically* and *scientifically*.

It is rather curious to notice that some planters state that they object to manuring on the ground of fearing over production. One can understand the objection being raised upon the ground of want of labour, but it seems a novel idea to fear overproduction in a country where new estates are constantly being opened up. Whether manuring should be resorted to or not resolves itself into a matter of cost. In estimating the value of the increased yield of tea, it is however important to remember that it is not the *gross*, but the net extra value of the tea made that should be put against the cost of manuring. This was pointed out by the writer when reviewing the results of the manure experiments recorded in Mr. Bamber's book. Thus, if the ordinary yield of 400 lb. made tea per acre be increased to 600 lb., we must deduct the cost of picking, making, packing and carriage to the seaport, and not simply calculate that 200 lb., if sold in Colombo at 40 cents per lb., would realise Rs0.

At present it appears that manuring consists of two kinds, *bulky* and *concentrated*; the former being represented by cattle-dung and lime refuse, and the latter by bones, fish and castorcake.

The last mentioned are described somewhat erroneously by certain planters as *artificial*s, though nothing can be more natural than the remains of animal or vegetable productions as natural fertilisers. These three fertilisers are valuable according to their richness in phosphates of Lime and Nitrogen per 100 parts as follows:—

	Phosphates.	Nitrogen.
Bone Meal	50 to 53	3½ to 4
Fish Meal	14 to 18	6 to 7½
White Castor	4 to 5	7 to 7½
Brown Castor	3 to 4	4 to 4½

It will be noticed that bones are highly phosphatic with comparatively little nitrogen, and that castor, especially the superior white quality, is highly nitrogenous and only very slightly phosphatic, while fish, which is often of very variable quality by reason of adulteration with sand, occupies a medium position.

With the aid of the local Analyst in Colombo, planters can always protect themselves at a slight cost against being imposed upon by the delivery of inferior materials. Sellers soon find out whether manures are subject to a careful and systematic examination by analysis, and will not run any risk with prudent buyers, for it is the careless and thoughtless buyer that is usually imposed upon.

Manuring will have to be done judiciously (if it is to be profitable), regularly and in small quantity, adapting the kind of manure to the requirements of the soil. If nitrogen only is required, castorcake, well crushed, will be one of the cheapest and most suitable. If phosphoric acid, so essential to the production of a quick growth of leaf, be required, a mixture of bonemeal and superphosphate may be advantageously applied. If potash, the dominant mineral element in the ash of the leaf, be required, potash salts in the form of sulphate of potash should be supplied.

The use of nitrates, whether as nitrate of potash or as nitrate of soda, which apparently have been applied to a limited extent, should be discouraged, because of their great solubility and the known heavy rainfall of Ceylon. These salts readily dissolve in their own weight of water, so that their application must be attended with great risk in a country in which the rainfall is sometimes as much as 23 inches in 24 hours.

In this country, nitrate of soda is perhaps the most economical, concentrated, nitrogenous manure that can be employed upon spring sown crops, which have only a few months to complete their growth, and under a rainfall of only a few inches per month. The same remark may apply to the use of sulphate of ammonia and also to Peruvian guano, both of which are too soluble to be used in any quantity in tea fertilizers. Those acquainted with the hilly districts upon which tea is grown in Ceylon are aware of the terrible destruction caused by wind and wash and that the preservation of the original surface soil should be the first consideration of the careful superintendent. The richness of a soil in humus or vegetable mould is indicated in ordinary soils by the richness in nitrogen: the best Ceylon soils contain as much as 50 in 100 parts of dry soil, while the poor soils contain only 10 of nitrogen per 100 parts of dry soil. And as every 10 per cent represents in round numbers 2 tons per acre to the depth of one foot, it will be understood that the difference between the accumulated fertility of one soil in respect of only one constituent, namely nitrogen, as compared with another soil, may vary as much as from 2 tons to 10 tons.

In the reply, marked 60, figures are given showing the effect of manure upon different plots of old coffee land 35 years old now in tea.

	per acre.				
	lb.	lb.	lb.	lb.	lb.
Before Manuring	201	304	143	188	305
After Manuring	425	726	310	317	637

The writer states that "the experimental handling of artificial manures has given castoreake and crushed bone the laurels and realized nearly 100 per cent increase." This, however, is only the gross increase and we should like to have the nett value of the increased yield of tea, also the cost of the application of the manure before deciding whether to repeat the dressing the next season. These experiments are very useful, so far as they go; but for general guidance and to afford practical information, it will be necessary to furnish further details. The composition of made tea naturally varies considerably: in the first flush and young leaf there is more potash and phosphoric acid with but little lime: but as the leaf becomes older and larger as well as coarser, the figures for potash and phosphoric acid decline, while those for lime increase. According to the writer's analyses 500 lb. Ceylon pekoe souchong removes:—

Organic Matters	..	441 lb.
Mineral Matters	..	29 "

The organic matter includes 19½ lb. of nitrogen, while the mineral matters include 11 lb. potash, 4 lb. phosphoric acid and 3 lb. lime.

These figures indicate the importance of bulky organic matter containing about 4 per cent of nitrogen and 5 per cent mineral matter. Hence the various kinds of crushed cakes naturally supply a manure specially adapted to the requirements of tea. If the freight would permit, it would be possible to send an excellent specially compounded manure direct from this country, and thus do away with the chance of local adulteration. To some extent this has already been done by planters who reside at home, and as several subsequent shipments have been made, the crop results extending over three years may fairly be assumed to be satisfactory. But in preparing any such special manures, it is essential, first of all to ascertain what the soil already can supply itself, and in what respect it requires assistance; otherwise the manures cannot be expected to be economical.

If the Railway authorities would enlarge the statement of their traffic returns and arrange that the quantities of bone meal, crushed cake, dried fish guano, superphosphate, chemical manures and nitrates were separately tabulated, very valuable information would be afforded to owners and managers of estates, as well as to those interested in the sale of such materials.—JOHN HUGHES, &c., District Agricultural Analyst for Herefordshire Analytical Laboratory, 79, Mark Lane, London. E. C.

THE INDIAN TEA INDUSTRY: PROPOSED CENTRAL RECRUITING AGENCY.—A meeting of representatives of the Tea Agency Houses was held at the Bengal Chamber of Commerce Rooms, Royal Exchange, to consider a scheme for the formation of a Central Recruiting Agency. There was a good attendance, and the Hon'ble Mr. Playfair occupied the chair. The Chairman stated, among other things, that the "annual outlay for importing labour the Chamber of Commerce estimate at R45 lakhs."—Prodigious R4,500,000!—and this amount, we take it, not in "advances" to be recovered, but all irrecoverable.

VARIOUS PLANTING NOTES.

THE PROCEEDINGS OF THE AGRI-HORTICULTURAL SOCIETY OF MADRAS for the last quarter 1896. This is no temporary body, but an established institution of 62 years' standing. We note that H.E. Sir Arthur Havelock is its present President. As might be expected, these proceedings show that a good deal of important work of a special character is being done and we can only regret that we have no similar institution in Ceylon to look after the interests of Agri-Horticulture in the Colony in a thoroughly business-like way.

TEA CULTURE IN MAURITIUS.—We are pleased to receive a letter from an old Ceylon planter with varied travelling experience like Mr. E. H. Edwards. A rumour, indeed, had reached Ceylon of his death and talking of coincidences, only yesterday did a Colombo merchant remark to us on his final disappearance, and behold, this morning's post shows that he (Mr. Edwards) is still in the land of the living, while he reports another ex-Ceylon planter, Mr. Cor on, as very sanguine of the success of tea culture in the sugar island. We should have supposed that "sugar" would pay too well in a silver-using Colony to make it worth while to go after tea; but the growth of a certain quantity of leaf for local sale and consumption ought to be profitable.—As for Mauritius rivalling Ceylon,—pooh!

THE DALUKOLA TEA COMPANY, LIMITED, may be congratulated upon their happy idea represented by the very handsome and taking Tin which they are issuing in commemoration of Her Majesty the Queen's record reign. It represents a golden sovereign, is about ten inches across and 1½ inches deep. The die is most excellently well cut, and faithfully reproduces the coin. The metal is the very finest steel plate; this was found necessary to stand the tremendous pressure of 20 tons in the hydraulic press in which the figure of the Queen's head is embossed. The work is executed by the foremost English firm in this class of work, and the result does them the greatest credit. The tin, filled with tea, retails at 2s, and will make an attractive window show. Over 30,000 of these tins have already been sold.—*Grocers' Journal*, March 20.

METHYLATED SPIRIT IN INDIA.—The quantity of spirit methylated in Bengal last year shows a considerable increase. In 1894-5 it was 54,282 gallons; in 1895-6 59,854 gallons. Methylated spirits are, of course professedly imported or prepared for use in arts and manufactures and in chemistry, and in this idea the duty thereon is fixed at a low rate of 5 per cent., *ad valorem*. It has lately been shown, however, that spirit methylated with wood-naphtha can be manipulated into a drinkable spirit, and the Bengal administration have therefore taken under consideration a scheme for denaturing the spirit in a more effective way. The medium with which the spirit is to be rendered "completely and permanently unfit for human consumption" is "caoutchoucine," with which it is to be mixed. A horrible sort of eau-de-Cologne used once upon a time to be made in Calcutta. It was done up in bottles imitative of the well-known bottles of the celebrated "Farina," and the lady new-comer to India, inexperienced in the boxwallah's wares, was liable to think that she had picked up a bargain indeed—until she tried the "perfume" upon her pocket-handkerchief. This country-made eau-de-Cologne, the manufacture of which was formerly carried on to a large extent in Backergunge, was prepared with spirit made from wood-naphtha; but, luckily, the manufacture of the indigenous eau-de-Cologne has almost ceased, and it is not thought worth while to make it a special matter.—*Chemist and Druggist*, March 20.

TEA REPORTS—AND TEA PROSPECTS.

A leading Colombo merchant said to us the other day that one consolation arising out of the present low prices for Ceylon teas must be the absolute discouragement they offer to the gentlemen or Syndicate who are so anxious to exploit machine-made China teas. With our low-country teas selling so cheaply as they do at present, there cannot be much scope for bringing forward China, Japan or even Java teas in competition, and one result ought, therefore, to be to drive out still more China teas from the United Kingdom and Australasia, and to give Ceylon and Indian teas a little better chance of competing with China and Japan in North America.

This mail brings us the Annual Reports on the Tea Market (for 1896) of Messrs. Geo. White & Co., and Messrs. Wilson, Smithett & Co. From the former we quote the list of averages for Ceylon districts for each month, with Nuwara Eliya, Udapussellawa, Dimbula &c. 9³/₄d average at the one end and Kurunegala, Polgahawela, Kegalla, &c. with 6d at the other. What is said in respect of "prospects" we quote in full as follows:—

PROSPECTS.

With every indication of a larger demand for British-grown tea from nearly all quarters of the globe, and a gradual extension of the Home consumption, the outlook is fairly favourable, especially as the present scale of values is moderate for all descriptions, and judging from the estimates, supplies from India and Ceylon for the current year, although heavier, are not likely to prove excessive.

It will be interesting however to observe the results of the introduction of machinery and modern systems of manufacture in the produce of China, although it is not considered probable that the amount shipped from that country to Great Britain will be augmented thereby, at all events for some time to come.

The vital point to those interested in the tea industries of India and Ceylon is the price which their productions will realize. The tendency is no doubt to a lower rather than a higher range. Writing on the 18th of March, 1887, we said, "The public has been accustomed to cheap (*i.e.*, low priced) tea, and the 1s 8d and 2s canisters have been reduced to 1s 4d and 1s 6d." Even allowing for 2d per lb. reduction in the Duty since then from 6d to 4d per lb., there has been a further marked decline in the retail price, a large proportion going into consumption at from 1s to 1s 4d per lb., while 1s 6d to 1s 8d per lb. is considered a liberal figure for the better kinds.

This tendency to a shrinkage in value, together with a possible higher rate of exchange, makes it more than ever a matter of necessity that the sale of British-grown tea should continue to be pushed in countries other than Great Britain with all possible vigour. Considerable progress has undoubtedly been made as regards Russia and the Continent generally, as well as in Canada and the United States.

To a great extent this result has been brought about by the good work done by both the India and Ceylon Tea Associations and those working in conjunction with them, but it is of paramount necessity that their efforts should be persisted in with even greater stress than heretofore.

From the Report of Messrs. Wilson Smithett & Co., we make the following quotations in the meantime:—

The weight of Ceylon Tea offered in auction between January 1st and December 31st, 1896, amounted to 92,000,000 lb., against about 80,000,000 lb. in 1895 and 74,000,000 lb. in 1894. The Average Price realised for that on Garden account being 8³/₄d per lb., against 8³/₄d in 1895, and 8³/₄d in 1894.

Exports.—It is very gratifying to be able to notice the steady increase in the demand for Ceylon tea

from the various extraneous markets. During 1896 the exports of Ceylon were nearly double those of India. The direct shipment from Colombo to Australia and New Zealand alone shew an increase of 2,500,000 lb. compared with 1895 and, in addition to the re-exports from this country, which mark an increase of 1,100,000 lb. or more than 16 per cent. during 1896, compared with the previous year, a considerable quantity has been transhipped without being landed in London, principally for the American and Canadian markets. The Russian demand remains the principal factor in the development of the export trade, important orders from that quarter being now received almost every week in time to materially assist competition at the public auctions.

Quality during 1896 was, we consider, fully up to the average. During the early summer months there was, as usual, a large proportion of dull and pointless tea, but later on a very satisfactory standard was attained, and the October and November arrivals were mostly of excellent quality, combining fine flavour and good strength. Two defects in quality demanding the attention of planters have become much more pronounced of late: we refer to the increasing number of "tarry" and "minty" teas; the former characteristic seems to be attributable to the leaf getting smoked during manufacture; it is easily detected in the aroma of the dry leaf, and often spoils a tea of otherwise good flavour and quality. "Mintiness" is a defect which it is more difficult to locate; high-country teas are chiefly affected by it, and it is most noticeable during the arrivals of the early months of the year; the flavour, which is very pungent and pronounced, closely resembles that on the wild currant or "Ribes" of our own gardens, and has been attributed to *Eucalyptus* as well as to some small aromatic herb, which it is said the coolies casually pluck. It has this peculiarity, that it does not, as a rule, taint the tea throughout; frequently after one "minty" infusion, which must contain a foreign leaf, the flavour will only reappear occasionally in subsequent infusions.

Our list of estates this year comprises 656 which have sold 20,000 lb. and over on the London market under their own marks during 1895. An asterisk has been placed against those marks, which were either wholly or partially sold in Colombo, as the returns in those instances are, in all probability, incomplete on account of the re-marking of a large proportion of Colombo-bought tea.

The general average realised during 1896 for teas on garden account suffered a decline of 3³/₄d per lb. compared with the previous year, and a glance at the results we have compiled will show this to be due to the lower range of prices current for common to ordinary kinds, the most important reductions being confined to low country estates, and to those where quantity rather than quality is aimed at; this feature of the market is more clearly noticeable in the results obtained in the various districts. Up-country gardens have, on the whole, well maintained their position, and many estates show a gratifying increase in the value of their produce.

The long list of Estate averages will be given in an early issue; but meantime we may quote a few of the more prominent as follows:—

200,000 to 500,000 lb.

(The three highest averages.)

		Av. price per lb.	
		1896.	1895.
St. Leonard's	H. H. .. 331,500	1s 2d	1s 1d
Campion	H. .. 280,500	1s 0 ¹ / ₄ d	1s 0 ¹ / ₄ d
Henfold	H. .. 231,500	1s 0	1s 0 ¹ / ₄ d
		100,000 to 200,000 lb.	
Silver Kaudy	H. H. .. 101,000	1s 2d	1s 1d
Goatfell	H. .. 173,500	1s 0 ¹ / ₄ d	1s 0 ¹ / ₄ d
Holmwood	H. .. 140,500	1s 0 ¹ / ₄ d	1s 1d
		50,000 to 100,000 lb.	
Bramley	H. .. 73,500	1s 0	10 ¹ / ₄ d
Carlabeck	H. .. 87,000	11 ³ / ₄ d	1s 0 ³ / ₄ d
Tillicoultry	H. .. 95,500	11 ¹ / ₄ d	10 ¹ / ₂ d
Pita Ratmalie	H. .. 96,500	11 ¹ / ₄ d	10 ¹ / ₄ d

	About lb. 20,000 to 50,000 lb.	Av. price per lb.	
		1896.	1895.
Park	H. H. .. 37,000	1s 2½d	
Excelsior	H. H. .. 23,500	1s 1d	
St. John's	H. .. 31,000	1s 1½d	8½d
Ormidale	H. .. 36,500	1s 0¼d	1s 1½d

Altogether the tone adopted in the London Tea reports is encouraging, at any rate for the immediate future, and it is quite clear that we cannot do better than to go on trying to conquer America and Russia for our teas.

COOLIES FROM NORTHERN INDIA.

LET not "Truth" (whose letter appears elsewhere) begin to crow until he has got his Bengali coolies and found them suitable for his work. "The proof of the pudding is in the eating thereof." Now, we know for a fact that every cooly entering Assam costs the planter R100 a head (irrecoverable) before a stroke of work is done. It will be strange if Ceylon can get coolies from the same region more cheaply.

But we have had an experience put before us gained by a Ceylon planter nearer home in India, which must be commended to the notice of "Truth." A Matale planter applied to a Madras Cooly and Planters' Agency whose advertisement declared their ability to supply coolies at a fixed rate per head. On 21st December last he got an answer that "advances and travelling expenses would amount to R11 per head, which must be remitted with order" besides the firm's commission of R10 per head. On 7th January R420 was remitted for 20 coolies. We have seen correspondence up to 3rd March in which various excuses are given; but we have not heard that the Matale planter up to this date has got either his coolies, or his money back. *Verb. sap.*

MATURATA :

SIR HENRY WARD AS A "V. A."

Recurring once again to the subject of the district that the Governor is about to honour with a visit, we may say that amongst the older planting divisions of the island Maturata has never seemed to us to quite take the position to which it is justly entitled. Looking at the richness of its soil and almost unequalled healthfulness of its breezy climate, one would have supposed that long ere now it would have been in the forefront of popularity. We have known Maturata intimately ever since the reign of the "Roses" on the one side and "Tip Thompson" on the other. Since the days of Robertson on Allecolleweve to the time when the old store echoed the melodious notes of "G.M.B." Ellanulla, with its rich dark loam of unknown depth, is by no means easy of access but once the hospitable bungalow is reached, who could desire a more delightful highland home? On Mandara Nuwara poor Middleton found life was not worth living; yet "W.W.W." could cheerfully hunt the elk by day and dine luxuriously in full dress togs at night. A breezy but rather rough and rugged planting school is Mandara Nuwara, hugging close to the foot of Pedro for shelter; yet we know that Boreas blows there in fitful and unexpected gusts. Albeit, that land of mountain and cloud has turned out some notable men in its day. Here, that favourite son of fortune, "H.J.V." began his planting career; here also,

the astute Arnold White, fresh from Leadenhall Street, first learned which end of a coffee stump had to be inserted in the soil.

In 1857 that Prince of V.A.'s, Sir Henry Ward, visited the district and wrote his model report:—

"The Ford, below the Fort, inconvenient at all times, is dangerous, if not impassable, during many months of the year; while the District is rising, every day, in importance from the number of Estates already opened, and the excellence of a large belt of unsold Land, running parallel with Mr. Robertson's Coffee Plantation, the superior quality of which is admitted by the best judges. I know no part of the Island, in which the two great branches of Ceylon agriculture may be seen in such close juxtaposition, as at Maturata. The Valley, extended by artificial Terraces up every Ravine, down which water can be made to pass, on its way to the River below, presents a vast expanse of green, reaching to the very crest of the surrounding hills; while, wherever Paddy Cultivation ceases, Coffee cultivation begins. In the immediate vicinity of the villages, there are gardens, in which Onions, and Potatoes, grow luxuriantly; and I had the satisfaction of hearing the Planters bear uniform testimony to the conduct of their Kaudian neighbours, who appear to be a peaceable, thriving, and industrious Race, where not contaminated by Low Country Singhalese—the outcasts, generally, of their native Districts,—or forced into brawls by Coolies belonging to the Estates. I was much struck, myself, by their manner, and appearance;—the wonderful ingenuity, with which they have turned the smallest, supply of water to account;—their ready appreciation of the advantages, which the District will derive from the opening out of the Country;—and with the justice, and simplicity, of their views, under the novel circumstances in which they are placed.

"For Maturata, instead of being one of the most secluded spots in the Island, is rapidly becoming the centre of an important District. The transfer of the Court from Newera Ellia to the Fort, where I have authorised the erection of a Small Court house, and Bungalow,—the prospect of a Bandy Road to Kandy, which must be steadily kept in view,—the establishment of a Post Office, and a Police Station,—the Bazaar, which is growing up, on the site of the old fortifications;—the opening, consecutively, of twelve new Estates, with every appearance of adding largely to that number, so soon as the Surveyor General is enabled to bring fresh Land into the Market;—and the progress already made in tracing the Road into Ouwah, by the Elephant Plains, which will make this the shortest Route to Kandy for the Coffee from the Badulla, and Oode-Pusilawa, Estates,—all these are circumstances, that must materially influence the prospects of Maturata, and ensure its rapid progress in cultivation, and wealth.

"No greater mistake can be committed, than to suppose that, in facilitating this progress, the Government is consulting private, not public, interests. Public prosperity is but the result of the aggregate prosperity of all the great interests, that compose Society. "The Planter does his part, by turning the jungle into cultivated land, and connecting his clearing with the Main Road of the District, to which it belongs. But that Main Road is a Public Road;—at least, it becomes so, from the moment that the District contributes its quota to the Commercial movement, from which so large a portion of the Revenue is derived. It may be difficult to define the precise limits of public and private, responsibility. Men, who want help from the Government must be ready to do their part in the work proposed. But the Government should also be liberal in its aid; for nothing can be clearer than the fact, that, in Districts like Maturata, there are large Government Interests, as well as Native, and Planting, interests at stake.

"The Crown has still a considerable amount of Land to sell. That Land will not be bought unless

a fair supply of labour can be secured;—and it is well ascertained that Coolies will not engage themselves upon Estates, where they are obliged to carry Coffee, from any distance to Kandy, and to bring back the Rice for their own consumption.

"To sell therefore, we must improve. Roads and Bridges, are as necessary as Surveys, to the profitable, disposal of Land. And my conviction is, that for many years to come, in the present position of Ceylon, the most certain mode of increasing the Revenue of the Island, is a judicious liberality in the use of the means, which it has. The Customs are the gauge of what is practicable, and what is right. So long as their increase corresponds with increasing expenditure, the Government is paid, indirectly for every shilling it lays out.

"With these views, I have urged upon the Surveyor General the immediate extension of his operations in the Maturatta District, with a view of dividing the Land in the vicinity of the Fort, into small building lots, and of bringing into the market, as soon as possible, some of the more valuable portion of the Coffee Land above it. I have also made a small grant of £80. for improving the communications with Newera Ellia, from whence the Estates draw many of their supplies; and, so soon as the Road from the Maha Oya is brought down to the Bridge over the Bilhool Oya, I shall propose to substitute an Iron Lattice Bridge, should those now on their way out to the Colony, be found to answer, for the small, and inconvenient structure, which though repaired by the Provincial Committee, was originally due to the liberality of the Father of the present Koralle of Wellegiriya, aided by a Kandian Priest."

Conscientious yet considerate, grand old Sir Harry never passed through a district without indicating the exact truth regarding its condition, possibilities and requirements. Mark how delicately he could touch upon the weak spots, as in the case of Rakwana where, he said, the coffee was "somewhat poor and thin." Here he had nothing but well-chosen words of praise, encouragement and practical sympathy. Well might the gentlemen, who in the present day inspect estates and quarterly repeat what must often be prosy platitudes, take a leaf out of Sir Harry's book, when their reports would at least, be more lively and prove more interesting reading.

The needs of the district are still the same and even more urgent than they were forty years ago; but with the development of tea, the claims of such a locality cannot much longer be overlooked. A light railway from Peradeniya through Nilambe, Deltota to Hewaheta seems feasible enough, *malgre* the Tramways Commission; and we trust the matter will not be allowed to sleep till this otherwise favoured district gets due facilities for sending its rich returns to market.

DR. ROBERT HOGG, who died on the 14th ult. at the age of seventy-nine, was one of the foremost men in horticultural circles. Originally a partner in a large nursery, now forming the site upon which the Imperial Institute, the South Kensington Museum, and other buildings are placed, Hogg for many years conducted, either alone or in connexion with the late Mr. G. W. Johnson, a journal known as the *Cottage Gardener*, which gradually evolved into the *Journal of Horticulture*. But probably his greatest claim to the appreciation of his colleagues and of those who are to come after him was the production of the "Fruit Manual," a standard work of original research in the shape of a descriptive enumeration of fruits cultivated in this country, which has gone through several editions, and is as well known to fruit growers on the continent as it is here.—*London Athenæum*.

CROPS IN JAMAICA.

The annual report on Jamaica, which the Colonial Office has just published, shows that the colony is, upon the whole, prosperous. The revenue during the financial year was £646,103 and the expenditure £626,934. There was an increase of £22,078 in revenue, mainly from increased imports. The public debt is £1,666,177, chiefly incurred in public works, especially railways, canals, and roads. It is stated that there is a growing desire to improve the quality as well as increase the quantity of the crops. The rate of increase in other products is greater than the decrease on sugar, and for this fruit is mainly accountable. The decline in the cultivation of sugar cane is persistent; the increase in coffee, ginger, cocoa, and tobacco has been great; and in bananas very much greater. Sugar last year was only 11 per cent of the total exports. The value of the imports last year was £2,288,946, against £2,191,745 the previous year, while the exports amounted to £1,873,105. About half the imports go from the United Kingdom, the United States coming closely behind. The trade with the latter is increasing rapidly, and American goods of many kinds are said to be supplanting English ones, partly due to greater enterprise of American manufacturers, but mainly to the greater facilities for trade with the United States. The population of the island is estimated at 690,667.—*London Times*.

MACHINE-MADE TEA.

GOOD NEWS FROM AMERICA FOR CEYLON.

During a recent trip to Cincinnati, O., covering ten days, the writer was surprised to find that wherever tea was served it proved to be Ceylon or India tea, a fact indicative of the phenomenal progress made in their introduction. When consideration is given to the fact that China monopolized the tea markets of the United States for over 100 years and that Japan contributed over 40 per cent of the supply since 1875, then we realize the tremendous prejudice which the advocates of machine-made tea have to overcome, and are the better prepared to estimate and appreciate the rapid hold gained for machine-made tea in this country within two years. In 1894 the imports were 4,700,000 pounds, in 1896, 9,570,000 pounds—a gain of over 100 per cent.

No one can successfully deny that the bulk of the importations of China and Japan tea have been of medium and low grade, with a large volume of trash. The law just passed regulating importations of tea will check the imports of poor and trashy tea, and bring the attention of consumers more and more to a consideration of the merits of Ceylon and India tea.

It has been difficult to impress upon consumers that a much less quantity of machine-made tea is required to make a satisfactory infusion than of China and Japan sorts, but this lesson they are acquiring rapidly, and thus discovering the economical advantages arising from the use of Ceylon and India growths, besides becoming wedded to their flavour. None are more enthusiastic advocates of British-grown tea than many who a few years ago discredited them in many ways.

A few days ago an importer, in commenting upon the remarkable increase in direct shipments of tea from Ceylon to America—viz., 64,966 pounds from January 1st to 26th of this year, against 10,415 pounds for the same time in 1895—said: "That is nothing to what it will be a few years hence, when they will have this market."

We do not, however, entertain the idea that the teas of China and Japan will be entirely displaced, but we do believe that the enterprise, push, pluck and perseverance of the Ceylon and India tea-growers in seeking a market here will result in such an increase in the use of tea as a beverage that machine-made teas will dispute for first place

with China. This is however, a very much more conservative view than many American dealers entertain.—*American Grocer*, March 10.

SUNNYGAMA (CEYLON) TEA ESTATES CO., LD.

The following is from the report to be submitted to the shareholders at the fourth ordinary general meeting, to be held at the company's offices, No. 138, Leadenhall Street, E.C., on Monday next:—

The directors beg to submit the annual statement of accounts for the year ending December 31st last.

CROP.—This again shows a substantial increase over that of last year, while the price obtained also shows some improvement. Advices from the estates are of a very satisfactory nature, showing that every care is being paid to the culture of the existing gardens, while the extensions of the past three years are reported as most successful. The cost of these latter is being defrayed from the capital raised by the late issue of £5,000 in Preference shares, but as this amount is being rapidly expended it is proposed to issue a further portion of the £20,000 of these shares authorised to be issued, to develop the large area of freehold land still cultivated belonging to the company; of this due notice will be given to the shareholders. The higher rate for exchange ruling during the year has, it may be mentioned, added about $\frac{1}{4}$ d per lb. of tea to the cost of production, and to this extent contracted the profits. Mr. R. B. Magor, one of your directors, retires by rotation, and, being eligible, offers himself for re-election.—*H. and C. Mail*, March, 26.

THE COMING RUBBER BOOM.

Nothing seems more certain than that the great rubber industry will be partially paralysed through exhaustion of present sources of supplies, and that the fortunate owners of rubber plantations, be they few or many, will reap huge fortunes. It is this certainty, proved by the rubber statistics, which is at the bottom of the great efforts now being made to obtain plantations in Mexico and elsewhere, but chiefly in the former country. Mexico is the home of the *Castilloa elastica*, acknowledged to be the best of the rubber-yielding trees from the planter's point of view. *Hevea brasiliensis* gives the most valuable rubber—Para—now worth 3s. 7d. per lb., while that from the *Castilloa* only realises 2s. 4d. But the difference in value is greatly owing to the better methods of preparation which obtain in Brazil. When the *Castilloa* milk has been taken in hand by a skilful British chemist, as it shortly will be, we shall, without doubt, see a marked improvement, and the price will be levelled up to within measurable distance of that of "fine" Para. The prospects of the rubber planter in Mexico, even at present values, are more rosy than those of any other arboricultural industry. And this applies, more or less, to every country in which the *Castilloa elastica* will thrive. A profit of 300 per cent. in the eighth year is what the experts are promising, and the figures are based in one instance on a selling price of 1s. per pound for the rubber, and in another on 2s., the first being less than half the market value of *Castilloa* rubber in London to-day, and the second $\frac{1}{4}$ d. below it. That rubber can be grown cheaper than it can be purchased from the native collectors is an absolute fact, and it is obvious that the quality must be far superior to any wild product, except, perhaps, Para, the method of preparing which does not seem capable of improvement. For joint-stock enterprise the cultivation of rubber trees in Mexico offers a fine field, as there is no substitute for rubber worthy of the name, and small probability of there ever being one. At present adulteration is rife, greatly to the detriment of the trade. We hear of powdered flint and cement being used to eke out the supply, and the demand for old worn-out rubber goods is very great. The only apparent remedy for this disastrous state of things is cultivation on an enormous scale.—*The Colonies and India* Mar. 20;

VARIOUS PLANTING NOTES.

COOLY DISTRICTS OF NORTHERN MADRAS.—It is rumoured—and we are very pleased to think correctly—that His Excellency the Governor has decided to send Mr. Ingramcotton on a visit to Bellary, Cudappah and the other cooly districts in North-Eastern Madras where distress if not famine is said to prevail, in order to enquire and report on the feasibility of drawing a supply of cooly labourers therefrom for Ceylon estates.

PLUCKING, PRUNING, AND PREPARATION OF TEA.—The *Indian Tea Planters Gazette* devotes the editorial in its issue of 10th April to this subject beginning as follows:—"The Editor of the *Ceylon Observer* has, we consider, conferred an undoubted benefit on the tea industry, not only in Ceylon, but throughout India generally, in issuing the sets of questions contained in the two circulars which he distributed to the planters throughout the island. The answers which have been received to the second set of questions are so instructive to all interested in tea, that we decided to reproduce them in our column, and we feel sure our tea-planter friends will appreciate the results of the efforts of our contemporary. The object of the enquiries was to elicit information, which would be helpful to planters in their endeavours, while securing from their estates the highest possible yield without injury to the bush, to maintain a high level of excellence for the tea they produce—in other words, to obtain the best possible prices." Our letters in answer to the circular are by no means all published, though pressure through an usual number of meetings and the holidays have recently delayed publication.

THE DESTRUCTION OF CEDARS.—The news that comes to us from various parts of the destruction of fine cedars like those at Goodwood should more than ever teach the need of yearly planting in parks. At one certain time some tree lover on a large estate plants a noble lot of cedars, but, as those who follow fail to keep up the stock, a great storm may some day destroy what all are so proud of. This could not happen to anything like the same extent if people went on planting young trees, not necessarily many kinds, but some like the cedar of Lebanon, that happen to do well in our climate, and have all the beauty and dignity that trees can have. The many catalogues issued help towards the neglect of the really precious trees by "bringing out" novelties from all parts of the world—absolutely unproved trees; whilst the planting of such grand trees as the cedar of Lebanon and the ilex of Europe are often forgotten. A mistake in cedar planting is the fashion of planting isolated trees with great branches growing out on all sides. Just think of the enormous surface exposed to strong wind that these great trees and branches offer! In their own country, where cedars are naturally massed together, although the gales are severe, the trees are not destroyed by wind in anything like the same degree. The cedar of Lebanon is certainly very beautiful by itself in this "specimen" way, but we think it at least equally beautiful massed in groups or even in woods. We have seen excellent results from planting cedars in mixed woods, where they make straighter boles. In their own countries, in addition to being massed and grouped together, the soil is very often stony and rocky, the growth is slower, and the trees take a firmer hold, whereas in our rich river valleys, where the Lebanon cedar is often planted in an isolated way, the growth is softer, and the resistance to wind less. We feel sure that a more artistic and natural way of planting would lessen the accidents to which this noble tree is exposed.—*The Field*,

THE HARBOUR OF COLOMBO, CEYLON; AND A PROPOSED RAILWAY TO CONNECT SOUTHERN INDIA WITH COLOMBO.

(Special Report for the "Ceylon Observer.")

On Tuesday, March 23, in the hall of the London Chamber of Commerce, Botolph House, Eastcheap, London, Mr. Donald Ferguson read a paper by Mr. JOHN FERGUSON on "THE HARBOUR OF COLOMBO, CEYLON, AND A PROPOSED RAILWAY TO CONNECT SOUTHERN INDIA WITH COLOMBO."

SIR ALBERT K. ROLLITT, M.P.*

had to leave the chair soon after the opening of the meeting to attend to his Parliamentary duties, and his place in the chair was taken by Mr. Thomas Christy.† There were also present:—Sir Charles Lawson, Mr. Henry Kimber, M.P., Mr. S. B. Boulton (vice-president of the Chamber of Commerce), Aldn. Haddon, J.P., Capt. G. Green, Dr. George Colborne, Messrs. W. R. White, W. Martin Smith, R. Paulusz, F.C.S., H. W. Cave, W. Martin Leake, S. J. Wilson, J. Hamilton, John Haddon, J. Davis Allen, J. B. Meredith, J. Fernando, F. J. Waring, C.M.G., J. Macarthur, J. L. Shand, A. B. Struthers, George W. Johnson (Colonial Office), Kenrie B. Murray (Secretary of the Chamber of Commerce), F. H. M. Corbet, John Kyle, J. Macintosh Smith, Zimmer, F. E. Mackwood, Peck, the Secretary of the Ceylon Tea and Timber Syndicate, Ltd., McEwan, Donald Andrew, E. Hewell, H. Flindt, Robert White, L. Clerc, Montrose, C. Ralston-White, G. L. Stenning, H. L. Forb's, G. W. Christison, H. T. Gardiner, A. M. Ferguson, T. E. B. Skinner (late Postmaster-General, Ceylon), R. H. Ferguson, Bagshaw, C. Thynne, Y. B. Howard, George D. Jennings, Alfred Beeston, Alex. Ross, A. L. Hutchison, J. C. Roberts, &c., &c.

* Rollitt, Sir Albert Kaye, (Islington, South div.) s. o. Mr. John Rollitt, of Hull, solicitor, by Eliza, d. o. Mr. Joseph Kaye, of Huddersfield, architect. B. a Hull, 1842; educated at King's College, and the University of London, of which he is a Fellow and Member of the Senate (B.A. 1st class honour 1863, LL.B. 1st class honours Principles of Legislation, &c., 1864 LL.D. first and University gold medallist 1866); D.C.L. Durham 1891; m. 1872, Eleanor Anne, 2nd d. of the late William Bailey, J.P., of Winstead Hall, Holderness, steamship owner at Hull, London, &c. (she died 1885). A solicitor in Mark Lane and at Hull, a prizeman of the Incorporated Law Society 1863. Is also a ship-owner at Hull, Newcastle, and London. Was sheriff of Hull 1875-6, and mayor 1883-4-5; Hon. Freeman of Hull; Elder Brother Trinity House, Hull; President of the Associated Chambers of Commerce, U.K.; chairman of the London Chamber of Commerce; president Hall Chamber of Commerce; president Municipal Corporation Association; F.R.A.S.; F.Z.S., member of the Committee of the British Association; Lieut.-Col. Engineer Militia (Humber div. Sub-marine Miners). Is J. P. co. of London, and D. L. London and Yorks. He was knighted in 1885. A "progressive and independent Conservative," and "through unionist," in favour of wide local government for Ireland.—30, Lowndes-square, S.W.; Dunster House, Mark-lane E.C.; Carlton, Constitutional, Savage, Ranelagh, and City Carlton Clubs; Cogan House, Hull; Cottingham, E. Yorkshire.—"Dod."

† Mr. Christy is a fellow of the Linnean Society, and very specially interested in the development of new tropical products and lands.

The Paper (read by Mr. D. FERGUSON) was to the following effect:—

"THE HARBOUR OF COLOMBO, CEYLON; AND A PROPOSED RAILWAY TO CONNECT SOUTHERN INDIA WITH COLOMBO."*

Paper by J. FERGUSON, Editor of the "Ceylon Observer" and "Tropical Agriculturist."

INTRODUCTION.

THE island of Ceylon is usually described as the first and most important of British Crown Colonies. It has an area of close on 25,000 square miles, and a population of over 3 millions. But two-thirds of the population are found in the South-west portion of the island; while extensive districts in the North-Central and Northern divisions have scarcely more than a few units to the square mile, although in ancient historical times these were the most populous and prosperous parts of the island. The ruins of the ancient capitals Anuradhapura and Polonnaruwa, show to what a pitch of prosperity the Sinhalese Buddhist kingdom before and after the Christian era had attained. This position the Sinhalese lost through the constant incursions of Tamils—alien in race and religion—from Southern India until—the bunds of their irrigation tanks cut, their towns devastated and destroyed,—the Sinhalese were forced back into the South and West of the island, and what were cultivated rice fields have, for many hundreds of years, been covered with heavy jungle.

The great Planting industry of Ceylon in tea, cacao, coffee, rubber, &c., is chiefly confined to the 4,000 square miles of mountain zone in the Central, South and adjacent lowcountry districts to the South and West. The natives cultivate cinnamon on the West coast, and coconut and other palms all round the coast, save for intervals on the North-West and North-East.

Apart from the ancient ruined cities, and the better-known central capital of Kandy, the island has long had three well-known towns or ports. The grand natural harbour of Trincomalee on the North-East coast may be counted among the half-dozen finest harbours in the world, and its possession for the Naval Headquarters in the East Indies, was a chief reason why, on the General Peace in 1815, England decided to give Holland the much richer and larger island of Java in exchange for Ceylon, which was then regarded, with Trincomalee, as very much the key to India. Then Point-de-Galle sprang rapidly into notice on the South of the island, as the Mail-steamer Port; while the Political and Commercial Capital was found in Colombo surrounded by country highly cultivated and a dense population, while Trincomalee had neither population nor cultivators to speak of in its neighbourhood.

Ceylon has always been closely associated with India, one of its ancient names describing it as "a pearl-drop on the brow of India"; while its people, the Sinhalese, originally came from the North of India; and the Tamils now settled in the North and East of the island are the same people as occupy all the Southern divisions of the Madras Presidency.

I will only say further, by way of introduction, that the construction of a first-class railway from Colombo to Kandy and its extension afterwards through the chief planting districts as well as another line South to Galle and Matara, consolidated the overshadowing importance to the island of Colombo as almost its sole export and import shipping port.

ADAM'S REEF AND ISLANDS.

As regards its geographical connection with India, I would point out that while the populous peninsula of Jaffna on the extreme North of the island

* This paper is printed from the writer's first draft, and may, in some respects, differ a little from the finished copy read before, and to be published by the London Chamber of Commerce.—E.D. T.A.

is separated from India by the generally shallow Palk's Strait or Bay,—on the North west, the connection by means of detached islands and coral reefs is a much closer one with Indian territory. It begins at Mannar, an island separated by a narrow channel from the mainland—and South of which, I may mention, the famous Pearl Oyster Fisheries of Ceylon have taken place from time immemorial, and as we all hope, will one day soon be resumed. The island of Mannar is $17\frac{1}{2}$ miles long, and after it we come on the series of coral reefs, sand-banks and tiny islands (numbering some 20 in all) known as "Adam's Bridge"—from the superstition (following a much older Hindu one in favour of a king of the monkeys) that here our first parents crossed when sent from the Garden of Eden to reside in Ceylon, Adam's Peak mountain being deemed further evidence—an old Muhammadan tradition which led to Arabi and his fellow Egyptian exiles being at first very much gratified when they learned that Ceylon was to be their place of banishment.

This Adam's Bridge extends a distance of 22 miles between the Ceylon island of Mannar and the island of Rameswaram, which appertains to India, and of this distance, half may be said to be spanned by tiny islands, while half is under water.

The island of Rameswaram itself is like that of Mannar about 17 miles long, and is chiefly notable for a famous Hindu temple, one of the four or five most noted shrines in all India for pilgrimages; although the pilgrims having to cross water and other discomforts in travelling at present, no doubt prevents Rameswaram being visited by more than a tithe of the devotees who crowd to more accessible shrines.

North of Rameswaram there is only the narrow Pamban Channel, with a navigable width of 80 to 130 feet, separating the island from the mainland of India. Altogether the distance between the two mainlands is about 57 miles, 35 of these being occupied by the two islands and adjacent channels, and 22 by Adam's Reef or Bridge.

THE CENTRAL POSITION OF CEYLON, AND OF THE PORT OF COLOMBO.

I would now refer briefly to the very central position of Ceylon as to Southern Asia and Australasia and as between Africa, the Eastern Archipelago and the Far East. The port of Colombo, it will be observed from the map of Asia, is perhaps the most central and convenient in the Indian Ocean and the opening of the Suez Canal at once gave it a special importance in reference to Madras, Calcutta, Rangoon, the Straits and China as well as to Australian Ports.

I should like to mention one or two striking facts as to its immunity from storms and the favoured position of the island altogether (almost inclining one to think favourably of its claim to be allied with Eden!). They are as follows (quoted from Ferguson's "Ceylon in 1893") :—

"The situation of Ceylon in the Eastern World is peculiarly favoured in certain respects. The atmospheric disturbances which periodically agitate the Bay of Bengal, and carry, in hurricanes and cyclones, destruction to the shipping in the exposed Madras roadstead and the devoted Hooghly, seldom or never approach the north-eastern shores of this island. If Java and the rest of the Eastern Archipelago boast of a far richer soil than is to be found in Ceylon, it is owing to the volcanic agency which makes itself known at frequent intervals by eruptions and earthquakes, the utmost verge of whose waves just touches the eastern coast of the island at Batticaloa and Trincomalee in scarcely perceptible undulations. On the west, again, Ceylon is equally beyond the region of the hurricanes which, extending from the Mozambique Channel, visit so often and so disastrously the coasts of Madagascar, Mauritius, and Zanzibar. The wind and rain-storms which usher in periodically the south-west and north-east monsoons, sometimes inflict slight damage on the coffee and rice crops, but

there is no comparison between the risks attaching to cultivation in Ceylon and those experienced by planters in Java and Mauritius."

The wind and rain storms which usher in the annual South-west and North-east monsoons have scarcely ever attained a dangerous force; and although they make it difficult sometimes to reach the harbours of Galle and Trincomalee, no such difficulty is experienced in reference to Colombo. It is no wonder, therefore, that after prolonged enquiry, surveys and reports as to the respective merits of Colombo and Galle, Sir Hercules Robinson (now Lord Rosemead) when Governor of Ceylon, on the final recommendation by the late Sir John Coode, decided that public money should be spent in giving Colombo (rather than Galle,) adequate protection and harbour accommodation for Mail as well as Commercial steamers and eventually as was hoped for the Navy as well.

The convenience of Colombo to the Imperial Government has been often proved for military purposes: troops thence have been readily transported to China and Labuan; during the Mutiny, Governor Sir Henry Ward sent nearly every British soldier in the island to aid Lord Canning; in 1863, the troop-ship "Himalaya" took the 50th Regiment on board at Colombo to suppress the Maori War in New Zealand; in 1879, the 57th Regiment was despatched at short notice to South Africa, followed by the 102nd transferred in the same way; in 1881 and later on the regiment stationed in Ceylon was utilized for Egypt. For wellnigh 50 years there has been no disturbance in the island calling for military attention: the Sinhalese are the most peaceable and loyal of British subjects.

Next let me mention that the port of Colombo is 900 miles from Bombay, 600 from Madras, 1,400 from Calcutta, 1,200 from Rangoon, 1,600 from Singapore, 2,500 from Mauritius, 4,000 from Natal, 2,200 from Aden and 3,000 from Fremantle, Western Australia. On the Malabar Coast of India, there is not a single harbour or port worthy of the name between Colombo and Bombay and the same is almost true on the Coromandel Coast up to the Hooghly, Madras being scarcely an exception.

COLOMBO HARBOUR WORKS.

On the 8th December 1875, the foundation stone of the first and principal Breakwater for the protection of Colombo Harbour was auspiciously laid by H. R. H. the Prince of Wales—then on his visit to India and Ceylon—Sir W. H. Gregory being Governor of the island. Sir John Coode planned and directed the work; Mr. John Kyle, M.I.C.E., (now of the new Dover Harbour Works) being Executive Engineer. In October 1876 when the Breakwater had been extended 350 ft. Colombo was visited by the late Duke of Buckingham, then Governor of Madras, and His Grace took a special interest in Sir John Coode's thoroughly solid, satisfactory work as contrasted with the cheap and unsubstantial harbour works constructed at Madras which had shortly before succumbed in a cyclonic storm, falling to pieces like a pack of cards. Looking at the spacious first-class harbour designed for Colombo, its central and commanding position and the absence of any good harbour in the Madras Presidency, the Duke of Buckingham declared that as the natural complement for its Harbour Works, Colombo ought to be connected with Southern India by a railway across Adam's Bridge. Governor Gregory favoured the scheme; but with the responsibility of the Harbour Works, and Railway Extensions in the Centre and South of the island, he could do nothing with the suggestion, nor could his successors for some 17 years. By the end of 1884, the South-west Breakwater, 4,150 feet long with a lighthouse at its terminus, was completed at a total cost—including foreshore reclamation and other allied work—of £705,000. This at once afforded full protection to Colombo Harbour for nine months out of twelve in the year, at any rate so far as allowing 24 boats for first-class ocean-going steamers to be fixed under lee of the breakwater. Sir John Coode felt all along that

his work would not be complete without another protecting arm for the harbour; and after his lamented death the design for this addition being entrusted to his firm (Messrs. Coode, Son & Matthews), Mr. Matthews visited Colombo, and as the result of his inquiry and inspection, the designs and estimates for two additional protecting arms—a Northern and North-Western breakwater—were sanctioned and these and a lied works (as shown in the plan on the wall) are now under construction, Mr. J. H. Bostock being the Resident Engineer. These arms are to be 1,000 feet and 2,670 feet in length respectively, are to cost £527,000 and to be finished by 1901 A.D.

The foreshore all round the harbour is to be reclaimed and suitable coal depôts are to be established for the mail as well as commercial and naval vessels, leaving plenty of room (much required at present) for the import and export trade of the port, for passengers' jetties and other requirements of a first-class harbour. When these arms are completed, the Colombo Harbour will have two openings each 800 feet wide; and the area enclosed will be 660 acres, affording accommodation for quite a fleet of vessels of all sizes and grades, it being noted that the tendency of these days is for steamers to remain in port as short a time unloading, coaling and loading, as possible,—quick despatch being the test of a port's convenience and good management.

The total cost of these Harbour Works £1,250,000 has been guaranteed by the Colony, the steadily increasing income from port dues, pilotage, rent, etc., fully justifying the outlay. There are now few busier ports, than that of Colombo, and not being properly a terminal port, it is fittingly called the Clapham junction of mail steamers and passengers for the East and far South. It is the great meeting-place for the steamers of the Peninsular and Oriental Company, of the Orient S.N. Company, of the Messageries Maritimes, of the Norddeutscher Lloyd's—all running to Australia and China as well as India; also of the British India S.N. Company with its complete Indian Coasting as well as Queensland Service; of Bibby's Liverpool, Marseilles and Rangoon line; of the Clan, City, Ducal, Ocean, and a great variety besides of British as well as foreign Steamer Companies. Every national flag is from time to time, displayed in the harbour, as many as 15 to 20 large ocean-going steamers occasionally arriving in one day. The aggregate inwards and outwards tonnage for Colombo now approximates to 6 million tons per annum.

One great advantage of Colombo harbour is the ease and safety of approach at nearly all seasons during night or day. The Colombo lighthouse stands 120 feet above sea level and the light is visible 18 miles off at sea. Harbour lights will mark the ends of the Breakwater arms and openings nearly 13 miles off. The average rise and fall of the tide is only about 18 inches.

GRAVING DOCK.

It was felt all along that without a Graving Dock, Colombo Harbour Works could never be considered complete, and after full consideration and negotiations between the Admiralty, the Colonial Office, the Treasury and the Government of Ceylon, it has just been decided (a few weeks ago) that a first-class Dock of the largest size be constructed at Colombo on a design by Messrs. Coode, Son and Matthews, 600 feet long by 62 to 85 ft. broad, 23 feet deep equal to taking in the largest ironclad afloat, at a cost of £318,000—half of which is to be provided by the Colony and half by the Imperial Treasury. The work is to be done by 1901 A.D. Colombo will then possess both the largest Artificial Harbour and Graving Dock in the world.

IMPERIAL IMPORTANCE OF COLOMBO.

After this, it is needless to dwell on the Imperial importance of this central port with its safe harbour and stores of coal—nearly 350,000 tons imported annually, at the most commanding point in the Indian Ocean. Modern batteries and guns for its defence have been already provided and it is anticipated, that, when the Dock is constructed, the East Indian Naval

Headquarters will be transferred from Trincomalee to Colombo. Thirty thousand passengers to or from all parts of the Eastern and Austral world pass through Colombo each year, and as to the local trade, the Ceylon Exports and Imports are now valued at £10 million sterling per annum, the former including 100 to 120 million lb. of tea, mainly shipped to London for consumption in the United Kingdom. Colombo has a population of 130,000 altogether spread over 11 square miles; it is one of the most beautiful and healthy of tropical towns, a good water supply being brought from a hilly district, 30 miles distant, into the City; while Mr. Mansergh, C.E., is engaged in designing improved Drainage and other Sanitary requirements. As to Railways, Ceylon has now 300 miles of first-class 5½-foot broad gauge line, the Northern terminus being Karmunegala, from whence a section of 71 miles is projected to the ancient capital, Anuradhapura; while between it and Jaffna a feeder line on 2½-foot gauge is recommended.

CONNECTION BETWEEN SOUTHERN INDIA AND CEYLON.

Turning now to Southern India, I may point out that there is a very close connection in trade and community of interests between the island and the mainland. Indeed, the great planting enterprise of Ceylon depends to a very large extent for its very existence on the free immigration of Tamil coolies from Southern India. These come over to the number of 120,000 every year, about 80,000 to 90,000 returning, and as many as from 300,000 to 400,000 of them altogether are employed in the island. This is besides a large number of traders, artificers, domestic servants, etc., coming to Colombo. These Indian coolies are all constantly coming and going—returning home to see relatives and invest their little savings. They often arrive a weak sickly people and with the good food and fine climate on the plantations often become a sturdy, sleek, happy class. Their favourite route used to be crossing at Pamban and by boats to Mannar and then walking down the long road to Matale; but of late years a daily steamer service between Tuticorin—by no means a convenient port—and Colombo, has tempted the larger number by that route, although they heartily dislike the sea.

Next a great quantity of rice is imported from Southern India—Ceylon not growing half enough to feed its town and immigrant population. There is also a large supply of other food products, live-stock, poultry, &c., from Southern India to Ceylon; and a certain quantity of raw material such as cotton. From Ceylon there is a large export to India, of areka (betel) nuts, copperah, coconut oil, &c.

COLOMBO AND AN INDO-CEYLON RAILWAY.

Travancore, a flourishing planting division in Southern India, may be considered an offshoot from Ceylon, its first planters having been trained in the island, and the natural market for its tea, &c., is Colombo—where there is now regularly established weekly public sales of tea. To all Anglo-Indians in the Madras Presidency—whether public officers, planters, missionaries or others—Colombo must become the favourite port; because there, they can get a steamer direct to almost any part of the world, which is not the case at Calcutta or even Bombay, while few steamers now call at Madras. With railway communication established between the Madras Presidency and Colombo, there cannot be a question that the latter would become the port for all the passenger traffic beyond seas; while such a line would carry all the coolies migrating to and fro, whose numbers to Ceylon especially, could not fail to increase very largely. At present, Ceylon planters would be glad of 50,000 to 100,000 more immigrants than they have and the requirements of the island are yearly increasing. Passengers in the shape of pilgrims for Rameswaram Temple, would certainly prove a growing item in the traffic of an Indo-Ceylon line. Colombo has already been made the Mail-port to a large extent for Madras and Rangoon and with a Railway all the foreign mails and passengers and a certain amount of goods for Southern India would pass through Colombo—a great advantage at such a time as this when

the Bombay route is almost barred on account of the Plague.

Then from a Military and Imperial point of view, an Indo-Ceylon Junction Railway could not fail to be of much importance to British troops kept in the comparatively cool healthy barracks at Bangalore, or higher up on the Nilgiris, who could, if required, be carried by rail for shipment at Colombo to any part of the African, Austral, Asiatic, European or American world. The British Infantry Regiment now kept in detachments at different stations (mostly very hot) in Ceylon, might well be dispensed with or kept ready at Bangalore more especially in view of a full local Infantry Volunteer Corps, Volunteer Artillery and Mounted Foot Companies to back the Royal Artillery in charge of the Batteries. For local disturbance of any kind, there is absolutely no need of the British regiment.

Having thus shown the intimate trade and cool relations between—and the great encouragement to connect Ceylon and Southern India by railway, I come to the question of the practical work required and the probable cost of the same.

THE INDO-CEYLON RAILWAY:—GAUGES.

The Standard Railway Gauge of India adopted by Lord Dalhousie is 5½ feet and Ceylon followed suit for its own Railways. But there are 700 miles of Railway on the metre-gauge in Southern India and there is only an extension of 100 miles from the town of Madura (60,000 people) through a populous district to Paniban required to complete the South Indian system. From Paniban there would then be unbroken communication by metre-gauge lines to the town of Madras serving all the Presidency territory between these points and across the Southern districts. In Ceylon there is no metre-gauge; but if the direct route from Mannar along the healthy open West Coast to Colombo* were adopted, there would be no interference with any existing railway in the island and the metre-gauge (served it might be from workshops in Southern-India) would find its own terminus in Colombo and its grand harbour. Such a line after the 100 miles to Paniban, would be 58 miles across the islands and reef to the mainland of Ceylon and about 140 from Manaar *via* Puttalam, Chilaw and Negombo into Colombo.* One great advantage on the Ceylon side of this route is that a profitable local traffic—in passengers especially—would be commanded all the way from Colombo to Chilaw. At present a canal serves a good deal for goods but it is crossed at intervals by rivers and; cost the Government a good deal every year to keep open; while there are complaints about the long delay in the transport of produce, fruit, &c., by canal. Puttalam is the chief seat of the manufacture of salt, used in the island—a Government monopoly. The objections to this route is the number of rivers that require to be crossed, especially between Manaar and Puttalam, so that a diversion inland has been proposed here.* At any rate some such route is the only one available for the metre-gauge and as affording the most direct and healthiest railway route between Southern India and Colombo.

There is another plan, however, for connecting India and Ceylon on the 5½-feet gauge, which has been constructed in Ceylon up to Kurunegala, while the Government favour an extension (through a country bare of people and traffic) to Anuradhapura.† There would then only remain about 60 miles to reach Manaar (via Madawachchi perhaps)—or 131 miles to make from Kurunegala on the 5½ feet line against 148 for the metre by the West

* It has been proposed as an improvement that the line should run from Colombo to Puttalam or Dutch Bay, thence to Anuradhapura and then to Manaar. Several leading Civil Servants with experience of the districts favour this route and there is no special objection to it.—Ed. T.A.

† Moreover a very arid, poor country in which planters see little prospect of successful cultivation.—Ed. T.A.

Coast. One drawback to the inland route, apart from its circuitous nature (making Colombo 119 in place of 148 miles from Manaar) and the unhealthiness (fever and malarial country) of a long expanse of jungle, is found in the fact that the section of the Colombo and Kandj line required to be used from Polgahawela to Colombo (46 miles) is already wellnigh fully occupied with traffic; while an Indian through train service should be direct, free from interruptions, well-equipped and comfortable.

The still greater objection to a broad gauge connection is the long distance on which a broad gauge would have to be laid in India—some 200 miles—before the broad-gauge system was reached at Erode. It has been said that adopting the broad-gauge would connect Ceylon with all India; but this argument is of little value; because it is to serve Southern India up to Madras that Colombo Harbour is adapted; and there can be no inconvenience if uninterrupted railway travelling can be commanded on the metre-gauge between the cities of Colombo and Madras.

Of course, there is the third course of breaking gauge either on the Ceylon or Indian side, the broad being now in Ceylon and the metre in Southern India. Imperial authorities should, in that case, decide on the gauge for the actual crossing between Manaar and Paniban.

SURVEYS, REPORTS AND ESTIMATES

I have now to refer to the Surveys and Reports which have been made by Engineers with reference to an Indo-Ceylon Railway. On behalf of the Ceylon Government, Mr. F. J. Waring C.M.G., Chief Resident Engineer for Railway Extensions, in April 1894, made a "Report upon an inspection of the route for the proposed Indo-Ceylon Railway from Paniban to Taladi near Manaar, and of the alternative routes by which a railway, if made, might be connected with the Ceylon Railway system." Mr. Waring's Report is a full and valuable one. Beginning at the Southernmost point of India, the results he arrived at may be summarized as follows:—

Paniban Channel crossing (including swing bridge 100 ft. wide) to cost ..	R450,000
Rameswaram island (50,000 devotees often at temples) 17½ miles at R55,000 ..	950,000
Adam's Bridge, 22 miles, 19 being islands, bridging between, 18,100 lineal yards of bridging, total cost ..	25,500,000
Manaar island, 17½ miles at R55,000 ..	960,000
Manaar Channel	520,000

Total for crossing from India to Ceylon about 58 miles R28,380,000 or at 1s 3d the rupee = £1,773,750. All on the 5½ feet gauge.

Before going further I may compare this estimate with that of Mr. E. C. SHADBOLT, Engineer-in-Chief, Madura-Paniban and other Railway Surveys, who examined and reported about the same time in April 1895 proceeding on the principle that the through line from Madura to Colombo would be on the metre-gauge; but allowing for a double line in the "crossing" from India to Ceylon. Mr. Shadbolt also allowed for a swing bridge 100 feet wide at Paniban, but he made heavy allowance for one mile of line on reef to reach the bridge. As regards this "crossing" we sum up as follows:—

Paniban reef 1 mile	R1,050,000
„ swing bridge 100 feet	R 300,000
Rameswaram island 20 miles	R1,000,000
Adam's Bridge 21 miles—building a solid line on the breakwater principle 12 feet high, 30 feet wide—in water, average depth 4 ft;—12 miles at R1,500,000;	
on low islands 6 miles at R1,100,000;	
on high islands 3 miles at R100,000 ..	R24,900,000
Manaar island 17 miles at R50,000 ..	R 850,000

Total for crossing bridge to Ceylon [£1,756,000] or R28,100,000

A sum singularly near to Mr. Waring's—considering that the two Engineers adopted differing modes of crossing the reef and estimated for different gauges,

Mr. Waring examined the country from Manaar or rather Taladi *via* Madawachchi and Anuradhapura to Kurunegala, a total of 132 miles which he would probably estimate to cost on light broad-gauge about R7,260,000—making a total of R35,640,000 for the Ceylon portion and the crossing on the broad-gauge; but to this would have to be added if the broad-gauge were adopted on the Indian side 100 miles of new line to Madura and alterations of lines for 38 miles to Dindigul and (in Mr. Shadbolt's opinion*) next 100 miles new broad line to Palghaut—in all an outlay of about R17,000,000—making a total outlay of R52,640,000 (£3,290,000) for 487 miles and making the railway distance between the cities of Madras and Colombo by broad gauge 821 miles.

On the other hand, taking the metre-gauge as running from Madras to Madura, Mr. Shadbolt estimates for 100 miles to Pamban at R4,177,460; the "crossing" as above 58 miles at R28,100,000 and then for 145 miles from Maunur to Colombo, Mr. Shadbolt allowed R100,000 a mile—he not having been over the country, while Mr. Waring (following his assistant Mr. Oliver who surveyed part of the route) put it under R85,000 for a broad gauge. For a metre-gauge therefore, Mr. Shadbolt should find R65,000 per mile sufficient and we get for 149 miles (more accurate than 145) a total of R9,685,000—giving a grand total for 397 miles of R41,962,460 (£2,926,655) and the distance between the cities of Madras and Colombo by metre-gauge 650 miles.

Mr. Waring suggests a shorter route by a new broad gauge line being made between Dindigul and Kundimudi and a mixed rail utilised on each side. The distance from Madras to Colombo would then be about 714 miles. But we do not know how the Madras authorities would favour this proposal; whereas a line to Palghaut has actually been projected.

SUMMARY OF ARGUMENTS IN RE ROUTE, &c.

I would now briefly sum up what may be said about the route for an Indo-Colombo line:—

- (1). That the Coast line from Manaar (possibly via Anuradhapura-Puttalam) to Colombo is by far the most direct and *healthiest* for through travellers.
- (2). That it can be on metre-gauge without interfering with the established the Ceylon Railway system.
- (3). That it can be constructed by a private Syndicate without adding to the financial responsibility of the Colony.
- (4). That it will serve a very important coconut-growing country—part of it extremely populous—and and also open up very desirable new land for palms, between Chilaw and Puttalam (and inland therefrom) which the natives are eager to buy.
- (5). It will give ready access to the Pearl Fishery grounds (and also to Dutch Bay).
- (6). Bring the coolies by a safe route and drop them at a depôt North of the Kelani whence they can

* Mr. Shadbolt's opinion is as follows:—

- (1). The line must be on the metre gauge. The whole of Southern India is occupied by this gauge.
- (2). The line must run direct to Colombo and not be hampered and depreciated by trying to work it in with existing lines.
- (3). With regard to Adam's Bridge the shoals have a tendency to increase and become more stable and a form of construction should be adopted which would encourage this.—See "Report" for views on the water currents.

These are three points in which I fancy I (Mr. Shadbolt) differ essentially from Mr. Waring.

The following are matters of speculation rather than observation:—

- (4). I believe the natural position of Colombo ensures it a future of immense importance. Its situation will make it for Asia what London is to Europe.
- (5). The political value of the railway would be enormous with regard to the Far East in allowing the military resources of India to be concentrated at such a commanding point.
- (6). The fear of Ceylon being administratively merged in India is absolutely puerile and rests on nothing. The idea of Madras annexing anything is almost unthinkable.

easily move to the upcountry line or afterwards be carried to Kalutara, etc.

(7). Such a line worked by a private Company under certain regulations as to charges, would give the Ceylon and Home Governments as well as the public a much-needed check (by way of comparison) on some of the existing Ceylon Government lines, as to outlay in upkeep, repairs, working expenses, etc.

(8). This Coast line would also enable us in Ceylon to compare the merits and demerits of the two gauges with reference to the opening of the North and East of the island.

(9). It should be a great advantage to have the same Syndicate making and working the line on both sides of the Adam's Bridge Viaduct.

(10). It is impossible for any impartial Anglo-Indian or Anglo-Ceylon resident to approve of the roundabout interior route from Manaar to Kurunegala, to Polgahwela and thence Colombo, with its unhealthy drawbacks for many months, as compared with the more direct sea-coast line for an Indo-Ceylon railway. How would it do to take *Anglo-Indian invalids* through the most feverish part of Ceylon?

(11). It is certain that a great part of the direct coast line will have eventually to be made even for *local traffic*. It will pay better than the line to Galle; and we all know how expensive it is to keep up a Canal crossed by rivers often in flood—and how slow the traffic is by boats. Steamers and coaches cannot overtake the passenger traffic between Colombo and Negombo and Chilaw, and steamers can run only to Kelaniya—3 to 4 miles from the heart of Colombo.

(12). There is, of course, the immense importance of a direct line from South India to the heart of Colombo with its grand, fully protected Harbour and Dock-to-be.

(13). And, also, the scope for settling some of the surplus population of South India in the region eastward from Manaar, Puttalam and Chilaw.

(14). As regards extending from Kurunegala Northwards, nearly every authority, who has thought of this, is agreed that a tramway (speed, 8 or 10 miles an hour) on the existing excellent North road would amply suffice to servo traffic and develop the country, as far as Jaffna.

TRAFFIC ESTIMATES.

I next come to Estimates of Traffic for the proposed line. These have never been the subject of a proper enquiry. The only published approximation is by Mr. Shadbolt, the Indian Engineer referred to. He first calculated that in order to secure a net return of 4 percent. on his total estimated outlay from Madura to Colombo of R48,700,000, the gross receipts must amount to R3,900,000 per annum. But in the first place, I have shown that with corrections on the Ceylon side which Mr. Shadbolt never inspected, his total cost should be reduced to R41,962,460; and in the 2nd place, Mr. Shadbolt's estimate of the emigrants and immigrants—based on figures of some years back—is far below the mark of the present day; while, indeed, the number coming to Ceylon from South India is now likely every year to increase—the Ceylon planters at this moment wanting 50,000 to 100,000 more labourers. As regards goods traffic it is very difficult to form even a guess; but I should certainly expect Travancore and South India tea generally to find its way to the Colombo market by rail, as also a certain proportion of rice and other produce. Mr. Shadbolt took no account (as he points out) in his estimate of first-class passenger traffic, or of local traffic, both on the Indian and Ceylon side. Now for the line from Madura to Pamban by itself, there is an estimate of traffic showing a net return of 13.55 per cent. on the capital outlay. No doubt this takes account of pilgrims to Rameswaram and emigrants to Ceylon. On the Ceylon side, I am clear that a line from Colombo to Puttalam ought to yield 5 per cent. on its cost simply from local traffic. That being the case and looking to the many ways in which the convenience and utility of the junction line would be realized—in military movements for instance—I think it would be safe to say that a net minimum return of 3 per

cent. might be anticipated on the total cost of a metre-gauge line from Madura to Colombo.

ANTICIPATED BENEFITS.

I would now attempt in a few words to summarize the benefits already indicated which would accrue from an Indo-Ceylon junction Railway to India, to Ceylon and to the Imperial Government. First, as to INDIA, we have a first-class Harbour made available for Southern India, which is without a single port of its own worthy of the name. Steamer communication with all parts of the world—even to the Pacific and East as well as South African Coasts—is maintained from Colombo. There is also a favourable market for South Indian produce, especially tea, coffee and rice. Next there is the beneficial outlet or its surplus population. Some of the Collectorates of the Madras Presidency are immensely indebted to Ceylon as it is: in the Madras famine of 1877, Ceylon saved as many lives of the famine-stricken as were probably rescued by all the other official and private relief applied. I think it is Sir Charles Bernard who has said that in Southern India there are several millions of people who, if they can get the equivalent of 2s 6d. per family per week, are well-off, but who, inasmuch as they often cannot make more than 1s 6d., are on the verge of scarcity and sometimes of famine. Now Ceylon not only wants an increased number of free immigrants; but it offers in its North-West and Central parts a great extent of land for gradual but permanent settlement to the overcrowded Tamils of Southern India,—a matter of immense importance to the Indian Government, since the distress and famine now prevailing in the North, may, any season, be experienced in the South as it was ten years ago.

The advantages to CEYLON are largely connected with a free and ample labour supply for its plantations, roads and other public works and for the taking up of waste land. An Indo-Ceylon Railway, in its saving of time, health and money to the poor coolies (as compared with the wearisome road and ferry route, and the troublesome steamer-crossing) would make no mean addition to the number of days' labour even without increased numbers. But these would be sure to come: a Planting Commissioner (Mr. E. J. Young) who went over the Madras Presidency some years ago and saw the chief authorities, made sure that unbroken railway communication was the one solution of a continuous labour difficulty—never more pressing than in the present year. Then, of course, unoccupied districts in Ceylon would benefit by development; while the port and market of Colombo could not fail to be directly benefitted when they became the chief outlet for the Madras Presidency.

Then as regards IMPERIAL interests, it might be enough to remind you how these are bound up with the advancement of British Dependencies. London secures all but an insignificant portion of the trade from Ceylon: the more that island is developed—and it has capabilities for supporting at least 8 to 10 in place of 3 millions of people—the more produce there will be to export, and the greater the demand for British goods—already very largely consumed by the native people of Ceylon. Anything, too, to relieve the pressure of population in India is a matter of Imperial importance. Mr. Chamberlain would find in an Indo-Ceylon railway a potent means of developing thousands of square miles of fine land now lying idle in the "public estate." But there are also the direct Imperial advantages from a Naval and Imperial point of view. To have a Naval basis in the Indian Ocean so convenient and secure as Colombo, facing the French in Madagascar, central for either the Malabar or Coromandel Coasts of India or for Burma and the Straits and commanding for Western Australia, would surely be an Imperial gain. Still more may be said in reference to military and strategic advantages; but on this I need merely quote Sir Charles Dilke when in a recent standard work he says:—"India under a better organization of Imperial Defence would become the Eastern centre of defence from which garrisons in half the world

would be aided and upon which, rather than upon home arsenals, they would depend for their supplies. * * * The creation of an Eastern Woolwich is an Imperial need."

But any decision that India shall be the source of succour and supply for our Eastern Possessions raises at once the other question, at what point on her vast coast line are the succour and supply to be made available? With the map before him no one will challenge the proposition that, given railway connection between India and Ceylon,—so that men and war materiel may be passed into the island promptly and safely,—Colombo is the point where our vessels and stations in Southern and Eastern waters might best obtain repair and supply. Put it this way. Wherever the Eastern Woolwich, to borrow Sir Charles Dilke's apt phrase, may be placed, the Eastern Portsmouth should stand in the utmost south, an arm outstretched to succour. And the two should be made one by railway,—by the Indo-Ceylon Railway.

The other day at the Society of Arts, Sir Charles Dilke spoke of Ceylon as "an important strategic point" and that "the garrisons of many islands and coaling stations would have to be increased in time of war which would greatly add to the burden of the Navy at an inopportune moment." But this is just what railway communication with India would obviate, as troops could be poured into Colombo—a very important coaling station—whenever war threatened, without ever troubling the Navy.

I have tried to show that, financially and commercially, there is justification for undertaking an Indo-Ceylon junction railway; but it will now be seen to be something more than a sound business undertaking, it is a necessary factor in the defence of the Empire under the conditions imposed by the armed approximation of France from the south-westward and the extension of the Russo-French alliance eastward.

In a letter published a few months ago in a London paper, M. de Lanessan (late Governor-General of French Indo-China) writes:—"The important works done at Colombo give her (*i.e.* England) not only a port of call perfectly safe at all periods of the year, but also *the command of the most central points of all the Indian Ocean.*" M. de Lanessan, I hear, is an expert in matters of this sort, and his opinion on the strategic importance of our port ranks high among the arguments for the equipment of Colombo as a naval base on a scale commensurate with her geographical position; and for the construction (as a part of that experiment) of the Indo-Ceylon railway.

Finally we have had the expression of opinion of the present Governor of Ceylon—His Excellency Sir J. WEST RIDGEWAY K.C.B., K.C.S.I., who, in his Opening Speech to this Legislative Council on Oct. 26th, 1896, declared:—

"I believe that railway extension to the North will soon lead to railway communication with India, and railway communication with India will, I believe, remove any labour difficulty that may arise. I believe that railway communication with India would be good for trade, and that in time of war Indian trade would prefer the land route to Colombo to the risk and dangers of the sea passage across the Bay of Bengal."

It might not be easy to fit the work of a Syndicate or Company—especially if adopting the metre-gauge—into correspondence with the existing Ceylon Government lines. Permission to lay a third rail, and for running powers would be required. But I am led to believe that to a responsible body undertaking an independent metre-line all the way from Madura to Colombo, by the coast route, the Governor of Ceylon and his Councils would offer no objection especially if the proposal came on at an early date.

"Ways and means" always form an important part in the consideration of a great undertaking of this kind. It is a matter of recent history, I believe, that a Syndicate promoted by a Bombay mercantile house and leading men on the South India Railway made proposals for an Indo-Ceylon Railway to the India and Colonial Office authorities,

and from the former, got a certain time-concession, now expired. A Syndicate or Company formed in this City of London with an intelligent appreciation of the benefits accruing from its work, ought, I should think, to be readily met by the Indian, Colonial and Home authorities. A joint guarantee of 3 per cent, the responsibility being divided between the Indian, Ceylon and Imperial Treasuries, ought not to be grudged and ought surely to suffice.

It has been suggested that as an Indo-Ceylon Railway would probably enable the Imperial authorities to station at Bangalore the British Infantry regiment now divided between Colombo and Trincomalee, so some financial aid towards the guarantee for the line might be got through the saving in the Military Contribution. Ceylon at present pays into the Imperial Treasury by way of Military Contribution about $\text{Rs. } 1,600,000$ (says $\text{£}100,000$) per annum. Part of this at least might be saved under the conditions already indicated and utilised to promote so useful a work for the Imperial, Indian and Ceylon interests as an Indo-Ceylon Railway.

While Indian and Ceylon Railways, in spite of many troubles, are—says a recent writer in the Indian press—paying literally “hand over fist,” it is anomalous that the English capitalist should continue to send his money for investment in South American and other such speculations. The fact probably is that in the City of London the promoter's, the broker's, and the gambling speculator's interests lie in far more tempestuous waters than in the calm harbours of Indian railway enterprise. Where out of India and Ceylon will be found many thousands of miles of railways worked under an unimpeachable system of audit, and costing in operating expenses only about half of their entire earnings? And yet capitalists shy of coming forward. Anything that the Governments of India and Ceylon can do to make it clear to the sensible English investor that in Indian railways there is a fair field for legitimate enterprise, will be a gain all round as well to the English capitalist as to the Indian taxpayer.

I send with this MSS. a copy of the Report of Mr. Waring, M.I.C.E., C.M.G., and also of that of Mr. Shadbol, the Indian Engineer, with their diagrams and plans, as referred to in my paper, to lay on the table for the use of members. I also forward a map of Ceylon with the Railway lines constructed, surveyed and projected, duly marked,

J. FERGUSON.

Colombo, Ceylon, February 25th, 1897.

DISCUSSION.

The CHAIRMAN:—I came here to learn, for it was quite sufficient for me to know that Mr. Ferguson of Colombo, had prepared the paper to be sure that there would be a great deal of information in it. (Hear, hear.) I think it will save a considerable amount of time if we do not follow the paper throughout. It is well-known to almost everybody in this room—because they are nearly all practical people, accustomed to trade with the East—that Colombo is a magnificent port. In the next place I think we can clear a good deal of ground if we do not follow the paper into the military question today. In the railway to unite Colombo with India, I think we shall find we have a sufficiently large field to cover this afternoon. Anyone looking at the map of Ceylon, and the map of Southern Asia, must see that Ceylon is the central point. Governments are not always in advance of the people, and the people themselves are not always ready to advance—especially people in new countries (and Ceylon is practically a new country). But Ceylon is ready for the new railway. If a railway could be made it is quite certain that it must pay. In America we see how much is being done to save a few hours, and sometimes even a few

minutes, in travel and transit. By this railway it is hoped to save days, and thus to bring Australia and Java and South and Central India into closer connection. There are so many practical people in the room, thoroughly conversant with this subject that I am sure you will be glad to hear them instead of myself. I may say, however, that I have heard that matters are rather more advanced than some of us had thought.

Mr. H. KIMBER, M.P.,* said:—I have just returned from a journey to India, in the course of which I went over the ground with which the lecturer has dealt in his interesting paper. There is no doubt that a line such as he describes, connecting Ceylon with the mainland of India, and connecting it by a bridge, is rather a more serious undertaking than he contemplates. But undoubtedly it will eventually be an accomplished fact, and it will, I am sure, be for the benefit of commerce generally and of India and Ceylon in particular. (Hear, hear.) I have been a Director of the Southern Indian Railway for years, and this line would be a branch of our main line. The concession which Mr. Ferguson referred to, granted some three or four years ago, having expired, fresh negotiations are now before the Government. We have had meetings to confer on the subject and to get into practical shape a project for construction by feeder line Companies, with a view—one view—of getting the subscription of Indian and Ceylon and English capital. The propositions to the Government offered two alternatives—one to do it under a 3 per cent guarantee, and one to do it under a $3\frac{1}{2}$ per cent qualified guarantee. In the first case (the 3 per cent) the terms can be obtained at the India Office: they were published last week in a Parliamentary return. The 3 per cent guarantee would be one by the Government, with certain conditions attached which I need not go into now. The $3\frac{1}{2}$ per cent is a guarantee by the parent Company out of traffic, the details of which are in a statement which I have not got with me; and I prefer not to give them from memory. I think this brings the railway very near to accomplishment. I saw Sir West Ridgeway in passing through, and had some conversation with him as to the railways upon the Ceylon side. The heads of the Ceylon Government are bent upon railway construction, and there can be no doubt that there will be progress on the Ceylon side trending towards the Indian Coast. Sir West Ridgeway told me the question was one of gauge. I pressed upon him as to Mannar that he should make that with the metre gauge. As ours is metre-gauge, and the gauge extends up to Poona, it will be seen that if they want to run from Ceylon up to Bombay quickly it should be by one gauge, and that one the metre-gauge. The position on that side we must leave for the Ceylon Government. Prospects as regards traffic

* Kimber, Henry. (Wandsworth.) s. of Mr. Joseph Kimber, of Canonbury. B. in London July, 1834; m. 1860, Mary Adelaide, d. of the late General Charles Dixon, R.E., of Rectory Grove, Clapham. Was admitted a solicitor in 1858, having previously taken the first prize of the Incorporated Law Society, and a second-class certificate in law at University College, London. Is a director of the South Indian Railway Co., chairman of the Natal Land and Colonization Co., and director of several colonization and other Companies. Is also a member of the Royal Colonial Institute. Has sat for Wandsworth since 1885. A “progressive Conservative.”—79, Lombard-st., E. C.; Lansdowne Lodge, West-hill, Wandsworth, S. W.; Carlton, City Carlton, St. Stephen's and Constitutional Clubs.—“Dod,”

on our (Indian) side are very good indeed. I don't suppose we have had a branch line which offers such good prospects in itself, even without the aid of a guarantee. (Hear, hear.) I left my big ship at Colombo and took a small ship to Tuticorin to see the approaches to the Indian coast. The distance from coast to coast (on the railway route) is, I think, about equal to the breadth of the English Channel from Dover to Calais. That is, of course, a formidable distance to get across. I saw not only Sir West Ridgeway, but also Sir Arthur Havelock and the Viceroy in Calcutta, and they all seem to look upon the Indo-Ceylon junction as a thing for future consideration entirely, not for the present. It would involve the making of a railway 20-odd miles across the water, and though it is true that for a great portion of that distance there are rocks and ground seldom more than seven or eight feet under the surface of the water, yet, even so, anyone with the slightest knowledge of engineering would know that it must be a formidable work. Then there comes a portion of very deep water, and how that is to be spanned is for engineers to explain. But the present suggestion is by steamers. A good port can be obtained on each side by steamers of considerable size. It is suggested that the existence of this ridge under water would afford in one monsoon protection on the one side, and in the other half of the year, during the other monsoon, the passage would be on the other side, by which the ships would be equally protected. So it is considered that the passage by water would be a tolerably easy one—considerably easier than the one of 150 miles that I made. It is altogether an undertaking of a most interesting character, and I am glad Mr. Ferguson of Colombo has brought it before us at this time, when discussion is taking place with a view to bringing the matter into practical shape. (Applause.)

Mr. F. J. WARING, C.M.G., said:—I spent some considerable time at Adam's Bridge, during which I made a survey of it. Mr. Ferguson was hardly correct in saying the ware is no "column".* I saw there was; it was all sand. As to the depth of water, I took very careful soundings and there is a maximum depth in one place of 34 feet. About half the distance is of sand and sand islands, and the other half water. About the route for the connecting railway between Adam's Bridge and the rest of Ceylon, I have advocated a line from Mannar to Madawachchi, where it would connect with the proposed Northern railway. Travelling from Mannar to Puttalam the country is quite uninhabited and any line passing through that country would there cross rivers at their deltas, where they are very low and subject to very serious floods, I think. † The rainfall for several months is practically nil. The line down the centre of the island, recommended by a Commission sitting in Colombo, would pass through country with a better rainfall—country which was at one time in a high state of cultivation, as is evidenced by the ruined tanks by which it is covered. I do not wish to be understood as indicating any doubt as to the practicability of constructing a line between Mannar and India. I believe it to be perfectly practi-

cable. But there can be no doubt whatever that it would be very costly, and I fear that the colony of Ceylon would hardly undertake that at present, though I think—and I have spoken with many officials in Ceylon upon the subject, and I think the general impression among these officials is that the line will come—that a line between Ceylon and India will come in the future, though possibly the present time is hardly ripe for it. There is one little point on which I should like to touch. I have been a great deal maligned. I have, I fear, the character of being a determined advocate of the broad-gauge, irrespective of any conditions whatsoever. That, sir, is not the case. I am not an advocate for broad or any other gauge. The gauge of a line should be a geographical question. But there is one thing I am opposed to, and that is a break of gauge. When once the gauge of a railway has been introduced into a country, after mature deliberation and great study of the question, I think that should be adhered to. We have in England the experience of the Great Western Railway. When it was constructed Mr. Brunel made light of break of gauge. History has shown us how great its evils are. It is no use to say there will no difficulty in an independent line from Mannar down the coast. It would not be independent, I think. The majority of the passengers would be immigrant coolies, the bulk of whom go to the different estates upcountry. Taking them down from Puttalam to Colombo would be distinctly sending them out on their way. They would have to go back again to reach the upland estates. I think the cry for a branch-line from Puttalam to Kurunegala would come at once, in order to save the coolies' travelling distance. (Hear, hear.)

Mr. F. H. M. CORBET:—We are once more greatly indebted to Mr. Ferguson. (Hear, hear.) The line may not be possible just at present, but it must come, and the sooner the better; and Mr. Ferguson has greatly helped to break the ground. (Hear, hear.) If there has to be a break of gauge we have to make it where it will cause the least inconvenience. Probably Puttalam would be the easier point. Even if goods were wanted upcountry their transshipment from Colombo would not be a very serious matter. The increase of passenger traffic between Puttalam and Colombo may be reckoned upon as a certainty. There is a thriving population between the two, and it lends itself to great increase should facilities for transport be given. Experience in Ceylon, has shown that within an exceedingly short time a population has clustered around railway stations, and has provided the traffic which the line was intended to serve, and as a rule, that has far exceeded the estimates formed at the outset. Everything in Ceylon has been in favour of railway construction. (Hear, hear.)

Mr. H. W. CAVE:—I think the railway should not go from Puttalam to Mannar; but as far north as possible. It would be the means of opening up the North-Central Province, which was, two hundred years ago, the support of millions of people. The district is now uncultivated; and, having recently spent considerable time in that part of the island, I express the opinion that if the railway were brought directly through the Province it would be the means of not merely bringing coolies to Colombo but would open up the whole of this Province. (Hear, hear.) No doubt if the railway were made, British enterprise would be the means of bringing the Province under cultivation once more. (Hear, hear.)

* Sic in reporter's notes, but must be some blunder.—ED. T. A.

† This is obviated by passing from Mannar via Anuradhapura to Puttalam.—ED. T. A.

The CHAIRMAN, in moving a vote of thanks to the author and the reader of the paper, said:—Mr. John Ferguson has done wonderful work for Ceylon, and India as well. (Applause.) It is no light matter to get up all this information and these statistics and place them here in the City of London, and get together the practical men who are here today, and who thoroughly understand the evolution of this railway. It does seem an extraordinary thing: it is many years since I was in Ceylon—before there was a harbour there at all—and people were quite sure there could be no harbour made in Colombo with stones, because of the force of the sea. This has been got over, and here we have a small break in between two large masses of country, and with plenty of material—and we hear this afternoon that it is just a question of gauge! Surely, if the foundations can be got in—and we know in England wonderful foundations have been laid for breakwaters—if that can be done it won't matter if there are three lines of rails down, because if they can get one embankment down that can stand the gauges. As to whether they should end in India or Ceylon, that is quite a separate question hardly worthy of discussion. The great question is how we are to bridge over this small strait between the Continent and Ceylon, was to give Southern India the full advantage of the Harbour of Colombo. (Hear, hear.)

The vote of thanks was passed by acclamation, and Mr. DONALD FERGUSON briefly responded, the proceedings closing with the usual acknowledgment of the CHAIRMAN'S services.

We may add here extracts from some letters received by the writer of the Paper, by a recent mail:—

Sir Thomas Sutherland, Chairman of the P. & O. S. N. Company, in a kind note of apology for inability to be present, remarks:—

"I ought to have been at the meeting of the Chamber of Commerce today to hear your paper read; but it has been impossible, for I have had so many things to do. As you have an excellent Chairman in Sir Albert Rollit—a man of encyclopædic knowledge—my presence was the less necessary. Your idea lies undoubtedly in the future, it must come about."

Mr. Matthews (Harbour Works Consulting Engineer) is good enough to write us by the mail:—

"I had a most important engagement fixed for today with a gentleman from South Africa, who has come home to consult us, and so was unable to get away in order to attend the meeting of the Chamber of Commerce at which your paper was read. I gather, however, from a letter to hand from Mr. Kyle, that he was present. Mr. Kenrick Murray sent us some cards, and I am today writing him a letter of thanks, informing him that it was with great regret that I was unable to attend. Had I had a few days' longer notice, I might have made arrangements accordingly, but I was not aware until yesterday morning that your paper had been fixed to come off this afternoon. Had time permitted I might also have got up a cartoon plan for the lecture room. If you require a small scale plan of the Harbour Works to illustrate your paper—as no doubt it will be published—we shall be very pleased to supply the same if you will let us hear from you."

A Ceylon proprietary planter, present, writes:—

"The whole thing was, I think, a great success, and your paper highly approved of, as well it might, for it was a very able document, and must have taken a lot of work to compile. I have no doubt that the railway will follow in due course, but let us urge *quickly*, for there is no use waiting till we go back from want of labour on our tea estates, and so

let the island lose its name to a certain extent. Moreover, with this plague and famine, labour ought to be got on a very cheap scale for the work on the line."

Another ex-Ceylon resident writes:—

"On Tuesday I was in London and heard your paper read by Mr. D. W. F. It was a capital gathering, representative both of the City and Ceylon. The room was quite full and all listened attentively. Very pleasing references were made to yourself personally and the work you have done and there was a general feeling which found expression in some words that fell from the Chairman that the reading of the paper before the London Chamber of Commerce meant a definite step in helping to the carrying out of the scheme. One heard with pleasure the speeches of the Chairman, Mr. Kimber, M.P., Mr. Waring, Mr. Corbet, and Mr. Cave, though one regretted that others in the room, well qualified to speak, did not make an utterance. Mr. D. W. F. read the paper well, and Mr. A. M. F. helped us in following his comments by pointing to the map. The paper was followed with evident interest by all present."

Mr. D. W. Ferguson writes:—

"I was glad there was a good attendance, but sorry more did not speak. You will see what Mr. Kimber said about the intention of the S. I. R. to extend the line to Pamban. He also said the money had been deposited for it. I went to Spottiswoode's to try and get the Parliamentary paper he referred to, but the only one I could get (which I send) does not give anything about a new proposal. Mr. Corbet is anxious that your paper should be read before the Imperial Institute!"

One of the most sensible criticisms on the Lecture was that offered by a City merchant, who has never been in the East; but who writes to us by this mail:—

"I listened to your paper on the 23rd inst. with much pleasure. It appears to me that you have made out a fine case for Colombo as the great Entrepot of the East. But if I might make the observation, there are two points which might be more fully dwelt upon, namely:—(1) The importance already of Colombo by reason of its own trade; (2) The trade between India and Australia which greatly needs such a facility as Colombo (with the proposed railway) would provide."

Mr. H. W. Cave writing to a friend, says:—

"I greatly appreciated Mr. Ferguson's able paper. He dealt with the railway question in the clearest and most forcible manner, so that it was no trouble to grasp the points urged from considerations so various. I ventured on a very few remarks in favour of the Anuradhapura route. The seacoast route would benefit India most, but the inland route would do much more for Ceylon, both for the native and European population."

[Mr. Cave has not been up the Chilaw road to see its industry and population and the forest reserves towards Puttalam: a divergence thence to Anuradhapura would, however, meet his views.—Ed. T.A.]

The accomplished London Correspondent of the *Western Daily News* wrote of the lecture as follows:—

"The last lecture delivered at the London Chamber of Commerce for the season was prepared by Mr. John Ferguson, the proprietor of the *Ceylon Observer*, and was read by his cousin, Mr. Donald Ferguson. He impressed upon the audience the importance attached to a railway which would connect India with the "pearl island." With conciseness Mr. Ferguson had traced the social advantages it would give to residents in Madras, besides accelerating their mails. The Empire would benefit its construction, for Colombo was the best and most accessible harbour to the South of India, which served as a connecting link with England, South Africa, Australia, and the Chinese ports. It would also be of material importance to the island itself, for at present the tea planters found a difficulty in securing enough coolie labour. On the other hand, the Tamils in the South

of India were either starving or else had to tramp along a dusty road through the centre of the island. Having explained the necessity of a railway track, the lecturer traced two alternative courses the first along the western shore, bounding a fertile tract of land but hampered by the deltas of rivers; the second, a longer one, through the centre of the island. Mr. Cave, however, whose book on the ruined cities of Ceylon is commanding so good a sale, spoke on behalf of the second line on the ground that it would pass across a district which two thousand years ago had been one of the most fertile in the colony, and which he held would come under cultivation were it more easy of approach to the native."

THE INDO-CYLON RAILWAY.

From the London Correspondent of a Colombo contemporary, we quote as follows:—

London, March 26.

We had a Field-day at the London Chamber of Commerce on Tuesday last on the subject of the proposed Indo-Ceylon Railway. The authorities of that institution evidently did not anticipate a large audience to hear Mr. Donald Ferguson read Mr. John Ferguson's paper: for they shut off half the Council Chamber by the moveable partition, and the result was that the scant space was inconveniently crowded. There was a goodly gathering of Ceylon men present, amongst them being Mr. T. E. B. Skinner, Mr. H. W. Cave, Mr. F. J. Waring, Mr. J. L. Shand, Mr. W. M. Leake, Mr. F. H. M. Corbet, Mr. A. L. Hutchinson, Mr. J. Hamilton, Mr. A. Ross, Mr. J. C. Roberts, Messrs. A. M. and D. Ferguson, &c., Sir Albert Rollitt occupied the chair at the opening of the meeting, but having engagements at the House of Commons he quickly made way for Mr. T. Christy, who had to admit that he came to the meeting simply as a learner.

MR. FERGUSON'S PAPER.

The paper ably set forth the advantages, both commercial and political, that the construction of the Railway would offer to all concerned, and as it will no doubt be published in extenso in Ceylon I need not deal further with it. The interest of the meeting centered in the speech of Mr. Henry Kimber, M.P., who, as a Director of the Great Southern India Railway, lately went over the ground, interviewing during his travels both Sir West Ridgeway and Sir Arthur Havelock. Speaking with full knowledge of his subject he announced that the scheme had now fallen into stronger hands and that its execution was nearer than most of us anticipated. He was further understood to say that his Company was prepared to construct the Indian portion of the new line as a branch of their system. Mr. Waring expressed an opinion, founded on personal observation, that there was no great engineering obstacle to bridging the straits, but the process would, he thought be a costly one. He also touched lightly on the vexed question of gauge, and playfully disclaimed the role of a thorough going opponent of narrow gauge lines: it was more the break of gauge to which he objected. But as was subsequently pointed out by Mr. Corbet, the Ceylon gauge being 5 feet, and the Southern India only one metre, if the two are to be made one line, there must be break of gauge somewhere for the coolies and for up-country traffic. Through goods from India sent for shipment for Colombo might indeed escape any break, if the metre gauge was continued from Manaar along the Coast to Colombo. Mr. H. W. Cave with his well-known predilections for the land of buried cities, laid stress on the importance of linking

up the Anuradhapura district with its fertile acres ready to support a teeming population now starving in Southern India.

From no quarter was there even a whisper of a doubt in regard to the eventual construction of the Railway or of its vast utility when constructed. And Mr. John Ferguson may be congratulated on having once more lent an effective helping hand towards the fulfilment of another great scheme tending to the further development of Ceylon.

VARIOUS PLANTING NOTES.

JAPAN.—As a result of brisk sales of tea during last year, probably in consequence of the unexpected small amount of production, there is now, says the *Japan Times* of March 27th, very little leaf left in the Yokohama market, and this is almost unfit for exportation. A remarkable appreciation of prices may therefore be expected when the new tea is ready, in the coming month.

PACKING OF TEA AT GARDENS is attracting the attention of the Indian Tea Association as its General Committee has received a communication, from the Committee of the Calcutta Tea Traders' Association, to the effect that a number of claims have been sent in to that Association during the past season for the particular kind of damage to tea known as "cheesiness," apparently resulting from the use of unseasoned wood for the boxes.

JAPANESE ENTERPRISE.—Mr. Shibusawa and a few other prominent capitalists of Tokiyo have a project on foot to establish a joint-stock emigration company, with a capital of 1,000,000 *yen*. The waste lands, stretching over 10,000 *cho*, in the districts of Kato and Kasai in Hokkaido, are to be put under cultivation by sending emigrants from the interior. The application made to the Government for renting the land has already been granted, so it now remains to have the company organized as soon as it is recognized by the authorities. Beans and wheat will be at first principally raised, but it is intended to ultimately plant other crops.

MR. KELWAY BAMBER having retired from the service of the Indian Government in order to join his father's analytical business in London, invites orders for analyses of soils, manures, &c. &c. and adds:—

My experiences in Assam tea districts and more recently in Kumaon will enable me to draw reliable conclusions from analysis and submit reports and recommendations, which would be of practical utility to planters. Besides work for individual gardens I shall be glad to try and elucidate any interesting questions affecting the tea trade generally, such as the chemical and other changes which occur in tea during the voyage home, when exposed to the high temperature and close atmosphere of the ship's hold.

INDIA-RUBBER.—Says *The Globe* of April 3—The prospectus is issued of the India-Rubber (Mexico) (Limited), with a capital of £406,000 in 40,000 ordinary and 6,000 deferred shares of £1 each. Subscriptions are now invited for 300,000 ordinary shares, and £200,000 7 per cent. first mortgage debentures. The company has been formed to acquire and develop an india-rubber plantation known as "La Esmeralda," in the district of Juquila, Oaxaca, Mexico, and also the india-rubber and chicle gum estates and plantation of "Llano de Juarez" in the district of Pochutla, Oaxaca. These two properties cover together 440 square miles, and are freehold; and it is estimated that there are upwards of 350,000 india-rubber trees available for tapping. The list opens on Monday.

Correspondence.

To the Editor.

AGRICULTURE IN ZANZIBAR.

Friends' Industrial Mission,
Pemba, Zanzibar, Feb. 24.

DEAR SIR,—I am in receipt of your *Tropical Agriculturist*, and offer my best thanks. I will endeavour from time to time to let you know what is going on here and what I am able to do in the way of agriculture. At present I have no land and do not expect to have for some months. Meanwhile I shall use my eyes to the best of my ability. Agriculture here is in a condition next door to hopeless—not the fault of soil or climate, but of the so-called agriculturists who are the slave owners. We await the "Anti-Slavery Crisis" and its result.—Yours truly,

THEODORE BURTT.

[The abolition of slavery, announced the other day, will delight Mr. Burtt.—ED. T.A.]

JAVA AND JAPAN TEAS.

London, March 19.

DEAR SIR,—It appears I was wrong in thinking that the Exchange on Java bills was based on the market price of silver. I was misled by the information I got out of Whitaker, when looking for the weight and value of the various silver coins. I find that the Exchange for demand bills on Batavia is 11.90 florins for the pound sterling, or nearly par—the sovereign being worth both in Holland and Java 12.10 florins.

It is very fortunate for Ceylon that this is so, and it fully accounts for the slow progress Java has made in producing tea, for at a par exchange, it would not pay at present prices for the ordinary run of tea.

Of course, I knew where the Japan tea went to—but it is Ceylon that is the intruder and competitor on the Japan in the American market.—Yours truly,

C. S.

CEYLON TEAS IN NEW ZEALAND.

CARELESS PACKING—QUARTZ MIXED WITH TEA—
DISCREDITING OUR TEAS—SHAME ON THE
CULPRITS!

Dunedin, March 22.

DEAR SIR,—We enclose herewith a sample of Ceylon produce which we bought for tea. The writer has had 25 years' experience in the tea trade in Mincing Lane, London, and in the Colonies, and has never come across this kind of leaf. Will you kindly inform us what it is? The consumption of Ceylon tea in New Zealand is very much greater than Indian tea and it is a great pity that such careless packing has taken place, and if continued, it will, no doubt, be detrimental to the future prospects of Ceylon teas.

Besides the quartz we forward, there were small lumps of dried earth and pieces of matting in the package. We could give you the name of the estate if required. We are large importers of Ceylon teas of all grades and shall instruct our Agents in Colombo to fight shy of this estate.—We are, Dear Sir, yours faithfully,
pro. ARTHUR BRISCOE & CO.,

J. H. BROOMHALL.

[We certainly think the name in such cases should be communicated to the Planters' Association and Chamber of Commerce; and if any-

thing like wilful carelessness were proved, general publicity as a punishment should follow. It is a very serious matter to discredit our teas in countries where we aim at driving out inferior Chinese teas. The enclosure sent us contains quite an appreciable quantity of Ceylon quartz! —ED. T.A.]

ENEMIES OF CACAO.

Greenwood, March 25.

DEAR SIR,—With reference to the letter of the Hon. T. N. Christie, *re* Cacao Disease, I wish to point out that in your morning issue of 26th November 1894, you published a letter from me with the heading "*Enemies of the Cacao Tree*" in which I mention:

TO THE BARK AND WOOD.

"*Tomici perforans*,' a small beetle one-10th of an inch long, inserts its eggs in lower part of stem when the bark weeps and decays, getting, a claret colour in well-defined patches. The grub tunnels the trunk, the beetle the branches. Few trees survive their attack.

"I daresay that it would pay cacao planters to offer a good premium for the best way to prevent the destruction made by the little beetle '*Tomici perforans*' alone; for it is yearly the cause of the destruction of a large number of trees."

I now wish to add that I still consider that only a prophylactic remedy can be successful and that the destruction of the infested trees do little good as "*Tomiciens*" is to be found in other dead as well as live wood in large quantities.

I have two species of mature cacao trees, which, although having been planted as supplies amongst the old Criollos, (of which few are remaining), have never been touched by *Tomiciens* nor by the black grub borer, and are flourishing in the open.

It is the reason for which I have not abandoned all hope for this cultivation in Ceylon; for they will probably prove to be towards "*Tomiciens*" what the American vine stock has proved to be towards "*Phylloxera*." It might be for the same cause that the cultivation of the Criollo kind has been formerly abandoned in Trinidad and the West Indies—anyhow, for its great liability to disease.

In your issue of Feb. 15, you mention in an article "Visit of a Java estate proprietor" that Mr. Van Sohn says: "The cacao cultivation generally is not at all promising in Java any more than in Ceylon. *Its worst enemy in Java is a BORING BEETLE.*"

It would be very interesting to know if it is the same "*Tomici*."—Yours truly,

A. VAN DER POORTEN.

TEA AND OTHER CULTURE IN MAURITIUS: MR. E. H. EDWARDS AND MR. CORSON TO THE FRONT.

Curepipe, Mauritius, April 2.

DEAR SIR,—I send you a cutting from "The Planters and Commercial Gazette" which may be of interest. Far be it from me to decry the island where I spent nearly twenty of the happiest years of my life, and where, after years of roaming, I would willingly end my days, but there is no doubt that the advantages for Tea Culture in Mauritius are very great. Land is in most instances cheaper, and the soil is undoubtedly better than in Ceylon, while, owing to the rapidly declining sugar industry, labor is becoming abundant.

Up to the present time the Experimental Farm is the only place where tea has been cultivated; it has been planted in many places and grows well, but, as you know, a tea plant to pay requires something more than to be simply stuck into the ground.

Many of your readers will remember the Mr. Corson, spoken of in the cutting: he is most enthusiastic over tea culture in Mauritius and I think he has every reason to be so.—Yours faithfully,
E. H. EDWARDS.

TEA CULTURE IN MAURITIUS

At the time that the Government of Mauritius decided to start experimental farms at Curepipe and elsewhere to test the suitability of soil and climate for the cultivation of products other than that of sugar, their action received the unqualified approval of all intelligent men interested in the agricultural success of the country.

It, however, now appears that beyond the essay made in the culture of tea little has been done. This is to be regretted, for beyond all question, there are many economic plants that could be grown to great advantage in Mauritius. It is true that at the Royal Gardens, Pamplemousses, there are specimens of many tropical and sub-tropical plants, but for some occult reasons, nothing has been, or is being done to encourage extended cultivation.

Shortly after the commencement of the Tea Experiment, the Government in a commendable liberal spirit, sanctioned the engagement of a competent tea-grower and preparer in the person of Mr. J. A. Corson. This engagement extended over a period of five years with an understanding, beyond the shadow of a doubt on Mr. Corson's part, that at the expiry of the time he should have the option of renewing his engagement for a similar term; but owing to a lamentable want of foresight in his own interests, Mr. Corson neglected to have the precise terms committed "to stamped paper." The first five years expired in December last, when he was told his services were to be dispensed with. A short time previous to this date the Government called for tenders for the lease of the farm, but although several offers were made, none came up to the requirements of the Government, and matters remain in *statu quo* for another year.

The action of the Government in entirely ignoring Mr. Corson's alleged right to the option of a renewal of service may be wrong, looked at from a moral point of view; but we think the time has come when the cultivation of the farm should pass into other hands than those of Government, and thus obviate the necessity of the latter, by the sale of its teas, coming into competition with private enterprise.

The object of the farm, so far as tea is concerned has been attained. Mr. Corson has established beyond contention that tea can be grown in Mauritius as well as, if not better, than in the island of Ceylon and the provinces of India. His books show that the fields in full bearing yield 600 lb. per acre, and this, too, on poor soil—while the value of the prepared leaf is equally satisfactory. Mr. W. J. Lloyd, a tea-taster and valuer, of the firm, Messrs. Barry & Co., Calcutta, when passing through Mauritius, a short time since, tested the Farm's teas with the following result:

		s.	d.	per lb.
Broken Pekoe	15 per cent value	1	3	"
Pekoe	55 " "	10		"
Common	30 " "	6		"
or an average of 9.551. per lb. The average for Ceylon teas for the last year was, we believe, 8d. per lb.				

With such satisfactory results both as to yield and value, the cost of production only has to be considered. It has been said that the expenditure at the Experimental Farm has been very heavy considering the returns. This is so, but it must be borne in mind that Mr. Corson has been receiving the same amount of salary for looking after 20 acres as he would, had there

been 200; buildings have had to be erected and machinery purchased, the cost of which it is scarcely fair to debit to two or three crops. Labor is nearly, if not quite, as cheap in Mauritius as it is in Ceylon, and the cost of transport from almost every part of the island is much cheaper.

Any further assistance on the part of Government in the shape of culture which would necessitate its teas coming into competition with private growers is unnecessary and to be deprecated; so, without wishing to appear ungracious, we think it should retire from the field.

Our readers may think we make a very hazardous statement in saying that in ten years time the output of tea in Mauritius will exceed that of Ceylon. Everything points to the culture of tea as the salvation of Mauritius as it has been of the sister island. But planters must go cautiously to work and above all things, not rush badly prepared teas into foreign markets.

A knowledge of the cultivation and preparation of tea is not acquired in a day and when acquired, has to be carefully applied. Mr. Chalmers, of the well-known firm, Messrs. Chalmers, Guthrie & Co., in a small pamphlet which he has written on the planting, cultivation and manufacture of teas, says:—"It is often said that tea is made in the field, and this is true, in so far, that good carefully plucked leaf is the essential basis of good tea. Manufacture is, however, responsible for much, and many thousands of pounds sterling are lost annually to the owners of tea property through neglect in this department."

For the future success of the tea industry in Mauritius it is imperative that there should be some experienced person on the spot who may be consulted on the culture and preparation of the leaf not so much for the local market as for that of England, the Continent, and America. Some locally made teas which sell freely here, were valued by Mr. Lloyd at from 4d to 5d per lb. Were these to be sent to England, a bad impression would be created as to the character of tea the island could produce, and of the capability of the planter to prepare it.

Many persons who recognise the advantages to be obtained from tea culture, hesitate to embark in it for various reasons. The principal ones are, their ignorance of its culture and curing, and the expense of the necessary building and machinery.

The culture can with care be mastered by following the instructions of an experienced man: the preparation and machinery &c., run hand-in-hand. A central factory would relieve both large and small planters of all apprehension on the latter score. There is already the nucleus of one at the Experimental Farm, which Mr. Corson is prepared to enlarge to meet the requirements of planters within a radius of 6 miles of Curepipe provided he can make arrangements with the Government to have a personal interest in the farm beyond merely that of Superintendent. It will be a thousand pities if the industry be allowed to flag through the Government and Mr. Corson not being able to come to some mutually satisfactory accord; to lose Mr. Corson's services at the present time is to throw away the money that has already been put into the Farm.

TEA AND INSECTS.

Dartry, Gampola, April 9.

DEAR SIR,—I send in a separate tin box some poochies that I found amongst my tea. They are most extraordinary looking things. Can you give me any information about them?—Yours faithfully,
J. A. ROBERTS.

[Mr. Stauforth Green is good enough to report as follows on the insects sent to us:—"Belong to the family Fulgora. The species emit a white waxy secretion in the immature state, sometimes taking a cottony form. Westwood mentions in his modern classification of insects, that "this production is collected by the Chinese and employed in the manufacture of the fine white wax so much esteemed in the East Indies."

They suck the pieces of stems and leaves, and in large numbers must do serious damage. The Frog Hopper, Frog Spit, or Cuckoo Spit, so well-known in England, is a member of the family."—ED T. A.]

THE CACAO DISEASE.

DEAR SIR,—Mr. Vander Poorten's communication regarding the cacao weevil *Tomieus* and the remarks thereon of Mr. Martin, of Yattewatte, are of undoubted value to cacao planters, as presenting to them the separate experiences of two different planters. And if you can collect the views of several Ceylon planters on this important subject, such information cannot fail to bear upon the future successful cultivation of cacao in our island.

When at the drafting of our Committee's Annual Report the consideration of this cacao enemy cropped up, it was referred to a Sub-Committee composed of cacao planters; and it was then thought that the subject was worthy of fuller investigation and discussion than the time at our disposal then permitted us, for the report had to be presented to the meeting almost immediately. But the time is now opportune, I think, for the exchange at leisure of our different views; and the publication of the results of individual observation with regard to cacao and its latest enemy.

It has been suggested that it would be important to make a careful study of the insect. No doubt this is a necessary step. But I consider that there is even a more important study than the life history of the weevil; and that is the life history of the cacao plant itself. For men of experience are too apt to keep to their own views, and the practice of their own methods till an enemy suddenly appears and disturbs their self-confidence and repose. Inquiry then follows with the result that things taken for granted previously become open to legitimate discussion. It may be taken for granted in this connexion that the weevil, which has become a new terror to certain plantations, is by no means a stranger. But the further acquaintance and familiarity with the insect through a knowledge of its life history is little likely to benefit the cacao planter, unless the doomed plant is studied with as much care and more than even the enemy which attacks it.

My own view of it, if it is of any value to my planting brethren, is that *the insect is not the cause of death to the plant, but one of the consequences of it.* And I maintain that without the opinion of a scientist upon the plant itself, in the first instance, no man is warranted in arriving at the conclusion that the weevil is the cause of its death. I should expect the planter, who ascribes the death of the plant to the weevil to be able to exclude all other cases before he lays the charge at the door of the insect *Tomieus*.

If we proceed a step further in the investigation we may probably be told by scientists who have studied the habits of the insect that Tommy belongs to a class of insects which delight in decayed or decaying timber. In which case the question at issue will be whether Tommy has of a sudden changed his natural instinct in the matter of his diet from decaying bark and wood to fresh, green, sappy plants, or whether the plant have from age, exposure to too much sunlight, poverty of soil, over-manuring, injury at the roots or their branches at the hand of man or other causes changed their condition from healthy and unpalatable wood to decaying and palatable matter; fit food for the worm! The

first step, therefore, in the investigation is to ascertain whether the tree attacked is healthy or decayed—dying—dead. When the planter first notices the weevil he also notices the fact that the tree has changed its condition and *per saltem* he arrives at the conclusion that "an enemy (*Tomieus*) hath done this thing." Now to argue by analogy one who meets with a carcass of an animal filled with maggots may, with equal reason cry: "Behold the maggot (here insert a sonorous aristocratic name to make it look learned)—behold the maggot hath killed the animal!"—
Yours truly, JAS. H. BARBER.

SANITATION ON ESTATES: COOLY LINES.

Kandy, April 10.

DEAR SIR.—In calling attention to the enclosed letter from the Colonial Secretary, I would endeavour to impress upon every member of the Planting Community the importance of carrying out the injunctions referred to in a thorough manner. We can hardly estimate what a frightful calamity it would be if the Plague were to break out in our midst, and for every reason of interest as well as humanity, we should do our utmost to ward off the evil.—Yours faithfully, J. N. CAMPBELL,

Chairman, Planters' Association of Ceylon.

Colonial Secretary's Office, Colombo, 1st April.

Sir,—I am desired to inform you, as you are probably aware, that the attention of the Government and the energetic action of all local sanitary authorities have been specially directed at measures for the prevention of the introduction of the Plague and for its resistance if it should unhappily make its appearance in Ceylon.

2. The Governor feels that he can with confidence appeal to the proprietors of estates for their co-operation in seeing that their cooly lines are cleansed and whitewashed, inside and outside, and that all the drains in the neighbourhood of the lines are cleansed and kept in good sanitary condition. This duty is indeed imposed on Superintendents of estates by the section 20 of the Medical Wants Ordinance, No. 17 of 1880, and the Governor has no reason to suppose that it is not ordinarily observed. But at the present juncture it behoves those in charge of estates to adopt some extraordinary measures of sanitation and, with this view, a circular injunction is in course of issue by the Medical Department.

3. I am therefore to invite your attention to the subject and to ask the Association to use their influence and action in securing the adoption of such extraordinary measures.—I am, &c.,

(Signed). J. J. THORBURN, for Colonial Secretary.

To the Secretary to the Planters' Association, Kandy.

LABOUR SUPPLY FROM NORTH INDIA.

DEAR SIR,—I enclose a letter (copy) *re-labour* which I have received from India. This is the only way to break the back of the present Cangan system and monopoly, I have no doubt we shall be able eventually to get this kind of labour down from Calcutta at 10 rupees a head which will make it far cheaper than the present. Then you save all head money and Canganies' names; the Zemindars at R40 a month, say looking after the lot.—Yours truly, TRUTH.

April 11th.

True Copy.

Stephen, Dass & Co. Factors and Commission Agents, Indentors, Market and Produce Suppliers, Benares.

Benares, 3rd April 1897. Dear Sir,—We are in receipt of your kind favour of the 23rd ult. We are willing to supply you the coolies at R20 per head including our commission, females at R25. We trust that these rates will not be considered excessive now as labor is scarce, owing to the opening of

new Railway and canal works. The Railway fare from Benares to Calcutta is about R7 and we have not yet heard from the B. I. S. N. Co. what they will charge to land coolies in Colombo, per head. There is also the Asiatic line they may take them cheaper. If you will instruct us, we will make the necessary inquiries for you. You required 150 coolies. We can give you the full number, duly registered and indentured for your Island. The coolies eat rice and they are a hardy race. We will require an advance of at least R2,500 to send them. Yours faithfully, (signed) STEPHEN DASS & Co.

CEYLON TEA IN RUSSIA.

Kandy, April 12.

SIR,—Mr. Rogivue, writing from Moscow on February 14/26 gives an account of a two months' tour undertaken by his agent, a Mr. Stromberg in the course of which some 28 towns in the Baltic Provinces, ranging in population from 7,000 to nearly 200,000, were visited. In each town Mr. Stromberg interviewed the principal tea dealers and others, and also distributed samples and brewed and distributed tea in the cup at the Hotels. He was unable, however, to undertake public lecturing for various police reasons which might perhaps be overcome with time and money. Mr. Stromberg's conclusions are that though few of the trade were willing to take up Ceylon tea they all admitted its good qualities, but some doubted it (sniting the Russian taste) and they would be certain to deal in it if either (1) they were regularly and frequently visited and promised and given the liberal assistance in advertising or (2) they were offered equal advantages as to credit with China tea and could get a bigger profit or (3) they experienced a demand coming from their customers, the public. Mr. Rogivue remarks:—

"Now Mr. Stromberg and I have both concluded, and I think you will also see from the report on this journey, that of the three conditions which in our opinion would ensure the more complete and full conversion of this country to Ceylon tea, the third (that of making the dealers feel a demand springing up among their customers) is the most hopeful and also the soundest and most enduring when accomplished, although it is the most difficult and the slowest to show any result.

"To do this I think we should increase our efforts to keep the name of Ceylon tea and its most conspicuous merits continually before the public by the newspaper announcements, as done in previous years, only on a more extensive scale if possible and by opening, wherever possible, new shops for special sale of Pure Ceylon Tea in packets (retail) and continuing my never-relaxing search for agents to undertake the exclusive sale of Pure Ceylon Tea."

Mr. Rogivue concludes his letter as follows:—"There is a matter to which I would beg the most earnest attention of all in Ceylon and that is, that from many independent sources I have heard complaints, among those who import your produce, that the quality of the tea is not what it used to be. I myself have noticed a falling-off in this respect, some marks which used to suit this market so well owing to their strength, and the appearance of the dry leaf being now so poor in both these respects that I have been obliged to give up importing them and find great difficulty in matching my old standards. As I have kept nearly all my old samples of teas I bought, I am able to make comparisons for a period extending over several years. The maintenance of the fine qualities which we advocate is naturally a vital question in the permanent conversion of new markets.

"I shall be very pleased to supply any Ceylon firm, who may desire it, with the addresses of direct importers of tea looked up by Mr. Stromberg."

Mr. Rogivue enclosed the following translation of a letter to a Russian newspaper dated 31st January, 1897:—

"Translation of a letter to the Editor appearing in the *Russkie Slovo* No. 30, 31st January, 1897 "To the best of my knowledge several newspapers have been lately advocating the closing of our ports to English ships in consequence of the Plague epidemic in India. Such an arbitrary measure is perhaps too strong, but it would not be at all too much to forbid, for the time being, the import of any food stuffs from India, such as for instance Ceylon Tea of which, according to the "Russian Telegraphic Agency," a large shipment has just been landed in Odessa. This tea is much appreciated and drunk amongst our people and is also, as I have heard, used to mix with other sorts of tea, not of Indian origin. We can very well do without this English product, for our friends, the Chinese, have always supplied us with their tea in sufficient quantities."—

I am, sir, yours faithfully, A. PHILIP,
Secretary, Thirty Committee.

HILL TRAMWAYS COMMISSION.

Colonial Secretary's Office, Colombo, 12th April 1897.

SIR,—I am directed to forward to you the enclosed copy of a letter addressed to the Hon. Mr. F. R. Saunders relative to the appointment of a Commission to report on Hill Tramways together with a copy of the report submitted by the Commission.—I am, sir, your obedient servant,
J. J. THORBURN, for Colonial Secretary.

Colonial Secretary's Office, Colombo, 6th Feb. 1897.

Sir,—With reference to the letter addressed by me to Messrs. Christie, Mackintosh, and yourself, bearing date the 3rd instant, I am directed to transmit to you the accompanying Commission under the hand of His Excellency the Governor and the Public Seal of the Island, appointing you to enquire and to report on the construction of tramways in the Hill Provinces of Ceylon.

2. His Excellency will be glad if you will enquire and report:—(1) On the advisability of constructing tramways whether for steam, bullock or other traction in the hill districts; (2) on their probable cost; (3) on the probable financial result of their working; (4) whether they could be constructed on the grant-in-aid system, and whether it would be desirable to encourage their construction by the means of private enterprise or of public companies, and if so, the shape which such encouragement (otherwise than by a guarantee of interest) should take; (5) the roads, if any, on or alongside which such tramways should be constructed.

3. The Commission is empowered to order such surveys as may be necessary for the purpose of their enquiry.

I am, &c., (Sgd.) H. L. CRAWFORD, for Colonial Secretary.

The Hon. Mr. F. R. Saunders, C.M.G.

THE HILL TRAMWAYS COMMISSION.

The Commission has held sittings at Colombo, Hatton, Badulla, and Nuwara Eliya, and in addition to obtaining information and arriving at a decision on certain general points connected with tramways and hill railways, it has inquired into the following specific schemes:—

- (a) Railway between Nanuoya and Nuwara Eliya, and an extension to Udapussellawa.
- (b) Scheme for the Dikoya district.
- (c) Do Dimbula district.
- (d) Do Badulla-Passara district.
- (e) Do. Pussellawa-Ramboda district.
- (f) Do. Hewaheta-Maturata district.

Among the more general questions considered by the Commission the following may be noted:—

1. *The necessity for Hill Railways.*—Some of the witnesses, notably those in the Badulla and Udapussellawa districts, were inclined to regard increased railway facilities as being almost necessary, but the Commission's opinion, on the facts brought before it, is that in most districts the cart transport service is fairly efficient, and that railways, although desirable and wished for, cannot at present be said to be necessary.

2. *Tramway vs. Railway.*—Assuming as the definition of the former, a line having a grooved rail laid flush with the roadway, the Commission is of opinion that tramways are not snitable. The rail is a heavy and expensive one, and between the rails and on the outside of each rail paving stones or concrete would be necessary to maintain the evenness of the roadway and prevent a dangerous blocking of the groove. Apart, too, from the excessive cost involved by the use of a grooved rail, the Commission is of opinion that such rails are unsuited to the comparatively heavy, powerful engines required to work on the steep gradients and sharp curves which would prevail on all the lines.

3. *Nature of the Roads in the Hill Districts.*—Speaking generally, the Commission finds that the existing cart roads are not of a nature to be really serviceable as tracks for narrow-gauge railways. They abound in the sharpest of curves, and the gradients are so extremely steep, often for several miles on end, that, without deviations in the form of zig-zags, locomotives work without racks could not pull an appreciable load behind them. Working under the most favourable conditions, a locomotive on a gradient of 1 in 20 (and there are many miles much steeper than that) would, in addition to itself, pull less than twice its own weight, and in unfavourable weather much less, so that, after allowing for the weight of the vehicles the influence of curves, and a necessary margin to meet ordinary conditions, the actual net load moved would be small.

The Commission has not sufficient information before it to express a decided opinion on the suitability of rack railways to surmount the long steep inclines, but obviously they would be much more expensive in construction.

The laying of railways on the roads would to a great extent unsuit them for heavy traffic, and the witnesses have differed as to the importance to be attached to this, although upon the whole they inclined to view the boon of a railway as being worth the partial sacrifice of the roads.

The estate factories have all been built in relation to the existing cart roads, and were entirely fresh alignments selected for the railways, new approach roads would be required to enable the traffic to get to the railway. This however, does not apply in the case of the Badulla scheme.

4. *Gauge of the Hill Railways.*—The Commission's conclusion on this point unhesitatingly is that the gauge to be adopted should be that of 2 ft. 6 in., which affords great advantages over the narrower gauge in the matter of locomotive construction. It is true that in some cases, at all events, a 2 ft. gauge would be more economical and more easily suited to the sharp curves, but as the Kelani Valley line (if constructed) is to be on a 2 ft. 6 in. gauge (and probably a large section of the northern line), there can be no doubt that the general economy and convenience of adhering to one gauge for all the branch lines would far outweigh the saving which might be effected in some cases by adopting a narrower gauge.

5. *Rates to be charged for Freight and Passengers.*—At the earliest stage of the inquiry it was quite evident that if the rates for freight now ruling on the Nanuoya extension were adopted for any of the schemes under consideration, the estimates would in all cases show a prohibitive loss on working. Nor is this to be wondered at; the volume of traffic to be dealt with on these feeder lines is naturally very much smaller and running a much shorter average distance than that of the trunk line, while the

gradients to be surmounted are extremely adverse. It is obvious therefore that the cost both per train mile and per ton mile must be heavy. The Commission has taken as its basis of calculation the rates of cart hire ruling in the district from point to point, and all the witnesses and representative bodies have agreed that they are willing to pay these rates to the railway if constructed. The Commission recommends that such rates should be the ones charged until any line shows a substantial clear profit more than equal to the charges for interest and sinking fund. The Commission recommends that the passenger rates should be on the same scale as those levied on the Nanu-oya line, except in the case of the Nanu-oya-Nuwara Eliya section, where rather higher mileage rates should be charged.

6. *Prospects of obtaining all the existing Traffic.*—Experience in connection with some of the Ceylon Railways has shown that it is not always safe to rely on existing traffic finding its way to the railway. Once a railway has been constructed and its manifold advantages secured beyond recall, the traffic which was promised and reckoned upon has sometimes only in part been given to the railway. The Commission therefore recommends that the Government should refuse to enter upon any scheme unless the owners of the estates interested are prepared to agree that all their traffic will be placed upon the railway (at rates agreed upon), and, in order to give binding effect to the agreement, consent to the imposition of prohibitive road tolls on estate produce and supplies. It is gratifying to record that all the witnesses examined by the Commission readily recognized the fairness and desirability of such a precaution, and approved in their common interests of the proposal.

SPECIFIC SCHEMES INQUIRED INTO.

(a) *Nanuoya to Nuwara Eliya, and an Extension to Udapussellawa.*—This line would be approximately 18 miles in length (5½ to Nuwara Eliya and 12½ on to Ragalla). Two traces for a 2 ft. gauge line were made from Nanu-oya to Kandapola, the one by Mr. Waring and the other by the Public Works Department. Speaking of the section to Nuwara Eliya, the former adheres to the existing cart road, and its gradients consequently are so steep that a system of rack rails has to be introduced. There does not seem in this case to be any advantage gained by adhering to the road, and, indeed the Commission understands that Mr. Waring only did so in terms of his instructions. The other trace, which runs through Crown forest above the road, is unfortunately, not to be relied upon, and will have to be discarded. The Commission has asked that a new 2 ft. 6 in. trace be surveyed and staked out at once, and recommends that it should leave the Nanuoya station on the goods shed side only. This will involve passengers crossing by a subway, but will obviate the inconvenience and danger of having two lines crossing one another, both on steep inclines. The trace should follow the direction taken by the Public Works Department survey, and only utilize the one portion of the cart-road immediately below Blackpool bridge for a maximum distance of 40 chains. On entering the Nuwara Eliya basin it should trend to the right and pass round between the lake and the racecourse to a point below the Priory, where the station would be. This route (and site) is approved of by the witnesses examined, and it is convenient for the extension to Udapussellawa. That extension follows, with some deviations, the existing cart road the whole way to Ragalla, but it is understood that the first section—to Lover's Leap bridge—is not to encroach upon or injure the driving road. From Kandapola to Ragalla the road will have to be greatly given up to the railway. Of the various district schemes, this is the only one where the project of using the existing cart roads is feasible without extensive deviations. The road will be of great use nearly all the way, and between Lover's Leap bridge and Kandapola is well suited for a hill railway. From Kandapola down to Ragalla the road is steep, but a gradient of 1 in 26 can be got, and

it is hoped few, if any, curves will be less than 100 ft. radius.

The Commission favours this project because it is undoubtedly desirable that the town of Nuwara Eliya should be connected with Nanuoya and as the roads are fairly suitable the continuation of the line to Ragalla will give it a traffic and a length favourable to its successful working. This, too, is the only one of the schemes in which the approximate length of the line can at present be determined.

The estates traffic is easily ascertainable, and the figures for it, up and down, are quite reliable. The Nuwara Eliya traffic is calculated from tally returns of the present road traffic, and is less reliable. The estimated cost of construction will probably be found to be fairly accurate, and it is unlikely that the working charges will, on the average, be much less than 3.30 per train mile to Nuwara Eliya, and 2.50 beyond.

(b) *Dikoya District Scheme*.—The roads in this district are far from suitable, and there is one section, at Wanarajah bridge, where the gradient is 1 in 16 for 500 ft., with a short bit of 1 in 13. It is considered certain that the railway would not get the traffic of the side valleys unless branches were constructed up all the roads; this necessitates a relatively large mileage to serve the district, and the short branches will add greatly to the cost of working, which has been placed at the high figure of 3.25 per train mile. Mr Harcourt Skrine brought before the Commission a scheme to run narrow gauge lines from Watawala station up the Maskeliya and Dikoya valleys. Taking advantage of the natural outlet of these districts, the suggested lines would be on easy gradients, and save the traffic climbing up to Hatton station. There would be much to recommend the adoption of such a scheme if the railway had not already been constructed to Hatton with the object of serving these districts. At present, when there are districts much more in need of increased railway facilities than Dikoya and Maskeliya, the commission would not be justified in suggesting the construction of an alternative outlet railway, even although it presented advantages over the existing outlet.

(c) *Dimbula District Scheme*.—This was a proposal to construct a line from Talawakele to Diyagama, 17 miles. The road is less unsuitable than the Dikoya roads, and the line, being without branches, could be more cheaply worked; but the mileage rates of cart hire are less than in Dikoya, and the revenue therefore is not so large as might have been expected. The Commission considers that this scheme will be found worthy of further investigation.

(d) *Badulla-Passara Scheme*.—The road between Bandarawela and Badulla was at once pronounced to be quite unsuitable (gradients of 1 in 15 ascending, and portions being as steep as 1 in 10 and 1 in 12), and it is evident that railway communication to these districts, which is much to be desired can only be given by adopting a trace independent of the roads.

The Commission strongly recommends that a survey should be made for a 2 ft. 6 in. gauge line, and until that is done the estimates of cost of construction and working must be considered as being but little better than guesses. The country is undoubtedly a very difficult one, and it is not possible to say what length of line might prove to be necessary to overcome the differences in elevation. The estimates of traffic and revenue are, particularly as regards the estates' share, quite reliable; but the question of the tonnage which at present travels between Madulsima and Batticaloa all finding its way to the railway would need to be a matter of definite understanding between the Government and the planters before the line was undertaken. The figures for last year show that about 600,000 lb. net of tea were shipped in 1896 from Batticaloa, out of an estimated total crop (Passara district) of 2,400,000 lb., while over 3,000 tons of Indian rice were imported at that port during the year.

Of all the schemes considered by the Commission, this Badulla scheme is the only one in which it is possible that any one might suggest an extension on the 5 ft. 6 in. gauge, and the Commission therefore thinks it well to point out that, while quite conscious of the evils of break of gauge on a continuation of a trunk line, or even a branch line, with heavy traffic requiring rapid transport, it is of opinion that for the types of branch lines coming within the scope of its inquiry, the inconveniences of break of gauge would be but little felt, and are far outweighed by the saving in first cost.

The fact that passengers have to change from one train to another is of no weight, as they often have to do so where there is no break of gauge.

The cost of transferring goods from one train to another is very small where labour is cheap and when the weight to be transferred does not exceed 20 to 40 tons per day, and that of easily handled goods. On this point attention is drawn to the evidence of Mr. Cantrell given before the Northern Railway Commission (Sessional Papers VI. of 1897, pp. 23 and 24).

There is no competition either in time or cost to be feared where consignors are prepared to have their roads barred for heavy traffic. On the freight rates per ton per mile, which vary from 30 to 75 cents, the cost of transferring will form a fractional charge.

In every scheme considered by the Commission it was clear that a standard gauge branch line would be so costly as to entirely preclude the possibility of its being constructed.

(e) *Pussellawa-Ramboda Scheme*.—The scheme as originally presented to the Commission includes three lines; 1, Gampola to Ramboda; 2, Gampola to Pooprasie; 3, Ulapane to Lower Ramboda; but a slight investigation showed that no case could be made out for Nos. 2 and 3, and the suggested line from Gampola to Ramboda is the only one worthy of consideration. In the sketch estimate annexed it will be seen that financially this scheme is one of the best, if the bulk of the Pundalu-oya traffic finds its way to the railway at Ramboda. It is not, however, clear to the Commission that those who now use the railway at Gampola would all bind themselves to use it at Ramboda if the extreme rate of 75 cents per ton per mile were enforced, and this is the rate quoted by the District Planters' Association, on which the revenue of the scheme is based. The cost of this line is rendered somewhat more uncertain than the others owing to the crossing of the Mahaweli-ganga at Gampola, which would probably necessitate a new and expensive bridge. The nature and extent of the deviations would have to be ascertained before it is possible to state how much the mileage of the railway might exceed that of the road distance.

(f) *Hewaheta and Maturata Scheme*.—This scheme, requiring a long mileage for a comparatively small tonnage, would not bear investigation. In the figures furnished to the Commission the Lower Hewaheta traffic was entered at a much larger figure than the Commission could accept, but in the summary of the scheme that unduly large estimate has been included.

7. The Commission concluded its inquiries regarding specific schemes with those just referred to, but in doing so the Commission does not imply that there are no other schemes worthy of consideration, or that its inquiry was exhaustive.

It was necessary that certain schemes should be inquired into, and in a rough way, their respective merits set out, and this has been done.

There can be no doubt that what is now required and generally wished for is that one line should be undertaken, and hereafter, when the knowledge gained by its construction and working is available, that the other schemes should be more definitely considered.

For the reasons which have been given in the sections dealing with the specific schemes, the Commission's recommendations to Government are—

(1) The construction of a 2 ft. 6 in. gauge line from Nanu-oya to Nuwara Eliya and Udupussollawa, subject, so far as the latter section is concerned, to

the conditions mentioned in paragraph 6 being adhered to.

(2) The survey for 2 ft. 6 in. gauge line from Bandarawela to Badulla and Passara.

P. A. MACKINTOSH.

SKETCH ESTIMATE OF THE VARIOUS SCHEMES CONSIDERED BY THE COMMISSION.

Details.	Nuwara Eliya and Uda Pussellawa.	Dikoya.	Dimbula.	Badulla and Passara.	Pussellawa.	Maturata.
Acres in cultivation	9,877*	25,000†	24,071†	27,105†	11,851†	—\$
Estimated tea crop, 1897	2,200,000	11,900,000	19,000,000	5,861,625	4,799,655	4,346,400
Mileage of suggested railway	18	27	17	36	21	40
Rough approximation of cost, including stock	810,000	1,485,000	850,000	2,160,000	1,050,000	2,000,000
Interest and sinking fund at 4 per cent.	32,400	59,400	34,000	86,400	42,000	80,000
Cost of working	73,475	130,767	92,284	146,016	85,176	148,720
Total yearly debit	105,875	190,167	126,284	232,416	127,176	228,720
Anticipated revenue	93,578	128,351	90,338	225,481	127,360	175,717
Net annual deficit	12,297	61,816	35,926	6,935	—	53,005
Net annual profit	—	—	—	—	184	—

* Of this only 6,684 acres are in bearing, but as High Forest, with 1,300 acres in cultivation, the traffic of which would come on to the railway, is not included, the traffic as soon as the total acreage is in bearing will probably be quite 50 per cent. more than has been included in this estimate of receipts.

† Not the total acreage of the district, but only that which it is anticipated would use the railway.

‡ Of this only 23,348 in tea, and a large portion is not yet in bearing.

\$ Not furnished by the District Planters' Association.

MEMORANDUM BY MR. P. A. MACKINTOSH.

Since the conclusion of the work of the Commission I have received from a well-known firm of Electrical Engineers in England, in reply to inquiries on my part, a list of electrical tramways or railways which they have equipped.

2. In this list there appears the case of the Beesbrook and Newry Railway, worked by electricity generated by water power through the medium of a turbine.

3. It has been in operation for 11½ years (although I had never heard of it, doubtless owing to its being such a short line), and it is claimed that it has throughout worked satisfactorily. The preponderance of the traffic is goods or minerals.

4. Some of the details connected with it I subjoin:—

Length of line	3 miles 2.4 chains.
Steepest gradient	1 in 50.
Available fall of water ..	28 ft. [very little].
Volume of flow of water per diem	3,000,000 gallons.
Average tonnage of goods carried annually	16,000 to 17,000 tons.
Average number of passengers carried annually ..	90,000 to 100,000.
Speed of trains	6 to 9 miles an hour.
Train mileage (in 1891) ..	21,468.
of cost haulage per train mile, of which nearly 40 per cent. was for rental of water power (in 1891)	3.94d.

5. It is stated that being an example of one of the earliest lines to be operated by water power, it is somewhat out of date, although it has operated successfully throughout; and certainly the cost of haulage seems to be extremely low.

6. This case at once suggests the possibility of working the Nanu-oya to Nuwara Eliya line through the medium of a turbine situated near Blackpool, utilizing the Nanu-oya in a similar manner, but with any improvements that may be possible. In the same way, for the line from Nuwara Eliya to Kandapola a generating station might be situated on the Kandapola-oya near Lover's Leap, while the section from Kandapola to Ragalla might possibly be treated in a similar manner from the adjoining stream, the capacity of which I am not, however, so confident about.

7. I think the matter is worth the serious consideration of the Government, and if they desire it, I will, during the progress of the survey now being begun between Nanu oya and Ragalla, have systematic gaugings of the three streams referred to taken before the rains set in, and levels taken to ascertain the available head of water, with a view to obtaining estimates, on the completion of the survey, for the equipment of the line for being worked by electrical power generated by water power

P. ARTHUR MACKINTOSH.

Avisawella, March 30, 1897.

MEMORANDUM BY THE HON. T. N. CHRISTIE.

Although I do not think that a slow speed train ascending steep gradients round sharp curves at all lends itself to electrical propulsion, I concur in thinking that the water in the streams should be ganged, and, if it occasions no undue delay, the question of the feasibility and cost of the scheme reported upon.

It must be borne in mind that the system of having a driver for each vehicle would not suit Ceylon conditions. No vehicle could be trusted to descend the gradients of the Nuwara Eliya line unless it was under the control of a driver of the same standing as the drivers on our existing line; and were one such required for each vehicle, the cost would be great. A system in which every vehicle, or almost every vehicle, had its own motor and yet the whole train was under the complete control of one driver, would, I think, be essential.

March 31st, 1897.

THOS. NORTH CHRISTIE.

DEAFNESS. An essay describing a really genuine Cure for Deafness, Ringing in Ears, &c., no matter how severe or long standing, will be sent post free.—Artificial Eardrums and similar appliances entirely superseded. Address THOMAS KEMPE, VICTORIA CHAMBERS, 19, SOUTHAMPTON BUILDINGS, HOLBORN, LONDON.

DUTCH BAY V. HARE ISLAND AS COOLY QUARANTINE STATION.

We had only time recently to allude to the opening slip in Mr. Harcourt Skrine's long and, in the main, instructive as well as interesting letter. Clearly he knows as much about his subject as any one in or out of the island, unless it be Capt. Donnan and Mr. Ingrams. With Hare Island, Tuticorin, he has had an intimate personal acquaintance; but his statements about Dutch Bay, we infer, are made on hearsay and inference from popular notions of the locality and, therefore, as we said, his criticism and comparisons in this direction would have been better withheld, until the official Report on the recent official inspection and consultation had appeared. Nevertheless, it is quite possible that a useful purpose may be served by the appearance of Mr. Skrine's very full letter at the present moment when the whole subject is likely to be under the consideration of the Government.

Now, we do not profess to be in a position to discuss "Dutch Bay" in the familiar way in which Mr. Skrine treats of Hare Island. But we are certainly prepared to traverse some of his statements or inferences. He is probably unaware that while the richest coconut-growing and one of the most populous native regions in the island, lies between Negombo and Chilaw, beyond the latter station the same great industry has, of late years very rapidly extended in the direction of Puttalam. The Rajakadalawa district on the Northern side of the Deduruoya is likely to be a specially favorite coconut district: it has been very largely taken up and estates seven years old and upwards are most promising. So much so, that the demand for land has carried wealthy enterprising natives and some Europeans well towards Puttalam; while our information goes to show that there is good soil and heavy forestland for some distance beyond that station. It is quite true that the annual rainfall of Chilaw does not exceed 54 inches and that of Puttalam 46 inches; but the coconut palm in many parts at least of those districts does not depend altogether on rainfall; for, there is water at no great depth in the soil—a brackish deposit in which the roots seem to luxuriate. So much for the character of the country in the Puttalam and Dutch Bay district and Mr. Skrine will understand that, personally, we should much prefer to see any line of railway run (not from Polgahawela or Kurunegala through a "miserable" country, but) from Colombo due North to Puttalam and Dutch Bay—a line that would pay splendidly for by far the greater part of the way, on its own local account. The cooly traffic would add to its success: coolies meant for upcountry would join at Kelani station, and there would be little difference in the journey, as Polgahawela is only a few feet above Colombo.

But this is all by the way. What we are chiefly concerned with today is to set Mr. Skrine right in reference to Colombo and the cooly traffic. It is not only absolutely wrong, but almost childish, to write of the press or intelligent public of the capital as being opposed to the use of this port for cooly traffic *per se*, or to suppose that any such motive as *odii profanum vulgus et arceo* has actuated any section of our community in desiring to see a convenient and suitable separate cooly port established

apart from the metropolis. Childish, we say, because there is assuredly no one in Colombo, official or unofficial, who has discussed this question, who is not as convinced as any planter can be, that on Cooly Immigration, more than on any other element, depends the prosperity of the Colony. Any policy calculated to check or discourage such immigration is only worthy of condemnation. But, on the other hand, let the planters remember that on the healthiness of Colombo—on steamers being able to call and go freely from this port with clean bills of health, depend issues of the greatest possible moment, directly affecting their great industry and equally striking at the prosperity of the island. Now, it is in the interests of both elements to the prosperity of the Colony—free immigration and unrestricted steamer freight—that we should like to see a separation effected through the establishment of a distinct Cooly Port. Suppose, for instance, the plague was reported to have reached Madras and to be extending farther South, that indeed a case had reached Colombo, and that therefore the need for extremely restrictive measures was recognised on all sides, would not the liability to interfere with the cooly traffic be vastly increased, no matter what local quarantine arrangements were made? And, on the other hand, would it not be a vast relief on such a (plague) crisis arriving, to feel that cooly immigration could not be prejudiced, because it had its own port, quarantine station, and depôts in the island at a point widely separated from the metropolis? Our illustration so far, is that of a case of plague arriving here, through no fault of the coolies; but suppose, on the other hand, that a case or cases of plague were directly traceable to the coolies, how much more serious a thousand times such immigration would then become, when associated with, or in the vicinity of, a city like Colombo, over-crowded and insanitary in many parts in spite of all that is being done—than if the plague cases appeared among coolies landing at Dutch Bay or any other similar isolated cooly port? But Mr. Harcourt Skrine will reply to this—as indeed he has already done—that we cannot divest ourselves of such traffic at this port: "the coolies" (like the poor) must be always with us—always coming and going by hundreds, if not thousands, to such a city as Colombo. That is very true; but of how far less importance that the ordinary cooly traffic of the city should be hampered, or even temporarily suspended altogether, than that the large and vital flow of Immigration for the plantations should come under the ban of the Port Surgeons of the great central Mail-steamer Port of the East. On due reflection, we think it will be found that the planters ought to lead the way in asking the Government to provide, if at all possible, a separate, convenient, and accessible port for their coolies to and from Southern India, so as to relieve all concerned of the risks attending the use of Colombo.

OUR ESTATE SUNDAY SCHOOL.

(Communicated.)

Our Estate Sunday School is unique, has been both peculiar and erratic, for although it now dates back for several years since it was founded, yet it has not always been active, given alas! to hibernate, as a supply of teachers failed. We have had times when the pulse of its life was

thready and weak, and others marked by big bursts of enthusiasm, when a new rush of talent was fresh to the work, and zeal the predominant leaven. Then there have been visions of progress: a Christian peasantry with a Christian conscience about, and we have even effervesced in these halcyon days into a regular night school, and gone in for a lavish expenditure, in slates, first readers, chalk and a black board.

The youth of the Tamil race is, as a rule, bright, interesting and intelligent: is teachable, and can be led, and takes to a Sunday School at first out of pure curiosity, and when that curiosity is satisfied, deserts without a qualm. A new teacher on the old theme crowds the withering loft—which is the hallowed abode of our effort—and unless the teacher be wise, he may be misled, thinking that they are stretching out hands in the manner that used to be depicted as the attitude of the heathen on the cover of a juvenile missionary magazine we were supplied with in the distant past, and that they were thirsting and crying for knowledge. If the teachers' Tamil be halting that is rather an advantage. It keeps the children quieter and extends the reign of curiosity until they find out what he is talking about.

In our school every new teacher is allowed a free hand, all "isms" and "views" occupy the one platform, and opinion weighs nothing. When the teacher is very zealous, I find he generally begins at the beginning and the knowledge which the estate children have of the ante-diluvians is simply astonishing. Those whose policy in education is thorough, put in a lot of time over the Garden of Eden while "the father of all such as handle the harp and organ," and the "instructor of every artificer in brass and iron" are not unknown heroes. Life however, is short, and zeal often burns out, and it is not to be wondered at, that the later history of Israel is pretty much a blank, for the children's curiosity is easily satisfied, and there is a lot of dry stuff in the hoary past. We have had teachers who took instead, the times of Christ as their theme, and expounded the words of the Master; but it is but scrappy knowledge the children have of the Divine Teacher, and His life on earth has been told only in part.

There has been a tendency in all the teachers—especially towards the end of their career when the school deserters were many—to fall back on "the terrors of the law" as persnaders, and when this has become very marked, I have always taken it to mean the shaking of the dust from off the feet, and the preliminary to leaving, I don't know that it does the children any harm—as a rule, the school had become very thin before these lightnings play the bolder spirits unabashed playing outside—but then there is such a satisfaction for the teacher to feel that when his message has been delivered and not taken much notice of, that some one will have to pay for that later on. The youthful Ramasami hears of the abode of the damned unmoved: in the world into which he was born terror stalks about day and night: destruction may overtake him here and now, so that a neenesis in the future is rather an improvement.

Our teachers have had many plans to keep up the flagging interest. Some have suggested "no Sunday School, no rice," and this has worked admirably, and perhaps if it had been persisted in as a steady policy, the children might now have been able to take high marks in Scripture knowledge; but it did not commend itself to all,

and indignation has been expressed at endeavouring to teach the children through the pangs of the stomach, rather than through the emotions of the heart.

To give an annual feast, the memory of whose richness, and the odour of whose savouriness was to permeate and influence the whole school year has been tried; but except for a few Sundays before the feast and one solitary Sunday after it, it might have been uncooked.

Picture books, and coloured tracts have been distributed: magic lanterns have been exhibited, and even a supreme effort made to win by a variety entertainment. This last was unique, and had a vista of such possibilities that I had a feeling—immediately suppressed of course—that it was not such a bad thing after all to be horn a heathen. I had had a good deal of my moral grounding driven into me with a stick or slipper, and was made to march to school and prepare the lessons *volens volens*, and no sugar piece in the matter; but here was my heathen horde, that used to have its rice stopped if it absented itself from school, soothed by sweets one day, pandered to by plantains another, sustained by bread the next, and with the sure prospect of having its nakedness clothed later on, dancing ever before it. When a boy, I used to hear on high occasions in church, of "a feast of fat things" of "wines on the lees well refined," and wondered what in the world "wines on the lees, well refined" could possibly be, and have been wondering ever since. Can it be any thing like the above? If so, I argue, that the circle has been rounded and the end is near. If the variety entertainment fails, what else is there to fall back on, except to shut the door of the withering shed for good and acknowledge defeat. But on second thoughts I won't; as long as teachers can be got, the school *shall* remain open. It may not be a model school, nor run on any kind of lines likely to obtain the approval of the experienced, but our aim is limited, and if after many days there be but one from its number found heading for the higher life or any turning at all toward righteousness, it will be reward enough.

THE CACAO PEST.

ITS NAME WAS NEVER HEARD:—WAS
SILENCE WISE?

"TROPICAL AGRICULTURE" of whatever branch, is well known to be an industry which involves many risks, but it has its compensations. For one thing it is unwise to prophesy about it; for, if "the swing of the pendulum" is unfavourable to the planter this year, it may be as much the other way later on. In the old coffee days it was not unusual to see the cultivator who was heavily indebted relieved of his worrying incubus by two or three good crops; while there was the other side, too, in which money was lost hand over fist. Cacao, during its short career in the island, has not been free from similar vicissitudes. We have had low prices, succeeded by a halcyon time when those who had cacao gardens looked upon every other product of the East as not in the race with the "food for gods," and were inclined to think, that they had found at last the ideal tropical product. This season of bright-eyed hope was alas! followed by collapse of prices! markets slipped away from us. Countries, which had imported largely, began to export cacao, and from the top figures of 130s to 140s a cwt., the

rates reeided to 60s or less, and reports came from London, that some kinds could not be sold at all, except at a ruinous sacrifice. It was another lesson to the sanguine planter of the need of caution.

When prices got low, cacao was not so much heard of, and when there was the added horror of trees clothed in verdure, and often laden with clustering crop, going out in patches, there was less said about it than ever. Those men immediately concerned were shocked and surprised, and bustling about, set their brains a working to devise means for checkmating further inroads. Applications of white-wash, kerosine oil, tar, and insecticides had each their day; affected and dead trees were rooted out and burnt; "poochees" were hunted for; botanical authorities interviewed and questioned; inquiries made here and there, as to what others were doing, but nothing to any good purpose—and things were allowed to go on.

Through some occult reason the subject was tabooed in public; most people seemed to know of it and yet it was never discussed; and the press, which ought to have been supplied with the information, was singularly free from any comments on the new horror, and when it was referred to, it was not in a way to cause any alarm. Even the latest Report of the Planters' Association is quite mealy-mouthed in its short paragraph on cacao—the watered-down result of a rather pessimistic paper which had been sent in—so we hear—but voted by some cacao men as disturbing and extreme.

Has this conspiracy of silence been wise? Now the trouble in cacao is becoming so general and so serious, that a specialist has been promised by the Government to investigate and advise; but many cacao planters feel that his work—if full value were to be got from it—ought to have been completed by now, instead of all having yet to be done. Ignorance still reigns, trees go on dying, and many more are marked out for death; planters do not know what to do, and the Specialist, who is to help, is not yet above the horizon, there is only the promise of his coming; while our local Entomologist, notwithstanding his able work, is not offered the opportunity of inspecting estates affected! Of course, in a land like this, where the "poochie" is so much in evidence, and comes and goes according to its own laws and seasons, if the trouble affecting the cacao were a "poochie," hope was ever ready to suggest the possibility of a natural change of conditions, bringing about a cure, or at least a mitigation. Cacao property was depressed enough with the low prices, and to bring into any kind of prominence this obscure and unknown ravisher, about whom so little was definitely known, was thought as being unnecessarily to alarm the monied class, and deemed unwise. Still it was known that cacao was a sensitive and tender plant which demanded and quickly responded to care, and that the red variety—which is suffering most here—had all but disappeared from the West Indies years ago, and the planters ought to have been particularly awake to signs of weakness in that direction and been more open. The land was not barren of counsellors. Planters got so much advice as to what should be done, by people who were not a bit wiser than themselves, that they would have been kept busy all the year round if they had followed a tithe of it. What they wanted, however, was not empirical counsel. Some, we fancy, were

sick enough of experiments and would have been pleased to follow authoritative advisers. Had the Scientist, which the Planters' Association asked for a year or two ago, been appointed at that time, his services at present would have been invaluable. There would have been no hesitation in consulting him, and his quietly working out the life history of the cacao pest, would not have attracted half the attention of calling in a Specialist from home.

Now that His Excellency has so readily agreed to the employment of a cacao expert, we trust that there will be as little delay as possible in setting to work. We still think Mr. E. E. Green ought to be asked to give a preliminary Report, or to consult with other local authorities; but, in any case, if a Specialist is to be got from England, we trust when he does come he will speedily get to the root of the matter, and put the puzzled and suffering cacao planter on the track of his enemy.

THE BORING BEETLE INFESTING CACAO.

Under date the 13th instant, Mr. E. E. Green writes to us:—"Under separate cover I forward a bulletin from the U. S. Department of Agriculture. In it you will find a paper upon the *Scolytidae* of the United States. I have marked several passages that may be of interest to your readers as bearing upon the boring-beetle infesting our cacao,—which belongs to this family." We quote the passages marked by Mr. Green:—

THE AMBROSIA BEETLES (*SCOLYTIDÆ*) OF THE UNITED STATES.

BY H. G. HUBBARD.

The term ambrosia beetles is here used as a convenient one to distinguish from the true bark-borers and bark-eaters the timber-boring Scolytidæ, which push their galleries deeply into the wood, and which feed upon a substance called "ambrosia."

The galleries of the bark-borers are superficial and lie within or just under the bark. The galleries of the ambrosia-eating beetles penetrate into the wood, and in all their ramifications are of uniform size and free from wood dust or other refuse.

Their food consists not of wood, but of certain minute and juicy fungi propagated on the walls of their galleries. The action of the fungus produces a stain in the wood, giving to the galleries the appearance of having been bored with a red-hot wire. These characteristic "black holes" serve to distinguish their work from that of all other deep-boring timber beetles.

All the growing parts of the fungus are extremely succulent and tender. When the plant is in active growth, the fungus appears upon the walls of the galleries like a coating of hoar frost.

Various disturbances of the conditions necessary to its growth are apt to promote the ripening of the fungus, and this is a danger to which every colony of ambrosia beetles is exposed. If through any casualty the natural increase of a populous colony is checked, there results at once an overproduction of the ambrosia.

It accumulates, ripens, and discharges its spores, choking the galleries and often suffocating the remaining inhabitants in their own food material. The same results may sometimes be brought about by closing the outlets of the galleries through the bark, or by spraying into them kerosene or some other noxious liquid. The inmates of the colony are thereby thrown into a panic, the beetles rush hither and thither through the galleries, trampling upon and crushing young larvæ and eggs, breaking down the delicate lining of ambrosia on the walls of the brood chambers and puddling it into a kind of slush, which is pushed along and accumulated in the passage ways, completely stopping them in places. The breaking down of the food fungus follows and in a few days the

galleries are filled with a paste-like mass of grannles or spores, or with threads of mycelium, in which the living insects are suffocated and destroyed.

INJURIES CAUSED BY AMBROSIA BEETLES TO LIVING PLANTS.—As a rule, populous colonies of these beetles and galleries so numerous and extensive as to be capable of doing serious harm are found only in trees, which before the attack began were sick unto death with maladies for which the timber beetles are in nowise responsible. The few species which enter the sapwood of vigorous trees do not form large colonies, and the effect upon the health of the tree is not appreciable. One or two species, it is true, have the habit of sapping the life of twigs or small branches with an encircling burrow, and a species of *Corthylus* does considerable injury in this way to young trees and to shrubbery in the forest.

REMEDIES.—From what has been said of the nature of the food of these beetles, it is evident that any method by which the entrances to their galleries in the bark can be closed will effectually put an end to the progress of their colonies.

Perhaps the best means of accomplishing this is by coating the trunks with dendrolene or raupenleim. A light brushing or spraying of the bark with creosote or kerozene will sometimes accomplish the same result, especially at the beginning of an attack. But this cannot be depended upon to permanently protect the trees.

COFFEE ON THE STRAITS:

CEYLON PLANTERS TO THE FRONT.

We quote from Report by the Acting District Magistrate, Mr. B. Kerkelev Kuala Kangsar, for February:—"Walked to Choping where there is some very fine coffee, six years old, and a big area being planted, and on to Tepus and Blanja." Also from report by the Acting District Magistrate, Krian, Mr. R. C. Gray for February:—"On the 19th I drove to Alor Pongsu with the Collector of Land Revenue, and there met the penghulu of Bagan Serai and Briah, and some applicants for land in the direction of Briah. We walked to Kuala Briah, and then went up stream some distance by boat to see the lie of the country. The land here is all apparently suitable for *bendang* cultivation, and I am informed that further up stream good land for coffee may be found, but we were unable to go far up the river on this occasion." Also from report by the assistant district magistrate, Tanjong Malaim, Mr. Hamilton for February:—"Mr. Tait has planted about 75 acres of coffee since October. He is pushing on with further clearing rapidly. The estate looks very well, and the young plants healthy. He intends putting in a few acres of tobacco as a trial crop shortly. One hundred and seventy-four acres were demarcated during the month, leaving a total of 527 acres undemarcated. The most important item during the month was the prospecting done by Europeans on the Klanang Road. The land here, the excellence of which had hitherto been known solely to native planters (mostly Javanese), having satisfied the prospectors, two applications for five hundred acres each were put in by Messrs C. R. L. Learmouth and J. D. Toynbee. Very shortly after this Mr. W. Greig came down and, after careful prospecting, forwarded three more applications for 640 acres each, from Messrs. F. H. Wiggin, H. M. Picken (both of Ceylon), and himself, respectively. Thus the aggregate of applications from Europeans during the month amounted to 2,920 acres, and as these applications are all for land on the south side of the Langat, where no applications from Europeans have yet been received, the importance of this new accession to the planting interest of the district can hardly be overestimated. It will certainly make all the difference to Jugra, which with a road to Kuala Klang, may now certainly be expected before many years are passed to develop into fair-sized market town, supplying the needs of the agricultural population which is beginning to accumulate at Klanang, Morib and Batu on the coast, as well

as the inhabitants of the more thickly populated mukims of Bandar, Jurga, Telok Penglima Garang, and Tanjong Duablas. On Monday (15th) I accompanied Messrs. Greig and Nissen, on a visit to Tanjong Ru. Arriving at this well-known point in the afternoon, after a long row and a walk along the sandy beach, we penetrated for upwards of a mile into the mangrove, but though we came upon small stretches of land where nibong and rattan were growing, the land appeared to be too low in this locality to grow anything but coconuts, and we had no time to reach the higher land in the interior of the island before nightfall, and so returned to Jugra. Next day (16) Messrs. Greig and Nissen visited Morib, and on Wednesday they went up by river to the river end of the Sungei Buaia Road and returned overland, reporting the upper end of the roads as being in a very bad state. I had no time to accompany them being engaged on the annual report. During the rest of the week Mr. Greig was prospecting at Klanang; Mr. Nissen returning to Klang on the 19th."

"TEA PRODUCING COMPANIES OF INDIA AND CEYLON."

Such is the title of a compact volume received by the mail from the compilers Messrs. Gow, Wilson & Stanton, the well-known Tea and Share Brokers of Rood Lane. The book is one of 172 pages octavo and as it shows the history and results so far of all the Indian and Ceylon Tea Companies, capitalised in sterling, it cannot fail to prove useful. From the preface we copy two sets of figures of interest:—

	Acres under Tea.	Acres in bearing.	Labour employed.	Crop produced lbs.
1895				
Indian	450,000	375,000	600,000	135,500,000
Ceylon	305,000	262,000	290,000	98,000,000
	755,000	637,000	890,000	233,500,000

The following is a summary of the capitalisation and of the working results of the year 1895 of 56 Indian Tea Companies, which may be said to be in *full working order*, and consequently their aggregate figures have a value as establishing some sort of a standard:—

Number of Companies	Extent of Cultivation Acres	Paid-up capital involved and debentures subscribed £	Cost to company per acre £	Crop produced lbs.	Av. lb. per acre	Total profit earned £	Profit per lb. of Tea p	Profit on capital employed %
56	152,547	6,907,000	45	58,476,132	425	538,349	2.21	7.157

A similar representative table cannot be given for Ceylon, as so many of the Companies are interested in other products besides tea.

Another quotation is encouraging:—

In regard to the future of the industry, two features present themselves for consideration:—*First.*—It may be taken that there is a natural average increase in the consumption of tea in this country to the extent of from 4,000,000 to 5,000,000 lb. per annum, and *Secondly.*—That markets outside the United Kingdom are continually expanding in the use of Indian and Ceylon Tea.

Then follow the 100 pages with particulars of Indian Companies, while a second division deals with some 52 Ceylon Companies alphabetically arranged, giving as a rule capital, debentures, name of directors &c., history, situation and area, results and dividends, and about accounts, voting

power, transfer forms, &c. We take the following notice from the *Home and Colonial Mail* :—

THE TEA-PRODUCING COMPANIES
OF INDIA AND CEYLON.

Under the above title Messrs. Gow, Wilson, and Stanton, who are tea share brokers as well as tea brokers, have issued a handy volume, which will be of great value to investors in tea shares and all interested in tea. It gives the history and results of the tea-producing companies of India and Ceylon, which are capitalised in sterling. In a preface to the volume it is pointed out that about £35,000,000 of British capital is invested in tea, and the book gives the most interesting *personnel* and data based on the latest obtainable results of the working of these companies. Attention is called to the fact that tea companies have been seldom saddled with extravagant promotion expenses, that nearly all these tea concerns are directed by business men and not mere guinea pigs, and also that these companies place unusually full and lucid yearly accounts before shareholders. These and other facts concerning the development of the tea industry, known perhaps to many of our readers, but not to the general public, cannot fail to prove of the greatest value in stimulating the interest of the investing public in tea. The book is most welcome, and we congratulate Messrs. Gow, Wilson, and Stanton upon its compilation and issue. It is published at the price of one guinea.

We have grumblers sometimes about the price of a Ceylon Handbook and Directory of 1,200 to 1,500 pages; but we feel sure merchants and others do not grudge the guinea for this book of 172 pages.

KELANI VALLEY TEA ASSOCIATION,
LIMITED.

The following is from the report of the board of directors, to be presented to the shareholders at their eleventh annual ordinary meeting, to be held at the office of the company on the 13th inst. The directors herewith submit to the shareholders the report and accounts of the company for the year ending December 31, 1896. During the past year no additions have been made to the company's acreage, but about 50 acres of native lands have recently been bought in order to obtain a satisfactory site, with good water power, for the new joint factory for Wereagalla and Parusella, which will shortly be erected in place of the factories now existing on the two estates, and which will tend to economise the cost of manufacture. The total crop secured from the four estates amounted to 6,38,145 lb., against an estimate of 566,000 lb., and showed an increase compared with that of 1895 of 40,950 lb. of tea, while the average yield for the four estates was 615 lb. an acre. The factories and machinery continue in efficient order, but as on previous occasions, the directors have written 10 per cent off their cost for depreciation, and the amount, £670 1s 6d; appears in the account. Although the crop is in excess of the estimate, and of that secured last year, the results of the company's working have not been so satisfactory as might have been expected, and show a considerable shrinkage from those realised in 1895, which is to be accounted for: 1. Owing to the Degalessa tea having, for a time, not maintained its usual standard of quality. 2. By lower markets and higher rate of exchange. 3. By reduction in the Ceylon receipts from the manufacture of tea for neighbouring estates, and owing to rice having been supplied to the labour force at its approximate cost. The company's net profits for the year, after deducting the sum of £670 1s 6d written off for depreciation, amount to £1,664 13s 5d, which with £118 11s 8d brought forward from last account, leaves £1,783 5s 1d to be now dealt with, and this it is proposed to appropriate as follows: Amount as above, £1,783 5s 1d; interim dividend of 5 per cent paid in September absorbed £813 5s.—It is now proposed to pay a final dividend of 5 per cent. (free of income

tax), making 10 per cent for the year, £813 5s; leaving a balance to carry forward of £156 15s 1d. In accordance with the articles of association, Mr. Donald Andrew retires from the board, and being eligible offers himself for re-election. Mr. J. B. Lauric, C. A., offers himself for re-election as auditor.—*H. & C. Mail*, April 2.

THE STANDARD TEA COMPANY OF
CEYLON, LIMITED.

Sixth Report of the Directors to the Shareholders. To be submitted at the general meeting, to be held on Wednesday, 14th April, 1897, at noon, at the Offices of the Company.

The Directors submit Statement of Accounts to 31st December, 1896. The Profit and Loss Account shows a profit on the working of the Estates in Ceylon of £12,317 11s 9d, which with amount brought forward from last year, less interest and home charges, shows a sum of £11,700 7s 11d available for division. In August 1896, the Directors, under the powers entrusted to them distributed an interim dividend for the six months ending 30th June, 1896, of 5 per cent. (10 per cent. per annum), absorbing £2,800. They now recommend a Dividend at the rate of 10 per cent. (making 15 per cent. for the year) absorbing £5,600; the placing £1,000 against depreciation; £1,500 to reserve; and the carrying forward to the next year £800 7s 11d. The results are not quite so favourable as last year, owing chiefly to less coffee and to higher Exchange. Still the Directors consider the results good, for it was always foreseen that coffee would sooner or later die out, and that Exchange was liable to be far less favourable.

The coffee produced in 1896 was about 321 cwts., which realised about £1,400, or less than half of the produce of 1895. The average Exchange for the Company as drawers in Colombo was 1/2 19-32nd against 1/1 1/2 in 1895, and 1/1 13-32nd in 1894. The difference in 1896 unfavourably affected the accounts to the extent of about £1,000. The Tea from the Company's Uda Pussellawa properties sold during 1896 maintained in Mincing Lane the same distinguished position it has hitherto occupied. It realised more per lb. in 1896 than in 1895, though the market average for Ceylon Tea was lower. For this much credit is due to the Manager at St. Leonards.

Mr. NORMAN GRIEVE, who has had occasion to travel in the East, availed himself of the opportunity of visiting Ceylon and of inspecting the Company's properties. He reports well of them and of the Estate Managers he saw.

Coneygar of 176 acres, of which 169 acres are under Tea, has been bought from Colonel E. A. Butler, as from 1st January, 1897, or, perhaps, it would be more correct to say, that Colonel Butler has contracted to join and to sell his Estate to the Company for 350 shares of £10 fully paid. The Directors consider this a fair contract, and expect the place to work in well with Gordon and St. Leonards, between which Estate it is situated.

The Company's Properties at the close of 1896 were 3,290 acres, with 1,519 acres of tea considered in fully bearing, viz:—

in Uda Pussellawa—

	acres.	Tea bearing.
St. Leonards	726	
Liddesdale	814	140
Eskdale	240	298
Gordon	386	154
Tulloes	419	165

in Up. Maskeliya—

Gouravilla	} 705	" 614	"
& Up. Cruden			

There are also 160 acres Tea in partial bearing, and some 601 acres in addition planted with Tea. On St. Leonards, Liddesdale, Gordon and Tulloes Estates there is still a certain amount of Coffee interspersed through the Tea.

Mr. ROBERT KAY-SHUTTLEWORTH, the Director who retires by rotation, being eligible, offers himself for re-election. By Order, A. TRAFFORD BROOKE, Secretary. 25, Fenchurch Street, London, 31st March, 1897.

COLOMBO PRICE CURRENT.

THE AGRICULTURAL MAGAZINE, COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* or *May* :—

Vol. VIII.]

MAY, 1897.

[No. 11.]

SEASON REPORTS FOR MARCH.

WESTERN PROVINCE.—Paddy. Preparations for Yala cultivation. Fruits and vegetables tend to be scarce and dear in many parts, though the supply of vegetables was fairly plentiful in Colombo.

The dry weather is to some extent interfering with Yala cultivation.

Central Province.—Paddy. Maha harvest being taken in or over, Yala cultivation commenced in many places. Crop fairly good.

Northern Province.—Paddy. Kalapokam crop taken and thrashing commenced in Jaffna, reaping going on in Mannar, outturn reported good though crop somewhat damaged by flies.

Southern Province.—Paddy. Yala going on in Galle, dry weather unfavourable to growth both here and in Hambantota. Tissa fields are ripe and in blossom.

Eastern Province.—Paddy. Early Munmari harvest on, and a commencement made with Pinwari. Caterpillars have done some damage to the young paddy. Prospects are however good. Cattle murrain dying out in Batticaloa district, only cases of a mild type existing at present.

North-Western Province.—Paddy. Harvesting going on in most places and thrashing also begun; prospects generally good. Murrain in two Korales in the Kurunegala district.

North-Central Province.—Paddy. In some parts Yala ploughing and sowing is going on, while in others the last crop is not quite done with yet. Occasional cases of murrain in Nuwaragampalata.

Province of Uva.—Paddy. Preparation for Maha harvest is going on. Judging from appearances,

good crops are to be expected. Some foot and mouth disease in Yatikinda.

Province of Sabaragamuwa.—Paddy. In the Ratnapura and Kegalle districts the Maha harvest is closing and Yala cultivation commencing; prospects favourable generally.

RAINFALL TAKEN AT THE SCHOOL OF AGRICULTURE DURING THE MONTH OF APRIL, 1897.

KAFFIR CORN.

This cereal which has lately been brought to the notice of the agricultural public in Ceylon through the columns of the local *Examiner*, and concerning which we have received many enquiries, is really an old acquaintance under a new name.

Kaffir corn, also called Guinea corn or the Indian or great millet, is botanically known as *Sorghum vulgare*, and in India as "Jowari" and "Cholum." By the last name it must be familiar to many who at first imagined the

Kaffir corn was something new to the island, where though not systematically grown, it is found in one of its many varieties wherever there are Tamil settlements, as well as in native chenai lands. Among the Sinhalese two varieties of it are known as "Idal-iringu" and "Karal-iringu." Kaffir corn has become a favourite crop in America, Africa and the Australian Colonies, but a few notes regarding the plant as grown in India, and particularly in lower India, should prove useful to our readers.

Referring to "Jowari" or "Juar" Dr. Watt says:—"It is a cereal which, after rice, is perhaps the most valuable single article of food in this country. If Bengal (the great rice-eating province) be left out of consideration, Juar takes the first place as the staple of Indian diet, and ranks a long way before wheat, barley or Indian corn;" and again, "sorghum holds in India a position very much like that of oats in Scotland."

By the natives of India sorghum is regarded as more wholesome than wheat or rice, because more easily digestible. It is ground into meal and eaten as cakes or porridge, and as parched grain is also used in various ways.

Apart from the highly nutritious nature of the grain, which compares very favourably with rice and wheat, sorghum has many good qualities which have led to its extensive cultivation. It grows on most soils, even very poor ones, though soils like those of the black cotton soil of India give the best returns. The more trouble the cultivator takes to plough deeply and work up the soil, the better output is he likely to get, no doubt on account of the firmer roots sent out by the plant. In India sorghum is generally grown as a mixed crop with dhall, green gram, &c. The returns of cultivated crops shows that no less than 25,000,000 acres are devoted to sorghum alone. Taking 6 maunds per acre as the average yield of grain for all India, the total comes up to 150,000,000 maunds or 5,357,142 tons, practically all of which is consumed in the Presidency.

We might write a great deal about the excellence of sorghum both as a cereal grain and as a fodder plant, and how much it is esteemed as such wherever it has been grown. We consider it eminently suited for pure cultivation or for systematic mixed cultivation in most parts of the Island on all high and dry lands unsuitable for paddy. Under irrigation it should succeed admirably in the North and North-Central divisions of Ceylon. It behoves Government to place facilities in the way of cultivators obtaining seeds of the best varieties of sorghum obtainable from India as well as America, and to issue a bulletin giving full instructions regarding cultivation &c., so as to encourage the regular cultivation of this valuable plant by the natives. By such measures it will be doing much towards bringing a large proportion of the high lands now lying waste and in jungle in many provinces under the plough.

By adopting the cultivation of a crop like "Kaffir corn" the people will be made less dependent on their paddy crops which in turn is so dependent on a copious water supply. Our cultivators are much in need of another cereal, and that a dry land crop practically independent of a water supply, natural or

artificial. Kaffir-corn should suit them admirably and also give them better opportunities for practising improved methods of agriculture than the growing of "swamp-rice" affords them.

With the small opportunities for reaching the cultivating classes, we did what we could to bring "Kaffir-corn" to the notice of the villagers by distributing seed from the School of Agriculture some years ago. The small plantation which existed at the school then was established from seed obtained through the kindness of General La Touche at that time resident in Ceylon. There is just one instance how much the school could do if funds and the necessary "machinery" were available to induce the cultivators of Ceylon to better their position. The possibilities of agricultural improvement, we affirm, are very great in Ceylon, but the means of effecting such improvement is wanting.

OCCASIONAL NOTES.

We have had an enquiry with reference to the cultivation of mushrooms, and as the information which was supplied should be of interest to our readers, we give it below:—To grow a crop quickly, it is necessary to engender a moderately lasting artificial warmth in the material employed; yet, if possible, with moderate latent heat only. The place best adapted for their production is a rather damp godown or out-house; in this should be arranged a row of shelves at a short distance from the ground, on which the materials in which the mushrooms are to be grown should be placed to the depth of eighteen inches, and firmly beaten down. The compost best adapted for this purpose is made up as follows:—Fresh horse droppings six parts, cow dung two parts, sheep dung two parts, garden soil four parts, and fresh wood ashes one part. Before these are mixed they should be allowed to dry in the sun for two or three days to take off the excess moisture. After being mixed, and the bed made on the shelves as described above, they should be allowed to remain for five or six days till fermentation commences. As soon as a moderate heat is perceptible the spawn should be added, this is done by making holes in the surface, about 12 in. apart and 3 in. deep; in each of these a small quantity of spawn, about 2 in. square is inserted, after having first been dipped in tepid water; these should be slightly covered with the compost, and the whole beaten down firmly. After a month the beds should be covered with two inches of light rich soil, and the whole beaten down, and then well watered; it will now require no further attention, beyond occasionally watering the walls and floor of the room to promote a damp atmosphere. If properly managed the beds should commence bearing freely in about eight weeks from the time of spawning them. On the plains the best time to start a mushroom bed is from September to March; in the hills from April to October.

With reference to the introduction of new vegetables, lately discussed in connection with agricultural shows, it is interesting to find a record of the first attempt to grow potatoes

in Ceylon mentioned in Digby's Fifty Years in a Crown Colony, vol. ii., page 218; the person referred to in the extract is Mr. J. F. Lorensz (father of Mr. C. A. Lorensz) who was at the time Magistrate of Matara. "During his tenure of office under Government he made several valuable reports on the agricultural condition of that part of the Island with which he was more intimately familiar, and Bennett, in his Ceylon and its Capabilities, mentions the fact that he was the first to try the cultivation of the potato in the Island."

We are glad to hear good accounts of Jadoo from the Superintendent of the Victoria Park to whom we sent a bale of the fibre. Mr. Alwis is greatly pleased with the results which have attended its use both in germination as well as ordinary growth. Among other plants on which the fibre was tried ferns showed up well, and Jadoo is found a particularly suitable medium for orchids. Mr. Alwis used the fibre with a due proportion of soil, and we have ourselves found that it is necessary to mix the two, as when pure, Jadoo would seem to become heated at our temperature. We would again remind those to whom we have supplied samples of the fibre that it must be well comminuted before use. As a mulch for plants grown in the open we found Jadoo answer admirably during the drought that preceded the late rains.

Mr. Cyril Barber who received his training at the School of Agriculture, and has been in charge of "The Grove" Ukuwella, left Ceylon on a holiday trip to England on the 14th ultimo. He returns in six months.

Mr. F. C. Fernando (son of Mr. Austin Fernando of Colombo) who was trained at the School of Agriculture, and afterwards joined the Forestry School, has been appointed Forest Guard at Anuradhapura. Mr. Fernando had a most creditable career in both the Agricultural and Forestry Schools, and we wish him all success.

The following is a list of the Agricultural students who were given appointments in the Forest Department: Messrs. Dissanayake, Thanthonis, Kodippily, Rajapakse, Mendis, Ratnayake, Fernando, Handy, and Weerasuriya. Messrs. De Silva and Wijeyratne have also held acting appointments.

We have heard with regret of the death of Mr. J. A. Kodippily, one of the most promising of the students who were trained at the School of Agriculture. Mr. Kodippily was an officer of the Forest Department.

An Agri-Horticultural Show was held at Nuwara Eliya on the 26th and 27th of March, and, from all accounts, was a very successful exhibition. It is a matter for regret and discouragement to find that the Government could not have seen their way to allow agricultural students the modest concession of travelling free by rail to be present at the Show. The oftener agricultural Shows are held the better for the agricultural interests of the Colony, but we should wish to see a few more Shows organized solely in the

interests of the native agricultural industries, on the lines of the successful Show held at Dalugama some years ago under the patronage of the late Mr. George Wall.

CHEMICAL MANURES.

Not long ago one of the local papers pointed out the evils that may be expected to arise for the want of proper checks on the sale of manures. Fertilizers are essential for successful or continued cultivation of any product whatever, hence in purchasing them we naturally wish to have some guarantee of their purity in order to avoid disappointment afterward. The composition of chemical manures may, of course, differ in different samples from natural causes, and not through the interference of man. If the fertilizing power varies with their composition then the value of manures must likewise vary, and they must not be expected to have a fixed price. No country is free from the unscrupulous dealer, who taking advantage of the good faith of his customers, sells his stuffs at a price higher than their actual value; and if this deception is possible in other forms of merchandise, much more so is it in the manure trade, the quality and value of which is not easily made out. In spite of the addition of sand, earth, coal dust and other adulterants, manures can still be made to preserve the appearance, colour, fineness and even smell of pure articles, though these mixtures have very little value. It is said that in the early days of the manure industry artificial mixtures of no value whatever were fraudulently disposed of to ignorant farmers. Such useless substances not only caused temporary disappointment and failure to those who depended upon them, but brought discredit on the real stuffs which the fraudulent mixtures were intended to represent. Those who dealt in these "frauds" did not anticipate that prejudices once formed, particularly among the less educated, are not easily eradicated, and that they (the dealers) were helping to work their own ruin as well as that of the manure trade; and if a check had not been placed on these "frauds," it is quite possible that the use of chemical fertilizers would have been entirely abandoned by this. Wherever agriculture receives the protection of Government, as it does in every civilized country, there are special laws to regulate the sale of manures. Ceylon is one of the few countries that has no Government institution, which being concerned with all matters agricultural, can offer to give a correct opinion and valuation of manures at a moderate fee. And yet we have representative members of Council calling for the abolition of the present School of Agriculture, which far from being thus threatened, should be aided and re-organized, so that it might bring forth the same excellent results that are produced by similar institutions in other countries. What could be expected from an institution which has no funds to expend in procuring draught cattle, carts, implements, manures, seeds, plants and all the necessaries for making a successful Agricultural School? The wonder is how it has done its work in the absence of all these!

But to return to my subject. The purchasers of manures should not pay for them at random—at so much per cwt., but at a certain rate per unit of the important ingredients contained in

them, in terms of guaranteed analyses which should be furnished by the vendor. The decision as to what manure suits particular crops and particular soils must rest with agricultural experts and institutions. Where fertilizers have to be mixed before use, it is important that those ingredients should not be brought together which will react upon each other so as to cause the loss of valuable manurial elements. Where stable manure is not obtainable or can only be obtained or applied at great cost, chemical fertilizers must of course be resorted to, though it is best that the two should be used together. Plants will not thrive the better for one essential element of plant food being in excess of the others but require them all in due proportion. By thoughtlessly adding a special fertilizer which might just be supplying the element which is already abundantly present in the soil, results wholly different from those expected will be got. Special manures will create a larger consummation of the elements of plant food *in the soil* and not supplied by the manure, so that the composition of the soil will be materially altered by its reserve materials being drawn upon. The effect of such special manuring is thus only of temporary benefit and ends by destroying the equilibrium, so to speak, of plant food in the soil, and so tending to interfere with the proper growth and development of the plant. To avoid such results intelligent cultivators have been making trials with different special manures, alone and mixed, but these experiments require to be carried out with the greatest possible care to be of any value. In the absence of any other agricultural establishment in Ceylon, I think the School of Agriculture (on a better site, and with average soil) should give itself up to energetically carry out experiments with different products. Given the chemical composition of the soil experimented upon, the result of these trial should provide a basis to work upon, and I am sure will be very acceptable and beneficial to the general agricultural community.

C. Z.

THE MERITS OF NATIVE DRUGS IN VETERINARY PRACTICE.

Certain drugs are commonly distinguished by the epithet "Native," and certain others "European." This is, in many instances, an arbitrary division, the crude drug being often termed "Native" and its refined preparation "European." Where the object of the refined preparation is to get rid of some deleterious substance or quality found in the crude drug, the former is, no doubt, preferable to the latter in proportion to the hurtful nature of the principle got rid of from the crude drug. In instances where a refined preparation contains the curative principle of the drug in an active and highly concentrated form and is intended to produce a prompt and sure effect, such a preparation is to be preferred especially in diseases which present urgent symptoms.

There are, however, many diseases of cattle, sheep and goats, in which it would be advantageous to use native drugs. Some vegetable drugs can be obtained almost at the very door of the villager without costing him a single

cent. In a fertile tropical country like Ceylon which abounds in vegetation of a vastly diverse nature, the number of native drugs obtainable for the treatment of cattle must certainly be great. Some of these are well known and are recognized even by European Veterinary Surgeons. There are others which are not so popular, and are known only to the native *vedarala*. Some insight into native medicine with a view to find out these drugs is highly desirable. For, although native treatment as generally practised is more empirical than rational, it cannot be denied that there are several drugs used by the *vedarala* which possess valuable healing properties. *Appropos* of this fact the following remarks occur, in a description of the native medicinal plants of Ceylon sent to the Colonial and Indian Exhibition of 1886:—"It must be admitted that the materia medica of the Sinhalese will compare favourably in many respects with the Pharmacopœia of the most enlightened countries of the West. Not only is every class of medicine well represented, and supplied in profusion by the boundless prodigality of nature in Eastern tropical climes, but some of the vegetable productions are valuable enough to deserve a place in the medicinal resources of Western science, while very many can easily and usefully replace the more expensive drugs of the same class which are imported into the Colony for use in hospitals."

Economy is an important consideration in the treatment of cattle. Things have to be done on a strictly commercial basis, and the question "Will it pay?" has to be seriously considered. The cattle-owner will find it an unprofitable concern when the cost of the medicines comes to more than the value of the sick animal. Even when the medicines do not cost quite so much, expensive drugs are undesirable, as the ox requires, for each dose, at least 15 or 20 times the quantity of medicine required for a human patient.

When a number of village cattle in a herd have to be treated, as in the case of an epizootic for instance, the owner can hardly afford to pay for expensive drugs; and where the percentage of cures will be necessarily small, as in a virulent outbreak of rinderpest, treatment with expensive drugs is out of the question altogether. For the small number of recoveries, which may be attributed to the action of the medicines administered, must bear the expense of the treatment of the whole number. It has, therefore, been recommended by veterinary surgeons in India that if anything like satisfactory results are to be obtained from the treatment of rinderpest, the drugs used must be as inexpensive as possible.

Native drugs are to be preferred for the treatment of cattle not only on the score of economy, but because they are much more easily accessible in out-of-the-way places. They can either be had from the jungle, or be purchased at the bazaar or boutiques. Under the class of bazaar medicines are also included mineral medicines in a more or less crude form.

Some vegetable drugs sold in the bazaar are, however, old and worthless. In the case of rare or valuable vegetable drugs that cannot be preserved raw for any length of time, it is desirable that some cheap standard preparations such as tinctures or extracts be made and preserved for use.

Speaking generally, bazaar or native drugs are more bulky and have to be given in larger quantities than European drugs possessing similar therapeutical properties. This, so far from being a disadvantage, should be considered a desirable quality in medicines intended for cattle. The capacious and complex nature of their stomach and the bulky nature of the food they eat, suggest the advisability of giving bulky medicines to cattle.

In the treatment of horses, however, native drugs are not as useful as in bovine practice. Horse owners being, as a rule, comparatively wealthy they can afford to use the more expensive European medicines, and often prefer to do so. Some veterinary surgeons consider it a retrograde step to use bazaar medicines in equine practice, and there is now a tendency to employ such new therapeutical preparations as Antipyrin and Phenacetin.

In prescribing medicines for the dog bulky and crude drugs are objectionable, and the agents used should be as palatable in order to avoid the risk of their being expelled from the stomach.

E. T. HOOLE.

Anradhapura, 22nd March, 1897.

DR. KOCH'S INVESTIGATIONS INTO THE CAUSE OF RINDERPEST.

In continuation of Dr. Koch's Reports given in the last issue of the *Agricultural Magazine*, we give the following two further communications referring to his researches into the cause and cure of Rinderpest, being the third and fourth of his reports upon the subject. The last contains results in regard to protective inoculation of the utmost importance to stock owners. We are again indebted to the *Agricultural Journal* of Cape Colony for the text of these reports, the date of the third report being January 31st, and that of the fourth, 10th February, 1897:—

DR. KOCH'S THIRD REPORT.

I have the honour to submit the following report upon the progress of my work on the Experimental Station at Kimberly. In my last account I had stated that I had inoculated two head of cattle with the cultivations given to me by Dr. Edington, and considered by him to contain the microbes of rinderpest. But it still remained for me to prove if the beasts operated upon were really susceptible to the disease. For this reason we inoculated them after the above mentioned period with rinderpest blood in our usual manner, with the result that on the fourth day an elevation of temperature appeared in the same way as noticed in all animals when thus inoculated. They now manifest the typical symptoms of rinderpest. There can be no doubt that these animals contracted the disease as a result of the inoculation, and I feel therefore justified in saying that Dr. Edington's microbes are not the cause of the cattle plague.

The inoculation experiments in sheep and goats were continued to the seventh generation, and in order to ascertain whether the disease produced was really rinderpest, I inoculated one heifer with the blood of an Angora of the second generation. This inoculation gave rinderpest to the animal, but though the course of the disease was rather a severe one, the beast recovered, and is

now again in good health. This raised the hope that the previous passage through goats may somewhat mitigate the disease in cattle, and I therefore infected four head of cattle respectively from a goat, an Angora, a merino and a Cape sheep, after the virus had passed five times through these animals. These four animals became diseased almost simultaneously after a surprisingly short period of incubation, and three of them have succumbed after an illness of seven and eight days.

The course of the disease in the two animals infected with the blood of the merino and Cape sheep was so violent and the pathological lesions as revealed by the *postmortem* examinations of such a severe nature, that I cannot believe in any attenuation of the disease as far as sheep is concerned, but am rather inclined to think that it would be cultivated in a more virulent form.

The hope that sheep may be used for the preparation of a vaccine proved therefore illusory, but on the other hand it seems not impossible that this increased virulence produces also a higher degree of immunity that is derived from the recovery from the natural infection, and that these animals may be more valuable for immunising experiments. Rather different was the result of the other two animals, which were inoculated with blood from an Angora and from a Cape goat, for the first one showed a high temperature only during five days, scarcely any diarrhoeic evacuations, and has now quite regained its health. The other one, into which I injected blood from the Cape goat, was a weak animal and did not recover; but on making the *postmortem* examination, I found that the pathological changes in the stomach and intestines were much less marked than in those animals infected with sheep blood.

In accordance with these observations, I think it probable that the rinderpest virus, after a repeated passage through goats, becomes actually but slowly attenuated, and I propose, therefore, to continue these experiments. As none of these small ruminants succumbed to the disease, I thought it advisable to destroy an animal for internal examination.

[The *postmortem* examination on the merino selected showed characteristic evidences of rinderpest.]

"Many farmers are of opinion, and this I have seen myself, that these animals may graze with diseased cattle without contracting rinderpest, while on the other hand some have reported that the pest had appeared in their flocks of sheep and goats, and carried them off in large numbers, after it had already disappeared amongst the large stock. My opinion on this subject is that sheep and goats at first contract rinderpest in such a mild form that it cannot be diagnosed, but that the pest gradually becomes more virulent through being constantly propagated through these animals' systems. Then the symptoms become naturally more distinct, and in some cases the disease may even take a fatal course.

For the purpose of mitigating the rinderpest virus by means of chemicals, I have been making the following experiments: I mixed rinderpest blood with glycerine in varying concentrations and also with phenol, and injected these mixtures hypodermically. As the animals treated in this

manner did not contract rinderpest as a result from the inoculation, there can be doubt that even the glycerine exercised a destructive effect upon the rinderpest virus, a circumstance which is the more remarkable as almost all infective materials, particularly the small-pox lymph, are not destroyed by it, but even preserved. After a sufficiently long time had elapsed I injected virulent rinderpest blood, and this second inoculation produced, after the usual period of incubation, genuine rinderpest. The phenol-cow, however, remained healthy, and it is not impossible that the first injection had a protective influence. I therefore repeated this experiment, and hope soon to be able to report to you on the result. Being aware that distilled water destroys the red and white blood corpuscles, and thinking that it may possibly also injure the rinderpest contagion, I diluted rinderpest blood with this liquid in a proportion of 1:20, and inoculated one beast with this material. The animal thus operated upon showed the first symptoms of rinderpest later than usual, but the course of the disease was just as violent and its termination fatal. In order to find how far the dilution of the blood can be carried without damaging its infective qualities, I diluted fresh rinderpest blood with the so-called physiological ClNa solution (0.6 per cent.) in a proportion of 1:500, and injected one cubic centimetre of this mixture. In spite of the extremely small quantity of infective material, which the animal received subcutaneously, viz., 1.500 c.cm. of blood, it contracted rinderpest after exactly the same time, and manifested the same malignant symptoms as those animals which had received 10 c.cm., a dose 5,000 times larger.

A most noteworthy experiment was the following:—I dried 10 c.cm. blood by the moderate temperature of 31 deg. C. during a period of four days, and after having dissolved it again in water I inoculated one head of cattle. This beast remained perfectly healthy, and I may therefore safely express the opinion that desiccation, even during such a short space of time, renders the rinderpest virus non-effective. This is highly important for the farming community, and I intend, therefore, making similar experiments with other media, particularly the skin and the faeces, in order to ascertain the influence which desiccation has upon them. I have already stated that blood, dried and dissolved again in the above-mentioned manner, did not produce any ill-effect upon the animal inoculated, and have now to add it also had no protective action, for the beast contracted rinderpest readily, when I subsequently inoculated it with fresh blood. Of all the animals which as yet have been suffering from rinderpest on the experimental station, four have recovered.

In my previous report I have already mentioned that they would serve for immunising experiments, but I thought it first necessary to convince myself if these animals were really perfectly safe against new infections. I therefore inoculated with rinderpest blood two "salted" animals and at the same time a fresh one. The result was, that the latter died of rinderpest, whilst the other two never evinced the least symptoms of the disease, not even the slightest rise of temperature. Having thus proved the thorough immunity of these animals, I drew from the stronger one a large quantity of blood and inoculated one beast with 100 c.cm. serum. After this animal, which on the next day

was inoculated hypodermically with 1.5 c.cm. of rinderpest blood, had remained well for six days, it was re-inoculated with a larger quantity of virus, viz., 1 c.cm. of rinderpest blood. Another animal was vaccinated with a mixture of both serum and blood, which previous to the operation was kept for one night in the ice-chest. This animal likewise did not show anything amiss during the next six days and was then on the seventh day inoculated with a large quantity of rinderpest blood. Both these animals withstood even the second inoculation without any injurious result. These experiments clearly demonstrate that the serum of immune animals possesses a certain protective power, but before having made further experiments it is not possible for me to say for how long a period this immunity will last and if this method can be carried out *in praxi*. I have tried to communicate rinderpest to other animals than ruminants on a somewhat extensive scale, but have not found any other species of which I could with certainty express the opinion that they are liable to the pest.

With reference to birds I may state without any hesitation that they are not susceptible. We have experimented on fowls, doves, pigeons, guinea fowls, and a crane, but with negative results. An eagle and a secretary bird I have fed for weeks on intestines taken only from rinderpest animals, but I have not observed the slightest ill-effect upon either of them. Dogs proved themselves perfectly immune. I also did not succeed in giving the pest to donkeys. Rodents, such as mice, guinea-pigs, rabbits, are also not susceptible. In pigs only it seems as if it were possible to transmit infective material successfully, but our experiments in this respect are as yet not complete.

The arrangements on the experimental station have proved themselves to be perfect, for we had no case of spontaneous infection since reporting to you last.

Another visit to several rinderpest farms in the Free State, and a small and quickly checked outbreak of rinderpest in a suburb of Kimberley afforded me again a splendid opportunity of making further observations and of procuring new material for inoculation and examination.—

DR. KOCH'S FOURTH REPORT.

I have the honour to report herewith several important facts resulting from my investigations on the Rinderpest Experimental Station.

In my last report I was already in a position to inform you that blood serum of cattle which had already recovered from rinderpest had a certain immunising effect upon the healthy stock when inoculated with it.

Its protective properties, however, are not very great, for 100 c.cm. of such serum are required to protect an animal against an inoculation with a small dose of rinderpest blood. This immunity is in its nature merely a "passive" one, and will only last during a short period.

For protective inoculation on a large scale such serum is not applicable, but I succeeded in immunising within a fortnight several animals by means of a mixture of serum and virulent rinderpest blood to such a degree that they were enabled to withstand an injection of 20 c.cm. rinderpest blood, a ten thousandth part of which is a fatal dose.

From this fact I judge that the immunity of

these animals is of much higher degree, and I believe it is an active immunity equal to that of a beast which has contracted rinderpest and recovered.

It is particularly important to know that only 20 ccm. of such serum are required to immunise one animal, and therefore one litre (nearly 1 $\frac{3}{4}$ Imperial pint) suffices for fifty head.

My further investigations concerning this *modus operandi* will aim at finding

If this immunity is obtainable in a still shorter period.

If a still smaller dose of serum will suffice and if it may be attained with but one injection.

A second and equally important fact is that one is able to immune healthy cattle with bile of such that have succumbed to rinderpest. In this case only one hypodermic injection of 10 c.cm. is sufficient.

This immunity sets in on the tenth day at latest, and is of such an extent even four weeks afterwards 40 ccm. of rinderpest blood could be injected without any injurious result. I therefore conclude that the immunity produced in such a manner is of an "active" nature.

The local result of an injection is merely a hard, somewhat painful swelling of a size of a man's fist, and which gradually disappears in the course of a few weeks, provided, however, that the bile is not in a state of decomposition as is not uncommon when an animal suffers from rinderpest. Under such circumstances an abscess may form, and which, however, does not seem to be detrimental to the process of immunisation.

Both these above-mentioned facts convince me that rinderpest can be eradicated with but little difficulty, and within a comparatively short time, by putting these methods into practice.

The method of immunising cattle with serum may be used in order to separate from infected areas those tracts of country which are still free from the scourge by means of forming a broad belt between them in which all the cattle are inoculated with the vaccin.

The protective properties of the bile will be of inestimable service in infected parts. Nearly every case of rinderpest supplies a greater or lesser quantity of vaccin for those animals which are still healthy.

I cannot but urge upon you the importance of bringing this method immediately to the notice of those cattle-owners whose animals are suffering from, or threatened with, the disease, as I am sure thousands of cattle may daily be saved by its application.

The *modus operandi* is very simple in both these methods, but it will nevertheless be desirable to teach as early as possible Veterinary Surgeons and other persons fitted for such work.

I am willing to give a course of instruction in the Experimental Station in Kimberley.

It may further be advisable to at once take into serious consideration the establishment in other parts of the country of branch stations of the Central Laboratory in Kimberley, to furnish them with the necessary equipment, and to appoint suitable persons to take charge of them.

With reference to your telegram dated 6th instant, I beg to add, that I do not consider it any more essential to experiment upon camels, as our

experiments performed on cattle have been so favourable.—(Signed) R. KOCH.

POTASH IN PLANTS AND THE NEED FOR SPECIAL POTASH FERTILIZERS.

Some months ago we referred to the belief that was gaining ground in agricultural circles that the value of potash in agriculture was not correctly estimated and that much benefit was to be expected from a more extended use of kainit and other special potash fertilizers. In countries where no particular use is made of ashes, it has been thought sufficient to use them for supplying all the potash that is considered necessary for cultivated plants. The amount of potash in woodashes and other refuse substances used for suppling this ingredient is never a uniform quantity. Thus wood ashes that are supposed to contain 5 per cent of pure potash are frequently found to have not more than 2 or 3 per cent, and the difference in the potash value of wood ashes cannot be detected by its appearance.

We have just been favoured with no less than three publications with reference to the value of potash in agriculture, two referring to the results obtained in the United States, and one dealing with experiments in Britain. In the last mentioned, entitled "Potash Manuring—its value to British Agriculture," the authors, Dr. Aikman and Prof. Wright, state that the necessity for potash manuring has not, hitherto, received the recognition that has been accorded in the the case of other two important plant foods, and that they (the authors) have set themselves to examine the cause of this comparative neglect of the potash manures, and to consider how far the neglect is justifiable in view of the results of a number of recent experiments.

It has not yet been made quite clear what function potash exactly performs in the plant, but that no plant is able to grow without it has been proved again and again. Soda, which is an essential element of plant food, was at one time thought capable of replacing potash, but this was shown to be false. No other substance can replace potash which is a necessary constituent of all plants. It is a noteworthy fact that even in plants grown in the vicinity of the sea potash is more abundant than soda, although the latter salt is thirty times more abundant in sea-water than the former. The quantity of soda varies very considerably in plants according to circumstances, but nothing like the same variation is found in regard to potash. Its functions in the plant though not well understood are known to be important—more important than those of any other ash constituent except phosphoric acid. According to Liebig it plays an important part in the distribution of the carbohydrates throughout the plant. It is always to be found in the actively growing parts of vegetation, as in the growing buds and shoots, and exists in relatively large proportions in the seed. In wheat grain, for instance, potash forms 31 per cents of the ash, while in the stem it forms less than 14 per cent. In the ash of plants potash occurs chiefly in the form of phosphate, chloride, and carbonate. It is believed that

most of the potash is absorbed in the form of sulphates and phosphates, and probably also as silicate. In whatever form it is absorbed it has at any rate been proved beyond doubt to be absolutely necessary for the growth of crops.

It is a generally accepted principle of manuring that potash manures need not be applied to clay soils which are considered to always contain a sufficiency of the constituent. Actual analyses and experiments on the field have shown, however, that this reasoning is not quite reliable. Though the presence of a fair proportion of clay in a soil may be accepted as a guarantee of the presence of potash, it is not always so. There are soils containing much clay that do not contain much potash. It has been found by experiments that potash manures produced a large increase of crop, though the field to which the manures were applied was of a stiff and clayey nature, such as would be described as a stiff clay loam.

Again, potash may be present without being effective. The ordinary methods of chemical analysis can determine the amount of potash in the soil, but of that amount it may happen that the greater proportion exists in a condition in which crops are unable to make use of it. The ordinary solvent agencies in the soil have but a limited power of dissolving insoluble compounds in which it chiefly exists, and that too only on the limited region of the soil particles with which they come into the most intimate contact. Hence a soil may be rich in potash, and yet that potash, or the greater part of it, may be quite unavailable, or be available in quite insufficient quantity for the needs of the growing crop which might, therefore, largely benefit by the application of an artificial potash manure. Before it can be safely concluded, from its composition only, that a soil will not be benefited by potash manures, it is necessary to know not only that the soil contains much potash, but that it contains it in a form in which it is readily available for the use of plants.

Some soils contain as much as 3 or 4 per cent and more of potash, while the soils which are generally poorest in this constituent are sandy and peaty soils, and these latter are generally found to produce a considerable increase of crop by the use of potash manures.

The variation in the amount of potash soluble in water in a soil usually ranges between a thousandth and a hundredth per cent. The remainder is usually present as hard insoluble compounds which are not available for the plant's needs, and only very gradually, with the lapse of time, become so. There are, however, certain compounds which, while not soluble in water, are believed to be more or less available for the plant. The water, in the soil by virtue of carbonic acid and certain other organic acids which are dissolved in it, has a greater solvent power on mineral substances than pure water, and this solvent power is further aided by the acid nature of the juices in plant roots. A striking instance of the power of roots to dissolve insoluble substances can be seen in nature by tracing the roots of such plants as ferns that appear to cling to the bare surface of rocks.

Dr. Bernard Dyer, who has been endeavoring to estimate the dissolving power of soil water and plant roots on mineral substances such as potash,

has come to the conclusion after a large number of determinations, that the sap acidity of roots is equal to a one per cent solution of citric acid. Testing certain soils with a solution of this strength he has found that the amount of potash available is very much greater than that indicated by testing it in pure water. Thus in two soils, in which the total amount of potash present was about $1\frac{1}{2}$ per cent, the available potash was four thousandth and three hundredth of a per cent respectively. This is much more than could be dissolved by pure water, yet this result also shows that only a very small proportion of the total potash in the soil may be regarded as immediately available to plants. Of this small proportion available, it must be noted also that a loss by drainage of the soluble potash in the soil is constantly going on to a greater or less extent.

In our next issue we shall continue our notice of the interesting pamphlet referred to by Dr. Aikman and Prof. Wright, so as to place the latest information with reference to potash in soils and potash manures at the disposal of our readers.

RUBBER GROWING.

The *Australian Tropiculturist* for March has a special article on this subject, referring to the industry as a new fortune-promising one and calling upon the Government to plant up all available coastal areas, since "flat alluvial river lands are regarded as the best soil for Indiarubber trees."

Regarding *Castilloa*, it is said that the tree thrives best in moist but not marshy forests, on a warm sandy clay."

"For each plant a hole should be dug 3 ft. in diameter, and 1 ft. deep, and filled with fine loamy soil to which a little sand has been added. The mixture should be well trodden down and watered night and morning for two days, when it is ready for the young *Castilloa*, which must be placed in its new bed at exactly the same depth as in the nursery; if it is weak, a stake support is very desirable."

To this might be added that the young plants should be at least 15 feet apart. But it cannot be reiterated too often that the locality must be a sheltered one.

A curious fact about the *Castilloa* is that frequently natural ropes of rubber are found hanging from the tree formed by the tapping of the bark by wood-peckers, the exudation of the creamy sap that coagulates as it trickles slowly down.

The method of harvesting the sap is as follows:—Immediately below the first branch a horizontal canal is cut, V shaped; from the point of the V downwards a perpendicular canal is cut till it joins another horizontal V, and so on down to the ground. The sap is guided into a receiver, and the water in it evaporates. Evaporation may be assisted by artificial heat, and coagulation is forced by an agent. Then Indiarubber is formed. The canals should be plastered with mud or clay, to protect the life of the tree.

The quantity of rubber produced from the sap depends largely on the coagulating agent used. Sixty per cent. ought to be converted into rubber. An ounce of alum in a pint of water (not Imperial pint) is a good agent; a weak alcoholic solution is better, because speedier.

The commercial profits in the rubber trade are so enormous as almost to challenge belief. The traders who deal with the natives frequently purchase for mere civilised trumperies hundreds of pounds' worth of rubber; these sell at the last-named price to the merchants; what the merchants make would be difficult to estimate. So long as this system is open to the enterprise of the New Guinea pioneers trading in the interest of Melbourne and Sydney syndicates, *they* are not likely to trouble to preserve the trees!

As one object of this article is to show that rubber-cultivation may be more profitable in the long run than rubber-piracy, it is necessary to quote figures as to profits made by such cultivators. Here, unfortunately, one has to go to the other side of the world for starters. A typical estimate of a 500-acre rubber farm in Nicaragua made the eighth year's profits £44,337 10s! "And the yield increases every year, with no outlay except for weeding and harvesting."

This calculation could scarcely apply to Queensland, because the cost of even kanaka labor would be more than that of Nicaraguan. But in a plantation of trees planted 15 ft. apart, coffee, sugarcane, and other shade-loving plants, yielding yearly crops, might be sown.

The life of a rubber-tree has never been exactly stated, but the New York *World* mentioned in 1892:—

"Three young trees transplanted from the forest to a cultivated field in Soconusco, Mexico, are now said to be seven feet in diameter, and have yielded rubber for more than 35 years; the present product averaging more than 50 lb. of gum per year."

The average increase is estimated to be 1 lb. of rubber for each year of the tree's life, up to a certain age. Trees tapped in the wet season are said to yield five times as much milk as when tapped in the dry.

GENERAL ITEMS.

A correspondent writing on scour in calves to an Australian contemporary gives the following remedy:—"Take a two quart pot and fill it loosely with young gum leaves; pour in as much water as it will hold and boil for a quarter of an hour. Mix a tablespoonful of flour and one teaspoonful salt smoothly in as much of the infusion (when cool) as will half fill a lemonade bottle, and give it to the calf twice a day, a little less or more according to its age. I have never lost a calf under this treatment, though it may have to be continued several days or a week."

In a review of the agricultural progress of India in the *Indian Agriculturist*, we read that "The most important matter is the proper education of the agriculturist, for the Government of India still hold to the opinion expressed in

the opening resolution of 1881, and again in the resolutions convening the Conferences of 1890, 1893, and 1895-96, that no important reforms can be safely or widely introduced into the agricultural system without the general co-operation of the farming classes, from whom intelligent and willing aid cannot be expected 'until their education has been so directed as to enable them to appreciate, and where expedient to adopt, the results obtained by the systematic and continuous inquiries of experts.' This view has been strongly confirmed by the various Conferences which have recently discussed the question, and has been supported by all local governments and administrations."

In Agricultural Ledger No. 23 on iron ploughs we read that in a great many parts of the Madras Presidency, during the last 10 or 15 years, iron ploughs have come into use and are now generally preferred to the heavy country ploughs for bringing waste and under cultivation, as well as for clearing cultivated land of deep-rooted grasses at intervals of three years and upwards.

All ryots who have tried them are of opinion that with iron ploughs a given area can be ploughed much sooner than with the heavy wooden implement, while the cost of thoroughly clearing land with hand implements is R15 or R20 per acre, the cost by means of the iron plough is not more than one-fifth as much. Experienced ryots say that the productiveness of land is not materially increased by deep tillage with iron ploughs, in the first year after the ploughing, but that it is in subsequent years. Iron ploughs are, therefore, highly appreciated for the comparative cheapness and rapidity of their work, and are often hired by the ryot at about 6 annas a day, or from R10 to R15 if hired by the month... Many a man who has no land whatever purchases an iron plough simply with the intention of making a profit by hiring it to the ryots.

We have to acknowledge the receipt of the following:—Agricultural Journal of the Cape of Good Hope; Sugar Journal and Tropical Cultivator (Queensland); Agricultural Gazette of New South Wales; The Central African Planter; Australian Tropicalist (Brisbane); Indian Agriculturist; Indian Agricultural Ledgers Nos. 39, 40 and 41; The Rural Californian; Agricultural Gazette (Barbadoes); The Ceylon Review; St. Thomas' College Magazine; Royal College Magazine; Our Boys; Report of the Department of Land Records, Agriculture, Madras; The Scottish Farmer; Journal of the Royal Agricultural Society, England; Proceedings of the Royal Physical Society; Proceedings of the Highland and Agricultural Society of Scotland.

We are in receipt of a copy of an elementary work on English Grammar, edited by Mr. L. E. Blazé, B.A. The little work supplies a decided want, and does credit to the author. We want more of these "indigenous" handbooks, written by competent authorities, and specially adapted to the requirements of the Ceylonese youth.

COLOMBO, JUNE 1ST, 1897.

|No. 12.

“PIONEERS OF THE PLANTING ENTERPRISE IN CEYLON.”

(*Second Series.*)

JOHN TYNDALL,

PIONEER PLANTER, VOYAGER AND EXPLORER ; ALSO AS “JACK
TYNDALL”—HUMOURIST AND RACONTEUR.

HE subject of our Memoir—universally known among his many friends, and indeed all over Ceylon, as “Jack Tyndall”—was educated at Elizabeth College, Guernsey, and H.E.I.C. Military College, Addiscombe. He came out to India in February 1845, and in the same year crossed over to Ceylon. He lived with Mr. G. S. Duff, Manager of the Oriental Bank, Colombo, for a month, and then took up a post on Sir John Wilson’s estate, Nilambe, as assistant under Mr. Louis Bird, where he remained for three years. Writing of this time, Mr. Tyndall says:—“My bungalow was called Polkavilla. In those days I did not kill myself with work, taking life remarkably easy, and I was much appreciated in consequence. These three years, I may say, were the happiest of my life ; and I always look back to them with a feeling of great pleasure, and to my *Peria Durai* and his charming wife, Annie Bird, I attribute most of this by being thrown into their society.” Towards the middle of 1848 things began to look very “blue” and depressing in Ceylon ; the value of Coffee depreciated ; failures of well-doing and respected firms in Colombo and Kandy shook confidence in the Island’s prosperity, followed a short time after by what was called the “Kandyan

Rebellion,” which might have been squashed—says Mr. Tyndall—by a dozen policemen, but led to troops being sent from India, and a foolish panic. “It was about this time that I went down to Galle for the purpose of meeting my sister and brother-in-law who were on their way to Hongkong. The steamer they were coming out by (P. & O., of course, the only line) broke down somewhere on the Alexandria side, and my stay was protracted from day to day in expectation of the Suez steamer’s arrival. (There was no telegraph in those early days.) Bogaars Hotel was then the chief hostelry (‘Grand Oriental’ not dreamt of), and though the proprietors did their best, the *cuisine* was not quite up to the mark, and with the house full of passengers, supplies fell short and complaints became day by day more aggravating. Amongst the hotel guests awaiting the steamer were Mr. W. W. Cargill, the chief originator of the Oriental Bank Corporation, Limited, and Mr. W. Ayrton, then a renowned Bombay lawyer, on his way to Calcutta, and who afterwards became M.P. for the Tower Hamlets, and Commissioner for Public Works in the Palmerston-Gladstone Ministry. As I had become very intimate with them, one evening when the conversation had again turned on the wretched food supplied, I said, ‘Do you like snipe ? for I know there is some good shooting in the paddy-fields away from

here, and I'll be bound to get some, and we will have a rare snipe curry.' 'By jingo,' said Ayrton, 'nothing could be better, Cargill and I are going out at daybreak to visit Parada,' (then Lord Elphinstone's Sugar Estate). 'We will drop you by the way at what you may fancy is likely ground, and call for you at the same spot, and bring you back to Galle with, I hope, a good bag of snipe.' To all this I agreed, and having borrowed a gun from one of my Rifle Officer friends, and a good stock of ammunition, I joined my two new friends at gunfire in the morning, and after driving about 6 miles, I saw some very snipy-looking fields, got down, my companions promising to call for me about 11 o'clock on their way back. As I anticipated the birds were numerous, and I had capital sport, bagging altogether some 18 couple. Crossing the fields, in making for the high road, I got into a treacherous bit of green stuff, and before I knew where I was, I was up to my armpits in a kind of quicksand. After great trouble, with the assistance of some natives, I was extricated, nearly losing my gun, but relieved of my trousers and the boot and sock on one foot. In fact, when I regained the high road, I stood in a shirt, a short jacket, and one sock and one boot; and pretty well covered with baked mud over everything. The heat being fearful, I don't know how many *kurumbas* I drank, they were past counting. Presently, Cargill and Ayrton appeared, who nearly fainted with laughter at my appearance; but vowed and swore they would take the snipe in, but as for taking me it was impossible, they couldn't tolerate the idea. However, I rose quite equal to the occasion, and swore that if they didn't take me I would shoot their blooming horse if they attempted to drive off; so at last we came to a compromise, and we drove to Galle. On getting there we found the Australian boat had come in, and the verandah full of passengers. My two friends 'nipt' out like 'long dogs' fearing my presence. I called one of the *Appus* and told him to bring me one of his cloths. Getting this well wrapt round me toga-like, I descended from the trap with the huge bundle of snipe and gun, and at once became the cynosure of all eyes.

"This adventure had such an effect upon Cargill, that he told me he would give me an appointment in the Oriental Bank Corporation in Calcutta, and that I should go by the incoming steamer then overdue. That Ceylon and its planting business was a thing of the past, and he had taken such a fancy to me that he would push my fortune in a better enterprise. Of course, I jumped at the idea, wrote off some wonderful letters to dear old Louis, telling how I was situated, to all of which I in due course received replies congratulating

me on my desertion, and wishing me all sorts of luck, but I felt very guilty when I found myself next day on board the 'Ava,' and leaving all my much-loved friends behind, ignorant of my whereabouts. In due time we arrived at Calcutta, and I was made Deputy Accountant with R400 a month. The position into which I had been hoisted, and my fitness for it, cannot be better described than in the remarks made on the subject of the Oriental Bank Corporation by some scribbling Baboo in the *Englishman*. After praising up the noble building in Tank Square, its Manager, and Sub-manager to the masthead, he proceeded to vent a torrent of abuse on the Accountant, who, he said, called the native clerks under him 'Soors' and various other terms of reproach unfit for publication. He then proceeded to tackle the Deputy Accountant (myself). 'The Deputy Accountant doesn't know the Debit from the Credit side of the Ledger (perfectly true). He has lately purchased an air-gun, with which he destroys pariah dogs from the verandah of this institution, thereby bringing much disgrace on himself and compatriots.' After some eight months of routine work, diversified by trips to the Sunderbunds, Budge Budge, and much festivity with old Addiscombe 'pals' at Dum Dum and Barrackpore, with occasional high jinks at Chandernagore, orders came over from Bombay to send somebody up to Tirhoot District to take charge of the produce in two large factories, which had been mortgaged to the Bank, the owner Colonel Pugh having failed. So, as I had some experience in Coffee, it was at once pronounced that I had an intimate knowledge of Indigo, Sugar, and Opium, and they appointed me to this duty, at which I was only too delighted, and a merry time I had in the Mozullerpore District, and fortunately acquitted myself admirably, more by good luck, than good management. A short time after my arrival, I had to render an inventory of all the Factories' belongings. This I did in great style, ending the list with 'Also an Alligator stuffed, 18 feet long, well suited for a Museum.' This fetched the Bombay Directors immensely, especially Harry Gordon. Having sent off to Calcutta a large instalment of produce, I proceeded with my excellent friend, the Manager, for a couple of months' sport in the Terai, where I saw the tiger for the first time, and had a most enjoyable trip. Shortly after my return, I sent off all the remaining produce and returned to Calcutta.

"By that time the Bank authorities had come to the idea that Nature never intended me for a Banker, so they supplied me with a 'Licet migrare' and 6 months' pay; so I travelled down to Madras, and stopped with my uncle who then was commanding the Queen's Depot at Poona.

mallie, and was afterwards Sheriff of Madras. When there I met a man who had brought over horses from Australia, and after a time we became great friends. He proposed that I should join him in the purchase of a small craft to take back his three grooms to Melbourne, then proceed to his station in Brisbane, and then go to the South Sea Islands to load up with sandalwood, and then sail for China to sell it. Well, whether the 'Bittern,' a schooner of 45 tons, would not sail, or how it was, we were 126 days at sea, the last 22 days living on a wineglass of boiled rice per man (12 all told), but we had plenty of sugar, all other provisions had given out, some being damaged and thrown overboard. After being nearly wrecked in Shark's Bay on the north of Western Australia, we at last dropped our anchor off Freemantle, and there my journey came to an end, as after some weeks, whilst re-fitting 'the Bittern' which was all gone to pieces, I met my first wife, the daughter of the late Colonial Secretary of Western Australia, Peter Brown. We were married on the 1st August, 1850, and embarked shortly after for Madras; from there after some weeks' stay I returned to Ceylon, and here begins the second episode of my Ceylon life. I may as well add here that my friend and companion on the 'Bittern' got safely to Brisbane, and afterwards sold her in Sydney, and the last of her was on some reef off the New Hebrides. He afterwards went into business in Burma, and died there and a more cheerful and unselfish companion, upright and honorable, never lived than William Birrell. Peace be with him.

"On my return to Ceylon I found temporary employment on the Kelliewatte estate, the property of Donald Steward, afterwards proprietor of Tyspane, Kotmale. Dimbula was then but little planted up. Adjoining Kelliewatte was Bogahawatte, the then property of Jack Bannister, and a most excellent neighbour he was. He afterwards married Miss Thwaites, a very charming woman. On this side of the Dimbula river, there were only in those days the Union estate managed by James Wright, and Niagara partially opened. On the other side leading towards Nuwara Eliya was Wattedgodde, then the property of William Fairholme and W. Johnston; beyond that Radella, the property of Fred and Edward Palliser; and farther on Palla Radella the estate of Andrew Hunter, a fine noble fellow he was, and universal favourite with everybody. The Lonisa estate was cleared and planted in this year (1850-51) up to 300 acres by James Wright of the 'Union' for Messrs. Odier. Some 100 acres of the Med. decoombra forest had been felled by the Messrs. Worms, but for some reason they never planted it, allowing it to revert to chena; and a great deal of trouble it gave me in 1868 from its

crops of weeds, when this magnificent property came into the hands of my employers, the Ceylon Company, Limited, after they took over Messrs. Worms' properties in 1863-64. I left Kelliewatte in March 1851, and became assistant to Frank Sabonadière on the North Division of Delta. There I remained until May 1852, when I bought Glenloch from Mr. Fimson, a Bombay Civil Servant. Previous to this I was on the point of purchasing Poooprassie, Pussellawa, a large acreage, about 200 acres opened, stores, bungalow, &c., &c., for £1500! Messrs. Gray & Co., of Bombay, were either the Proprietors or Agents (I forget which), but I was told to go and settle up matters with old 'Billy Thompson,' their Colombo Agent. Duff advised me to beat him down on his £1,500 figure, and I got as far as offering him £1,450. 'No,' said old Billy T., 'the price is £1,500, and there is a man coming here at 2 o'clock to buy it at that figure, but I want you to buy it. Now,' said he, 'I'll lend you the odd £50 to complete the purchase, as I want to do you a good turn, and you will make a fortune out of the place.' But I would not consent to this kind offer on his part. At 2 p.m., Mr. Segar of the hotel came in and stumped up the £1,500 on the spot, and I believe he did make a fortune out of it. I think I gave £4,250 for Glenloch. Estates were then rather a drug in the market, but the prosperity of the Island was at this time (1852) on a fair way to recovery. In 1854 I sold some 380 acres of forest land (60 acres planted) to John Northmore, and left for England in May, returning to Ceylon in February 1855 to Glenloch. Shortly after my return I planted some 40 acres additional to this property. We had admirable neighbours round about us:—my dear old friend, George Shirreff, next door on Helbodde, Frank Sabonadière on Delta, Capt. Reddie at Huntley Lodge, Lyon Fraser on Tavelantenne, and Jack Gordon (afterwards of George Steuart & Co.'s) on Wavendon. Besides these, Maurice Worms on Rothschild, Gabriel living chiefly in Colombo, and the 'Reverend John' on Melfort. Those were rare old days, and we saw much of one another, and nothing could equal the good fellowship which existed between us. Of all these there remain only Jack Gordon, and the 'Reverend John,' I believe, to show for the lot, always excepting John Northmore lately returned from Hatton very much alive. In 1856-57 I bought part of General Fraser's estate, Rangbodde, which I called 'Bluefields' after a Jamaica property of my uncle's. In the same year I was sent for by the Governor, Sir George Anderson, who informed me that he had received instructions from the then Secretary of State (Sir Rondell Palmer*) to do all he could to advance

* More likely Sir John Pakington?—ED. T. A.

my way in life, either in the U.C.S. or the Rilles. As I thought I was too old for the latter, and indifferent to the former, I declined Sir George's offer with thanks, but at the suggestion of Rawdon Power, then Colonial Secretary, he insisted on my being made J.P. for the Kandyan Districts! Whilst at home in 1854 I was offered a Commission to go to the Crimea, but my wife would not hear of it. I was also offered the Command of a Tug Steamer to tow vessels up the Dardanelles, whereby a lot of money was made; so much for chances in that noble profession which I never studied:—"The art of getting on in the world." During Sir Henry Ward's time I had the honor of receiving great kindness at his hands, and his last words to me on his leaving Government House to embark for Madras were:—"That as soon as he could, he would give me the best appointment he could." Alas! at the end of another month he was no more, and the Government of India lost a great statesman and an able Governor when he died, and one who would have made a great name in India.

"A short time after this I sold Bluefields, and left for England. In 1864 I came out to Madras and had charge of large properties on the Nilgiris.* Having on several occasions from my love of sport hazarded shooting trips into the most deadly malarious jungles, from which my health suffered to such an extent that I was only too glad to return to Ceylon, and taking charge of Meddecoombra, which then had 300 acres just planted, and which before I left grew to 1,500. At the end of 1870, I was made one of the Inspectors ("V.A's") of the Company, Mr. William Rollo being the other. I held this office until I left for England in 1884, terribly broken down in health. In 1870 I accompanied H.R.H. the Duke of Edinburgh on a shooting trip to the Trincomalee jungles, and received Sir Hercules Robinson's full approval!—and nothing else. I returned to Glenloch as a residence in 1870, and went home on six months' leave, in 1875, losing my beloved wife, a few days after landing, from bronchitis. I returned to Ceylon with my two daughters in the following November. In 1878 I came home for a few months to marry my present wife who was Miss Laura Darby, of Leap Castle, King's Co. Ireland. By my first wife I had four daughters, one of whom I lost in Ceylon in 1878. By my present wife we have four sons, and a daughter. It is a great wish of mine to return to Ceylon for a couple of months and revisit old scenes. Alas! I shall find but very few of the friends

of the olden days, but from the few that are left I do not doubt I should receive a hearty welcome. I can look back to my days of coffee planting in Ceylon with the greatest pleasure, for I enjoyed the life thoroughly."

So closes the neatly written *MSS.* sent us by Mr. Tyndall; but he added below:—"I daresay I could write a good deal more, but I must be content with a skeleton sketch of one who enjoyed life socially, never had an enemy, but made many true friends. By-the-way I forgot to say that I was dreadfully ill in 1872 and went to Australia for three months." We well remember that illness: Wm. Grant of Dikoya, very ill, occupied one end of the hospitable bungalow of John Lewis Gordon, in Steuart Place, Colpetty, when John Tyndall, supposed to be dying from abscess in the liver, was brought down from Pussellawa and placed in the opposite wing. His wonderful constitution and the indefatigable nursing of his devoted wife pulled Mr. Tyndall back from the grave, while Mr. Grant sank under his fever attack. Then the great object of all was to prevent Tyndall from realizing that his dear friend Grant had gone, lest it should depress and throw him back. This avoidance and all about the funeral were managed without the remaining patient having any suspicion. We were at Galle when poor Tyndall came down to take steamer to Australia: he was miserably weak and thin, but would insist on sitting about the centre of the big table where some 150 passengers were dining. Each course he had to refuse; but still the servants pressed until, overcome at last, Tyndall so shouted, "No! didn't I tell you" as attracted all eyes, but made him free of worry for the rest of the evening. He came back, after three months' absence, quite another man. One of the incidents we recall of his Visiting Agent days was his bringing to Colombo, and specially to the *Observer* Office, the news of Mr. Slorach—a well-known Engineer and Coffee Store Manager—having picked up a magnificent gem on his estate in Haputale, a stone of the finest water which he was bringing to Colombo, and that he (Mr. T.) had seen it. By-and-bye Mr. Slorach turned up, full of the fun, his gem being a big lump of "lime-stone"—considered so valuable on a coffee estate, however, as to well deserve the epithet of "precious stone." After leaving Ceylon finally in 1884, Mr. Tyndall was one of the earliest to open a London Agency for the sale and distribution of Ceylon teas, in conjunction with one or two more well-known Ceylon men, fixing his city headquarters in Billiter House. The Firm was said at one time to have the services of two baronets in securing orders and extending its influence. Then came

*It was from this quarter that a Colombo businessman got an answer to certain enquiries from Mr. Tyndall, by telegraph, in a form which became a common saying in Ceylon for many years, namely, "What a world it is, Mr. Venn!"—ED.

a story to Colombo of a strange placard that our old friend had stuck up in the lobby of his office which had brought down a remonstrance and protest from a London policeman on the beat. By this time, Mr. Tyndall had become the "Raconteur" of the *Ceylon Observer*, and many a passage in his planting, hunting and roving days has he; from time to time, described in our columns. He also forwarded to us the printed "placard" which had been the subject of remark among his friends and accompanied it with the following:—

"The enclosed may be of use to you, so I lose no time in sending it out. No Policeman ever appeared here, except to ask for a Christmas Box. I am on the best of terms with the Force. You will find this admirable policy yourself.—Yours sincerely,

JOHN TYNDALL."

The placard itself ran as follows:—

NOTICE.

All Beggars and Pedlars entering this Office will be shot dead.

Mr. Tyndall continued to attend to his London business up to a few months ago when he was laid aside by severe illness, from which, again, recovery was deemed very unlikely, if not impossible; but in a letter from him dated 6th May in the same clear neat hand, the writer was able to announce convalescence—after passing through severe influenza, pleurisy, &c.—though he naively added:—"I naturally find that I don't pick up my strength as I did when I was forty years younger. However, with the constitution of a Wilson's Bungalow buffalo, and a heart as young as a two-year old, I hope to pull along a bit yet. I am just going down to my brother-in-law's, at Castle Fraser, Aberdeenshire, and with bracing country air and the wine of the country, I hope to be 'o'er all the ills of life, victorious'—immediately if not quicker"—and he winds up by hoping, very shortly, to send a contribution from "Raconteur" for the *Observer*.

Well past the allotted "three-score-and-ten," it will be judged that Mr. John Tyndall is a wonderful specimen of the early Pioneer Planter and Sportsman in Ceylon. That his vigour and hearty good spirits may long continue will be the wish of his many friends in Lanka as of all readers of the *Tropical Agriculturist* and *Ceylon Observer*.

Agricultural Pests:

WITH METHODS OF PREVENTION.

BY MISS E. A. ORMEROD,

(LATE CONSULTING ENTOMOLOGIST TO THE
ROYAL AGRICULTURAL SOCIETY OF
ENGLAND).

VI.

ORCHARD PESTS.

Attack of apple sawfly may be taken as an example of how easy it is, without observation, for an infestation which bears much resemblance to some other kind to escape requisite notice, *i.e.*, such notice as causes proper measures to be taken, instead of trouble and money being spent to no purpose on applications suited to another attack of which the chrysalis stage is passed in a different locality. Apple sawfly presence has long been known in this country, but so far as I am aware has been little observed, and it was not until the summer of 1891 that I had an opportunity of studying the characteristics. In many respects the attack of those caterpillars to the apple fruit much resembles that of the too well-known codlin moth caterpillars. It may, however, be certainly distinguished by the sawfly caterpillar having a greater number of sucker-feet beneath the body, that is, six pairs which, with the pair at the end of the tail, and the three pairs of claw-feet, make in all twenty. There is the further characteristic of the caterpillars possessing a most unpleasant bug-like smell. Thus they may be distinguished from the codlin moth caterpillar, the larva of the *Carpocapsa pomonella*.

With regard to methods of prevention. In the case of either of the attacks it is desirable to gather up and destroy prematurely fallen apples, which from their bored and injured state show that they have fallen from caterpillar presence within, and may, therefore, very likely be then infested. But beyond this, the chief means of prevention are on quite different principles. The codlin moth caterpillar (to a great extent), after leaving the little apples, creeps up the trees, and changes to the chrysalis state in crevices of the bark. The sawfly caterpillar, on the contrary, goes down into the ground to form its cocoons. It is, therefore, needless to point out that any amount of scraping, washing, and cleaning the bark is merely money thrown away, if all the while the enemies against whom these operations are directed are lying from two to six inches under the surface of the neighbouring ground.

The turnip sawfly (*Athalia spinarum*) sometimes causes overwhelming mischief; but this is not a regular yearly attack, by reason of rotation of crops, and because in regular course of autumn cultivation the cocoons are thrown up, or buried beneath their natural resting-places. The progress of the injury is very rapid. The bright orange sawflies lay their eggs in slits sawn in the leaves. One female will lay over two hundred eggs. The eggs hatch in about five days; the time varies with the state of the weather; if warm and favourable, they will hatch sooner. The twenty two-footed grubs are greenish at first, then black, then slaty, and are full-grown in about three weeks, during which time they eat voraciously. They go down into the ground to change, and the new brood of sawflies in summer comes up, ready to lay eggs and start a new attack in about three weeks. With this attack we can, as with most others, do something by ensuring vigorous plant growth; but all methods that have been found useful to check attack will be found to be based on the special habits of the caterpillar. During its three weeks' life it changes its skin about once a week, and to manage this it must hold fast by means of the pair of sucker-feet at the end of its tail, to a leaf or stem, so as to have something to drag against in the struggle to get free of its cast coat. If it cannot do this it dies. Also it has only the

power of spinning a thread to let itself down, or to come home again by in passing alarms, during the first few days of its life. After that, if it falls to the ground, it can only return by crawling.

The remedies which are chiefly used all turn directly on these habits. The plan of driving sheep through an infested field, or of brushing the plants with boughs, either carried by hand or fixed on a scufflery or, again of dragging a cart-ropo over the plants, all turn on endeavouring to make the caterpillars loose their hold, which we see amounts, with a large proportion, to the same thing as killing them outright.

As in the case of turnip flea beetle, various kinds of dressings may be of use, such as lime, &c., if applied so that they stick to the insect and leafage; and also all measures to keep the earth moist enough to run on a good crop, and keep the sawfly from enjoyment of the full light, heat, and drought, in which it delights, will be of service.

There is one other kind to be noticed, because it differs greatly from those just named in its habits. It is the corn sawfly (*Cephus pygmeus*) which feeds more especially within the wheat stalks; and its presence may be partially known by the blasted ear. This whitish maggot has only the rudiments of the three pairs of claw-feet; and when its work of mischief to us is done, it rests for the winter in a silken case, very near ground level, in the sawn through stalk. To prevent attack recurring, it is a perfect treatment to gather together the infested stubble and burn it. This is an exception to the usual form of life and place of change of sawfly larvæ, and therefore must be treated differently; but there is the same principle to be followed as with caterpillars and chrysalids of other kinds of sawflies, and also of butterflies and moths; that is, firstly, to find out where they pass the winter, and then to turn them out from their shelters.

The amount of injury caused by various caterpillars, and especially from time to time by those of the turnip sawfly, is so serious that a great deal has been written (of more or less use) on the subject; but in the short notes of the five kinds of attack mentioned above, it will be seen that whether as infestors of the forest tree or the garden fruit bush; as feeders within the firm fruit of the apple, or on the succulent leaves of the turnip, or carrying on their injurious work hidden within the growing wheat-straw; or, again, whether the larvæ or caterpillars are possessed of 22 or 20 feet, or (for practical purposes) of no feet at all, there is one method of prevention applicable to them all—to turn out the cocoons and destroy them.

The families of the parasite wasp-flies are important to us, as a means of keeping the increase of other insects in check. One division of these is that of the Ichneumon flies. These are much like the Ichneumon parasite of the corn sawfly. They are lightly-made insects, with a longish body and abdomen; long legs; a small head with long horns, often having a ring of white on them; and an ovipositor, sometimes short, sometimes long, and often permanently extended like a large and long sting. With this they insert their eggs, for the most part into the grubs of other insects, but sometimes into their eggs, and occasionally into the chrysalids; and those kinds furnished with long ovipositors pierce with them through bark or solid wood, and thus insert their eggs into beetle grubs, or whatever their selected victim may be, which, although out of sight, their instinct tells them is within, ready to act as food to their maggots; and thus they give us help which nothing else affords.

In the case of corn-ears which are infested by aphides, many of the aphides, instead of being of the natural colour, green or yellow, brown or other tints, will be seen to be of a rich, brown, or almost black. These have been killed by the ichneumon. The female of the *Ahhidius* inserts a single egg into abdomen of many aphides, one after the other, and the maggot, which hatches from the egg, consumes all that is eatable, until its live host is reduced to a state which will not carry

on life any longer. Its uninvited guest goes through its changes within to an ichneumon fly, and presently quits the hared skin, which is distinguished, as just observed by its colour. Sometimes every aphid on a corn-ear is thus destroyed, and there are other kinds of allied parasite flies which help us similarly.

One of the forms of attack which is the plainest to be seen is that of the cabbage ichneumon fly. This little fly lays a vast number of eggs, sometimes more than sixty, in one caterpillar of the large cabbage butterfly. Here the maggots hatch and feed, avoiding by instinct such parts as the consumption of would cause a fatal loss, to the host, and, consequently, to the guest. The containing caterpillar—the live food, that is—meanwhile feeds and grows, not only until it attains its full size, but it may often be known from uninfested ones by its swollen appearance. It has not, however, power to turn to the chrysalis state: when the time for this comes, the maggots within pierce its skin, and each one spurs for itself a small cocoon of yellow silk, in which it goes through its changes to the complete insect by the side of the dead body of the exhausted caterpillar. These little ichneumon flies are one of our protections against great increase of the caterpillars, and the small silken cocoons, which are easily seen when they lie together in masses on cabbage leaves, should never be destroyed.

Another kind of small ichneumon fly (*Hemiteles melanarius*), preys in the same way, by means of its maggots, inside the chrysalids of the greenveined cabbage butterfly. These infested chrysalids may be known by their dark brown colour, and should never be destroyed, as each one is a case—package, so to say—full of checks to a troublesome crop preyer.

All these ichneumon flies are very much alike in shape, and their wings are much veined.

The parasite wasp flies of the two other families, which are most important to us (*Chalcididae* and *Proctotrupidae*), are, for the most part, very small, with almost, or quite, veinless wings. The *Pteromalus puparum* is one of the kinds which destroys chrysalids of the large and small cabbage butterflies. This very small fly is stated to lay its eggs on the outside of the chrysalis, as soon as it has cast off its caterpillar skin, and is still soft and tender. The maggots from these eggs soon hatch and eat into the chrysalis, and sometimes as many as from two hundred to three hundred live thus in one chrysalis, where they change to the perfect parasite fly, and come out soon in summer to continue the useful work. In winter some remain in the chrysalis.

The use of these *Pteromali* is well shown by their work in North America, in checking increase of cabbage butterfly.

The small white cabbage butterfly made its appearance (or, at least, was first observed there) at Quebec about 1859, and gradually spread and caused much damage, but, for several years no parasite appeared to check it. In 1871—that is, about twelve years after the appearance of the butterfly—it was announced that the parasite we are now speaking of had appeared: the British parasite had followed the British butterfly, and was doing its appointed work. In 1875 it (the parasite) had become quite common in the State of New York; and later on it was observed to be still on the increase.

The great benefit gained by natural helpers of this kind has caused it to be suggested that we should rear them. This matter seems rather hard to manage; also we do not often benefit much by upsetting the regular balance appointed; but it is often in our power to follow up a hint of this kind, by remembering that when an out-of-the-way insect enemy has appeared, we may very likely be able also to introduce its regular check and leave the results to follow in due course. Sometimes, also a new infestation may be traced home to the country from which it came by means of its accompanying parasites. In the memorable appearance of the Hessian fly in this country, we had no clue to lead us to the

knowledge of whether it had come from America or from the Continent of Europe, until examination of its parasites showed that, with the exception of one kind common to both continents, the others were not American, but Russian.

The parasite flies of wheat midge show the shape of two other kinds of these minute flies. The *Macroylenes*, of the family of the *Chalcididae*, is supposed, from its habits, to destroy the midge-grubs; and the *Platygaster*, of the family of the *Proctotrupidae*, has been watched in its operations of laying one egg in each midge-grub it attacks.

There are other kinds of parasites of nearly-allied kinds, which we have not space to enter on here; but the general principle of preserving a useful amount of them is so important that, though it is a very difficult matter to protect them, it is as well to be careful about setting on foot regular measures calculated to lessen their numbers. It may be doubted whether, in regard to help from parasitic insects, we do not suffer, rather than benefit, as much as is supposed, by *great* encouragement of birds. We cannot tell accurately what amount of the small parasite flies are taken as bird food, for their small bodies are probably soon digested; but it appears reasonable to suppose that as we know some birds take them, others also do so, and in this way do the reverse of helping. I would not for an instant suggest clearing away birds; but it would be well to bear in mind that the works of creation are founded on a principle of order, and of relationship of one part to another; and if we use such power as we may have to alter any detail, we are likely to suffer. We have altered the amount of food for insects by the enormous necessary increase in food crops; but it appears to me that to try to keep these insects in check by calling in birth-help in legions—which grub up the plants to be protected, and eat up the eaters of the insect foes, and likewise (when insect food fails the many mouths) betake themselves to the wheat-ears—is very much like bringing in the rats to drive out the mice.

The families of wasps, bees, and ants are included in another great section of this order, called the *aculeata*, because they, or most of them, are furnished with a sting, much resembling in appearance and pain of application a needle, known in Latin as *Acus*. These have been written on for so many years that we need not enter on them at length; but it is well to observe that the hive bees, the social wasps, and social ants, are remarkable for much of the work of the community being carried on neither by the males, nor as a regular thing by the large females, which are commonly known as queens, but by a large body of abortive females, or neuters, commonly known as "workers."

In the case of the Queen bee, we have a clear instance of the way in which different food and accommodation acts in altering, or rather, in fully developing the powers; and gain matter for thought, at least, from the fact that a precisely contrary treatment, such as compressing, starving, chilling, &c., brought about by common farming measures, will not (or probably may not) be without effect in stunting the growth and otherwise lessening attack.

PRODUCTS OF THE CITRUS TRIBE IN SICILY.

Reporting on the trade of Sicily, Mr. E. M. de Garston gives some interesting facts connected with the staple products, such as essence of Lemon and other produce of the Citrus family, the different trades dealing in these being of a very interesting character. The Lemon essence industry is a very important one in Sicily, where the abundance of raw material naturally renders the manufacture of the so-called oils of Lemon and Orange a very profitable undertaking; 37,941 kilos. of these essential oils were shipped during the year 1895, over 32,000 kilos. of which was taken by Great Britain.

Oil or essence of Lemon is obtained by pressing or bursting the oil-glands in the rind of the fruit, and this is done either by hand or by machinery; that obtained by the first process being by far the best in quality. In Palermo the essence is all pressed at night. The workmen are supplied with a certain quantity of rinds, divided into equal portions to each between so many gangs, each under the supervision of a foreman. Each man holds two sponges between the fingers of the left hand, and works the rind about in the best way to fracture the oil-vessels. This is caught in the sponges, which, when sufficiently charged with oil, are squeezed into an earthenware receiver; a considerable proportion of the product thus obtained consists of ordinary Lemon-juice left adhering to the rind, together with more or less of the Lemon-pulp. This, however being heavier than the essence, sinks to the bottom of the receptacle, and the essence remains on the top. As the first of these receivers becomes full, the workman blows the floating oil into the second jar through a species of channel formed in the side of the first, and when no more of the essential oil is transferable by blowing, the remaining essence which may yet be floating in the original receiver is carefully absorbed with a sponge, and thence squeezed into the second receptacle, which only contains pure essence.

The remainder, namely, the essential oil which may still have been left in the rinds, is by some manufacturers extracted by distillation, and forms a second quality of essence. By others, again, it is expressed by subjecting the partially exhausted rinds to mechanical pressure in bags. To ascertain, however, if the obtainable essence has been thoroughly squeezed out by the original hand process, the rinds are tested by a foreman, who presses the supposed exhausted peel into the flame of a candle, when, if any combustion is visible, it shows that the pressers have not done their work properly. The essence obtained by the foregoing process undergoes no further manipulation beyond being collected, and after careful filtration through filter-paper it is ready for shipment in the usual coppers of 100, 50, 25, 12, 5, and 2 lb. each. When freshly expressed it has a delicious smell of the fruit, which is greatly injured by distillation.

From the leaves, flowers, and fruits of the several species and varieties of the Citrus genus a large variety of products is obtained. The blossoms in their natural state serve to flavour drinks and sweetmeats. When distilled they yield two very much esteemed products, namely, orange flower-water and an essential oil known as Neroli. Moreover, when candied, they form a delicious sweet, much in vogue in some regions of Sicily. The orange flower-water is made of equal portions in weight of blossom and water, which yield on an average about one-fifth of the combined weight of water and flowers. Notwithstanding the abundance and excellent quality of the raw material, so to speak, still the best manufactories of Orange flower-water are to be found outside Italy. As to candied sweetmeat concocted out of the blossoms, it is doubtless more wholesome as well as more palatable than many other productions of the confectioner's art. The flowers in the first place are selected with care, weighed, immersed in cold water for twenty-four hours, after which they are dipped simply in cold water, rewashed in cold, and finally spread out on a linen cloth or sheet to dry. When completely dry, they are laid out in low, wide dishes, each flower separate from its fellow, and are then sprinkled with double their weight in sugar, administered at intervals during a period of eight days or thereabouts. Moreover, during the same period the flowers should be frequently moved and kept in the shade; at the expiration of this time they are once more placed in the sun, whose rays dry them completely.

The raw juices of all the different varieties of the species of Citrus, except that of the Bergamot, are available for commerce; but the juice of the Lemon is the more highly prized, on account of the greater amount of acidity it contains. But the raw juice,

"Agro-crudo," however rich in acid particles, can never vie in this respect with the same juice in a concentrated form with the "Agro-cotto," in which form it enjoys besides a great superiority over uncondensed juice in durability and in reduction of volume. This concentrated juice is prepared in the following manner. It is first of all clarified by being left to stand, then boiled in large cauldrons of tinned copper, one-third full, and the boiling liquid frequently stirred with an iron rod having its head wrapped in common canvas, or in rags which have thus to keep the bottom of the boiler clear of all sediment; those necessary additions to the boiling liquid which the constant evaporation of the aqueous particles renders expedient are supplied by smaller supplementary boilers in which the liquid is kept sufficiently hot to hinder any interruption in the ebullition of the juice contained in the large vessels. When the required density is obtained, a point which is easily ascertained through the medium of the citrometer, it is poured into vats to cool, and finally drawn off through ordinary funnels into casks.

The adulteration of the acid or juice is facilitated by the ready absorption of certain well-known and easily-obtainable substances, which increase the weight of the acid-juice when concentrated. The most commonly employed substances for the purpose of adulteration are tartaric acid, chloride of sodium, and sulphuric acid. The methods employed in Sicily in order to detect the cheat, if not so scientific and perhaps less accurate than those in use in England, are at least inexpensive, simple, and sufficiently effective. Citrate of lime, which seems to be the safest form in which the acid principle can be conveyed, and is the substance whence the citric acid is directly manufactured, is now prepared to some extent in Italy, although up to within the last quarter of a century this preliminary process was considered impracticable from a remunerative point of view. A very well known authority on the subject laments in forcible terms the remissness and ignorance of his countrymen in Sicily, which alone permits foreigners to reap that harvest which Italians neglect to gather and garner for themselves. The objections raised in bygone days, from the supposed impossibility of procuring at home a sufficient quantity of proper chalk, have been shown to be utterly mistaken with respect to the production of citrate of lime. Objections of a similar nature are now mooted with regard to the production of citric acid, and have been partially disproved already by the establishment of a British firm in Messina, which has undertaken successfully the manufacture of citric acid in conjunction with tartaric acid.

With regard to the essential oil industry in Sicily, it is said to be both widespread and prosperous. Essence producers and exporters are numerous. The essential oils are derived from all varieties of the Citrus group, though they differ considerably in quality, that expressed from Bergamot being the best, and then follow the Lemon, Orange, and Citron, the relative value of the essence being in inverse order to that of the juices.

The mode of payment of the workmen engaged in expressing the essential oils is peculiar. Instead of being paid at a fixed rate per day or hour, or for the weight or number of rinds expressed, he is remunerated according to the amount of essence he succeeds in extracting out of a given weight of rinds.

It is stated that, though the bulk of the oil produced in, and exported from, Sicily is quite pure, yet it is sometimes adulterated with other essential oils, and sometimes with turpentine, or even with resins. The occurrence of these adulterations seems to have discredited and unsettled the market value, so that it became necessary, or at least expedient, in some cases to submit it to analytical test before exportation. Owing to these precautions, the character for genuineness of the Sicilian essential oils has been redeemed, or rather maintained.—*John R. Jackson, Kew.—Gardeners' Chronicle.*

PLANTING NOTES.

FRUIT FROM THE CAPE.—Since our last report the "fruit ships" have arrived from the Cape; the first, the "Scot" bringing 55 boxes of Pears and 294 boxes of white Grapes; the second, the *Avondale*, bringing in 539 boxes of white Grapes. We are informed that, with the exception of 30 boxes, these consignments turned out in good condition, and realised fair prices. The faulty boxes above noted were very over-ripe, and hardly saleable.—*Gardeners' Chronicle.*

LONGEVITY OF THE LARCH.—The *Chronique Agricole du Canton de Vaud* contains various records concerning the age attained in Switzerland by the Larch. There are at Mayens-de-Sion two old Larches which measure from 20 to 22 feet round the base, and 65 feet in height. Both are referred to in a plan of the grounds dated 1546, where they are mentioned as "the two Larches before the house." They were then a good age, and now are 351 years older. These years do not seem to have weakened them, as they are in full vigour. Another Larch is found on the Alp de Torrent, near Albinen; it is called the boundary-tree, as every hundred years the people of Albinen and Louécheles-Bains go out to it to re-mark the boundary. On its trunk a sort of niche has been cut in the bark, and on the exposed wood are engraven the dates from 1400 to 1700. Larch wood has considerable durability; the above journal mentions a *châlet* at Louécheles-Bains where the piece of wood which supports the ceiling is of Larch, and bears the date 1536.—*Gardeners' Chronicle.*

INSECT POLICE.—We take the following extract from an article of Mr. R. C. Perkins, published in a recent number of *Nature*, p. 499:—"The first importation of Coccinellidæ to destroy hordes of scale-insect in the Hawaiian Islands was made in 1890, when *Vedalia cardinalis* Muls, a native of Australia, was sent over by Mr. Albert Koebele. At that time many trees were in a deplorable condition from the attacks of *Icerya*, Monkey-pod trees being particularly badly infested—so much so that they were being largely cut down as the only recourse. The *Vedalia* was a complete success; it became perfectly naturalised, increased prodigiously for a time, practically cleared the trees, and then, as the *Icerya* became comparatively scarce, decreased in numbers, while at the present time it is evident that the number of the scale and its destroyer has arrived at a fixed proportion. Previously to its introduction here the same lady-bird had done excellent service in the fruit orchards of Lower California. . . . In many parts of the islands the Bananas and Palm-trees have been severely attacked by the larva of a species of *Pyrilidina*. There is little doubt that in course of time this plague will be entirely kept under by a fine Chalcid (*Chalcis obscurata*, Walk.), introduced from China and Japan, which has already multiplied enormously at the expense of these caterpillars—so much so, indeed, that in many localities the trees have now entirely recovered. Again, within the last few years a Lamellicorn beetle (*Adoretus nimbrosus*) has been introduced from Japan. This insect speedily multiplied prodigiously, and soon destroyed nearly every Rose-tree in Honolulu, and subsequently attacked the foliage of many other trees. The cultivation of Roses—once a feature of the city—became impossible; while a remedy seemed hopeless. One day, however, Mr. Koebele discovered a parasitic fungus, and by cultivation of this, and infecting healthy beetles, soon spread it far and wide. Whether the fungus will prove entirely effective is not at present certain, but in any case it will be a most useful aid. The writer has seen the ground under trees, which were attacked literally strewn with dead beetles—all killed by the fungus—and beneath the surface of the soil the larvæ had likewise perished. It is at least certain, therefore, that myriads of the beetles were destroyed very shortly after the fungus was spread around by the individuals that had been infected."—*Gardeners' Chronicle.*

THE MAYFIELD (DIMBULA) TEA CO. OF CEYLON, LIMITED.

Capital £100,000, in 5,000 6 per cent cumulative preference shares of £10 each (which have priority as to capital and dividend), and 5,000 ordinary shares of £10 each.

Present issue—3,300 per cent preference shares, and 3,300 ordinary shares of £10 each.

The purchase of the following tea estates has been arranged, viz.:—Mayfield and Chalmers, situated in the Dimbula district, and the Nicholaoya group, situated in the Matale district, comprising the following acreages and particulars:—

Estates.	Tea over five years.	Tea over three years.	Tea not yet in bearing
Mayfield ..	404 Acres.	12 Acres.	— Acres.
Chalmers ..	260 "	—	30 "
Nicholaoya ..	312 "	87 "	48 "
	676 "	99 "	78 "
Estates.	Tea total.	Cardamoms.	Timber planted.
Mayfield ..	416 Acres.	—	36 Acres.
Chalmers ..	290 "	—	—
Nicholaoya ..	447 "	15 Acres.	—
	1,153 "	15 "	36 Acres.
Estates.	Forest.	Chena and Patana.	Total acres of estates.
Mayfield ..	88 Acres.	36 Acres.	576 Acres.
Chalmers ..	10 "	57 "	357 "
Nicholaoya ..	400 "	409 "	1,271 "
	498 "	502 "	2,204 "

Mayfield and Chalmers are taken over as from the 1st of January last, and Nicholaoya from the 1st of July, 1896, the Company taking the benefit of the produce from these respective dates. The production of these estates for the current season is estimated at not less than 421,000 lb., which with the cardamoms may be expected to yield a net revenue of £5,450. As, however, there are 177 acres of tea not yet in full bearing, and as there is still a considerable area available for the planting of tea, the out-turn should be considerably increased year by year. The Company will acquire the three estates, machinery, and buildings for the sum of £63,000, the price fixed by the Vendor, which is considered not an excessive price, considering the good reputation of the estates. After payment of the purchase-money there will be left the sufficient sum of £3,000 for the general purposes of the Company. The Vendor pays all expenses of every description down to allotment. Taking the value of the uncultivated area and cardamoms at £5 per acre, and deducting the £3,000 for general purposes, the purchase price of the area under tea works out at about £50 per acre.

EDERAPOLLA TEA COMPANY OF CEYLON, LIMITED.

The following is from the report of the board of directors, to be presented to the shareholders at their first annual ordinary meeting to be held at the offices of the company, 16, Philpot Lane, E.C., on the 13th inst:—

The directors have pleasure in submitting to the shareholders the report and accounts of the company for the year ending December 31, 1896. The company was incorporated on November 29, 1895, and the prospectus issued on December 3, when the applications received for shares were far in excess of the number offered for public subscription.

Since the company acquired Ederapolla and Ardross Estates sundry native lands have been purchased, and the total acreage is now as follows:—Tea in full bearing, 471; partial bearing, 81; not in bearing, 48; clearings, 87½; Jungle, 189; Paddy Field, 7; Paddy, and Scrub, 10½; total, 894. The total

crop secured amounted to 358,324 lb. of tea, being 48,324 lb. over the estimate, and the average yield of the two estates was 640 lb. per acre. On Ardross 11 acres and on Ederapolla 33½ acres of jungle have been felled and burnt off for planting this year, and on both estates there are fine nurseries with abundance of plants for the company's requirements. The directors have had very satisfactory reports on the estates from Mr. Thomas Smith, of Barnagalla, who in his report of January 26 last, writes as follows:—"I consider the estates throughout the whole year have been worked to the very best advantage under the able management of Mr. Watt," and it affords the directors pleasure to endorse and confirm the opinion thus expressed of the services of their general manager. The company's net profit for the year amounts to £2,795 15s 10d; and this it is proposed to appropriate as follows:—Amount as above, £2,795 15s 10d; interim dividend of 5 per cent paid in September, £1,100. It is now proposed to pay a final dividend of 5 per cent (free of income tax,) making 10 per cent for the year, £1,100, and to write off half the preliminary expenses, £300 8s 1d; leaving a balance to carry forward of £295 7s 9d. In accordance with the articles of association, Mr. G. W. Paine retires from the board, and, being eligible, offers himself for re-election. Messrs. Cape and Dalgleish also offer themselves for re-election as auditors.—*H. and C. Mail*, April 2.

BANDARAPOLA CEYLON COMPANY, LIMITED.

The following is from the report of the board of directors, to be presented to the shareholders at their fourth annual ordinary meeting, to be held at the offices of the company on Wednesday, 14th inst.:—

The directors have now the pleasure to submit to the shareholders the accounts and balance-sheet for the year ending December 31, 1896.

The net profits for the year in question amount to £2,438 3s 10d, to which has to be added £216 19s 4d brought forward from 1895 accounts, giving a total sum to be dealt with of £2,655 3s. An interim dividend of 5 per cent (free of income tax) on £16,000 paid in September, amounted to £800. It is now proposed to pay a final dividend of 5 per cent (also free of income tax) on £18,500, making 10 per cent for the year absorbing £925; and to write off for depreciation on old buildings and machinery £500; leaving a balance to carry forward to next account of £430 3s 2d.

During the past season the crops secured from the company's property amounted to 346,150 lb. of made tea and 142 cwt. 3 qr. 13 lb. of cocoa, as against 182,512 lb. made tea and 80 cwt. 3 qr. 13 lb. cocoa for the previous year, an increase which the directors considered extremely satisfactory. The price realised for the tea shows a slight falling off as compared with 1895, being 6.432d, as against 6.788d per lb. The old tea on Baudarapola, 286 acres, gave 867 lb per acre, and that on the 98 acres of Muendeniya land, only three years old, and raised principally from seed at stake, has given 718 lb. per acre, a phenomenal return, and the 1895 planting promises equally well. For the current season the directors have sanctioned a further clearing of about 50 acres to be planted in tea, and this is being proceeded with by the Ceylon manager. During the severe rain storms experienced in the latter part of 1896 the foundations of the wheel-pit at the factory were carried away, the wheel-pit subsiding, and the wheel being considerably damaged. The directors are glad to report, however, that, through the energy and promptness of the Ceylon manager, the damage was to a great extent minimised, and they take this opportunity of recording their appreciation of the energy and capacity for overcoming difficulties displayed by Mr. Anderson under very trying circumstances. They are also indebted to the managers of neighbouring estates for their kind assistance on that occasion. All the damage has been repaired, and the erection of an engine and boiler

tasters, and has been sold at full market prices. It need scarcely be said that the experiment was due to British enterprise and capital.

AND IN VARIOUS COUNTRIES.

Much the same thing is going on in Johore, but it is obvious that such undertakings must feel their way warily. Natal has not yet entered the market as a tea-producing colony; but planting on a small scale has been carried on there for some years, the output, which is of good strength and flavour, being locally disposed of. From Java to Jamaica is a far cry; but while most persons have heard of, if not tasted, the tea-grown in the former, few are aware that the plant once evinced a considerable liking for the soil and climate of the West India island. Experiments on an extensive scale are now being carried out in Brazil, the planters of which country are said to be fully convinced that tea can be profitably grown there. But the suggestion appears to have been first made, and the necessary capital found, by British residents, who have long had the subject under consideration, and who appear to have satisfied themselves of the hopefulness of the prospect. Both soil and climate are regarded as exceptionally favourable, as are the general conditions and cost of labour—the latter, indeed, being commonly the crux of the whole question. In their mere "tea-producing qualities" the provinces of Rio de Janeiro and Sao Paulo are spoken of as being fully equal to Ceylon, and satisfactory results have already been obtained from some of the plantations.

IN CALIFORNIA.

But the most interesting, and not perhaps the least promising, of recent trials in this direction are those which have for some time been in progress in South Carolina, under the auspices of the United States Department of Agriculture. Probably the first tea-bush grown in America was planted near Charleston by M. Michaux, a French botanist, in 1804. The failures to develop from this starting-point anything in the shape of a settled industry have been hitherto almost continuous. But there nevertheless exists a confident belief in America that all the tea required there will ultimately be produced in that country. Every fresh effort is regarded with enthusiasm, though the main hope seems to be based on the fact that the flora of the chief tea-producing countries of the East largely finds its counterpart in South Carolina. The tea grown there has proved of good flavour, but somewhat lacking in the "body" to which the wide use of Indian tea has accustomed ourselves. This, however, is considered to be less due to climate or soil than to a defective method of treating the leaf during the manufacturing stages. The necessary tea-seed is still imported from Asia, and the American Consuls at the Eastern tea ports are instructed to spare no efforts to secure the best that can be obtained. All these operations, therefore, can only be regarded as still occupying the experimental stage; and the same must be said of many successful trials of the same kind now going forward in Australia, Tasmania, and New Zealand.

THE LABOUR QUESTION.

For, to quote a local opinion, "there is labour to bestow on such a cultivation"—that is to say, no labour at the low rates of payment which only could be offered. And this is the governing condition of the entire question. Considerably more than a million native labourers are employed in the tea-growing industry of India and Ceylon, the pay of a coolie being about 8d. a day. Women and children receive from 4d. to 6d. The rates are equally low in China and Japan. It is obvious that European—still less British—labour cannot be diverted to tea-growing on any soil with the smallest prospect of financial success. The work of planting and manufacturing is neither heavy nor exhausting, and may be regarded as almost the natural heritage of the comparatively puny races engaged in it. Anglo-Saxon muscle and energy must find an outlet in other directions. Whether the Russians will succeed with their imported Chinese labour is an interesting question which time alone can answer. A new taste may ultimately prevail in regard to the flavour

of tea, and more delicate growths, yielding perhaps less body, again come into fashion. Commercial enterprise can be trusted to note any such change, but the close of the nineteenth century sees the tea industry of British India and Ceylon still steadily progressing.—London *Standard*.

ECHOES OF SCIENCE.

The exploitation of the "Kiekxia Africana," a rubber-bearing tree, promises to be important for the West African Colonies. At Lagos the milky juice evaporated gives a superior quality of rubber. All the colonies of the Gulf of Guinea possess this tree.

White mustard has been tried as a forage for cattle in Tunisia, and found to do well. It is relished by cattle, and contains a good deal of nourishment (88.2 per cent of water, 2.6 of proteic matter, 0.41 fatty matter, 2.4 matter soluble in alcohol, 1.7 of starch, and 2.4 of cellulose with mineral matters).

With reference to "Manna," Mr. Timothy, of Tooting College, cites a passage in Daniele Bartoli's "Asia," where he describes the island of Ormuz as a barren waste without even thorns or birds—"but every morning a dew falls, which congeals into grains, has a very sweet taste, and is called "Manna." The tamarisk (*manifera*) grows in Arabia on sandy soils and brackish shores; therefore, Mr. Timothy thinks the manna of Ormuz may have been blown to the island from Oman, on the eastern shore of Arabia, across the Persian Gulf. This appears to confirm the belief that manna comes from the tamarisk, and is not a lichen.

PRODUCE AND PLANTING.

CHINA AND ITS TEA MANUFACTURE.—Every rumour about the awakening of the Chinese to the task of improving their position in the tea markets of the world naturally attracts attention in India and Ceylon. Is China about to start on a fresh tack, and use those imitative faculties with which the nation is credited?

The tea market has been won by Indian and Ceylon planters, and it must be held against all comers. There is undoubtedly a movement in China towards putting the commercial house in order, but the Chinese move slowly, and every day lost to them strengthens the hands of those who now have possession of the tea market.

BLENDED TEA.—We pointed out in a recent issue how expert tea blending has become a powerful factor in the tea trade, and that the art of judicious blending is cultivated very much more extensively now than formerly. The question of blended tea is one, says the *Produce Markets Review*, which calls forth a considerable amount of attention and enterprise on the part of the grocery trade, the demand having increased to an extent little dreamt of a few years since. The phenomenal growth of the blended tea trade as a whole shows that it answered a great public want. As a matter of fact there is an increasing necessity for general traders, such as the grocers have become, to buy everything ready for use. Further, the great fall in the price of tea and the consequent disproportionate diminution of the retail profit upon it, have increased the disinclination of the grocers to continue the disagreeable operation of blending in their own place. Ordinary buyers also find that a very great saving in capital is effected by ceasing to hold heavy stocks in bond, especially as the latter often deteriorate in value as teas are now made. Again, in former years people had only to consider one market—

that for Chiua tea. Now they have in addition to study Indian and Ceylon kinds; as well, and owing to the enormous extent of some of the districts, especially in India, there are infinitely more varieties in the character of tea than used to be the case. While these facts impose increased difficulties in the way of retail blending, they at the same time afford a far greater opportunity to the wholesale blender than he could possibly have had a few years ago; in fact, the increased number of markets and varieties gives just the opening required, and, coupled with the use of machinery and the other causes named above, mainly account for the increase in the trade. The standard for blending has also greatly risen and is more difficult for the retailers to meet, unless they work on a very large scale. Years ago ancestral methods of tea mixing were no doubt all very well; but they are useless in the present days of keen competition, especially as most of the teas and flavours that used to be the favourites are practically obsolete. The public may be left to judge for itself whether it is not the fact that the grocer in a fair way of business can supply, with a return to himself, teas 4d to 6d per pound, or say, 30 per cent, cheaper than those advertised at gigantic cost. Among the special points for the ordinary run of grocers to study in connection with this and other forms of competition is undoubtedly the purchase of properly blended tea.

INSULT TO INJURY.—When will a revision be made of the interesting information given in official publications about tea. No product is so maligned as tea. Indian and Ceylon kinds are usually ignored altogether, but a correspondent calls attention to an extract from a "Manual of Military Cooking" which is more than ordinarily awful. "Tea: That usually purchased for the Army is black congou from China, and of good medium quality. The following is a favourite and inexpensive mixture:—1 lb. of Moning congou, $\frac{1}{4}$ lb. of Assam, and $\frac{1}{4}$ lb. of orange pekoe. *It is often adulterated by the addition of the horse-chestnut, elm, willow, poplar, sloe, hawthorn, &c. Of these, the only leaves resembling it are those of the willow and sloe.*" Shades of Assam pioneers—the bare suggestion of sloe leaves and horse-chestnut in the same paragraph with Assam; but perhaps the compiler of this archaic stuff has lively remembrance of the cheap China tea once in vogue.—*H. and C. Mail*, April 2.

CACAO AND COCOA BUTTER.

LONDON, April 1.

This letter ought properly to be headed "Club-Echoes and Cocoa Nibs" this week, for I have heard a good deal more about

COCOA

than tea during the last two or three days, having been in the company of a cocoa expert during a great part of the time. The cocoa manufacturers are all on the *qui vive* at present, a certain new maker whose name must be familiar to every person who opens any newspaper, but need not here be more explicitly referred to, having arisen among them, who is advertising so extensively and so unblushingly that all the old established firms are "sitting up" as the saying is. This gentleman or firm rather I suppose, for it is freely asserted there is a company behind, is calculated to be getting £20,000 a year by the sale of a brand of cocoa he pays £40,000 to advertise, and the consequence of this tremendous advertisement is that retail dealers are deluging the old established manufacturers with letters telling them as Demetrius did of old, that their trade is in danger. However, as my informant said, "working at such a heavy loss can't go on very long in the nature

of things, and *ultimately we will all benefit* by this immense booming of our article." This remark struck me as bearing on the great question of tea advertising so frequently referred to in the *Tropical Agriculturist* and I started on an enquiry as to how cocoa was pushed in new countries eliciting the following information which may be interesting. "When we introduced our cocoa into America," said the expert, "I gave our man a year to do it—to his disgust rather, for he had not been anticipating such a prolonged time of it over there, but—it was a year and a half before he got back. He travelled all over the states opening cocoa shows and starting demonstration lectures in every good-sized town, as well as advertising liberally in the papers. He couldn't work by advertisement alone. You need to show the good folks in America in a practical manner that what you've got to sell is worth buying. Now we've established a good market over there, and cocoa, which in this country in 1861 was only used in the proportion of one-eighth of a pound yearly per head of the population, is now gone up to rather more than a half of a pound annually per head. The advance of cocoa is slow certainly in comparison with tea, but it has all along been wonderfully steady. Another thing—the sale of *pure* as opposed to adulterated cocoas has also grown steadily. The public are beginning to know what good cocoa means now, and won't drink the mixtures of sugar starch and potatoes that used to be sold for cocoa."

In regard to the sale of

COCOA BUTTER,

which is an article in considerable demand among the sweets manufacturers, it is rather curious to note the effect of the recent duty on the import of the butter into this country, a duty that was intended entirely to benefit the home manufacturers, but which has had precisely the opposite result. The duty has raised the price by two-pence a pound to the home manufacturers and chemists, who were dependent on the foreign makers for their supply, and has cheapened the market for the foreigner in his own country.—So much for protection.

PROGRESS IN STRAITS.

KINTA.—Agriculture is making gradual but steady progress throughout the district. There are now seven estates alienated to European planters, and negotiations are pending for the granting of several other important concessions. Almost all these estates are being taken up for the cultivation of Liberian coffee, which has also been extensively and successfully planted upon land held by natives in all parts of the districts.—*Report, Commissioner of Lands, 1896.*

B. C. AFRICA: TANGANYIKA.

Mr. John Gibbs, manager of the African Lakes Corporation, Ltd., recently returned from a journey to Lakes Tanganyika and Mweru. We are informed by Mr. Gibbs that he went up Tanganyika as far as Ujiji. It is probable that Mr. Andrew Law, the Company's agent on Tanganyika, will next May make a voyage up to Ujiji and the north end, and inland from there towards Lake Victoria Nyanza, so as to obtain particulars about the route from Tanganyika to Uganda. Mr. Gibbs informs us that while at Ujiji he saw English newspapers dated 24th October last, which had reached Ujiji

on the 3rd January, only some 72 days from London, which is a great improvement on the time taken in former days. We understand that the African Lakes Corporation are opening a store at Ujiji.

Mr. Gibbs also visited Lake Mweru, and, crossing that lake in Captain Weatherley's steel boat, spent a few days at Mr. Crawford's mission station in the Congo Free State.

On Saturday, the 20th February, a sale of cattle was held at Zomba, at which 90 beasts of various descriptions were disposed of, realising a total of £109. Cows with calves were sold for £2 each, heifers, 30s. each, bulls, £1, and bullocks, 23s.—*British Central Africa Gazette*, March 1.

WHAT THE PEOPLE DRINK IN AMERICA.

A great deal of loose talk is indulged in by many unknowing ones as to what and how much the people drink, but few know the exact facts. We are pleased, therefore, to submit the following table of statistics, from the U. S. Agriculture Year Book, showing the consumption of tea, coffee, wines, distilled spirits, and malt liquors, in the United States since 1870, per capita of population:—

Year ending June 30	Tea Pounds.	Coffee Pounds.	Wines Gallons.	Dist. Spi- rits Pr f gal.	Malt Liquors Gallous.
1870..	1.10	6.00	0.32	2.07	5.31
'71..	1.14	7.91	.40	1.62	6.10
'72..	1.46	7.28	.41	1.68	6.66
'73..	1.53	6.87	.45	1.63	7.21
'74..	1.27	6.59	.48	1.51	7.00
'75..	1.44	7.08	.45	1.50	6.71
'76..	1.35	7.33	.45	1.33	6.83
'77..	1.23	6.94	.47	1.28	6.58
'78..	1.33	6.24	.47	1.09	6.68
'79..	1.21	7.42	.50	1.11	7.05
'80..	1.39	8.78	.56	1.27	8.26
'81..	1.54	8.25	.47	1.38	8.65
'82..	1.47	8.30	.49	1.40	10.03

'95..	1.38	9.22	.28	1.12	14.65

—*Dietetic and Hygienic Gazette*.

On the above, a very competent Ceylon writer now in America, writes:—"See how coffee and malt liquor, the drinks of the German and other European elements of population have increased, whereas spirits have fallen off, and Tea makes no progress although price is less than half of what it was 20 years ago."

THE DELGOLLA ESTATE COMPANY, LIMITED.

DIRECTORS:

Wm. Duff Gibbon, Esq., Chairman; Edwin Spencer Fox, Esq.; Frank M. Laurie, Esq.

REPORT OF THE DIRECTORS,

To be submitted to the Annual General Meeting of the Shareholders to be held at the Registered

Office of the Company at Kandy, on Wednesday, 21st April, 1897, at 3 p.m.

The Directors have now to submit their report for the year ending 28th February, 1897, together with a statement of accounts showing the results of the Company's work for the past season.

It is recommended that the balance of R5,009.73 shown in the balance sheet be carried forward, and that no dividend be declared. It has been thought advisable to finally close the Organisation Account, and the total amount outstanding R694.66 is now therefore written off.

COCOA.—The heavy and continued rains of the autumn and latter portion of the year had a bad effect upon crop, and as a result there have been secured 409 cwt. out of an estimated yield of 475 cwt. Some of this came into the poor market of last year, but the larger portion is meeting the improved position which has recently been arrived at in the home market, and the last sales showed a very satisfactory result.

On Isabel Estate a good many bearing trees succumbed to the pest so prevalent in this and other districts, but upon Delgolla the loss has not been so heavy.

LIBERIAN COFFEE continues to be disappointing, and only about 25 cwt. were secured. It seems that the fears expressed before are to be fully realized in respect of this product, and that there is but little prospect of benefit from it in the future. Prices also discourage the cultivation.

COCONUTS.—The number of nuts obtained were about 9,550 in excess of the estimate, and 138,050 were secured on an estimate of 128,500 this being some 38,894 in excess of previous year, when 99,156 nuts were gathered. The show of nuts now on the trees in all stages of growth lead the Directors to believe that there will be a considerable increase in the yield of the coming season.

TEA.—In view of the Isabel estate consisting solely of cocoa, it was deemed advisable to plant tea where opportunity served, and this having had the approval of the Shareholders has been done. Some 50 acres have been holed and drained, 45 of which are actually planted with good local jāt, and the result so far is satisfactory. The Directors think it advisable that other 50 acres should be taken in hand in the coming season. The planting of tea will very much increase the value of this part of the Company's property.

DIRECTORS.—Mr. Frank M. Laurie retires from the Board in rotation, and being eligible offers himself for re-election.

Mr. E. S. Fox resigns his Directorship, and the appointment of a Director in his place rests with the meeting.

AUDITOR.—The election of Auditor for the ensuing year has also to be made by the meeting.

By order of the Board. J. MUNTON, Agent and Secretary.

MEMORANDUM OF CULTIVATED AREA—APPROXIMATE.

309	acres	old cocoa,	25	interspersed with Liberian
		Coffee, and	140	acres with coconuts.
16	acres	Cocoa	6½	years old with Coconuts.
30	acres	"	4	" and Liberian
		Coffee.		
60	"	"	3	"

				of 5 years, with Cocoa planted in 60 acres.
60	"	Cocoa		at Isabel.
75	"	Grass and old land,		of which 45 acres rea

677 acres.

EXPORTS OF COTTONSEED OIL.

The following are the official returns of the exports of cottonseed oil, in gallons, during the month of January, 1896 and 1897, furnished by the Bureau of Statistics, Washington. Total gallons, 1897 2,891,213, 1896 1,156,564.—*Oil Paint and Drug Reporter*.

QUEENSLAND AGRICULTURAL COLLEGE.

We have received a copy of the Prospectus of the Queensland Agricultural College, which is stated to owe its inception to a popular demand for increased energy in developing the latent resources of this semi-tropical dependency—a demand which goes to prove once again the healthy and enterprising state of public opinion which exists in the Southern Colonies and is bound up in the watchword "Advance Australia." The Section of Agriculture in Queensland was created an independent administrative Department in May 1896, with the Hon. A. J. Thynne as Minister in charge. Parliament voted the following sums for the use of the College:—An initial vote of £5,000 for the establishment; another vote of £1,400 for furniture and additions to the building, and £4,000 for salaries, apparatus, tools, stock, &c. The School is purely agricultural. The training, studies, and work of the teachers and pupils are all planned to the end that they may help young men to a knowledge of the methods and reasons of agricultural practice. The course of study, as given in the Prospectus, is as complete as it well can be, and the staff includes about a dozen instructors. Considering the advanced constitution of the College, the belief of the promoters that it "will play an important part in the improvement of agriculture" in the Colony, is a reasonable one.

In any undertaking,—and particularly in an institution of this nature,—it is most important that there should be no mere temporary makeshift measures, no impediments arising from a grudging of funds, and that ample facilities should be given for allowing the influence of agricultural education to spread freely among those interested. We note that special provisions are made for the carrying out of practical experiments in the field. Such an admirable scheme is what might be expected where there is a qualified head to foster the cause of agricultural education, such as the Queensland Minister of Agriculture. Without the influence of an expert, and where it is left to the mercy of officers with no special qualifications, the cause is doomed to failure. Even in India there are Directors of Land Records and Agriculture, who are highly trained agricultural officers; but in Ceylon,——well, things are different.

We heartily wish the Queensland College a prosperous career, and that abundant success may crown its laudable efforts to improve the Agriculture of that rich and extensive Colony.

 IMPRESSIONS OF A RAMBLE FROM
YATIYANTOTA TO NAWALAPITIYA.

April 26.—If impressions of a ramble from Yatiyantota via Bulatkohopitiya up through part of Dolosbage on to the Nawalapitiya station is worth inserting, here you are. Leaving Yatiyantota by hackery, a drive of 15 miles or so brings you to Bulatkohopitiya, a small village with bazaars and the ever promiscuous arrack standing on an elevated position inviting Ramasami and Appuhami to wet their whistle ere they tramp on their weary journey. I had a good view of Knavesmire estate which bids fair to rival Yataderia in the no distant future. I passed through Glenalla, that fine property of the Hon. the Legislative Member,—it is a pity though that the cart road goes no further, for I heard very unkind things said of the M.L.C. and his

"dog in the manger" policy, twig! Glenalla seems in all probability to have been the *ultima thule* aimed at, on that much agitated question of road extension, to join on the Dolosbage road at Meenagalla. If so I cannot wonder at the anathemas heaped on the Hon.'s head and shoulders. * Going up further, past Waharaka through anything but a road, more like up and down draius, you get to a forest, on both sides of which lies old Damblagolla and Ugieside, looking fine covers of tea. A bit further and Havilland is reached. Here a most elaborate factory is in full swing with a fine show of the latest machinery. This place I remember in coffee when the Bros. Whitham were lords of the show. It never proved an *Eldorado* in the bean (!) like all Dolosbage, but in tea it can hold its own against many estates I know of. There the land is steep but the soil makes up for that. I now hurried on and pushed ahead till I got to Kelvin. Here the tea looks very encouraging: particularly the indigenous tea took my fancy. Originally planted from Horagalla and Seaforth, it has a very even jât throughout. I was told here my nearest way to Nawalapitiya was up through the bungalow facing down the other side to Seaforth, cutting off miles of a rugged road through Kellie Group on to Windsor Forest. Shades of evening made me decide on the nearest way out, so up we went and down a most precipitous hillside short-cut to Seaforth. Here the tea was looking its best, the old seed-bearers being well to the fore. Fearing darkness would overtake me, I had little time to see much, and on we went through some fine patanas, once the flourishing Nagasena. I wonder this estate, which has such a nice lay of land, has not been put into tea. Old Yakdessa forest on the other side looks as if it could make tea sing if only planted on it. Next I passed through Stow Easton, the "Fortune Killer," of the Brothers Hipplesley, to think that £7,000 was sunk on this place or the bulk of it seems a dream. The coffee I hear snuffed out in 3 years or so. No wonder it did, there is not a vestige of soil on the two sides of the tavalam road which passes through the place. Some seed tea on very poor washed-out soil I came upon, which did not say much for its capabilities in growing tea. The upper parts which lie under a precipice ought, I think, to do well; but what I saw below will not make its owner fat. Next is Horagalla: here the tea seems growing on freer soil, although indifferent. The seed-bearers I passed through are looking remarkably well, the effects of manuring. The young tea shows up pretty fairly well, but not a patch on the teas I came through up to Seaforth. It was now quite 6 o'clock. Weary and worn I pulled my aching limbs or rather dragged them past a vast tract of patana for nearly 4 miles, when to my great relief I landed on the cart road at Rambukpitiya, a small village bazaar. Judging from the sleek healthy appearance of the Moormen traders I should think this was a very flourishing little hamlet. 3 miles more and I was at the Central Hotel, Nawalapitiya, and oh! with what relish did I not quaff down that bottle of "Pilsener." A change and dinner and into bed till I was woke up with "Sar! I'm ready." 6 a.m.—into the train and off to Kurunegala. Will let you know of that historical feverish country in my next.—C.P.

 BRAZIL COFFEE NOTES.

A communication to the *Commercio de S. Paulo* from Campo Alegre says that the coffee crop in that district, which has been a failure for the last three years, promises this year to be "very good," and will repay the planters for the sacrifices which they have made.—*Rio News*, March 9.

* Absurd: the road has always been planned to go right on to the Nawalapitiya one and so it must.—Ed. T.A.

U. S. COFFEE IMPORTS IN 1896.

The corrected report of the United States Bureau of Statistics makes the total imports, exports, etc., of coffee for the calendar year as follows:—

IMPORTS.		1895.	1896.
From—		Pounds.	Pounds.
United Kingdom	..	4,205,826	4,865,154
France	..	1,870,717	1,359,373
Germany	..	2,739,813	5,584,094
Netherlands	..	4,033,274	2,986,267
Other Europe	..	555,590	2,857,892
Central America	..	52,320,272	39,534,589
Mexico	..	31,961,939	19,641,868
West Indies	..	18,532,745	8,709,433
Brazil	..	426,579,035	447,603,789
Other South America	..	73,484,884	74,088,756
East Indies	..	16,166,002	16,648,642
Other Asia and Oceanica	..	2,228,255	4,408,731
Africa	..	34,616	102,037
Other countries	..	2,625,351	1,510,927
Total	..	642,338,319	629,901,602
Value	..	\$96,512,370	\$79,999,590
Import cost per pound (cents)	..	15.02	12.70
Percentage of Brazil	..	66.4	71.06
Percentage of Asia and Africa, direct	..	2.8	3.3

The exports of coffee were 8,187,993 pounds in 1895 and 8,471,938 pounds in 1896, which, deducted from the imports, leaves the net imports, which are reckoned as consumptions, as follows:—

NET IMPORTS OR CONSUMPTION.

1895 (pounds).. 634,150,326 | 1896 (pounds).. 621,429,664

The above shows that consumption did not increase, although it was aided by a decline of 2.32 cents per pound on the average cost of the total imports. Taking the population at 70,000,000, the per capita consumption is 8.95 pounds. The above, on the basis of 131 pounds to the bag, represents an import of 4,743,738 bags, and compares with the Coffee Exchange statistics as follows:—

	Bags.
United States Bureau of Statistics	.. 4,743,738
New York Coffee Exchange	.. 4,588,496

Difference 155,242

This is a small difference between the Government statistics and those of the New York Coffee Exchange, in view of the arbitrary reduction into pounds of bags, bales, packages and barrels, varying from 60 to 200 pounds, as is necessary in the Exchange or private compilations. Besides, there are transshipments from one domestic port to another which are liable to be included in the arrivals or imports at both places.

The Coffee Exchange report of imports from Brazil is absolutely correct, and for the year 1896 compares with the Custom House figures as follows:

	Bags.
New York Coffee Exchange	.. 3,416,592
U. S. Bureau of Statistics (131 lb. to bag)	.. 3,416,823

Difference 231

This is a mere bagatelle and proves the correctness of both reports of the imports of coffee from a country furnishing over 71 per cent. of the total imports and shipping it in bags of uniform size. There is every reason to have confidence in the statistics of the New York Coffee Exchange.

The following statement shows the movement of coffee in Europe and the United States for 1896, as follows:

	Bags.
Stocks in Europe and United States, Jan. 1st, 1896	.. 1,675,160
Arrivals in United States and Europe	.. 11,617,901
Total Supply	.. 13,293,061
Less Stock, Jan. 1st, 1897	.. 1,630,970
Deliveries	.. 11,662,091
Coffee Exchange Report	.. 11,627,881
Difference *	.. 34,210

The above shows the present annual requirements of Europe and the United States to be, in round numbers, 11,650,000 bags. In 1896 the receipts of coffee in Rio and Santos were 7,319,000 bags, equivalent to 62.82 per cent. of the total requirements of Europe and the United States, thus leaving only 37.18 per cent. to be met by Mexico, Central America, other parts of South America than Brazil, Africa and the East Indies.

During the period 1880-89 Brazil furnished 50 per cent. of the world's supply, since which time coffee-planting has so extended as to increase Brazil's contribution 25 per cent. more than it was six years ago. An extension of the industry has also taken place in Mexico, Central America, the United States of Colombia and Venezuela, so that a supply of 5,000,000 to 5,500,000 bags from those countries may reasonably be looked for. Last year all other countries exported to Europe and the United States about 4,000,000 bags.

It is apparent that the world's production of coffee is at present largely ahead of its requirements, and is likely to remain so until prices recede to a point low enough to retard the industry. Nothing but an extensive failure of the crops can prevent coffee ruling on a low basis for some years to come.—*American Grocer*, March 17.

THE COFFEE WAR.

The long-looked-for decision of Judge Morris, of the Court of Common Pleas, has been rendered in favor of the defendants, the Woolson Spice Company of Toledo, O. This suit was brought by T.J. Kuhn and the Arbuckle interest, who claimed that the Woolson Spice Company was selling coffee at a loss against the interests of the minority stockholders, and therefore a perpetual injunction was asked for, and that a receiver be appointed. Judge Morris holds that the matter of the price at which the company may sell its coffee strictly pertains to the internal management of the concern, and so long as they act in good faith the directors cannot be interfered with by the court which cannot restrain a corporation from selling at a low price, even though the minority stockholders can show that sound business discretion would dictate a different policy. The testimony, however, showed that the Woolsons were selling at a fair margin of profit. The application for a perpetual injunction was therefore denied. With regard to the other point, the court holds that the agreement of the majority stockholders to sell the product for a time at such a price as will drive a competitor out of business will not make the corporation an unlawful conspiracy against such competitor, nor liable for his actual loss, nor entitle him to relief in the courts. A competitor for public favor must bow to that law of trade that allows every man to dispose of his own property, in the ordinary course of business, on such terms as he sees fit. The motion for the appointment of a receiver was therefore overruled.—*American Grocer*, March 24.

* Due to variation in European reports.

PLUCKING, PRUNING AND PREPARATION OF TEA.

(Continued from page 776.)

REVIEW OF LETTERS NO. LIII TO NO. LX.

In Letter No. 53, "B.P." from Dimbula enters very fully into the several questions on which information is desiderated—although, in a manner, he ignores the suggestions contained in our circular. He denies that coarser plucking is responsible for the fall in prices, as he believes that more care is taken now to secure good leaf than formerly; and herein he differs from "M.D." who holds that the injurious influence of coarse plucking cannot be gainsaid. This is attested by the Colombo Sales List which disclose sales at eight and nine cents per lb. If coarse or careless plucking is not responsible for such figures, the fault must be in the factory; but it is difficult to see how it can possibly pay to pluck, manufacture, pack and transport teas which fetch such prices, even if we take no count of the bad names they must give Ceylon teas, and the pressure they must cause in an already over-supplied market; and we agree in the drastic proposals of our correspondent in respect of such teas. "Balangoda" is not inclined to hold plucking, pruning or manuring much to blame, but thinks the fall in prices explicable by the larger area of low-grown teas, and the larger quantities which have to be passed through factories which are inadequate and imperfectly equipped. Rush of leaf and insufficient labour aggravate the mischief; and these he holds to be quite sufficient to account for the fall. "G.B.K." from the Central Province does not expressly name coarse plucking; and he is evidently able to find an explanation for the fall in other directions; and the main reason, in his view, is insufficiently equipped factories, both as respects machinery and withering accommodation. He instances in case of estates which have, by manuring, increased the yield per acre by 200 to 250 lb., and yet expect the factories which sufficed for the smaller quantity to be equal to the largely increased output. While quite prepared to admit that intelligent supervision is very necessary in the field, he insists that sufficient time is not spent by Superintendents in the factory, and that too much is left in the hands of underpaid native teamakers. If the "boss" on an estate considers factory work a matter of subsidiary importance, and visits the factory seldom, and even then hurriedly, it is not to be wondered if his delegate show no inclination to magnify his office. On the effect of manuring, as on the question of coarse plucking, "M.D." and "B.P." are clearly at issue. The latter feels no doubt that artificial manures, while increasing the quantity, has an evil influence on the quality—though he does not say in what respects and in what manner; but, inasmuch as quality has been affected where there has been no manuring, he refuses to hold manuring alone responsible for deterioration. We are not sure that it would not be more logical to acquit manuring altogether of blame, in the absence of definite evidence of the harm it has done or can do. "M.D." takes this view when he argues that manuring, if only the proper substances be applied, ought to improve quality, reasoning by analogy. The flavour of fruits is

known to be improved by scientific culture; if fruits, why not leaf? On the evil effects of severe pruning these two correspondents are agreed—"M. D." declaring it to be a pernicious system, which, however, is fast dying out; while "B. P." characterizes the practice as a fatal error which has done as much to bring down prices, as anything practised outside the factory. On the work of the factory, the two correspondents differ again—the last-mentioned denying less attention to manufacture; while "M. D." feels that there are too many "meets" and distractions to allow of the watchful care so necessary in tea. One thing seems clear to us that no Superintendent, who does not subordinate ease and pleasure to work, who does not do his best for his employer by active personal supervision of both field and factory work, can be said to be earning his salary, or to deserve to advance in his profession. Large rollers too, do not turn out as fine work as the smaller ones of old; and "B. P." holds the proprietor, rather than the Superintendent, responsible for low prices, and sets forth quite a catalogue of delinquencies, in insufficient space and machinery; stinginess in dealing with teamakers; cheap and insufficient management; inability of V.A.'s to give young Superintendents practical lessons in manufacture or to correct their errors; want of encouragement to good Superintendents. Indirectly, he hints that absenteeism is responsible for these blunders; and that an old bush cannot give as good tea as a young bush.

Of the next four letters the one from "W. B. J." of Agrapatana enters most fully into the questions propounded. Like "S." from Rangala, he is not inclined to acquit coarse plucking of responsibility; but he holds that it is chiefly practised in the low-country, as, at higher elevations, the tendency is to pluck even finer than before. On the other hand, "M." from North Matale is silent on plucking, holds over-production the principal offender, has no experience of manuring and acquits pruning and the factory, except when there is a rush of leaf; while "W. A." from Maskeliya expressly denies the evil influence of coarser plucking, as all grades have gone down, and perhaps the finer most. But surely, this is fallacious. We have seen that our best teas have not fallen off in price appreciably, that some maintain their old prices, and some have even advanced; and when the plucking is coarse, can it be said that the finer grades of the break are not also affected? It is gratifying to have from the same correspondent, as a result of a good deal of experience, the opinion that manuring does not affect prices prejudicially, while severe and too frequent pruning does, and is resorted to as a simple method of increasing the yield, without considering the slow replacement of the lost wood; and he instances Kandapola, where tea is allowed to run three years unpruned, with the result that prices are maintained. "W. B. J." goes even further on manuring, and holds that at his elevation it actually improves the quality, if judiciously practised; but he thinks severe pruning less prevalent than it used to be. "S." expects to be able to pronounce more confidently on the influence of manuring on flavour 12 months hence; but want of care and attention has, in his opinion, a great deal to do with poor teas. "W. B. J." shares the latter opinion; and, while admitting that the rapid increase in acreage has increased the number of factories, he doubts the adequacy of the accommodation supplied.

This deficiency, coupled with night work and lack of experience to keep pace with the growing demands for teamakers has had an evil influence; and the remedy should be efficient and close supervision in both field and factory. "W.A.", however, is sceptical about less care being responsible in any way for prices, seeing how much better, and more elaborate is the machinery now used in factories; but may not too much be left to improved appliances by those—only a few, it is to be hoped,—who are inclined to take things easy? "S." evidently thinks this happens in many factories in which the coolies and the teamaker are not adequately supervised. On the whole, "W.B.J." is not inclined to think our present teas, from any well-ordered factory, worse than those of previous years; and accepts the larger profits now, or recently, earned on most estates as evidence that the most profitable system is being pursued. But is that conclusion inevitable? Some planters hold strongly that a reduced output would benefit not only individual estates, but the local tea industry, generally, by inducing keener competition. But each must judge for himself.

(Letters Continued.)

No. LXI.

[Some Colombo opinions, from Brokers and Merchants :—]

1. There seems to me no doubt that the coarser plucking in Ceylon has in a great measure been the cause of the gradual decline of the average. Of course, a planter knows what pays him best and he naturally adopts that policy, but it looks almost as if he were killing the goose with the golden egg.

Ceylon used to more than hold its own with India, but now India, with a larger export, has lately had a much higher average, which is due, in a great measure, I understand, to improved quality caused by finer plucking. Nos. 2 to 6 are questions which should be answered by planters themselves, and I do not think that a mere expert on the value of the tea should presume to criticise planting work. LEDGER.

No. LXII.

I am strongly of opinion, and have been so for some time, that the value of our teas is greatly depreciated by want of sufficient attention to preparation in the factory.

The Superintendent of a large estate spends very little of his time in the factory, and the preparation of the tea is left to a native teamaker who simply works by rule of thumb.

This is where India beats us: no Ceylon teas come up to Indians in make and appearance. There European Factory Superintendents are largely employed.

Inadequate factory work will certainly spoil the best leaf that comes into a factory.

MERCHANT.

No. LXIII.

1. I do not think coarser plucking has had much to do with the lower prices.

2. No, certainly not.

3. This not to a large extent.

4. Yes, certainly a great deal is due to this. Everything is left to the *Teamaker*. In old days men employed Kanacapulleys on R15 per month, and bossed him;—50 per cent of the new generation of planters employ teamakers who boss the durai!. Not *fine* plucking, but *careful*

plucking such; as is carried out by Mr. Megginson on St. John's; round the estate once in 9 days at outside; and far more attention to the bush for the first six months after pruning, and much more attention to the factory will remedy our poor prices provided we can obtain coolies to do the work.

MERCHANT No. II.

No. LXIV.

Coarser plucking undoubtedly has a lot to do with it; but played-out soil and the absence of *manure* is telling on the plants and will continue to do so until more attention is given to it. T.

No. LXV.

Overproduction and higher exchange account for most of it. So long as producers can get remunerative prices for low grades they won't leave off going in for quantity.

No doubt, Indian planters have gone in for finer plucking and they have certain advantages—better soil, better weather for withering and, I think, better withering accommodation. I think Indian tea will always beat Ceylon tea in regard to leaf. W. S.

No. LXVI.

In reply to your questions as to the causes which have brought down the prices for Ceylon teas, my humble opinion is as follows :—

1st. Coarser plucking is not the rule on estates, but quite the exception; greater care is taken in the field the last few years than formerly. When very coarse leaf comes into the factory it will seldom have any bad effect on the best teas as it all comes out in the sifting and is sold as eongou and red leaf.

2nd. Manuring old tea and when unpruned, will not have any bad effect on the leaf, but manure applied to pruned trees does undoubtedly give a weaker tea in the cup for several pluckings.

3rd. Pruning.—This is a work that does *not* receive the attention it should. Trees are not *pruned* in our days!—they are *cut down*. An order is given to cut a field a foot, or 15 inches or 18 inches—the lower and more severe it is cut, the weaker the tea in the cup is for several pluckings. I have seen ten-year old tea cut down 9 inches to a foot. The reason given was: "to get good strong healthy branches"—well it took three years to grow the size the trees were when pruned, the pluckings all that time have been a loss, and the trees have not such good stems as they had previous to the heavy pruning. My humble opinion is that tea, ten years old and over, should never be pruned down below two feet and when pruned that height, every small twig should be cut off carefully and cross branches thinned out &c.—that is, the tree should be *pruned* and not merely *cut down* and this can't be done properly under R9 to R10 per acre. Slashing away at the trees the severe way now carried on gives poor leaf till the tree has recovered its branches and foliage.

4th.—Preparation in Factories. There is greater care taken in factories than formerly. In fact sometimes too great a zeal is shewn, and the teas may slightly deteriorate in consequence. What I mean is this: Young Planters are far too ready to be everlastingly tasting their teas, and they will then go to the teamaker, who goes to the cooly rolling and the cooly firing and give *fresh instructions!* This goes on daily in some

factories till the coolies do not know how to act! They do not know for two hours together if they are making proper teas or not. This causes factory-bulked teas to differ much in daily make and therefore in the bulk. If I find a carefully-made tea being made say on the first day of the month, I never bother the rolling or firing cooly. I find they will make the same tea right through the month if *not* interfered with. Coolies in factories are, as a rule, not only very careful if a certain work is given in their charge; but they are also very proud of doing the work. In this way—as I have shewn above—alone do I consider that some bad effect to bring down prices may occur. Teas from some factories that I know, fetched 1s and 1s 3d regularly in the home market a year or two ago and only get 8½d to 9½d now: this has nothing to do with the actual manufacture of those teas; the teas are as good as they ever were. It is the demand for that certain tea that has disappeared.

5th.—Shortness of Labour. The leaf has to be plucked every 8 to 9 days, and if this can be done regularly, the bud and two first leaves with that length of stem is taken, and another full leaf or sometimes half or three-quarter leaf, all make a good tea. Should the estate be short of labour and cannot get over the fields before the shoots get hard and bangy, it makes a most serious difference in the quality of the tea. It is very necessary for good quality tea to have lots of withering room. If withering room could be arranged so that one leaf did not lie on another, and when withered—sharp rolling, and firing, *no fermenting*—we should make better teas.

6th.—The causes for the fall in prices are overproduction, combination amongst buyers, and the ups and downs in the value of the rupee. It is quite evident that the home and local weekly market are always fully supplied with teas. It is quite the usual thing for buyers to go in a half each for a certain grade of tea, and also for buyers to agree that "if you buy the pekoe of that estate, I'll take the other," so there is no high bidding. It might be asked why Indian teas average better than Ceylon teas. It is because London buyers get orders from their constituents to 'send a quality as near as possible to the last lot, our customers like it' and this will go on till one day the shop-keeper can't get the exact tea he wants. So he blends and makes the best he can to suit, and the Indian and Ceylon will very soon be on an equal footing.

7th.—Undoubtedly, the Ceylon Tea Planters keep the pot boiling through Exchange! Take our local sales: the difference between 1s 2d and 1s 3d in the rupee makes a difference of fully 15 cents a lb. in the price we get for our teas,—where shall we be if the rupee stands at 1s 4d—

—Yours faithfully,
OLD DIMBOOLA.

March 6.

LXVII.

Hatton, March 20.

DEAR SIR,—In answer to your circular of 12th Feb. *re* Ceylon tea.

1st. I don't think coarser plucking has been resorted to.

2nd. Manuring with eastorcake and bones is a great cause of prices coming down; this is my experience.

3rd. Generally, pruning is lighter than it was formerly.

4th. Less attention in factory may be in some cases.

5th. This is the great evil, short labor force.
6th and 7th, Overproduction and manure not properly applied. S.

LXVIII.

(1) I do not think coarse plucking has anything to do with it as most estates pluck finer or rather more carefully than they did a year or two ago.

(2) Not having manured to any extent I cannot express an opinion.

(3) Yes, I should say in some cases the severe pruning carried out has had a good deal to do with the fall in individual prices.

(4) I think more care is taken now than formerly in preparation.

(5) Not at all, as in my case I have plenty of labour.

(7) I think overproduction is the chief cause.
"D."

No. LXIX.

Kandy North, March 3.

DEAR SIR,—Your questions are stiff ones; on that account difficult to answer.

(1) Coarse plucking has nothing to do with it. The leaf plucked now-a-days is far finer than that plucked in earlier years—say '84 or '85.

(2) Don't think manuring is to blame either. Manuring of tea is not carried on as a rule, on an estate very short of labour. Manure is generally applied in slack months as the harvesting of flush will permit.

(3) This is a system not much in favor now-a-days—old soils do not grow wood fresh enough for this style of whittling.

(4) Only teas with quality fetch a price now-a-days; given carefully plucked leaf of this sort; and with usual factory attention, those teas command their price no matter how graded.

Teas which command long prices are not, as a rule, handsome to look at.

Careful supervision is wanted both in field and factory.

(5) Have been fairly well off in this respect, far better off than in days when better prices obtained.

Were the London stock of teas only by millions less, I don't think it would be a bold thing to state that we would soon be on a par again with prices ruling for Assams.—I am, yours faithfully,

"STILL ONE OF THE CREEPERS."

LXX.

March 18.

DEAR SIR,—In reply to your questions as to the causes which have brought down the average price of Ceylon tea, I am of opinion that this may be attributed to,—

1st. Increased supply.

2nd. The falling-off in quality of high-grown teas from the older estates.

3rd. A larger proportion of low and medium grown teas.

Both plucking and manufacture have improved in this district of late years and this is shown by the averages obtained in 1895 as compared with the previous year; the Ceylon average for these two years was stationary, but several places in the Kelani Valley obtained better prices in '95 than in '94. Manuring and heavy pruning have not lowered prices in this district.

but have tended, more particularly, with a low jât, to improve the teas.—Yours truly,

A.C.K.

PLUCKING, PRUNING AND PREPARATION OF TEA:

REVIEW OF LETTERS NOS. LXI TO LXX.

The first six letters in the previous batch constitute a departure, in some respects, from the character of the sixty letters which preceded them. The earlier replies to our questions were almost without exception from residents on estates. Among the six now under review are several Colombo opinions, from Brokers and Merchants. "Ledger" feels no doubt that coarser plucking explains in great measure the fall in average prices; and while he concedes to the planter the right to decide which system pays him best, he questions whether the goose which lays the golden egg is not being killed by excessive plucking. Ceylon, which had held its own against India, has now to be content with a lower average; while the rest which Indian tea bushes annually enjoy, should ensure them a longer life. "Merchant," on the other hand, is silent on plucking, but holds strongly that the value of our teas is greatly depreciated by want of sufficient attention in the factory. The superintendent of a large estate spends very little of his time in the factory; and the native teamaker simply works by rule of thumb; whereas in India European teamakers are employed, and hence the superiority in make and appearance of the teas produced there. Yet, when Mr. Mitchell and Sir John Grinton propounded a scheme for training tea-makers in the Technical School, where scientific and practical instruction might be combined, the Planters' Association rather doused the proposal with cold water; and it was dropped. "Merchant No. 2" does not think coarser plucking has had much to do with lower prices; but he, too, is emphatic against the system which leaves too much to the tea-maker, and contrasts the old *régime* under which the superintendent "bossed" the kanackkappulle, and the present, under which 50 per cent of the *durais* are bossed by the tea-makers. Not fine, but careful, plucking once in nine days at most, attention to the bush for at least six months after pruning, and more care in the factory, are the remedies prescribed. "W. S." holds over-production and higher exchange responsible for the fall. That would be a reversal of the bi-metallist theory that gold prices would rise with the rise in exchange; but so long as quantity pays, the system which raises alarm concerning over-production will be followed. Both "W. S." and "Broker" recognise the influence of poor and worn-out soil in regard to which India has the advantage of us, backed up by annual wintering and more favourable climatic conditions. Some of these disadvantages should be sought to be overcome by systematic and intelligent manuring, and "Broker" expresses his belief in the necessity of greater attention to this remedy. "Old Dimbula," in a long and interesting letter, denies either that coarser plucking is the rule, or that when coarse leaf goes into the factory, it can have any bad effect generally on the good teas which are separated in the sifting. But may not the sharp juice and the joint rolling and fermentation tell on the flavour?

The theory that manure produces a weaker tea from the pruned bush, and has no injurious effect on the liquor from old unpruned tea, is one that demands investigation, as it is not easy to understand why a bush weakened by pruning should not have tone given to it, and thereby to the leaf, by manuring. It is more easy to assent to the remarks on pruning, which deserve attention—condemning, as they do, the cutting down and hacking, misnamed pruning, which obtain so widely. Judicious pruning should seek to conserve the healthy wood, while removing small twigs and cross branches; and bushes ten years old and over, says our friend, should not be cut below two feet, as the old stems can never be replaced, and it is long before the bush under maltreatment can regain its branches and make a show of healthy flavoured foliage. So far from there being neglect in the factory, greater care than ever is bestowed on preparation. If anything, there is misguided over-zeal which leads to uncalled-for interference with the factory staff, instead of allowing it to work throughout a month, with similar leaf and under identical conditions, in accordance with instructions, which have produced good tea at the beginning of the month. Needless interference and fresh instructions prove puzzling, while they lessen their pride and interest in the work of the tea-maker and his helps. As a rule it is contended, that there is no falling-off in the teas, but the demand for particular manufactures has abated. Shortness of labour does tell on quality by bringing in hard and bangy leaf; and also lack of withering accommodation; but when the market is fully supplied much is made of the slightest deterioration to account for prices which are mainly regulated by the demand.

"S" from Hatton and "A.C.K." deny the prevalence of coarse plucking; while "D" and "Still one of the Creepers" from Kandy North, maintain that coarse plucking has nothing to do with the fall in prices. The last-mentioned acquits manuring, as also heavy pruning, which is getting discredited especially on soils which refuse to grow fresh wood; but he bespeaks more careful supervision in field and factory, and believes that if the stocks in London were less, prices would improve. At present, only teas with quality fetch good prices, however graded, and the highest priced teas are not the handsomest. "A.C.K.," too, holds large supplies as the principal cause of the fall in prices, combined with the larger proportion of low and medium-grown teas which now find their way into the market. The view that the falling-off in quality of high-grown teas from the older estates has had any appreciable effect, is likely, we fancy, to be disputed; but much must depend on the definition of "high grown" and "older estates." Attention is drawn to the higher averages obtained in 1895 over 1894, in proof of improvement in plucking and manufacture; while manuring and heavy pruning have helped, rather than sent down, prices. While "D" refuses to express an opinion on manuring with limited experience, "S" is confident that "manuring with castoreake and bones is a great cause of prices coming down." We should have been glad of the facts and experiences on which this dictum is based, as manuring is now generally considered an essential of cultivation, and the two articles named are in almost universal use, presumably because they have been found helpful to the planter. "S" claims that pruning is lighter than it was, while attention to the factory has fallen

off; "D" holds severe pruning responsible to a great extent for bad prices, and believes that preparation commands greater attention than before. Both agree that overproduction is the chief cause. Altogether, the ten letters under review are not the least suggestive of the series, though they disclose at the same time a remarkable divergence of opinion on most points.

(Letters Continued.)

No. LXXI.

THE INFLUENCE OF TEA SEED IN REFERENCE TO INDIFFERENT TEAS.

20th April.

DEAR SIR,—In view of the discussion you recently started in your columns (and for which we are one and all very thankful to you), *re* fall in tea prices, and the different opinions you elicited as to its various causes which have been voluminously and fully ventilated,—has it ever entered the minds of any of your contributors that *tea seed*, from which estates were planted not long ago, and are still being planted may have a part to play in the output of indifferent teas, wanting in strength and flavor? Common sense speaks for itself. It is an admitted fact that weak, unhealthy, un nourished parents cannot and never could have healthy robust offspring. In like manner tea seed from bushes grown on wasted and worn out estates where other products had held sway for half a generation or more and the soil whereof was originally poor stuff, cannot possibly be expected to maintain healthy seed-bearers and be parents to healthy tea bushes. Where fertilizers can be cheaply applied year after year it may not be so. What about our steep outlying districts where communication is often only a narrow rugged bridle path for miles; these are all at a decided disadvantage. The seed from these seed-bearers must be and will be lacking in stamina, yet seed has been indiscriminately bought and a vast acreage planted. However good a *jât* may be if the parent trees are on exhausted soil and are poor specimens my humble opinion is that plants raised from such seed will remain tainted with poverty of sap;—manuring might give it a flicker which never can be upto much. The taint of the parents remains embedded; weak and debilitated as years roll by, they will never produce a healthy succulent flush, however nice an appearance the fields may present to the onlooker. At the infancy of tea in Ceylon, say 1880, there were but 3 or 4 places from which seed was procurable. The seed-bearers were about 6 and 7 years old and in their prime, the seed then and for a few years after might have been all that could have been desired and may be so now. I know these places and I was told they have had their seed-bearers planted on virgin soil, what about the worn-out places since sprung up some of them having seed-bearers? "Nous verrons." Every man before buying seed ought to satisfy himself that the seed he gets are not from seed-bearers planted on exhausted and worn-out soil, that is if he has a future to look forward to for producing a rich marketable tea full of strength and flavour. Don't touch seed-bearers on *old* coffee land which never even grew coffee for three years.

By the bye, can you kindly enlighten us as to whether the owner of a paddy-field, after his harvest is reaped, has power to prevent one going over his fields after snipe or say to shoot over

his field? Opinions differ—we have decided to make you our referee.

SNIPE.

[Surely, permission of the paddy-field owner has to be got: would "Snipe" allow his native neighbours hunt for hare in his tea-fields without leave asked and obtained?—ED. T.A.]

LXXII.

Passara, March 2, 1897.

(1). Of course, rough leaf plucking gives rubbish, but if leaf is plucked medium, and there is room on tats, the tea should be fairly good.

(2). Manuring, I believe, will spoil quality, especially artificial, as the flush comes on so rapidly and is always sappy.

(3). Severe pruning would not spoil quality if the bushes were not plucked so soon, if 10 leaves were left and then *knifed* across, I believe the effects of pruning, so far as quality goes, would be obviated. *I have proved this.*

(4). It is my full belief that *proprietors* err and severely so, in not employing highly-paid Europeans to make their tea, but the well-paid and experienced Manager is required just the same. Men must supervise all works: but no Assistant will remain stewing in a factory on R150. [I believe that this is a great reason why India has gone up; their estates are so large that *they always* have European supervision of best quality making their teas, etc., etc.] Only give them one month in factory and one in field, they are always bright and pert. At the same time if Ceylon proprietors order their managers into the factory and let natives supervise the field,—the results would be still more disastrous.

(5). Men must make up their minds when short of labour to abandon some fields or *only pluck* or rather tip the flush, never minding how many leaves are left; the present method of chasing 14 days' flush has for result rubbish. *First pluck* fully developed leaf—small shoots make tasteless tea; (2) have no end of room to lay leaf thin on tats. In wet weather, apply heat—but never until leaf has naturally withered for 10 hours at least; fire low. Employ better paid tea-makers, either *European* or high class natives,—be liberal with tat room. Good teas cost money and are worth it; the present mode of cheese-paring and demand for big crops will not pay. Except in poor *jâts*, avoid severe pruning, but all this will be no use without a better paid man employed in factory. Managers, at least conscientious men, are given far too much work in field, factory and *office*; they have found this out in *India*, hence their good prices.

R.

No. LXXIII.

Lower Ambagamuwa, March 6th.

1. Coarse plucking is undoubtedly the principal factor in reducing one's prices; but there is just this which some folk lay well to heart "I have quantity and that leaves me a miserable balance on the right side." I question this though! Experience has taught me that quantity when "weighed in the balance is found wanting." Not only are you frantically making efforts to *advertise* your estate, you are further materially helping to reduce the Ceylon average which must sooner or later tell on quantity producers. That coarse plucking has a good 5 per cent. of red leaf is an admitted fact and any percentage of reddish leaf in your break does for you, I have been a sinner but sinneth not now!

2. Manuring tea has always produced good results, a much more sappy leaf has been my experience after the manure has begun to act; I do not think it destroys flavor but this it does; it produces a far richer outturn, a dark black tea full of strength.

3. Pruning: I have always pinned my faith on a medium pruning, but that once in seven or eight years you require to cut down into the white wood is no new discovery; but this does not suggest a hacking down as I have noticed on some places; a judicious low pruning can with very little care be resorted to without injuring your bush, the white wood takes longer to respond to pruning, but when it once does, which is generally about the 3rd month from pruning, your bush presents quite a virgin look; I adopt manuring whilst I have this pruning going on; the flush from these fields is, as a rule, poor in liquor until such time as the new shoots attain the size of your ruling pencil (I do not know how big that is) but an ordinary ruling pencil; it takes a good 5 to 6 months before you have such wood; from thence on to 10 or 12 months it needs no pruning and your flushes are all that can be desired.

4. I am of opinion we are now far more advanced in the preparation of tea than we were 10 years ago when we realized 1s. 6d. average. Even now we can hold our own if more care is paid to the quality of leaf we manufacture. Tea-making begins in the field, so said the great teaman "Cameron."

5. Shortness of labour must and will tell; the only remedy is to cope with a sufficient acreage to keep in touch with your labor force and prune the balance, it is no use trying to haul it all in once in 3 weeks!! I pity the tea you manufacture from such leaf.

C.T.

No. LXXIV.

Kotagala, March 6.

DEAR SIR,—Replying to your questions in the issue of 2nd.

1. Coarse plucking is not sufficiently general to seriously affect the general average.

2. The same remark I think applies to manuring, individual cases might be affected by either treatment temporarily.

3. Severe pruning does affect the quality of the tea adversely for some time.

It is necessary to prune down some time and it is well to let good strong shoots up after this before tipping.

4. A great deal can be done with care and judgment in the factory, at the same time sufficient accommodation and proper arrangements are necessary. It is not so easy handling large quantities of leaf in a single factory, as it is to deal with a reasonable amount—whatever the accommodation may be.

5. The general average may be affected by shortness of labour during April and May, but not I think at other times. Apart from overproduction and increased supply in competition at sales, the soil after a few years seems to have lost something that it formerly possessed. Other things being equal I have noticed the tea from 3 to 5 years old has a point and quality in it that in many cases go off and do not come again. For one thing there is less "bloom." Of course the richer and less exposed to wind and wash the soil is, the longer the tea will be in shewing this falling-off. What is wanted is

an expert to experiment on different estates in Ceylon, something in the way Bamber seems to have done in India. He must be a first-class chemist.

W. H. M.

No. LXXV.

Kalntara, March 10.

DEAR SIR,—I find I have omitted to reply to your enquiries of 12th ulto., *re* decline in price of Ceylon teas. The subject is a very big order and I really cannot find the time to treat it as my experience would show me it deserves. Taking your headings, however, as they stand:

(1) Off flat land you cannot in the lowcountry or elsewhere expect much quality in the teas. In such cases I would go for a big yield. On a hilly place I would try and combine quality with quantity. You can't lay down a fixed rule, or generalise from the question you ask.

(2) I don't believe in these light artificial manures, they are "killing the goose," but proprietors expect bigger and bigger yields and we, as managers, are expected to give them.

(3) Pruning, as a rule, is certainly too heavy in the island, but there are many exceptions.

(4) To a certain extent. Men used to do the factory work themselves. Now many take it for granted they had nothing more to learn, and leave too much to tea makers. Yes, you can only make "the best of a bad jât" with badly plucked leaf—but it is equally easy to spoil good leaf by injudicious manipulation in the factory.

(5) Personally on this estate, I can't get the leaf I want, because we are largely dependent on Sinhalese labor, and they hang back unless they can pluck large averages. Thus, when we are shorthanded with Tamils, the Sinhalese will wait until they know they can pluck 30 lb. or 40 lb. off a certain field and then they come and pluck it, resulting in coarse leaf etc., etc. The remedy—is more Tamil labor when we can get it.

To sum up—an exhausting climate on a poor soil, and further exhausting bushes (which have not the rest of a winter as in India) by application of stimulating manures will, I greatly fear, land us in serious difficulties sooner or later. Under its present conditions I am no believer in the continuance of the enterprise and I was one of the earliest engaged in it.

MANAGER.

LXXVI.

High District, March.

DEAR SIR,—1. I don't think coarser plucking has had much to do with it. Some lowcountry Managers brag about their big yields, but they are a small proportion.

2. I have very little experience of manuring, some of my neighbours manure—with prices much the same as before manure was applied.

3. Good tea is never made after severe pruning and the longer the bushes run from pruning the better the tea.

4. Pluckers require a lot of attention, so do teamakers and factory hands: if neglected, prices will fall.

5. Shortness of labour has a lot to answer for. This estate has always been fairly well-supplied with coolies.

6. A much larger acreage now in bearing under 2,000 feet, which, as a rule, gives quantity, and not quality.

7. Too many cricket, tennis, and race meetings; also an oversupply of horses, which must be exercised.

P. A.

LXXVII.

Nawalapitiya, March 15.

DEAR SIR,—I have noted the opinion of some writers that we are plucking now no worse than we were wont to do 6 or 7 years back: this is not so. Some may who can, but there are others who have no other alternative left them and these are in the majority. 7 or 8 years ago we had an ample labour force to cope with our crops, and a gathering in of the harvest every 9th day the rule, not the exception. At present time the exigencies arising from an unavoidable source—a crippled supply of labour with extended cultivation—makes it an almost impossibility to gather in green leaf more than once a fortnight, and when the rush comes on for 3 weeks or more with the inevitable result. This is what makes the plucking coarse. I do not say that we pluck or take off much more than we did—but 1st and 2nd leaf and $\frac{1}{2}$ 3rd leaf as of yore—but *these* same leaves which come off every 9th day, now come off every 15th, or in some instances every 21st day. Mark the difference of quality from such leaf manufactured! Here is where I come in with the remedy: those estates which cannot cope with all their crop for want of labour must resort to prune down to keep in touch with a 9-day plucking. When this is done, and which ought to be done, the question of over-production and glutting the market with rubbishy teas is practically solved. If we are to place 119,000,000 lb. of tea on the market now,—with a 9-day plucking, we cannot do much more than 104 or 109 million. With this difference flashed across to Mincing Lane, up goes the market. We may put in 120 or even 200 million of rubbish predominating, but with the present labour supply we cannot—decidedly cannot—put in a tea from a 9-day plucking.

Apart from this—factories purchasing leaf from natives! What an amount of injury is being done; in most cases it is left to a native to receive this leaf from Dick, Tom, and Harry, and the results can be better imagined than described. I have seen leaf in purchasing factories. It made me wince to think of our primitive days when we had to depend on manual power to roll our leaf. The quality of leaf I see and saw will no more roll under Ramasami's greasy hands and fingers than a desiccator fire-brick would. Thanks to heavy machinery (if it can be only withered)—the whole tea bush might be transported and rolled into tea, with results of overproduction! And no margin of profit, but a large debit in the no distant future and with it the ruin of a flourishing enterprise. It will be no use to individually try to rectify these evils. All must join hands to save Ceylon's reputation by manufacturing no more muck.

C. T.

LXXVIII.

Pundalnoya, March 19th.

DEAR SIR,—I can only repeat the opinion of the greater number of your correspondents that plucking and manufacture are carried on as carefully today as ever. Manuring is not sufficiently general to have appreciably affected prices. Heavy pruning, doubtless, affects quality for the time; but this has been a factor more or less from the beginning; and the general opinion appears to be that the increased yield more than balances the reduction in quality. However—as I do not manufacture my own teas—I am really scarcely qualified to give an opinion.

There is another question that I should like to see sifted out, viz:—the benefits or otherwise to be derived from the burying of prunings. One of your correspondents ridicules the practice on the ground that a plant could not make use of its own waste products. This might be true (though it is an open question) in the case of leaves, &c., shed naturally after the reabsorption of the sap. But in the case of prunings, the leaves and branches are cut off in their full vigour and must contain a large amount of plant-food capable of re-assimilation. And then there is the question of "soil ferments," to which so much attention is now being paid by scientific agriculturists. It has been clearly demonstrated that many substances, while not themselves available as plant-food, may, by their decay, set up fermentation, liberating the so-called "nitrifying organisms" and gases which help to make the inert nitrogen in the soil available for the use of plants. It is at least possible that the fermentation of buried prunings may do good in this way.

We have always heard that lime is prejudicial to the health of the tea plant. Has this been properly tested? It appears from recent papers* on the subject, that "the introduction of lime into the soil . . . favours in a high degree the evolution and development of the nitrifying ferments" which—in the absence of lime—are hindered by the accumulation of free nitric acid resulting from their action. It seems possible that the bad effects said to have sometimes followed the burying of green prunings may be due to this want of lime.

There is at any rate one very appreciable advantage in the practice—if properly carried out, and that is the check that it gives to insect pests of all kinds. For this purpose it is, of course, essential that the work should be effected as soon after the pruning as possible.—Yours truly,

E. E. G.

[We have heard of a little lime being used with buried prunings with most satisfactory results.—ED. T. A.]

LXXIX.

Peradeniya, March 30.

DEAR SIR,—1. I don't think that coarse plucking has much to do with the decrease in prices, but no doubt many estates, which used to go in for fine teas, now make a medium quality.

2. I have no experience of manured tea myself, but the general impression seems to be that manuring is rather inclined to detract from, than improve the quality of the leaf.

3. I don't think the pruning *usually* adopted is so severe as to damage the average quality of Ceylon tea.

4. I think as much care is bestowed on manufacture as ever. No doubt finest leaf can be spoilt by careless withering or manufacture, but, on the other hand it is impossible to make good tea from coarse or uneven leaf—the great secret of making good tea is to have even leaf and a good and even wither.

5. We have never been so short of labour as to affect our work seriously in field or factory

* Bulletin of the Botanical Department, Jamaica, Nov. 96, p. 241. "Soil ferment important in Agriculture," by Dr. W. H. Wiley.

and have always had sufficient factory accommodation.

6. Here we have manufactured a similar quality of tea since 1891; and so far as our experience gained in Mincing Lane, goes, our teas are intrinsically the same as ever. I am, therefore, inclined to think that apart from overproduction and similar causes, the only cause that can be given for the average of our teas dropping below that of Indians is a change of taste in the London market.

W.

LXXX.

(1) Coarse plucking of leaf has got little to do with it, except in the heavy flushing months.

(2) Manuring with good tillage, in my opinion, improves the quality of the tea.

(3) Severe pruning affects quality adversely for a few months.

(4) I don't think the manufacture gets less attention than it did years ago: good tea cannot be made out of bad leaf, but good leaf may be spoiled by careless manipulation.

(5) Shortness of labour has affected the field work at times, especially in April and May.

(6) Supply, being in excess of demand, is in my opinion the principal cause of the falling-off.

A. C.

LXXXI.

April 3.

DEAR SIR,—It is difficult to say what the exact reason is which has brought down the average price of Ceylon tea, but I have little doubt in the lowcountry coarser plucking has a good deal to do with it, as so many estates find quantity pays better than quality, though in Assam and Darjiling I have never seen finer and more regular plucking than is now carried on in most upcountry Ceylon estates.

(2) The amount of manuring gone in for in Ceylon is not, in my opinion, sufficient to reduce the average of the whole output of Ceylon.

(3) No, severe pruning will, of course, give weak liquored teas for a good many months after the bush has come into plucking; but this wears off the farther away the bush gets from pruning, and it must be remembered that in India, too, severe pruning is gone in for, when the bush requires it, and the same fall has not occurred in Indian prices.

(4) As one of those who hold that the tea is made in the field, I still believe a great deal could be done by the Manager or Superintendent, as he is called in Ceylon, being more in the factory himself and being able to drop in every now and again. At present this is impossible owing to the distance the bungalow very frequently is away from the factory, and the numerous duties, compared to those of an Indian man, he has to perform—field work, factory work, accountant and clerk. In India it is an unheard-of thing for the Manager to be his own clerk, a native writer is kept on a small salary of R15 to R20 per mensem, the Manager's more valuable time and energies being given wholly to his work. The distance the bungalow is very frequently away from the factory at once strikes an Indian planter, where if it was found necessary to build the factory some distance from the bungalow, the latter would at once be removed to within a stone's throw of the factory.

(5) Not at all.—Yours truly,

EX-INDIA PLANTER.

LXXXII.

1. Nothing.
2. Nothing.
3. Nothing.
4. Everything. You bet.
5. About 10 per cent leaf lost.
6. Sport! Sport!! Sport!!!

The above ought to be of more value than all that has been written on the subject because it is undiluted.

V. A.

LXXXIII.

April 25.

DEAR SIR,—In reference to the interesting correspondence in your paper *re* tea prices, will you allow me to suggest a solid though unpalatable reason for the recent depreciation of prices:—In former years pure Ceylon tea was extensively advertised and “boomed” in Great Britain; this with the comparatively small supply created a rise of prices above the normal value. Now advertising of Ceylon tea at home seems to have practically ceased and the supply being larger, prices have gone down to their proper level—it is merely a case of supply and demand.

In my experience plucking has been finer, pruning as good, and manufacture more carefully attended to than formerly; still prices have decreased.

Indian teas were not “boomed” by bogus auction sales, etc., as ours were, so they have not had the rapid rise and fall in prices; their better soil, of course, gives them the advantage in the long run.

Can you inform us if the Company for the sale of pure Ceylon tea in packets is still in existence and, if so, how it is prospering?—Yours faithfully,

SAHIB.

LXXXIV.

Manuring Tea.—I consider every owner of manure applied to our tea bushes helps to increase the yield, but, the tea plant being unlike coffee, in that, it is a deep feeder, the best way to manure it is to dig a deep narrow hole, say 2½ by 6 ft. as near the tap root as possible, particularly in lowcountry where the bulk of the manure applied to the surface, either by digging or holing, is devoured by white ants who eat up as well every particle of organic matter, as a rule, within 6 inches of the surface. Coffee simply refused to grow in such land, and went out, long before leaf disease appeared in Ceylon, and no wonder when the white ants devoured everything but the tap root, and, in many instances, the very bark of the coffee trees was eaten by them. This accounts therefore, I think, for tea flourishing where coffee refused to grow. Seeing, therefore, that tea has practically no surface feeding roots, would it not be better to apply our manure as near the tap root as possible, particularly at low altitudes?

OLD TEA BUSH.

[This concludes the correspondence in answer to our two circulars and the same will now be published in a separate form for easy reference.—ED. T.A.]

PLUCKING, PRUNING AND PREPARATION OF TEA:

REVIEW OF LETTERS LXXI TO LXXXIV.

WE have now to deal with the concluding letters of the series, on the important questions which we had placed before our readers, beginning

with the "R." from Passara, while admitting that rough plucking must give rubbish, believes that medium plucking should give good results if only there is withering space; "W.H.M." from Kotagala does not believe that coarse plucking is sufficiently general seriously to affect the general average; "Manager" from Kalutara counsels quantity off flatlands in the low-country, which cannot produce quality, leaving quality and quantity combined for hilly places; while "C.T." from Lower Ambagamwa reckons coarse plucking as undoubtedly responsible for lower prices, and refuses to believe that the bigger gross yields really compensate for a lower average price. His experience is that coarse plucking gives about 5 per cent. of red leaf, and reddish leaf in a break "does for you." He has ceased to sin after his experience! Of manuring he speaks favourably, as giving a rich strong liquor from the sappy leaf it produces, without injuring flavour; and in this opinion he differs from "R." who condemns manuring, because he thinks it spoils quality, through hastening flush and producing a sappy leaf—which ought to be an object, one should think. "W.H.M." does not believe manuring general enough to affect prices one way or the other; while "Manager" deprecates light artificial manures, as tending to the big crops in which proprietors delight and which he considers equivalent to "killing the goose." Pruning, too, as generally practised, he regards as too heavy; and "W.H.M." agrees with him, as it spoils quality for some time; and they are both supported by "C.T." who pins his faith to medium pruning, but with the reservation that once in seven years the white wood has to be cut into. This, however, is different from the hacking down, which is practised in some places, and which is unreservedly condemned. Low pruning, even when judicious, delays crop, as the white wood takes long to respond; but when it does, say about the third month, the bush presents quite a virgin look. We can quite see that this result is hastened and aided by manuring; and herein "C.T." differs from some of the earlier correspondents who strangely held the tonic responsible for weak liquor. "R." holds that severe pruning would not spoil quality, if the bushes were not plucked too soon; and he has proved that "if 10 leaves were left and then knifed across," quality would not be prejudiced. In the opinion of the last-named, proprietors make a great mistake in not securing well-paid Europeans for the factory. The manager cannot be dispensed with for general oversight, but an assistant will not consent to be stewed in a factory on Rs50 a month. If the estate be large enough to maintain two assistants, as is the case in India, they might be set to field and factory, turn about, with best results. "C.T." holds that we have advanced greatly in tea preparation during the past 10 years, but more care is necessary in the quality of the leaf that is manufactured; and on that shortness of labour tells. The remedy is to pluck only such acreage as can be comfortably compassed, and to prune the rest. "R." agrees that it is better to abandon some fields than to harvest 14 days' flush, and "Manager" leans to the same view—his experience with Sinhalese being that they hang back, and only come when there is heavy plucking. A larger force of Tamils is necessary to cope with this difficulty. "W.H.M." desiderates care and judgment in the factory, and an expert to inquire into the cause of the deterioration of tea as the bush ages and into the best means of

overcoming this drawback. "Manager" holds that the idea that everything that should be known about manufacture has already been learnt, is a serious drawback, and that, if it is true that good tea cannot be made of bad leaf, it is equally true that good leaf can easily be spoilt by injudicious manipulation. He is inclined to take a pessimistic view of the situation, caused by the application of stimulating manures to enfeebled bushes, in an exhausting climate on poor soil; but is not the generalisation hasty? There are bushes in the island 20 years old and more, which seem none the worse for continuous plucking.

"P. A." from a high district, denies the evil influence of coarse plucking which is resorted to only by a minority in the low country; he has no experience of manuring, but his neighbours who practise manuring maintain old prices; severe pruning affects quality for a time, and therefore plucking should be deferred till the bush has recovered itself; both plucking and manufacture need constant oversight, and neglect of it at once tells on prices; so does shortness of labour; so do too many cricket, tennis and race meetings, and too many horses to exercise; while the growth of low country plantations, which produce quantity, rather than quality, tells on the average. "C.T." returns to the charge [is it the same "C.T."?] with a strong indictment against delayed plucking. The system of plucking may be the same as of old, but there is a difference between flush taken off every ninth day, and leaf plucked every 15th or 21st; and the resulting tea cannot be the same. With deterioration in quality, is accompanied avoidable excess in quantity. The restriction, by one man alone, to plucking only the flush he can properly overtake, will not stay the outturn of muck. United action alone can tell by reducing quantity, and thus helping prices. The mischief is aggravated by the purchase of leaf from natives, whose only object is quantity! "E.E.G." from Pundaluoya holds that plucking and manufacture have the same care now as ever before; that manuring is not sufficiently general to tell appreciably on the average; that heavy pruning, though it tells on quality temporarily, makes up for it by an improved yield. On the burial of prunings he offers some interesting and suggestive remarks which deserve attention, and on which we should like to have the opinion of competent authorities. We have never been in sympathy with those who express distrust of the waste products of a tree as food for that tree, as, in nature, the process of such assimilation must be of constant occurrence; but we can quite understand dead leaves and twigs harbouring fungi and insects which may prove injurious to a shrub, and also the utility of substances which, while guarding against these dangers, would hasten decomposition and otherwise render the plant food more easily assimilable by the bush. That lime can be injurious to plant life is well known, but it is so only in excess, or in special conditions of soil. In a stiff clayey soil, for instance, we do not see how it can be injurious to a tea-plant; and as a matter of fact we know it has been used with the best results in the case of buried prunings.

The last six letters do not suggest many new points, but illustrate rather the diversity of views and the difference in practice which the seventy-seven letters which preceded them exhibited. "V.A." however, arrests attention, alike by his brevity and his decision. Coarser plucking, manuring, severe pruning have had, in

his view, "nothing" to do with the fall in prices; less attention to manufacture "everything." The explanation, thereof, is "Sport! Sport!! Sport!!!" while shortness of labour accounts for the loss of about 10 per cent. leaf. The general verdict would seem to be that, if there could be another reduction of 10 per cent. through the same cause, prices would look up! "V.A." may be thought to prescribe hard measure for superintendents, but there can be little doubt that sport—an excellent tonic in its proper place—absorbs a little too much of the time of some men and boys alike, and that it is a sore temptation to those who have yet to learn self-control, self-denial and the merits of the *via media*. While "W." and "A.C." do not think that coarse plucking has had much to do with sending down prices, an "Ex-India Planter" has little doubt that coarser plucking in the lowcountry has had a great deal to do with it; but in the higher districts the plucking is not to be beaten for fineness and regularity by Assam or Darjiling. Severe pruning is only a temporary drawback, and is practised in India without permanent effects on prices; but the manager should be oftener than he is in the factory, and to enable him to drop in more frequently, his bungalow should be closer to the factory, and he should not be required to be his own clerk. "Sahib" thinks that prices have simply gone down to their proper level, now that Ceylon Tea has ceased to be a novelty in the United Kingdom, and has ceased to be boomed there by special advertisements. "Old Tea Bush" confines himself to the question how best to manure tea, and suggests that it be buried deep as near the taproot as possible, away from the attention of white ants; but do white ants devour all they attack and do they not leave behind a pulverized residuum which is easily taken up by the roots after a shower or two? Here endeth our review of the letters seriatim. We may have a few remarks to offer on them, as a whole, at an early date. Meanwhile we have to thank our numerous correspondents for the readiness with which they responded to our call.

We have already dealt with the series of most interesting and instructive letters, numbering eighty-three in all, on the above subject, as they appeared, in batches of eight to twelve, summarizing their more salient contents and offering such remarks on them as we thought were called for by the circumstances. No single letter, so far as we are aware, escaped our notice. It remains that we should take a general view now of the series as a whole, and indicate some of the chief points which the letters have brought out, or emphasized, in regard to the great industry with which the prosperity of the whole island is so intimately wound up. We do not pretend to offer an exhaustive review, or one which can in any way be regarded as authoritative. We know that among our readers are many men of high attainments, and of far greater special knowledge than we can lay claim to; and we have no doubt that practical planters, as not a few have already acknowledged, have noted the weakness and strength of the Tea Enterprise indicated by the letters under review—so full of knowledge and yet differing so widely, indicating such keen powers of observation and yet acknowledging the need of more light. Still, a few observations from the standpoint of a comparative outsider may not be out of place—especially when they are inspired by hearty sympathy with the enterprise and even a deep personal interest in it.

On the question of Plucking, the general conclusion at which we arrive is that, while shrewd and experienced planters differ, whether coarse plucking is on the increase or not, being chiefly guided in their opinion by the practice of their several districts, there is practical unanimity that the principal cause of the increase of the coarser qualities of teas, is the extension of estates in the lowcountry. The acreage under tea in the lowcountry has been extending much faster than in the hill districts, and as hot steamy places yield quicker and heavier flushes than those at high elevations, there has been a preponderance of teas of the lower qualities as compared with high-grown flavoury teas. Whether that fact supplies a full explanation of the fall in average prices may be doubted. It unquestionably explains the fall to some extent. Among the other causes must be mentioned the undoubted fact that a large number of estates go in for quantity, and the equally undoubted fact that scarcity of labour leads to delayed plucking by which much of the finest flush is lost. The latter fact is not of the planter's own making. Scarcity of labour leads to alternatives—the plucking of fields at longer intervals than one would of choice, and the abandoning of some fields for a season, with the immediate result of estimates running short. It can scarcely be expected that a superintendent would care to incur the latter risk, except under express instructions. It may be as much as his place is worth! Coarse plucking with a view to maintain a high rate of yield is matter of choice; and it has been defended on the ground that it pays. That the system is more remunerative than medium, or even fine, plucking, has been denied; but, clearly, there can be no hard and fast rule, and the plucking which pays best on one estate or in one district need not necessarily be more paying on another. It is useful, however, to remember that 10,000lb. at 6d may really leave less to the proprietor than 9,000lb. at 6½d. Against the gross gain—£6. 5s.—must be set the extra cost of plucking, manufacturing, packing and transport of 1,000lb. of tea which may swallow up the whole of the apparent gain. Apart from that, there is the influence to be reckoned on the market of a diminished output, and of an improved average quality. A reduction in the outturn of 1,000 lb. here and 1,000lb. there, can scarcely affect the general average of prices for the whole island; but the reduction of the total exports by one-tenth, now that they have topped 100 million lb. would mean an appreciable quantity off the market.

The general consensus of opinion is against severe pruning which has been described as hacking, and which, we are glad to learn, finds fewer adherents year by year. It is admitted, however, that at intervals—the longer the interval the better for the bush—there must be a change from light pruning; but experienced planters distinguish between heavy pruning and cutting down or hacking. There is no change in the old belief that the liquor is weak for some time after pruning—the weakness and the duration corresponding to the severity of the pruning. Intimately connected with the influence of pruning is that of manuring, which some writers have stated has the same effect of weakening the liquor. The balance of authority seems to be against this view. Not only so, but also in favour of the opinion that the liquor is strengthened by the greater robustness of the bush which manure induces. This strikes us as the more reasonable view; and our explanation of

the alleged debilitating effect of manuring is that that effect is produced, not by the manure at all, but by its unskilful application, causing injury to the feeding roots. The majority of writers deny any evil effect on the flavour of tea by manuring, and claim that a sappy leaf, which a few planters condemn, produces a strong flavoured liquor. However that may be, there can be no question that manuring increases the crop; that preference is felt for bulky manures, if they can be got, over artificial; and that, although the good sense and habits of observation of our planters have protected them from disastrous blunders, a good deal yet remains to be learnt of the needs of our soils and the constituents of manures, before it can be claimed that our tea-fields are receiving the best treatment possible for crop and for flavour.

We now come to the final question of Preparation. There is no difference of opinion as to the absolute necessity of ample withering space and the general deficiency in regard to it. A good wither is essential to the manufacture of good tea; and most estates or factories are realising this fact, and making adequate provision. On the personal question, opinions seem to be fairly divided—some writers holding that as much care and attention are devoted to manufacture as ever before, while some are very strongly of opinion that the claims of sport are a bar to that earnest, habitual and close oversight of the factory, without which quality gradually deteriorates. Others again think that a more intelligent and better-paid class of tea-makers—preferably Europeans—are called for; but in this climate, continuous work in a heated factory is not what the European would choose; and we see no reason why local talent should not be rendered equal to all factory needs. Of course, there must be strict and conscientious supervision. On the whole, nothing contained in the interesting correspondence we have dealt with, is calculated to cast doubt on the soundness and the permanency of the Tea Industry of the island, and, so far as we can see, it depends on proprietors and superintendents whether it shall take front rank in the competition with other countries. We should not despise the aid of science; we should not be above attention to the details of work, whether in field or factory; and, provided our labour supply does not fail us, we need be in no fear of over-production or of fluctuating exchange, though these may incommode tea, off and on, as they do all Eastern enterprise and chiefly agricultural enterprises.

PLANTING AND PLANTERS IN THE STRAITS.

NOTES: VISIT BY THE ACTING BRITISH RESIDENT TO THE COAST DISTRICT.

I left Seremban, with Mr. Aldworth, 7-30 a.m., 11th March, for Kuala Sawah by rail. We were met there by Mr. C. M. Cumming. Drove to his new land at Niato and arranged for sites on State land for his coolie lines and house. Visited his nurseries, through which elephants had walked two days before. Drove to Ribu and visited Mr. McClymont's estate thence on to Rantau and breakfasted with Mr. Cumming. Mr. Porcher called for me at 1-30 a.m. and drove me or Linsum. We walked over several fields and saw all the estate. At 4 p.m. I started for Pengkaln Kempas, stopped at the Malacca Towkay's tapiocai and pepper estate at the 9th mile Jerak, and, after some conversation with Siew Hin, drove on to Linggi where I passed through some very fine kampongs. Reached Pengkaln Kempas at 6 p.m. and found Messrs. Bowen and Hooper (Contract Surveyor) waiting for me.

March 13th.—At Telok Kemang we got on to the cart road and rode on to Pasir Puteh, reaching Mr. Engler's clearing at 11 a.m. He was flying the red ensign in honour of my visit. His house is beautifully situated on a small hill facing the sea which, at this point, forms a bay, and at each end of the bay there is belt of virgin forest standing higher than the intervening land. The shore of the bay is of marvelously white and fine coral sand such as I have only seen in the Cocos Islands. Mr Engler has already planted up 50 acres with an average of 52½ nuts to the acre. His methods of cultivation are very thorough, every particle of superfluous covering to the stem, fronds and nuts of the palm being removed so as to give no harbour to beetles, ants and other insects. The foot of each palm is kept picked and raked, and the result of these operations is apparent in the few old palms near his house which are bearing heavily. He is very anxious to extend his cultivation and I commend his methods to the notice of the Kuala Selangor Company, who would do well to induce him to join their syndicate. At 3 p.m. we rode on and passed through the following holdings of Europeans—viz., Mr. F. A. Swettenham's, the late Mr. Lister's, Messrs. Coates and Tunnicliffe's, Mr. D. C. Neave's, Mr. Watkins', Mr. Douglas's, Mr. Keyser's, Mr. McClymont's, Mrs. Neave's, Messrs. Cumming's, Porcher's, and Bagnall's, the Selangor Sanitarium, the Negri Sambilan Sanitarium, and Mr. Rowland's. Mr. W. W. Bailey and Mr. C. R. Paterson (a Ceylon tea-planter) drove up while we were thus engaged, and as they were bound for Seremban we all went on together as far as Beranang, seven miles from Semenyih and 16 from Seremban, where we remained for the night and our visitors went on to Seremban.

THE NATAL TEAS.

(By a Ceylon Planter.)

Mr. John Fraser has sent us through Mr. Gordon Frazer, samples of teas made by him on the Barragreen estate and for which he got the chief prizes at Johannesburg Exhibition. Messrs. A. H. Thompson & Co., Brokers, have courteously furnished the following report on these teas:—

DESCRIPTION.	COLONBO	
	LONDON VALUE.	EQUIVALENT @ EXCH. 1/3¼.
Gold Orange Pekoe Leaf Blackish small even well made with tip ..	1/	69
Liquor strong dark good quality.		
Pekoe Leaf Blackish even well twisted few tips ..	8½-9	46-50
Liquor Brisk dark fair strength and quality, Pekoe Souchong Leaf Blackish well made ..	7	38
Liquor strong dark little coarse.		

Valuations are quite nominal as we have no quotations for Natal Teas on the market, but judging from the leaf and liquor we think them well worth the above.

The samples can be seen at the Tropical Agriculturist Office.

MEETING OF THE CEYLON RHEA FIBRE SYNDICATE.

TO BE WOUND UP.

A meeting of this local Syndicate was held at the office of Mr. E. John at Chatham Street on April 30, when it was decided to go into liquidation. The Syndicate started rhea cultivation on a small scale in the Kurunegala district, where about 12 acres were planted, R3,000 being sunk in the scheme, but there was a lack of confidence in the scheme, therefore the decision to wind up.

BRITISH NORTH BORNEO NOTES.

Telegraph communication with Sandakan has been opened as far as Sinogal beyond Tamoi, on the Kinabatangan, since the early part of March. As Messrs. Applin and Reynolds are on the spot, we may expect very shortly to hear that it is extended considerably. Mr. Reynolds has opened the Eastern Section as far as Imbok.

Rhea has been found growing in abundance at Koyah and a large sample has been asked for to transit to the Court at home. It appears to be *Rhea* (or *Bohmeria*) *nivea*.

Three fine specimens of orchids are on view at Messrs. John Little & Co.'s, says the *Singapore Free Press*. There is a *Dend. Phal* var. *Hololeuca* which is said to be worth £50, there being but one other plant in England. An *Angreecum Sesquipedale* from Manila, and a fine *Cyp. Sanderianum* from Sarawak with ten flowers, are also shown by Mr. J. A. Pereira. It is somewhat remarkable that while Central Borneo and Sarawak abound in orchids of great beauty and variety, the species found in North Borneo are comparatively few and insignificant.—*British North Borneo Herald*, April 1.

ECONOMIC CURIOS.

The following are verbatim extracts from notebooks of students in economic botany which were submitted to a well-known lecture as an indication of the progress of his class:—1. "Catechu is used in diarrhoea, likewise to open and clean throats." 2. "Absinthe. It has been proved that a man who uses this liqueur in a great abundance is able to loose his mind soon." 3. "Coffee is pupped (pulped) in a machine." 4. "Liberian coffee was thought that it would withstand the insect ravishes."—*Chemist and Druggist*, April 24.

THE RUBBER FORESTS OF THE HUKONG VALLEY.

The report of Mr. H. N. Thompson, Assistant Conservator of Forests, on the Hukong Valley and Upper Namkong basin, contains much interesting information on the fauna and flora of that region. As Mr. O'Brien pointed in his report a few years ago on the rubber forests of Upper Burma, the tree in the Hukong Valley is not a gregarious one. Mr. Thompson tells us that it appears scattered generally through the dense evergreen forests, but nowhere does it reach the density per acre of an average teak forest. "Occasionally, a family group of four or five trees may be met with; these are very rare, indeed, and the usual thing is to come across a mature tree every 200 or 300 yards in the richer forests." At the headwaters of the Namkong Chaung the average was not quite one large tree to every two acres. When the tree is surrounded by dense shade, to get to the light it grows to enormous heights, and some of those seen by Mr. Thompson were the largest trees of any species he had ever seen. So exacting is its demand for light that no seedlings were in the soil, but were invariably growing at a great height from the ground on other trees. A few illustrations show the young seedling growing "up the stem of its host, encircling the latter with its aerial roots and sending them downwards towards the ground till they form great supports on which the main trunk of the fig stands; meanwhile the host is gradually killed off and eventually disappears altogether and the rubber tree is left standing on five or six even more thick aerial roots." The *figus elastica* appears to be able to accommodate itself to many varieties of soil, and apparently grows best at a considerable altitude. Thus, Mr. Thompson records, it grows in abundance on Loimaw hill at an altitude of 5,000 feet, and is

reported in various other high altitudes in that region. The Kachins say it does not grow where there is snowfall, but this seems doubtful.

The tract north of the Tanaikha is still the richest in the valley but the difficulties of transport are increasing as the more accessible trees have been worked out. Here a Chinaman Law Lawkha has a practical monopoly of the market. On the spot the price of rubber is two rupees per viss.* A few years ago a trade route was started across the mountains to Myitkyina, but the trader who opened it was murdered, probably, Mr. Thompson thinks, at Law Lawkha's instigation, and the blackmail levied by the Sana Kachins has killed the trade on that route. Some of the rubber around the southern basin of the Tanaikha is supposed to be taken down the Chindwin to Chindat, but this seems doubtful. The natural and short-st route is down the Nampyu to Ra and Palawbum and thence by mules to either Laban or Tingring, and so by boats and mules to Kamaing and Mogaung. With regard to the output of this tract, i.e., from the forests lying at the sources of the Nampyu to the west of Maingkhwan, Mr. Thompson says it is very difficult to estimate it. No reliable information can be obtained from either the Singphos or the Chinese traders employed in buying it, as both parties are interested in keeping the real state of affairs dark. Of course the usual cry is that the forest is getting worked out, that they have now to search for indiarubber at great distances from the lines of export, and that consequently the duty levied by us ought to be reduced. The fact, however, still remains that the local Sawbwas have in no way whatever reduced the tax levied by them on rubber collected in their districts or passing through to other places. I questioned four of the most influential Chinamen living at Laban, and who are agents of the large Bhamo and Mandalay firms, as to the out-turn from this portion of the valley during the present season; but their statements were so very conflicting and contradictory that no reliance whatever could be placed in them, and under such circumstances it would be misleading to give any figures.....As a single instance of the contradictory statements given by the Kachins, I may say that they informed me repeatedly that the yield of a large unworked indiarubber tree in one season does not exceed ten viss—a very different figure from that usually given, and which of course is too low, as I have personally seen about double that quantity extracted from a large tree." The rubber forests at the headwaters of the Namkong Chaung are rich in rubber. The tree grows in abundance along the banks of the smaller streams and is also frequently met with on the higher slopes of the hills. On these hills Mr. Thompson found the *figus elastica* attaining as great a height as 200 feet and a girth round the outside of the aerial roots of 100 to 130 feet.

The only forest produce collected in the tracts examined by Mr. Thompson appears to be rubber, and the Kachins from far and near come in to collect it in the dry season. "During my visit to the Upper Namkong and Namsong basins, I twice came across 'octrois' built on the edge of the streams by Singphos from Palawbum and the Amber mines. Toll on all rubber brought down these streams from their headwaters was collected at these stations and none was allowed to pass unless this tax was paid. It was usually taken in kind and amounted to much as ten per cent, the collectors having to pay ten viss for every hundred collected by them. The Singphos from the Hukong Valley must have known that they were poaching in these forests, as they decamped as soon as they heard of my arrival." One local viss, it seems, is equal to one and a half standard viss, so the Chinamen must make a very good thing out of it. The Chinamen of the district are all engaged in the rubber-trade. "Great quantities of rice, silk pasos, gaungbaungs, etc., and stores, are kept by them and sold to the Kachins (at ruinous rates) who pay the price of the goods in indiarubber."

* A viss 3.65 lb.

Every tree in the basins of the Loglai and Taron is known and their positions are pointed out from father to son. It may be taken as correct that the rubber collected in the forests north of the Gedu confluence goes to Assam, while that collected in the forests south of the Gedu goes down the Hukong Valley. All the rubber that goes to Assam is carried by Naga coolies, who can always be had after the crops have been gathered and who are probably more efficient when working in their own country than any other coolies in India. Taronku, the great rubber centre of the tract under notice, is situated at the Taron-Gedu confluence, and the most valuable portion of the forest lies up the Taron river to the Chaukkan pass, along the route traversed some years ago by Colonel Woodthorpe and Major Macgregor. At Taronku a fee of Re. 1.8 or three seers of rubber is levied on every man who wishes to cut rubber in the forest. Besides this fee, Mamyung village also collects tribute from the cutters passing through it. Rubber in this tract is getting scarce every year, as the trees are overworked, and it often takes a man no less than forty days to collect a coolie load of rubber. Most of the trees seen by Mr. Way's party had been tapped, and up the Loglai and Turong rivers the trees near the streams are either dead or dying from being overworked. Here the Singphos entirely control the Nagas and stand to them, says Mr. Thompson, in very much the same position as a tea-planter and his coolies. Their word is law and is enforced by a very few Singphos over a great number of Nagas. The number of rubber-cutters who leave their villages for the Turong forests is known, and even if they succeeded in evading the impost of the Singpho villages through which they pass, they would inevitably in the long run have to pay up. The rubber when first collected is fairly pure, but the Nagas have learnt from the native bunnias the trick of adulterating it with earth and stones, and so Assam rubber is not looked on with favour by Calcutta brokers. It may be added that the same applies to the rubber that finds its way into the Rangoon market, the Chinamen being adepts in skilfully concealing in the rubber earth and stone, principally the latter.—*Rangoon Gazette.*

TEA PLANTING IN SOUTHERN INDIA.

We continue to get glowing accounts of the region which is being developed for tea in North Travancore by Sir John Muir's Consolidated Company. The exact acreage taken up it is impossible at present to say; but the latest visitor to the spot, so experienced a planter as Mr. R. Morison of Kalutara, declares that his feeling was as if he were looking over Dumbula in forest with a certain number of clearings. The land runs up to a higher elevation than we have in Ceylon; but the bulk is between 4,000 and 6,000 feet; and Mr. Morison is full of admiration of the forest and rich soil. Mr. Milne has got his work cut out for him; but progress is being made and there seems to be no expectation of labour going short. The expectation is that within a few years, 30,000 to 40,000 acres will be planted with tea in this region. Not only planting; but surveys, roadmaking and railway projecting are the order of the day in connection with this big Company's North Travancore land.

COCA AND COCAINE.

Prior to the discovery of cocaine and its wonderful anaesthetic properties, which promoted the development of the export of coca, its consumption was limited to the demand from a few provinces in the neighborhood of mining districts where nothing can be accomplished without it, for, when it fails, the laborers refuse to work. It is therefore an indispensable article for the exploitation of the mines of

Peru. Thus we see, that in order to work the mines of Hualgayoc, it is necessary to take there coca cultivated at Cajabamba and Huamaluccho, situated on the banks of the Marañon River.

Twenty years ago the culture of coca was limited to the localities most favored by the climate and the low price of labor. In the province of Otuzco it was cultivated on a large scale, only on the farms of Choquisongo and Saniamas, which supplied the local consumption and that of the mining districts of Salpo and Sayapullo. But an important change has since taken place in that province, which is, today, the greatest producer in the north of Peru, exceeding Huamacho and Cajabamba combined, in quantity and quality, notwithstanding the fact that most of the trees are young and do not yield a full crop; that is to say, they do not produce as yet a quintal per thousand plants, as is the case with those over six years old. This quantity is the average of the crop per year.

The following table shows the actual and approximate production of the province of Otuzco and the number of plants:—

Localities.	No. of Plants.	Annual Crop. Quintals.
Choquisongo	.. 200,000	360
Huayobamba	.. 600,000	809
Cayencsal and Saniamas	.. 150,000	400
El Rajon	.. 100,000	210
Llagueda	.. 50,000	100
Sacamaca	.. 300,000	300
Las Pampas and Callancas	600,000	1,000
Compin and Anexes	.. 600,000	1,400
Chuquillanqui	.. 100,000	100
Total	2,700,000	4,700

It will be seen by these figures that the total annual production amounts to 4,700 quintals (about 200,000 pounds), which, in a few years hence, when the plants are fully developed, will reach between ten and twelve thousand quintals.

There are two firms in Trujillo, who purchase coca for the manufactories of Lima; but, as they have the monopoly, being the only wholesale purchasers at auction, they put up or lower the price as they please; and as the firms in Lima pay 30 soles per quintal, delivered on board at Salaverry, they make a very profitable transaction. Mr. Genaro Risco, owner of a farm at Huayobamba, and Mr. Jose Antonio Delfin, at Cayanchal, intend to establish a manufactory of cocaine on their property, so as to be independent of that intolerable and ruinous monopoly, and inaugurate a wholesome trade competition.

In the Review *El Tiempo* the current price of cocaine in Lima is quoted at 60 centavos per gram; and as a quintal of coca yields from 8 to 12 ounces, according to locality and quality, it results that a quintal of coca leaves, costing between 15 and 20 soles, produces 184 soles' worth of cocaine; from that amount must be deducted the price of reagents; kerosene, caustic soda, sulphuric acid, carbonate of soda the cost of labor; but which still gives a handsome profit. The wages vary from 20 to 30 centavos, two meals, and a ration of coca per day. In some places, like Huayobamba and Sacamaca, the culture is done on shares, the laborers receiving half of the crop and delivering the coca dried and in bales. Excepting the farms at Chuquillanqui, situated on the banks of the river of that name, all the others are near the Usquil River, which joining the former at the foot of Huancay, form the Chicama River.

The best condition for the successful culture of coca is a temperature not lower than 21 degrees and not higher than 30 degrees. In regard to the altitude best adapted for its development, the farms of Callancas, Huayobamba, etc., are generally at a height of 3 000 or 4,000 feet above sea level; there are a few, however, at 5,000 feet, but their products are inferior. Those of Chuquillanqui and some others are at 2,000 feet,

The quality varies; the coca grown in a dry soil is better than that cultivated in damp localities, like that from Chuquillanqui, which, although reaching three or four feet in height, has not the same strength and properties as that from Callancas and Huayobamba. There are about eighty small coca planters in Las Pampas and Callancas; over one hundred in Compin, and scarcely twenty in Chuquillanqui; it is but a few years ago that the cultivation of the plant has been introduced in those places, and therefore too recently for its full development.—*El Comercio, La Paz.—Oil Paint and Drug Reporter.*

COCONUT OIL.

THIS, the staple oil of the Colony, is in very small demand at present, and no sales can be made locally beyond what will satisfy a somewhat limited demand from India, the Straits and China.

The present depression is mainly, if not entirely, brought about by exceptionally abundant supplies of tallow in Europe and America—the chief competition with coconut oil in the manufacture of soap, candles &c., and the outlook is anything but reassuring to holders of coconut oil.

The stock of tallow in London under last advices was 52,211 casks, against 45,716 and 20,650 casks respectively at same period of 1896 and 1895. Spot prices in London of coconut oil and tallow in April of 1895-7 were :

1895	Ceylon Coconut Oil	-	£23. 5
1896	do	-	22-15
1897	do	-	22- 0
1895	Tallow (good mutton)	-	23- 0
1896	do	-	19-15
1897	do	-	19- 5

It will be noticed at once that while the price for tallow has receded £3-15 per ton, Ceylon coconut oil only shews a decline of £1-5 per ton. This is mainly due to exceptionally small stocks of coconut oil being held in London of late years, not exceeding on an average 600 tons, and if any important quantity was shipped to the United Kingdom, prices would in all likelihood run down almost to a par with those for tallow. As we go to press telegraphic advices quote coconut oil on spot nominal £21-10, no sales and prices tending downwards. Only once within the last ten years has the spot price of coconut oil in London been lower than it is at present, this was in October 1892 when the price was £21-5.

Our exports of coconut oil (taken from Ceylon Chamber of Commerce returns) to India the Straits and China were :

6,260 tons in	-	1896
1,859 "	-	1895
1,407 "	-	1894
7,663 "	-	1893
against exports to Europe and America of		
10,650 tons in	-	1896
16,740 "	-	1895
22,809 "	-	1894
11,747 "	-	1893

The Eastern markets (especially Calcutta) are very important ones as the foregoing figures show; yet it is to Europe and America that we must still look for the chief offtake of coconut oil, and so long as competing products, such as tallow and palm oil, are in abundant supply there, so long, we fear, must we look for a weak market and low prices on this side.

It is true that the manufacture of desiccated coconut is increasing steadily, and it may be noted that the exports for 1896 are 2,000,000 lb. in excess of these for 1894, but the consumption of coconuts which this increase represents, is not of sufficient importance to tell on the market for copra when oil is depressed in the main consuming countries through successful competition of other oils and greases. So far as we can see relief is not likely to be forthcoming in the near future, if tallow continues to flow into the consuming markets in such quantities as to prevent any appreciable diminution of stocks. Growers of coconuts must therefore, we fear, be prepared to receive on the average lower prices in 1897 than they have been accustomed to receive in recent years.

BULKING OF TEA.

(From Our London Letter.)

LONDON, April 9.

THE CEYLON ASSOCIATION IN LONDON AND THE INDIAN TEA ASSOCIATION (LONDON) have this week been called upon once more to deal with complaints of the indifferent

BULKING OF TEA

offered for public sale—in many instances the entire absence of bulking. The loudest complaint came to the Ceylon and Indian Associations through the London Tea Brokers' Association from the London Wholesale Tea Dealers. The Committee of the Tea Dealers' Association passed a resolution which stated that the requirements of the clause in the public sale conditions which declared that "these teas have been inspected, and bulked (if necessary)" had not been carried out in a great many cases. The Committee added that they must insist on this condition being faithfully observed, and that in the event of any parcel not having been bulked in the Indian Warehouse a statement to the effect that it had been bulked in India and Ceylon, and inspected in London, should be inserted in the catalogue. The Tea Brokers' Association sent this resolution on to the Ceylon Association in London, and the Indian Association. Mr. W. G. Price, the Secretary to the Tea Brokers, also received a letter on the subject from Messrs. J. Tetley and Company, who stated that they had had many complaints of great irregularity in the bulking of Ceylon tea, and quoted from a letter written by one of their agents which said that irregularities had been of "such frequent occurrence as to call for imperative action on the part of the wholesale trade." "Nothing," the letter went on to say, "can be more destructive of confidence in the merchant, or create a greater feeling of insecurity in the mind of the buyer, than a false sample—which, in plain English, is what careless or neglected bulking amounts to." Mr. T. J. Lipton goes farther than this, for he has circularised the buying-over workers, vowing that he will, in future, decline to look at any "bought-overs" unless the teas are guaranteed as having been bulked in London, and asking that no samples shall be submitted of teas that are not thus guaranteed.

A meeting of the Tea and Produce Committee of the Ceylon Association was held on Monday to consider the matter, the members present being Messrs. J. Hamilton, W. Herbert Anderson, W. J. Thompson, T. Stretch, F. H. M. Corbet, A. L. Hutchison, J. L. Shand, W. M. Leake, G. White, A. Brooke, A. G. Stanton, S. J. Wilson and C. J. Scott. It was decided "to invite the

attention of importers of Ceylon tea to the imperative necessity for complying with the conditions of the clause referred to, so that buyers may operate with the fullest confidence in the future." The Committee pointed out that inasmuch as careless or neglected bulking of necessity involves unreliable samples, the complaint is undoubtedly a serious one; and they regretted to find on inquiry that the complaint was not altogether unfounded. The Committee of the Indian Tea Association have called the attention of importers of Indian tea to the matter.

Before this letter reaches you, Messrs. Gow, Wilson & Stanton's work on the

TEA PRODUCING COMPANIES OF INDIA AND CEYLON

will be in your possession. I had a talk with Mr. Wilson today about the book, further supplies of which are being loudly called for from the publishers. Mr. Wilson tells me that the main object of the book—which is to bring to the notice of the public the fact that there is a very large field for investment of capital in the tea-producing industry—seems likely to be attained, judging by the large amount of notice it has attracted in the London and provincial newspapers. Lengthy notices have appeared in the *Manchester Guardian*, the *Newcastle Daily Chronicle*, the *Statist*, the *Dundee Advertiser*, the *Scotsman*, the *London Telegraph* and the *Money Market Review*, and shorter notices in scores of other papers in all parts of the country. This bold advertisement of the British-grown-tea enterprise must do good. The *Economist*, in the course of a very friendly review, remark that the authors do not offer any opinion as to the extent to which the new areas steadily being brought into cultivation both in India and Ceylon are likely to affect the relations of supply and demand. In its leading article last Saturday the *Financial Times* names the compilation "The Tea 'Burdett'" and deals at great length with the tea industry from the investor's point of view. Speaking from this point of view Messrs. Gow, Wilson & Stanton mention several features shown by tea companies as being especially satisfactory. The statement of this side of the case, says the *Financial Times*, is undoubtedly correct as regards by far the greater numbers of these companies, though an exception could be pointed out here and there. It may be objected against the book that it only brings the history of the large majority of the companies up to the end of 1895, but it was impossible to do more than this, except in one or two cases, since the reports of most of them for 1896 will not be issued until May or July next. For last year the consumption of Ceylon tea is given at 80,294,000 lb., or 35 per cent of the total. All this, says the *Financial Times*, is very re-assuring for holders of India and Ceylon producing companies' shares; and almost equally so is the increase in consumption of tea per head of the population. In fact, we have almost as good a right now to be called a nation of tea-drinkers as we have to be called a nation of beer-drinkers.

THE ACME TEA CHEST COMPANY are likely to send out their Assistant Manager, Mr. H. J. Stewart Brown, to exploit Ceylon. The Acme is taking wonderfully in India and is becoming a big industry as may be seen from the extract given elsewhere entitled "New Industry for Glasgow."

TEA BULKING.

A recent mail brings us news of a great outcry from the Associated Wholesale Tea-dealers in London against the carelessness displayed in respect of the bulking of Ceylon tea offered at public sale. The Tea and Produce Committee of the Ceylon Association in London have met to investigate the charge, and have practically entered a plea of "Guilty" on behalf of their clients - or at any rate of some of them. Of course, neglect of bulking is a very serious matter, as everybody is aware who knows anything of the method of operations in the tea trade. Bulking in London is a very costly thing, and though only an unscrupulous importer would, to save charges, deliberately violate established conditions of sale, it has come out in the inquiry made by the Ceylon Association Committee that there is sometimes a certain looseness of statement as to whether parcels of tea have really gone through the bulking process before leaving Ceylon. The long-suffering wholesalers do well to be angry when they come across more than a stray instance or two in which sample and bulk seem to be almost entire strangers to one another; but they cannot complain of the spirit in which they have been met by the Ceylon Association (and by the Indian Association, for Indian tea was complained of, too). No doubt the representations of the Association will receive due consideration in the proper quarter.

THE PANAWAL TEA COMPANY, LIMITED.

Report of the Directors of the Panawal Tea Company, Limited, to be presented to the Shareholders at the Fifth Annual Ordinary General Meeting, to be held on Friday, 23rd April, 1897, at the Office of the Company, 39, Victoria Street, Westminster, S. W., at 3 o'clock in the afternoon.

The Directors have the pleasure to submit the General Balance Sheet and Profit and Loss Account for the year ending December 31st, 1896, duly audited:—

	£	s.	d.	£	s.	d.
The net amount at credit of profit and loss account, including balance brought forward at 31st December, 1895, after providing for General Expenses, Directors' and Auditors' Fees.				2,035	12	11
An interim Dividend of 4 per cent. on the Ordinary Shares for the half-year ending 30th June, was paid 3rd October, 1896, amounting to....	680	0	0			
It is proposed to pay a final Dividend on the Ordinary Shares from 1st July to 31st December, 1896, at the rate of 4 per cent. (making a distribution for the year of 8 per cent. free of Income Tax), which will absorb....	680	0	0			
Dividends on the 7 per cent. Cumulative Preference Shares were paid for 1896 in full, amounting to.....	371	0	0			
It is proposed to write off part of the cost of New Extensions. Machinery, &c., completed during the year.....	213	17	7			
Leaving to be carried forward to next year a balance of....	90	15	4			

£2,035 12 11 £2,035 12 11
 The Directors recommend the distribution of a dividend at the rate of 4 per cent. on the Ordinary Shares of the Company from 1st July to 31st December, 1896, making, with the Interim dividend paid to 30th June,

1896, a distribution at the rate of 8 per cent. for the year.

The acreage of the Company's properties on 31st December last was:—

Tea in full bearing	510
Do. in partial bearing.. ..	67½
Do. under two years old	100½
Do. do. one year old	16
Jungle	363½

1,057½

The Directors consider the result of the year's working to be on the whole favourable, having regard to the serious rise in exchange and the somewhat lower price realised for the Company's tea during the year. The loss occasioned by the rise in exchange during the year represents over 2 per cent. on the Ordinary Share Capital of the Company. The fall in prices and the deficit in the yield, as compared with the estimated crop, may be attributed to the abnormal rainfall, which was 50 inches over the average. The crop realised for 1896 was 279,191 lb., as against an estimate of 290,000 and a yield of 250,352 lb. in 1895. The cost of tea f.o.b. Colombo was 23½ cents per lb. The new central factory is now approaching completion, and it is hoped that when in working order it will effect an improvement in the quality of the tea and a reduction in the cost of manufacture. The Interests Deposits stand in the Balance Sheet at £1,520. The deposits the Company is in a position to pay off out of part of the profits realized on the recent sale of the Rangegama Estate, and they have accordingly given notice to do so on or before the 30th June next.

HILL TRAMWAYS FOR ESTATES IN CEYLON.

If any further evidence were required of the unreliableness of the Report so hastily compiled by the so-called Hill Tramways Commission, it is afforded in the proceedings at a recent meeting of the Udapussellawa Planters' Association. If there was one line more than another which might be deemed ripe for report, owing to previous prolonged investigation, it is that of the proposed Nannuoya-Nuwara-Eliya-Kandapola Tramway. The Commissioners must have had all the information collected by their predecessors before them; and yet if Messrs. E. E. Nicol and E. J. Brown are to be relied on—and their Resolution on the subject was carried unanimously—a very large portion of the traffic of the districts was omitted altogether from the Estimates adopted by the Commission! This is scarcely credible—and we have not time as we write to verify the charge propounded by the Udapussellawa planters; but if it holds good, of course the Commission's Report falls to the ground as worthless; while if our Udapussellawa friends should be mistaken, it would, at least, show a great want of clearness in compilation when such an almost unprecedented charge could be formulated. The planters allege that all the Nuwara Eliya traffic is omitted and also the traffic of the Nuwara Eliya and Kandapola estates! If this can really be demonstrated, it must prove fatal to the Commission's Report which had then better be laid on one side for correction and revision generally.

Revision is the more necessary; because it is evident that several other districts have had less than justice done to them. We ourselves hold the Commissioners to be too hasty in condemning offhand the Peradeniya-Deltota-Hewaheta Tramway. If laid on the existing road as far, at any rate, as a central point like Deltota itself, it should show a remunerative margin. Now, again we have the report of proceedings held by

residents in the Northern Districts meeting at Teldeniya and they make out a very fair *prima facie* case for reconsideration, although the Commission was in too great a hurry to wait for their information. Delay in this case is accounted for by the scattered nature of the districts concerned. This Northern or North-Eastern road tramway is, perhaps, one of the most promising yet propounded; and altogether, we trust the Governor will see his way in due season, to reopen the Enquiry and afford an opportunity for a more careful and correct Report on the subject of Hill Tramways.

A TEA COMPANY AMALGAMATION.

We observe that meetings of shareholders of the Nedeem, Kumai, Chengmari, Baintbari and Toorsa Tea Companies have been convened for the 15th instant with a view to sanctioning their transfer to a London Company to be formed with a capital of £400,000, of which only £360,000 will, in the first instance, be called up. The capital of this Company will be divided into two-thirds 5 per cent. cumulative preference and one-third ordinary shares.

The properties to be taken up are:—

	Total area.	Area under plant.	Price. £
Nedeem	3,781	2,018	245,000
Chengmari	6,188	1,432	9,000
Kumai	2,089	656	36,000
Baintbari	910	383	12,000
Dalgaon	2,200	1,001	30,000
Toorsa	8,288	535	25,000
	23,456	6,025	338,000

Working capital 22,000
£360,000

In addition to the 6,025 acres under cultivation, a further extension of 1,025 acres is contemplated in 1897, and it is estimated that a further 5,000 acres are available for planting. The price to be paid works out £56 per acre under tea. The profits from the Nedeem, Chengmari, Kumai and Baintbari Companies for the last three years have been:—

	R
1894	298,011
1895	234,278
1896	271,937

which have been divided in dividends and applied to extensions. The Nedeem Company has paid a dividend of 20 per cent some years past, and is considered one of the finest gardens in the Dooraes. Taking exchange at 1s 3d. the amount required to pay the preference dividend on the new company will be R192,000 so that it will be seen that these shares are amply secured. The amount to be paid for each garden works out per share about as under:—

	R
Nedeem	390
Chengmari	310
Kumai	313
Baintbari	120

These figures compare favourably with present prices here. The new Company will be called the Nedeem Tea Company and should be a most successful one. Amalgamation, such as these, are steps in the right direction in the tea industry. The reserve capital of £40,000 is intended to be applied to developing the Dalgaon and Toorsa concerns. The present shareholders will have the right of retaining one-third of their interest if they desire to do so—*Capital*.

BRITISH NORTH BORNEO.

A special meeting of members of the London Chamber of Commerce was held on 7th inst. at Botolph House, when Mr. W. B. Pryer, formerly senior resident, British North Borneo Company's service, and recently manager of the North Borneo Development Company, delivered an address on "Prospects of Commercial Development and Planting in British North Borneo." Mr. James Chambers (vice-president of the Chamber) took the chair.

Mr. Pryer, having described the geographical features of the island and climate, particularly in its northern part, said that, owing to immigration of different nationalities, there could be no doubt that the population would be a very mixed and confusing one, but also without much doubt that the Hakkas from South China would form the main bulk of it. Sandakan Bay claimed to be one of the finest harbours in the world, rivaling Rio and Sydney; several rivers, creeks and waterways ran into it, giving access to a large area of fertile land. As the rivers which ran to the north and south of Sandakan all had bars at their mouths, their trade and produce had to be carried in shallow draught steamers, and transhipped at Sandakan, which, therefore, had a large future before it. Forest produce included Indian rubber, gutta-percha, birds-nests, beeswax, camphor, dammar, rattans and timber. Indian rubber, gutta-percha and rattans had been largely exterminated in many of the districts where once they were abundant, so that now there was even difficulty in getting seeds for their proper cultivation, which was to be regretted, as, if planted and looked after in a proper way, they were an extremely remunerative and very inexpensive crop to raise. Every dollar invested in doing this a few years ago would have been worth twenty now. Timber was more likely to attract the attention of capitalists. The greater part of North Borneo was virgin forest, and it has been calculated that the amount of good timber per acre averaged about 200 tons. The best kind was known as billian or iron-wood, which was in considerable request in China for piles and beams, whilst it was said to be unsurpassed for railway sleepers, and there was likely to be a huge demand for it when railway making commenced in China in earnest. In the south-east part of the country there were very extensive coal fields, and outcrops of coal occurred in several other places right across to Sandakan Bay. Gold existed over a considerable area up the Segama River and inland from Darval Bay, but, so far, the quantity obtained had been small. Diamonds and other precious stones had been found two or three times in different parts of the territory, as well as specimens of cinnabar, copper, antimony, arsenical silver, and other metals. A hill of mica had been discovered up the Labak, and it was impossible to say what the real mineral wealth of the country was until its centre part had been more thoroughly explored. Indications of petroleum oil occurred in two or three places, and exploring rights had recently been granted. Should oil be found it would give a tremendous fillip to the country. It had been said by people who knew the country and its resources best that North Borneo was the least crowded and most promising of any British possession that now offered a field for the employment of British youth and British capital, and it was without question in its soil that the future prosperity of the country and of all connected with it chiefly laid. As many of the country's products specially lent themselves to manufacture, they would, no doubt, soon see springing up, in the most advantageous positions, sugar-mills, coconut and cotton-seed oil mills, cotton ginning works, additional sawmills, paper-making works, fruit canning works, and many others. There was no reason why North Borneo should not have as many people to the square mile as Java, with its 22,000,000 inhabitants. To show what could be done, he mentioned an estate twelve miles north of Sandakan, started five years ago, where there was at that time nothing but virgin forest. Today there were over 1,000 people there, some of them getting their livelihood from

wages, others cultivating the soil on their own account, while over a space of some 1,500 acres the forest trees had been replaced by valuable produce-yielding plants. What had been done on the 1,500 acres could be done, and would be done, sooner or later, on an indefinite number of similar areas in the country. In time Borneo would be the chief supplier of cotton to China and Japan and of sugar to the Hongkong refineries; would supplant the Philippines as the chief producers of Manila hemp; run Singapore hand in the export of copra, sago, tapioca, and gambier, and he also hoped that North Borneo would be one of the main contributors to the world's supply of india-rubber. The cultivation of these articles offered, as far as human foresight could go, the safest and best of investments. The main need in connection with the country, it seemed to him, was actual proof that such was the case, and when it was made clear from actual demonstration that coffee, copra, land and other things, under proper management, were almost as safe as Consols, and out and away more remunerative, there would be no lack of capital forthcoming.

A discussion took place on Mr. Pryer's interesting paper, and the meeting closed with a vote of thanks for the same.—*L. & C. Express*, April 9.

"HARD TIMES AND DRINK."

Under this heading, the *American Grocer* of March 24th has the following interesting review:—

COFFEE.

Measured by the number of gallons of the beverage consumed, coffee ranks next to beer as a popular beverage. The net importations for ten years and per capita consumption has been as follows:—

Year.	Pounds.	Av. import cost—cents	Per capita Pounds.
1887	500,819,587	10.7	8.53
1888	408,562,775	14.0	6.81
1889	561,132,100	13.0	9.16
1890	490,161,900	16.0	7.83
1891	511,011,459	*19.0	7.99
1892	629,671,748	*20.0	9.61
1893	551,395,250	14.0	8.24
1894	517,068,994	16.4	8.01
1895	643,234,766	14.7	9.22
1896	572,671,840	14.6	8.04

* Overvalued by reason of depreciation of Brazilian paper currency.

All coffee is imported in the raw bean, and on the average loss 16 per cent in roasting, and allowing for which leaves a net consumption in 1896 of 481,044,346 pounds. The import cost was \$83,534,366, or 14.6 per pound. Coffee retailed in 1896 from 20 to 36 cents per pound, and averaged about 25 cents. Assuming that one pound of coffee makes two gallons of infusion, we have a year's consumption of 962,088,692 gallons at a cost of \$120,261,086.

TEA.

The per capita consumption of tea does not increase; in fact, is less than it was twenty-five years ago, when it averaged one and one-half pounds, against one and three-tenths pounds in 1896. The net imports, assumed to represent consumption have for ten years past been as follows:—

Year.	Net imports. Pounds.	Av. import cost, per lb. cents.	Consump'n Per capita Pounds.
1887	87,481,186	18.7	1.49
1888	83,944,517	15.8	1.40
1889	79,192,253	16.0	1.29
1890	83,494,956	15.0	1.33
1891	82,395,924	17.0	1.29
1892	89,610,741	16.0	1.37
1893	88,131,088	16.0	1.32
1894	91,801,565	15.1	1.34
1895	96,437,042	13.5	1.38
1896	93,340,248	13.5	1.31

The import cost of the tea received in 1896 was \$15,585,741. The retail cost was at least double this or \$31,171,482. Ranhofer, *chef* at Delmonico's, uses four gallons of water to one pound of black, and three gallons to one pound of green tea. Others estimate 200 cups to the pound, and some only 100. India and Ceylon tea will make fully 50 per cent. more of infusion than can be made from the best China and Japan sorts; in fact, sixteen gallons of proper strength are made from one pound of leaf. It is safe to say that one pound of tea as ordinarily brewed will make five gallons of beverage, on which basis there was last year a total consumption of 466,701,240 gallons, costing 63.5 cents per gallon, thus making tea the cheapest of all beverages in general use. If machine-made (Ceylon or India) tea is used, a gallon of good tea will cost the consumer from 3 to 5 cents per gallon.

COCOA, CHOCOLATE, ETC.

The 1896 imports of crude cocoa, leaves and shells, amounted to 23,276,597 pounds, valued at \$2,387,078. Of manufactured cocoa there were 1,244,309 pounds imported, valued at \$410,219, or a total import of cocoa and preparations valued at \$2,797,327, deducting from which \$166,415 worth re-exported, we have as the import cost of the cocoa imported \$2,630,912. A large part of this is used for confectionary and other purposes than a beverage, but it is safe to estimate that the retail cost of the chocolate and cocoa used as a beverage does not exceed \$3,000,000.

THE TOTAL DRINK BILL.

Bringing together into one group, we find that the United States consumed in 1896, alcoholic and non-alcoholic stimulants to the value of \$1,016,126,400 as follows:—

	Dollars.
Alcoholic drinks	861,693,832
Non-alcoholic Stimulants—	
Coffee	120,261,086
Tea	31,171,482
Cocoa	3,000,000
Total	1,016,126,400

The above represents a yearly per capita expenditure for beverages of \$14.31 for the 71,000,000 inhabitants of the United States, or 4 cents per day. Evidently hard times have cut down the appetite for beverages of all kinds, and render distilleries hazardous industries. Breweries and coffee mills are far better property.

PLANTING IN SUMATRA.

British capital has found a home in almost every part of the world where it can earn for its owners even bread and cheese, but, as far as we know, the industrial wealth of the Dutch Indies has not received any stimulus from English enterprise. This is certainly not because there is no scope for profitable investment in the rubber, tobacco, or coffee industries of the island of Sumatra, so much as that when the Hollander has a good thing he likes to keep it to himself—as we see every day in the Transvaal.

The cycle trade is making us all very cosmopolitan in our tastes, for we must have rubber to keep the great Dunlop Company earning dividends (as long as may be) on its famous five millions of capital, and the world's supply of this very useful gum is certainly not on the increase. On the East Coast of Sumatra the rubber-tree flourishes, and there can be no doubt that before long an enormous trade will be developed. The natives tap the wild trees, and have been in the habit of exporting considerable quantities of rubber gathered in this wasteful and unskillful manner; but of late years systematic planting and cultivation of the trees has been practised, and in the Tandjong Kassau district already many fine estates have thus been formed. Some idea of the profitable nature of the trade may be obtained when we say that 100,000 trees produce at a low estimate an annual revenue—after deducting expenses—of from £25,000 to £30,000.

Coffee, which in Sumatra is free from disease, is also a staple product of the island, and, no doubt, the fortunes which, a few years back, were made in Ceylon

out of its cultivation will be repeated in Sumatra. Taking the yield of each tree as only three pounds, an estate of 300,000 trees should give an annual profit of well over £10,000. Ramie and tobacco are both profitable crops, and it is said that petroleum will also be found shortly among the large exports of the island. Meanwhile, the Dutch companies which are working in Sumatra appear to have been very profitable investments for the dwellers by the Zuyder Zee, as may be seen by the following list of shares dealt in at Amsterdam—

	Premium on Shares. per cent.
Amsterdam Deli Comp. Aand 378
Deli Batavia Maatschappij Aand 325
„ Cult. Mij. Arondsburg Aand 34½
„ Maatschappij Aand 595
„ Tab. Mij.—pref. Aand 8
„ Langkat Tabak Mij C. v. A. Nom. gor. K. 11
Medan Tab. Mij. Aand 98
Padang Tabak Mij. Aand 9
Senembah Mij. Aand 388½
Serdang Tabak Mij. Aand 15

The field appears to afford considerable scope for British enterprise, and, provided the management of the plantations is associated with partial Dutch control, so as to cope with the natural exclusiveness of the Government, large dividends should be raised by similar companies which our countrymen may properly establish, and which we hear, efforts will shortly be made to to organise and offer for subscription.—*Sketch*, March 24.

PLANTING PROSPECTS IN BRITISH CENTRAL AFRICA.

An interesting account of planting and prospects of coffee in British Central Africa and German Territory has been supplied to a representative of the *Ceylon Observer* in an interview with Mr. E. Von den Hoff, a gentleman who had been prospecting for several years in Central Africa, and arrived here recently.

COFFEE,

at Blantyre and Zomba, has been a failure in Mr. Von Hoff's opinion. The first crop is always very good, but the crops after that are uncertain, and for three or four years sometimes there is no margin of profit. Almost everybody has been trying to form Companies as soon as coffee fields are opened, and on could rent out a 200-acre plantation for £100, crop and all. The first crops being so very good, a great many people were induced to settle there.

[All this differs so much from the Reports of Sir H. Johnston, and our own correspondents, Messrs. Moir and Brown, as well as the Nyassaland Company's Manager, that we must await further information.—*Ed. T.A.*]

TRANSPORT AND LABOUR.

Transport is miserable and costly; labour is also difficult to get, and has to be got from great distances from the interior. Wages are low, and 4s a month and 1 yd. of cloth a week is the usual wage. Very great many planters pay in calico. The labour is procured from different districts in the Nyassa and each head costs about 10s to get down. There were men who carried on work in that direction and they used to bring down 500 to 600 at a time for different planters. They had to send coffee by carriers a good distance to Katongo on the Shire River and load into river boats and pass into the Zambesi to Chinde where it was loaded on larger German boats and taken to Beira for transshipment to Europe.

SOIL AND CLIMATE.

The soil is not very good where estates have been opened. It is a medium quality around Blantyre, and in the interior rather remarkable as regards soil. It is not a country for white men to stay in. I have been away up to Tanganyika and have crossed it and saw nothing in land fit for white settlers. There was plenty of fever—blackwater fever of a dangerous type, and affecting natives also at times. I went up with a caravan to the interior to prospect for coffee-land, and found one portion on the Northern

Nyassa very good for the purpose, but transport will cost so much that it will not pay to open up land there. Labour there was also very poor; the people there do not know how to work properly; they have their banana and manioc plots and remain contented, doing no work. Regarding rainfall in B. C. A. the rains commence in October and continue to December and sometimes commence as early as September. Five months generally in the year they have rain and then no rain at all. The dry season is very bad and the weather very much hotter than in Colombo. There is water in plenty with such large rivers in Blantyre itself, and water is the chief mode of transport.

COFFEE DISEASE.

The trees come into bearing three years after planting, and the first crop is very good, but the following crops are uncertain. Coffee disease has also broken out, the branches dying off completely and trees gradually dying off; they could not account for it though some experts have been trying to find out the cause. Some planters cut out their five or six year old trees, when attacked with the disease, about a foot and a half completely, and new branches come up, the trees being quite bushy like tea. Trees occasionally recover when attacked but a great many die off. On most estates in British Central Africa the disease has appeared. The estates opened up show a large number on paper. Though a good many persons have been trying to form Companies, nothing has been done. The estates are all owned by private owners. At present you can buy land 200 acres in coffee and 300 unplanted, with buildings, etc., and well laid out for £2,000. Most of these estates have their pulping and other machinery, and every year new machinery is being imported. [And yet we are to believe the estates leave no margin of profit!—Ed. C. O.]

The coffee is of very good quality and they got the best prices of any coffee in the world, realising £115 per ton in England. What with transport and other difficulties the planters do not get more than £60, a good lot being eaten up by middlemen, transport agents, etc.

EXPORTS.

In Tanga (German possession) they have all this while exported only about 200 bags coffee, land being planted about four years ago. They have greater difficulty in the matter of transport and labour.

In Blantyre it was not so bad, but at times great difficulty was experienced in the matter of food there being so many people about.

SUGAR PLANTATIONS.

Several Companies have started sugarcane plantations and very large tracts have been opened out, and they are doing very well. These are chiefly in Portuguese territory on the Lower Zambesi, tracts larger than the coffee estates opened in B. C. A. They must have at least about 1,500 to 2,000 acres in course of cultivation, and there is a very large factory and new machinery ordered from Natal to double the output of the sugar factories, so that they are having double their sugar crops. Two Companies were started—one English and one Portuguese—two years ago, and they are in full swing now. In the matter of export they find things easier and they also do not pay import duty on goods imported, and that is the reason why their plantations are easier.

LIBERIAN COFFEE

has just been planted on the lower portion of the Zambesi by the Portuguese and the prospects are good.

Mr. Hoff leaves this evening by B.I. boat for Tuticorin and Madras, proceeding later on to Rangoon.

THE TEA CROP ESTIMATES FOR 1897—BY DISTRICTS.

By applying to the Chairmen and Secretaries of the various District Associations, we have been enabled to add to the estimates of the current tea crop furnished to the

Planters' Association Committee, the acres in each case on which they were based. From these again we have worked out the average yield for each district, taking only, of course, the tea in bearing into account. From two districts alone—Nilambe and Pundaluoya—have we failed to get the required acreage returns. It will be observed that without these two districts and native gardens, the total area cultivated, in our table, is 314,776 acres and in bearing 246,901, showing 68,875 acres of young tea. It will be remembered that a certain amount has to be added to all these figures to get the exact totals for the island. But meantime the vast majority of districts are fairly represented. It will be observed that the maximum average yield per acre is 567 lb. for the Kelani Valley; while Udupussellawa—strange to say—gives the minimum in 331 lb. We should suspect some blunder here; but we must go by the figures published and sent to us. Dimbula and Dikoya are wonderfully close in their averages—457 and 459 lb. respectively. The table is as follows:—

District.	Acres Cultivated.	Acres in Bearing.	Estimate of Crop for 1897 lb.	Average lb. per Acre.
Ambagamuwa ..	13,862	12,565	5,416,000	431
Badulla ..	12,348	9,121	3,461,625	379
Balangoda ..	5,011	2,211	831,000	375
Dikoya ..	27,577	25,261	11,600,000	459
Dimbula ..	45,059	42,232	19,323,510	457
Dolosbage and Yakdessa ..	15,927*	*	5,726,000	
Haputale ..	13,794	9,556	3,618,250	378
Kalutara ..	14,000	12,000	5,000,000	416
Kelani Valley ..	28,303	22,956	13,021,200	567
Kotmale ..	8,262	7,643	2,853,000	373
Maskeliya ..	18,806	18,128	7,143,500	394
Maturata ..	6,160	5,100	1,833,400	359
Upper Hewaheta ..	3,899	3,436	1,463,350	425
Lower Hewaheta ..	3,771	3,355	1,050,000	313
Nuwara Eliya ..	5,672	4,600	1,922,600	417
Northern Districts ..	39,178	34,217	14,114,981	412
Nilambe	2,000,000	
Passara ..	10,000	7,000	2,800,000	400
Pussellawa ..	17,845	16,135	6,534,600	404
Pundaluoya	1,395,000	
Rakwana ..	4,000	3,565	1,284,600	360
Udupussellawa ..	9,877	6,684	2,203,000	331
Udagama ..	1,425	1,136	525,000	462
Native and unestimated	4,000,000	
	314,776	246,901	119,120,616	

* Insufficient figures furnished to give correct area of tea not in bearing.

It scarcely looks from our Export table so far, as if the total estimated crop for 1897 was to be fully secured? Up to 27th April, our exports of tea are rather over 34 million lb. or 3 million in advance of same date last year; but the excess must be 11 millions over 1896, to give us a total crop of 119 million lb. for 1897. Everything depends on the current quarter, the second, which is always out busiest in the shipments of tea.

PICKINGS WITH A LOCAL APPLICATION.

COFFEE is advancing in popularity in the Mackay district of Queensland. There is little doubt, says the *Queenslander*, that its cultivation will go a long way towards saving the Mackay planters who cannot make sugar-growing pay. It is well-known—bitter experience has taught the lesson over and over

again—that it is impossible to continue for many years taking one kind of crop from the land without returning to it in the form of manure the constituents which that crop specially draws from the soil. This is already becoming apparent on some sugar lands in the Mackay district, and therefore it is well for farmers to learn all they can about coffee, for which the locality is declared by an old Ceylon planter, to be admirably adapted. With annually diminishing yield, and grub and other pests by the cane to contend with, the planter would be in a sad plight were there no opening for him to continue his occupation in some form or other. Coffee seems to present this opening.

From the "Mercury" we gather some particulars of the present position of the budding

COFFEE INDUSTRY AT MACKAY.

For many years past Mr Costello, at Millicent, near Habana, has grown coffee on a commercial scale, and at the present time he has some 35 acres under crop, the splendid coffee from which finds a ready sale in the town. But the attractions of cane-growing appear to have kept others from following his example, and until recently no attempt has been made to extend the industry. However, the failure of coffee in Ceylon and other places, and the rapid rise in the value of the staple, led more or less directly to Mr. John Dansey, a Ceylon coffee planter, visiting Mackay about twenty months ago. With a natural leaning towards the crop of which he had so much experience, he saw in the climate and rainfall and soil of this district an excellent opportunity of establishing coffee-growing on a large and payable scale. A company having a capital of £6,000 was registered in July last year, and acquired some 300 acres at Mount Jukes, Mr. Dansey being intrusted with the work of opening up the estate. No time was lost, and the necessary buildings were erected, the machinery ordered from Ceylon, which machinery will be here in the course of a month, and a nursery of young coffee plants made. Seed was obtained from all available sources, considerable amounts being taken from locally-grown trees. There is now an a nursery of a hundred thousand plants, which number will be doubled next year, and these have made such progress that planting out has been commenced, and in a few weeks twenty-eight acres will be carrying young trees. In addition to this area planted by the coffee Company, private individuals have planted in the vicinity of Mount Jukes some forty acres on the Bowen road about an equal amount will be put in shortly, while down at Plane Creek small areas are also being put under the same crop. Then the company proposes to increase its area by fifty acres each year, until the whole of the available coffee land on the estate is planted up.

The General Exploration the Land Syndicate, Limited, intend to go in for

COFFEE IN BRITISH CENTRAL AFRICA,

after a favourable report by a Mr. Barclay, an experienced Nilgeri planter, and in order to mitigate the ravages of the "borer" and secure other advantages, the planting is to be done under shade. But how? "By planting Liberian coffee among the Arabica"—so that the "shade" as well the crop will give a return.

Among what may be termed

ARTIFICIAL FODDERS

suitable for dairy cows coconut meal is said to have a high value. This fodder is now extensively used in European dairying countries, particularly Sweden and Denmark, where it has become indispensable where stock are kept. The meal has lately been introduced into New South Wales, where it is sold in Sydney in cwt. bags at 5s per cwt. This coconut meal is said to be more largely used in Denmark and Sweden than linseed cake or bran, and is regarded as a very valuable food, not only for cows but for horses, pigs, and poultry. Coconut meal forms part of the daily ration of horses, from 3lb. to 6lb. being added to chaff, according to the size of the horse and its work. Mixed with skim milk it is said to be splendid for fattening pigs. Young poultry fatten very rapidly on coconut meal, which, under proper conditions of feeding, gives better results than grain.

New avenues for the disposal of an over-abundant

MAIZE CROP

are always welcome to growers of that cereal, but we doubt whether the latest discovery will meet with general approval in Queensland. It is said that a Chicago man has discovered a process for manufacturing white powdered sugar from corn. The actual tests were made some time since, and were entirely successful. The Chicago Sugar Refining Company is now turning out an article of powdered sugar, made wholly from corn, that is equal to anything on the market. It is a secret process, and the statement is made that it is expected to eventually make all grades, even to a yellow sugar. This new sugar has been put upon the market at about 1½d per lb. less than the "trust" price. It is not of quite so fine a grain as the regular powdered sugar, but this is claimed as an advantage, as it will not cake or become lumpy. It possesses 97 per cent of saccharine strength, against 98 per cent of the regular powdered sugar. The foes that beset the path of the poor sugar cane-grower are multiplying. First beet, now corn; what next?

The industry of

RABBIT PRESERVING

and exporting has attained such dimensions in the South that it is a question whether the benefit derived from the rodent is not greater than the harm it has done. Rabbits have certainly reduced the capacity of the land for carrying sheep and cattle, but their capture has provided work for probably a larger section of the population than have been driven out by their depredations. Some idea of the magnitude of the trade in Victoria alone may be gathered from the fact that last week there was a danger of the cold stores at Flinders street, Melbourne, becoming blocked with rabbits. Although 96,000 had just been shipped in two steamers for England, there remained in store 150,000 rabbits, and the number was being added to at the rate of 10,000 or 12,000 a day.

A project for the establishment of a meat and rabbit preserving factory in the Mount Gambier district is being warmly taken up, and it is expected that business will begin in April and that 2,000,000 rabbits will be sent from the neighbourhood during the coming season. So that South Australia is also entering into the rabbit business in earnest.

BATTALGALLA ESTATE COMPANY.

The seventh annual report of the Battalgalla Estate Company, Limited, is issued, with balance sheet. Here again the 1895 standard is happily maintained. The Directors in their report state that they are pleased to be able again to give a satisfactory account of the Company's working for the past year. There has been an appreciable increase in the yield of tea, the total quantity manufactured having been 222,281 lb. against 170,560 lb. the previous year. The average selling price in London has been 9'62d against 10'44d the previous year, and in Colombo 5'50d against 6'25d. Out of the crop the Company sold in London 174,580 lb. realising net £6,274 16s 3d and in Colombo 43,655 lb. realising net R16,610'20. These figures compare with 126,951 lb. realising net £4,967 9s 6d, and 39,958 lb. realising net R17,904'33 in 1895. Exchange has ruled higher during the year. The original £4,000 debentures having expired were duly paid off. A fresh amount of £10,000 has been authorised, of which £1,000 were issued in replacement of above. The remaining £6,000 will only be issued in the event of fresh property being acquired at some future date. The usual 10 per cent has been deducted from factory account, and £295 from the estimated value of the Asiatic Produce Company's shares owned by the Company. A 5 per cent dividend was paid in October, and 10 per cent is now proposed—15 per cent for the year, same as 1895.—£101 12s forward. The board consists of Messrs. E. H. Hancock, Charles A. Reiss and Adolf Zimmern. The first gentleman retires by rotation, and offers himself for re-election.—Local "Times," April 29.

TOBACCO AND CEYLON PLANTERS.

(From a South Indian Expert)

I have read, with great interest, the various opinions expressed upon tobacco past and future in Ceylon. These opinions call, as you suggest, for a reply from me. A good deal appeared from me under the above heading, in your March and April issues of the *Tropical Agriculturist*.

When comparing your planters' opinions with my own, interested readers must feel that my statements were correct and are justified by facts. With all due deference, most of the writers, who give their experience, show a lack of that practical knowledge of the subject, necessary to make this industry a success.

So far as I am aware (I am open to correction,)—from information gained in the island, from men who were interested in the late Ceylon Tobacco Coy.—tobacco was a success and a great success, so long as the expert or experts from Sumatra had anything to do with it, and failed when, after these men severed their connection, the Coy. worked without them. At all events, there is a startling difference in the prices obtained. Mr. Vollar, whose name has been identified with tobacco from the first, and whose opinion deserves the greatest consideration, says:—"There is no doubt we can grow first-rate cigar tobacco, but so far we have failed in the curing of the tobacco, &c." Now, neither the soil nor the cultivation has to do with the curing of the leaf; this is a process only, and one that is essential after the leaf is harvested. Tobacco is not tobacco until the leaf is cured and fermented. It is obvious therefore, that to be successful, special knowledge is necessary, and like most things, such special knowledge is not obtainable from books. Bad curing will make the best leaf worthless, while good curing will often convert inferior leaf into good smokable tobacco, though possessing the attributes of inferior leaf. Then again "(1) Too tight rolling; (2) Leaf too strong and coarse; (3) lignoring down; (4) and certain ingredients to improve flavour, &c." are hardly faults of cultivation and could easily be overcome by practical knowledge.

Tobacco necessarily requires attention to business; perhaps more so than any other product, in its handling on the field and off, and the planter who prefers "Tennis, and Mounted Fut" had better not try tobacco, for he will surely fail and fail badly.

The trade at home pay for cigars what they are worth and not what they cost. R15 per 1000 f.o.b. would represent a very poor cigar whether from India or Ceylon, and would, even at that price, find a small sale only. There is no demand for a coarse cigar; what is required is one that is well made, mild in flavour, pleasant in aroma, packed well and manufactured with consideration to the peculiar requirements of the country to which they are to be exported; for such there is a large and increasing demand, and profitable prices are offered and obtained.

It is purely a question of practical knowledge of planting, curing and manufacturing, coupled with an intimate knowledge of the trade.

THE PATIAGAMA CINCHONA CO., LTD.

The annual general meeting of this Company was held at the office of Messrs, Bois Bros. & Co.

Colombo, on 1st May, when the following annual Report was adopted:—

"The Directors herewith beg to submit their Fifteenth Annual Report:—The estimate of Tea for the past year was 60,000 lb.: but the actual crop has fallen somewhat short of this quantity, being only 57,431 lb. which was sold in Colombo at an average rate of 49.13 cents per lb. On a reference to the annexed account, it will be seen that the actual working of the year shows a small margin of R1,942.95. The Directors recommend that the balance now at credit of Profit and Loss Account should be appropriated in reduction of Suspense Account, which represents the loss incurred in working the Estate previous to 1890 whilst the Tea was coming into bearing; and they trust the Shareholders will approve of this recommendation. The Shareholders have to appoint a Director in place of Mr. C. E. H. Symons, whose term of office has expired; and it will also be necessary to appoint an Auditor for 1897.—By order, Bois Bros. & Co., Agents & Secretaries."

A special general meeting followed when the following special resolution was passed:—

"That the Directors be empowered to issue mortgage debenture bonds to the extent of £5,000 sterling, bearing interest at the rate of 7 per cent per annum, for the purpose of paying off the existing debentures aggregating £4,000, and to provide funds for the cost of planting tea on the Company's estate."

SALE OF HUNUPITIYA MILLS, NEGOMBO.

Messrs. Baker & Hall have just sold Hunupitiya Mills (bought only the other day) to the Ceylon Tea Plantations Company, which is now an extensive owner of coconut property.

Since writing the above, a correspondent writes:—"It is the intention of the Company to use the mills as a central depot for their coconut business, their interests in the Negombo district being gradually extended. The mills are said to be capable of turning out 1,000 chests of desiccated coconut and a large quantity of oil monthly."

NEW INDUSTRY FOR GLASGOW.

In about three weeks hence there will be started at Polmadie what is practically a new industry not only in that district but in Glasgow. The manufacture of steel tea chests will form the chief business, and will be carried on by the Acme Tea Chest Company, Limited, at what will become known as the Glasgow Steel Works. In a small way a commencement was made about three years ago in John Street with the manufacture of packages, but so great has the demand now become for the steel tea chests that it was necessary to erect extensive works. After tea growers in India and Ceylon were persuaded to give the new invention a trial, no fewer than 150,000 chests were sent abroad in one year, and during the year closing, which is the third of the company's existence, 300,000 chests have been sent to India and Ceylon. When the new works are in full operation it is hoped that the produce will be something like 1,200,000 tea chests per annum; and that there will be such a demand seems assured when it is remembered that some 5,000,000 chests are used every year, without Japan, and that tea-growers everywhere admit the advantages of the patent boxes over the wooden chests. The new industry will consequently before long give employment to between 500 and 600 workmen, including mechanics, joiners, sawyers, and labourers. Should all go well, it is also proposed that the company produce their own steel plates, as meantime the plates coming from Wales are found irregular as regards hardness and softness. The features of the new steel chest may be summed up thus:—That the same size

carries much more than the old wood chest, the freight is less, the tea is delivered in fresher and better condition in London, and the saving to the grower is considerable. When the chest is made up it has a very neat and clean appearance, and resembles very much an average sized safe. The fact that 1,000 "Acme" chests will bring home 106,000 lb. of tea, while 1,176 wooden lead-lined chests, of the same outside measurement, will be required for the same quantity, demonstrates clearly one advantage of "Acmes" over wooden chests. A saving of about 1s 6½d per 100 lb. of tea arises from using the "Acme" chests. The manufacture of the chests was this week described to a party of pressmen, who were shown over the new establishment. Of course the chests are not made up here, but are sent abroad packed flat in strong wooden cases, holding from 10 to 100, and at the tea gardens they are constructed, the process of putting a chest together occupying only three minutes. The preparation of the plates is an interesting process, and simplicity characterises the whole invention. The top and bottom are of wood, lined with thin metal. The whole surface of the chest inside and out is coated with a solution of lead and tin. After being pickled in acid and washed the sheets are passed through an ingenious machine which performs coating automatically. The sheets are then trimmed to gauge by guillotine machines and taken to the large press, which at one stroke practically makes the body of the chest; between the dies of this chest the plate is stamped and shaped under a pressure of some 250 tons, and when it issues it can be bent in half a minute by hand into the form of a chest, and closed by the patent fastening made simultaneously by the same machine. As they come from the machine, the plates may be shipped off to Ceylon, where they are made into tea chests by the most unskilled of the natives. As regards strength, lightness, and durability, the steel chests far surpass the old wooden ones, and a great matter is that leakage is impossible. At Polmadie entirely new machinery has been laid down, and the company will find great advantage in having the Caledonian Railway siding running into the works. Coal, for instance, may be placed at the furnace doors from the waggons, while the goods will be conveniently despatched. There is an installation of electric light throughout the works. Mr. James T. Tullis is chairman of the directors, Mr. P. Strat Brown managing director, and the other directors include Mr. James Couper, jun., and Mr. John Bennie.—*British Daily Mail*, April 2.

EMPIRE AND TEAPOT; IN AN INDIAN TEA GARDEN.

(BY W. R. LAWSON).

Darjeeling.

Tea has become a great cosmopolitan industry. India alone supplies the world with over one hundred million pounds of it every year, which, valued at a moderate average of a shilling per pound, amounts to five millions sterling. Perhaps two out of the five millions are distributed in England in dividends on tea shares.

To India itself tea has been an incalculable boon. Like jute, it is almost a monopoly, and districts of Bengal have been enriched by it which might never have been good for anything else. Assam and the whole frontier country east of Darjeeling were almost impenetrable jungle until the pioneer tea-planters bowed their way in, and transformed the jungle into a garden.

Calcutta as a port owes a great deal to tea. Practically the whole output of the Assam and Darjeeling gardens passes through it, and for the shippers it is a profitable business. One firm in Calcutta ships thirteen million pounds a year—a huge business in itself, and leading to many other valuable contingencies. A member of an old Calcutta firm remarked to me a few days ago. "I sometimes wonder where we should have been if new lines of business like

tea and jute had not opened up so providentially for us. It is only five-and-twenty years since I joined this firm, and today we are dealing in hardly a single thing that I began with. They are changing all the time, and we have to change along with them."

Tea plantations are now scattered all over India though by far the largest area of them is in the Brahmapootra Valley running up through Assam. Very fine tea is grown on the Nilgiri mountains, on the west side of Madras province, and not far from the Wynaad gold fields. When

THE FATE OF THE GOLD FIELDS.

still trembled in the balance, some of the pioneer companies, with commendable forethought, provided themselves with large areas of waste land for planting. If the quartz failed them they thought they might find some compensation in tea or coffee.

On the north side of Calcutta the tea gardens most easily reached are those of Darjeeling. They can be included in the regular Darjeeling trip, now the greatest trial that most tourists find in India. You can start from Calcutta by an afternoon train on the Eastern Bengal Railway, dine on a ferry boat, crossing the Ganges at Damorkdea, and breakfast next morning in full view of the Himalayas.

From Saraghat, on the left bank of the river, you travel on a metre-gauge line—the Northern Bengal—to Sibguri, where you change again on to the 2ft. gauge mountain line. This latter line—one of the few successes that Calcutta finance has yet scored off its own bat—rises about 8,000 ft. in less than fifty miles. It corkscrews round and round the mountain sides, curling itself into loops, and cutting track above track, until you can look down on three or four of them in successive terraces.

The Canadian Pacific may show some bits of equal magnificent engineering in the Rockies, but it has no such long continuous climb as there is on the Himalayan Railway. The nearest approach to its wonderful scenery is on the Mexican Railway between the city of Mexico and Vera Cruz, where precipitous mountains have to be scaled by cutting track above track in winding terraces. It lacks, however, the glorious background of the Abode of Snow. The foothills of the Himalayas have a prolific vegetation, the endless variety of which taxed even the descriptive power of Sir Joseph Hooker. The terai, or flat land skirting the foothills, is

A FAMOUS GRASS COUNTRY,

at least by repute, for in this year of universal drought most of it is as dry and dusty as a brickfield. From the terai the little railway climbs first through a semi-tropical belt of ferns and acacias, with feathery bamboos waving over them. Gradually orange trees, lemons, banyans, and cotton trees mingle with the bamboos. Many of them are hung with creepers radiant with bright coloured orchids and convolvulus

This orchid belt covers the lower valleys and extends from 1,000ft. to 4,000ft. up the mountains. Then a third belt begins quite distinct from either of the lower ones. European trees—oak, beech, and maple—intermingle with palms and fig trees, while the ground is carpeted in many parts with European mosses. In this half-tropical, half-European belt we find the tea gardens. Wild tea bushes have shown here and there among the brushwood all the way up. Now and then on a patch of clearing beside a railway station or a native village a young garden may have been seen struggling into existence. But that sort of tea is only for home use. The growers pick it as it comes, dry it in the sun, and in any case are sure of a strong flavour, which is what they most appreciate.

Scientific tea-growing has yet to come. From 2,000 ft. or 3,000 ft. up we may have been passing tea gardens all the time, but they are not visible from the railway. They only come in sight when we rise high enough to look back on them from the crest of a mountain that may have taken us hours to scale. Then the panorama which unfolds itself is superb. Between dense black masses of junglo broad

stretches of bright green flash out in the sunlight. In some cases an entire mountain side has been cleared, and acres of tea bushes are already in leaf. Elsewhere clearing has just begun. Twenty or thirty acres have been cut out of the jungle, and the first planting hardly shows as yet above ground. This year another big cut will be made in to the jungle, and twenty or thirty acres more will be planted. A tea garden in a good district is always extending itself, always.

DRIVING BACK THE PRIMEVAL FOREST, and adding to the countless rows of green bushes.

At Kursslong, about twenty miles from Darjeeling—that is, on the lower side of the mountains—we get into the heart of an old and well-developed tea district. It is one of the oldest in India, its first garden having been started about 1856. Whole valleys have been cleared and planted, acre has been added to acre till the area of some of them is to be reckoned by square miles. Whole lakhs of rupees had been laid out on some of them, and as a rule well laid out. They are no longer gardens, but "tea estates," and when the proprietors got too rich or too lazy they had themselves converted into limited liability companies, with directors in Calcutta or London, and brokers running after their shares. The manager of a large tea estate generally finds life worth living even in these high latitudes. His white-washed bungalow, perched on a commanding ridge, is conspicuous for miles around. Sloping lawns and bits of garden give it a homely look, and at the same time guard it from miscellaneous intrusion.

But there is one ugly feature it seems never able to get rid of—its galvanised iron roof. Neither slate nor tile is ever to be seen here. It would cost a ransom to bring them up from the terai, and so people do without them. Churches, hotels, Government offices are all roofed with the glistening white iron sheets, which make sunlight hideous. On the tea estates entire houses, or rather sheds, are made of them. The manager's bungalow probably overlooks a hollow crowded with galvanised iron buildings. There will be a group of "firing-houses," where the tea is "fired," or dried, a row of sheds for stores or workshops, an engine-house, with a long, iron chimney, stables for a score or two of hill ponies, and a crowd of huts for the coolies. The headquarters of a large tea estate may form a very considerable village, and it has to be held under very strict rule.

LABOUR IS A SERIOUS ITEM

in the production of good tea. Nearly all the gardens having been formed in what was one desolate, uninhabited jungle, no local labour was to be found. It had to be imported from distant parts of Bengal, and though hundreds of thousands of coolies have migrated to Darjeeling and Assam, the cry is still for more. Tea planting extends year after year, and the supply of labour cannot keep pace with it. Special laws have to be passed to facilitate the recruiting of coolies in the populous parts of the country, and that has become an important business of itself. I travelled lately from Patna to Benares with a free-spoken Yorkshireman, who described himself as a labour agent. He had got a telegram that morning from a tea planter in Assam asking him to send up seventy or eighty coolies at once. He was now on his way to execute the order, and he described to me minutely how it would be done.

He had several recruiting depôts in Oudh, and the North-West, where coolies are thickest. Each depôt had its recruiting agent, who picked up men in the street or on the road wherever he could find them. They were kept till the agent went round, as he was now doing, to draft a new lot. He would select the number he needed, and have them medically examined. Then he would take them before the nearest magistrate and have their agreements read over to them in his presence, the magistrate's duty being to see that they understood the agreements and made them of their own free will. The next step was to rig them out in warm clothes adapted to the hills, and to rig their

families also. Finally, they were all put on board a train, with a personal conductor, and sent on to their destination. Usually they engage for three years, and many of them re-engage for a second term. The majority, however, grow home-sick, and return to their native villages to starve.
—*Daily Mail* April 2.

VARIOUS PLANTING NOTES.

CROTON-SEED remains scarce. Two small parcels, totalling seven bags, have come to hand from Colombo, and will probably be offered for sale next Thursday.—*Chemist and Druggist*, April 24.

TAMARINDS.—The first arrival of the new crop *Barbados tamarinds* was offered at auction, but little demand was shown, and the whole supply, consisting of 175 barrels of fine quality, was bought in at 16s. per cwt. Twenty casks of dark *East Indian tamarinds* were also bought in at 9s. 6d. per cwt.—*Chemist & Druggist*, April 10.

THE PRUNING OF TEA.—An old Ceylon Planter at home, who has read the recent correspondence on this subject with interest, thinks that sufficient attention has not been given to the evil effects of gormandizers, which on some estates are allowed to shoot up, to the detriment of the tea bush.

CHANGE OF ADDRESS.—We are requested to state that from and after the 5th inst. the registered address of the Ceylon Tea Plantations Company, Limited, Central Tea Company of Ceylon, Limited, Digalla Ceylon Tea Estate Company, Limited, Ceylon Proprietary Tea Estates Company, Limited, Travancore Tea Estates Company, Limited, and Selangor Coffee Company, Limited, which have hitherto been 21, Mincing Lane, E.C., will be 20, Eastcheap, E.C.—*H. and C. Mail*, April 2.

NATAL FIBRE.—We (South Africa) have had a call from Mr. D. W. Watt of the Natal Fibre Extracting Company, who is shortly returning to the Garden Colony after a successful business sojourn on this side. Mr. Watt tells us that certain Glasgow folk to whom he submitted specimens of Natal fibre declared the same to be the finest they had ever seen. He is taking back with him a decorticating machine with which he hopes to begin work immediately on his arrival in the Colony.

THE MAYFIELD TEA ESTATES COMPANY.—Notwithstanding the adverse criticism in city papers, this Company has been, we hear, successfully floated, as indeed might be fully expected. The Dimbula estates—Mayfield and Chalmers—are, of course, first-class properties and we hear such accounts of the young tea on virgin forestland on Nicholoya and of the handsome reserves still on that place, as show that in this Matale place also, a very good purchase has been made.

DR. P. C. PLUGGE, Professor of Pharmacology at the University of Groningen, Holland, is about —says *Chemist and Druggist*—to undertake a journey to Java for the purpose of making certain pharmacological investigations in the Buitenzorg Botanical Gardens. The Professor intends to devote special attention to research into the properties of Indian medicinal-plants, and to gather a supply of material for further investigations after his return to Holland. Professor Plugge was formerly engaged as a pharmacologist in the service of the Government of Japan.

A VERY IMPORTANT SHIPMENT OF TROPICAL fruit has been made by the Queensland Government—the first of its kind—as an experiment; and very shortly the consignment will be here. The fruit includes mangoes and pineapples, and these are of the finest description. It is to be hoped that the consignment will arrive in good condition. The Queen has graciously consented to accept some specimens of the fruit, and, if all goes well, some will be forwarded to Her Majesty. The fruit is coming by the “*Junna*.” The mangoes are from Townsville, and the pines from Brisbane. The fruit is gathered in a nearly ripe state, and it will now be seen whether it is possible, by careful packing and by taking every precaution, to convey tropical fruits from Australia to England in the same way that oranges can undoubtedly be sent. *European Mail*, April 7.

PRIVATE ESTATES IN JAVA.—For some years the Colonial reports—says the *L. and C. Express*—contain a list of the number and value of the private estates in Java with a specification of the owners, whether Europeans, Chinese, natives, and foreign Orientals. The report of 1895 mentioned that the estates of the Europeans amounted to 29, of the Chinese to 22½, and those of natives and foreign Orientals to 2 million guilders. Since then a modified list has been issued. Successively a number of estates have been converted into limited companies, and the following figures are now mentioned:—Estates of limited companies 16, of Europeans 16, of Chinese 18, of native and foreign Orientals 2½ million guilders. A fault in this statement is that it does not show which of the limited companies are managed by Europeans and which by Chinese.

THE CACAO DISEASE IN MALAYA.—Mr. James R. Martin, who has prolonged experience in Yattawatte, writes a reassuring letter on the subject to our evening contemporary. We quote as follows:—

“This disease has existed amongst cocoa in Ceylon for the last 10 years, but in many instances the estates where it first appeared are now doing well and giving good crops. The acreage under cocoa has certainly not increased since 1893, but the crop for the last year was the largest on record by a good deal, and the official estimate for the present year exceeds that. I remember quite well the scare about *Helopeltis*. Cocoa planters were then reminded of the fate of cinchona, and were told that the product was ‘doomed’ and that they were ‘ruined men;’ but those expressions merely preceded the five most prosperous years the product has known. No doubt the assistance of an expert will be a great advantage in cocoa and other cultivations, a fact that Mr. Christie has suddenly awoke to.”—Since quoting this, the important letter which will be found on our 5th page has reached us from Mr. J. H. Barber. It will be seen that Mr. Barber discusses the point raised by Mr. VanderPoorten and that he is inclined to the view which Mr. E. E. Green expressed on the stem sent to him by Mr. Gibbon. Still, here is what another cacao grower writes to us:—

“With a specialist on the horizon, to say whether the pest is a pööchie or a fungus would not be wise. All the same if it is not a pööchie I’ll be surprised. It is remarkable how vigorous the suckers come up, if the attack is not too low down after the tree has been cut down.”

Now, surely our friend knows how “Specialists” are divided and subdivided now-a-days—he has read of the *savant* who refused to be called a Scientist, Naturalist or even an Entomologist; he only knew of one species of beetles—a subdivision of Coleoptera? Now we have in our midst a working Entomologist—why are his services not availed of?

COOLIES AND PLANTERS.—There can be no doubt of the scarcity of coolies in many directions in the planting districts, and the tricky cheating disposition which is spreading among both kanganis and coolies is much to be deplored. It will inevitably spread much farther too, unless strongly discouraged and repressed, no matter at what immediate cost, by the planters themselves. Here is an illustration: a kangani interviews a planter about bringing him a gang of coolies; but first their debts must be paid—these debts consist, say, of R1,000 to the estate they were on and R1,000 of outside boutique and chetty debts. The latter must be paid and the money is wanted for them; but inasmuch as the estate Superintendent refused a “*tandu*,” he, the kangani, having given proper notice, does not mean to pay the R1,000 due to the estate—but will let the owner whistle for it! Fortunately, the Manager applied to was one of a good old school who at once hooted the kangani making this dishonest proposal, out of his presence and off the estate. But are there any Superintendents—hard up for coolies it may be—who would entertain a dishonourable and dishonest proposal of this kind? We trust not. On the other hand what about the refusing of “*tandus*”—is that right or even wise when application is made in the proper way? We think not; for the risk is thus run of losing both coolies and advances—the only remedy being a civil action—and we all know what that is worth.

“A GENTLEMAN OF JAPAN”—is the heading of an article reproduced in a tiny circular from the Canadian *Grocer*. We quote as follows:—

Mr. H. Komada, Kobe, Japan, manager of the Japan Tea Exporting Association, arrived in Montreal a few days ago to visit their Canadian representatives, Morrow & Ewing, Montreal. Mr. Komada is the founder of the Japan Tea Traders’ Association and takes an active interest in its affairs. The association has over one and a quarter million members. In fact, every proprietor and dealer in teas in Japan is required by law to join and obey the bylaws of the association. Mr. Komada says that the Japanese tea merchants are much exercised over the enormous strides which have been made by Ceylon teas in Canada during the last year or so. The advertisements in the Canadian *Grocer* had interested the trade here in Ceylon teas, and were creating a feeling against China and Japan makes. By constant repetition the trade all over Canada were beginning to believe things about Japan teas that were not altogether fair. Buyers were in consequence turning to Ceylons, and the demand for Japan teas had fallen off very much. Wholesale merchants and dealers who were pushing other makes a year ago were now advertising to the consumer all over Canada nothing but “pure Ceylon teas.” The matter had come before the Japan association, and some action would be taken to counteract these influences. It was quite true, he said, that in Ceylon teas were made by machinery, while in Japan they were still made by hand, but he explained that as the Japanese were a very cleanly people there would be no danger of dirt entering their makes, or of disease being communicated. He admitted, however, that the Chinese teas were often very dirty. In fact, he added, that the Chinese were very dirty, and prepared their teas as much with their feet as with their hands.

He found that there were a great many inferior Japan teas coming to this market. They were not shipped by the desire of the Japanese themselves, but by foreign firms. They were what is known as third pickings, and the foreign houses ordered these to get low-priced teas. The Japanese at home would not use them, and they were trying to prevent foreign houses buying and exporting them. Handling of low-priced teas injured the dealers who bought the early pickings at higher prices,

THE STANDARD TEA COMPANY OF CEYLON.

The sixth ordinary general meeting of the shareholders of the Standard Tea Company of Ceylon, Limited, was held at the Registered Office of the Company, 25, Fenchurch Street, London, on Wednesday, the 14th day of April at 12 o'clock, noon.

Among those who were present were Messrs. Alex. Brooke (in the chair), William Rollo, Henry Atkinson, R. A. Bosanquet, John Anderson (of Gorthie), Frederick Hadden, Edward S. Grigson, Thos. S. Grigson, S. Wilson, Geo. Seton, Geo. Stehn, Jas. Mackintosh Smith.

The SECRETARY (Mr. A. Trafford Brooke) read the notice convening the meeting.

The CHAIRMAN said:—Gentlemen, you will, I fancy, take the accounts and report as read in the usual way. You will note the Directors recommend the same dividend as last year, though you have not had the same profits, owing to the increase in the tea not quite compensating for the falling-off in coffee, and the rise in the rate of exchange in 1896. The increase in tea has, however, done pretty well towards filling up the gap. Our first year the income from coffee and bark was nearly half our total income this year the coffee gives about 5 per cent towards total income. It is therefore satisfactory that the tea has done so well, and you see by the report that we have a good deal of land still only partially bearing, or not bearing at all. The exchange has not treated us as well this year as in 1894 and 1895. The close connection of Ceylon with India made us a sufferer in exchange, and the severe famine there did us no good even in the matter of labour in which some thought it might help. It seems a little strange that it should be such an anxiety to Ceylon Planters to obtain labour, while the anxiety of Indian rulers is to find labour for their teeming population. The Ceylon Association and H.E. the Governor have, however, this matter in hand, and it may be hoped they will persuade the Indian rulers into measures to overcome the conservatism of the Northern coolies. I suppose it will not be a much greater difficulty to induce such coolies to come to Ceylon now than it was at first to obtain Tamil labour. The high rate of exchange has been somewhat artificial. Money has been very dear out in the East. In the old days the Exchange Banks and others would have purchased and shipped silver to relieve the tightness, but this cannot be done now for the Indian mints being closed it cannot be coined into rupees, so that practically the only way to relieve the scarcity of money was by remittance by Indian Council bills at a high exchange. While our Indian currency, the rupee, is made so much dearer, our tea rivals in China, who have full use of cheap silver, gained 12 per cent on us and 12 per cent on 8d. tea is a penny per lb. That penny is a substantial bonus to the Chinese tea producer. I do not know that I have more to say except that the Ceylon management has continued to give satisfaction. You may hear something upon this subject from Mr. Norman Grieve. Of the purchase of Conygar I need say little beyond what is told you in the report. The Directors believe it will prove a fair purchase; it is wedged in between our Gordon and St. Leonards estates. I shall be happy to answer any question that any shareholder may put to me, and I now beg leave to move that the report and accounts be received and adopted.

Mr. NORMAN GRIEVE said:—Mr. Chairman and gentlemen, I have much pleasure in seconding the adoption of this report, and I should like in a few words to state the impression I have gained by being out in Ceylon. Of course I saw a great many changes in point of view of labour. Everything is wonderfully altered since I was there. I can see dangers in some quarters and considerable difficulties which will have to be contended with in others. So far as our properties are concerned, I carried away the impression we had very much less to fear than many of our neighbours. I have had occasion to visit a number of estates belonging to other companies during my stay in Ceylon, and in no quarter did I find that

any property was more efficiently managed or possessed better managers. In the matter of management I can see difficulties in many places. There are a large number of experienced men who have come home, and consequently there is a considerable tightness in the market for able managers. We, however, have, I am glad to say, in Mr. Bagot and Mr. Craib and the other gentlemen who manage our estates a most efficient staff. In proof of this you need not go further than the report, when you consider that we have not only shown good results, but have increased the price of tea since last year. I think I do not speak too highly of our manager on St. Leonards; his value to the company is great. There are of course drawbacks here and there. All superintendents have now a very anxious time in the management of their labour. Every district has to contend with unscrupulous people who are increasing the advances on coolies in a most reckless way; but this system I regard as tantamount to a rise of wages. It has this advantage—the screw can be put on more easily. When the time comes if you make a specific advance in the rate of wages, it is very difficult to make a reduction. On this advance system there is a possibility of going back to the old system again and dropping the advance. I do not think that on our estates we have suffered as badly as many other places I visited, and I believe this is due to the excellent managers we have on our properties. There is a great feeling of clannishness amongst coolies, and when they are under a man whom they thoroughly trust they are not so willing to move from estate to estate. I can speak with the greatest confidence with regard to the future of the properties. I think that this company can contemplate with comparative equanimity the possibility of difficulty in the money market, exchange, or the prices of tea, as compared with many other undertakings. I was much struck in St. Leonards with the very large amount of undeveloped land. We have a very large area, which has hitherto been under coffee, which is now under tea. Similar land, on an adjoining estate is giving as much as 600 lb. to 700 lb per acre. I should certainly advocate the dismissal of coffee soon because it is a vanishing quantity. I should therefore devote the whole of the valuable area to tea, and not postpone any longer than is necessary the day when it will be bearing tea. We have a valuable and an increasing valuable property to deal with, and I think this company is very much to be congratulated on the position in which it stands. We shall have, like everybody else, to be careful and economical, and endeavour in every possible way to keep down the cost of production. The men we have in charge of our property are alive to this necessity, and are unsurpassed by any I came across during my travels in Ceylon. I have much pleasure in again seconding this motion.

The CHAIRMAN:—Before I put this motion to the meeting I ask any shareholder for remarks or enquiries.

Mr. SETON:—Mr. Chairman, I should like to ask what probability there is of these £6 paid shares, which constitute the chief part of the capital of the Company being paid up in full. Of course, I am quite aware that if we do not want money, there is no object in calling it up, but if they could be paid up without injuring the financial position of the Company, I think the shares would have a greater value on the market.

The CHAIRMAN:—When we started our Company, it was with rather large ideas. We thought we should buy many more estates and that we should call up this reserve, or unpaid liability and use it in paying for these estates never obtained. The ideas of Ceylon estate owners went rapidly far ahead of ours, and we have done very little towards buying property on the scale at one time contemplated with Conygar, the Vendor, stipulated for, and we agreed to pay him in shares. So for the present I do not see that there is much probability that we shall call up that liability.

Mr. HADDEN:—Mr. Chairman, if I am in order,

I should like to know what the Reserve fund is invested in?

The CHAIRMAN:—The Reserve Fund has been used to pay off our debts and is invested in the estates and we have benefitted by it by saving interest and increased profits. Compare the cost of the estates in the balance sheet £75,000 with the paid-up capital £56,000. If we had not had that £7,500 we should have been owing *pro tanto* more on Debentures on mortgage or something, and you would have been paying interest on it.

A SHAREHOLDER:—I see the price of the St. Leonards tea was higher in 1896 than in 1895—was the quantity as great?

The CHAIRMAN:—The quantity increased also. The Maskeliya is not so satisfactory, as we had an increased quantity and a smaller net result there.

Mr. SETON:—I note, Mr. Chairman, we do not see details of actual crops gathered in. They are not mentioned in the Report.

The CHAIRMAN:—We never have mentioned it.

Mr. SETON:—Then the shareholders have not the pleasure of seeing whether they have increased or decreased their tea crops.

The CHAIRMAN:—They have increased very steadily, indeed you can see that the large proportion of our increase is in tea. The crops of tea were 602,000 this year, 572,000 last.

The SHAREHOLDER:—Nothing to be ashamed of that is clear.

The CHAIRMAN:—If there is no other shareholder who wishes to ask any question I beg to move that the report and accounts be adopted. Those in favour—those against.

The motion was carried unanimously.

The CHAIRMAN:—I propose that a dividend of ten per cent free of Income Tax on the £56,000 paid-up capital be declared, which, with the interim dividend distributed 5th August, 1896, makes 15 per cent for the year 1896; that this final dividend be payable on and after 15th April; that £1,000 be written off for depreciation; that £1,500 be placed to Reserve, and that £800 7s 11d be carried forward to the year 1897.

Mr. ROLLO:—I have much pleasure in seconding that.

The CHAIRMAN:—The motion has been proposed and seconded, those in favour—those against. The motion was carried unanimously.

Mr. EDWARD S. GRIGSON:—I have much pleasure in proposing that Mr. Robert Kay-Shuttleworth, the retiring director, be and hereby is re-elected a director of this Company.

Mr. ANDERSON:—I beg to second that.

The CHAIRMAN:—It is proposed that Mr. Robert Kay-Shuttleworth be re-elected a director. Those in favour—those against. The motion was carried unanimously.

The CHAIRMAN:—I have a letter from him expressing very great regret that he is not here today. He is unfortunately detained by severe sickness of his wife, in San Remo, and I beg to thank you in his name for your re-election.

A SHAREHOLDER:—I beg to propose that Messrs. McAnliffe and Davis, Chartered Accountants, be elected Accountants of the Company.

A SHAREHOLDER:—I have much pleasure in seconding that.

The CHAIRMAN:—It has been proposed and seconded that Messrs. McAnliffe and Davis be elected Auditors of the Company.

Those in favour kindly intimate the same in the usual way.

The motion was carried unanimously.

The CHAIRMAN:—Gentlemen, that ends the business of our ordinary meeting: and we now become an extraordinary general meeting.

EXTRAORDINARY GENERAL MEETING.

The CHAIRMAN:—I propose that the capital of the Company be increased to £150,000 by the creation of 5,000 new shares of £10 each.

Mr. W. ROLLO:—I beg to second that

The CHAIRMAN:—Gentlemen, it looks a little bit inconsistent, after my remarks to the shareholders, that we should propose to increase our capital at the time when we intimated we saw no immediate use for money, and the only estates we have lately bought we paid for in duly paid shares. We think, however, that times may change, and it might be better to be authorised to leave the option of this extra capital.

The motion was put to the meeting and carried unanimously.

The CHAIRMAN:—This, gentlemen, concludes our business.

Mr. R. A. BOSANQUET:—Before we close this meeting I should like to be allowed to say a few words. I am sure it is quite a pleasure to hear this favourable report; sometimes things look all *coulour-de-rose* and sometimes we see clouds ahead. I have listened with much interest to Mr. Norman Grieve, and it has made me wish that I too might visit Ceylon again; but, perhaps, sometimes it is as well not to get too close to these difficulties. I wish to propose a vote of thanks to the Chairman and directors and to couple with it that of the eminent Agents in Ceylon whose services to the Company are and have been great, Messrs. Geo. Steuart & Co., and I have no objection also to include the estate managers.

Mr. I. MACKINTOSH SMITH:—I have much pleasure in seconding this.

The motion was put to the meeting and carried unanimously.

The CHAIRMAN:—I thank you for myself and my colleagues, the estate superintendents and for Messrs. George Steuart & Co., but there is a gentleman here, Mr. Thomas Grigson, who can more appropriately reply for the last.

Mr. GRIGSON:—After all that has been said it is not necessary I should occupy your time beyond thanking you very much for the Resolution you have passed. To hear of Mr. Grieve's visit to Ceylon shows a favourable prospect for the operations of the Company in the future.

The proceedings then terminated.

THE EDERAPOLA TEA COMPANY OF CEYLON, LIMITED.

The first annual ordinary meeting of the Ederapolla Tea Company of Ceylon, Limited, was held at the office of the company, 16, Philpot, Lane, E.C., on Tuesday, April 13th, 1897, at 2 o'clock p.m., Mr. G. W. W. Paine (chairman), presiding.

Notice convening the meeting having been read by the secretary, the chairman said he supposed they could take the report and accounts as read. He had very little information to give the shareholders on this occasion, it being their first general meeting since the formation of the company. They had had sundry tempting offers made to them to purchase land recently developed, but they preferred to purchase virgin soil and develop gradually for themselves. As the shareholders would notice in the report they had already purchased some native lands adjoining their properties, and they intended, as opportunity arose, to extend their boundaries by the acquisition of any suitable native or Crown lands that might be for sale in their vicinity.

The chairman considered the dividend of 10 per cent a very good one for the first year's working, considering the rate of exchange had been against them. With a more favourable rate of exchange and a better tea market they would hope for an improving dividend. The quality of the tea had much improved since the company had taken over the estates, and great credit was due to Mr. Watt for his continual and successful exertion to improve the quality of the tea. Mr. Paine then gave particulars as to the new clearings, and no questions being forthcoming the following resolutions were put to the meeting and carried unanimously.

Proposed by Mr. G. PAINE, seconded by Mr. PORTER:—"That the reports and accounts as presented to the shareholders be received and adopted."

Proposed by Mr. PAINE, seconded by Mr. MACMARTIN:—"That a final dividend of 5 per

cent. (free of income tax), making 10 per cent. for the year, be declared, payable forthwith."

Proposed by Mr. PORTER, seconded by Mr. SIMPSON:—"That Mr. G. W. Paine be re-elected a director."

Proposed by Mr. STOCKS, seconded by Mr. J. C. ANDERSON:—"That Messrs. Cape and Dalgleish be re-elected auditors for the ensuing year."

Proposed by Mr. G. W. PAINE, seconded by Mr. SIMPSON:—"That a vote of thanks be and is hereby given to the Ceylon and London staffs for their efficient working of the Company's properties and business."

Proposed by Mr. ANDREWS, seconded by Mr. SIMPSON:—"That a vote of thanks be and is hereby given to the chairman and directors of the company."

In responding, the Chairman mentioned incidentally that there was a considerable enquiry for their shares at £14 per £10 share, and the proceedings were then brought to a close.

THE BANDARAPOLA CEYLON TEA CO., LD

The fourth annual ordinary meeting of the Bandarapola Ceylon Company, Limited, was held at the office of the Company, 16, Philpot Lane, E.C., on Wednesday, April 14, 1897, at 2:30 p.m., Mr. G. W. Paine in the chair.

Owing to very few shareholders being present the proceedings assumed a formal character, and the following resolutions were passed unanimously.

Proposed by Mr. G. W. PAINE, seconded by Mr. C. J. SCOTT:—"That the report and accounts as presented to the shareholders be received and adopted."

Proposed by Mr. G. W. PAINE, seconded by Sir George A. PILKINGTON:—"That a final dividend of 5 per cent. (free of income tax) be declared, payable forthwith, making in all 10 per cent. for the year."

Proposed by Mr. G. W. PAYNE, seconded by Mr. H. FRASER:—"That Mr. C. J. Scott be re-elected a director of the Company."

Proposed by Mr. GEO. G. ANDERSON, seconded by Mr. D. ANDREW: "That Mr. John Dalgleish, C.A., be re-elected auditor for the ensuing year."

Proposed by Mr. G. W. PAYNE, seconded by Mr. H. FRASER: "That a vote of thanks be given to the Ceylon and London staffs for their efficient working of the company's property and business."

Proposed by Mr. D. ANDREW, seconded by Mr. W. D. CAMPBELL:—"That a vote of thanks be, and is hereby, given to the chairman and directors of the Company."

The proceedings then terminated.

THE NAHALMA TEA ESTATES CO., LD.

The third annual ordinary general meeting of the shareholders of the Nahalma Tea Estates Company, Limited, was held at the offices of the Company, 39, Victoria Street, Westminster, on Tuesday last.

The chair was occupied by Mr. Arthur Marshall, Chairman of the Directors.

The Secretary having read the notice convening the meeting, and the minutes of the previous meeting having been read and confirmed, the Chairman moved the adoption of the report, which, he remarked, spoke for itself. The proposal was seconded by Mr. FORSYTHE, and carried unanimously.

Mr. ABERNETHY proposed, and Mr. S. MACBAY seconded, the payment of a dividend at the rate of 2 per cent. on the ordinary shares, making 6 per cent. for the year. The resolution was carried.

The CHAIRMAN then proposed and Mr. ABERNETHY seconded the re-election of Mr. FORSYTHE, the director retiring by rotation. The resolution was carried *nem con.*

Mr. BATTEN proposed the re-election of the auditors of the Company Messrs. Fox, Sissons, & Co., and the proposal, having been seconded by Mr. FORSYTHE, was carried unanimously.

The proceedings closed with a vote of thanks to the Chairman.

CEYLON TEA

LIMITED.

Report of the Directors to be submitted at the Tenth Annual Ordinary General Meeting of Shareholders to be held at the Office of the Company, on Thursday, 29th April, 1897.

The Directors have the pleasure to submit the General Balance Sheet and Profit and Loss Account for the year ending 31st December, 1896, duly audited.

	£.	s.	d.	£.	s.	d.
The net amount at Credit of Profit and Loss Account, including balance brought forward at 31st December, 1895, and after providing for General Expenses, Directors' Fees, Income Tax, &c. is ..				50,652	16	1
An interim Dividend of 7 per cent. on the Ordinary Shares was paid 28th October, 1896, amounting to ..				11,716	12	0
It is proposed to pay a final Dividend of 8 per cent. on the Ordinary Shares (making 15 per cent. in all, free of income Tax) which will absorb ..				13,390	8	0
Dividends on the 7 per cent. Preference Shares were paid for 1896 (less Income Tax), amounting to ..				5,486	17	3
It is proposed to add to Reserve Fund ..				14,542	14	9
It is proposed to write off for Depreciation ..				4,000	0	0
And to carry forward to next year a balance of ..				1,516	4	1
				<u>£50,652</u>	<u>16</u>	<u>1</u>

The Directors are pleased to be in a position to recommend a total Dividend of 15 per cent on the Ordinary Shares, this being the tenth consecutive year in which a like dividend has been declared. It is proposed to write off for Depreciation the sum of £4,000, and to add £14,542 14s 9d to the Reserve Fund, which, with the addition of £457 5s 3d derived from profits on Sale of Investments during the year, will stand at £83,000. The yield of tea was 470 lb. per acre over plucking area of 7,998 acres have and this is the largest average outturn the estates given since the formation of the Company. The yield for 1895 was 437 lb. per acre. The crop for 1896 was as under:—

Estate tea	Tea manufactured		Total.
	Bought leaf	tea for others.	
lb.	lb.	lb.	lb.
3,763,167	505,586	1,214,843	5,483,596

The gross price realized for the Company's teas sold in London was 8-14d as against 8-09d per lb. in 1895. The average rate of exchange during the year was unfavourable, compared with that for 1895, being 1s 2-3-6 7-4d as against 1s 1-1-3 5-2d. Appended to this Report will be found a statement of annual crops, acreages in bearing, yields per acre, profits earned, and amounts set aside for Reserve Fund and Depreciation for the last ten years, also a statement of the properties held by the Company at 31st December 1896.

From the Coconut Estates 875,570 nuts were harvested, and the outturn from the Mill at Sirangapathe was 3,016 cwts. of Copra and 3,540 cwts. of Fibre. Another Mill is being erected on the Mawatte Estate, and as the various Coconut Estates come into bearing, satisfactory profits from this portion of the Reserve investment may be looked for.

Mr. H. V. Masfield has been appointed Ceylon Manager in place of Mr. G. A. Talbot, who has retired from that position and joined the Board of the Company. The Directors again cordially desire to express their satisfaction with the work performed by the staff in Ceylon and London during the year. Under the Articles of Association, Mr. David Reid vacates his seat on the Board and Mr. G. A. Talbot,

who has been elected since the last general meeting, also retires, but both being eligible, offer themselves for re-election.

ACREAGES OF TEA ESTATES AT 31ST DECEMBER 1896.

THE RANGALLA TEA COMPANY OF CEYLON.

Report of the Directors for the year ending 31st December, 1896, to be submitted at the annual general meeting of shareholders, to be held at the Offices of the Company on Wednesday, 21st April, 1897.

The Directors have the pleasure to submit the balance sheet and profit and loss account to 31st December, 1896, duly audited.

The nett profit, including the balance of £952 5s 10d brought forward from last account, amount to	£2,724	14	7
The final dividend for the year 1895 was paid on 9th April, 1896 amounted to	£880		
An interim dividend for the year 1896 was paid on 24th Sept. amounting to	660		
	1,540	0	0
Leaving a sum of	£1,184	14	7
Which it is proposed to apply as follows:—			
In payment of a final dividend of 5 per cent for 1896—free of income tax—			
(making 8 per cent for the year	£1,100	0	0
Balance to be carried forward to 1897 account	84	14	7
	£1,184	14	7

The Company's produce has been disposed of as follows:—

6,710 lb. tea sold in Bombay and Colombo.			
221,620	London.
228,360 lb. tea sold, realizing			£6,219 3 9
5,262 lb. cardamoms			
gross = 4,842 lb. net, sold in Ceylon, realizing			594 2 1
Total			£6,813 5 10

The sales of tea show a nett average price per lb. of 6.54 pence, being equal to say 45 rupee cents per lb. Exchange for the Company's drafts during the year has averaged 1/2 17-32, as against an average Exchange for 1895 of 1 1/2 5-16, the difference thus materially and adversely affecting the profit.

The acreage of the Estate is as follows:—

Tea in full bearing	..	591 1/2	acres.
.. .. partial bearing	..	63	"
.. .. not in bearing	..	61 1/2	"
Cardamoms	..	56	"
Grass and Fuel Timber	..	25	"
Forest and Waste Land	..	444	"
Total			1,241 acres.

The yield of tea per acre has been 380 lb. as against 340 lb. for 1895.

During the year, an additional expenditure of £166 17s 1d has been incurred on capital account for tea clearings, whilst the sum of £81 5s 1d has been realised by the sale of tea plants. The capital expenditure has again been reduced by writing off £300 for depreciation of machinery, and this policy should be continued.

Manuring has been a great success, both in regard to yield and in the improved appearance of the tea bushes, and it is intended to treat 216 acres during the present season.

The prospects for the current year are quite satisfactory, the estimated yield being 250,000 lb. of made tea, and 1,500 lb. dry cardamoms, the estate Manager's latest advices reporting 5,000 lb. tea and 800 lb. cardamoms in excess of last year. All hands were busy plucking, and the labour was proving sufficient.

THE POONAGALLA VALLEY CEYLON COMPANY, LD.

Report of the board of Directors to be presented to the Shareholders at their First Annual Ordinary Meeting, to be held at the Office of the Company, 16, Philpot Lane, London, E.C., on Wednesday, the 28th April 1897, at 2-30 p.m.

The Directors have pleasure in submitting to the Shareholders the Report and Accounts of the Company for the year ending 31st December 1896.

The net profits for the year amount to £1,831 8s 2d, and this it is proposed to appropriate as follows:—

Amount as above	£1,831	8	2
An Interim Dividend of 3 per cent (free of Income Tax) paid in Sept. amounted to	£525	0	0
It is now proposed to pay a Final Dividend of 3 per cent (also free of Income Tax) making 6 per cent for the year absorbing	525	0	0
To write off the whole of the Preliminary Expenses	119	6	1
	1,469	6	1

Leaving a balance to carry forward to next account of

£362 2 1

The Company was incorporated on the 26th October 1895, and the Prospectus issued on the 30th of that month, when the applications for the Share and Debenture Capital were considerably in excess of the amount offered for public subscription.

Since the Company acquired the properties from Sir George Pilkington, a small addition of about 20 acres has been purchased from Government, the land in question adjoining Udahena Estate, and the tota

acreage, as shown in the December Estate Reports, now stands as follows:—

	Tea in bearing.	Not in bearing.	New clearings.	Tea & Coffe.	Coffe.
Lunugalla	228	..	47	69	48
Udahena	140	63	59	30	10
Cabragalla	120	23	..	30	25
Poonagalla	117	110	13	..	25
	605	196	119	129	108
	Ravines and Waste.	Jungle and Patna.	Fuel Trees	Nurseries.	Total
Lunugalla	17	363	40	8	820
Udahena	10	322	19	..	653
Cabragalla	17	..	10	..	225
Poonagalla	..	613	7	3	888
	44	1298	76	11	2586

The total crops secured amounted to 204,763 lb. of tea and 1,651½ bushels parchment coffee (or 337 cwt. 2 qrs. 8 lb as shipped) against Estimates of 200,000 lb. and 1,230 bushels respectively. As coffee will, without doubt, before very long cease to be a source of revenue to the Company, the Directors have thought it expedient to instruct their Managers to plant tea under all the coffee on the Company's Estates, so that when the latter product dies out, as seems inevitable, the former may be well on its way to supply its place. Where desirable, the Managers have been instructed to apply stimulating manure to such of the coffee as appears to warrant a moderate expenditure, with a view to obtaining in the meantime the most that can be secured from the trees. The Directors have recently had satisfactory Reports on the Estates from Mr. A. T. Retlie. The properties appear to be in good heart, and the Board have authorised the erection of wire shoots where necessary, recognising that any labour-saving appliances are very desirable, and tend to economy in working the Estates. The first of these shoots has been successfully erected between Udahena and Lunugalla Estates, and is working in a very satisfactory manner.

HIGHLAND TEA COMPANY OF CEYLON.

REPORT OF THE BOARD OF DIRECTORS

To be presented to the Shareholders at their First Annual Ordinary Meeting to be held at the Office of the Company, 16, Philpot Lane, London, E.C., on Wednesday, 28th April, 1897, at 3-30 p.m. The Directors have pleasure in submitting to the Shareholders the Report and Accounts of the Company for the year ending 31st December, 1896. The Company was incorporated on the 6th April, 1896, and the Prospectus issued on the 11th of that month, when the Shares offered for public subscription were largely over applied for. As mentioned in the Prospectus, the Estates were taken over by the Company as from 1st January, 1896, and the Accounts now presented therefore cover a period of twelve months.

The net profits for the year amount to £2,905 4s. 3d., which it is proposed to appropriate as follows:—

Amount as above	£2,905 4 3
An interim dividend of 4 per cent. (free of income tax) paid in September absorbed	£1,280 0 0
It is now proposed to pay a final dividend of 3 per cent. (also free of income tax), making 7 per cent. for the year, amounting to	960 0 0
To write off half the preliminary expenses	261 1 10
	<u>2,501 1 10</u>
Leaving a balance carried forward to next account	£404 2 5

The total Crop secured during the year amounted to 195,020 lb., being about 357 lb. per acre over the Tea-producing area of the two Estates, an average which the Directors hope to see considerably increased in the near future. No acquisitions have been made since the Company took over the Properties, and the total acreage therefore remains as stated in the Prospectus. The Directors have arranged with Mr. R. C. Grant, of Yuillefield, to visit and report on the Company's Estates once a quarter. His last visits to the Properties were early in February when he was able to report that all Estate Works were being carried on in a satisfactory and efficient manner. A new Bungalow will be erected on Chrystler's Farm Estate during the current year, this being a very necessary addition to the Estate Buildings, which was foreshadowed in the Prospectus. In accordance with the Articles of Association the Shareholders will be invited to fix a sum for the Directors' remuneration.

[For report of the Eastern Produce and Estates Co.—see Notes from the Metropolis, 2nd page.—Ed. T.A.]

THE KELANI VALLEY TEA ASSOCIATION, LIMITED.

The eleventh annual ordinary meeting of the Kelani Valley Tea Association, Limited was held at the office of the Company, 16, Philpot Lane, E.C., on Tuesday, April 13, 1897 at twelve noon, Mr. G. W. Paine in the chair.

Before proceeding with the business in hand Mr. Paine said that at the desire of the board he took the first opportunity of expressing their great regret at the recent death of Mr. John Anderson, their late secretary and colleague, and practically the founder of the Company, and after some sympathetic remarks, concluded by proposing that a vote of sympathy be accorded to the family of their late friend, which was seconded and carried unanimously, the secretaries being desired to convey the resolution to the family.

Notice convening the meeting having been read, and the report and accounts having been taken as read, the chairman then alluded to the report as not being so favourable as previous reports had been, and dealt with the reasons given in the present report for the shrinkage of profits as compared with those earned in 1895. He mentioned that in addition to the loss of profit occasioned by a higher rate of exchange and a lower market for their teas, there had been a further leakage caused by an error of judgment on the part of their manager, Mr. Mitchell, in entrusting the manufacture of Degalessa Tea to an assistant with not sufficient experience, an unfortunate accident which the directors took immediate steps to correct as soon as the error was discovered.

The CHAIRMAN then stated that the loss of revenue had practically occurred during the last half of the year, for when the accounts were made up in September for the purpose of declaring an interim dividend, the profits then apparent showed a return on the capital of about 20 per cent. per annum, without, however, deducting the usual percentage for depreciation. The increased expenditure over that incurred in 1895 was due, he said to the cost of manufacturing the extra crop of 40,960 lb. of tea, to manuring 200 acres, and, as before mentioned, to the higher rate of exchange, in order to lessen the amount of Mr. Mitchell's work and responsibilities the directors had given independent charge of Weregalla and Parusella to their sub-manager, Mr. Wyness, and they had every hope that the new arrangement would be for the benefit of the company, and with a view of saving the cost—already a severe item—of firewood, the directors had secured 50 acres of land near the river, where a new factory for Weregalla and Parusella was to be erected, which would be worked to a great extent by water power, and thus reduce expenditure on fuel.

The chairman then intimated that either he or Mr. Porter, the managing director, would be pre-

pared to answer any questions the shareholders might put to them, when Mr. Menzell said that after the explanations given by the chairman he had little to ask, but he thought Mr. Mitchell deserved great blame for the falling off in quality of the tea, and after Mr. Dodds had referred to the same subject the following resolution was then proposed by the chairman, seconded by Mr. Davies, and carried unanimously: "That the report and accounts, as presented to the shareholders, be received and adopted."

Mr. G. W. Paine proposed, seconded by Mr. Andrew, "That a final dividend of 5 per cent (free of income tax), making 10 per cent for the year, be declared, payable forthwith." Carried unanimously.

On the motion of Mr. Paine, seconded by the Hon. D. A. C. Scott, Mr. D. Andrew was re-elected a director of the company.

Mr. Dodds proposed, Mr. Menzell seconded, and it was carried unanimously, that Mr. James B. Laurie be re-elected auditor for the ensuing year.

A vote of thanks was also passed to the chairman and directors, and Mr. Paine having replied to the compliment, the proceedings then terminated.

VARIOUS PLANTING NOTES.

COFFEE.—The coffee market has been demoralised by the heavy output from Brazil. The downward movement in prices has been very severe, the kinds of coffee undergoing the greatest depreciation being those below 90s. per cwt., the lower the grade the severer being the fall, which in extreme cases has amounted to nearly 16s from the highest point in January; good Santos, which was then worth 51s to 55s for "future" delivery, having recently been sacrificed at 37s 6d to 40s per cwt.—*H. & C. Mail* April 23.

"TIMEHRI."—The Journal of the Royal Agricultural and Commercial Society of British Guiana has just reached us for December, 1896—with Contents; Papers.—Other Times, other Manners, by the Editor; Migratory Birds in British Guiana, by J. J. Quelch, B.Sc. (Lond.), C.M.Z.S.; A Literary Half-hour, by W. Alleyne Ireland; Tobacco Cultivation and Manufacture, by H. B. Van Rée; Some Notes upon Fly Fishing in British Guiana, by "Oxon."; Up the Cuyuni in 1837, by William Hillhouse; On the Potaro, by C. A. Lloyd; Early English Colonies in Trinidad, by Hon. N. Darnell Davis; Reports of Society's Meetings, from July to December, 1896.

PLANTING IN THE STRAITS.—In the Annual Report of the Perak Museum we read:—An interesting series of samples from the Frans Krian sugar estate, was presented by Mr. F. Pulsford. Specimens of cleaned Perak grown ramie fibre, and many other vegetable products were added to the collection. Amongst these mention may be made of some particularly well cured liberian coffee from an estate near Gopeng, contributed by Mr. F. D. Osborne. This coffee has been fetching a better price in Singapore than any other produced in the Straits. The high value placed on it is due to its colour and not to any superiority of the bean. The Liberian coffee grown on the hill at Waterloo estate apparently has a finer bean than any from the plains. Some trees planted by Mr. Cecil Wray, in 1880-1, are well grown, vigorous bushes in full bearing, while trees of four years old planted by Sir Graeme Elphinstone, on land cleared twelve years previously, compare most favourably with bushes of the same age on the low lands planted on newly cleared forest land. The collection of Perak woods now numbers 207 examples. It is of more than ordinary interests as it shews that there are so many fine and handsome woods in the jungles besides the four or five kinds known to Europeans.

DIMBULA, April 23.—The Labour question all-important now and for some time in all its various heads and ramifications. It includes all others—plucking, pruning, manuring and everything. It is the "be all and end all" of planting prosperity now and always. And the question of most importance that can occupy your mind and the pith of the T.A. is the settlement (a settlement) of an efficient supply of coolies. On a small acreage like mine here the question does not show itself so much, but I have seen flash not very far off on a London Company's estate that might have been shorn with a grass hook, and men get desperate when these things happen!

LIFE IN PALERMO, SICILY.—Some of our readers may remember Mr. J. R. W. Pigott, when a planter on A'uwhare, Matale. He afterwards entered into the service of the Foreign Office as an Agent in British East Africa at Mombasa, and from there he has been promoted to the British Consulate, Palermo, Sicily. From a letter of Mr. Pigott, dated 30th April, we quote some interesting paragraphs as follows:—

"Tea is practically unobtainable here. In one shop Horniman's pure tea is sold, but it is not good and is very expensive.

"I came here last October, having left East Africa in May last just after our rebellion was put an end to. In October 1895 I had a bad attack of congestion of the lungs and applied for six months' furlough in the spring. Lord Salisbury then telegraphed to me that owing to my long service in East Africa he had decided to appoint me to a European post and offered me the Consulate for Sicily to reside at Palermo, which, of course, I accepted as in duty bound. Palermo is, as you know, a lovely place; but the inhabitants are, as a rule, great ruffians and do not compare favourably with my East African friends. There are very few English residents here, and of those all who are able to do so go away for four or five months every year in the summer."

TEA CROP PROSPECTS OF INDIA.—The *Indian Planter's Gazette* of May 1st has the following deliverance:—

As yet it is too early to do anything but make a guess at what the season is likely to be, but rumours are floating about that there is to be a huge increase in the crop of this year, although, upon what grounds this calculation is made, it would be difficult to say. The latter end of 1896 was abnormally dry, and up to date the rainfall has been very scant in the tea districts generally, and the result must inevitably be short output. Up to date we have no hesitation in saying that the amount of tea made is not anything like up to last year's; and even if rain does now come it will take the bushes a full month to recover the broiling they have had. Anyone visiting the tea districts must be struck by the want of leaf on the bushes, and unless the plant is in vigorous health, the only outlook is poor quantity and poor quality. It looks as if the season in the three districts were now a days be coming more assimilated to that of Calcutta and Lower Bengal, for it is only within the last few years that there has been what we might call a distinct lull between the "Chota" and "Burra Bursats," and there is no doubt that this is telling upon many of the older gardens, and when to this has to be added a period of drought of unusual length, the idea naturally is a short crop, *i.e.*, from old tea, for in writing thus we do not take into account the young tea that is coming into bearing, and of which, no doubt, there will be several million pounds. Last season's rainfall was short in all the districts, and what was perhaps more felt, was its uneven distribution. The outlook for all kinds of crops is very depressing, unless there is a good monsoon, and the scarcity of water is being already felt in some parts, more than the shortness of food supplies.

BROKEN TEA AS A DRUG IN THE MARKET.—In our circular of 25th May last year we drew the attention of producers to the contracting value of small leaf broken pekoes, and, as the course of the market since then has fully confirmed our remarks, we would again point out the importance of reducing the percentages of small leaf pekoe fannings, often invoiced as broken pekoe, small fannings, and broken teas of all descriptions. A clean leafy broken pekoe with some make, and as free as is possible from an admixture of fannings, is to be aimed at, and a good deal can be done towards reducing the proportion of the latter grade by more attention to withering and care in assorting. These remarks apply more especially to those gardens and districts where large crops of ordinary consuming quality are produced. The reason for the receding value of small broken, a situation which in all probability will become more marked as we proceed, is easily explained, when it is understood that the large and yearly increasing exports to foreign markets from Calcutta, Ceylon, and London, consist practically of leafy tea only, *i.e.*, pekoe and souchongs, thus leaving a comparative over-supply of small broken leaf kinds for home consumption.—*Messrs. Carrett's Calcutta Tea Report*, May 5.

FIJI AND ITS FUTURE.—A correspondent long resident in Fiji writes about its prospects as follows:—

Sir J. B. Thurston's death was a sad one. He was a hard-working Governor. For the Colony's sake I think it is a good thing that a man of entirely new blood like Sir G. O'Brien has been appointed as Governor to Fiji. The Colony will never go ahead till the Government alters all their land and labour regulations. All the land belongs to the natives and they are not allowed to sell nor even to lease without Government sanction and then only for short periods of about 10 to 15 years; I think the latter is the term fixed by Ordinance. There are tens of thousands of acres of jungle which are not likely to be used by natives. Some of this ought to be surveyed and given out *free* to would-be *bona fide* planters if they agreed to cultivate. Unless something of this sort is done they will not get people to go there and invest. The natives ought to be encouraged to go to works, especially the rising generation. As I have often stated it is absurd that Fiji with its native population of say 100,000, a large proportion of whom ought to work, should have to import labourers from Bengal, Solomons, Hebrides, and Line Islands. There are difficulties of course, but if the question were properly managed the natives should do most of the work required by the few planters at present in the group. The missionary influence is very strong and all those in authority hitherto have fought shy of interfering with it in any way.

But surely the missionary influence is not against the people working; only we suppose the Fijians—like the Sinhalese—as a rule prefer to be their own masters, doing as much or as little as may suit themselves.

"THE CULTURED PLANTER" is the title of a "skit" contributed to the *Indian Planters' Gazette* in which a tea planter of the old school is approached by the impersonation of the modern class of young Assistants and an amusing interview winds up as follows:—The younger man speaking;—

"We who speak unto you, the nature of whose being we have already defined unto you, require many reforms and ameliorations in our lives as tea-planters, and we consider that tea estates being in such a healthy condition as present statistics prove them to be, that now is the time to bring our wants and desires before those whose business it is to superintend our welfare. We desire more substantial remuneration for the risking of our precious lives in this deadly climate; we desire compensation for cutting ourselves adrift from the

society of our fellowmen, sometimes to live upon gardens a score or so of miles away from another European; we desire that considering our expensive education, and the superior intellectual attainments, which we bring to bear upon the science of tea that first-class libraries should be provided at the cost of the company, in every Superintendent's bungalow; that these should include the classics, poets, histories, literatures, biographies, rare volumes of prints, not forgetting a current supply of light novels and books of the day, so that the taste of any moment can be gratified. Regarding the last named we suggest that a monthly box direct from Mudie's, would admirably serve the purpose. "We desire bungalows of uniform perfection, with all the latest improvements of architecture, and artistically decorated, so that our taste in art may not perforce deteriorate by the distressing vision of white-washed walls. We desire a billiard room for every bungalow, and a table of the best procurable; the room of course to be fitted up with all the necessary luxuries, regardless of cost; so shall we maintain our skill at the art of handling a cue, and be fit to compete with our fellowmen when we return to the outer world of civilisation. So also shall our hands and thoughts find occupation during the long, dark, lonely evenings of the cold weather. "We require pianos for all—Erard's or Broadwood's for choice—and band instruments with of course a good European bandsman, would be a pleasant addition to every large estate. The bandsman could be selected from the coolies, and at our dinners the strains of a well-trained band would be a soothing accompaniment to the rythmical measure of the punkah. "We need very urgently punkah-pulling machines guaranteed not to get out of order, a tower clock to be erected near each factory with the same necessary qualifications as the punkah-machines, and punkahs for the tea-house so constructed that they have no effect upon anything except human beings. "We desire bicycles to be provided for everyone, as well as a good supply of horses, a dog cart and barouche and pair, for each man, so that during the hot weather he need not have the exertion of driving himself, also a motor car. We need first-class servants, especially cooks and butlers, supplied free of charge, and an extra supply kept upon each garden in case of emergencies arising; a large ice-machine for each estate is a *sine qua non*, and a matter deeply affecting the health of the Europeans. What would Mr. Labouchere say did he but know that inhuman Directors of tea companies have actually hitherto failed to provide their European *employes* with this necessity of life in the plains of India? The omission is preposterous, and we earnestly charge you to publish the facts in the public newspapers so that the oversight may be immediately remedied, by act of Parliament, if need be."

"One moment," I broke in "forgive my interrupting you, but don't you think all these requirements of modern planters is rather a large order? If you were to go at it more gently now, suggesting, let us say, a billiard table to be provided for each estate, and after getting that to ask for something further, there might perhaps be some chance of getting one or two of the more sensible suggestions taken into consideration; but to go at it hammer and tongs as you

"Ancient Relict of Antiquity," thundered my visitor; "we selected you as our mortal mouthpiece, not as a critic of what modern cultured planters should or should not consider necessary to their welfare! Do not presume to interpolate your pragmatistical observations! Be it borne in upon your limited knowledge, that billiard tables and the necessary accessories *have* already been supplied to several estates in Assam at the cost of the company. This is a step in the right direction, and our modest request is that the custom should become universal. "In addition to the needs we have already enumerated we require a steam-laundry, so that our shirt-fronts may be properly starched and ironed; we also desire—" but I could stand no more, and fled from the room, leaving him to vanish to whence he came.

"TIMEHRI."—The only matter to notice in the latest number of this British Guiana Magazine, is a Report on Economic Products exhibited at the Horticultural Show of 1896. But there is really nothing new to us in the report itself—only it is interesting to see the list of products actually shown, which we quote as follows:— (making a few exceptions as to details):—

Class E. Economic Products. Section I.—Open to Amateur Exhibitors. Coffee (cleaned).—The sample to which we awarded first prize was an excellent sample of creole coffee of almost perfect colour and very well cleaned, its only defect being in some irregularity of the sizes of the beans. That to which the second prize was awarded was distinctly inferior to the former, but still was a sample of high class coffee of not such perfect colour, and not quite so well cleaned. The other samples exhibited were of inferior colour, and in many cases the beans were very imperfectly cleaned. We would impress upon cultivators that if ever this Colony is to again attain eminence in coffee production, it is essential for every care to be exercised so as to obtain coffee of good colour, perfectly cleaned and even in size of bean, especially avoiding the presence of broken beans.

Coffee, Liberian (cleaned).—We cannot accord to this the same praise as to the exhibit of creole coffee. The sample to which the first prize was given was distinctly the best shown, but all were inferior to samples we have previously examined of this product.

Cocoa Beans, (cured).—This class of exhibits was distinctly inferior to the similar exhibits in the Show of 1895. In that Show the first prize was given to an exhibit of fairly cleaned regular sized beans, having a fair break, but somewhat dark in colour. The second prize-sample closely approached the first in quality and we had some little difficulty in making an award between them. We are inclined to ascribe the falling off in general quality of this class of exhibits to weather conditions, unfavourable for the production of fine full sized beans.

Kola.—Three exhibitors only competed. Two which received prizes, sent samples of good colour, well dried, and of fair size. The third, although undoubtedly the finest sample as regards size of the nut, undoubtedly had been spoilt in colour during curing.

Rice, Cornmeal, Plantain Meal, Cassava Meal, Farine, Arrowroot, Tapioca, Tous-les Mois.—Never a taking looking starch, the samples exhibited did not add to its reputation; Other Starches. Vanilla.—Two samples exhibited, unfortunately the finer of the two was spoilt by the oil with which it had been dressed having turned rancid; Honey, Tobacco.—This class of exhibits showed us that, as last year the curing of tobacco is not understood in this Colony. A faint odour of ammonia, the origin of which is open to conjecture, is not an improvement to leaf tobacco; a mouldy condition again is not usually considered to be typical of merit in tobacco, and these two appeared to be the points at which the majority of the exhibitors aimed. The first prize only was awarded and to a sample in which these points were not present. Cayenne Pepper, Guinea Pepper, Black Pepper, Essence of Pepper, Pimento, Dried Ginger, Pickles, Hot Sauce, Chutnee, Curry Powder, Guava Jelly, Other Jellies, Prepared Chocolate, Crushed Food.

Section II. Open to Artizans and Labourers only.—Preserves, Jellies, Pickles or Hot Sauce, Coffee (cleaned), Liberian Coffee, Cocoa, Rice, Corn, Starch, Leaf Tobacco, Raw Cotton (cleaned).

A letter was received from Mr. Norman Forster, Manchester, stating it was his intention to cultivate jute in British Guiana, if he gets a land concession.

RHEA FIBRE: ITS CULTIVATION AND MANUFACTURE.—A paper was read before the Indian Section of the Society of Arts at the Imperial Institute, London, by Mr. Thomas Barraclough, on the 12th inst.
