lecturer, said that any new raw material to be a subject of interest to those engaged in industry and manufacture. It might also be of importance to the country as a whole. Therefore he held that no suggestion of a new material should be scouted or scorned, although he knew that there were a number of persons in the world who thought that nothing was of importance. It appeared to him that there were three conditions which any new material must comply with if it was to be of use. 1. There must be a fairly plentiful supply of it, actually or prospectively. It was no use to have a material with which only a small quantity could be produced annually. 2. It must be capable of manipulation, so as to get it into the form of yarn or thread that it might be put on to the weaver to be woven into a fabric. Of course it was possible that special machinery might be required, and that the opportunity would be given to inventors to overcome there must be no absolute bar to the manipulation of the material. 3. The cost must not be excessive as compared with existing materials, except in cases where the material discussed might be possessed of some special beauty or characteristic of its own. Mr. Barraclough, at the outset of his paper, said he thought he would be able to show that rhea fibre complied with the three conditions laid down by the lecturer. He maintained that it was the strongest fibre known, and the longest of all textile fibres with a brilliancy or lustre superior to all others. In certain classes of goods only an expert could distinguish between silk and ramie (a generally used name for rhea). After discussing the best methods of cultivation, Mr. Barraclough inquired into the causes of the failure of rhea fibre. This he attributed largely to ignorance of its nature and requirements by planters. Climate and soil also had been unsuitable, and the treatment mistaken. The so-called decorticating machines had further contributed to failure because in removing the skin they had removed the internal pith or wood, products which were called in the trade "ribbons." Similarly a large proportion of the decorticating processes injuriously affected the strength and lustre of the fibre, making it harsh and difficult to dye. Mr. Barraclough said that ramie could never supersede silk, although the conjoint use of the two materials increased daily. Ramie might, however, be expected to supplant flax in certain descriptions of goods while in mixed woollen goods it would play a less important part. Everything pointed to a gradual but certain development. A discussion, in which Mr. S. G. Lane-Fox, Mr. Macdonald, and others took part, the lecturer said that the difference of opinion which had been expressed as to the best manner of preparing ramie for textile use would perhaps be fruit. As to its cost, it must not be excessive. It must come into something like the price of cotton. He thought it important that the manufacture of ramie should take place on the spot where it was grown. This he said, speaking from general principles, was to avoid freight charges, and that there was much to be done in the development of this fibre. Manufacturers must not give it up in spite of the disappointment of the last twenty years, but must pursue the question until they can be trusted to reach a satisfactory result.

IMPERIAL CEYLON TEA ESTATES,
LIMITED.

REPORT OF THE DIRECTORS to be submitted at the Annual Ordinary General Meeting of Shareholders, to be held at the Company's Offices, 9th, Fenchurch Avenue, London, E.C., on Thursday, 22nd April, at 3 o'clock. The Directors have pleasure in submitting the General Balance Sheet and Profit and Loss Account to the end of 1896, duly audited.

The nett amount at credit of Profit and Loss Account is .. £3993 4 10

It is proposed to pay a Dividend of 5 per cent (free of Income Tax) on the three issues of Shares from the respective dates that they rank for dividend, viz :—

- Shares :—Nos. 1—5,215, from 1st Jan. to 31st December, 1896.
- Shares :—Nos. 5,216—7,200, from 1st March to 31st December, 1896
- Shares :—Nos. 7,201—9,000, from 1st June to 31st December, 1896.

This will absorb .. £3,959 11 8 and the balance will be carried forward.

The result of the Company's operations has not been as satisfactory as was originally anticipated. This is partly due to the disappointing working of the Mottingham and Binoya Estates from the 1st July, 1895, until they passed into the actual possession of the Company, and partly to the high level of exchange during the year, as compared with the moderate prices ruling in the Tea market, in addition to which, the change in Proprietorship and Superintendence of the several Estates, acquired since the Company's formation has somewhat disarranged the working, and affected the profits.

The Company's properties, however, are now all in thorough working order, and the Colombo Agents report favourably of the prospects of the present season. The Directors are satisfied that the Shareholders may look with confidence to much better results in the future than is shown by the first year's working.

The following is the total acreage of tea, &c., forest and waste land, and the crops secured to end of 1896 :—

	Tea Acreage.	Coffee Acreage.	Forest Waste.
Binoya	441	—	458
Mottingham ..	221	—	37
Edinburgh ..	382	—	50
St. Vigeans ..	185	—	—
Friedland ..	163	—	2
Nonpareil ..	200	200	149
	<u>1,592</u>	<u>200</u>	<u>696</u>

	Tea Crop in lbs.	Coffee, in bushels.	Cinchona in lb.
Binoya	211,990	—	—
Mottingham ..	105,328	—	—
Edinburgh ..	132,378	34	—
St. Vigeans ..	51,215	—	—
Friedland ..	41,522	—	—
Nonpareil ..	—	863 13-16	39,260
	<u>542,443</u>	<u>897 13-16</u>	<u>39,260</u>

The tea crop figures represent the quantity despatched by each estate, from the date on which it was taken over by the Company.

The Directors have pleasure in submitting the general balance sheet and profit and loss account for the year ending 31st December 1896, duly audited.

	£	s.	d.	£	s.	d.
The net amount at credit of profit and loss account, including the balance brought forward, is ..				5,120	10	8
An interim dividend of 5 per cent was paid on 17th Sept. amounting to ..	2,500	0	0			
It is now proposed to pay a final dividend of 5 per cent (making in all 10 per cent per annum, free of Income Tax), which will absorb ..	2,500	0	0			
and to carry forward to next year a balance of ..				120	10	8
				<u>5,120</u>	<u>10</u>	<u>8</u>

As will be seen from the accounts, the directors have acquired—for the very moderate sum of £541 16s—the Kehelgama estate, adjoining Aberdeen. The property is 322 acres in extent and will be valuable for Aberdeen as a Timber Reserve. The capital expenditure has been further increased by outlays on tea clearings, buildings, &c., amounting to £1,615 5s 2d, against which the directors have written off £300 for depreciation of machinery, &c. The directors have also entered into arrangements for the purchase, as from the 1st January last, from the Dunkeld Estate Company, Limited, of the Dunkeld Estate, in the district of Dikoya and adjoining the Company's Elstree property. This should prove an advantageous arrangement, as Dunkeld is a valuable tea garden and is very centrally situated for working in with the Company's other estates.

The average exchange for the year has been 1s 2 31-64d as compared with 1s 1 29-64d last season, and this has materially increased the sterling amount of the estate expenditure.

The following is the total acreage of tea now in bearing, forest and waste land, and the crops secured in 1896.

	Tea in Bearing.	Forest, Waste, Grass.	lb. of Tea.
Aberdeen ..	387	93	137,545
Calsay ..	351	36	109,260
Luccombe ..	717	200	245,030
Glencages ..	222	—	90,442
Uda Radella ..	450	105	167,368
Thornfield ..	255	35	133,147
Kehelgama ..	—	322	—
Total ..	<u>2,382</u>	<u>791</u>	<u>882,792</u>

As compared with last year these figures show that the tea in bearing has been increased by 143 acres, and the production of tea by 58,294 lb. The reports from the Agents and Managers in Ceylon, continue to be of a satisfactory character, and the directors look forward with confidence to a favorable result from the present year's working.

MANGOES IN ENGLAND.

"Imperialist" in the *Colonies and India* writes :—The consignment of tropical fruit from Queensland to the Agency here arrived in excellent condition so far as the mangos went, but the pineapples, unfortunately, were spoiled. There were about sixteen cases in all, and one case of mangos in fine condition was sent to the Queen. Cases of the other mangos went to Mr Cham-

state. The fruit was put in a cool chamber, and it seems to have been overlooked that in the cool chamber any article remains in *statu quo*, and thus the fruit arrived exactly as it left, unripe, and naturally after the voyage this unripeness could not be remedied. However, the fact that the mangos came in a satisfactory state is gratifying, and shows that, if the fruit is gathered in really good condition, it can evidently be imported here in a state fit for market.

COCONUT CULTIVATION IN SAMOA.

The single exportable staple for which Samoa is eminently adapted, and the one upon which all its business at present rests, is the coconut (*Cocos nucifera*). It is to Samoa what cotton and corn are to the United States; all that grain, meat, and wool are to the Australian Colonies. The export of the copra alone, save with trifling and inappreciable exception, represents the entire agricultural productive capacity of Samoa, and through this source all the money that trade and commerce bring into the islands finds its way. The United States Consul-General at Apia says that if the coconut crop were an absolute failure for a single year, the entire export of the kingdom would not amount to more than £1,200 and this illustration will adequately represent the prime importance of this single article to the country and its needs. The accepted method is to plant the coconuts in rows forty feet apart, setting the trees thirty feet in the row. The coconut loves the sunshine and free circulation of the air, and to flourish in perfection it should stand on the outer verge of the shore, its roots striking into the sea water, its branches or palms tossing in the breeze. The lowlands of the beach in the Samoan Islands are more or less covered with the groves, while on the mountains or highlands no tree is found. The smaller size of the trees and the poorer yield is plainly to be noticed on lands at an elevation of from 400 to 600 feet situated at as short a distance as 2½ and 3 miles from the shore. Standing immediately on the beach the tree inclines outward over the water; growing inland it points by its leaning in the most direct way to the sea. The nuts ripen throughout the year, hanging in clusters close in and around the stems of the palm branches, which spread about on all sides, and reach upward from the clustered head forming the top of the tree. The height of the trees, is from 30 to 80 feet. The trees come into bearing at the sixth year on suitable soil, and are believed to reach the full limit of production at from 15 to 20 years of age. Many groves known to be 30 and 40 years of age are now bearing in undiminished abundance, and they so continue to do to a great age. Persons who profess to be able to determine the age of trees by the marks left on the bark where the branches have successively fallen, estimate in this way that many still vigorous trees are 70 and 80 years of age. The habit of the coconut to reach out over the water, seems to be a provision of nature for its propagation and distribution. The nuts falling into the sea will float for weeks in the bitterly brackish waters of the tropic seas without injury to the germinating quality. Once thrown upon the warm sands of a beach, or tossed by a wave upon a reef above the surface, it soon puts forth its palm from the smaller end, while from the round and larger end the tender roots strike into the soil or decayed coral, as the case may be. Many lagoons which have risen within living memory, and which for years remained without sign of vegetation are now covered with the coconut, although hundreds of miles from other islands. The value of the coconut is not confined to the single export product, copra. The tree and its products are devoted to many uses. The wood in the green state is very porous and spongy, having consequently a great degree of resistance to rifle shot. In the native wars in the past it was much em-

ployed in the building of defensive works. When thoroughly seasoned it lasts for a long time underground, and is valuable for all purposes for which posts are employed. The oil enters in many forms into the domestic uses of the natives. It forms the basis of all their liniments and emollients in their pharmacopœia. The nut is one of the standard articles of diet. Breadfruit, taro, bananas, and coconuts form the staple articles of food, ranking in importance in the order mentioned. The fibre furnishes all the sennet, or braided twine and rope, for all uses. The leaves of the great branches, which dry rapidly, are used for kindling, for torches, and light and firing for the household. It is generally estimated that an acre of land should yield, when the trees have reached the period of full bearing, about half a ton of commercial copra. Copra "making" is at best a slow and laborious process, and is effected as the nuts ripen, from about the middle of April till the middle of October or early part of November—that is during the dry season, but the making is more active in July, August, and September. A boy or man, with a piece of sennet about eighteen inches in length, looped on either foot, will climb the slender, swaying tree with as much ease and rapidity as if it were a ladder. The notches or corrugated surface of the bark catches the bit of sennet between the feet, while the weight of the body pressing downward, clamps as it were the hollow of the feet firmly on either side of the trunk. By this means the tree is ascended by a series of jumps. The climber with a big knife cuts away the matured nuts, which cluster close about the butts of the branches. As they fall they are gathered into piles about the base of the trees. On the plantations they are gathered into baskets slung on donkeys, or swung on poles borne by two men, to be finally piled into great heaps near the copra shed. The nuts are not husked, the thick outer husk having become hard and brown, like wood. They are dextrously split in two by an axe, and the hard white flesh is cut out with a large knife. Nothing remains but to spread it on mats or boards in the sun. When cured it is thrown into a heap in the shed, where it remains until placed in sacks to be carried out to a small boat, which in turn transfers it to the small schooner or cutter lying in deep water, and from this in turn it is again taken to be stored elsewhere, or transferred to the deep sea vessel for its final voyage. Copra yields perhaps a greater per-centage of oil than any other of the great oil-producing staples under the modern process, whereby it is mixed with water, heated, and subjected to two pressings, giving as high as 62 and 64 per cent. of pure oil. The coconut crop of 1894 was by far the largest ever known in the island, and the extent of the increase is illustrated by the fact that while the export of copra in 1891 amounted to 4,842 tons, in 1892 to 4,871 tons, and in 1893 to 4,602 tons, it rose in 1894 to 6,214 tons, an increase of 1,612 tons over the year before—an increase of about 33 per cent over the years 1891 and 1892. In the trading stations in Samoa enormous profits are made in the copra trade.—*Journal of the Society of Arts*, April 9.

AMSTERDAM CINCHONA-MARKET.

Our correspondent writes that the Amsterdam cinchona-market remains extremely firm. All the lots bought in at the last auctions have since been sold at prices fully equalling the unit-rate at the auctions. There appears to have been an error in the figures of the Java shipments in March as first telegraphed. A corrected message gives the March exports at 578,000 half-kilos instead of 350,000. At the next auctions on May 6th at least 5,834 packages of bark (possibly more) will be offered for sale. The feeling in the market is firm, and higher prices are expected.—*Chemist and Druggist*, April 17.

RAISING DUTY ON NATAL TIMBER.

Hitherto black wattle poles from Natal have been admitted into the Transvaal on a 1½ per cent. duty. This (says the *Comet*) has suddenly

been raised to 7½ per cent. without further notification than a demand at the Customhouse for the increased duty. In such matters the authorities might be reasonably expected to give importers adequate notice, instead of springing such a change upon them without any warning.—*Natal Mercury*, April 2.

TEA CROP ESTIMATES AND DISTRICTS.

The difficulty attending the estimating of the tea crop for districts that may be said to run into, or overlap, each other, may be judged from the following extract of a letter sent to us by Mr. Alex. Wardrop of New Forest, Delagoa Bay:—

"Referring to your letter of 24th April, I have collected statistics of acreage under tea in the Nilambe district, which show a total of 1,875 acres of tea in bearing and 640 acres not in bearing. I would point out, however, that probably all the Upper Nilambe estates have already been included in the Pussellawa return, as these places belong to that P.A. as do also some in Ramboda and others near Gampola. The Pussellawa district, as defined in the Directory, cannot claim anything like the 17,000 odd acres in tea with which it is credited in the published returns."

Of course, the Committee of the Planters' Association in calling for crop estimates must have taken care to define the several districts. It would be safest, we think, to follow the Estates Directory as it is in everybody's hand and one estimator could not then fail to know what the other was doing.

TEAS IN UNITED STATES: REPORT PREPARED BY A COMMISSION OF EXPERTS.

The following has been sent to us by our Tea Commissioner in America:—

It will be remembered that under the Act of Congress approved March 2nd, 1897, and entitled "An act to prevent the importation of impure and unwholesome tea," it was provided that a board of seven tea experts should be appointed by the Secretary of the Treasury to establish standards in advance of the tea season for the guidance of the tea examiners at the various ports. The following gentlemen were appointed upon this board:—E. A. Schoyer, of E. A. Schoyer & Co., Chicago; A. B. Upham, of Sprague, Warner & Co., Chicago; H. G. Woodworth, of Robinson & Woodworth, Boston. A. P. Irwin, of Irwin McBride, Catherwood & Co., Philadelphia; Wm. P. Roome, of Wm. P. Roome & Co., New York; Thos. A. Phelan, of Geo. W. Lane & Co., New York; R. B. Bain of San Francisco. The law provided that a Chairman should be elected by the board, to whom all communications should be directed, and upon the first meeting of the board in the Appraiser's Office, in this city, Thos. A. Phelan was elected Chairman. Mr. Phelan in an interview with a representative of this journal yesterday summarized the work of the board as follows:

"The Board devoted itself to the establishing of standards the whole of last week and have established the following standards:—

- No. 1—Formosa Oolong.
- No. 2—Foochow Oolong.
- No. 3—Amoy Oolong.
- No. 4—North China Congou.
- No. 5—South China Congou.
- No. 6—India Tea.
- No. 7—Ceylon Tea.

"In each of these standards the maximum percentage of dust and fannings must be of limited amount to be settled later. This percentage of dust and fannings is liable to be made up of extraneous matter.

No. 8.—Pingsuey green tea.

"As this standard is of better make or style than was necessary to represent the quality of infusion the rule must be specially emphasized to examine with reference to liquor and infused leaf only.

No. 9.—(A) Country green tea.

No. 10.—(B) Country green tea.

No. 11.—Japan tea, pan fired.

No. 12.—Japan tea, sundried.

No. 13.—Japan tea, basket fired.

"Dust and fannings, in the last three mentioned standards, are not to exceed a limited amount, to be settled later.

No. 14.—Japan tea, dust or fannings.

No. 15.—Scented orange Pekoe.

No. 16.—Capers.

"It is understood that the comparison of the standards with teas delivered must be made upon the drawing of the tea as well as the appearance of the leaf after infusion, and that little or no consideration will be given to the make or style or color of the teas in the dry leaf.

"The standards selected for Oolong, including Formosa, Foochow and Amoy teas, are about two grades above the very lowest quality that has heretofore been admitted, so that hereafter anything under what would be called good common to fair Oolong will be excluded. The same applies to Congou teas as well as to India and Ceylon.

"Great care was given to the selection of standards for Pingsuey green tea, as this is a kind of tea which has heretofore been mixed with spurious leaf and has had an excessive amount of coloring matter, making it unfit for use. The standard selected is absolutely pure, having entire freedom from any scum, and it also has a clean green leaf after infusion, so that such a tea in the future will be free from all objection and have some merit. The same applies to the two standards selected for country green teas, which practically exclude all the kinds known as low grade of Shanghai packed, excepting, perhaps, the very best of this description. It will also exclude what is known as 'Smoky Tychow teas,' with scum in the liquor.

"The Japan tea standards represent about two grades above the lowest quality heretofore admitted and might be called in the trade as good common to low medium grade. They are free from any objection in drawing quality or scum, or exhausted leaf. The same applies to the dust or fannings which will probably exclude about 1-4 to 1-3 of the amount of dust and fannings previously admitted, including all with excessive coloring matter and scum.

"The standards selected for scented orange Pekoe and capers are of the very finest quality and have no objectionable characteristics.

"It is to be hoped that the Tea Examiners at the three ports of entry, Chicago, New York and San Francisco, will be men of such character as to be thoroughly reliable in order to make this law effective. Upon these three men will depend whether this bill will be a success in carrying out the object of providing for the American people teas absolutely pure and without objection. If they do their duty the finest crop of tea that has ever come to America will be in the possession of the American people next season, beginning June 1st."

PRUNING, PLUCKING AND PREPARATION OF TEA.

Doors, April 17.—Preparation in the factory is now more carefully supervised, and, owing to improved machinery and good buildings, carried out in a more systematic manner. To make good tea there can be no hard and fast line drawn between field work and factory work. The greater the care taken from the pruning of the bush in the cold weather up to the time it is packed, the better the quality is likely to be. No one has yet discovered, and I don't think ever will, a system whereby leaf which has been grown on sickly bushes due to bad pruning and bad cultiva-

tion, or allowed to become old, before being taken off can be made into tea of good quality in the factory. Carelessness in the factory may spoil good leaf, but, as a rule, I think the factory gets more than its fair share of supervision in the plucking season. When we think of the number of hands employed in the field as compared with the factory, at least 10 to 1, probably 15 to 1, and very often one European in the factory and one in the field only, the deficiency of supervision of the latter becomes more apparent. Again, in the field, in plucking each bush should be plucked according to its growth, and every individual shoot in the same way, so as to secure evenness of quality. Leaf plucked unevenly upsets nearly every stage of manufacture. Young leaf withers more quickly, rolls easier, ferments more quickly than older leaf, hence if we attempt to do what we should for the young leaf, we do not treat the older properly and *vice versa*. Again in the factory we deal with three or four mannds of leaf at a time, and so many of the machines are now automatic that less supervision is required than in the old days of hand rolling and *chula* firing. The weak point in this district lies, I think, in the plucking, not only as regards quality, but also in regard to quantity.—*Indian Planters' Gazette*.

NATAL TEA.

Mr. J. Fraser, the lately-appointed manager of the Barrow-Green Tea Estate, Natal, is to be congratulated on the successes he has scored with his teas. The Barrow-Green teas took first prize in all three classes, viz., golden pekoe, orange pekoe, and pekoe souchong; and also the gold medal for the best exhibit of teas of all kinds. The judge in his report says:—"Upon the general quality of the first prize teas, I think it shows a distinct advance. The teas are well made, the leaf is young, and the liquor strong, and there is an absence of the usual herby flavour so prevalent in teas from Natal. A special prize is awarded, notwithstanding that only one competitor exhibits in this class. A full set of teas also exhibited but no competitor. I think a prize (or at any rate some recognition) should be awarded considerable trouble and expense having been incurred by the exhibitor, who could not foresee that others would not compete." Mr. Fraser's success is all the more gratifying to him, inasmuch as he is a new arrival. He only reached Natal from Ceylon, on February 28th; but on hearing that an exhibition was to be held here a fortnight ahead, he proceeded without the loss of an hour to prepare his samples which are now on exhibition, although when Mr. Fraser arrived the leaf had not been plucked nor even the cases made. Mr. Fraser's energy has happily been well rewarded.—*South African Republic*, March 18.

THE VALUE OF AGRICULTURAL EDUCATION IN INDIA: A HINT FOR THE LOCAL GOVERNMENT.

The Government of Bombay have (says the *Times of India*) taken a most prudent and necessary step for the encouragement of agriculture. It will be remembered that the Famine Commission recommended—in accordance with the declared policy of Government—that the Revenue Department, the officers of which are intimately concerned with the agricultural interests of the country, should contain a leaven of officers possessing some knowledge of agricultural science and practice. Since then a conference has been held presided over by Mr. Chatfield, Director of Public Instruction, and including among its members the Director of Agriculture, Sir E. Buck, the Secretary to the Government of India, in the Revenue and Agricultural Departments, and Mr. Ozanne, the recommendations of which were

adopted by the Government of Lord Sandhurst. The result has been the declaration that Government is ready to place holders of the agricultural diploma, according to the higher standard now to be exacted, on a par with graduates of the University for employment in the Revenue Department. Says the *Times of India*:—"we congratulate the Government on having taken the shortest road to revive interest in agricultural study and to obtain for the Revenue Department a body of men instructed, and therefore likely to be interested, in a science, the practical importance of which to the interests of the people can hardly be exaggerated.

We think it high time that our local Government thought of placing the Colombo Agricultural College on a proper footing, instead of allowing it to languish as it has been doing for lack of proper support and a liberal policy. Below we give recommendations with reference to Agricultural Education in India.

THE AGRICULTURAL EDUCATION POLICY IN INDIA.

Among the recommendations made by the Committees appointed to confer with Sir Edward Buck at the instance of the Government of India are the following:—

That agriculture should not appear as a separate subject in the curriculum of rural primary schools, but that the effort should be to impart an elementary knowledge of it in the group "object lessons and elementary science" which group should be made a *compulsory* subject.

That agriculture should be recognised as a separate optional subject for boys after they have passed the Fourth Standard, and that until properly qualified teachers become available, the study of a text-book of agriculture in Lower Secondary schools will be better than nothing.

That the first necessary step is to provide for the training of the teachers of Lower Secondary and Primary rural schools, and that to this end every training institution, where such teachers are trained should have on its staff a master qualified to teach agriculture and have attached to it a school garden.

That to secure an adequate supply of trained teachers for the rural Primary and Lower Secondary schools, an agricultural class should be developed in selected educational institutions where the general education will be carried on up to the Upper Secondary Examination, and special education in agriculture up to the intermediate standard. Such classes will need a small demonstrational farm for teaching purposes.

That the early establishment of experimental farms as separate organizations, and designed for carrying on agricultural investigations, is desirable.

That a list of the principal agricultural defects of different districts should be drawn up, and that these should be gradually investigated in the order of their importance.

TEST-SOLUTION FOR CINCHONA ALKALOIDS.—A mixture of equal parts of a 10-per-cent solution of sodium thiosulphate and a 5-per-cent solution of copper sulphate. Add this drop by drop to the liquid to be tested. In presence of quinine, quinidine, cinchonine, or cinchonidine, a yellow, amorphous precipitate is formed within a minute.—*Joworowski*.

THE NEED OF THE DAY IN CEYLON:
"A DEPARTMENT OF AGRICULTURE."

Ceylon, although ahead in much, is still behind in a good deal as compared with its neighbours. So much of our prosperity depends on Agriculture, that one would naturally conclude the Government would see to it that every kind of scientific assistance was rendered to those who are engaged in the work, and when difficulties arose, or a blight of any kind threatened the prosperity of any of its branches, that there was a Department of Agriculture to which men might go for expert advice. But as we all know, this is not so. Just at present there is considerable anxiety as to where the cacao pest may land its planters and those dependent on the industry. It may be something else later on; indeed there is much even now that ought to be studied in respect of our tea and coconuts, not to speak of minor, new and untried products. India has its Agricultural Department and special officials—so has Java, where indeed all the cadets for the Covenanted Civil Service have to acquire a special grounding in Agricultural knowledge before they are allowed to take up revenue or administrative work. In Java, moreover, there is a considerable scientific staff ready at all times to turn its clear light on obscure causes of destruction, and to work out the life history of enemies of products as well as to suggest and experiment with remedies. But here we have not even an Entomologist in the Government service to verify a "poochee"—much less an allowance made to a competent Entomologist available on the spot—but have to depend on the gracious services of private observers who have taken to the study for pure love of it.

When one thinks how much money is at stake in connection with the Agriculture of Ceylon; how every race which people this island are more or less employed in it; how even the very stability of the Government depends on its prosperity, it is passing strange that so little is done to guard its interests or guide its destinies. When an Entomologist was asked for by the Planters' Association, the request was refused, and it is only when the steed has been stolen that our authorities bestir themselves and endeavour to lock the door, by promising to import a specialist to ferret out the reason for the large mortality in cacao, but without the proper preliminary inquiry by Messrs. Willis and Green to show in what direction—if any—the services of a scientist from Europe is necessary.

A London merchant, who has interests in cacao in Ceylon, has been writing out, regarding the Government Reports which the Republic of the United States issue from its Departments of Agriculture, for the advice and guidance of fruit-growers there. These Reports are extremely practical, and explain how insect pests or fungoid growths—special enemies of the American fruit-growers—can successfully be combated; and for the lazy or unbelieving, there are photographs of "struck" and barren-looking trees which have been incared for, to compare with other vigorous and crop-laden ones which have been regularly sprayed. It is an object lesson which carries conviction, and the fruit-grower if his garden or plantation be a failure, has himself to thank for the want of success. For he is not left as is the cacao, the tea and coconut planter in Ceylon to puzzle out what ought to be done:—that has been scientifically worked out for him, and he is directed as the case may

be to spray the stricken trees with kerosine, preparations of arsenic, sulphate of copper, with lime and water, &c., &c. The fruit-grower of America knows now that if he neglects the insecticides and fungicides, his time and labour will be wasted, and that spraying at insect or fungoid enemies, must be regarded as a regular and necessary part of a fruit-grower's work. There is nothing new nor wonderful in this: it is as true now as it was when "Adam delved and Eve span" that "in the sweat of thy face" are cacao and fruit, like all other products, to be reaped.

In the Ceylon crusade against the cacao pest, men seem to be all at sixes and sevens. That it is a fungus is the belief of some, while others hold it is a beetle; and as for remedies, the white-wash and tar brushes have been much in evidence, and after that too often comes alas! the saw and the furnace. Cacao culture here is a comparatively small affair as compared with tea or coconuts; but it is an extra string to the bow of the island's prosperity, and is not grown without profit. If the men who are interested in it only knew what to do, there would be a determined effort to do it; but they light their enemy in the dark, waste their strength in wild blows at nothing—and many are so sick of experiments that they are letting things take their course till the expert promised, has arrived, studied and spoken. Had there been a Department of Agriculture to turn to or even an Entomologist to examine carefully, experiment and then advise, this weary waiting might have been avoided, and less treasure lost. Scientific advisers are the need of the day.

As if to emphasize the lesson sought to be enforced on His Excellency the Governor and his Executive in the foregoing, we have now to direct attention to the instructive letter of Mr. A. Van Der Poorten, in which that accomplished cacao planter gives his experience of enemies of his product. He apologises most unnecessarily for his imperfect expression in a language not his own; but would that all our English cacao planters could tell us as much and as clearly as this Belgian gentleman. The indebtedness of the Ceylon Planting Enterprise in times past to gentlemen who owed their birth to the Continent of Europe, for valuable observations benefitting the community as a whole, is well-recognised and historic. The accomplished compiler of the "Enemies of the Coffee Plant"—long a most useful and standard work—was the late Mr. Nietner of Pundalnoya, a Prussian. The letters of Mr. G. A. Cruwell (Cruvelli) in the *Observer* on coffee planting here and in other lands, added much to our information in times past, and other planters could be mentioned to whom Mr. Van Der Poorten is a most worthy successor. He shows very clearly where and when he should have been glad of the aid of a scientist in trying to understand fully, and to combat the particular enemy of his trees; and we can simply repeat that it must be deemed a lasting disgrace to the Government of Sir Arthur Havelock that it should have refused the Planters' Association the aid of an Entomologist at the time a special appeal for one was made. Now, we have a Governor whose fault—if fault it be—is to act perhaps too impulsively and with a desire to have affairs which require a good deal of consideration and careful inquiry, cleared out of hand right off, in the minimum of time. The Hills

Tramway Commission (with a Chairman and leading unofficial member who only had a few weeks to spare in the island after their appointment is a case in point—and so, to some extent, is the offhand promise of a “specialist for cacao diseases” without any proper attempt at defining what he is to do. There is time, however, to have both these slips—failings on the right side, we confess—rectified and good then can only result. We should certainly like Sir West Ridgeway to consider how this great Agricultural Colony can secure a Scientific Staff such as Java, or more than one of the fruit-growing States of America—say California—is favoured with. Would it be considered dreadfully heretical to advise the reduction of our nine Government Agencies into four or five Collectorates, and the devotion of the salaries and allowances so saved, to the establishment of an Agricultural Department and Scientific Staff to deal specially with the enemies to which all our food, fruit or other commercial products, are subject? We have often pressed this view on successive Governors and the longer we live in the island and watch what is being done in India, in Java, in New South Wales and Queensland, and in the United States of America,—the more we feel the necessity for the development of a truly active Agricultural and Planting policy on the part of the Government of Ceylon. How to make two blades of grass grow where only one grew before,—how to increase the fruitfulness of cacao, Liberian coffee, coconuts, &c., by showing how enemies can be fought and got rid of—is, after all, a far more useful service than the devising of better means of collecting revenue, or the watching over land applications, encroachments and sales. Since the abolition of the only semblance of land revenue assessment and collections in Ceylon, what have our nine Government Agents to do of any importance that would not be disposed of by two or three Collectors from Southern India? A thousand worries and trifles affecting Kachehri routine, do not and ought not to count in such a case.

TOBACCO CULTIVATION IN JAFFNA.

(Communicated.)

Tobacco is cultivated in different parts of our Peninsula, mainly in country plots where the soil is most adapted. Though the use of tobacco is strongly condemned by many; yet we find no decrease either in its cultivation or use to any appreciable amount. There can be no doubt that the cultivation of tobacco in Jaffna is steadily advancing as may clearly be known from two facts viz., the fact that extensive tracts of land which were at one time left in a state of chronic uncultivation, unsubjected to the plough or hoe, have now been developed and turned into fruitful tobacco gardens; and the fact that a large quantity of tobacco as well as cigars is sent occasionally from Jaffna to the Metropolis, Galle, Malabar Coasts and other emporiums.

The cultivation of tobacco plants requires as careful study and attention as any others. In tobacco plants there are different kinds, of which the following are well-known to our tobacco planters. *Chonian* (of which there are two species white and black) *Amnicathan*, *Thattim* and *Kulayan*. The young plants are obtained from seeds, which are smaller than the mustard seed. They are at first reared in the nursery for about a month and a half. Then they are planted in parallel straight lines, care being taken to preserve a distance of a couple cubits between two plants. The time of planting usually begins in November and continues till February. Before plant-

ing, the ground should be well manured, ploughed and hoed, the manures used being cowdung, green leaves of plants such as *Karilay Poovarasu* etc. After planting, the next thing to be done is watering. While young the plants should be watered daily; but after they attain a couple of months growth they are watered every other day. The plants then grow up day by day assimilating the manure, the air, and the water and spreading their leaves all round the stem, till they reach the stage of blossoming. At this stage the most essential part that should inevitably be performed in growing tobacco, is topping. It is usually best done by cutting off the heads of the plants beyond a certain limited number of leaves, which vary between 10 and 14. As the result of topping, secondaries will make their appearance at the joints of each leaf, and unless these be carefully pulled off the total amount of money labor and time spent on it would be of no avail. The very object of topping is to make the leaves increase in length breadth and thickness. The task of pulling off the secondaries is as necessary as that of topping. This is done usually thrice until the plants attain their full growth. The rain at this time is unwelcome to the plants, since it washes off the sap and tears away the leaves. A bumper tobacco crop in its state of full development is indeed very pleasant to look at. The signs of full development are some colored marks, or spots on the leaves. The leaves are then cut off with a part of the stem and subjected to the manifold processes of curing. It should be noticed that like tea and coffee, paddy and other plants, the tobacco plant is not free from the attacks of disease or worms. The most destructive of the latter are the *Allukanavan* and the *Arrakottian*.

If careful attention is paid to the manuring planting and pruning of the tobacco plants they are sure to grow well and be remunerative.—*Patriot*.

FACTS, FIGURES, AND THEORIES ON THE DECLINE OF CHINESE TEA. INDIA AND CEYLON AS COMPETITORS. DECAYED TEA PORTS.

(FROM OUR SPECIAL SHANGHAI CORRESPONDENT.)

The history of commerce presents few examples of a national industry having to pass through such an ordeal as the China tea trade is now undergoing. Year by year for the greater part of a generation it has declined, until now it is a mere shadow of its former self. But beyond the fact of the decline we know little either as to its extent or as to its economic effects on the Chinese tea growers. How they have adapted themselves to the disastrous change, or if they have paid any attention to it, is a mystery. Whether or not they have found new markets elsewhere in place of those lost to them in Western Europe is open to dispute. Whether or not they have reduced the tea growing area is a question differently answered by various authorities. All we can make sure of is that the British tea trade with China is rapidly shrinking up.

The present season (1896-97) so far from holding out any hope of improvement exhibits more rapid retrogression than ever. With one solitary exception every port of shipment exhibits a decrease. The exports to Great Britain from the commencement of the season to the middle of January fell from 43,362,000 lb. to 37,336,000 lb. The northern, central, and Southern districts have all the same tale to repeat of reduced demand. The Hankow and Shanghai shipments, which take the lead in quantity, lost nearly three million pounds as compared with the corresponding period of 1895-96, their aggregate to date having been only 18,410,000 lb. against 21,317,000 lb. The central districts shipping by Foochow are more than two million pounds short—12,749,000 lb., against 14,676,000 lb. The Southern districts shipping from Canton and Macao are over one million lb. short—an aggregate to date of 6,317,000 lb., against 7,368,000 lb. on the corresponding period of last season.

So far as concerns our own market these figures only bear out what was already matter of general knowledge. They cause no surprise as some of the other figures do. China was supposed to be finding compensation in America for her losses in Europe, but that turns out to be

A FOND DELUSION.

This season's shipments to the United States and Canada have fallen off to almost as large an extent as those to Great Britain. They aggregate up to the middle of January 49,755,000 lb., or fully 3,000,000 less than the corresponding aggregate of last year, which was 53,128,000 lb. China's final resort is Russia, but here again we encounter a sharp shrinkage—at least in the shipments to Odessa. Their total for the season has so far been only 22,949,000 lb.—fully 4,000,000 lbs. less than last year's total of 27,240,000 lbs. More tea may have gone overland to Siberia, but that is hardly likely in view of the growing diversion of Russian trade from the overland to the sea route.

The tone of recent official reports on the tea trade is generally speaking, bad. The Imperial Commissioner of Customs at Hankow predicted some time ago that the tea trade with England would decrease year by year, which it has done. He also expressed his belief that if India and Ceylon tea can be produced to suit the Russian taste, the Russian trade will likewise go. The Foochow Commissioner says of his district that in the preceding ten years the tea trade had declined 50 per cent., "chiefly owing to depreciation in quality." Foochow had become a mere by-port, and its foreign colony had shrunk to a few hundreds; the actual census was 350. The amount of business done by them was no longer half what it had been, and the foreigners employed in the Arsenal and other public institutions had been almost entirely supplanted by natives. The melancholy conclusion he came to was that present indications for the tea industry "are more than discouraging."

Amoy is another of the dried up tea ports from which a voice of lamentation has been raised. In the official review of its Customs the writer observes that "exports have increased or maintained a sound average, with the exception of a serious decline in tea. Careless cultivation and dishonest packing had already killed the Congou trade of Amoy in 1881; now local Oolongs are hardly worth the cost of shipment." Only a demand for low-priced teas kept the market alive at all, and that was being threatened by Japan. As a tea port the principal use of Amoy was the

MARKETING OF FORMOSA TEAS,

which are transhipped there. This Commissioner gives a welcome indication of how the case is regarded by the Chinese themselves. "Strangely enough," he says, "the natives appear to view the ruin of this important trade with absolute indifference, and without moving a finger to retrieve their position."

But for an example of the utter ruin and decay which may overtake a once flourishing port, Whampoa is the place to go to. In the days of the old tea clippers Whampoa was the rendezvous for the annual tea race to London. Situated in a bend of the Pearl river, a few miles below Canton, it was a very convenient place for ships to finish loading at, and equally convenient to start from. They could drop down the river in a few hours and get clear away to sea. They were great days those of the Agamemnon and the other tea clippers racing home, with a £500 bonus waiting for the captain of the first arrival. I steamed past Whampoa lately in the moonlight, and found it a picture of desolation. Not an ocean-going ship lay in its beautiful bay, and hardly a sound was to be heard from the shore. Poor Whampoa looked like a city of the dead.

A good many explanations have been offered of the phlegmatic resignation with which the Chinamen bear what any other people would consider a national disaster. Most of them are conjectural, but one or two have a plausible appearance. It is affirmed that the heavy decline shown in the tea exports is to some extent misleadinn. These returns are made by the Imperial Maritime Customs, and cover only teas

shipped in foreign bottoms for foreign account. Teas passing through the native Customs are not included, any record made of them being taken by the native authorities, who keep it to themselves. Recently the native junks have competed strongly with the foreign steamers for tea freights, and have undoubtedly been securing a larger share of them. Part of the decrease shown at inland ports may therefore be only a transfer from one channel of export to another.

Another theory with more substance in it is that it took a long while for much of the loss to reach the tea growers. During the intermediate stage the greater part of it fell on the merchants and the middlemen. This explanation is contended by the well-known fact that for years past

TEA EXPORTING HAS BEEN A LOSING BUSINESS.

The trade reports of the native tea markets all agree on that point. In a review of the last Canton season it is said "The result was again disastrous to shippers in spite of the fact that teas were laid down cheaper than ever known before." Teas shipped from Ningpo during the same season were of inferior quality and adulterated as well, the result being that "of the thirty odd native hong engaged in the Pingsuey tea trade, not more than four or five made any profit at all. The rest are reported to have lost sums varying from 5,000 to 8,000 dollars."

In view of the many interests involved in this tea question, I have taken every opportunity here of making local inquiries regarding it. English shippers at Shanghai and Canton have favoured me with their views, which, as a rule, are decidedly pessimist. One whom I met at Canton had been in the trade over 20 years, and he considered it irrecoverably gone. The competition of India, Ceylon, and Japan was growing too keen for the Chinamen, who would not wake up to it till too late. Others took a more hopeful view, and anticipated a revival not only so, but they thought it might come comparatively soon. So far the new producers have had everything on their side—virgin ground, ample capital, skilled management, and all the best mechanical appliances for curing the tea. The Chinameu, on the other hand, had been handicapped by worn out ground, no capital, little or no technical skill, and no mechanical assistance.

It is by no means out of the question for the Chinese tea growers to retrieve themselves, and turn the tables on their Indian competitors. A first step in that direction is already being taken in some of the tea districts where "firing," that is, drying the leaves by machinery, is being introduced. The drying is done in half the time that the Chinese method of sun-drying required, and at half the cost. When plants which have outgrown themselves and become stale are renewed, Chinese tea may recover much of the fine flavour it has lost. More careful sorting and packing, less adulteration, and a return to the straightforward business methods of early days will all help to rehabilitate its damaged credit. The Chinese tea grower is not played out yet any more than the Caucasian is, but it is about time for him to turn over a new tea leaf.—*Dundee Advertiser*.

MR. RHODES AS COFFEE PLANTER.

The rumour that Mr. Rhodes is going to apply his many-sided mind to coffee growing on a colossal scale in the Shire Highlands of Central Africa, is causing a good deal of interest amongst those who are already engaged in the industry in that part of the world. It would be singular if Mr. Rhodes should really return, in the zenith of his fortunes—so far as money-making is concerned—to an occupation which he attempted with scant success at the outset of his colonial career. Long years ago he was a coffee planter in Natal, but discarded the life for the more exciting one of diamond hunting at Kimberley.—*Daily Chronicle*, April 10.

NUWARA ELIYA TEA ESTATES COMPANY, LIMITED.

Report of the directors to be presented to the first annual general meeting of shareholders to be held on Friday, the 30th April, 1897, at the offices of the Agents, Messrs. Frith, Sands & Co., Winchester House, Old Broad Street, London, E.C., at 12 o'clock noon precisely.

The directors beg to submit to the shareholders the balance sheet and profit and loss account up to 31st December, 1896.

The accounts shew a surplus of £9,910 0s 10d from which debenture interest £1,590 is deducted, leaving a balance of £8,320 0s 10d. An interim dividend of 4 per cent. was paid in September, 1896 which absorbed £4,053 6s 8d. The Directors now propose to pay a final dividend, making 6 per cent. for the year, on the four issues of shares from the respective dates that they rank for dividend, viz. :—

	£	s.	d.	£	s.	d.
Shares Nos. 1— 3,300, from 1st Jan. to 31st Dec., 1896, at 6 per cent per ann.	1,980	0	0			
Less Interim Dividend paid..	1,320	0	0			
				660	0	0
„ 3,301—11,500, from 1st Feb. to 31st Dec. 1896, at 6 per cent per ann.	4,510	0	0			
Less Interim Dividend paid..	2,733	6	8			
				1,776	13	4
„ 11,501—13,700, from 1st July to 31st Dec. 1896, at 6 per cent per ann.				660	0	0
„ 13,701—15,870, from 1st Nov. to 31st Dec. 1896, at 6 per cent per ann.				217	0	0
This will absorb				£3,313	13	4

Of the balance, £953 0s 10d, it is proposed to apply £300 to a Sinking Fund against the premium paid for leases, and £653 0s 10d towards the liquidation of the sum of £1,109 2s 1d, the amount of the formation expenses of the Company.

The crop of tea from the Company's estates amounted to 565,692 lb. of which 535,675 lb. was manufactured at the various factories on the properties, and green leaf, representing 31,860 lb. Tea, for which accommodation for manufacture was not available at the time, was sold to a neighbouring estate: 1,843 lb. Tea was also made from purchased leaf. The cost of manufacture and placing on steamer at Colombo was 4.88d per lb. The average exchange for the year was 1s 2 $\frac{3}{4}$ d., and the average gross sale price of the tea 10.30d. In addition to the tea crop, about 220 bushels of coffee, and 76,340 lb. of Cinchona bark were gathered and sold in Colombo.

The Company acquired at first only the estates of Park and Concordia; since then several other properties have been purchased as detail in the accompanying statement of acreage. As shewn in this statement, 2,171 acres are now under tea in various stages, and the estimate for 1897 is for an outturn of about 180 lb. per acre for the area in full bearing, and about 250 lb. from that in partial bearing.

The policy of the directors, which has been ably carried out by the Manager in Ceylon during the past year, has been to effect such alterations and improvements in the general condition of the estates and factories as will ensure the best possible results in the future.

With this view extensions were completed during the year to the factories at Naseby and Parkstates, and commenced to those on Pedro and Court Lodge, while entirely new factories, on Portswood and Concordia, are now practically finished. The want of these materially affected the first year's profits.

The General Manager reports that all the estates are now in thorough order, and anticipates much improved results in the current year. This is borne out by telegrams giving figures of yields very largely in excess of those to same date last year.

STATEMENT OF APPROXIMATE ACREAGES REFERRED TO IN THE REPORT.

Estates.	Tea in full bearing.	Partial bearing.	Not in bearing.	Jungle.	Patna Scrub and Waste.	Fuel Trees	Total.

VARIOUS PLANTING NOTES.

COFFEE IN NEW SOUTH WALES.—A Sydney merchant writes:—"There is a little boom on about trying coffee on some of our Northern rivers' lands—about the Richmond: on the flats they grow maize and sugar, but they have hill lands, too."

THE MOST EXPENSIVE PRODUCT in the world is said to be the charcoal thread which is employed for incandescent lamps. It is chiefly manufactured in Paris. It is sold wholesale by the gramme (15 $\frac{1}{2}$ grains). In reducing its price to the basis of pounds weight, it is found that the filaments for lamps of twenty candles are worth £1,600 per lb., and that for lamps of thirty candles they are worth £2,400 per lb. The former have a diameter of twenty thousandths of a millimetre (millimetre=0.0394 in.), and the latter four and a half thousandths of a millimetre. The filaments for lamps of three candles are so light that it would require nearly 1,500,000 of them to weigh 1 lb. As the length of each is 10 cm. (3.937 in.), their total length would be 187 miles.—*Egyptian Gazette*, April 9.

CHINA AND JAPAN TEAS.—It will be seen from the following return that 6 million lb. less of China tea have gone to Great Britain in the season now closing than in 1895-6. To Russia—that is Odessa—the decrease is nearly 5 $\frac{3}{4}$ million lb. To North America there is a comparative falling-off of nearly 5 $\frac{1}{2}$ million lb. of China and 5 $\frac{3}{4}$ million lb. of Japan teas. The total figures in the China papers are as follows:—

	1896-97 lb.	1895-96 lb.
Export from China to Great Britain ..	37,414,332	43,503,555
Export from China to United States and Canada	50,548,770	55,959,010
Export from China to Odessa	22,949,123	27,240,863
Export from Japan to United States and Canada	42,526,802	48,223,444

Correspondence.

To the Editor.

MANURING OF TEA ESTATES AND
MR. JOHN HUGHES' REMARKS.

DEAR SIR,—The net value on the increased tea yield will temporarily drop to one set of factors, but is not touched on another. Cultivation with artificial manures may be a means to one of two ends, bush-making or crop, and to take the latter with no care of the former is but caterpillar policy! A heavy pruning, followed by application of manure previous to a season of a "rush of leaf" will, of course, aggravate the poor liquoring teas primary flushes give. But such drastic measures are to be followed by bush-training and how to "tip back" etc is another tale. Say the cover of tea over area has thus been a tained pruning is only necessary at greater intervals of time, your second application of £ s. d. comes on six months after the 2nd pruning and can it be otherwise than that better leaf will be obtained from the improved wood? I have had better results from an application costing R5 an acre than where I have spent twice the amount and this is yet another tale.

It is difficult when writing on a subject such as this to refrain from running into other than the immediate factors and these major tactics of agriculture are a cheap enough education when one may read what Messrs. Hughes, Baumber and Cochran have to say and so keep a tea farmer from blundering in his work; and to be versed in a little elementary chemistry and geology facilitates a ready understanding of their writings.

"REPLY MARKED OO."

BHANG AS A FEBRIFUGE.

Colombo, April 27th 1897.

DEAR SIR,—In the *Ceylon Observer* of Saturday (24th inst.) inquiry is made by D.F. (page 2nd "An Olio") from some medical man as to whether "bhanga" is used as a febrifuge, and mention is made of what Knox, in his "Historical Relation of the Island of Ceylon," says about it. I have referred to Knox's book and find the statement in the place indicated (page 154). After Knox's escape from Kandy, he proceeded Northwards and had to drink of the water of tanks in the Vanni which he describes graphic ally—"having no springs, we were fain to drink of ponds of rain water, wherein the cattle lie and tumble, which would be so thick and muddy, that the very filth would hang in our beards when we drank." He goes on to say that he had been accustomed "to drink pure spring water only," but the bad water he was compelled to drink brought on "violent favors and agues." He learned, however, of "an antidote and counter-poison against the filthy venomous water," which is thus described:—"It is only a dry leaf; they call it in *Portuguese*, *Banga*, beaten to powder with some of the country *jaggory*, and this we eat morning and evening upon an empty stomach. It intoxicates the brain, and makes one giddy, without any other operation by stool or vomit."

A good account of Indian hemp or gunjah may be found in the "Bengal Dispensatory and Pharmacopœia by W. B. O'Shaughnessy, M.D.,

Professor of Materia Medica in the Medical College, Calcutta," published in 1841. This work was the basis of the "Pharmacopœia of India" by Dr. Edward John Waring, published by the authority of the Government of India, in 1868. The "Pharmacopœia of India" gives the therapeutic uses of Indian hemp, but it is not stated that it is used in fevers. Dr. O'Shaughnessy (afterwards Knighted in acknowledgment of his great services for projecting and carrying out the system of electric telegraphs in India) gives a more detailed account of the medicinal uses of Indian hemp, and states the properties which are assigned to it by Sanscrit, Arabian, and Persian writers and by modern European authors. No mention is made of its use in fevers.

The intoxicating properties of Indian hemp or gunjah were well known, but there was uncertainty as to its medicinal virtues. Dr. O'Shaughnessy made many experiments to ascertain the action of the drug on man and animals, and he gave it to some patients. On one patient, it had the remarkable effect of producing a cataleptic fit. Dr. O'Shaughnessy's investigations satisfied him that it is a useful remedy in some diseases, and his recommendations led to its introduction into European medical practice.—Yours faithfully,
JAMES LOOS, M.D., Retired Colonial Surgeon.

TEA PLUCKING.

May 5th, 1897.

DEAR SIR,—As regards the letters on tea plucking, etc., I should like to know whether it has been ever *proved* that coarse plucking gives a larger yield than good medium.

Take this instance: Mariawatte pluck their famous 100 acres once a week, to get in 4 pluckings a month, and the leaf they get off it by this means is certainly *good medium*. Supposing, however, they changed their system to 10 days plucking, they would only get in 3 rounds instead of 4 in the month, they would get coarse leaf, and *ceteris paribus* would they get a bigger yield at the end of the year than they are doing now? Observe they lose a round a month, and the bushes would get far too high, and I imagine it would be a case of "far too lightly plucked" by the V. A. at the end of the year.

The yield would be bigger for the first 2 or 3 months; but afterwards!

This must be the opinion of most men or why are they so anxious to have abundant labour?

The answer is because they want to keep well up with the flush, *bully* the bushes, and get their estimates. S.

CACAO CULTIVATION IN CEYLON
AND ITS ENEMIES.

Greenwood, Madawellatenne.

DEAR SIR,—I fully agree with your forcible article on "The Cacao Pest" (see page 801) I must, however, take personal exception to your remark:—"The press, which ought to have been supplied with the information, was singularly free from any comment, etc."—As far back as July 28th, 1890, you published a letter from me under the "nom de plume" *Eldorado*, mentioning the first cacao disease, about which even a greater reticence was observed, and which was never investigated by a scientist, but which I had good reason to put down to a root *Mycelinm* and not to *Helopeltis* which was often absent in fields badly attacked. This disease

which I have shown to have been the cause of the abandonment of *one-third* of the then cultivated area and which had such a fatal influence on crops, virtually disappeared in this district since 1893. It is in January 1892 that I noticed here the first serious attack of about 30 trees in a lump, by an insect which I then identified as "Tomiei Perforans"—with apologies to Mr. Barber for my audacity to still use what, to his ears, is a "sonorous, aristocratic name, to make it look learned."—Before, the attack was sporadic and seldom fatal; but this time these trees, which were among the best in my garden, vigorous and healthy, of 12 years of age, growing in deep alluvial soil, fairly shaded, nearly all succumbed. *Criollos* they were, but since then among the large yearly increase of trees attacked, there was the same proportion of hybrids and many Forasteros.

In his interesting and sarcastic letter which appeared in your issue of 12th inst., Mr. Barber pleads the case of "Tommy" as he prefers to call the beetle.

He has evidently read "The Agricultural Pests of India" by Surg.-Gen. E. Balfour and assimilates the information therein contained: "*Tomiei*.—The species of the genera *Hylesinus*, *Scolytus* and *Tomicus* are small beetles, but numerous and common. *Tomiei* chiefly affect bamboos and are very destructive to them. The *Hylesini* also attack the bamboo, but not so vigorously as their smaller brethren, the *Tomiei*, and both are detected by the powdery excremented matter which they and their larvae throw out. One small species of *Hylesinus* in great numbers attacks the dead wood of the cheer pine, and when hatched underneath the bark, they bore in all directions, the tendency, however, being to reach the centre of the log. They do not attack living trees nor logs that have had their bark stripped off. *Tomicus perforans monographus*, in 1860, attacked the beer barrels in the Commissariat stores of Burma and Lower Bengal, and the contents oozed out from a multitude of pores, causing great loss. The soldiers gave the insect an apt name—they called it *Tippling Tommy*."

I have had a similar experience here in 1882 with two hogsheads of wine stored in a locked place. After two weeks I found one empty, and of the other, $\frac{1}{4}$ had oozed out through a great many drillings made by Tommy. I now coddung the wood on arrival.

Mr. B. writes that "the question at issue will be whether Tommy has of a sudden changed his natural instinct in the matter of his diet from decaying bark and wood to *fresh, green, sappy plants*," etc. It is clear that Mr. B.'s multifarious occupations have not allowed him to investigate the case with his usual acumen, for he would have found that his client Tommy not only attacks cacao trees, without visible tare, but also the very sappy Dadap tree.

He further states:—"When the planter first notices the *wccvil* (sic) he also notices the fact that the tree has changed its condition and *per saltem* he arrives at the conclusion that "an enemy (*Tomieus*) hath done this thing." Well, if not *Tomieus*, find the enemy! He exists, for it cannot be supposed that under 20 years of age the cacao tree should be decrepit here when it only attains majority at that age in other countries.

From his above statement I infer that it may be new to Mr. B. that a metamorphosis does precede the appearance of the beetle. It is the

grub, which issues from the microscopic egg deposited in the bark, which does the greatest damage. It is only when the grub is at work in the wood that its presence is disclosed. How much time the grub is at work I leave to the scientist to discover. To my knowledge, planters have given up the hope to find a remedy, because having applied some, they found soon that the disease broke out under the application; but this was no proof of its inefficacy for the eggs had been laid or had hatched at the time of the application or even the grub had begun drilling. The trials of the supposed prophylactic remedies must be made therefore in a very methodic way.

I have remarked that the beetles born in the trees are of a very different appearance to those which tunnel the branches (the latter being the same as the Tippling Tommy) but their greater sturdiness might be due to development.

As to Mr. Barber's view "*that the insect is not the cause of death to the plant, but one of the consequences of it*" (the italics are his), I maintain that the insect being always present before, at and after decease of the victim, the circumstantial evidence points to him as being the murderer if no other cause of death can be brought forward. And would Mr. B. acquit the man who would plead that the victim he slew was decrepit?

I join issue with *Tomicus's* champion in asking for light, practical light, and scientific light, but the latter cannot be given in the form of a diagnosis but only after a serious and long study by a trained entomologist. I do certainly think that Mr. Green would be *the man*.

The damage done is already very large on many plantations and the increase has no check. In this district (Kurnegala), I know several places where tea, Liberian coffee and coconuts are being planted in view of a complete destruction of the cacao.

Craving your indulgence for my ungrammatical English.—I am, dear sir, yours truly,

A. VAN DER POORTEN.

THE COCONUT PALM IN THE GODAVARI (KISTNA) DISTRICT.

SIR,—About the period that you discovered that the first of my Christian names was not Ananias after I had been remarking that Godavari coconut trees produced 200, 300, and rarely 500 nuts per tree per annum, surprise was expressed that the *small inferior nut* should be planted at all in this part of the world. Could you kindly tell me in what way, though smaller, this nut is inferior; as local tradition has it that the smaller nut is more flavoursome, and the only quality in favour of the larger nut is the far larger quantity of juice (milk). I should like to know what is the Ceylon market value of the large nut, for it seems to me that, if only 70 large nuts can be grown per annum against 300 small nuts, unless the large nut has more than four times the market value of the small nut, the smaller one is more profitable. I have said four times, but probably it should be six or seven times owing to the larger extent of land occupied by the greater number of trees to produce an equal number of nuts, not to speak of the nurture of a greater number of trees.—I am, dear sir, yours faithfully,

A. N. LUSHINGTON (Kistna District.)

[Ceylon coconuts this year have mostly run about R30 per thousand—what are Mr. Lushington's prices? But is it not the case that in speaking of 200 nuts and upwards per tree per annum, apart from the smaller size, Mr. Lushington's

ton's experience is of a few trees—and not even a few acres each with 80 trees per acre? In Ceylon we can show wonderful results from a few trees or small gardens, but our statistics are based on plantations of from 100 up to 500 acres each.—ED. T.A.]

OUR AMERICAN TEA COMMISSIONER AND HIS GOOD WORK.

New York, April 1.

DEAR SIR,—I send you a copy of the report prepared by experts for the new tea standards here. Dust and Fannings are to have a bad time.

I also enclose a few of our advertisements for this week.

I note that in his speech at the Planters' meeting, Mr. Sackville said "*Canada has for many years been receiving funds from the Thirty Committee and its predecessor the Tea Fund.*" is this correct? Many years? Did the *Tea Fund* give anything for Canada? The *Committee* did not begin subscribing till late in 1895.—Yours truly,
WM. MACKENZIE.

P.S.—Fear of a duty may partly account for the increase. Be that as it may, Sheppard's tea circular gives the following figures:—

Direct shipments to North America from London of Ceylon and Indian teas.

Jan. and Feb. 1896 ... 262,000 lb.

„ „ 1897 ... 1,202,000 lb.

Your papers show now a large direct shipment increase from Colombo.

[The report on the new tea standards will be found in another column. The advertisements are of the usual attractive character, one being from the "Youth's Companion" regarding which our Commissioner remarks that it is the "second dearest paper in America, the "Lady's Home Journal" being the first. This advertisement costs about £48 an issue in this paper. Nearly all homes take those papers. As to the direct shipments of tea from Colombo the last table of exports and distribution issued by the Chamber of Commerce shows that the export to America this year up to 27th April was 213,201 lb. as against 90,907 lb. in 1896.—ED. T.A.]

"ROSES—ROSES—ALL THE WAY."

Upcountry, 15th May.

DEAR SIR,—That letter on Rose Culture by "Practical Horticulturist" is most interesting and ought to be of great use to all amateur rose-growers. There are acres and acres of abandoned land that might be turned into rose gardens, and gallons of perfume might be distilled therefrom; all we want is some capitalist to take the initiative in planting acres of roses, and then get an expert to show us how to extract the valuable attar of roses. The climate of Ceylon is so diversified that the resources of the island as to New Products are endless; in favoured spots plums of sorts, figs, raisin, vines &c. might be grown most profitably.—Truly yours,

UPCOUNTRY.

PLUCKING TEA IN APRIL: A GOOD THING BUT REQUIRING MORE COOLIES?!

DEAR SIR,—To continue my letter of the 5th inst., I am convinced that were all estates to have sufficient labour to keep the bushes closely plucked in April and May, the result would be that the Ceylon output would be 15 to 20 per cent higher than it is at present, so perhaps it is as well we

can't get sufficient coolies though the quality would be better if it could be manufactured. Again had we sufficient labour in those 2 months, what would we do with the coolies in the non-flushing months?

It is in April and May that the cry is for coolies; in most other months there is an over-sufficiency. Now there is a well-known estate that has solved its labour difficulty. It prunes the *whole* of the tea in February, March and April; there is therefore no work in April, and the tea comes into bearing from June onwards, when better prices prevail, and they have an even output throughout the year, Surely that is solving the difficulty!

All estates (below 1,200 ft. where they mostly prune once a year) might not care to do this, though it seems a sane idea, but at any rate men ought to try and get a *minimum* of their tea in full bearing in April, and not prune so much in July and August so as to get a *maximum* of tea in bearing in April which they can't possibly pluck or manufacture properly. Some men lose about 30 per cent of their yield by this means, they leave so much on the bushes, that the tea has to be pruned before it would flush again. So they go on year after year, crying out for labour in April, and wanting to lend coolies half the other months.—Yours faithfully,
S.

P.S.—Once a bush gets out of hand it is *doomed*, and has to be pruned, it will give fine results for a few weeks, then comes the "banjy" and then the knife. Besides a man who builds a factory for say 100,000 lb. of tea doesn't supply machinery and withering accommodation for say 35,000 in 2 months.—S.

TEA PLUCKING IN APRIL: A COUNTERBLAST.

May 17.

SIR,—In your issue of 11th instant there is a letter signed "S." on the subject of "Plucking tea in April.

Half the output of Ceylon is produced at an elevation of 4,000 ft. or upwards where rushes of leaf are so very exceptional that there is little or no difficulty in securing the whole lot!

That the other half of Ceylon could turn out an extra 30 or 40 million lb. annually I don't believe, but even were this possible, I think it a wise dispensation of Providence that the labour question steps in to save those lowcountry men from ruining themselves and their bushes by such awful overproduction. Were all estates to follow the advice of "S." and have no work whatever during April (as per that well-known estate which is evidently managed by a man smart enough to take advantage of his neighbour's idiosyncrasies and doubtless makes them pay through the nose for his labour during that month) we should be in a nice fix, as though Ramasamy can appreciate taking it easy as much as any one, he'd look somewhat askance when told he'd have a month's holiday at his own expense and that there really was no pay whatever for April in Ceylon as by "S." established.

The idea of pruning the whole of an estate either below or above 1,200 ft. all at once is a most insane idea; but I know there are men, or machines, who believe in and do this. The result is 3 days' work a week for months and then 7 days a week are not sufficient for the rest of the year. At one time the tea is simply rubbish and at another far above anything it ever fetches and yet we are told this is the way to maintain an even outturn throughout the year!

Distribute your pruning throughout the year both in the low and upcountry; send your advances to the Coast and covet neither your neighbour's ox nor ass and if I mistake not you'll sleep the sleep of the just and earn a decent dividend.—Yours faithfully,
FARMER.

THE LABOUR QUESTION.

CEYLON PLANTING DISTRICTS—"AFTER EIGHT YEARS."

SIR,—It is long since I wrote you, but I wish to say another word or two about the LABOUR MATTER. Commenting on my last letter you say "Whenever coolies are very scarce—at a high premium—the Law and the Law Courts go wrong somehow in the planters' estimation." That may be. But at the present time I absolutely deny that there is any scarcity of labour in Ceylon. It may be that the Government is short of coolies. The disgraceful state of the main roads in the planting districts points directly to this conclusion. But the planters are certainly not short-handed. I have been travelling constantly for two months, and I have not seen a single estate weedy—nor have I heard of flush being lost, but I have seen ravines being cleaned, and roads being tidied. True, it is the dry season when weeds are not in evidence; but, dry or wet, these are not works that would be carried on if labour was scarce. As to the "Law and the Law Courts going wrong" they went so very wrong under the presidency of the Ilbert Judge* that we got the Penal Code which was supposed to put everything so very plainly, that the punishment so exactly fitted the crime, as to make it impossible for the veriest tyro of a Police Magistrate to make an error. The Penal Code is still in force, is it not? And still a cooly has but to appeal to secure reversal of a well-deserved sentence. Scarcity of labour is a very good cry for those—and there are always some—who cannot get coolies, but as a matter of fact it is all *mon vil et mademoiselle Elise Martin!* A kink in the judicial brain accounts largely for the trouble, as it did in the time of the Ilbert bill, when labour was certainly not scarce.

That coolies are *unsettled* all over the country, and that "advances" have gone up to scandalous figures, is only too true, but many causes contribute to this state of affairs. Among others I would mention creepers, conductors, tea-makers, the operations of a certain large firm, and, not least of all, want of loyal co-operation among the planters themselves. I was much struck at the isolated sort of way in which neighbouring men were working, and talking to an old friend on the matter I was reminding him how in '78 and '79, after the famine, when the chetties were trying to keep up the price of rice, we all combined, and each District Association fixed the price from month to month until rice fell to its normal figure. "Those days are past," he said, "there's no cohesion and no cooperation among planters nowadays. It's each for himself and the devil take the hindmost." "But surely the P. A. could regulate to some extent the rate of advances?" "No good, old man; no good. The P. A. is only a talking shop." Ichabod! I thought; and was sad.

* I have not come into contact with the creeper; but what I have read about him has made me

feel towards him much as Mr. Potter of Texas felt towards Dukes and Dudes. However, whatever his personality, the fact of his position being an irresponsible one is quite sufficient for a kangany to make capital out of and turn to his own advantage. It appears to me, too, that planters as a rule—of course there are exceptions—are not in touch with their kanganies as they used to be, and that far more is left to the conductor and the tea-maker than was in years gone by. I was very much astonished at the advance in the position of these two servants of the estate since my day. And to my mind this largely accounts for the "tricky and cheating disposition which is spreading among kanganies and coolies." These words I quote from a recent *Observer*; of course Ramasamy will get the better of his master if he can in fair fight; but I submit that as a rule he is not, or was not, of a "tricky and cheating disposition." This he gets from the conductor and the tea-maker. These gentry read the newspapers, discuss them with the kanganies and concoct schemes for raising advances, sharing the spoil between them. Emissaries from—say Balangoda—who are sent on the crimp, as often as not work through the tea-maker who, needless to say, is not any poorer by the transaction; of this I am well assured. Other kanganies who are not anxious to leave a comfortable district for the hardships of new clearing work feel, nevertheless, that they are left out in the cold in the matter of advances, and I know of one district where many head kanganies are banded together in a sort of union to force up advances. An old planter the other day told me that he knew that thousands and thousands of rupees given out as "Coast advances" went only to enrich local boutique-keepers. It is a thousand pities that some big head kangany can't be "jugged" for obtaining money under false pretences; but to hope for such things is like crying for the moon. In view of the free credit given to kanganies, of the absolute lack of security in the matter of Coast advances, and of the fact that no interest is charged on such loans, the planter is entitled to special protection in such cases as the following which I quote from the *Observer* of 31st March: "A kangany interviews a planter about bringing him a gang of coolies; but first their debts must be paid, these debts consist say of R1,000 to the estate they were on, and R1,000 of outside boutique and chetty debts. "The latter must be paid and the money is wanted for them; but inasmuch as the estate Superintendent refused a tundu, he, the kangani, having given proper notice, does not mean to pay the R1,000 due to the estate—but will let the owner whistle for it!" Possibly the Superintendent committed an error of judgment in refusing the "tundu." Certainly the kangani deliberately contemplated a crime (*morally*) in evading his debt, though *legally* he was only approachable by civil action. It would be interesting to know how long that R1,000 had been outstanding without interest; also how much the kangani had made in re-lending it. I remember a case coming before me once in which one cooly had a claim against another for an incredible sum. All the kanganies were witnesses and thought it unjust that the defendant should appeal to master. I found that the poor wretch had paid his debt over and over and over again; but it had originally been outstanding for three months and the interest had been agreed on at the rate of 50 cents. per rupee per month, or 600 per cent per annum!!!

* No—Mr. Ilbert was not a Judge, but legal member of the Viceroy's Council, and it was the "Ilbert bill" that made him known.—ED. T.A.

Of course I ruled that the debt had been paid; but my decision, though acquiesced in, was considered by the kanganies as hard lines on the usurer! One of the most successful head kanganies I ever knew charged his coolies 15 per cent per annum on their debts, and kept his books perfectly.

In the *Ceylon Observer* of 2nd April you have a column headed

“COOLIES—COOLIES—COOLIES.”

When things arrive at such a pitch, surely the P. A. can—and should—take the matter up and legislate for itself and its members at all events. In 1879 it reduced wages and head money all over the country,—why not tackle advances in 1897?

“Every member of this Association pledges himself to reduce his outstanding advances as speedily as possible, and in future never to have on his books advances at a higher rate than R20 per head of his total labour force.” I maintain that this is quite feasible. Let “Jack Campbell” thus signalise his *first* year of office and earn the gratitude of his brother planters.

WILD MAN OF THE WOODS.

THE TREATMENT OF RAMIE OR RHEA FIBRE.

(To the Editor of the *British Trade Journal*.)

SIR,—I am exceedingly pleased to gather from F. C. T.'s letter, dated Foochow, December 18th, 1896, that the Ramie-growing district of China is likely to be opened up. China is a grand field for ramie, rhea, or China grass culture. We should be pleased to open up with any capitalists willing to start a plant in China. We should recommend the degumming process to be carried on whilst the ribbons are yet moist. We are willing to provide decorticating machinery, degumming plant, and teach our process of filassing to a substantial company, and take our payment in shares.

We could supply our patent machinery in any quantity, and would undertake to act as brokers or contract for the material. There are many advantages in filassing on the estate before the gum has time to harden:—(1) It is much easier to do; (2) The quality of the fibre is better; (3) There is a great saving in freight.

We shall be glad to hear from F. C. T.—Your faithfully,

EDWARDS RADCLYFFE.
(The Ramie Syndicate, Ltd.)

(To the Editor of the *British Trade Journal*.)

SIR,—I have worked for years at rhea. I have spent therein thousands of pounds. My work and my money have brought me the clear conviction that if a machine is used to treat rhea, the result is a damaged article. If chemicals of any kind are used, the result is equally fatal. The time within which the damage will declare itself is uncertain, but it is latent, and will become active. Therefore, I have adhered to my system of hand-labour, and of excluding the use of any acid or caustic, relying for my solvent on water only, used according to my patent process, as described in paper enclosed.

Thus only can the cultivation of rhea be carried out by small proprietors so as to give them a crop which will be more remunerative than any other. The decortication of rhea is specially suited to small cultivators, because women and children do this work better than any machine, because by hand-labour the whole of the fibre is obtained, and nevertheless the cost is less than that of any machine I know of. My subsequent treatment is of the simplest kind, and should be compared with the skilled labour, the chemical knowledge and manifold displacements required by processes involving the necessity for expensive plant and experts to control it.

I write with confidence respecting decortication, as a company of which I was one of the largest share-

holders imported from China hundreds of tons of rhea ribbon decorticated by the use of water only (in the form of condensed steam), and they arrived perfect in quality, and with every particle of fibre left intact.—Yours, &c,
EDWARD CASPER.

PLANTING NOTES.

MR. JAS. A. GAMMIE of Mungpoo, Darjiling, who did so much in the early days of the cinchona enterprise in promoting cultivation and in the manufacture of the alkaloids for the Indian Government, is about to leave India.

CENTRAL TRAVANCORE: PEERMAAD, 9th May. —*Weather*.—Rainfall for April, 4.25. Rainfall for year to date, 10.50. *Crops*.—Tea flushing hard. Every available cooly on plucking. *General Health*.—Good. *Labour*.—Somewhat short. —*Planting Opinion*, May 15.

THE RHEA FIBRE TREATMENT CO. has appointed Messrs. A. Whitly & Co. Sole Agents in Ceylon for the purpose of purchasing any rhea ribbons that may come into the market. We hope there will soon be an appreciable supply. Ceylon can grow any quantity of rhea or ramie.

COFFEE IN BRAZIL.—A statement has been for some time current—says the latest *Rio* paper—that another important coffee plantation in São Paulo has been sold to foreigners, the price mentioned being £200,000. As the reports are contradictory, we have been waiting for details and names, but thus far without success.

RAMIE.—Mr. Barraclough in his lecture on “Ramie” at the Society of Arts, tried hard to steer clear of controversial matter; but—says the London correspondent of *The Indian Engineer*—in the discussion that followed, the advocates of the various systems went at it hammer-and-tongs, and were only stopped by the merciful time limit, or they would have been still going at it now.

COFFEE PLANTING PROGRESS IN SUMATRA.—Our correspondent writes:—“Here (district Serdang) all are busy planting. Two years ago there were 3 coffee estates in the district. Today there are 23 and land is hardly to be got. There is a Coffee Planters' Association, one of whose rules is a fine for non-attendance unless a proxy or excuse for absence is sent!”

COCOA AND THE BROKERS.—Some weeks ago we had occasion to point out how the price of coffee, among other products, could be sensibly raised by direct sale to the large grocers, instead of through the usual channel of public auction. This is what the *Produce World* says on the matter as regards cocoa:—“In proof of what we have written in previous numbers that there surely remains yet something to be done in the matter of bringing the planter and consumer more directly into touch with one another, it may be noted that a company has lately started with the idea of selling to the consumer at the lowest possible prices, reports that they have been successful in placing among other articles cocoa at the rate of 84s to 85s per cwt. of identically the same quality as that which has been offered and sold at the public auctions in Mining Lane at as low a figure as 50s. Undoubtedly there are many difficulties the company referred to will have to encounter before they are able to get this method of trading into an easy style of working. It nevertheless shows quite clearly that the middlemen are to a very great extent to be dispensed with entirely, and we beg to tender our heartiest congratulations to the Company in question on their new method of sale.—*Planting Opinion*, May 15.

ITALIAN CORAL.—The coral industry, which is of considerable importance in Italy, from the maritime point of view, also employs both capital and labour for working up the raw material procured by the fishermen. Leghorn and Naples, and particularly the former, are the great centres of the coral-working industry. There are no complicated processes, it being only necessary to select from the rough material the better qualities according to colour, and the better portions of such qualities, and to form them into beads of various shapes to suit different markets. The work is almost entirely done by girls, who saw, turn, file and polish the raw material. Prices vary greatly according to the shades of colour and to the size of bead of uniform shade which can be produced. "Of late years the average price has fallen considerably," says Mr. FitzGerald Law, Commercial Attachè, "owing to the increased production of what are considered inferior qualities, but the price of the best-coloured coral remains very high, reaching exceptionally to as much as £12 per ounce." The exports of coral, rough and worked, amounted in 1895 to somewhat over £1,000,000 sterling. About 60 per cent. of the exportation is to British India, and the demand for the African market is said to be most promising for the future.—*Journal of the Society of Arts*, April 9.

AGRICULTURE AND PLANTING IN BRAZIL.—One of the most elaborately prepared volumes that reach us year by year, is a bulky paper-covered quarto (about 500 pages) from San Paulo, entitled this time:—

Relatorio Annual do Instituto Acronomico do Estado de S. Paulo (Brazil) em Campinas 1894 e 1895 Volume VII. e VIII. Publicado Pelo Director Dr. Phil. F. W. Dafert M.A., Com a collaboracao dos Snrs. F. M. Draenert e L. Rivinius e dos Membros do Instituto, San Paulo, Brazil.

The index shows—apart from Administration—chapters on Agricultural Chemistry; experiments with Coffee (accompanied by a series of engravings of the bush); Viticulture; Veterinary; Hygiene; Commercial and Industrial; Meteorology; Rural Economy, &c. The statistics are very elaborate: the letter press is all in Portuguese. There is a great deal about coffee and sugar preparing machinery with detailed illustrations. The whole reflects great credit on the Brazilian, or San Paulo, authorities and their officers.

LIBERIAN COFFEE.—The production and export of Liberian coffee is becoming a subject of great concern to the farmers of the Republic. The phenomenal increase in its production is worthy of consideration. The coffee exported during the fiscal year, 1896, amounted to 600,000 pounds, while the exports for the year ended June 30th, 1896, amounted to 3,000,000 pounds. Farmers, merchants, and people generally have turned their attention to coffee growing. While no American ships touch at any Liberian port, yet more than one-fifteenth of the coffee produced is shipped to the United States *via* Liverpool. Coffee is the largest export, yet palm oil, palm kernels, piassava, and rubber are shipped in great quantities. It is asserted that if ships from the United States touched at Monrovia, Bassa, and Cape Palmas, half of the imports would be American, and, in turn, the exports would go to the United States, as the people, with the exception of the few Europeans residing in Liberia, prefer American produce. The reason for this preference is that the people are immigrants from the United States, and in habit and life are American. It is stated that a direct line of steamers from New York or Boston, touching at Monrovia once in two months, would be a paying enterprise.—*Journal of the Society of Arts*.

PLUCKING AND PRUNING OF TEA.—An old "V. A." writes to us:—

"To show you the depravity of planting human nature I may tell you that I meet planters who believe that the letters you have published on Manuring and Plucking and Pruning tea are mostly manufactured on the premises—as there is so much they don't appreciate in them! The bulk of the creeper and assistant-dom of the present day is far more interested in the district tennis and golf tournaments than discussions of subjects they are paid to become masters of."

We are obliged to our friend and fully empower him to refer any sceptic to a visit to our office where the MSS. of the 150 to 170 letters printed can be produced for his benefit. But planters who do not care much for their work or its improvement, are just those who are most likely to cavil on any excuse, however forced. Here, however, is what Mr. John Hughes of Mark Lane—one of the most competent authorities—writes to us by last mail:—

"Plucking and Pruning discussion is of real interest and has a genuine ring about it. Have written a letter to London Ceylon Association Tea Committee drawing special attention to the matter."

FORAGE PLANTS.—IN the Report on Natal Botanic Gardens for the year 1896, by J. Medley Wood, A.L.S., Curator, which has just reached us, we find several interesting paragraphs:—

Mr. F. Lamson Scribner, the United States Agrostologist, says:—

"I send you by mail today a small sample of seed of one of our native forage plants *Atriplex canescens*, James, locally known as 'Shad Scale,' 'White Sage,' or 'Sweet Sage.' It was formerly one of the chief reliances of the cattle men on the arid plains from Western Texas to Arizona, but has now become almost extinct, occurring only on steep cliffs and in protected situations where cattle and sheep cannot reach it." This plant will have a fair trial here and will be noticed in a future report.

Desmodium tortuosum, "Florida Beggar Weed."—In September I received from the same gentleman a packet of seed of this plant about which he says that it is "A wild forage plant highly esteemed in the subtropical portion of the United States. It produces a fodder of fine quality in large quantities, and grows best on sandy soils containing lime. On cultivated lands it grows often 8 to 10 feet high. The haulms, though woody, are eaten by cattle and working stock of all kinds. Beggar Weed makes an excellent green manure. In Florida it is extensively used as a renewer of worn lands. It promises to be a plant of much agricultural value in the warmer countries." This seed was sown at once on receipt, and the plants are now from 12 to 15 inches high, and growing vigorously, seed will most likely be obtained from it for distribution, and I quite expect to be again told that "cattle will not eat it," but farmers must surely understand that cattle require a little management before they will take to a plant so different from their ordinary food plants as these are, but a little care and trouble will soon overcome the difficulty, as I know from personal experience.

Mr. Nock of Hakgalla gives his opinion of the plant for Ceylon, in a letter as follows:—

"The paragraph about 'Florida deggar weed' is interesting. I have a few seedlings planted here for trial, which have only just been planted out; but one should soon be able to see if it is likely to suit Ceylon."

DEAFNESS. An essay describing a really genuine Cure for Deafness Ringing in Ears, &c., no matter how severe or long-standing, will be sent post free.—Artificial Eardrums and similar appliances entirely superseded. Address THOMAS KEMPE, VICTORIA CHAMBERS, 19, SOUTHAMPTON BUILDINGS, HOLBORN, LONDON.

COLOMBO PRICE CURRENT.

(Furnished by the Chamber of Commerce.)

Colombo, May 25th, 1897.

EXCHANGE ON LONDON: CLOSING RATES, Bank Selling Rates:—On demand 1/2 11-32 to 3; 4 months' sight 1/2 1/2 13-32; 6 months' sight 1/2 7-16. Bank Buying Rates:—Credits 3 months' sight 1/3 1/2 to 17-32; 6 months' sight 1/3 9-16 to 19-32. Docts 3 months' sight 1/2 17-32 to 9-16; 6 months' sight 1/3 19-32 to 5.

THE AGRICULTURAL MAGAZINE, COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for June:—

Vol. VIII.]

JUNE, 1897.

[No. 12.

SEASON REPORTS FOR APRIL.

WESTERN PROVINCE.—Paddy.

The usual preparation for Yala has in some villages been delayed in the Colombo district; preparations in progress in Negombo district; in Kalutara district, sowing over, except in Rayigam Korale, where it is going on, and with the favourable weather the plants are looking well. A good harvest may be looked for in the Western Province. Rain fell in most parts during the month. Vegetable supply good in Colombo and Rayigam Korale, but bad in Negombo and the Pasdum Korale. Fruits generally scarce except in the Rayigam Korale.

Central Province.—Paddy in various early stages, crop prospects considered good, but it is too soon to form an opinion. Rainfall sufficient: in Matale 9·09 in. registered.

Northern Province.—Paddy. Kalapokam 1897, paddy being threshed. Moderate amount of rain; in Jaffna 1·04 in. registered, in Mannar 2·71 in. Cutting and curing of tobacco going on in Jaffna and Mannar. Prospects of tobacco in Mullaitivu not so good as last year, owing to damage by previous rains.

Southern Province.—Paddy. Yala cultivation in progress. Rainfall plentiful, in Galle 13·77 in. registered. Fruit and vegetable supply good in Galle district but poor in Hambantota.

Eastern Province.—Paddy. Great damage caused by floods. 3,000 acres of ripe paddy under water in South Batticaloa. Sowing of about 5,000 delayed and 600 bushels paddy prepared for sowing will not be fit for the purpose, so that fresh seed paddy will have to be prepared. Cattle murrain decreasing in North Batticaloa. Damage in Trincomalee comparatively little, but there has

been an outbreak of cattle murrain which, however, is reported to be on the decrease.

North-Western Province.—Paddy. Maha harvest nearly over and preparations going on for Yala. Rainfall good, and health of cattle satisfactory.

North-Central Province.—Paddy. Yala cultivation commenced in most parts; rain plentiful and tanks well supplied. Rainfall at Anuradhapura 7·13 in. A few occasional cases of murrain in Kalagam Pattu and Tamaukaduwa.

Uva Province.—Paddy. Sowing for Maha almost over. Rainfall 10·2 in Badulla. The crop of Indian corn is fair.

Sabaragamuwa Province.—Paddy. Maha harvest almost over and Yala cultivation being taken up. Prospects are satisfactory. In Ambanpitiya in the Kegalle district the rainfall registered was 21·14 in., and in Ruwanwella 11·89 in.

Greatest amount of rainfall in any 24 hours on the 2nd Sunday inches 2·55.

Recorded by A. R. JEREMIAH,

KAFFIR CORN.

The above is the name by which Sorghum vulgare is known in South Africa. In the United States it is called broom corn (compare the Sinhalese name "Edal" iringu), in the West Indies Guinea corn, in India as Juar or Jowari and Cholam. Kaffir corn has the advantage over other cereals of thriving and giving large crops in hot arid regions. In Syria, North Africa, and the Soudan, where it is called *Dhurra*, it is the chief sustenance of the people, and is also considered a necessary diet for horses. In addition to its valuable use as a food, a kind of beer is made in Africa from the malted grain, and the leaves and young stems form excellent fodder for animals, whilst the stalks are sometimes used for manufacturing sugar. The flour of the seeds is very white and makes good bread, and the panicles, after the removal of the seed, becomes hard and rigid, and are used extensively in America and even England, for the manufacture of brooms and clothes brushes. Numerous varieties of the plant are now cultivated extensively in all the warmer regions of the earth under various names.

Sorghum will grow and yield a crop in nearly every soil, but the most suitable is a rich light sandy loam, well drained and not too moist. The climate should be a dry one, and to obtain large crops the temperature should never fall below 60° F. Kaffir corn stands drought remarkably well, so that the hot and dry districts are well adapted to its growth.

The land having been ploughed and harrowed so as to bring it to a good tilth, the seed is sown in furrows, or drilled in by the means of one of the useful seed drills now made by the manufacturers of agricultural implements. The lines or furrows for the seed should be from three-and-a-half to four feet apart, and the plants should be thinned out after they have sprouted, so that the seedlings may not be less than twelve inches apart in the rows. As soon as the corn is a few inches high, the field must be thoroughly weeded, and a second weeding may be necessary later on, or a light plough or cultivator may be run between the rows so as to turn up the soil and destroy the weeds. Very soon the plants will cover the land by their luxuriant foliage which grows with such rapidity. The best season for sowing is June, and crops may be reaped in four or five months afterwards; although when grown under favourable conditions, returns have been got in three months. When the corn has arrived at maturity, it is harvested by cutting off the ears near the top of the stem and then carrying them in baskets to the house or shed. The ears are kept in heaps for a few days, and afterwards they are spread on the floor of the building, and the grain is threshed out by means of a fail. In some parts of the East, Sorghum, like rice, is threshed by bullocks being made to tread on it, and this process dates far back into primitive times. Indeed, in some Eastern countries, agricultural systems and manufacturing processes have been handed down unchanged from remote ages to modern times; descriptions by ancient writers of the every-day life of the people being in some instances faithful delineations of what is seen at the present time.

The crop of Kaffir corn from an acre of land varies considerably fifty bushels, however, may be considered as a good average return. But double that quantity is by no means an unusual crop on good soil.

OCCASIONAL NOTES.

The present month will witness the 60th anniversary of the reign of Her Gracious Majesty the Queen, who through her wise policy and even by her noble example has done much to encourage and advance the peaceful art of agriculture. It was during Her Majesty's reign that Agricultural Colleges were founded, and we would fain hope that this "Jubilee year" will see the adoption of a liberal policy (too long delayed) for agricultural education in this Colony.

The present number brings the 8th volume of the Agricultural Magazine to a close, and we again thank our subscribers for their kind support and the press for its patronage.

With this issue we forward to those of our subscribers who we venture to think take a special interest in the School of Agriculture, copies of "Addresses on Agricultural Education in Ceylon," being a reprint from the *Ceylon Observer* of the Prize-day Speeches delivered at the School of Agriculture, Colombo, since the founding of the institution.

Our correspondent "Traveller" is doing good service to the school in contributing a series of Notes in which he declares his intention of reviewing the past work of the institution. We trust his contributions will serve the desired end, to place fact in their proper light.

Dr. Henning's instructions how to inoculate for rinderpest are most welcome, and are clear enough to encourage some of our enterprising stock-owners to operate on their own cattle.

THE SLAUGHTER OF CATTLE.

The *Australian Tropiculturist and Stockbreeder* is publishing a series of prize-essays on this subject which is of more than ordinary interest to us, and we therefore take over from the valuable pages of the paper referred to the following essay by W. J. Evans, who writes briefly and to the point:—

To deal fully with this subject it is well to describe the treatment to which cattle are subjected previous to slaughtering. To preserve the good colour and keeping qualities of the meat it is necessary that all cattle, whether very fat or not, should be given rest for at least an hour in some place or shed near to the slaughter-house. Food should be withheld from them for the same period, but in no case longer than three hours. Water should, for drinking purposes, be always plentifully provided. The quality of a carcass is greatly reduced if the animal is slaughtered in a heated condition; the fat, when cold, appears of a bloody hue, caused by the presence of a quantity

of blood, which should be absent; and as blood is the first thing to become putrid the necessity of slaughtering cattle in a cool condition, and consequent thorough bleeding, is obvious. The flesh of a healthy and well-fed animal is of a bright colour and firm to the touch. The fat should be of a yellowish white, and without blood stains.

It is unnecessary to state that every animal slaughtered is not always of the primest quality; although such animals cannot be condemned as unfit for food. The lean flesh of such inferior beasts is pale and flabby, while the fat is of a bloody appearance. To improve the colour, bleeding is often resorted to. This is done by either cutting the tail or the large vein of the neck by means of a small circular blade inserted in a handle of steel. When the operator is satisfied that a sufficient quantity of blood has been drawn from the animal, the flow of blood is stopped by sewing up the wound. Although unlawful, it is a treatment that aged rams and ill-fed calves very often undergo. It is an old custom, and a very cruel one, causing unnecessary suffering to the animal, as there is strong reason to believe that this treatment is useless for the purpose to which it is intended. In the case of calves, a good meal of milk, given to them about an hour previously, will do all that can be done to whiten the flesh, and is, of course, the most humane treatment possible.

In slaughtering it should be the object of the butcher to cause as little suffering as possible to the animal. Much depends upon the skill of the operator in felling, especially in the use of the pole-axe. The pole-axe is an efficient instrument when skillfully used, but such skill is not always forthcoming in every butcher. There is, besides, a certain amount of danger accompanying the use of the pole-axe; should the animal not fall at the first blow, and the head rope be, perhaps, not too strong, the consequent struggles of the animal may result in its breaking loose, when, if it should turn "wild," the butcher and his assistants may expect a lively, and very often unpleasant time. This is the old method of felling, but we have now a very simple and effective instrument, namely, "Greener's Humane Killer," a bell-shaped apparatus, made so as to be held on the forehead of the animal by the hand, and in which is inserted a small bullet cartridge, which when discharged cause instantaneous death. It is by far the quickest method, as it does away with the necessity of pithing. The animal should be bled immediately it falls. This is done by partially cutting the large artery leading from the heart and lying just at the point of the lung cavity. The knife should not enter the cavity, as, in such case, a quantity of blood flows in and smears the inside parts. Beasts are also bled by cutting the throat from ear to ear; this is not a good plan, bleeding by the heart artery is by far the best and most effective for bullocks. Calves and sheep are treated in this form by the neck veins; this is done to prevent the necessity of trimming the shoulder parts, the extreme neck parts in the case of calves and sheep being of the least value.

In dressing, the skin should be taken off and offal taken out as quickly as possible for, in all weather, the sooner a carcass can get cold the better.

In wiping the carcass a cloth rung out of very hot water should be used. In no case should a quantity of cold water be used over a carcass, as it tends to give it a dull appearance and renders it more liable to get putrid if kept for a period. The following rules may be summed up as a guide to thorough slaughtering, viz.:—1. Proper rest for the animal; 2. Instantaneous death in felling; 3. Thorough bleeding; and 4. Quick despatch in dressing."

PREPARATIONS FROM MANIOC OR CASSAVA.

Manioc, the tuberous roots of *Manihot utilisima*, is generally consumed by the people of this country after cleaning and boiling, and few know of other and more wholesome preparations.

In order to prepare what is known as *Cassava meal*, the tubers, after having been washed, are divested of their dark coloured rind by being peeled with sharp knives. The peeled roots are then reduced to a coarse meal by being pressed against a rapidly-revolving wheel covered with a copper or tin grating surface, or they may be rubbed down to meal by means of a flat tin grater nailed on a board. In the latter case, however, the operation is very laborious, but still a large proportion of the Cassava meal made in the island of Dominica and elsewhere is prepared in this tedious way; the natives fix the large flat grater against a tub, and, leaning over it with tubers in each hand, they grate quickly and rhythmically to the sound of a drum, and it is said that they are encouraged to extra exertions by the stimulating influence of inspiring local songs, and more often than not by large portations of intoxicating drinks! The pulp which is produced is put into bags and pressed so as to force out the poisonous juice. The Indians of South America and Dominica do the pressing by means of curious baskets called "matapies." These baskets are made of plaited strips of the long smooth stems of a native plant closely allied to that producing arrowroot.

When empty the matapie is long and narrow, but when filled with the grated roots it becomes short and thick. It is then hung to the branch of a tree and heavy weights are attached to the lower end. The baskets then become longer, and by the constricting pressure most of the juice is forced out. Afterwards the meal is sifted by means of sieves, which separate the woody fibres and the small portions of the roots that have not been properly grated. The meal is then dried rapidly in large, shallow, flat iron pans set in masonry, with a flue passing underneath so as to conduct the heat from a wood-fire. The meal is spread thinly in the pan and constantly moved backwards and forwards with a wooden rake. The heat must not be so great as to brown the meal, the object being not to bake the product but to dry it. In the process of drying any remaining traces of the highly-poisonous juice are rapidly dissipated. "Cassava bread" is the name given to the thin round cakes made of the wet meal and dried on hot plates or on flat pieces of tin held over the fire.

Cassava starch is considered a very superior quality of starch, and as it can be made cheaply, it should prove a suitable occupation for the natives of this country. The method of preparation is very simple. The grated Cassava meal is stirred up with water, and then passed through sieves. This is done several times so as to wash the starch clean, and the mesh of the sieves is decreased in size after each working, so as to leave the starch free from any foreign substance. After the last washing the water is allowed to remain for a time, when the starch will settle at the bottom of the vessel. The clean fluid at the top is then drawn off or decanted, and the starch is dried in the sun.

Another preparation from manioc is what is familiar to all householders as *tapioca*. In describing the preparation of Cassava meal it will be remembered that the juice had to be forced out of the rasped roots by pressure. Now if this poisonous juice be allowed to settle, a considerable quantity of very fine starch will be deposited. The juice is poured off and the starch is heated on tin plates or in flat iron pans; the starch grains then swell up and burst and become agglutinated together, thus forming the tapioca of commerce, which is a large export from Brazil. The starch grains having been ruptured by the heat, they are partly soluble in water, and for this reason tapioca is especially valuable as food in cases of weak digestion.

There is still another product of manioc, and that is the substance known as *Cassareep*. The poisonous juice of the tubers of the bitter variety of Manioc, and which is invariably thrown away, is convertible into this substance which is of considerable value. The juice is simply boiled down until it becomes of the consistence and appearance of molasses. In this condition it is a powerful antiseptic, and it is capable of preserving all kinds of meal in a fresh condition for considerable periods. It is the basis of many celebrated sauces and of the well-known "pepper pot" of the West Indies. Thus by reason of the boiling process the poisonous juice is convertible into a wholesome food product, for which there is usually a ready sale in England and elsewhere. As the juice of the bitter Cassava contains so much of poisonous prussic acid, the greatest care must be taken to keep it away from children and animals. Many deaths have brought about by carelessness in the disposal of the juice, so that too great precaution cannot be taken to prevent accidents. It may be mentioned that the Indians of Guiana use the chillies known as "red pepper" steeped in rum as an antidote to the poison.

NOTES FROM A TRAVELLER'S DIARY.

So much has of late been talked about and written on the subject of agricultural education in this island, that I think it the duty of every one, who takes any interest in it, and who knows something about it, to express his views clearly on the subject, so as to keep the public well informed of the *pros* and *cons* of the question.

The Agriculturist, whether planter or "goyiya," has to direct his attention to the soil, and it is

necessary for him to know what is its nature before he sets to work to cultivate it. It is not my intention to write a treatise on soils, but anybody who is acquainted with what is taught about soils in text-books on Agriculture, will admit that all scientific facts regarding them, explained in as simple a manner as possible, will be of immense benefit and interest to those who have to do with the soil.

Again as Agriculture is the art of cultivating the soil so as to produce crops from the various plants of use to man, it is necessary for the cultivator to have a knowledge of all that concerns the life of a plant. Some knowledge of Botany, therefore, will also be of material benefit and interest to him. And so with other subjects allied to Agriculture, and which go to constitute a complete course of study as imparted in Agricultural Schools and Colleges.

Propagation of plants; climate as affecting the growth of various crops, manures, rotation of crops, drainage, irrigation, tillage operations, pruning, budding and grafting, treatment of cattle in health and disease. &c., are subjects about which the Agriculturist ought to know something. A knowledge of all these will at least enable him to go about with his eyes open, while the influence that he could exercise on the people among whom he moves, is from an educational point of view, incalculable.

Perhaps much of what I have said so far may appear to be out of place in dealing with the question of the Agricultural School of this island, which is at present engaging the serious attention of Government. So much ignorance, however, has recently been displayed even in the very first principles of Agricultural education by some of the leading men of the island, in whose hands the welfare of the people lies, that it is but right I think that the public should be given an idea of the kind of knowledge which is imparted under the subject of Agriculture.

The present agitation for the "mending or ending" of the Colombo School of Agriculture originated, as we all know, on a motion by the Hon. the Tamil Member of the Legislative Council, in which he wanted to make out that the Agricultural School was an unqualified failure, and that, therefore, it should be done away with. If I remember right, it was then mentioned that "English Agriculture" was of no use to this island, and that the natives knew more about the cultivation of coconuts and other crops than Englishmen. As instances it was mentioned that an Englishman once ordered his coconut trees to be washed with soap and water, and that an Agricultural student did not know the distance at which coconuts should be planted!

All these utterances were at the time considered to be amusing enough and merely put down to ignorance of the real state of affairs. Matters, however, have now turned serious, and from all that I could gather there are many others who are adopting the ideas of the Hon. the Tamil Member, and who are bent upon making an end of the School of

Agriculture. It must, however, be encouraging to those who are immediately concerned in the welfare of this useful institution, to know that we have a wise, shrewd and far-seeing ruler, who will not be easily led away by the crude ideas of others. H.E. the Governor, however, does not yet appear to have been informed of all that has been done by the Agricultural School. In his speech at the late Agri-Horticultural Show at Nuwara Eliya, His Excellency alluded to the School of Agriculture, and we were told that a Commission had been appointed to inquire whether the School should be "ended or mended." It is also satisfactory to find that His Excellency is convinced that some system of Agricultural education is necessary for this island, and such a system, he hopes, will be devised by the Commission.

I do not say that the Agricultural School has so far been altogether a success. There are many useful things which it might have done, and upon which I mean to comment later on. But it is at the same time incorrect and unfair to say that the School has altogether been a failure. It will then be of interest to inquire at this stage what the School has done so far, and to what extent it has been of benefit to this island.

We will begin with coconuts, as this product was prominently referred to in the Legislative Council by the Hon. the Tamil Member stating that the Agricultural students had not been taught how to plant them. It will be of interest to those concerned to learn that a very useful pamphlet on coconut plantation has been compiled in Sinhalese, and published some years ago by a student of the Colombo School of Agriculture. This pamphlet fully deals with the subject. I know personally that many a native planter has been greatly benefited by this little work. The Sinhalese press spoke very highly in its favour. The improved system of coconut cultivation at present noticeable in some parts of the island, especially in native gardens, is, I make bold to say, in a great measure the due to influence of the School of Agriculture. An alarm was raised in some quarters of the island some time ago that the coconut palm was attacked by a serious leaf disease which threatened to destroy it altogether. The School of Agriculture promptly came to the front on this occasion, and by careful investigation and publication of much useful information on the subject, soon dispelled all fear of any such possible calamity and gave an impetus to more liberal cultivation. One of the oldest and most experienced journalists of the day then wrote a leader on the "Progress of Agriculture," in which he highly complimented Mr. Green, the founder of the School of Agriculture.

"TRAVELLER."

INSECT PESTS. (Continued).

Insects are remarkable for the fecundity of each species as well as for the great number of species. If all the progeny from a single pair of almost any species of insect were allowed to survive long enough to procreate, but very few years would

elapse in a land before that particular species would quite exterminate itself with all that it fed upon, so immensely superabundant would it have become. The myriads upon myriads of locusts which overrun this country are known to all, and yet these locusts cannot be called remarkably prolific insects. The number of eggs they lay is small compared to the number laid by many other insects; at the most it is not over one hundred and fifty. The number of individuals which might arise from one aphid during the course of a single season is almost incalculable. It amounts to billions of billions, numbers entirely beyond human comprehension. If, according to Dr. J. A. Lintner, in speaking of the Hop Aphid (*Phorodon humili*), every individual should attain maturity and produce its full complement of young (which, however, can happily never occur in nature), we should have as the number in the twelfth brood alone, disregarding those of all the preceding broods (thirteen broods in one season have been observed) no less than 10,000,000,000,000,000,000 (ten sextillions) of individuals. Figures in a case like this fail to convey any adequate conception.

The writer quoted, to impress the enormity of the number, makes the following computation, using space and the velocity of light, which is about eleven and one-fifth million miles per minute as his measures: "Were the brood marshalled in line with ten individuals to the linear inch touching one another, the procession would extend to the sun (a space which light traverses in eight minutes) and beyond it to the nearest fixed star (traversed by light only in six years) and still onward in space beyond the most distant star that the strongest telescope may bring to our view, to a point so inconceivably remote that the light could only reach us from it in twenty-five hundred years!"

Aphides are small insects and an individual inflicts but an infinitely small drain on the sap of a plant. But when this drain is magnified a million times, the loss to the plant is sadly apparent. The number of aphides infesting a certain cherry tree, ten feet in height, was once estimated to be twelve millions, or more than seven times the total population of Cape Colony. The number which are often seen congregated on a single head of cabbage must be over one hundred thousand.

VORACITY AND DESTRUCTIVENESS OF INSECTS.

Not alone are insects remarkable for their incalculable numbers, but for their extraordinary voracity and rapid growth as well. Mr. L. Trouvelot, a French naturalist, in studying one of the silk worms (*Telea polyphemus*, Cram.) found that the larva when full grown weighed four thousand one hundred and forty times as much as it did when hatched from the egg; and that during its growth it had consumed food to the amount of eighty-six thousand times its original weight. If a man grew in a similar proportion, he would weigh twelve tons and consume two hundred and fifty tons of food. Another writer mentions a flesh-feeding larva which consumed two hundred times its weight in one day, and a certain caterpillar which increased in weight ten thousand times in thirty days. The losses incurred through the ravages of insects are

enormous. In 1893, the estimated losses to grain crops in the Cape caused by "locusts and other plagues" were nearly twenty per cent. of the harvest for mealies (Indian corn), about fourteen per cent. for wheat, and from seven to twelve per cent. in the case of other cereals. Some of this loss was due to diseases, but probably insects were responsible for a loss of at least ten per cent. of the total harvests, and for very much more in the case of mealies.

The annual loss through insect ravages in the United States is said to average one-tenth of the crops. Mr. B. D. Walsh, at one time State Entomologist of Illinois, thirty years ago estimated that insects annually inflicted a loss of no less than sixty million pounds sterling in the country, and subsequent writers think his estimate a moderate one. Most certainly these great losses to the agriculturist cannot be entirely checked, but to some extent they are preventable, and to this extent they should be prevented.

POTASH MANURES AND THE NEED FOR SPECIAL POTASH FERTILIZERS.

Many experiments may be quoted which show that active potash manures produce increase of crops on soils that already contain potash in plenty. Hence, though a deficiency in a soil necessarily points to its requirement in the manure, the presence of abundant potash in the soil by no means proves that potash manuring is unnecessary. Medium soils and clay soils may, in many cases, require potash manures, just as surely as light soils and peaty soils; and, without actual experiment, the assumption that potash manures are not required does not appear, in view of these experiments, to be warranted in regard to any soil.

And even in soils where farmyard manure has been liberally applied, there is no sufficient ground for assuming that artificial potash manures, in readily available forms, may not be applied with advantage.

In the popular assumption that potash manures are not required on clay soils, the fact has been overlooked that the nature of the manure required is determined in much greater degree by the kind of crop grown than by the character of the soil. All kinds of ordinary soils possess, in greater or less measure, the chemical constitution and physical characters that are required for the growth of any crops that are suitable to the existing conditions of climate. But it has been proved by numerous practical experiments and observations that crops differ greatly in their power of utilizing the several constituents contained in the soil. Some crops have a difficulty, in most soils, in providing themselves with enough nitrogen, some in providing themselves with enough phosphoric acid; others are unable to obtain sufficient potash. It follows that the substance which plants take up influence and produces the greatest increase of yield when applied to them in readily available forms in manure.

There are various sources from which the soil may be replenished and the crops provided with potash. In the first place there is farmyard manure produced by the consumption of cakes and other foods rich in potash. Were the supply of

potash from this source abundant enough and cheap enough, none other would be required. But great as is the total quantity of farmyard manure that is available, it is not adequate for the purpose. The straw or litter which is generally associated with cattle manure contains a considerable percentage of mineral food. The ash ingredients in straw amount to about 5 per cent or about 112 lbs. per ton, of which 15 to 30 per cent is potash. Taking the mean of a very large number of analyses of farmyard manure, it may be said that in the ash of well-rotted dung, the amount of potash is from 5 to 7 per cent, that is, one ton of manure contains only from 9 to 15 lbs. of potash. Heiden calculates that 25 tons of farmyard manure would not suffice to restore the potash removed by an ordinary rotation of crops sold off the land, even if every ounce of potash in the manure were to find its way into the roots of the crops, which is not possible. More probably nearly double that quantity would be required to make good the loss. It is hardly necessary to say that so large an application of manure is very rarely customary, and that in general farming practice there is a large deficit to be made good by the application of artificial manures. This is especially the case in this country where litter, which supplies the bulk of the potash of farmyard manure, is practically entirely absent, and where the manure generally purchased has, as a rule, suffered much from exposure to sun and rain.

Moreover, on many soils and especially on light sandy and on peaty soils, the policy of an enlightened management would aim beyond the mere restoration to the soil of the potash removed by the produce of the land carried off it. As they are always deficient in potash, it is a necessary condition of good cultivation, if any steps towards their improvement are to be taken, to endeavour to enrich them by adding to their deficient stock of phosphoric acid and potash. For such a purpose applications of farmyard manure alone are insufficient.

The chief commercial manures which are sources of potash are kainit, chloride of potash, and sulphate of potash. We shall refer to these and give full details regarding composition, price, &c., in our next, but in the meantime would wish to refer to the use of potash manures as a means of enriching cultivated soils in another sense.

A very important aspect of potash manuring is that connected with the growth of certain leguminous crops, and their method of obtaining nitrogen. It is only within the last few years that the very important discovery has been made that certain kinds of plants are able to draw upon the air for their stock of nitrogen. Hence, a very cheap way of manuring land with nitrogen is to grow such crops, and then plough them in, so that the nitrogen they obtain from the air in the course of their growth may be added to the soil, and thus furnish a store of nitrogen for other plants which do not possess this property. Such plants, however, in order to grow luxuriantly, require to be well supplied with the two mineral ingredients, potash and phosphoric acid. To manure such crops with costly nitrogenous manures is simply to waste money, and to neglect one of the best means at our command of enriching the soil in nitrogen. The growth of leguminous crops, therefore, is a valuable

means of manuring the soil with nitrogen. The more the growth of these nitrogen-collecting crops is promoted, by the application of liberal quantities of potash and phosphatic manures, the greater will be the quantity of nitrogen drawn from the air.

It was on this principle that the famous experiments of Dr. Schultz-Lupitz in Germany were based. He grew leguminous crops on light soils, and, by a liberal application of potash and phosphates, he enriched the soils not only in these minerals, but also in the nitrogen collected by the crops from the air, and thus succeeded in converting poor and barren soils into soils of fine fertility, capable of growing very good crops of suitable kinds.

It would be difficult to exaggerate the importance of this discovery for the future of agriculture. It is well known that what is called the "condition" of soils, or their capacity for growing large crops, is in very great measure dependent on the amount of nitrogen they contain. No substance in soils is more generally deficient, and none is more easily exhausted. While mineral substances such as potash and phosphoric acid are firmly held by soils, nitrogen, in the form of nitrates, is washed largely into the drains every winter. In all regularly cropped soils, unless heavily manured, the nitrogen suffers a steady decline, and the soil becomes constantly less productive. The nitrogen can of course be restored by frequent and abundant manuring, but this can only be done at a great expense. No other manurial substance costs so much as nitrogen, and none is so apt to be wasted in the application; hence enormous sums are paid every year for nitrate of soda, sulphate of ammonia, and other manures intended to supply the soil with nitrogen. But it has now been shown that the nitrogen in soils can be very largely increased without any such expenditure. The growth of suitable leguminous crops, such as clovers and vetches, is a certain means to that end. These crops can be grown successfully on most soils without nitrogenous manures, provided they be supplied with abundant potash and phosphoric acid. Large crops can thus be obtained, and whether they be consumed on the land or cut and removed from it, the root residue left in the fields enriches the surface soil so much in nitrogen that its fertility and productive capacity are greatly increased. The effect of the growth of a good crop of clover in promoting the subsequent growth of a large crop of wheat has been long known, Schultz-Lupitz has clearly shown that the same principle may be applied not only to assist the growth of one particular crop, but also to raise more permanently the condition of the soil, and thus to convert worthless soil into fruitful fields. The use, therefore, of potash and phosphatic manures applied to the clover and vetch is not only the production of an increase of these crops, it is also a means of adding, without further expense in manures, a large addition of nitrogen to the soil in the valuable form of an accumulation of organic matter capable in great part of rapid decay, and thus of accumulating such a store of fertility as will result in the subsequent production of large crops.

FRUIT CULTURE.

[The Department of Agriculture of Cape Colony has lately issued a "Manual of Practical Orchard Work" by P. MacOwen and Eustace Pillans. The subject of fruit culture is most admirably treated of in this little work, and, as we consider (what everyone will readily admit) that there is a great deal of ignorance of what may be called the first principles of fruit culture in this country, we have compiled a paper on the subject from the Manual referred to, and have no doubt that many landowners will be thankful for the valuable information which we are able to offer them.—ED. A.M.]

The Artificial Character of Modern Fruit Trees.

1. Cultivation implies, first, a previous knowledge of the nature and constitution of the living being we propose to care for, and secondly, a previous knowledge of the soil and atmosphere in which it holds its dual life. It is only by such preknowledge that the cultivator can suit the conditions of growth to the wants of the thing to be grown, and thus place it in the best possible position for fulfilling the history of its life. Nothing short of this work, done of set purpose and as the outcome of exact knowledge, can be called *cultivation*.

2. But it is something more than this. It is not enough to reproduce plants in the precise form in which they exist in nature. Firstly, the cultivator, for his own benefit, aims at guiding and controlling the growth of certain plants so as to make them develop very differently from their normal original condition. Thus in one plant he endeavours to obtain seeds of large size and bland taste, in another the effort is to do away with seeds as far as possible and produce a large succulent fruit, in others, shortening of the axial growth, and great enlargement of the leaves is aimed at. The plant then with certain limits is, like clay in the hands of the potter, capable of being remodelled, by causing this or that organ to take on an excessive and unusual development, without at the same time interfering with the balance of functions necessary for its general health. This complex art is one great part of *cultivation*. To practise it with success obviously demands something more than the loose, popular notions of plant-life, which are picked up without special study or thought, or come by imitating the traditional methods of our neighbours.

3. Secondly.—For many hundreds of years a close watch has been kept upon the seedlings arising in the reproduction of all cultivated plants. Whenever a sport or other chance variation has appeared, presenting characters of a desirable kind, the gardener has quickly to detect it, and to give it permanence by such methods as budding and grafting which are unfortunately almost unknown in Ceylon. And this continual watchfulness, awaiting the chance of betterment by natural variation has produced the kinds of fruits approved and cultivated all over the world, so that in fruit culture as with all knowledge, we are today the heirs of countless benefactors who have preceded us and handed down to us their best results. It must, therefore, be always borne in mind that the objects of our culture are distinctly artificial products obtained by centuries of selection and variation, and do not exist as natural forms of vegetation, nor can they put up with the conditions that suffice for the latter. As soon as skilled care ceases they cannot escape deterioration

and ultimately dying out. And this indispensable skilled care is orchard work or fruit culture—a special branch of cultivation which requires a special knowledge of principles and practice.

(To be continued.)

DR. KOCH'S RINDERPEST CURE.

The following is a reprint of a report (for which we are indebted to the *Agricultural Journal* published by the Department of Agriculture of the Cape of Good Hope) by Mr. Otto Henning, who assisted Dr. Koch during his investigations into rinderpest. Mr. Henning has lost no time in ascertaining the proper method of applying Dr. Koch's system of inoculation, and his report gives a very clear idea of the manner of operating, and we are sure our readers will be glad of the information with which we are able to supply them:—

Inoculation.—When rinderpest breaks out amongst a herd, the best plan is to inoculate with the bile at once.

Description of Inoculation.—The bile must be taken from an animal that has suffered severely or died from rinderpest. The latter is better, but then the bile should be taken as soon as the animal dies, and, above all, before decomposition has set in.

Removal of the Bile.—To remove the bile the animal must be laid on its left side. Afterwards the skin and flesh along the left side must be cut through with a clean, sharp knife. A man sitting across the chest of the animal must now hold and raise the ribs with his right hand. By doing this the gall bladder, which is located immediately under the right ribs, becomes visible. After this the same man must, with his left hand (which must be clean), take hold of the gall-bladder at the bottom and raise it slightly.

A second man, with a small clean knife in his right hand, and in his left a clean cup or glass, now removes the bile in the following manner: Putting the cup against the gall-bladder, let a small incision be made with the knife, so that the fluid can flow into the receptacle. Great care must be taken that no blood or yellow water, that may perhaps be among the diseased intestines, runs along with the bile. The man who cuts through the skin and flesh to get at the bladder must also take care that he does not cut into the stomach or intestines, otherwise the fluid in the gall-bladder will become unfit for use.

Bile suitable for inoculation should be dark or dark-green, and must not have an offensive smell. Yellow or dark-brown bile, and which contains shreds of the gall-bladder, is poisonous and unsuitable. Bile which gets mixed with the intestines on removal can naturally not be used.

The quantity of bile necessary for inoculation is 10 cubic centimetres—that is, one-third of an ounce, or about a third of a tablespoonful. If less than this quantity is used the result is uncertain.

The following day there is a swelling on the spot where the injection has taken place, which gradually disappears in the course of a week or two. This is sometimes bigger than a man's fist.

Sores only occur when the hands or instruments of the operators are dirty, or when the bile smells badly.

The quantity necessary to inoculate a beast effectively being so great, syringes must be used. And, therefore, I am sorry to say that these must be first imported. The Free State Government has cabled to Germany for some thousands, and their arrival will immediately be made known, so that farmers can carry out the inoculation in the proper manner.

How to Make the Injection.—The animal must be thrown upon the ground and its legs tied. The best place to inject is between the front legs, as there the skin is thin and loose.

The syringe is filled with gall, and the needle is then stuck deep into the skin, so that the point lies loosely between the skin and the flesh. The bile is then slowly injected and the hole made by the needle pressed together by the thumb and second finger of the left hand. The needle is then withdrawn and the fluid under the skin well rubbed in, so that it cannot escape through the incision in the skin, which would make the inoculation ineffective.

I have to add that this mode of inoculation will only prove effective in the case of animals which have not yet had the disease. It is useless for infected animals.

Professor Koch has not yet concluded his experiments, and he hopes in about a month's time to make known other methods of salting animals. By that time syringes will probably have arrived, and it will afford me much pleasure to prepare the inoculating fluid and personally instruct farmers how to use it.

N.B.—It is of great importance that all sick animals, whether they show symptoms of infection before or after inoculation, shall be immediately isolated from healthy animals, as animals inoculated with the bile are not immune until after about ten days.

SOME CROP NOTES.

Tobacco.—There is no crop grown which varies so much in quality, because of the soil upon which it is grown and the fertilizers used, as tobacco. For a leaf of high quality for smoking purposes it is essential that the soil be light and rich in vegetable matter. A low, rich clayey soil will produce a rank and heavy crop, but will not produce tobacco of fine quality. The fine gold-leaf tobacco of North Carolina, so highly prized for cigarettes, is grown upon a light gravelly soil. A red clay produces sometimes a fine, rich mahogany-coloured leaf of high value. Limestone soils, too, will produce tobacco of high grade.

The heaviest crops, though not the highest in quality, are grown after a leguminous crop such as beans. The next year with proper fertilizing the same land will bring a crop of higher value. Potash is of the utmost importance to tobacco, which consumes large quantities of it; but in order to obtain a leaf that will burn well, all the forms of potash salts which contain chlorine, such as the muriate (chloride) and kainit, must be avoided. The sulphate of potash is the form in which potash should be provided. Stable manure is preferably applied to the crop preceding tobacco, rather than directly to the latter. The most suitable fertilizer for tobacco should contain of available phosphoric acid, 7 per cent; potash,

10 per cent; nitrogen $3\frac{1}{2}$ per cent. The use of dried blood manure upon tobacco has given very profitable results.

As most tobacco is used for smoking purposes, the chief aim of the grower is to obtain a leaf with good burning qualities. Heavy loam—clay or peat soils will not do this. This plant being of tropical origin, a warm soil is essential, and one with but moderate quantities of organic matter produces the leaf of finest texture. Rank organic manures, tankage, fish, &c., must be avoided, as well as all materials containing chlorine.

GENERAL ITEMS.

The *Gazette of India* contains a series of lengthy Resolutions dealing with the recommendations of the Agricultural Conferences held in 1893 and in 1895-96. One of these—the sixth deals with the subject of agricultural education in country schools. For the present the Government of India consider the following conclusion to be justified by the discussions which have been held:— (1) That agricultural degrees, diplomas, or certificates should be placed on the same footing as corresponding literary or science degrees, etc., in qualifying for admission to Government appointments, and more particularly those connected with land-revenue administration; (2) that there should be not more than four institutions giving a high-class diploma, *viz.*, at Madras, Calcutta, Bombay, and some places in the North-Western Provinces, and that these should be utilized by other provinces; (3) that the diploma should eventually be compulsory in the case of certain appointments. *e.g.*, agricultural teachers at training schools, assistants to the Director of Agriculture, etc.; (4) that the practical instruction of candidates for certain subordinate appointments at a school-class or an experimental farm should be further considered; (5) that the special school course leading up to the agricultural diploma, degree or certificate, is required; (6) that the practice of allowing school-masters either before or after appointment to pass through a course of a few months on a Government farm is one which deserves consideration.

The Department of Land Records and Agriculture in the North-West Provinces and Oudh have issued a bulletin on a new method of tree planting, in which it is advised that when one to two year-old trees are planted out, the roots should be cut back to stubs about an inch long, and the trunk pruned to a branchless whip of from one to three feet high. It is said that by this system the roots grow directly downwards and avoid the drought which is so disastrous to young plants when planted out in the ordinary method. It is directed that the roots be cut cleanly in a horizontal plane, a hole two inches in diameter be drilled in the ground and the earth trampled close round it. Experiments at the Botanical Gardens, Saharanpore, have proved that the new system answers admirably for fruit trees, such as the apple, pear, vine, peach, and plum, provided they are operated on *when dormant*. It is not recommended for ever-green fruit trees, such as mangoes, leechis, oranges, loquats, etc.

The attention that is paid at Birmingham to the encouragement of the art of preserving eggs is as commendable as the methods for attaining the end in view are various and peculiar.

This year the winning collection had been simply wiped over with white of egg, and marvellously sweet and fresh their yolks and whites looked, considering that they had reposed at Bingley Hall since August 1st. Twelve months ago the prize dozen had only been rubbed with butter, wrapped in paper, and packed in lime, such processes being simplicity itself and proving conclusively that the disagreeable methods of coating the shell with olive oil and with beeswax are superfluous and unnecessary. It may be added that the second prize collection this year was merely coated with white of egg and packed in flour.

Lord Arthur Cecil writes as follows in the *Live Stock Journal Almanac* for 1897 with reference to the shoeing of horses:—

First of all, then, the one golden law to be observed is that nothing whatever should be cut or rasped from the under surface of the healthy foot, beyond the loose flaps which occasionally become detached from the frog. In a contracted or unhealthy foot it may be necessary occasionally to open the heels a little, but the less this is done the better.

Secondly, the whole of the surface of the bottom of the wall of the foot should be protected by iron, though the heels should have room to expand. Nothing, in my opinion, is so injurious to the foot as too closely-fitting shoes.

Lastly, as regards shoeing, it is a mistake to suppose that the knife or rasp should *never* be applied anywhere. Horses' feet do not all grow exactly rightly—owing, I believe, to over-civilisation—and each foot requires individual study in rasping or paring round the edges to reproduce the wonderful equality and rotundity of the natural foot, which generations of domestication have as much lost as human finger-nails must have altered from talons.

The *Veterinary Journal* referring to rinderpest wrote lately as follows:—

"Various observers have stated that they have discovered organisms which they consider the cause of the disease. Semner describes a streptococcus liquefying gelatine; Metchnikoff, a short bacillus with rounded ends, found in the intestinal ulcers and in the blood; Laweljeff, spore-bearing bacilli, which in cultures are transformed into isolated micrococci or arranged in chains, and he states that inoculation with these cultures induced rinderpest. Dr. Lionel Beale described a granular matter, which he considered to be living particles—germinal matter. He also thought that they constituted the morbid poison. But up to the present time there is no unanimity amongst observers as to what kind of microbe is the pathogenic one; we must, however, conclude that the disease is of a microbic origin, and, as in some other diseases, that an anti-toxin or antitoxin may be discovered. Let us hope that Prof. Koch will succeed in making this discovery, and thus gain the farther admiration of the scientific world."

Since this was written Dr. Koch's discovery has been made.

The following is the Constitution of the Department of Agriculture, Queensland, which no one will dare say is undermanned:—

Minister of Agriculture ...	The Hon. A. J. Thynne,
	M. L. C.
Under-Secretary in Agriculture	... P. M'Lean.

Instructor	..	E. M. Shelton, B.Sc.
Colonial Botanist	...	F. M. Bailey, F.L.S.
Government Entomologist		Henry Tryon.
Ornator, Botanical Gardens	...	Philip MacMahon.
Overseers of Nurseries	...	E. Cowley and D. Buchanan.
Fruit Expert	...	A. H. Benson.
Chief Clerk	...	Ernest Scriven.
Chief Inspector of Stock and Registrar of Brands	...	P. R. Gordon.
Deputy do	...	J. E. de Villers.
Director of Stock Institute and Government Bacteriologist	...	C. J. Pound, F.R.M.S.
Veterinary Inspector	...	W. C. Quinzel, M.R.C.V.S.

The strength of the Victoria Regia has been demonstrated by the fact that it has borne the infant son of Lord and Lady Leamington, who has been photographed while sitting on a leaf of this giant lily, the diameter of which was found by measurement to be 4 ft. 6 in. Another child photographed in the same position was found to weigh 51 lbs.

It is a popular idea that the seeds of many plants pass unharmed through the digestive canal

of birds, and, being voided with the excrements, reach the ground in a peculiarly favourable condition for germination; and this is generally believed to be especially the case of the mistletoe, the seeds, in this case, being deposited on the branches of the tree on which the mistletoe is parasitic. In a paper contributed to the *Transactions* of the Linnean Society, Mr. F. W. Keeble shows that this is at all events not universally the case with the *Loranthaceae*, especially with the Cingalese species of *Loranthus*. The species of this genus with tubular flowers which are natives of Ceylon are ornithophilous (visited by birds, the bird most effective in their pollination being a honey-bird, a species of *Nectarinia*). In the large-flowered species, the buds remain closed; but, when tapped, the corolla-lobes fly open with an explosion, and the pollen is scattered. The closing of the flower-buds appears to serve the purpose of protecting the pollen against rain, while the violent expulsion of the pollen aids in its carriage by the visiting birds, their beaks being frequently found to be covered with pollen after visiting the flowers. When the fruit is ripe, the bird eats the succulent portion only, wiping out the seeds with its beak on to a branch of the tree, to which they thus become attached by their viscid coating. If swallowed, the seeds are found to be digested and destroyed. —*Nature*.

AT NO. 19, BAILLIE STREET, FORT, COLOMBO.

OVERLAND CEYLON OBSERVER

This popular weekly "resume" of Ceylon News gives regularly full Commercial Intelligence regarding the conditions and prospects of Ceylon Produce and Estate Crops, as well as all the Island news of general interest.

Those having Ceylon interests and Ceylon people going home generally order the Overland "Ceylon Observer" to keep themselves "au courant" with what transpires in the Island.

PUBLISHED WEEKLY

AT NO. 19, BAILLIE STREET, FORT, COLOMBO.

THE MOST COMPLETE WORK OF ITS KIND PUBLISHED.

FERGUSON'S
CEYLON HANDBOOK AND DIRECTORY

OF

Mercantile, Planting and General Information.

THE ATTENTION OF BUSINESS MEN OF ALL KINDS is called to the unrivalled advertising advantages offered in this publication, which is not only PLANTERS' VADE-MECUM but the MOST COMPLETE BOOK OF REFERENCE for everyone engaged in Ceylon trade. As no Business Establishment in Ceylon, House doing business with Ceylon, or large Estates can afford to be without it, the advantages of advertising in the Directory are obvious.
