— WE learn that the HORTICULTURAL COLLEGE AT SWANLEY, which has already had a practical recognition by Government in the form of a small grant of money, has now received more substantial help from the Kent County Council. After close and careful inquiry it has been determined to devote annually a sum of £2400 of the money provided for technical education for the benefit of the college in the form of fifteen scholarships at £60, tenable for two years, and ten others at £30 per annum. These scholarships are to be open to pupils or past pupils in elementary schools, teachers, and youths whose parents are in receipt of an income not exceeding £400 a year. Of course this is not all gain to the College, since the holders of these scholarships have to be trained, boarded, and lodged. But it is hoped that it will give a sufficient lift to this Institution to start it on a course of prosperity and usefulness. It has hitherto been going on a joint-stock basis, but the help of the County Council will permit of the College being reconstituted, and the commercial element being eliminated. The Council, we understand, is to be represented on the Governing Body, so that the College is not only now receiving the recognition and pecuniary assistance of the public, but is to an important extent under public control.

— THE LACQUER TREE, RHUS VERNICIFERA.—It is stated that sixteen years ago, Professor Rein, the well-known authority on Japanese art and industry, planted in the Botanical Garden at Frankfort some specimens of the Lacquer Tree (*Rhus vernicifera*), from which the Japanese obtain the juice employed in the production of their famous lacquer-work. There are now at Frankfort thirty-four healthy specimens of the Lacquer Tree, 30 feet high and 2 feet in girth 1 yard from the ground; and the young trees, which have sprung from the original tree's seed, are in a flourishing condition. It seems to be proved, therefore, that the Lacquer Tree is capable of being cultivated in Europe, and it only remains to be seen whether the juice is affected by the changed conditions. To ascertain this, Professor Rein has tapped the Frankfort trees, and has sent some of the juice to Japan, where it will be used by Japanese artists in lacquer-work, who will report on its fitness for lacquering. In the meantime, some of the most eminent German chemists are analysing samples of the juice taken from the trees at Frankfort, and samples of the juice sent from Japan; and should their reports and the reports from Japan be favourable, it is probable that the tree will be largely planted in public parks and other places in Germany. In course of time a skilled worker in lacquer would be brought over from Japan to teach a selected number of workmen the art of lacquering wood, and in this way it is hoped that a new art and craft may be introduced into Europe. Professor Rein has been conferring with the authorities at Kew as to the results of his experiment.—B.

— SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, 56 feet above mean sea level, October.—Mean temperature of month, 48.5°. Maximum on the 4th, 61.4°; minimum on the 31st, 27°. Maximum in the sun on the 4th, 107.4°; minimum on the grass on the 31st, 21.2°. Mean temperature of the air at 9 A.M., 48.8°. Mean temperature of the soil 1 foot deep, 50.5°. Nights below 32°, in shade four, on grass fifteen. Total sunshine, eight-three hours, or 26 per cent. of possible duration. We had five sunless days. Total rainfall, 3.70 inches. Maximum fall in twenty-four hours on the 6th, 0.98 inch. Rain fell on nineteen days. Average velocity of wind, 10.2 miles per hour. Velocity exceeded 400 miles on six days, and fell short of 100 miles on six days. Approximate averages for October:—Mean temperature, 48.2°. Sunshine, eighty-three hours. Rainfall, 2.84 inches. The first three weeks were wet and stormy, the last week fine and dry. Temperature and sunshine about the average.—JOSEPH MALLENDER.

— THE CROFT ANGRY APPLE.—Mr. G. W. Cummins, The Grange Gardens, Carshalton, writes: "I think if you could publish the enclosed it would bring out some interesting discussion from your Scotch readers. Miss MacKnight sent Apples of the variety to our Conference last week, and Mr. Barron remarked that at the Apple Congress in 1883 fruit under the name of 'Croft Angry' was exhibited by Mr. Fairgrieve of Dunkeld, and was considered by the Committee to be the same as Dutch Mignonne, but the one sent to us was quite distinct, being small and flat with a large open eye."

The communication referred to is as follows:—"Its Scotch name—Croft Angry—is a corruption of 'Croft-an-Righ' (the King's Meadow) in old Gaelic or Norse (which was spoken in Galloway up to 'the Union,' 1707). The Croft-an-Righ was meadow lands given 1160 by order of David I. (of Scots) to the Church; whereon Fergus, his Governor of Galloway, built at Wigtown a Priory of White Friars. (Monks of the Primontrentian Order followed agriculture and gardening as a part of their religious life.) The wig (or bay) on Sulbach's Sea—now the Solway—was mild and fertile, and within a short distance of Whithorn—the Candida Casa of the Romans, where St. Ninian of Galloway built the first stone building for Christian worship in Britain. 1267 Devorna Gilla, descended from Fergus, and daughter of Alan of Galloway and also the mother of John Baliol, King of Scots, built Sweet Heart Abbey. Both there and at Dundreman Abbey (benefited by Alan) this Apple was grown and called by this name. These two Apples are from a tree, 40 to 50 feet high, in the garden at Beechwood, Wigtown, N.B. The tree was planted by John Simson, Esq., a great gardener, at least sixty years ago, and was known to be a true graft of an old tree believed to be grafts of the original stock. By Galloway tradition this Croft Angry is called the first Apple known in Scotland. Owing to the storm on October 13th the fruit is pulled too early, and is bruised. The tree was well laden with such Apples as these, none larger nor many less. It ought to hang to November, be golden in hue when ripe, and keep till after Candlemas."

— "ALL the world has agreed," said Downing in his *Horticulturist* some forty-five years ago, "that there is nothing more perfect of its kind than the RURAL ARCHITECTURE OF ENGLAND. The cottages of that country are as widely different in effect from those of any other as the Anglo-Saxon race differs from all else, civilised or barbarous. What this difference consists in there are, perhaps, few who take the trouble to analyse. Many persons suppose it to lie in pointed gables and high roofs. Still, these were not originally English, but were borrowed from Flanders, yet the Flemish cottages have little or none of the peculiar beauty which charms us in those of England. Others have imagined that it is something especially becoming in the features of the English landscape itself. Yet this can hardly be true, since we have seen faithful copies of the English cottage built in this country in equally picturesque scenery without producing upon the mind the same impressions as the original edifice. The secret charm of the English cottage lies, we imagine, in its home-expression and its rurality. . . . The English cottage, even of the humblest class, is surrounded by trees, embowered in vines and creepers, and hedged about with shrubs to a degree quite unknown in any other country. The love of trees and flowers is a universal passion in that country, and man, woman, and child, among the cottagers, take an especial pride in the green adornments of their home. Sips and roots find their way from the pleasure grounds of the nobleman's mansion to the humble garden of the cottage; and there is a personal and individual care bestowed upon them, even by those who have scarcely any other of the refinements of life, that neither the people of the Continent nor of this country have as yet any positive share of. The effect of all this taste is to spread a beautiful drapery about the rural cottages of England that renders what would otherwise be scarcely more than rude cabins little gems of rural and picturesque beauty. Indeed, strip most of the loveliest cottages of England of their sylvan and floral enrichment and they would absolutely lose their whole power of charming."

— FRUIT CULTURE IN TRINIDAD.—From an advance copy of Sir William Robinson's Report to the Colonial Office on the colony of Trinidad, we are able to give some details of fruit growing in that island. The Governor is able to report that this industry, which he foresees will be of incalculable benefit to the colony, and which he has spared no endeavour to promote, has at length commenced to show some encouraging results. The Central Agricultural Board, a most useful and influential Association, has energetically worked with His Excellency in this object, and has been the means of stimulating enterprise and spreading valuable information throughout the length and breadth of the island by its discussions and publications. It was in the spring of 1889 that small shipments of fruit, chiefly Oranges and Bananas, were first made to the American markets by the newly subsidised line of steamers. These shipments were necessarily of an experimental character, and produced very varying results, some fruit fetching fair prices, and others being sold at a loss. This, however, is not difficult to account for. The shipments were of a spasmodic character, and the processes of packing and picking, which demand the greatest care, were but little understood. The first operations, too, were commenced at a rather unfavourable period of the year, in which Trinidad fruit had to compete with that from other well-known fruit growing countries where the requirements of the market were thoroughly understood, and it is not surprising, therefore, that the pioneers of the new industry were somewhat disheartened at the results obtained. The Central Agricultural Board and its agents, however, urged the people to persevere, and in the opinion of Sir William Robinson the industry may now be considered to be firmly established. The principal exports have consisted of Oranges, Limes, and Bananas. Experiments have been made with other products, but not with satisfactory results. Five thousand two hundred crates of Oranges were shipped in the four months ended December 31st, 1890, which constituted the season for that year. Two larger plantations were started during the year, and numerous smaller ones. A notice written by the Governor calling attention to the advantages of this industry was extensively circulated throughout the colony in English, Spanish, French, and Hindustani. Trinidad Limes were first placed on the New York market in 1889. These did fairly well, and in 1890 there was a considerable increase in the shipments. Several abandoned Lime plantations have been reclaimed, and the exports of this product will, no doubt, increase rapidly, as it has been discovered that they can compete favourably with Sicilian Lemons. The shipments of Bananas have considerably fallen off in 1890 as compared with 1889. The fruit spoils very quickly, and it has been found that small quantities cannot receive the special

care and attention which they require. Large areas are, however, being planted up with Bananas, but the excessive rainfall of 1890 has somewhat retarded operations. Dried Bananas have been placed on the Canadian and American markets with the most encouraging results.—(*The Times*).

## GLOUCESTER ROOT, FRUIT, AND CHRYSANTHEMUM SHOW.

NOVEMBER 9TH AND 10TH.

THIS Society held their annual Exhibition in the Corn Exchange, Gloucester, on the above dates, and was a thorough success in every way. The prize list for fruit is an extensive one, and the large quantity of excellent fruit staged on long tables reaching the whole length of the large hall made a very imposing display. Potatoes, also, were of extraordinary merit; in fact, roots and tubers of all descriptions were good. Groups of Chrysanthemums made an attractive change from the other portions of the Show.

Grapes were in fine form, C. Lee Campbell, Esq. (Mr. S. T. Wright, gardener), Glewston Court, Ross, being first with perfect Alieante extra good in size of bunch, berry, and colour, Mrs. Gambier Parry (Mr. Sowray, gardener) being a good second with the same variety. The latter exhibitor was first in the white class with fine Muscat of Alexandria, Mr. J. H. Jones, Churchdown, second with the same kind not up in colour. For twenty-four dishes of Apples (prize given by Mr. J. Watkins), Mr. C. Lee Campbell was a good first, Mrs. Gambier Parry, Highnam Court, Gloucester, second. For collection of dessert, The English Fruit and Rose Co. (Cranston's) were first with an extensive display of fine fruit, the most notable being Winter Peach, Worcester Pearmain, Duchess of Gloucester, Yellow Ingestrie, Gascoigne's Seedling, Cheshunt Pippin, Crimson Queen, Col. Vaughan, and many others. Mr. C. Lee Campbell came second with fine fruits, but less in number than the first. In the single dish classes Mr. C. Lee Campbell was first with Ashmead's Kernel, Ribston Pippin, and King of the Pippins. For a collection of culinary Apples The English Fruit and Rose Co. was first, the following being fine, Peasgood Nonesuch, Tom Putt, Lady Henniker, Mère de Ménage, Striped Beefing, Herefordshire Beefing, Bismarck, The Queen, Loddington, &c., Mr. C. Lee Campbell being a very close second, having large well coloured fruit. For a collection of Pears, Mr. J. Watkins, Withington, Hereford, had one of the finest lots staged this year, the fruit being very large and finely coloured. Amongst many others the following were conspicuous—Chaumontel, Maréchal de Cour, Marie Louise, Forelle, Napoléon, Van Mons, Léon Leclerc, Doyenné du Comice, Bergamotte Dussart, Glou Morceau, Easter Beurré, &c., Mr. C. Lee Campbell being second with a smaller lot. For a collection of cider Apples, Mr. J. Watkins was first with exceedingly highly coloured fruits. This exhibitor brought a large collection of Apples not for competition, but the space available would not allow of its being staged.

Groups of Chrysanthemums covering 50 square feet were very good, Mrs. Gambier Parry being first with a remarkably fine well-arranged group; Dr. Needham, Barnwood House, Gloucester, coming second, and Messrs. Roberts & Starr third. For twenty-four blooms, Japanese and incurved, the most successful exhibitors were Mr. W. Gammidge, Greville House, Gloucester, and Messrs. Roberts & Starr. For twelve blooms Mrs. Gambier Parry and Mr. W. Martin, Norton Court, Gloucester, were the chief prizewinners. For Anemones, Mr. C. Lee Campbell was accorded first honours, the blooms in each class being of fair size and fresh.

A good deal of attention was directed to a large case of dried fruits by the process of evaporation. The fruit was arranged tastefully in divisions, and consisted of Prune Damsons, whole Apples, conserved Apples, Apple rings, Pears, Plums, &c., also samples cooked; in either state they were good. The whole were done by Mr. W. A. Trotter, gardener to F. Ricardo, Esq., Bromsberrow Place, Ledbury, and open a new field for preserving fruit, as Apples may be done at a cost of 5d. per bushel; Plums also at a similar rate, and they would compare very favourably with any of the dried fruits we get from abroad.

## THE KENT COUNTY SHOW OF FARM FRUIT, MAIDSTONE.—NOVEMBER 10TH AND 11TH.

THIS comparatively young Society held its third annual Exhibition of hardy fruit in the Corn Exchange on the above date, and is, it is gratifying to note, giving substantial proof of its usefulness in the development of the love of fruit culture amongst farmers, &c., from the fact that the entries of the present year increased something like 560 per cent.; and that of the high-class exhibits, which were truly remarkable for uniformity, size, and colour, Apples especially in every class being excellent, and Pears not one whit behind. The Committee and Hon. Secretaries, Mr. Seymour and Mr. T. Frost, who are most painstaking and courteous to all, may be highly congratulated on their success, and the Society is certainly deserving of the strongest support.

The only class open to landowners, their gardeners, and nurserymen was for the best twenty-four dishes, open-air grown, and here several of the Palace prizewinners again tested their strength; but the superb examples exhibited by Roger Leigh, Esq., Barham Court (gardener,

Mr. Woodward), easily secured the premier position, every fruit being without spot or blemish, and of immense size. The Apples were Peasgood's Nonesuch, Bismarck, Alexander, Mère de Ménage (finely coloured), Reinette de Canada, Warner's King, Stone's Washington, Brabant Bellefleur, The Queen, Lord Derby, and Belle Dubois. Pears—Pitmaston Duchess, Doyenné du Comice, Durondeau, General Todleben, Easter Beurré, Beurré Diel, Beurré Superfin, and Nouveau Poiteau (fine in the extreme). Mr. Thomas, Sittingbourne, was placed second, and exhibited in his usual good style. The third prize fell to Lady Fletcher, The Kenwards (gardener, Mr. Smith), whose best dishes were those of Pears, Pitmaston Duchess (large), Catillac, &c.

In the class for twelve dishes of farm-grown Apples and Pears, each dish to consist of twelve dishes, distinct, brought out a fine display. The first prize went to Mrs. Fremein, Teston, with a faultless collection of the following Apples:—Stone's, Peasgood's Nonesuch, Melon (very good), Glory of England, Cox's Pomona, Mère de Ménage, Lord Derby, Warner's King, and Stirling Castle. Of Pears—Catillac, Pitmaston Duchess, and Marie Louise; Mr. S. Goodwin, Mereworth, securing the second position with fruit finely coloured but smaller than those of the first; and Mr. Thomas third with very fine Cox's Orange, The Queen, &c. For one sieve of dessert Apples Mr. Thomas took the lead in a spirited competition, his Cox's Orange being very fine; followed by Mr. Mainwaring, Brenchley; Mrs. Fremein, and Mr. Fearon, Mereworth, respectively, with the same kind. Mr. Chambers was first for cooking ditto, his Warner's King being large, clean, and fresh. Mr. Goodwin was second with highly coloured Cox's Pomona, the third and fourth going to Mr. Warde, West Farleigh, and Mr. Fearon. In class for four quarter-sieves dessert ditto Mr. Goodwin took the lead, showing capital Ribston Pippin, Cox's Pomona, Cox's Orange, and Worcester Pearmain. Mr. Thomas was second, his Sam Young and Barchard's Seedling being very good; Mrs. Farmer, Battle Hall, Leeds, being placed third. For two quarter sieves Mr. Fearon took the lead; Mr. Blest, Watlingtonbury, was second; and Mr. Bryan, Mereworth, third. For the best four quarter-sieves kitchen Apples Mr. H. Leney, West Farleigh, took the lead, closely followed by Messrs. Framlin and Farmer. In the two ditto Mr. A. Ward was first with Stone's and Warner's, Mr. Fearon second, and Mr. Bryan third. In the class for Pears, two quarter-sieves, Mr. Blest secured the highest honours with large Pitmastons and Marie Louise. Second, Mr. Goodwin, with clean Hacon's Incomparable and Maréchal de Cour. A collection of any other sort not named in schedule was poorly represented, as was dried fruits. These two classes, it is to be hoped, will bring out more competitors another year.

## GRIFFINIA HYACINTHINA.

AMONGST the numerous floral attractions in Messrs. B. S. Williams and Son's Victoria and Paradise Nurseries, Upper Holloway, a group of Griffiniias was a short time ago a special feature, and no doubt many visitors have been induced to commence the culture of these plants by a sight of these in the nursery mentioned. The stout scape of flowers so beautifully tipped and edged with blue and white, and the bold handsome foliage, render the plants most charming for winter flowering, and it is remarkable they are so seldom seen in gardens where the floral display for the winter months is a source of constant anxiety.

Mr. Baines recommends the following treatment:—

"An intermediate heat, such as that of a vinery where a little fire is used, will answer for them quite as well as a warmer situation, but they should never, except in warm weather, be subjected for a long time to a greenhouse temperature, even when they have completed their growth and are at rest, or they are liable to suffer. The only drawback to their more general cultivation is their scarcity consequent upon their slow habit of growth, a circumstance still further aggravated by keeping them quite dry when at rest. Nothing can be more injurious to any evergreen bulb than this kind of treatment when carried too far, and especially in the case of Griffiniias. Unlike *Eucharis amazonica*, Griffiniias cannot be grown and periodically rested so as to induce them to flower several times in the year; on the contrary, they need a long season to become fully developed, and want a long rest afterwards before flowering, during which the soil should be kept much drier than when they are in active growth, but should never be so dry as to cause the leaves to flag. Another reason why these plants are scarce is that so few succeed in raising them from seeds, the failure being often attributable to the seeds being covered with soil, whereas they should be allowed to remain on the surface of the soil in the pots, otherwise they will decay.

"Griffiniias can also be increased by separation of those bulbs that are produced as offsets in the same manner as with *Amaryllis*, but their progress is very slow, and the roots are so closely interwoven as to render their separation almost impossible without considerable mutilation. When they are to be divided, the ball should be turned out of the pot and the whole of the soil washed very carefully from amongst the roots,

by which means they may be more readily disentangled without so much breakage. They should then be placed singly in from 4 to 6-inch pots, according to the size of the bulbs, and treated as hereafter described for

and irregular in shape. They must be allowed to remain on the plants until they either fall off of their own accord or can be removed by very slight pressure, and should then be sown immediately. For this purpose

FIG. 83.—GRIFFINIA HYACINTHINA.

plants raised from seed. After blooming in summer or autumn the seeds make their appearance, growing to the size of Potato Apples, but in appearance more like small green unripe Tomatoes, being corrugated

use an ordinary seed-pan proportionate in size to the number of seeds, put an inch of drainage in the bottom, and on this a little sphagnum or turfy material."

## CHRYSANTHEMUM SHOWS.

DEVIZES.—NOVEMBER 10TH.

THE Chrysanthemum Shows at Devizes are connected with a bazaar held for benevolent purposes, and the prize schedule is limited somewhat in extent accordingly; but if quantity is wanting, there is no lack of quality, valuable prizes always being offered, and these invariably attract some of the best growers of the day. Mr. T. King, the well-known gardener at Devizes Castle, has sole charge of the horticultural part of the display, and, it is almost needless to add, arranges everything in a very satisfactory manner.

Four good prizes, the first being £6, are offered for groups of Chrysanthemums on a space not more than 12 feet by 6 feet, and these brought together four grand groups, all of which would have been thought quite good enough to win a first prize anywhere else. After a very close scrutiny by the Judges the first prize was eventually awarded to Mr. W. Hale, gardener to C. N. May, Esq., Elm Lodge, Devizes, who had a grand bank of plants, the individual blooms generally being large, fresh, and brightly coloured, such Japanese varieties as Carew Underwood, Sarah Owen, Mons. Bernard, Etoile de Lyon, and Avalanche being particularly good. Mr. H. Clack, gardener to Major Colston, Roundway Park, was a very good second. Mr. F. Perry, gardener to Captain Spicer, Spye Park, third; and Mr. W. Mansell, gardener to W. Brown, Esq., Browfort, fourth. Mr. Perry's group comprised several extra finely flowered plants, Stanstead White being particularly good, a bloom of this being singled out for the award of a certificate for the premier Japanese in the Show. For twenty-four blooms of incurved Chrysanthemums, not less than eighteen varieties, the first prize was of the value of £10 10s., and this was well won by Messrs. W. & G. Drover, Fareham, Hants, who had, perhaps, the grandest lot of blooms ever seen in the south-western counties. These consisted of Emily Dale (3), all wonderfully fine, one of the blooms being selected as being the best incurved bloom in the Show; Alfred Salter (2), Lord Alcester (2), Empress of India (2), Lord Wolseley, Mrs. S. Coleman, Violet Tomlin, Prince Alfred, Princess of Wales, John Doughty, Queen of England, Charles Gibson, Lady Carey, Miss Haggas (2), Lady Dorothy, Empress Eugénie, Jeanne d'Arc, and Nil Desperandum. Mr. W. Neville, gardener to F. W. Flight, Esq., Twyford, was a very creditable second, the prize being a silver cup value £5 5s., his blooms being smaller than Messrs. Drovers', but otherwise perfect. The third prize was awarded to Mr. W. Robinson, gardener to Lord Justice Lopes, Heywood House, who also had a very good lot of blooms.

A silver cup value £5 5s. was offered for twelve Japanese blooms, distinct, and here again Messrs. Drover were first, having large though not very richly coloured blooms of E. Molyneux, Sunflower, Stanstead White, Etoile de Lyon, Sarah Owen, M. E. A. Carrière, Boule d'Or, Mr. C. W. Wheeler, Mons. Bernard, W. H. Lincoln, Condor, and Mrs. F. Jameson. Mr. Neville took the second prize for five better coloured blooms, and which were improved by additional space being given them, Etoile de Lyon, Mrs. Wheeler, and Mrs. F. Jameson being among the best. Mr. W. Robinson was third, and Mr. G. Pymm, gardener to Mrs. Gouldsmith, Trowbridge, highly commended. The best twelve reflexed, in not less than six varieties, were shown by Mr. W. Robinson, who had solid bright coloured blooms of Cullingfordi, Bronze Christine, Peach Christine, Mrs. Forsyth, Pink Christine, Cloth of Gold, and King of Crimson. Mr. W. Hale was a good second. For twelve incurved varieties, distinct, Mr. Neville took the lead with a good lot, his best being Mrs. Coleman, Miss Haggas, Princess of Wales, and Violet Tomlin. Mr. Robinson was second, and Mr. H. C. Baylis highly commended. A class was also provided for twelve incurved, with 4 inches of stem and their own foliage, and with these Mr. W. Hale was first, having a very good lot of blooms, consisting of Empress of India, Princess of Wales, Mrs. Heale, Lord Wolseley, Lord Alcester, Miss Haggas, Jeanne d'Arc, John Salter, Violet Tomlin, Cherub, Lady Hardinge, and Princess Beatrice. Mr. W. Robinson was second. The last-named was easily first in a well-filled class for twelve Anemone-flowered, in not less than four distinct varieties, showing capital blooms of Jean Marty, Fabian de Mediana, Madame R. Owen, Miss Annie Low, Lady Margaret, Sabine, E. C. Jukes, Mr. Judge Benedict, W. & G. Drover, and M. Charles Lebocq. Mr. H. Clack was second, and Mr. Pymm highly commended. Baskets of autumn foliage and berries were numerous and well shown by Mr. Den, the Misses Cunningham, and others, and it must not be omitted that the valuable challenge cup offered for the winner of the greatest number of points gained at each show was finally won by Mr. W. Hale, gardener to C. N. May, Esq.

YEOVIL.—NOVEMBER 10TH.

THE Yeovil Chrysanthemum Society held its annual Exhibition of plants, cut blooms, fruits and vegetables in the Town Hall on the above date, and was the best hitherto held by the Society, of which the Mayor (Dr. Colmer) is the President, W. Cox, Esq., J.P., being the excellent Chairman of the Committee and a staunch supporter of horticulture in the Yeovil district, and Mr. Oakley the Honorary Secretary.

*Groups and Plants.*—These were arranged, as is usual, in the Corn Exchange, and produced a fine effect as viewed from the top of the stairs leading to the Justices' rooms, in which the cut blooms, fruits, and vegetables were effectively staged. In the class for a group of Chrysanthemums covering a space 10 feet by 6 feet, Mr. Crossman, gardener to J. Brutton, Esq., Yeovil, was an easy first out of three good groups, staging capital grown and efficiently arranged plants in pots ranging from 9 inches to 3 inches in diameter, clothed with

luxuriant foliage, the blooms being very fresh; those on the outside row of plants in the 3-inch pots and about 9 inches high, were nearly, if not quite, 3 inches in diameter. Mr. G. Gear, gardener to Benjamin Penny, Esq., Yeovil, was second; and Mr. C. Anthony, gardener to Thomas Moore, Esq., also of Yeovil, was an exceedingly close third, both arrangements being very meritorious, as also were the plants.

Mr. F. Biss, gardener to J. Bradford, Esq., Yeovil, had the best group of miscellaneous plants; Mr. W. Appleby, gardener to T. W. Dampier-Bide, Esq., Yeovil, the second; and Mr. J. Allen, gardener to Rev. W. L. Cotter, West Coker, Yeovil, was third best, all staging suitable and tastefully arranged plants, the first-prize group winning more on account of the plants having been less formally arranged than of their quality, which, however, was good.

*Plants.*—Mr. Crossman was first for three incurved varieties with nicely trained and well flowered plants of Mrs. Dixon, Prince of Wales, and Mrs. George Rundle; Messrs. C. Anthony and G. Gear being second and third respectively. Mr. Crossman was again to the front for a number of Japanese varieties, Mr. Gillingham, gardener to Miss Phelps, Yeovil, being second, and Mr. J. Barrett, gardener to Dr. Daunt, Ilchester, third. Mr. C. Anthony was first for three Pompons, Mr. Crossman being a close second. Mr. Crossman had the best specimen plant of incurved, showing Mrs. Dixon in good form, Mr. Barrett being second. Mr. Crossman was again well to the front with a specimen reflexed in fine condition, Mr. Sampson, Bridport, being second, and Mr. C. Anthony was third. Mr. Crossman was also first for specimens of Japanese and Pompon varieties.

In other classes for table and miscellaneous plants the competition was keen; all the principal prizes were secured by Messrs. Gallop, Anthony, Gillingham, Copp, Drake, and Shire.

*Cut Flowers.*—These were shown in quantity and quality better than at any previous Show of the Society, the principal class being for twenty-four blooms—twelve incurved and twelve Japanese, distinct varieties, the first prize being a cup or £3. Out of seven good stands put up Mr. Copp was first with a good all-round lot, the blooms being large, solid, even, and fresh. They were—Japanese: Criterion, Edwin Molyneux, Sunflower, Condor, Ralph Brocklebank, Madame J. Laing, Stanstead White, Carew Underwood, Sarah Owen, Baronne de Prailly, Comte de Germiny, and Avalanche. Incurved: Miss Haggas, Queen of England, Empress of India, Novelty, Golden Empress, Lady Hardinge, Mrs. Shipman, Mrs. Heale, Baron Beust, and Barbara. Mr. J. Lloyd, gardener to Vincent Stuckey, Esq., Langport, was a good second, and Mr. T. Wilkins, gardener to Lady T. Guest, Inwood House, Henstridge, was a close third. Mr. Gallop showed capital blooms in this and the next class, but was disqualified in both for staging two blooms of Empress of India under its right name, and that of Duchess of Manchester. With twelve incurved, distinct, Mr. Lloyd was well first, staging capital blooms of Golden Empress, Empress of India, Queen of England, Alfred Salter, Miss Haggas, Violet Tomlin, Nil Desperandum, Alfred Lyne, Cherub, Jeanne d'Arc, and Lord Alcester. Mr. J. Barrett was second, and Mr. Crossman third, both showing creditable blooms. Mr. Wilkins had the best stand of six incurved, and Mr. Copp the second best. Mr. Lloyd secured first place for twelve Japanese, distinct, out of eight good stands put up, staging Triomphe de la rue des Châlets, W. H. Lincoln, Stanstead White, Sunflower, Edwin Molyneux, Louis Boehmer, Ralph Brocklebank, Avalanche, and Etoile de Lyon; Mr. Copp being second, and Mr. Sampson third. Mr. Wilkins had the best stand of six Japanese, showing good blooms of Maiden's Blush, Gloriosum, Edwin Molyneux, Etoile de Lyon, Stanstead White, and Mons. H. Elliott; Mr. Sampson was second. Six lots were staged. Mr. Copp had the best stand of reflexed, Mr. Sampson the second, and Mr. Crossman the third best, all showing well. Mr. Crossman was the only exhibitor of twelve bunches of Pompons staged with foliage, and he was accorded first honours. Floral arrangements were well represented by Miss Tucker and Miss Harris, both of Yeovil, their arrangements being light and tastefully set up.

Fruit was well shown. Three collections, consisting of six kinds, were staged by Mr. Lloyd, Mr. Crossman, and Mr. Daley, gardener to Col. McGregor, Maperton, who took the prizes in that order. The first prize collection consisted of good Black Alicante and Trebbiano Grapes, Hero of Lockinge Melon, Marie Louise Pears, Ferris Apples, and Nottingham Medlars, a good all-round lot for the time of year. Mr. Crossman's collection contained good Alicante Grapes, Coe's Golden Drop Plum, and Marie Louise Pear. Mr. Lloyd was well to the front with two bunches of Alicante Grapes in good condition as regards size, shape, freshness, and colour; Mr. Wilkins being second, and Mr. Daley third. In the any other black Grape class Mr. Lloyd was again placed first for good well-coloured examples of Gros Colman, being followed by Mr. G. Gillingham and Mr. Wilkins in that order. The prizes for two bunches of Muscat of Alexandria went to Messrs. Gallop, Daley, and Crossman. In other classes the prizes went to Messrs. Wilkins, Lloyd, Daley, Gallop, Gillingham, Copp, and E. Hall.

Collections of vegetables and salading ingredients were capitally shown in amateur, cottager, and open classes. The most successful exhibitors in the latter were Mr. W. E. Hall, Mr. Crossman, and Mr. Allen; Mr. Copp securing first honour in Messrs. Jarman's special prize class for six kinds of vegetables with extra fine produce. The two admirable and most tastefully arranged collections of salading set up by Messrs. Allen and Crossman attracted a good deal of well merited attention.

Non-competitive exhibits came from Messrs. Veitch & Son, Exeter, who staged sixty dishes of Apples of fine quality, among which may be

mentioned The Queen, Cox's Pomona, Sandringham, Hollandbury, Herefordshire Beefing, Cellini, large, clean, and well-coloured fruits. Messrs. Jarman & Son, Chard, staged fifty dishes of excellent Apples; and Mr. B. R. Davis, Yeovil, seventy-two dishes of Pears and Apples.

#### LEEDS PAXTON SOCIETY.—NOVEMBER 10TH AND 11TH.

THE third annual Chrysanthemum Show of the above-named Society was held in the Leeds Town Hall on the above dates. Prior to this Society taking up the work of conducting it, the Leeds Chrysanthemum Show was in a languishing state, being very indifferently supported by either the resident gentry as subscribers, or by the public as visitors to the Show, but owing to the untiring work of an energetic committee and executive, such state of things has been entirely altered since the Paxton Society took it in hand, and the finances of the Show are now in a very satisfactory condition. A reference to the balance-sheet for 1890 shows that the subscription list amounted £150; gate-money, tickets sold, and from other smaller sources of income, £126, which enabled them, after paying a prize list of £138 10s., and all other expenses of working, to show a balance to their credit of £68.

The present year promises to be equally successful in finances as it undoubtedly was as a Show. The first class in the schedule was for a group of miscellaneous plants arranged for effect on a space of 120 feet, circular, and this brought four competitors all with meritorious exhibits, which added immensely to the beauty of the Show. They were very close in points of merit, and some difficulty was found in rightly apportioning the prizes. They were ultimately awarded as follows:—First, Mr. J. Frankland, gardener to W. Barron, Esq., M.P.; second, Mr. W. Townsend, gardener to E. B. Faber, Esq.; third, Mr. G. Cooper, gardener to E. W. Beckett, Esq., M.P.; fourth, Mr. P. Massey, gardener to J. Wilson, Esq.

The class for a group of Chrysanthemums arranged for effect in a space not exceeding 80 square feet (semicircular), brought only two competitors, the one obtaining the first prize from W. Boston, Manor Farm Nurseries, Carthorpe, Bedale, being especially meritorious. The second prize was taken by Mr. J. Eastwood, gardener to Mrs. Tetley.

The several classes for trained specimen plants of Chrysanthemums were all very well competed in, but the plants shown were of a different character to those of previous years, which have usually been large, rather tall specimens, with a flat or slightly convex head 4 to 5 feet across. This time they were, as a rule, only about half that size, neat, well grown, and well flowered bushes about 2 feet over, just the best kind of plants for conservatory decoration, and deserve to be encouraged. The principal prizetakers for these were Mr. J. Eastwood, and Mr. R. Harburn, gardener to A. Kitson, Esq.

Ornamental, stove or greenhouse, and table plants were well shown. The principal exhibitors and prizewinners were W. Grix, gardener to Sir James Kitson, Bart., G. Cooper, J. Wilson, and P. Massey.

The greatest interest in the Show was probably centred in the open class for thirty-six blooms of Chrysanthemums, eighteen incurved and eighteen Japanese, for which a challenge cup, value 15 guineas, and £9 in cash, was offered as first prize; second prize £6, third £3, fourth 30s. For these prizes five competed, the first prize and cup going to Mr. W. H. Hotham, gardener to W. Robinson King, Esq., North Ferriby, Brough; second, Mr. J. P. Leadbetter, gardener to A. Wilson, Esq., Tranby Croft, Hull; third, Mr. T. Carling, gardener to Mrs. Cope, Dove Park, Woolton, Liverpool (winner of the cup last year); fourth, Mr. J. Bell, gardener to Mrs. Roundell. The varieties contained in the first prize stand were—Incurved: Queen of England, (2), Lord Wolsley, (2), Empress of India, Mrs. Robinson King (?), Prince Alfred, Alfred Salter, Mr. Bunn, Formosum Album, Novelty, Refulgens, Nil Desperandum, Jeanne d'Arc, Jardin des Plantes, Mrs. Shipman, Lady Hardinge, Beauty of Hull. Japanese: Stanstead White, Fimbriatum, Edwin Molyneux, Sunflower, Avalanche (2), Puritan, George Daniels, Coronet, Madame J. Laing, Val d'Andorre, Boule d'Or, Mrs. J. Wright, M. Freeman, Madame Louise Leroy, Ralph Brocklebank, Madame Baco, M. J. M. Piguy. The finest incurved flower in this stand or in the Show was a grand flower of Mrs. Robinson King, a new golden yellow sport from Golden Empress, as deep in colour as is Jardin des Plantes, and with the fine build and shape of Lord Alcester, a splendid acquisition. It was unanimously awarded a certificate by the Judges.

The same exhibitor was first for twelve blooms, incurved, open, with Queen of England, Lord Wolsley, Lord Alcester (2), Nil Desperandum (2), Prince of Wales, Mr. Bunn, Mrs. G. Rundle, Beauty of Hull, Mrs. Dixon, Lady Hardinge. For twelve blooms, Japanese, open, Mr. J. P. Leadbetter was first with Condor, Madame C. Audiguier, W. H. Lincoln, Belle Paule, Bouquet de Dame, Val d'Andorre, Puritan, Stanstead White, Madame J. Laing, Fair Maid of Guernsey, Cesare Costa, and Madame Baco. The other prizes in the open classes were all well competed for, the principal prizewinners being those above named, with Mr. C. H. Simpson, Messrs. H. Clark & Sons, Mr. Moore, and Mr. Jno. Gould.

In the gentlemen's gardeners' class and amateurs a silver challenge cup, value ten guineas, and £5 cash, was offered as a first prize for twenty-four blooms, twelve incurved and twelve Japanese, distinct, which was well won by the energetic Chairman of the Committee, Mr. W. Grix. Second, Mr. J. Gordon, gardener to M. Bottomley, Esq. Third, Mr. J. Eastwood. The smaller classes for gentlemen's gardeners and amateurs were well competed for, the principal exhibitors being Messrs. Grix, Walton, R. Cross, W. Appleby, P. Massey, and J. W. Frankland. There was a fine display of made-up flowers in the form of bouquets, Chrysanthemums, and Ferns, bridal and ballroom, ladies'

sprays, and gentlemen's coat bouquets, the principal prizewinners for these being Messrs. W. Frankland, Halley and Bullock, W. Grix, T. Newbould, T. Massey, and W. Moore.

Fruit was well shown, especially Grapes, the stands of which were both numerous and good, Messrs. J. Johnson, P. Massey, C. H. Simpson, and W. Hotham being the principal prizewinners for these; whilst the same with Messrs. Grix and Moore were successful in the various classes for Apples and Pears.

A large ante-room was also well filled with a very fine display of vegetables, exhibited principally by the gardeners of the district, whose names appear above. A class was also provided for a dessert table, 8 feet by 4, completely laid for six persons, decorated with flowers and Fern. Two competed, and their work proved very attractive to the ladies, and an excellent relief and addition to the Show. Mr. G. Cooper, gardener to E. Beckett, Esq., M.P., was first, his decorations being especially bright and attractive, but rather too crowded; Mr. Wm. Brown, the Green Dragon Hotel, being placed second with a light arrangement, somewhat lacking in floral embellishments.

#### CIRENCESTER.—NOVEMBER 11TH.

FOR a first attempt this was a remarkable success. The Corn Hall is admirably adapted for a Chrysanthemum show, and with plenty of good material to work with, Mr. Frank Sare, the energetic Honorary Secretary, and an efficient Committee, contrived to arrange a very effective Exhibition to the best advantage. Nearly everything in season was well represented, the quality in many instances comparing very favourably with what has been seen at other south-western shows this season. There should be a good future for this Society.

There were two classes for groups of Chrysanthemums, and both were well filled, two sides of the hall being given up to these. The first prize for a large group was well won by Mr. T. Arnold, gardener to the Earl of Bathurst, who had a capital lot of dwarf disbudded plants, being very neatly and effectively grouped. Mr. D. Elkins, gardener to A. Cator, Esq., was a close second, having fewer blooms, but they were of good quality; while the third prize went to Mr. W. Taylor, gardener to T. W. C. Masters, Esq., who also arranged a very creditable group. With a smaller group Mr. C. Orpet, gardener to Miss Brown, was well first; Mr. J. Painter, gardener to C. Green, Esq., second; and Mr. C. Chapple, gardener to R. Anderson, jun., Esq., third; an extra fourth being awarded to W. Geater, gardener to J. Hyde, Esq. The classes for trained plants were not so well filled, but these could very well have been dispensed with. Mr. G. Bastin, gardener to G. Holloway, Esq., Stroud, took first for six trained plants of incurved varieties and a like number of Japanese varieties, having very creditably grown specimens in each instance, and a few other fairly good plants were shown. Miscellaneous groups were arranged by three exhibitors, but Mr. Arnold was easily first, having several Lælias, Dendrobium Dearei, Dendrobium Ainsworthi, Cypripediums, Oncidium Rogersi, Calanthes, Palms, Aralia, Ferns, and such like very prettily grouped. Mr. O. Orpet was a creditably second, and Mr. D. Elkins third. Mr. O. Orpet had the best Bouvardias; Mr. G. Rice, gardener to Mrs. Bulley, the best Zonal Pelargoniums; and Mr. T. Arnold the best Primulas; competition being fairly keen in each instance.

In the open class for thirty-six cut blooms in equal numbers of incurved and Japanese varieties Mr. C. Mayo, gardener to A. Apperley, Esq., was a good first, having fresh good blooms of incurved, Golden Empress of India, Empress of India, Violet Tomlin, Miss Haggas, A. Salter, Lord Alcester, Mrs. Coleman, J. Doughty, Jardin des Plantes, Princess of Wales, Guernsey Nugget, Lord Wolsley, Isabella Bott, Barbara, Mrs. Heale, Bendigo, Jeanne d'Arc, and Princess of Teck. The Japanese were Etoile de Lyon, Fair Maid of Guernsey, E. Molyneux, Sunflower, Val d'Andorre, Maiden's Blush, Mr. H. Cannell, J. A. Laing, Bertha Flight, Puritan, Pelican, Mr. J. Laing, Baronne de Prailly, Mrs. J. Wright, Jeanne Délaux, Gloriosum, Louis Boehmer, and R. Brocklebank. Mr. G. Price was second, his best being Violet Tomlin, Jeanne d'Arc, Queen of England, and Refulgens. Mr. Bastin was third. In the local classes for thirty-six blooms a second prize was awarded to Mr. G. Price. The same exhibitor was also first for twelve Japanese varieties, having among others very good blooms of W. W. Coles, Etoile de Lyon, Sunflower, and Mons. Bernard. Mr. G. Bignell, gardener to Mrs. Brewin, was second, and Mr. D. Elkins third. Mr. G. Price was first for twelve incurved, Mr. D. Elkins second, and Mr. G. Hansford third; and with six of one variety Mr. Elkins was first for good Princess of Wales, Mr. G. Price being second. The best twelve reflexed blooms were shown by Mr. G. Price, a first prize also going to Mr. D. Elkins for Anemone-flowered varieties. The vases of Chrysanthemums and any kind of greenery, especially those shown by Mrs. Sare and Mrs. Fowler, were very tastefully arranged, as also were the baskets of autumn foliage and berries shown by Mrs. Rawlins, Mrs. Sare, and others.

Fruit was very well shown. Mr. G. Hansford was first for three bunches of Muscat of Alexandria Grapes. Mr. W. H. Saunders, gardener to J. Taylor, Esq., second; and Mr. Arnold third. In the class for black Grapes Mr. G. Price was well first with Alicante in good condition, Mr. Arnold being second, other exhibitors having fairly good Mrs. Pince and Black Hamburg. The best six varieties of dessert Apples were staged by Mr. J. Baker, gardener to Colonel Porter, Mr. W. Taylor being a close second. The last-named took the lead with six varieties of culinary Apples, and Mr. J. Arnold second. Pears were also well shown. Mr. W. Taylor was first for six varieties; and Mr. G. Gegg, gardener to Mrs. Haines, second.

The greater portion of one end of the hall was taken up by two grand banks of plants, arranged, not for competition, by Messrs. J. Jeffries & Son, Cirencester. One was composed principally of very well grown Chrysanthemums, all the best varieties being represented, and the other of choice flowering and fine-foliaged plants in excellent condition.

#### LOUGHBOROUGH.

THE seventeenth annual Show of Chrysanthemums was held in the Town Hall on the 11th of November, and was one of the best shows they have had. There were two groups of Chrysanthemums, Messrs. Biddles and Co. being only just first, Mr. Hickling being second. There were two groups of foliage and flowering plants, Mr. Hickling winning easily, Messrs. Biddles second. The Rev. J. Bird of Walton Rectory won all the first prizes both in incurved and Japanese, cut blooms, his incurved blooms of the following being nearly equal to those shown at Liverpool last year:—Alfred Salter (very fine), Queen of England, Golden Emperor, John Lambert, Empress of India, and Lord Alcester. He also had very fine blooms of Etoile de Lyon and Condor in the Japanese. About 120 dishes of Apples and Pears were shown for competition, and a very good collection of nearly 100 dishes were shown (not for competition) by Mr. Roberts, gardener to Hussey Packe, Esq., Prestwold. Dinner table plants were well shown, but specimen plants of Chrysanthemums were poorly represented. A few years ago these were the special feature at the Loughborough Shows.—ALMA.

#### TORQUAY.—NOVEMBER 11TH.

As usual, the Bath Saloons were chosen for the autumn Exhibition of the Torquay Horticultural Society, and rightly so, for they are specially adapted for a meeting of this sort, allowing of ample space for the effective arrangement of the exhibits, which was carried out this time with commendable taste. The groups of Chrysanthemums, of which there were about twenty, were arranged in circular form on the floor of the large tennis court in conjunction with the groups of miscellaneous plants on raised platforms 1 foot high, the base of which was covered with green baize; these were of square form, the corners of each being so arranged that they pointed to the openings made between the circular groups; and as these, composed of Chrysanthemums, were restricted to 6 feet high, and it was stipulated that a tall Palm or foliage plant should be employed in the centre of each and a dressing of Fern allowed at each base, the effect was not marred by excessively tall plants and bare stems that are so often displayed in Chrysanthemum groups. It was a treat much appreciated by the visitors, as ample space between the groups was left for promenading. The miscellaneous plants were mainly flowering ones, with a judicious addition of foliage plants and Fern to give the whole an harmonious effect. Around the sides of the building were arranged in bank-like form the collections of plants, mainly from nurserymen, not for competition, which were freely exhibited, adding considerably to the decoration of the room. The Committee, with Mr. J. N. Whitehead as Honorary Secretary, deserve praise for the manner in which all the details were carried out of so successful an Exhibition.

Groups deserve a first notice, so numerous were they contributed. The principal class was that for one of 8 feet diameter, arranged for effect, and which was to contain not less than eighteen varieties. In this four competed. The premier award went to Mr. A. Searle, gardener to J. N. Whitehead, Esq., Gnaton, Torquay, the plants being dwarf, carrying good foliage and fine blooms, while the arrangement left little to be desired. Mr. J. Hunt, gardener to P. B. Drinkwater, Esq., Lyncombe, Torquay, was a good second. Mr. J. Slowman, gardener to Captain W. Fane Tucker, Braddon Tor, Torquay, third. Six competed in the 7 feet groups, with similar conditions binding the exhibitors. Mr. W. Satterby, gardener to Mrs. Matthew, Braddon Villa, Torquay, was the most successful among six competitors, Mr. F. Ferris, gardener to J. W. Kimber, Esq., Tracey, Cockington, second, both showing much taste in arrangement. Mr. J. Slowman gained premier award in the group for miscellaneous plants of 7 feet square with a light arrangement of suitable material. Mr. W. Satterby second. Specimen Chrysanthemums call for little comment, they being but moderately contributed both in numbers and quality. Orchids were shown well. For three Mr. G. Lee, gardener to W. Lavers, Esq., Upton Leigh, Torquay, was first, having *Cypripedium Harrisonianum*, *Miltonia candida*, and *Oncidium ornithorhynchum* in creditable condition. Mr. G. Medland, gardener to Morton Sparke, Esq., Torquay, second. Mr. Lee staged a plant with three good spikes of *Cymbidium giganteum superbum*, a good variety, in the class for one Orchid. Mr. G. Medland second.

Cut blooms were not only staged in large numbers but were of commendable good quality right through. The principal class was that for thirty-six distinct, half to be incurved and the remainder Japanese, a silver cup being given as first prize. Five competed, first honours being easily secured by Mr. G. Foster, gardener to H. Hammond Spencer, Esq., Glenaragh, Teignmouth, with the following in very fine condition. Incurved:—Alfred Salter, Miss M. A. Haggas, Jeanne d'Arc, Golden Empress, John Doughty, Lord Alcester, Nil Desperandum, Empress of India, Mrs. S. Coleman, Princess of Teck, Violet Tomlin, Lady Dorothy, Mrs. Heale, Princess of Wales, Refulgens, Queen of England, Jardin des Plantes and Lady Hardinge. Japanese:—E. Molyneux, Etoile de Lyon, William Lane (very fine), Puritan, Vivand Morel, W. W. Coles, W. H. Lincoln, A. H. Neve, Mons. Bernard, Mdme. Laing, Japonais, Sunflower, Gloire de Rocher, Louis Boehmer, Stanstead White, Beauty of Castlewood, Florence Davis, and Mdme. Baco; Mr. J. Stiles, gardener to Miss Fripp, The Grove, Teignmouth, second with a good stand; Mr.

A. Searle third with a creditable collection. For twelve incurved, distinct, Mr. J. Stiles won with medium sized, neatly dressed blooms of the following varieties: Empress of India, Lord Wolseley, Princess of Wales, Jeanne d'Arc, Golden Empress, Queen of England, Miss M. A. Haggas, Violet Tomlin, Lady Hardinge, Nil Desperandum, Prince Alfred, and Baron Beust; Mr. A. Searle a good second; Mr. H. Veale, gardener to the Rev. A. H. Timms, Wolborough Rectory, third. For twelve Japanese, distinct, Mr. G. Foster was an easy first with William Lane, Etoile de Lyon, Vivand Morel, W. H. Lincoln, Condor, Sunflower, E. Molyneux, Japonais, Cesare Costa, Gloire de Rocher, Florence Davis, and Louis Boehmer; Mr. A. Searle second; Mr. J. T. Ebbutt, gardener to the Rev. H. A. W. Hamilton Gell, Winslade, Exeter. For six varieties Messrs. Foster and Searle were the winners in the order that their names are given. For the best six large flowered Anemone varieties, Japanese excluded, Mr. Foster, with Lady Margaret, Mrs. J. Benedict, and Miss Annie Lowe, was first, staging full solid blooms; Mr. Searle second.

For the same number of Japanese Anemone varieties, Mr. Searle won with M. C. Lebocqz, Jeanne Marty, and Fabian de Médiana in good condition. Mr. W. H. Veale second. For six any one variety of reflexed, Mr. Stiles won with Cullingfordi in a strong competition. Mr. Foster second. The positions were reversed in the next class, six large flowered Anemones, one variety, the best Mrs. Judge Benedict, very fine. For six incurved, one variety, Mr. Foster won with Empress of India, full and fresh. Mr. Searle second. Mr. Foster again won in the class for six of any white Japanese with Stanstead White; Mr. Searle following with Avalanche. For six yellow, one variety, Mr. Searle with Boule d'Or was first from Mr. Foster, he having W. H. Lincoln. For twelve of any Japanese variety, Mr. Stiles won with Etoile de Lyon, a bit pale, though full, from Mr. Foster's Avalanche. Mr. Stiles won for six blooms, any single variety, with Admiral Sir T. Symonds, extremely fine; Mr. Searle followed with the same variety.

Vegetables were both numerous and good. For six varieties, Mr. W. Satterby was first among several others who staged well. Fruit was shown both largely and well.

Groups of plants not for competition were sent by Messrs. Curtis and Sanford, Devon Nurseries, Torquay; Mr. W. B. Smale, Torquay; Messrs. Horn & Sons, St. Mary's Church; and Messrs. T. Allward and Son, Braddon's Hill Nursery, Torquay. Messrs. R. Veitch & Son, Exeter, sent a collection of Apples of good quality of leading varieties.

#### MONMOUTH.—NOVEMBER 11TH AND 12TH.

THE Monmouth Chrysanthemum Society held their annual Exhibition again in the Rolls Hall, and was equal, if not superior to any former Show. The groups were not so plentiful as usual, but the cut-bloom classes were well filled with fine blooms generally. Fruit also was of a high quality; Apples being better shown than at any previous Show. New exhibitors were rather numerous, and much interest is taken in the Society by the gentry for a long distance round. The silver cup given for the best group, arranged in a space of 84 feet, brought only one exhibitor, Mr. J. M. Bannerman, Wyastone Leys, Monmouth, who staged a very fine group, which well deserved the first honours awarded. For a group occupying a space of 36 square feet, Mr. Panter, Whitchurch, Monmouth, was an easy first; Col. H. C. Gould, Leasbrook, second; Mrs. Victor Hughes, The Priory, third. In the trained specimen classes Mr. J. M. Bannerman was the chief prize winner.

In the cut-bloom classes the competition was keen, the blooms being of a high order of merit. For twenty-four varieties of incurved, Mr. J. M. Bannerman was first with Alfred Salter, Lady Hardinge, Jardin des Plantes, Queen of England, Miss M. A. Haggas, Princess of Teck, Golden Empress, Violet Tomlin, Charles Gibson, Lord Alcester, John Lambert, Refulgens, Queen of England, Empress of India, Mrs. S. Coleman, Mrs. W. Shipman, Prince Alfred, J. Salter. C. Lee Campbell, Esq., Glewston Court, Ross, second with Miss M. A. Haggas, Miss V. Tomlin, Baron Beust, Mrs. Naish, Lord Wolseley, Prince Alfred, &c., fine. For twenty-four Japanese Mr. J. M. Bannerman came first with E. Molyneux, R. Bottomley, C. Sharman, Mr. H. A. Neve, Madame C. Audiguer, Mrs. J. Wright, A. Clibran, H. Cannell, Thomas J. Laing, M. J. Pigny, Etoile de Lyon, G. Daniels, Volunteer, Japonaise, Stanstead White, Mr. F. Jameson, Condor, J. Delaux, Mr. E. A. Carrière. C. Lee Campbell, Esq., second: his Etoile de Lyon, E. Molyneux, Carew Underwood, Mrs. Alpheus Hardy being very good. Rev. G. Herbert, Llangarren, Ross, third. For twelve incurved, V. H. K. Collin, Esq., Whitchurch, was first; Rev. G. Herbert, second; and Mr. G. Temset, English Bicknor, third. With twelve Japanese, Mr. W. Digwood, The Gardens, Pengethly, Ross, was first; V. H. K. Collins, Esq., second; Mr. G. Temsett, third. In the twelve reflexed class, J. M. Bannerman, Esq., was first, with King of Crimson, Phidias, Pink Christine, Peach Christine, Dr. Sharp, Mrs. Forsyth, Cloth of Gold, &c.; C. Lee Campbell, Esq., second; Rev. G. Herbert, third. For twelve Anemones, C. Lee Campbell, Esq., was an easy first, with Lady Margaret, Gluck, Jeanne Marty, James Weston, George Sands, Souvenir de Madame de Blandanière, Duchess of Edinburgh, Acquisition, Emperor, &c.; Rev. G. Herbert, second. Twelve Pompons were well shown by Rev. G. Herbert; W. Morris, Esq., High Street, Ross; Rev. W. S. Clarke, The Thorn, Ross, who won in the order named. J. A. Rolls, Esq., The Hendre, Monmouth, exhibited, not for competition, some excellent Japanese and incurved blooms, second to none in the Show, also a splendid spike of *Phalænopsis amabilis*; likewise a beautiful group of flowering and foliage plants. Bouquets, sprays, wreaths, &c., were very good. Mr. E. T. Hill, Westbury-on-Trym, and Mr. J. Nowel

Hereford, being the chief prizetakers; the latter showing a magnificent wreath, which attracted much attention.

The fruit classes were well filled, C. Lee Campbell, Esq., being first in black Grapes with three fine bunches of Alicante; Mr. J. Nowell, second, with the same variety; Captain Marling, Clanna, Sydney, third, with Gros Colman. White Grapes, three bunches, first C. Lee Campbell, Esq., second Captain Marling, both showing Muscat of Alexandria; Mr. E. T. Hill, third, with Buckland Sweetwater. For six dishes of Pears, Captain Marling, Mr. E. T. Hill, and the Rev. — Tweed, won in the order named. In the Apple classes C. Lee Campbell, Esq., was first for the best collection, for the best six dishes for dessert, and for three dishes of culinary; other prizetakers being Mr. T. Barratt, Walford, Captain Marling, Rev. Tweed, Mr. E. T. Hill, Rev. G. Herbert, and Mr. W. Luton, Hilston Park.

Vegetables were well exhibited, C. Lee Campbell taking first honours for the collection given by the Society. Messrs. Sutton & Sons, and Messrs. Webbs, amateurs and cottagers, staged highly creditable produce in the classes provided for them, each year showing a decided improvement on the previous one, and must be gratifying to all concerned.

#### TIVERTON.—NOVEMBER 12TH.

THIS fixture clashed with several other south-western shows, and as a consequence there were fewer entries than usual in the principal cut bloom classes, though in all other respects the display was fully equal to what has been seen in former years. The show of Apples and Pears was both extensive and good, and more than compensated for other failings. Mr. R. P. Cosway is the Honorary Secretary of the Society, and with him are associated a good working Committee of gentlemen interested in horticulture and professional gardeners.

Groups of Chrysanthemums were numerous and good, the various exhibitors running each other more closely than often happens. For that of the largest size Mr. T. Tapscott, gardener to Col. Greatwood, was first, having well-grown plants with fine blooms very effectively arranged in a semicircle. Mr. C. Mayne, gardener to Mrs. Las Casas, was a very creditable second. With a smaller group Mr. J. Williams, gardener to Mrs. Lane, was first, having a very well-finished arrangement, and a capital box of blooms. He was closely followed by Mr. Sedgbeer, gardener to Miss D. Carew; the third prize going to Major Carleton. The best six plants of incurved varieties were shown by Mr. G. Splatt, gardener to the Rev. T. U. Cross, who was also first for a similar number of Japanese varieties, Mr. J. Prescott being second in the latter class. Mr. Splatt was the only exhibitor of six mixed varieties, and was deservedly awarded a first prize. A feature at the Tiverton Shows are groups of Zonal Pelargoniums 3 feet square, a wonderful lot of small, grandly flowered plants being got into that space. Mr. G. Splatt was well first, Major Carleton second, and Mr. A. Burroughs, gardener to Mrs. North-Row, third. Mr. A. Burroughs was first and Mr. Splatt second with Primulas. Mr. C. Mayne, gardener to Mrs. Las Casas, had the best table plants, Mr. J. Parkhouse being second, and Mr. Burroughs was first for six good pots of double Violets, the second prize going to Mr. H. Solman, gardener to W. H. Dunsford, Esq.

The Japanese stands made a good display. With eighteen blooms, distinct, Mr. A. Burrows, was well first, having good blooms of Golden Dragon, Edwin Molyneux, Pelican, L'Adorable, F. A. Davis, Louis Boehmer, Avalanche, and M. Garnier. There was much better competition with twelve Japanese varieties, and with these Mr. G. Heath, gardener to Sir W. H. Walrond, was first, his best blooms being Etoile de Lyon, Avalanche, Edwin Molyneux, Mr. C. W. Wheeler, Belle Paule, Stanstead Surprise, and Meg Merrilies. Mr. S. Tottle, Taunton, was second. The best six Japanese were shown by Mr. A. Burroughs, who had fine fresh blooms of Mr. Cannell, Etoile de Lyon, Edwin Molyneux, Louis Boehmer, Avalanche, and Meg Merrilies. Mr. G. Splatt was second. For twelve incurved varieties Mr. S. Tottle was first and Mr. C. Mayne second. Major Carleton was the only exhibitor of six Anemone-flowered varieties, and was deservedly awarded a first prize. The class for twelve mixed Chrysanthemums was very well filled. Mr. Splatt was first, the blooms of J. Delaux, Sunflower, Mrs. E. W. Clarke and Amy Furze being noteworthy. Mr. T. Heath was second, and Mr. J. Parkhouse third. Mr. Solman had a first for a well-made hand bouquet composed of Chrysanthemums and Fern fronds.

The best collection of twelve varieties of dessert Apples was staged by Mr. A. C. Williams, gardener to W. C. Sim, Esq., who had a capital lot of well selected fruit. Mr. H. Solman was a good second; and Mr. T. Heath third. Mr. Williams was also first for twelve varieties of culinary Apples; Mr. T. Heath being a close second. Mr. S. Tottle staged the best six dishes of dessert Apples; Mr. J. Abram being second. Mr. A. C. Williams had a first for six varieties of Pears, and was second with three varieties, Mr. T. Heath being first. A large number of classes were provided for individual varieties of Apples and Pears, in most of which the competition was keen, the names already given occurring very frequently in the prize list. Messrs. Robert Veitch and Son, Exeter, arranged a fine display of Apples and Pears not for competition; as also did Mr. G. G. Selater, Exeter; Messrs. Jarman and Co., Chard; and Mr. W. Melford, Tiverton.

#### BIRKENHEAD AND WIRRAL.—NOVEMBER 12TH.

THE fifth annual Exhibition of Chrysanthemums, Fruit, &c., was held on Thursday, November 12th, in the Hall of the Young Men's Christian Association, Grange Road, and as regards the exhibits showed a falling off from last year, there being only two entries of forty-

eights and twenty-fours. The Exhibition was opened by the Mayor of Birkenhead (Alderman Willmer), who, in an excellent speech, commended the Society to the hearty support of the inhabitants of the town and surrounding district, and it is to be hoped the remarks made will have the desired effect of adding greatly to the subscription list for next season. Before commenting on the prizewinners there is one point which I think the Committee might remedy on a future occasion—viz., by adding the addresses of the various exhibitors. To simply give the names leaves a rather vague impression, and at a Show such as that at Birkenhead ought to be remedied.

The cut blooms formed the chief centre of attraction, and with one or two exceptions they were of the highest quality. In the open class for forty-eight, Mr. Malcolm, gardener to J. Tomkinson, Esq., was deservedly awarded chief honours, the Japanese being solid and fresh all through. They were as follows:—Etoile de Lyon (2), Sarah Owen (2), Condor (2), M. Bernard, Stanstead Surprise, Louis Boehmer (magnificent) E. Molyneux, Ralph Brocklebank, Val d'Andorre, Criterion (fine), Avalanche, Sunflower (2), Golden Dragon (2), Madame Baco, Belle Paule, Ada Spaulding, Jeanne Délaux, Soleil Levant, and Puritan. Incurved:—Lord Alcester (2), John Lambert (2), Queen of England (2), Golden Empress, Beauty, Jeanne d'Arc, Violet Tomlin (2), Mrs. S. Coleman, Mrs. Heale, Pink Venus, Prince Alfred, Miss M. A. Haggas (2), Lord Wolseley, Princess of Wales, White Venus, Lady Harding, and Barbara. The other exhibitor was Mr. T. Watson, gardener to T. S. Hannay, Esq., whose incurved varieties were very fine, but the Japanese were somewhat weak, Stanstead White and Miss Anna Hartzhorn in the Japanese being especially fine, and Lord Wolseley in the incurved—altogether an excellent stand.

For twelve incurved Mr. T. Ranson, gardener to H. R. Rodger, Esq., Spital, was a good first, having Robert Cannell and John Salter fine. For twelve Japanese the same exhibitor was again first, having capital blooms of M. Bernard, E. de Lyon, Gloire de Rocher, and W. W. Colcs. In each case he was followed by Mr. G. Lyon, gardener to J. H. Kenion, Esq., Rock Ferry, who had some beautiful blooms; the third positions were occupied by Mr. T. Winkworth, gardener to Ralph Brocklebank, Esq., Childwall Hall, and Mr. S. E. Haines, gardener to M. Laird, Esq., Claughton. In the local class for twenty-four blooms Mr. Ranson achieved another success, his best Japanese being Gloire de Rocher, Etoile de Lyon, Stanstead White, Mrs. F. Jameson, Japonais (very good), Puritan, and W. H. Lincoln. Incurved: Robert Cannell, Violet Tomlin, and Mrs. Heale. Second, Mr. S. E. Hains, with good blooms. With twelve incurved and twelve Japanese Mr. G. Lyon was well ahead, his blooms being remarkably good throughout, and fine in colour. In the former Lord Wolseley, Violet Tomlin, and Refulgens, and Avalanche and Condor in the latter, stood out conspicuously. The second honours in each class fell to Mr. T. Watson, Mr. A. H. Neve and Advance being very good in the Japanese. For six incurved, the same number of Japanese, and in the class for twelve blooms for those who have not shown more than twelve blooms, Mr. J. Williams, gardener to C. J. Proctor, Esq., Noctorum, secured first positions. In the class for six incurved and six Japanese for those who have not won a prize, and for six untrained plants, Mr. A. Price, gardener to F. Jevons, Esq., Claughton, was placed first; Mons. Bernard and E. Molyneux being good in the latter class. J. Darlington, Esq., was placed first in the class set apart for those who do not employ a gardener.

Fruit was largely shown, but the evidence of the season was apparent, from what shown last year. For six dishes fruit (Pines excluded) Mr. J. Barker, gardener to J. W. Raynes, Esq., Rock Ferry, was placed first, his best fruit being Muscat and Alicante Grapes and Marie Louise Pears; Mr. M. Quirk, gardener to W. Porter, Esq., Thingwall, being a close second, his best dishes being the same as the former. Mr. Hannagan, gardener to R. C. Naylor, Esq., Hooton Hall, third, with good Conqueror of Europe Melon and Figs. Two bunches black Grapes: First, Mr. T. Ferguson with large well-coloured bunches of Gros Guillaume; second, Mr. Quirk; third, Mr. J. Barker. Two bunches white Grapes: First, Mr. W. Wilson, gardener to H. Cunningham, Esq., Gorse Cop, Gateacre, with beautifully finished samples of Muscat of Alexandria; second, Mr. J. Barker, with the same variety, but not quite finished; third, Mr. Quirk. Four dishes of Pears: First Mr. Hannagan, second Mr. Ferguson, third Mr. R. Hannagan, gardener to T. Comber, Esq. One dish Pears: First Mr. Winkworth, with well-finished Marie Louise. Six dishes culinary Apples: First Mr. J. Davis, Bodenham, Leominster, with Lord Suffield, Stirling Castle, Striped Beefing, Mère de Ménage, Warner's King, and Blenheim Pippin; second Mr. Hannagan; third Mr. Ranson. Mr. Davis secured honours for six dishes dessert and second for single, the first prize for a single dish being taken by T. Williams, Esq., Higher Bebington, all with Warner's King. Four dishes dessert: First Mr. Hannagan; second Mr. A. Brown, gardener to G. Webster, Esq., Upton, Mr. R. Hannagan, was first with single dish of dessert.

Primulas, Hyacinths, Cyclamens, table plants, and Mignonette were well represented, the prizes going to Messrs. Hains, Sanbach, Esq., Price, and Brown in the order named. For one bouquet Mr. J. Donovan, 34, Westbourne Road, Birkenhead, had an easy first, beautifully arranged, the same exhibitor having on view a splendid anchor composed of the choicest white flowers and Violets, to which a certificate was accorded. The same distinction was awarded to Mr. Henry Middlehurst, seedsman, Manchester Street, Liverpool, for a superb collection of Potatoes, bulbs, &c. Other local nurserymen received awards of merit. Mr. G. Burden, gardener to G. Cockburn, Esq., Lingdale Lodge, Oxtou, exhibited his sport from Princess Beatrice. It is of a similar build to the parent, but of a bronzy rose, much after the colour of Mrs. Shipman. An

excellent concert had been arranged for the evening, and it was a wise hit the Committee made in holding it in the gymnasium attached to the building. Not only was the hall packed in every part, but those who had inspected the beauties of the flowers went afterwards to enjoy the music, thereby leaving room for all to inspect the Show. The Secretary (Mr. Swan) and the Committee arranged everything most successfully.

#### WARE.—NOVEMBER 12TH AND 13TH.

THE second annual Exhibition of this Society was held in the Town Hall, Ware, on the 12th and 13th inst. In point of entries the large classes showed a falling off in entries, probably owing to some of its prominent members exhibiting at the National Society's Show. The general quality of the exhibits, however, fully maintained its standard. Judging from appearances we should also say the Show will prove a financial success. The collection of Chrysanthemums in pots occupying 24 square feet, had but two entries. Mr. G. Fulford, gardener to R. Walters, Esq., Ware, taking the leading honours easily, Sunflower, Louis Boehmer, Barbara, Mrs. Alpheus Hardy, and Violet Tomlin were the chief features. The second prize was awarded to Mr. Collins, gardener to Stanley Gray, Esq., Ware. The group of miscellaneous plants received but one entry from Mr. G. Fulford, which was deservedly awarded the first prize. The specimen plants were below the usual standard, and, like the leading classes, was weak in competition. Primulas are very good, Mr. A. Gull, gardener to J. W. French, Esq., Gt. Amwell, taking first; Mr. R. Smith, gardener to A. Cox, Esq., Ware, and Mr. W. Patmore, gardener to R. Allen, Esq., Ware, taking the other prizes in the order named. The classes for Cyclamen and Zonal Pelargoniums were rather weak. The Committee should see to these classes another year.

Cut blooms.—The principal prize for twenty-four blooms, twelve Japanese and twelve incurved, found Mr. Cox, gardener to Colonel Trotter, Brickenden, just leading, his superior finish to the incurved flowers no doubt gained the victory. Avalanche, Beauty of Castlewood, E. Molyneux, Gloire de Rocher, Golden Empress, Violet Tomlin, and Empress of India were his best. Mr. G. Fulford was well ahead with Japanese, but a little roughness was apparent in the incurves. His best blooms were Stanstead White, Etoile de Lyon, Meg Merrillies, and Puritan. In the class for twelve incurved Mr. G. Fulford was adjudged first prize. The sixes did not contain anything very striking. Mr. J. Turk, gardener to P. Bosanquet, Esq., Little Berkhamstead; Mr. Dover, gardener to — Barklay, Esq., Hoddesdon, and Mr. E. Collins, taking the prizes in the incurved section in the order named. The Japanese again found Mr. J. Turk to the fore, while Mr. R. Dover and G. Collins followed. The class for reflexed flowers was very weak, both in quantity and quality. Anemone varieties showed an improvement, Mr. J. T. Walters, gardener to E. Clapham, Esq., Cheshunt, leading, following at a respectful distance was Mr. J. Turk. Mr. R. Smith came first with Pompons.

In the Grape classes Mr. R. Smith was awarded premier honours with Alicante; Mr. Gull following with good bunches of Lady Downe's slightly deficient in colour. Apples and Pears were a great feature of the Exhibition, and made a nice show in themselves. The baskets of vegetables were well filled and arranged. Numerous classes are given for amateurs, likewise for cottagers. The amateurs have certainly advanced very much, both with pot plants and cut blooms. The baskets of vegetables in the cottagers' class was keenly contested, the quality throughout the class was excellent. Groups were staged by Mr. W. M. Alexander, gardener to E. S. Hanbury, Esq., Messrs. Francis, nurserymen, Hertford, and Mr. Chapman, Bluecoat Nurseries, Ware. The whole Exhibition was tastefully arranged, and reflects great credit on Messrs. J. Rogers, jun., and G. Fulford, the Secretaries, and their efficient Committee.

#### WIMBLEDON.—NOVEMBER 12TH AND 13TH.

THIS, taken as a whole, was a very pretty Show, some falling off of exhibitors being manifest in one or two classes, principally in those for groups and specimen plants; but although not so well contested as in some previous years, there was still some remarkable fine quality displayed in the exhibits of at least one competitor in each of these classes.

Four classes for groups were arranged in the schedule, and all were competed for by several exhibitors in each class. The most interest naturally centred in the larger Chrysanthemum group, for which a silver cup was offered as first prize, which was well and worthily won by Mr. F. Chandler, gardener to the Rev. Canon Haygarth, The Vicarage, Wimbledon, who set up a really excellent group, the plants throughout well grown, having good foliage, and fine fresh flowers. An excellent feature also in its arrangement was that the colours were, so to speak, grouped, and regard paid to the harmony thereof; a point deserving more consideration at the hand of even experts in grouping than it has up to the present time received. Two other exhibitors competed in this class, but their groups were of indifferent quality, and not calling for further notice.

In the various classes for specimen plants of Chrysanthemums also one exhibitor had most excellent exhibits in each class, of course taking all the first prizes in these classes. This was Mr. W. Thornton, gardener to J. Crocker, Esq. The second prizes fell to the share of Mr. J. Bentley, but his plants were much inferior to those of Mr. Chandler.

In cut flowers, the class of most importance was one for forty-eight blooms—twenty-four incurved, not less than eighteen blooms, and

twenty-four Japanese, distinct. Prizes, a challenge cup value 15 guineas and cash £5 as first, given by W. B. Faulkner, Esq.; second, £4; third, £3, these given by the Society. This is the second time of offering the cup. Last season it was won by W. Mease, gardener to A. Tate, Esq. Downside, Leatherhead, and this time the same exhibitor has again been successful; but as it has to be won three times Mr. Mease has again another year to enter the arena and do battle for it before it becomes his or his employer's absolute property. Mr. Mease's flowers were of very high quality throughout, and he was easily first, his varieties were Japanese, Etoile de Lyon, E. Molyneux, Vivian Morel (very fine), Mrs. Cannell, Meg Merrillies, Boule d'Or, W. W. Coles, Sunflower, Madame Baco, Mrs. Neve, Triumph des Chatelets, Mrs. Wheeler, Stanstead White, Lilian B. Bird, Carew Underwood, R. Brocklebank, Puritan, Sarah Owen, Mr. H. Cannell, Album Finbriatum, Madame J. Laing, Thunberg, Avalanche, and Mrs. E. W. Clarke. Incurved varieties: Lord Alcester (2), Princess of Wales (2), John Salter, John Lambert (2), Empress of India, Miss Haggas (2), Violet Tomlin (2), Queen of England (2), Golden Empress, Jeanne d'Arc, Mrs. Heale, Empress Eugénie, Mrs. Shipman, Lady Dorothy, Hero of Stoke Newington, Mrs. N. Davis, and Princess Teck. The second prize in this class was taken by Mr. Carpenter, gardener to Major Colis Brown, Byfleet, with a very good lot indeed of both Japanese and incurves. Mr. C. Gibson, gardener to J. Wormald, Esq., Morden Park, was third, with neat bright flowers.

For twenty-four blooms, twelve incurved and twelve Japanese distinct varieties, Mr. Mease was again first, his varieties being incurved: Queen of England, Empress of India, John Lambert, Lord Alcester, Golden Empress, Mrs. Coleman, Miss Haggas, Princess of Wales, Violet Tomlin, Mrs. Heale, Jeanne d'Arc, Hero of Stoke Newington. Japanese: Etoile de Lyon, Condor, E. Molyneux, Vivian Morel, Sarah Owen, Avalanche, W. W. Coles, A. H. Neve, Boule d'Or, Madame J. Laing, Madame Baco, and Mr. H. Cannell. Three competed in this class, Mr. C. W. Knowles, gardener to Mrs. C. Egerton, being second; Mr. H. Alderman, gardener to Gilliat Hatfield, Esq., third. In another class for twelve incurved, distinct, W. Mease was again first; Mr. J. Wilkins, gardener to J. M. Pearson, Esq., second; C. W. Knowles third. In a corresponding class for twelve Japanese, Mr. Mease was again first, Mr. Wilkins second, and Mr. H. Alderman third.

Dr. Walker, the popular Hon. Secretary, had several meritorious exhibits in cut blooms, being first with six incurved, second six Japanese, and third for twelve Japanese. Two National Society's certificates were given, one to each of the two exhibitors in the amateur classes, whose exhibits were most meritorious, one being awarded to Dr. Walker and the other to W. B. Faulkner, Esq. A pretty and attractive stand of Pompons was shown by Mr. H. Alderman. Bunches of three on stems with foliage, twelve varieties, to which first prize was awarded.

Miscellaneous groups of foliage and flowering plants were somewhat numerous, but of no very high order of merit. Baskets of plants were, however, remarkably well shown, these being ordinary nursery baskets some 3 feet 6 inches in diameter filled with foliage and flowering plants, bright and tastefully arranged. First, Mr. Newell; second, Mr. W. Thornton. The show of Apples was a remarkably fine one—notably three dishes shown by Mr. H. Alderman, the varieties being Peasgood's Nonesuch, Blenheim Orange, and Wellington.

#### WINCHESTER.—NOVEMBER 12TH AND 13TH.

A COMPACT Exhibition, of excellent quality, was that held in the Guildhall in this ancient City on the dates named; in fact, it was one of the brightest yet held by the Society. Mr. Shenton, as usual, had all the arrangement quite of a desirable kind.

Cut blooms formed the most important feature of the Show, being numerous and of good quality. The principal class was that for forty-eight, not less than eighteen varieties of incurved in twenty-four blooms, the same conditions governing the Japanese section. Unfortunately but two entered—Messrs. Drover, nurserymen, Fareham, and Mr. Neville, gardener to F. W. Flight, Esq., Cornstiles, Twyford, Winchester. The former secured an easy victory for a capital stand of blooms in both sections. The names were—Japanese: Mrs. C. Wheeler (2), Sunflower (2), Etoile de Lyon (2), Sarah Owen, E. Molyneux (2), Condor (2), Mrs. F. Jameson (2), Stanstead White (2), Boule d'Or, J. Delaux, M. Bernard, Pelican (full), Lilian Bird, M. E. A. Carrière, Louis Boehmer, Carew Underwood, W. H. Lincoln, and Mrs. Alpheus Hardy. Incurved: Empress of India, Golden Queen of England (2), Alfred Salter (2), Lord Alcester (2), Empress of India (2), Golden Empress (2), John Doughty (2), Miss M. A. Haggas, Mrs. S. Coleman, Robert Cannell, Queen of England, Mrs. Heale, Charles Gibson, Jeanne d'Arc, Princess of Wales, Mrs. N. Davis, Lady Carey, Princess of Teck, and Lady Dorothy. Mr. Neville's stand contained some very good blooms, but on the whole they were smaller than those in the winning stand.

For twenty-four cut blooms, not less than eighteen varieties, any section, Mr. N. Molyneux, gardener to J. C. Garnier, Esq., Rookesbury Park, Wickham, was an easy first, staging sixteen incurved and eight Japanese, all of good quality. The principal sorts were Etoile de Lyon, Golden Empress, Princess of Wales, Miss M. A. Haggas, and Cherub, Mr. C. H. Holloway, gardener to F. W. C. Reed, Esq., Down Grange, Basingstoke, second, with smaller flowers; third Mr. Budd, gardener to F. Dalgety, Esq., Lockerly Hall, Romsey. In the class for twenty-four Japanese, Mr. Trinder, gardener to Sir H. Mildmay, Bart., Dogmersfield Park, Winchfield, easily won with large, heavy, and brightly coloured blooms, the more noticeable being Sunflower, Louis Boehmer, Mons. Elliott (very fine), Mrs. Falconer Jameson, Stanstead White, Madame

Laing, and Madame C. Audiguier. Mr. Neville a good second. For twelve incurved, distinct, Mr. N. Molyneux had but little to spare in wresting from Messrs. Drover the premier award, his blooms were neat and good in quality; the names were Empress of India, Golden Queen, Golden Empress, Lord Alcester, Mrs. S. Coleman (extra), Miss M. A. Haggas, John Salter, Princess of Wales, Hero of Stoke Newington, Mrs. Heale, Nonpareil, and Violet Tomlin. Messrs. Drover's second prize blooms were heavy, but a trifle wanting in freshness. Mr. Neville third.

For twelve, in not less than eight varieties, there was capital competition, Mr. E. Carr, gardener to W. A. Gillett, Esq., Fair Oak, Bishopstoke, first; Mr. F. Smith, gardener to Mrs. Barry Dowling, Rathmines, Winchester, second. For twelve Japanese, Mr. N. Molyneux easily gained the premier position with heavy, well-arranged blooms, Etoile de Lyon, W. W. Coles, and Puritan being worthy of mention. Mr. Budd second. Mr. G. Meldon, gardener to Miss Turner third. Reflexed varieties were but poorly represented. Mr. G. Meldon staged the first prize lot, Mr. E. Carr second.

Plants in groups were arranged around the sides of the hall, and made a bright feature. For the best group of Chrysanthemums Mr. F. Smith, gardener to Lady E. Wodehouse, Mayfield, Winchester, was an easy first with plants dwarf in growth, carrying good foliage and blossoms. Second, Mr. J. Wareham, gardener to Mrs. Gunner, Winchester; third, Mr. G. Smith, gardener to Major Chichester, Medcroft, Winchester. For a group of miscellaneous plants arranged for effect, Mr. E. Astridge, gardener to W. Barrow Simmonds, Esq., Abbots Barton, Winchester, was first with a neat arrangement. Mr. F. Munt, gardener to Mrs. C. Warren, Northlands, Winchester, second. Mr. Kaines, Winchester, secured leading honours for specimen Chrysanthemums for both three incurved or reflexed, three Japanese, and for single specimen, any variety, with fairly meritorious exhibits. Mr. J. Amys, gardener to the Hon. Mrs. Elliott Yorke, Hamble Cliff, Netley, had the best table plants, a good six. Primulas were a strong class, Mr. G. Meldon being an easy first.

The following classes were well contested, making a praiseworthy display. For the best arranged stand of Chrysanthemums and other flowers Miss Ladhams, Shirley, Southampton, led; Miss Nelly Owen, Basingstoke, second; Miss Kate Golding, Portwood, third.

The next class, that for a stand of cut hardy shrubs, Ferns and Grasses, produced a remarkable display. Miss Flight gained premier position for one of the best arrangements we have seen, the colours being well blended, and yet withal simple; Miss Ladhams second, Miss Nelly Owen third.

Fruit was contributed in small quantity, but of excellent quality. Grapes were a distinct feature. For three varieties, one bunch of each, Mr. Budd gained leading honour with Alicante, Muscat of Alexandria, and Gros Colman, in good condition. Mr. T. Hall, gardener to S. Montague, Esq., M.P., South Stoneham House, Southampton, second. Two bunches any black variety, Mr. J. Gardner, gardener to Colonel Stratton Bates, Twyford Lodge, was an easy first, staging Alicante in grand condition; Mr. G. Meldon second with the same variety. For two bunches white, Mr. F. Farwell, gardener to F. Bowker, Esq., sen., Larkhills, Winchester; Mr. Budd second. Apples, both kitchen and dessert, were well represented; in the former class Mr. G. Best, gardener to C. W. Chute, Esq., The Vyne, Basingstoke, secured leading honours. Mr. Amys had the best three dishes of dessert, capitally coloured fruit of popular kinds. Mr. Hall staged a fine lot of Pears, for which he received first prize. Vegetables are always well shown here. For eight varieties Mr. Best won easily; Mr. Amys second.

#### EXETER.—NOVEMBER 13TH.

THE Devon and Exeter Horticultural Society were rather unfortunate as regards weather for their Show, held in the Victoria Hall on Friday last. The Exhibition, taken collectively, was, however, one of the best ever held in the city, the cut blooms of both Japanese and incurved being very good, although the competition was not so keen in some classes as last year. The groups were effective, being mostly circular, and arranged in the body of the hall. A Palm is allowed for a central plant, and small Ferns and Grasses for the edging, which adds very much to the general effect.

*Cut Blooms.*—In the leading class (that for forty-eight, twenty-four Japanese and twenty-four incurved, in not less than eighteen distinct varieties of each), a silver cup value 5 guineas was offered as first prize, with proportionate second, third, and fourth prizes. Some excellent flowers were staged in this class, Mr. Stiles, gardener to Miss Fripp, The Grove, Teignmouth, securing the first place with very good incurved and Japanese, consisting of the following incurved:—Back row: Empress of India, Lord Wolseley, Golden Empress, Jeanne d'Arc, Lord Wolseley, Queen of England, Lord Alcester, and Empress of India. Second row: Violet Tomlin, Miss Haggas, Baron Beust, Queen of England, Prince Alfred, Golden Empress, Lady Dorothy, and Alfred Salter. Front row: Jeanne d'Arc, Miss Shipman, Lady Hardinge, Baron Beust, C. Gibson, Princess Teck, Nil Desperandum, and Princess of Wales. The Japanese were—back row: M. Bernard, Etoile de Lyon, E. Molyneux, Avalanche, Etoile de Lyon, Lady Lawrence, M. Bernard, Boule d'Or. Second row: Condor, Mr. Wheeler, Mad. Laing, Sunflower, Belle Paule, Comte de Germiny, Avalanche, and Madame Baco. Front row: Beauty of Castlewood, Mr. H. Cannell, Belle Paule, W. W. Coles, Louis Boehmer, Lady Lawrence, Mad. C. Audiguier, and Mr. H. Cannell. Mr. Copp, gardener to W. S. E. Earle-Drax, Esq., Dorset, was a good second, but was weaker in his incurved, although some were very fine; and in his stands were found the premier Japanese and incurved blooms in the Show, the

former being a large solid flower of Lord Alcester, the latter a very fine Stanstead White. Third, Mr. Foster, gardener to H. Hammond-Spencer, Esq., Torquay, noticeable among his incurved being a magnificent bloom of Mrs. Coleman.

For twenty-four Japanese, distinct, Mr. Hawkins, gardener to H. Fowler, Esq., Taunton, was a good first, having Florence Davis (fine), Gloire da Rocher, Baronne de Prailly, Souvenir d'Angèle Amiel, Japonaise, E. Molyneux, W. H. Lincoln, Etoile de Lyon, R. C. Kingston, Mrs. Cannell, Sarah Owen, Madame Laing Mrs. Wheeler, Miss Hartzhorn, Mrs. F. Jameson, Aida, Boule d'Or, Mr. Bernard, Louis Boehmer, Mr. Hardy, Madame Baco, Thunberg, Mrs. Townshend Clarke, and W. W. Coles; Mr. Foster second; third, Mr. Scarle, gardener to J. N. Whitehead, Esq., Torquay.

For a similar number of incurved blooms, Mr. Lloyd, gardener to V. Stuekey, Esq., secured the leading place, followed by Mr. Southey, gardener to Colonel Lueas, both stands being only fairly good. In the following class for twelve distinct, Mr. Copp was first with a very strong stand, Miss Haggas, Queen of England, Lord Wolseley, Venus, and Violet Tomlin among the best flowers. Mr. Searle was second.

In the class devoted to twelve Japanese was found the strongest competition in the Show, and here Mr. Southey was first with good flowers as follows: Madame Laing, Fair Maid of Guernsey, Comte de Germiny, Sarah Owen, Avalanche, Sunflower, Etoile de Lyon, Elaine, Belle Paule, Stanstead Surprise, Lady Lawrence, and Baronne de Prailly; second, Mr. Stiles; third, Mr. Heath, gardener to Sir W. H. Walrond, Tiverton. Prizes were offered for six yellow Japanese, one variety, and also for six of any other colour, the competition in each class being keen, and the flowers very good. For the former Mr. Stiles was a good first with Mr. H. Cannell (very fine); second Mr. Southey, with Sunflower. Mr. Hawkins came first in the latter with Louis Boehmer; second, Mr. Stiles with Etoile de Lyon. Prizes were offered for single Chrysanthemums, but no exhibits were forthcoming.

*Groups.*—Here Mr. Rowland, gardener to W. Brock, Esq., Exeter, was invincible, easily winning the first prizes in the three classes with a very excellent arrangement in each instance. In class 2, for eighteen plants arranged for effect in a circle, this plants were remarkably good, and arrangement all that could be desired. The same remark applies to his group of miscellaneous plants. Mr. Ebbutt, gardener to the Rev. F. Hamilton Gell, was second in the two classes.

*Fruit.*—The show of fruit was extensive, no less than thirty-eight classes being devoted to Apples and Pears; the competitors being plentiful made quite an imposing display. Some very good Grapes were also staged. The three bunches of white Muscats from Mr. Connelly, gardener to J. R. C. Talbot, Esq., were extra good, and easily gained the first prize. For three bunches of Alicante Mr. Dark, gardener to J. M. Miller, Esq., was first with very large clusters of perfect colour. Second, Mr. Martin, gardener to Lord Poltimore. For three bunches of any other variety Mr. Lloyd was a good first with splendid Gros Colman; second, Mr. Dark, with Lady Downe's. Mr. Garland, gardener to Sir T. D. Ackland, won the first prizes for a collection of twenty-four dishes of Apples and that for nine dishes of Pears with splendid samples of each. Mr. Martin was second for Pears. For six kinds, first Mr. Dark, second Mr. Garland. A class was devoted to the best Pears for flavour, some twelve dishes being staged. Mr. Heath was awarded premier honours for delicious Doyenné du Comice; Mr. Garland second with the same variety, scarcely ripe.

Messrs. R. Veitch & Son, Exeter, contributed, not for competition, a collection of Palms and other plants that were much admired, also 200 dishes of Apples and Pears, finely coloured. Messrs. Slater and Randall, Exeter, and R. Smith, Worcester, also sent fruit.

#### LEICESTER AND MIDLAND CHRYSANTHEMUM SOCIETY.

NOVEMBER 13TH AND 14TH.

THIS Show, which was held at the Temperance Hall, Leicester, proved to be an excellent one, and was considered by the Judges superior to any of those held in previous years. The Society have been hampered in their operations by the room being much too small, and hitherto they have been unsuccessful in securing one sufficiently large, and at the same time of a suitable character. The Show this time was very attractive, but unfortunately it left too little space for visitors and the public. It is hoped the Committee will be able to secure a larger room for future shows.

The groups of Chrysanthemums arranged for effect, four in number, two on each side of the hall, formed a very conspicuous feature, and the quality was decidedly better than that of previous years. Far the best, and an excellent one in all respects, was that exhibited by Mr. J. Underwood, gardener to R. Walker, Esq., Enderby Hall; second, W. Calvert, gardener to G. Oliver, Esq.; third, Messrs. J. & H. Hickling, The Old Nurseries, Loughborough.

The most important classes in point of interest were the two for cut blooms, open, twenty-four incurved in not less than eighteen varieties, and twenty-four Japanese, distinct varieties. In the former, Mr. A. Coombes, gardener to the Earl of Dudley, Himley Hall, was first with a fine and fresh lot, his varieties being—Back row: Lord Wolseley, Lord Alcester, Golden Emperor, J. Lambert, Golden Empress, Alfred Salter, J. Lambert, and Empress of India. Middle row: Miss Haggas, Violet Tomlin, Jeanne d'Arc, J. Doughty, Mrs. Heale, Violet Tomlin, Miss Haggas, and Lord Derby. Front row: Mrs. Shipman, Jeanne d'Arc, Sir S. Carey, Jardin des Plantes, Mrs. Coleman, Mr. Brunlees, Mrs. Heale, and Barbara. Second prize, Rev. J. Bird, Walton Rectory

Loughborough. Third, Mr. R. Adams, gardener to P. Harter, Esq., Lubenham, Market Harborough. In this class there were six competitors.

Class 2, for twenty-four Japanese, distinct, brought eight competitors, who made a fine display. The first prize was at first awarded to Mr. A. Coombes, whose stand unquestionably contained the finest flowers, and fully merited the first award; but afterwards it was discovered that he had (undoubtedly inadvertently) failed to comply with the schedule, which called for twenty-four distinct varieties, whereas he had staged only twenty, having four duplicates. This caused his stand to be disqualified, much to the regret of the Committee, and the first prize fell to the lot of Mr. R. Adams, who had in his stands the following varieties:—Back row: E. Molyneux, Sunflower, La Triomphante, Sarah Owen, Moonlight, Madame J. Laing, Avalanche, and Etoile de Lyon. Middle row: Stanstead White, Mons. Bernard, W. W. Coles, Holborn Beauty, Triomphe de la Rue des Châlets, Ralph Brocklebank, Madame Baco, and Alberic Lunden. Front row: Belle Paule, Boule d'Or, Annie Clibran, Mrs. Wheeler, Mrs. J. Wright, Val d'Andorre, Meg Merrilies, and Mad. C. Audiguier. Second, Mr. P. Blair, Trentham. Third, Mr. Thos. Mayes, 75, Alexandra Road, Kettering. Mr. Blair had in his second prize stand several notable flowers of new or very rare varieties, principal amongst which were Vivand Morel, very fine; Lillian B. Bird, a most chaste and refined flower, which must become popular; Mrs. J. Thompson, a large and deep back row flower, somewhat similar in form and colour to Belle Paule, but larger, and more deeply coloured; Centenary, a very striking flower, incurved Japanese, with long and broad waxy-looking petals of a pale lemon yellow, shaded darker; Sugarloaf, a deep incurved Japanese, shaped somewhat like a sugarloaf, very distinct, colour inside of petals red, outside pale yellow, striped with gold yellow; Mrs. J. S. Fogg, a golden yellow incurved Japanese, moderate size; and Wm. Lane, a flower similar in form and character to Madame Baco, of an orange buff colour. In the same exhibitor's stand of twenty-four incurved vars. was a remarkable bloom of a new variety named Madame Darrien, bronzy buff or orange bronze in colour, and resembling in size and shape a fine bloom of Princess of Wales. The Judges formed a very high opinion of this flower, as being likely to prove a most valuable acquisition.

In class 3, open, six blooms incurved and six blooms Japanese, Mr. H. Dunkley, gardener to S. Symington, Esq., Brooklands, Market Harborough, was placed first; Mr. W. Bolton, gardener to Major O'Neal, Ratcliffe Hall, second; and Mr. Hickling third.

Class 8 was an important one, being for twenty-four blooms distinct, twelve incurved and twelve Japanese, open to gentlemen's gardeners and amateurs residing within the county of Leicester, and in which the Leicester tradesmen's cup, value £5, was offered. The winner was the Rev. J. Bird, Walton Rectory, Mr. Dunkley being second, and Mr. W. Bolton third. The varieties in the first prize stand were—*Incurved*: Empress of India, Alfred Salter, Golden Empress, Queen of England, Miss A. Haggas, Jeanne d'Arc, Prince Alfred, Lord Alcester, Barbara, Mrs. Coleman, Princess of Wales, and John Salter. *Japanese*: Etoile de Lyon, E. Molyneux, Avalanche, Madame C. Audiguier, Mons. Bernard, Condor, Thunberg, Fair Maid of Guernsey, Stanstead White, Sunflower, Middle. Lacroix, and Criterion. For twelve blooms, six incurved and six Japanese, Mr. Dunkley was first, with Mr. Read second, and Mr. Bolton third. For twelve blooms incurved, amateurs only, Mr. Whait was first, Mr. C. Day second, and Mr. Read third. In a corresponding class for twelve Japanese Mr. Read was placed first, Mr. Day second, and Mr. T. W. Bell (the popular Hon. Sec.) third.

The remaining classes were of minor importance, the principal prize-takers being Mr. A. E. Jayes, Mr. J. Whait, Mr. Yeomans, Mr. C. Day, Mr. H. Bell, and Mr. T. W. Bell.

The exhibits not for competition were somewhat numerous. A fine bank of decorative plants came from Mr. G. Barry, gardener to — Snow Esq.; also many fine decorative plants from the Hon. Sec. A splendid lot of more than 100 dishes of Apples came from Mr. G. Bunyard, Maidstone. There was an exhibit of forty-eight varieties of Chrysanthemums, including many new kinds, from Messrs. W. Clibran & Sons, twelve blooms of Louis Boehmer, and made up flowers such as an anchor, a basket, a bouquet, ladies' sprays, coat-hole flowers, &c., came from W. K. Woodcock, Barkley Road Nurseries, Syston, Leicester. Too much praise cannot be given to the Hon. Sec., Mr. T. W. Bell, for carrying out his part of the work of organising and completing the arrangements so satisfactorily.

#### SHEFFIELD, HALLAMSHIRE AND WEST RIDING.

NOVEMBER 13TH AND 14TH.

THE Show this season, which was held in the Corn Exchange, Sheffield, was quite equal in point of merit to those of preceding years. In the two most important classes for cut flowers—viz., those for twenty-four incurved varieties and twenty-four Japanese, the entries were not so numerous as last year, there being six competitors in each class, as against seven in incurved and eleven in Japanese in the previous season, but the twelve sets of twenty-four each this year shown formed a very fine table of flowers, the quality being throughout good, and the competition exceedingly close.

The first prize for twenty-four Japanese was won by Mr. Vaughan, gardener to T. Brocklebank, Esq., Liverpool, who had large solid flowers of White Empress (2), Emily Dale (2), Queen of England (2), Lord Alcester (2), John Salter, Golden Empress, Prince Alfred, Miss Haggas, Lord Wolseley, Beauty (2), Violet Tomlin, Mrs. Heale, Princess of

Wales, Jardin des Plantes, Lady Dorothy, Jeanne d'Arc, Mr. Bunn, and Barbara. Mr. R. Parker, Impney Hall Gardens, was second; Mr. A. Coombes, Himley Hall Gardens, Dudley, third; and Mr. P. Blair, Trentham Gardens, Stoke-on-Trent, fourth. In the corresponding class for twenty-four Japanese, Mr. R. Parker was successful in obtaining the first prize, his varieties being:—Back row: Vivand Morel (very fine), Boule d'Or, Etoile de Lyon, E. Molyneux, Sunflower, Stanstead White, Baronne de Prailly, and Florence Davis (fine). Middle row: Meg Merrilies, J. Délaux, Golden Dragon, Avalanche, Gloire de Rocher, Madame C. Audiguier, R. Brocklebank, and Mrs. F. Jameson. Front row: Thunberg, Sarah Owen, Madame Jno. Laing, Triomphe de la rue des Châlets, W. H. Lincoln (fine), Puritan, Middle. Maria Hoste, and Mrs. A. H. Neve. The second prize went to Mr. A. Coombes, who had a very good stand, especially fine being Mrs. Jameson, Etoile de Lyon, Stanstead White, Japonais, and Alberic Lunden. Mr. C. Osborne, gardener to H. T. Robinson, Esq., Liverpool, was third; and Mr. P. Blair fourth.

In the classes for twelve incurved varieties, open, and twelve Japanese, open, there was good competition, Mr. R. Parker obtaining the first prize in each. His twelve incurved consisted of Golden Empress, White Empress, Lord Wolseley, Lord Alcester, Mrs. Coleman, Violet Tomlin, Queen of England, John Doughty, Princess of Wales, Miss Haggas, Princess of Teck, and Mrs. Heale. His twelve Japanese were Florence Davis (fine), Thunberg, Louis Boehmer, Etoile de Lyon, Avalanche, Ralph Brocklebank, W. H. Lincoln, Gloire de Rocher, Vivand Morel, Sunflower, and Triomphe de la rue des Châlets. For the twelve incurved, Mr. C. Osborne was second; and Mr. W. Welton, Grimsby, third. For twelve Japanese, T. Vaughan was second, and T. Hargreaves third.

The classes provided for groups arranged for effect were numerous and the competition keen. In that for a group in a space not exceeding 64 square feet the first prize was taken by Mr. W. Redmill, gardener to J. G. Lowood, Esq., with a beautiful group, equal to the best we have seen this season. The plants were very dwarf, with large fine foliage and flowers, the latter being very bright and fresh. The arrangement was excellent. The second prize group was shown by an amateur, Mr. H. Greaves, and was very commendable. Third Mr. E. Pidsley, gardener to Mrs. H. Wilson, Westbrook. For six Chrysanthemums, trained specimens, Mr. E. Pidsley was first with neat well-trained bushes 2 feet to 2 feet 6 inches over. For the three each incurved and Japanese trained specimens, Mr. C. Scott, gardener to J. Colley, Esq., was first, and for three trained Pompons Mr. Pidsley was again first.

A class for a group of miscellaneous plants, arranged for effect in a space of 64 feet, brought two of the best groups of the kind we have seen this autumn, and which were greatly admired. Mr. E. Pidsley was placed first and Mr. W. Collier, gardener to J. Eaton, Esq., second. Miscellaneous groups by amateurs were both numerous and good. Mr. G. Walker was first, J. A. Roberts second, R. Gascoigne third, and J. W. Jarvis fourth. British Ferns also, which are invariably shown well at Sheffield, were this year quite equal to former years. For a group Mr. J. Eadon was first, Mr. J. G. Newsham second, and Mr. W. Smith third. For six pots Mr. J. Eadon was first, Mr. W. Smith second, and Mr. J. G. Newsham third. There were other classes for Ferns and Selaginellas.

Cut flowers in the district and amateurs' classes, also in the cottagers' class, were shown in immense numbers, and in quality almost equalling those in the open class. Great strides in this respect have been made by the amateurs and cottagers during the last several years. In the district class for twelve incurved large flowers, Mr. S. Gilbey was first, Mr. C. Scott second, and Mr. Redmill third.

For twelve Japanese, Mr. C. Scott was first, Mr. J. H. Clements second, and Mr. W. Redmill third. For a hand bouquet of Chrysanthemums—first, Mr. F. Stocks; second, Mr. E. Pidsley.

For six Chrysanthemums incurved, distinct, cottagers' class many competed, and the prizes, eight in number, were won as follows:—First, B. Glossop; second, R. Smith; third, D. Lynn; fourth, J. Beighton; fifth, W. H. Hinchliffe; sixth, W. J. Carnall; seventh, W. Fenwick; eighth, A. Jones.

Six Japanese—First, T. Mallinson; second, R. Smith; third, W. Powell; fourth, W. H. Hinchliffe; fifth, D. Lygo; sixth, W. Fenwick; seventh, W. H. Milnes; eighth, J. Beighton.

Many more classes besides those above recorded were provided, but want of space prevents us giving details. Messrs. Fisher, Son, and Sibray, Messrs. Crossland & Sons, Mr. S. W. Seagrave, Mr. H. Slaney, and Mr. W. Artindale all exhibited groups of plants not for competition, the three first named being each very fine banks of decorative plants. That of Mr. Seagrave contained a splendid specimen of *Asplenium nidus* 4 feet across. Mr. Nelson of Catcliffe Nurseries, near Rotherham, showed a grand collection of about 100 dishes of Apples, splendid in quality, and very bright in appearance considering the black and smokey district in which they had been grown.

There was a large attendance during the afternoon of the first day, and the Show will undoubtedly prove a financial success, equalling, if not exceeding, that of last year. The Society is now very strong, and appears likely to go on increasing in strength.

WE have reports of several other shows that arrived late, and which it is not possible to insert this week. They were sent as soon as the writers could prepare them, and we cordially thank all our friends for their ready and appreciated co-operation.

## FRUIT FORCING.

**PEACHES AND NECTARINES.**—*Earliest Forced House.*—The trees must now be started to ripen the fruit in May, when the varieties consist of Hale's Early, Stirling Castle, Royal George, and Crimson Galande Peaches, with Lord Napier, Elruge, and Dryden Nectarines. The very early varieties, Alexander, Waterloo, and Early Rivers Peaches, with Advance Nectarine, need not be started until the new year to ripen at the time named. The trees should be thoroughly examined for brown aphids, and if there be the least trace of the pest the affected parts should be brushed over the same way as the growths with tobacco water, and the house thoroughly fumigated on two consecutive evenings. If the lights have been off, the border will have been thoroughly moistened down to the drainage, but there must be no mistake about this, for it is important that the trees have sufficient water at the roots; therefore if any doubt exists as to the moisture of the soil give a thorough supply slightly in advance of the temperature of the house. Weakly trees will be benefited by an application of liquid manure. Fire heat need only be employed at night to exclude frost, and by day to insure a temperature of 50°. Commence ventilating at 50°, and close the house at that temperature, ventilating fully without lowering the heat below 50° in the daytime. Syringe the trees in the morning and early afternoon of fine days until the buds begin to show colour, but then (and on dull days prior thereto) discontinue the syringing, yet maintain a suitable moisture in the atmosphere by damping the paths, borders, and other available surfaces on bright mornings and fine afternoons, admitting a little air constantly at the top of the house. Aim at bringing the trees on gradually to secure well developed blossoms, strong in the stamens with anthers laden with perfect pollen and the pistils stout, well advanced above the ovary, and perfect for fertilisation. These, however, will be perfect or imperfect, as they were formed in embryo in the previous season; but they can be enfeebled by bringing them on too rapidly, and made thin in the petals, weak in stamens, and slender in pistil, with ill-developed ovary, by not affording time for their perfect development.

*Houses Started at the New Year.*—Trees started early in the year for affording fruit at the end of May or early in June, the trees being the older forcing varieties, must now be kept as cool as possible. This is best effected by keeping the roof lights off the house until the time of starting. The severest weather does not injure the wood or buds, and the trees are insured perfect rest, so far as it is practicable in our climate. The lights, however, should be replaced about a fortnight in advance of starting the house, and they must be cleansed, repaired, and, if necessary, painted. The woodwork of the house must be washed with soapy water, and the walls washed with hot lime. Pruning will have been attended to, which is a light affair where proper attention has been given to disbudding, retaining growth only essential for extension and next year's crops, and cutting out, after the fruit is gathered, the useless wood. The trees, however, must be examined to remove wood not required and that having been overlooked during growth. Brown scale is sometimes troublesome, and it is impatient of extremes. Syringing with water at a temperature of 140° to 160° frees the branches of the pest, but the water must not be used excessively, it suffices to thoroughly reach every part with the hot water. Frost also has a very decisive effect on brown scale, and trees exposed in the rest season are seldom affected with it, but it is often introduced from plant houses by persons in charge of ventilation. Trees under fixed roofs may be cleansed of scale by washing them with a solution of softsoap, 4 ozs. to a gallon of water, using a stiffish brush, taking care not to dislocate the buds. Secure the trees to the trellis, allowing plenty of space in the ties for the swelling of the branches. Remove any loose inert surface soil, supplying fresh loam not more than a couple of inches thick on the roots, and to which has been added a quart of bonemeal to every bushel, and double that quantity of wood ashes, the whole well incorporated, or 4 ozs. of the following mixture may be applied as a surface dressing per square yard, steamed bonemeal 7 lbs., kainit 3 lbs., mixed. Superphosphate may be used instead of steamed bonemeal, and nitrate of potash instead of kainit, but 2 ozs. only of the mixture must be applied before starting the trees, and a similar dressing when the fruit is about the size of marbles. Mulching with short manure should be deferred until the trees are somewhat in growth. Houses with fixed roof lights should be kept as cool as possible, ventilating to the fullest extent except when severe frost prevails.

*Houses for Starting in February.*—The trees started early in February ripen the fruit late in June or early in July, and will now require similar treatment to that advised for those in the house to be started in the new year. The roof lights are very much better removed, but it is a common practice to use houses of this kind for plants requiring protection from frost, especially Chrysanthemums. It is not a good practice, for the Peach trees are deprived of that rest so essential to success, and it often excites the trees prematurely, being then followed by a check, as is usually caused when the Chrysanthemums are over by throwing the house open, inducing the buds to fall. It is also a bad system to leave houses and trees unattended after the leaves fall until the absolute necessity

arises for starting the trees. The trees are never handled so safely as when the wood contains least sap, which is as soon as the leaves have fallen, and the delay is taken advantage of by red spider, thrips, and other insect pests to find safe retreats. The house, therefore, should be thoroughly cleansed, the trees pruned, readjusted to the trellis, and every needful operation performed, so that a start can be confidently made when the time arrives.

*Houses Started in March.*—The trees in these structures and closed early in March, will ripen their fruit in July if brought forward by artificial heat, but where warmth is only given when the trees are in blossom, and to secure the safety of the young fruit from frost, the fruit will not ripen until August or September if kept cool. The house may be a Peach case or glass-covered wall, with sufficient hot-water piping to exclude frost, afford a genial warmth when the trees are in blossom, accelerating the ripening as may be necessary, and ripening the wood in cold districts. The trees are now leafless where they have been subjected to artificial heat to ripen the fruit in August, and should undergo the operation advised for those in the early house. The roof lights should be removed, the hot-water pipes emptied, leaving the lights off until the blossoms show colour, unless it is desired to start the trees before. If the lights are fixed, the ventilators should be thrown open to the fullest extent except when frost prevails.

*Latest Houses.*—Late Peaches are quite as valuable as early ones, considering that they are had at much less cost, for all that is necessary for late houses is a gentle warmth in spring and in autumn, and not always heat at those times. The fruits are noble at dessert, and when well done good in quality. Make no attempt to remove the leaves until they part readily from the trees by shaking the trellis. Cut out all the wood that has borne fruit and all superfluous growths. Do not allow the soil to become very dry, but if necessary give water to moisten the soil down to the drainage. Keep the house cool by free ventilation, clearing away the leaves as they fall. Trees that grow too luxuriantly should be root pruned and lifted whilst the leaves are upon the trees; but the wood being unripe, they must not be lifted until the leaves have for the most part fallen, or the unripe wood will shrivel and die. If the wood does not ripen well, turn on the heat by day with moderate ventilation, and turn it off in the afternoon, so as to have the pipes cool before night, and then open all the ventilators, unless frost prevails, when ventilate according to circumstance, for a sudden collapse of the foliage is detrimental to the trees' health. When the wood does not ripen up to the points of the shoots a trench may be formed at some distance from the stem, and the roots be cut, which will check the tendency to growth and induce ripening. After remaining open ten days or a fortnight the trenches may be closed, making the soil firm, and giving a good watering.

*Wall Cases or Unheated Houses.*—In some localities Peaches and Nectarines do not succeed against walls, and they are covered with glass, under which the trees afford more satisfactory crops. The walls should have south aspects in the northern parts of the kingdom; in the south late Peaches and Nectarines ripen well in September and October in structures facing west. They are not, however, always satisfactory. Sometimes the border is at fault and the trees make late growth, not ripening the wood well. Where that occurs the trees should be lifted and the roots laid in fresh compost nearer the surface. This must be done carefully and not too soon, the leaves having for the most part fallen. If judiciously performed next year's crop will not be jeopardised, but the blossoms will set well, stone certainly, and good fruit 'e ha' by good management. Too severe root-pruning must not be practised. If the drainage is not good it must be rectified, and the soil being unsuitable it should be put right by removing a part and adding fresh. Patching bad borders is not good practice, and it is often more profitable to make new ones. The border should have 3 or 4-inch drains, with proper fall and outlet to carry off superfluous water, and 1 foot of drainage over the drains formed of brickbats, rubble, &c., roughest at bottom and about the size of road mettle at top, with a 3-inches layer of older mortar rubbish over the drainage. Two feet depth of soil is sufficient, making the border 2½ feet deep in the first instance to allow for settling. The top 3 inches of a pasture where the soil is a rather strong calcareous loam is most suitable, and if interspersed with pieces of limestone and flint it could not possibly be improved upon by any admixture. If light add a fourth of clay marl, dried and pounded, and one-sixth of old mortar rubbish, or weathered chalk if deficient in lime, incorporating all well together, and placing in the border rather firmly. The border need not be wider than 4½ feet in the first instance for young trees, and all are accommodated in a border 1 foot wider than the extent of the roots, adding to it as the roots extend. A narrow border is superior to a wide one, only due regard is had to watering and feeding, with judicious mulching. If new trees are to be put in select those just coming into bearing—say two or three years trained to walls, and lifted in the preceding year to moving. Carefully lifted and planted they will bear fruit the season following planting, and not being overcropped will not be materially hindered in extension. Introducing new trees and the lifting and replanting Peach and Nectarine trees should be effected as soon as practicable, as upon that depends success in the following year. By a judicious selection of varieties fruit of first-class quality may be had in a Peach case from the beginning of July until early October. Peaches: Alexander, Hale's Early, Dagmar, Crimson Galande, Goshawk, Alexandra Noblesse, Dymond, Belle Beaue, Barrington, Princess of Wales, Sea Eagle, and Golden Eagle. Nectarines: Advance, Lord Napier, Dryden, Rivers' White, Pine Apple, and Victoria. Those varieties are good and come into use successively as named.

## THE BEE-KEEPER.

WE have received notice that the article which appeared on page 211 of the *Journal of Horticulture* for September 3rd, 1891, under the heading of "Punic Bees, and Those who Know Nothing About Them," and signed "A Hallamshire Bee-keeper," charges the editors of the *British Bee Journal and Record*, Messrs. Cowan and Carr, while purporting, in answer to an inquiry, to give all the information in their power about the so-called Punic bees, deliberately suppressed facts within their knowledge, and thus gave a false account of matters of interest to the readers of their journal. That the article also insinuates that Messrs. Cowan and Carr have some personal and unworthy motive for concealing facts which it is plainly stated they must have known. There was no mention of the Punic bees in the *Record* of June, 1890, nor has there been any allusion to them either editorially or by any of its correspondents. There is also no statement in the *Record* for June, 1890, that Mr. Carr had a Punic stock in his possession, and he has never written anything about Punic bees.

It is suggested that the appearance of the article in question might be due to an oversight, and not to any intention to injure anyone. That is certainly the case, for it is far from our desire to make reflections on the reputation of those for whom we have never entertained feelings other than those of true respect, and we now desire to express our regret that the article referred to appeared, and to withdraw all the charges and insinuations therein contained.

### APIARIAN NOTES.

#### THE WEATHER.

ON the 11th inst. our barometer sank in two hours from 29° to 28°, indicating a storm, which we entirely escaped, the bees carrying a good deal of pollen on that and the subsequent day.

#### A VISIT TO CARLUKE.

I paid a visit to some of the oldest bee-keepers of that district lately, and as some of these old bee-keepers were those the late Mr. Pettigrew was wont to speak of as getting large yields of honey from their big straw hives. It was interesting to me to learn from them that they did not entirely agree with Mr. P.'s teachings. Their success, they said, depended more upon their management than of wood *v.* straw hives. Pettigrew advocated the wide hive, but my informers told me distinctly that their success was entirely due to deep but narrow hives, *à la* Stewarton; and that in a cold season it was vain to expect a big yield of honey from wide hives, and it was only from what some sarcastically termed "water stoups" that surplus could be expected in unfavourable seasons.

#### INTOXICATED BEES.

While reading the interesting notes on hardy flowers at pages 401-2 by Mr. S. Arnott, they brought to memory his promise of last year to investigate the cause of bees becoming torpid when working upon *Sedum Fabaria* or *S. spectabile*. Owing to the unfavourable state of the weather, and the influence it has upon some flowers more than others, in preventing them being in a fit state to induce bees to work upon them, I have been unable to carry out my projected experiments. Although the plants flowered well this year, they were not much visited by bees in the past autumn. *Sedum ibericum* during summer was as usual very attractive to them. On one occasion I observed a few bees alight upon the large purple heads so pretty at that season. I had only a few steps to take to reach the plants, but although a few seconds only had elapsed, two of about a dozen of the bees at work were in a torpid or intoxicated state. A shower of rain put an end to what I had hoped to be a discovery—that the flowers, in addition to the secretion of

honey, also distil something of an intoxicating nature. Although most of the bees seemed to be unaffected, the two in question were instantly affected, which I thought from the effects of sipping a sort of ether, which sometimes stands in little globules on the top of the petals. I held the two bees in my hand for thirty minutes before they recovered from their torpor and was able to fly. I hope Mr. Arnott will give us the benefit of his observations.

#### WINTER WORK.

Now that the winter is upon us with its long evenings, these can be devoted to thought, study, and work: there is no room for idleness in any calling whatever. In the bee world past experience points out clearly the improvements necessary to make things go smoothly and as we desire. Go over every empty hive, repairing every defect, and add any improvement suggested to you, until you have reached your ideal or what you consider a perfect hive. Thereafter make a pattern, not a model, thinking and studying every requirement as you go along; pass nothing that is likely to be an eyesore or that which will give trouble in the future, and omit nothing that you see will be of benefit to the bees or the hive.—A LANARKSHIRE BEE-KEEPER.

\* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**A Yellow Chrysanthemum, Florence Percy (E. A. W.).**—It is difficult to say whether your plant is really a sport from the variety you name, but it has something of the same character. Increase your stock, grow the plants well, and it would be easy to determine next season if it is what you suppose.

**Chrysanthemum Mrs. Alpheus Hardy (Martin Lilsbury).**—We thank you for the bloom which you have been so good as to send for the decoration of our sanctum. The bloom was fresh and neat, though, as an incentive to you, we may say that several have been exhibited this year of at least twice the size, and in other respects as perfect in form and florets.

**Chrysanthemum Etoile de Lyon and Stands for Blooms (R. M.).**—According to the National Society's catalogue, *Etoile de Lyon* was sent out by Boucharlat in 1888, and it would no doubt reach England soon after it was announced. The size of stands for twelve blooms as adopted by the above-named Society is as follows:—Length, 24 inches; width, 18 inches; height at back, 6 inches; in front, 18 inches; the holes to be 6 inches apart from centre to centre. No limit is, however, imposed upon stands for Japanese blooms.

**Gooseberry Hedges (C. P.).**—About 9 inches asunder is a suitable distance for planting. We cannot add any other reason for the circumstance of birds not taking the buds of Gooseberries, grown as represented last week, as freely as from bushes. You are quite right in your assumption that the word "leads" was a misprint, and ought to have been "buds." We have known Gooseberry bushes practically ruined by sparrows pecking out the buds while those on hedges or cordons in the same garden were seldom interfered with by the mischievous birds.

**Boiler and Piping for Tomato Houses (R. C.).**—A 3-feet terminal saddle boiler will heat the quantity of 4-inch piping necessary for the Tomato houses. To warm the houses properly you will need two rows of 4-inch pipes on both sides of the houses if spans, or four rows of piping in front or near if lean-to's. It is a great mistake to restrict the quantity and size of piping, as the pipes require to be kept hot when few and small to secure the requisite temperature, which is not good for the plants nor their owner, as there is a great waste in fuel. What is wanted is heat in the pipes and reserved there, 4-inch pipes being more economical than 3-inch.

**Maturing Ripe Cucumbers for Seed (E. C.).**—The proper plan is to lay the ripe Cucumbers on a shelf in a heated structure till the

## HOLIDAY NOTES IN SWITZERLAND.

WHEN the opportunity was afforded late in the past summer for a journey to Switzerland it was gladly seized, and a portion of the annual holiday tour, which has for some years been devoted to gardening explorations in various directions, was at once allotted for the purpose of what appeared likely to prove the most novel and delightful yet enjoyed. As soon as the needful preparations were completed the journey was commenced, and the route chosen for the first stage, London to Paris, was *via* New-haven and Dieppe, not only on the ground of economy, but because another glimpse might be obtained of the charming scenery of Normandy, to which reference was made on a previous occasion. Unfortunately, time did not permit the acceptance of an invitation to spend a few days among the orchards in this part of France, though undoubtedly such an inspection would have yielded considerable interest. However, it is a pleasure deferred, and Paris offered so much of horticultural importance that thither we sped without undue delay.

Some of the leading features of Paris that concern "Journal" readers have been noted several times, and it is not my intention to refer to them here now, but when the pages are less crowded than at present a few ideas that were gained on the last visit may form the subject of a chapter or two.

Probably the majority of tourists from England proceed to Geneva from Paris by the night service, but I elected to journey by a morning train, as I especially wished to see something of the land cultivation in the large part of France through which the line passes by way of Dijon. Judging gardening or farming from the windows of an express train is not, perhaps, the most satisfactory method of arriving at accurate conclusions, but it is surprising how much may be learnt even in this way with a little knowledge of what to look for. After passing the forest of Fontainebleau the open country is entered, and then for some hundreds of miles, until, in fact, the Vine growing districts are reached, the system of "petite culture" can be studied to the heart's content. On both sides of the line can be seen a succession of narrow strips of land, varying slightly in size, but rarely assuming the extent of our British fields, devoted to different crops, Maize and Sugar Beet preponderating largely, and striking a stranger from our side of the Channel more particularly. They were indeed the only crops that appeared to be flourishing; most of the others, and especially the grain crops, seemed to be suffering from soil exhaustion, due no doubt to continuous cropping and few or scanty manurial applications. As regards the actual working of the land and the general cleanliness there was little cause for dissatisfaction, much less than I had been led to expect, for I have seen thousands of acres of farm land in the south and west of England in far worse condition. Much labour is expended upon the land, but the results do not seem to be in due proportion, at least that is the only judgment I could form from a hurried inspection in the way described; but the characters were so well marked, and repeated with little variation over so large a tract of country, that the conclusion was inevitable.

Dijon was at last reached, and we looked in vain at the station or near it for any representative of the celebrated Rose so popular at home, and which bears the name of this ancient town. A good chance has been missed there to produce an effect that

would have been most interesting to the numerous travellers who pass through Dijon to other parts of the Continent, and if some of our horticultural station masters had been in charge there—and I know several who are devoted rosarians—it would not be difficult to imagine the good old "Gloire" in possession of every available space for the display of its floral charms. The horticultural taste which imparts many attractions to country stations on some of the leading lines in Britain is singularly deficient in such portions of France as I have had the chance to visit.

To enable us to reach Geneva, however, and to say something about the special object of my visit within the limits allowable this week, we must hurry on, as we did after leaving Dijon, into a delightfully picturesque country with Vine-clad hills in every direction, and even the precipitous sides of the elevations of mountainous proportions were similarly covered to a great height, and surprise was excited as to how the Vines were reached for cultivation or gathering the fruit. The Vines themselves presented a pleasing effect in their abundant foliage, but little could be seen of the Grapes, which were not fully ripe or were nearly concealed beneath the leaves, and the vineyard at Castle Coch, near Cardiff, which I had seen a short time before, was much more luxuriant and attractive, possibly more so than the Grape growers of this district would appreciate. Large quantities of wine are produced in the country around Macon, which gives its name to a kind of mild claret or Burgundy, extensively used in Switzerland, and really a pleasant beverage when of good quality.

After running along a considerable distance in view of a long range of hills on the left, the line turns off rather abruptly, gradually ascends, and passes through a series of deep valleys and cuttings with towering hills and precipitous declivities, rocky watercourses, and all the characters of the Derbyshire scenery as witnessed from the Midland line through the Peak district, but on a larger and grander scale. About half an hour of this most pleasureable part of the journey and the "shades of evening" began to fall so fast that all was soon buried in darkness, and it was an agreeable conclusion to a twelve-hours journey when the train drew up at the Geneva platform and a friend was found waiting to accord a true British welcome.

It would be impossible in one communication to relate all the experiences gained during my short sojourn in Switzerland, and in the present chapter a general survey only can be attempted, the details will be filled in another time when opportunity permits. First let me say that, surprising as it may seem, all my anticipations were fully realised, and for a somewhat sanguine temperament this is saying a good deal. In truth, much was found that surpassed all that I had imagined, not only in the glorious Alpine scenery and the marvellous lakes about which we have heard and read so much that something uncommon was naturally expected, but because it was my good fortune to witness some gardening triumphs which, with our insular prejudices strong about us, we do not look for on the Continent.

Pregny, the Swiss residence of the Baron and Baroness Adolphe de Rothschild, is situated a few miles from Geneva, at an elevation of several hundreds of feet above the great lake, of which, together with the Alps and that embodiment of majestic sublimity, Mont Blanc, it commands a superb prospect. Admirably, indeed, has the site been chosen for the scenery it affords, but as is usually the case with exposed and elevated gardens, many difficulties have in consequence had to be overcome. Gardening on the Continent, too, is very different from what it is in England, the fierce heat of summer and the long dry periods with the keener cold of winter have to be taken into consideration, and very serious obstacles do such conditions present to success. It is, however, difficult to imagine what more could have been accomplished at Pregny; the garden, park, and grounds constitute what a good authority has aptly termed "*une œuvre complète*," distinguished by excellent taste in design, and by no mean skill in execution.

Upon the highest portion of the park, or "*campagne*," as it is termed, stands the Pavillon de Pregny, a stately and substantial mansion; from this the ground slopes somewhat in an easterly direction towards the Lake of Geneva, and from the terrace a magnificent view is obtained of Mont Blanc. Probably so fine a prospect could not be secured anywhere else. The weather was exceptionally clear and favourable at the time of my visit, and never while memory endures shall I forget the first glimpse I had of those wonderful snowclad summits, glistening under a brilliant summer's sun, the clear blue sky above, and the still richer blue lake in the foreground. It was a scene upon which poets might exhaust their powers, and still convey a poor idea of the reality. Certainly, therefore, it would be useless for me to attempt so fruitless a task. One aspect of the great mountain must, however, be noticed, and that is at evening when the sun is declining, for it presents a solemnity and grandeur that could scarcely be surpassed. The first change is shown in a beautiful rosy flush overspreading the snowy slopes, that so exactly resemble the profile of a gigantic face upturned to the sky; then this slowly disappears, and is succeeded by a weird and awful tint, comparable only to the pallor of death, which fades into the grey dusk as the shadows creep up the sides until darkness hides all from view.

The slopes of Pregny have been very carefully planted. No labour has been spared to produce a garden thoroughly English in its prevailing characters, and to provide what should be essential in a true garden, both variety and repose, with no jarring formalities to destroy the effect, and every care to conceal the art so requisite in forming an establishment of this kind. Many trees are developing into handsome specimens, and there are plenty of shaded, cool, refreshing retreats provided by trees and shrubberies, and one of these is represented in the woodcut (fig. 85, page 455). To the general design of the park the Baroness Rothschild has given close attention for several years, as it is her favourite summer residence, and her taste is manifest in every portion of the estate. Even in what seems a small matter like the following, it is astonishing how much is added to the pleasing effect of the garden generally:—The edges of the lawns, instead of being flat where they adjoin the walks, are slightly raised and rounded, so that at a distance when looking across the lawn the walk is not visible; much care is also taken in managing the curves of the walks with the same object—namely, the avoidance of long stretches being exposed at any point.

Mention has been made of the lawns, and these alone are marvellous, for out of England it is doubtful if such close, green, fresh, and beautiful expanses of turf could be seen. As they have been entirely formed from seed it can be imagined what care and trouble have been required to bring them to their present state of perfection in such a situation. Many good examples of successful lawn formation from seed have been recorded at various times, but this is the most remarkable that has ever come under my notice.

Advantage has been taken of a steep and in places a nearly perpendicular deep slope to form a rockery of imposing extent, and thoroughly natural in design and planting. Huge boulders are covered with climbing, drooping, and creeping plants of many kinds, the lower portions are devoted to aquatics, and every stone is being covered with some appropriate occupant. Most noticeable in all parts was the graceful *Desmodium penduliflorum*, which succeeds capitally, and might be seen in England much more frequently. A spray is depicted in fig. 86, page 459, showing the drooping character of the shoots, and a large specimen laden with its bright purplish crimson flowers has a charming effect.

Many important features at Pregny remain to be described, including the large collection of Orchids and other plants, and the extensive fruit houses and the fruit garden at Saconnex, and the exquisite villa lakeside resort, the Port Gitana at Bellevue, but I have encroached so far upon the space at my disposal that

reference to these departments must be deferred. It only remains to add that the gardens are under the charge of Mr. Andrew Methven, who has afforded ample proof of his ability as a practical Superintendent, such, indeed, as might have been expected from the good work he had previously performed in the north of England. I must also take advantage of this opportunity to record my thanks to M. Kirsch, the Agent of the estate, to M. Offerdinger, the Secretary, and to M. Duchosol, the Assistant Secretary, for many courteous attentions and kind services rendered during my visit to Geneva.—LEWIS CASTLE.

## HARDY CLIMBING PLANTS FOR NORTHERN DISTRICTS.

(Continued from page 425.)

### VIRGINIAN CREEPERS.

FROM the showy *Clematis* let us pass to the useful foliage plants, the Virginian Creepers or *Ampelopsis*. Of these splendid climbers two only are generally grown, *Ampelopsis hederacea* and *A. Veitchi*. Both are deciduous; but before they finally cast their leaves for the winter a beautiful transformation of the foliage is effected from rich dark green through intermediate shades to fiery crimson. The common *A. hederacea* is an universally useful European climber, and flourishes on any soil or aspect, not only in any district in England or Scotland, but in Germany, France, and Russia, and even as far south as Italy it is said to be a popular climber. In ordinary soil it will grow from 30 to 40 feet in height, and in a richer soil, combined with a suitable aspect and support, it will reach a height of 60 feet. For a town garden there is no climber more suitable except Ivy, and it ought to be more frequently planted.

When in luxuriant condition, and at the time of the full development of its annual growth, the young shoots of this variety have a remarkably graceful appearance as they hang loose and free upon a dense background of green foliage. The upper shoots, when the plant is wanted to extend and cover more space, should, at this period I am speaking of (which is during the month of August), be carefully fastened to the wall or trellis.

The leaves begin to change colour in September, and during the early part of October the tints are very pleasing; but on south and south-west aspects the colouring is richer than on less sunny positions. Sometimes the leaves change colour and fall very quickly, this happening with more frequency when the roots are growing in dry or poor soil. There is no objection to seeing this Virginian Creeper planted and trained on a wall of Ivy, which hides its bare stems in winter and forms a background for its glowing colours in autumn. It is also useful as a summer covering for rough banks, old walls, unsightly outbuildings, bare tree trunks, and other objects.

An even more valuable and pleasing *Ampelopsis* for a prominent wall than the preceding is the pretty little miniature Virginian Creeper, *A. tricuspidata*, perhaps better known as *A. Veitchi*. It is a smaller leaved variety, with slenderer growth, but equally as hardy and free growing. The colouring, too, of the foliage in autumn is altogether richer in the variety of tints, and the leaves are retained on the plants much longer. The growths of this variety cling to a wall, preferably a smooth one, with more than the tenacity of Ivy, appearing to be pasted on the surface, so close and fast do they adhere. There is no need for nailing or fastening of any kind, except when just first planted. It should always have a south aspect when possible, as its unique growth warrants a good position and the best attention. Rather lighter soil, well and fairly deeply prepared, should be provided for it when planting.

There is a more robust variety of *A. Veitchi* now being sent out, which has all the good qualities of the type even more pronounced, and is known under the name of *Ampelopsis Veitchi robusta*. There is also an evergreen variety, namely *A. sempervirens*, having pretty dark green leaves, and is useful on account of its evergreen character.

### IVIES.

Passing now to another climbing plant of an evergreen character we find in the various sorts of Ivies a wide variety of useful plants, most of which are adapted for climbing. The common Irish Ivy (*Hedera canariensis*) is well known and popular for all purposes. *H. algeriensis*, *H. Rægnieriana*, the Giant Ivy, and *H. dentata*, a lila ge-leaved varieties, also including *H. amurensis*, said to be the

largest leaved variety of any in cultivation. The small leaved Ivies include *H. chrysocarpa*, *H. lucida*, *H. donerailensis*, the leaves of which assume a purple bronze in winter; and *H. caenwoodiana*, a quick grower, and one of the best of the small varieties.

The variegated kinds are very suitable for low walls, such as those below projecting bay windows and other low positions, and include the following—*H. canariensis aurea maculata*, the golden variety of Irish Ivy; *H. marginata elegantissima*, with silvery margin; *H. argentea elegans*, *H. marginata grandis*, and Silver Queen. These are a selection of the numerous varieties of Ivies, and may be useful as a guide, but the best plan in purchasing plants is to see them at the nursery. There are few more interesting sights in a garden than a good wall of the various varieties of Ivy. The contrast in growth, the difference in vigour of the plants, the various tints of colour, and the differing shapes of the leaves are an interesting and gratifying study, and apart from all these in a long wall of Ivies, all planted at the same time, what diversity of general growth is apparent. The rapid growers will soon reach the top of the wall, others will grow in a pyramidal or pointed fashion, reaching various heights, or exhibit some other peculiar form of growth, making charming contrasts one with the other; and then when winter comes how pleasant and cheerful looks the Ivy wall. The dreariness of everything around brings it into bold relief.

For general purposes, however, and all kinds of positions, the chief among all Ivies is the Irish Ivy, which has, and probably now does, clothe more old castles, church towers, cottage walls, and roofs and gable ends, than any climbing plant in existence. If you want a climbing or a creeping plant for the worst position in the garden, to cover an old tree stump, to hide a wall, to clothe a dark damp patch of earth or bank, or to form an undergrowth or top-growth anywhere plant this Ivy, but plant it carefully if the position is unsuitable for starting quick growth, and give attention until established. If simply inserted in hard dry ground it may fail to grow, especially if left to itself and no moisture given. Ivy is easily propagated in moist ground, autumn being a suitable time to insert cuttings. They may be inserted where they are to remain, or on a piece of ground from which they can be readily removed for planting.

Good moist deep fertile soil is the best for the Ivy as a climber, but for creeping purposes, after once established, moisture is of more importance than depth of soil, and this is the reason that Ivy does well as an undergrowth. Some assert that Ivy causes dampness to buildings against which it is grown, but I have no hesitation in saying it is a false idea, arising probably from the fact of Ivy being planted in positions that are naturally damp, and from which, moisture-loving plant as it is, it was unable to absorb all the superabundant moisture within its reach. Instead of being a damp-promoting plant it is quite the opposite, its leaves being suspended on the plants in such a manner as to throw off the rain that falls upon them, thus keeping the building it covers quite dry. Therefore those who plant Ivy to obviate dampness, may rest assured it will have the desired effect, if, as indicated above, the position is not naturally too damp.

The small kinds and the choice forms of Ivy are chiefly of slower growth, though some of them grow quickly enough, and they require a better prepared soil, light rather than heavy, when planting, and also the use of established plants from pots is preferable for these kinds than it is with the common and larger.

There is no hard and fast time for planting Ivy. They generally succeed planted at any period of the year, especially those from pots. Those dug from the open ground are better if planted in autumn or spring. At two periods of the year the Ivy is specially beautiful and enjoyable. One is at midsummer after the new growth is made following upon severe cutting-in in April, which it is perhaps needless to say Ivy on walls annually requires. At this period the leaves have just attained to their full development, and are of a rich light green, with a texture as soft as velvet, and a shining surface like polished stone. The other period is in mid-winter, during mild pleasant days in December, when the litter and untidiness of autumn are gone. Then the dark leathery foliage is pleasant to look upon amid the dreariness of wintry scenes.

In an interview that the late Hans Christian Andersen, a popular writer twenty years ago, had with the present Poet Laureate, Tennyson, he remarked to the poet that Ivy seemed to be his favourite plant, to which Tennyson replied, "To tell the truth it is. Ivy needs no nursing. It knows neither cold nor heat. It is the plant of immortality."—E. D. S.

(To be continued.)

CYPRIPEDIUM INSIGNE SANDERÆ.

ONE of the most useful Orchids in cultivation is *Cypripedium insigne*, and at different times some fine varieties have been imported, which have taken a prominent place in collections where Orchids are especially grown for use. Probably the most distinct and beautiful yet obtained is that named above, for which the Royal Horticultural Society's Orchid Committee awarded Baron Schröder a first-class certificate on November 10th last. The flower is distinguished by its uniform soft, yet clear and bright shade of yellow with a greenish tint, except the dorsal sepal, the upper part of which is pure white with the exception of a few dots in the centre.

The following is the history of the plant:—About three years ago Messrs. Sander of St. Albans flowered this variety amongst an importation of *Cypripedium insigne*. They divided the plant into two; one was sold by Messrs. Protheroe & Morris for 70 guineas, the other half passed into the possession of Mr. R. H. Measures, The Woodlands, Streatham, who in turn divided his plant into four parts, which has been distributed as follows:—One found its home with Mr. R. J. Measures, Camberwell; another crossed the Atlantic to be placed in the finest of Transatlantic collections, that of Mr. F. L. Ames, near Boston; the third remains at The Woodlands; while the fourth has been procured by Messrs. Sander for the sum of £250. This is one of

FIG. 84.—CYPRIPEDIUM INSIGNE SANDERÆ.

the most remarkable instances of increased varietal value, for ordinary forms of *Cypripedium insigne* can be secured for a few shillings.—C.

## NOTES ON ASPARAGUS.

### MAKING ASPARAGUS BEDS.

It is both unwise and unsafe to transplant Asparagus before the spring, the best time as a rule being when the first shoots are several inches long. If this period of activity is long anticipated the chances are the greater portion of the roots, most of which are unavoidably broken in lifting, will perish, and the top growth be either very weakly or else fail altogether in consequence of this injury. There is, however, no good reason why the beds should

not be prepared now or any time during the winter for planting next spring, this being especially desirable where the subsoil is of a heavy clayey nature. Asparagus revels in a fairly rich and deep root run, but the less clay there is about the better, excessive moisture being most detrimental. It pays well, therefore, to remove a good depth of clay subsoil and to substitute a variety of other substances, soluble or otherwise. Raised beds are certainly the best for heavy land, and they may be either 5 feet wide and hold three rows of plants, or 3 feet wide for two rows of plants, alleys 2 feet wide being allowed between them. Commence by staking out the first bed, and then throw out all the best of the top soil right and left.

Next dig and wheel away a good spit or more of the clay or clayey subsoil, place a 3 inch pipe drain through the middle, cover this and the bottom of the bed with brick ends, coarse mortar rubbish, clinkers, or stones, a little finer material being spread over this. Continue by wheeling in all the road trimmings, decaying garden refuse, charred clay, or even ballast, and any other slowly decaying material that can be looked up or which is an eyesore above ground, and well mix the lot with about half of the garden soil first thrown out, the lightest or best portion of the latter to be reserved for surfacing the bed, and with this should be mixed as much sand, sea sand being preferred if procurable, fine mortar rubbish, the remains from a garden "smother" or slow fire, leaf soil, old potting material, decayed manure, fresh loam, and such like. All being evenly and thoroughly mixed together and laid up roughly till planting or sowing time arrives, a capital root run will be provided and a strong start being made. Beds thus well made can be enriched from the surface at will, and would produce extra good Asparagus for a quarter of century or longer.

#### FORCING ASPARAGUS.

Nothing is more easily forced, and no extra early vegetable gives more pleasure to those whose good fortune it is to get it. Unfortunately early forcing necessitates the breaking up of established beds, unless, indeed, the requisite number of strong roots are specially prepared for the purpose. The usual practice is to break up the oldest bed every winter, strong roots being thus obtained, and to meet the demand for open air produce another new bed is formed every spring. This naturally entails a considerable amount of work, but the labour is not wholly expended on the Asparagus, especially seeing that when once the ground is well prepared and kept manured for that important crop it is in splendid condition for any vegetables, plants, bushes, or fruit trees that may succeed it.

Hard forcing is most undesirable, but if the start is made at once abundance of good Asparagus ought to be available at Christmas. Heated pits, deep enough to hold a hotbed 3 feet in depth of well sweetened stable manure and leaves is the best position for forcing Asparagus, ordinary garden frames on well made hotbeds also answering well. Directly it is found there is no danger of overheating cover the beds with a layer of rich moist soil, and on this closely pack the carefully lifted roots, covering with about 3 inches more of the same kind of soil, somewhat fine this time. One well filled light would be enough for a small establishment, but two or three are none too many where extra large dishes are required. A bottom heat of from 60° to 65° is quite high enough, ought not to be exceeded, in fact, while the top heat may well be 5° lower. Heavily mat over or cover the lights with litter in preference to turning on much fire heat, the unheated pits and frames especially requiring this attention, more light being admitted when top growth is strong.—W. I.

#### STRAY NOTES.

THE Rose analysis so ably set forth by "E. M." (on pp. 319, 320) cannot fail to be interesting to Rose lovers and exhibitors, and we ought all to be grateful to him for the pains he has taken in the matter. Statistics are very useful, but it has been said they may be made to prove anything; and somehow I cannot help fancying that the Rose elections we used to have seemed to produce more trustworthy results, though it is difficult to see how this could be. It should be remembered that not only did we want (as "E. M." says) an early season in 1891 to make things square, but a hot dry time was even more needed—for instance, Maric Rady in H.P.'s, and Madame Hippolyte Jamain and Madame Margottin in Teas, have really not had a chance of late years. The earliest H.P.'s with me are Violet Bowyer

(generally the first), Lady Mary Fitzwilliam, and Mrs. Baker; the latest, Alfred Colomb, Camille Bernardin, Pierre Notting, Earl of Dufferin, Emile Hausberg, and A. K. Williams. I do not know how it is the latter is so late with me, but certainly the best and strongest shoots on cutbacks generally do not flower till all shows are over. Of those that have "disappeared," I think John Stuart Mill will certainly be heard of again in a good season as nearly a first-class Rose, though I had not one worth looking at this year, and Lord Macaulay I find a good doer, seldom failing, though not first-class. But none of the Teas which have gone from the list are really now worth growing, and I am surprised that Devoniensis holds its place so well. Madame Hippolyte Jamain, La Boule d'Or, and Madame Margottin will probably, however (as I have said) make up lost ground when a dry season comes, and the same may be said of the H.P.'s Reynolds Hole, Monsieur Noman, Marie Rady, and Star of Waltham, &c.

"E. M." has naturally not gone entirely by the order of merit as shown in his analysis in selecting varieties as "the cream of the Rose world, few of which are difficult to grow;" and but little fault can be found with his selection of H.P.'s, though Prince C. de Rohan is lucky to get a place, and Her Majesty, Etienne Levet, Lady Mary Fitzwilliam, and Xavier Olibo (or for the matter of that any Rose) are surely not more difficult to grow than Horace Vernet. But in his list of Teas and Noisettes it is strange indeed to find such sorts as Catherine Mermet, Comtesse de Nadaillac, The Bride, Niphetos, Souvenir d'Elise, Maréchal Niel, and Madame de Watteville omitted from a selection of the "cream of the Rose world," none of them with me being more difficult to grow than Innocente Pirola. But it is indeed an awkward task to make out a list of certain number of best Roses, suitable for all and sundry, though it is one I am often set to do.

Horace Vernet, H.P., gives me more trouble to grow than any other Rose, and I sadly fear that the difficulty is increasing, and that the constitution of this grandest of show varieties is getting even worse than it was. Here is a Rose, which, with a strong shoot and uninjured bud, is pretty sure to come good, and, being good, would find A. K. Williams its only rival perhaps to the title of King of Show H.P.'s; yet how seldom is it shown, 15.3 being its figure, while that of Madame Gabriel Luizet is 38.3; and how seldom comparatively do we find it taking the medal as best H.P. I find it by no means always doing well even as a maiden. I have seen a long row of them looking very bad, and this would not be the fault of the stocks, as with me it refuses to take or grow at all except upon the best and strongest of stocks. I wish some means could be found of instilling new vigour into this splendid sort, for a strong growing, hardy and healthy Horace Vernet would be as great a boon to exhibitors as almost any grand new Rose.

My standard stocks, got by myself last February, when the worst of the winter was over, have done very well, 2 or 3 per cent. only having failed. They were cut to a maximum height of 2 feet, and budded with Teas. I am surprised to see that it is a common practice to take off all laterals that are not wanted for budding. It is true this very much facilitates this operation; but I am accustomed to cut off nothing, not even strong shoots, like suckers coming from the bottom of the stem; for though it may not be desirable to encourage suckers which you cannot effectually extirpate later on, yet my idea is that all growth strengthens and increases the roots, and is as good for the next season as so much manure. It may be true that a standard stock can be too strong for some of the weaker Teas, but at all events a stock can always be weakened in as many minutes as it would take weeks to strengthen it, for it is a good deal easier to destroy roots than to make them.

The result is a veritable jungle, and untying the buds was not child's play, for they were utterly hidden under a complete hedge of Briar growth. Instead of now cutting away all this tangle, I am going to lace the long shoots in or clip it like a hedge, and my idea is that I shall then get a natural thorny platform or hedge on which it will be easy to lay mats or Fir boughs for the protection of the inserted Tea buds during the winter. The use of collodion will hardly be needed here, I imagine; but I hope to experiment with it elsewhere.

The raisers of the two English gold medal Roses of last year offered this summer twelve buds for propagation at the same usual price as a pot plant, viz. 10s. 6d. I think this was decidedly a good bargain for amateurs. The expense and risk of the carriage of a pot plant are avoided; one very seldom gets a decent bloom from such a plant; the plant itself rarely does any good afterwards; and, except with very strong growers, if you get twelve good buds for propagation from one such you are extra lucky. From a dozen such buds thus purchased and put into strong Briar cuttings, I have got this year no less than six which have "run out." I like to see H.P.'s run out, one is pretty sure of them then, and I have never lost any of such shoots by frost. I am speaking of course of those buds which grow at once of their own accord, not those which are forced to it by the cutting back of the stock and consequent weakening of the roots. Why do some buds run out more than others? I suppose it is that in those cases the act of budding and the subsequent union have been most perfect, for it is by no means always on the strongest stocks.

The question of the date of the Metropolitan Show is a very important one. There is no written law, I believe, that it should be the first Saturday in July, and, as that will be July 2nd in 1892, and July 1st in 1893, it is well worth the consideration of those interested whether a more suitable date could not be found. The Crystal Palace Show is the show of the year, and, therefore, it seems to me it should naturally be as near as possible to the very centre of the season, taking the average situations of the members of the N.R.S. into consideration.

If we take four weeks for the season, the last week in June and the first three in July would probably be the nearest representative of the time, and I think the list of fixtures on the back of the N.R.S.'s schedule will bear me out in this. This would make July 7th about the centre of the season, and if it must be Saturday, the one nearest to this date would be the proper time. It is true that by this arrangement the date might be as late as the 10th of the month, but I should still contend that this would on an average be nearer the centre of the season than the 3rd; and the metropolitan and provincial exhibitions might thus be brought pretty close together. But I see no harm in that worthy of comparison with the effect of having the principal Rose Show when many have got hardly any Roses out.

Another argument on this matter is that the early date of the Crystal Palace Show is, to my mind, at the root of all this controversy in the Journal and a contemporary about large amateur growers showing in small classes. I think I shall not be wrong in taking it that almost all the small growers who are aggrieved in this matter are in southern or metropolitan districts, which are three or four days ahead as an average of those north or east. The consequence is that the small growers are ready at an early date, when the large must show in small classes or not at all; and it should be noted that, as regards ability to show in large classes, the date had better be too late than too early; we may still get some blooms, though not so good, of the earlier sorts in the latter part of the season, whereas we cannot possibly show in the large classes if our Roses are not yet out. I hope this matter may be taken up, and elicit a good body of opinion one way or the other.—W. R. RAILLEM.

#### SEMI-EARLY OR OCTOBER FLOWERING CHRYSANTHEMUMS. 1891.

WHEN we come to consider the changes in these this season we find that, although they are not so numerous as those that flower before the end of September, still there are quite sufficient good new ones in this class to effect a material alteration in the stocks to be cultivated by those who are selecting the newest and best varieties.

M. Henri Devred will perhaps turn out one of the very best of the season. It grows about 3 feet high, and bears flowers 5 inches across. It has good foliage. It is a kind of incurved Japanese, a most profuse flowerer of a very beautiful pale terra-cotta tint, probably the most elegant and charming of any that colour. It is a powerful plant, having the strength to develop every bud it forms into a good flower. To me it is one of the best new plants of the season, and it will most likely prove a friend to both exhibitors and florists, being very acceptable, as its colour is fashionable.

M. Maxime de la Rocheterie grows about 3 feet 6 inches high, with flowers 3 inches across. It is a red Japanese, so red and bright as to be as near scarlet as any one I remember, and more that colour than the Comtesse Foucher de Carcil. It comes just enough later than that to form a succession. It is a profuse bloomer and a real good sort without a bud taken off. It slightly resembles Léon Collin when flowered under glass.

M. Jacob is a reflexed crimson, 4 feet high, with flowers rather over 3 inches across; it slightly resembles Cullingfordi, but is about a month earlier, and is rather earlier than Wm. Holmes, flowering at the beginning of October; and with Souvenir de M. Menier, which is rather later and darker than Wm. Holmes, we have three good successional crimsons for October. It does well with all the buds left on.

Secrétaire Alfred Bleu is a most striking Japanese with broad thin Sunflower-like florets, which are of a pale yellow. The habit is rather slender.

Alfred de Montebello is a very much reflexed mauve Japanese, with blooms  $3\frac{1}{2}$  inches across. The plant is just over 3 feet high; very full foliage. It flowers at the beginning of October. M. Albert Galy is a Japanese variety, 2 feet 6 inches high; very good stout plant, bearing flowers 3 to 4 inches across, orange bronze in colour. It flowers at the end of October. Madame E. Bellan, a beautiful light mauve Japanese, with straight pointed rather broad petals.

M. Jules Paquet (certificated).—This is a white Pompon under glass, with reflexed flowers  $2\frac{1}{2}$  inches across. It grows a little over 2 feet high, has profuse foliage, and is of a very stout habit.

Bouquet de Dame, a white Japanese about 4 feet high. This is truly an October flower, through its habit of perfecting its first bud into a fine flower in September 4 to 5 inches across without a bud taken off, being then very much less in height, about 3 feet, than afterwards, when it branches out and covers itself with flowers, for it has the power to bring out all the buds it forms, making a fine decorative plant, and is a large producer of bloom fit for cutting. It is really a useful addition to the decorative sorts; besides, it will be very valuable to future October shows, where large white flowers are required to win prizes. To show how the trade appreciate it I may mention that I have already seen it in the window of one of the first shops in London. It has had a first-class certificate.

M. B. Bahuant is a new incurved variety of first-rate quality for

exhibition purposes, but does not seem likely to serve well where it is not disbudded. Its form is globular, or rather deeper than that, for when well grown it is a deep flower with the petals large and wide, of a kind of pink, shaded with grey outside. There is no doubt this will figure at future October shows. It is not a very tall plant, about 3 to 4 feet. It has had a first-class certificate.

The following are probably future October show flowers:—Mrs. E. Beckett, a very fine white Japanese, certificated when shown by Mr. Beckett; it was raised by Mr. N. Davis of Camberwell, London. Edwin Beckett, a superb yellow Japanese with the habit of Avalanche, also certificated when shown by Mr. Beckett; it was raised by Mr. N. Davis, and is another very fine show flower.

Kate Wells is a reflexed Pompon of a remarkably bright scarlet crimson colour, about the brightest ever seen, and to add to its striking appearance every floret is imbricated and tipped with the brightest gold. M. Vauvel is a fine bright pinkish mauve Japanese; Mad. Eulalie Morel is a pink-and-yellow middle Japanese, very good; Georges Devred is a most beautiful lemon-yellow Japanese; Mad. Henri Galice is a Japanese of quite a new shade of rich bronzy orange yellow; R. du Mensil de Montehauveau varies from deep magenta to purple, Japanese.

Of last season's new sorts that we have become better acquainted with the first is Mrs. Hicks Arnold. It is an excellent plant, and as a flower producer has very few equals. Its profusion of bloom is immense, being of that stout character that it stands wind and rain to a wonderful degree. All this it will do without a bud taken off, producing great branches of flowers.

Louis Boehmer, I think, may be fairly classed among the October flowers, for there will be a difficulty in keeping it back for the November shows in the south of England, many plants being fully out here by the end of October. No one need fear that there is any difficulty in growing this plant like there has been with Mrs. Alpheus Hardy, it is quite different from that. It grows and does well. Some plants put in as cuttings on April 25th were in bloom before October was out. This, as many know by now, is a kind of incurved Japanese about 4 feet high, with flowers 6 to 7 inches across, when disbudded a kind of magenta colour with hairs like projecting thorns on the backs of the florets as they incurve, giving quite a different appearance from any other Chrysanthemum except Mrs. Alpheus Hardy. I have little doubt we shall have more of this type, perhaps this will sport to white in time. I hear already of a yellow one very bright, but do not know if it is a sport or a seedling. I may mention, in conclusion, that P. Radaelli has kept its character well this adverse season, and has covered itself with beautiful white flowers this October.—W. PIERCY.

#### DWARF JAPANESE CHRYSANTHEMUMS.

I GIVE a list below of the best Japanese Chrysanthemums of dwarf habit suitable for producing exhibition blooms or for decoration. They are mostly sturdy and robust growers, and require little or no support in sticks except in their early growth.

Achievement (E.).—Seedling from Madame Desgranges, creamy white, vigorous habit, 3 to 4 feet.

Autumn Queen (E.).—Rich yellow, another seedling from Madame Desgranges, 3 to 4 feet.

Mrs. F. A. Spaulding (A.).—Bright nankeen yellow, splendid habit, 3 feet.

Carrie Denny (A.).—Incurving, orange yellow, very distinct, 3 to 4 feet.

William Lane (E.).—Bright cinnamon shaded rose, vigorous grower, and fine habit, 3 to 4 feet.

Mrs. G. C. Schwabe (E.).—Delicate rose shaded salmon, gracefully falling over, very durable, 3 to 4 feet.

Louis Boehmer (A.).—Incurved, strong grower and good habit, back of petals hairy, like Mrs. A. Hardy, 3 feet.

Mrs. W. Baker (A.).—Yellow, very pretty, fine for decoration, 3 feet.

W. H. Lincoln (A.).—Yellow, robust habit, producing large stiff florets and extra fine flowers, 3 feet.

Beauty of Castlewood (A.).—The best Japanese ever sent from America or any other country, rich crimson, incurved, very large, requires good cultivation, 3 feet.

Miss Anna Hartzhorn (A.).—Opening blush showing to white, the best of its colour and form, 3 feet.

Miss Esmeralda (A.).—Similar to Beauty of Castlewood, but a better grower, 3 feet.

Sunset (A.).—Semi-double, very long spreading petals and foliage, and rich in colour, yellow and red, 3 feet.

We Wa (A.).—A dwarf Mrs. C. W. Wheeler, habit of Beauty of Castlewood, a fine American variety, should be better known, 3 feet.

Mr. Robert Owen (F.).—Seedling from Avalanche, white flamed rose, 3 to 4 feet.

Avalanche (E.).—A well-known variety of fine habit, 3 to 4 feet.

Criterion (E.).—Another well-known kind, 3 to 4 feet.

Enchanteresse (F.).—Rose and violet, drooping florets, very dwarf, 3 feet.

Etoile de Lyon.—Very large, deep rich rose and lilac, 4 feet.

Feu de Bengale (F.).—Orange and red tipped yellow, 3 to 4 feet.

Madame Desgranges (F.).—White, very early and free, 3 feet.

Golden Madame Desgranges (or G. Wermig) (E.).—Light yellow, 3 feet.

Jessica (A.).—Fine white, 3 to 4 feet.

L'Adorable (F.).—Creamy yellow, edged violet rose, fine dwarf habit and vigorous, 3 feet.

Lucrèce (A.).—Pure white, a splendid variety of dwarf habit, producing large flowers, 3 feet.

Maret Postula (F.).—Violet rose, rather early, 3 feet.

M. Freeman (F.).—Rose, very pretty form, incurved, 3 to 4 feet.

M. W. Holmes (F.).—Rich crimson and gold, splendid habit and constitution, 3 to 4 feet.

Mrs. Burrell (E.).—Primrose form of Madame Desgranges, 3 feet, early.

Mrs. Hawkins (E.).—Bright yellow variety of Madame Desgranges, 3 feet.

Mr. Hugh Graham (A.).—Pink and white, large full flower, rather late, 3 feet.

President Hyde (A.).—Bright yellow, reflexed, one of the best, 3 to 4 feet.

Princess Blanche (F.).—Creamy white, very dwarf, 2 to 3 feet, late.

Thomas Stephenson (E.).—An improved Criterion, 3 to 4 feet.

Thomas Cartledge (A.).—A very distinct Japanese with twisted florets, 3 feet.

Trompe du Nord (F.).—Crimson maroon, fine old variety, 3 feet.

Val d'Andorre (F.).—Chestnut red, very fine habit, and large flower, 3 to 4 feet.

The initials following the names mean F, French; A, American; E, English.—R. OWEN.

#### JAPANESE CHRYSANTHEMUMS FOR CUTTING DOWN.

Now we are thinking of Chrysanthemums, would some grower kindly give a list of twenty-four Japanese which will best lend themselves to the cutting down process? the varieties being for grouping only, not for cut blooms, and for shows about November 12th to 17th.—NORTH COTSWOLD.

### CHRYSANTHEMUM SHOWS.

#### CHESHUNT.

THE annual Exhibition of Chrysanthemums at Cheshunt is invariably a pleasing gathering, especially for the Judges, who are not overburdened with arduous duties, and thanks to the attention of the considerate members of the Committee, the subsequent proceedings are even more satisfactory. St. Mary's Hall, in which the Show is held, is not very spacious, and therefore would not permit a great extension of the display, but several improvements may be introduced with advantage. For example, more groups and plants are wanted, and if the prizes could be slightly increased in these classes it might have a stimulating effect upon local growers. The cut blooms are satisfactory, so also are the hardy fruits and the vegetables, but a class for a stand of Chrysanthemum blooms, or something to show their decorative value, would be a charming addition to the Show, and add considerably to its interest. A class for table plants also would be useful, as these are excellent for the centres of the tables between the stands of cut blooms.

In general quality this year's Show was very satisfactory generally, and there has evidently been a steady advance in this respect for some time, proving that the Society's work is producing an effect. The chief class was that for twenty-four cut blooms, twelve incurved, and the same number of Japanese, with not more than two of any variety, and here Mr. Cox, gardener to J. Trotter, Esq., won first honours, showing of Japanese Madame Baco (2), Avalanche (2), Val d'Andorre (2), Boule d'Or, Beauty of Castlewood (2), M. Bernard, J. Herrin, and E. Molyneux; of incurved, Lord Alcester (2), Empress of India (2), Queen of England (2), Alfred Salter, Golden Empress (2), Princess of Wales, Mrs. S. Coleman, and Violet Tomlin. Mr. Walter, gardener to E. Clapham, Esq., was second, his Japanese being very fresh and even. The best twelve Japanese came from Mr. Collins, gardener to S. Warren, Esq., who had fine blooms of Etoile de Lyon, Madame Baco, Ada Spaulding, Condor, Beauty of Castlewood, Stanstead Surprise, E. Molyneux, J. Délaux, Sunflower, Avalanche, Mrs. Wheeler, and E. A. Carrière. Mr. Cox took a similar position for twelve incurved, staging good examples of Queen of England, Violet Tomlin, J. Salter, Lord Wolseley, Empress of India, Nil Desperandum, Golden Empress, Robert Cannell, Mrs. S. Coleman, Lord Alcester, Princess of Wales, and Jardin des Plantes; Mr. Collins being second in this class. Messrs. Turk and Horner had the best six Japanese. Anemones were capitally shown by Messrs. Walters and Horner; Pompons by Messrs. Searles and Horner, reflexed by Messrs. Turk and Walters; while in a mixed class for twelve blooms, four each of Japanese, incurved, and Anemones, Mr. Turk was first with very fine blooms, followed by Mr. Walters.

For groups of Chrysanthemums and miscellaneous plants arranged for effect Mr. Rowdon, gardener to J. Walters, Esq., won the leading prizes. An interesting class in this section was for a collection of Pompons not more than 2 feet high in pots not exceeding 6 inches in diameter. Mr. Bettesworth, gardener to R. Ewing, Esq., won first with plants not more than a foot high bearing abundance of flowers and most useful for decorative purposes. They are raised from cuttings inserted in late spring or early summer three or four in a pot, and bushy little specimens are thus obtained. Mr. Walters was second with similar plants. Primulas were good from Messrs. Walters and Turk and G. Warren, Esq.

Apples were capitally shown by Messrs. Bettesworth, Jones, Turk, Rowdon, and Ambrose; Grapes coming from Mr. Collins, who was first for a large bunch and berries of Waltham Cross Seedling; and Mr. G. Warren was second for Black Hamburg. The non-competing exhibits included five stands of very handsome Chrysanthemum blooms, chiefly Japanese, a most tasteful basket of Chrysanthemums from Mrs. Horner, and some elegant Bamboos from Messrs. Paul & Son.

The Judges were hospitably entertained at luncheon by Mr. George

Paul, who subsequently conducted them round the surprising establishment of Mr. Edward Rochford, where the cultivation of Grapes and plants for market is carried out on a marvellously extensive scale. An inspection of the interesting "Old Nurseries" at Cheshunt concluded the business of a most agreeable day.

#### TEDDINGTON.

FOR eight years the Chrysanthemum Show at Teddington has been conducted with much energy, a considerable share of success, and most satisfactory results as regards improvement in the culture of the favourite autumn flower. Several influential amateurs in the district have taken a prominent part in advancing the interests of the Society, and the shows are invariably distinguished by a most commendable freshness and equality of merit. Cut blooms of course always constitute the special feature, and are largely represented; but specimen plants, groups, fruit and vegetables form important departments, the competition is sure of these classes being extremely keen. The Committee and the Hon. Sec., Mr. D. Anderson, were well rewarded for their efforts this year in a large and excellent display, one of the best in all real good quality that the Society has yet held. Especial credit is due to Messrs. Furze, Douet, and other gentlemen for the eager part they take in the work of promoting the Show, and they are certainly performing a most useful service to the district.

Noting the cut blooms first, the chief class was that for twenty-four cut blooms, twelve incurved and twelve Japanese, distinct, in which a challenge cup, value 5 guineas, was offered as the first prize (to go to the subscriber) and £1 10s. for the gardener. The conditions being that the winner should hold the cup until the next exhibition, when it would be returned to the Society; but if the same exhibitor should win the cup twice, not necessarily in consecutive years, it becomes his absolute property. This is the third that has been offered at Teddington on similar terms. The first was offered in 1884, and was finally won in 1886 by Mr. Furze. The competition for the second commenced in the following year, and was completed in 1889, Lieut.-Gen. Vials being the winner. The third has now been won twice in succession by Mr. Furze, and therefore becomes his property. It is worthy of remark that the gardener at The Rosclands has amply proved his skill as a Chrysanthemum grower, for he has been successful in this competition no less than five times—a good record.

The varieties in Mr. Furze's premier collection of substantial handsome blooms were as follows—Incurved: Empress of India, Emily Dale, Violet Tomlin, Golden Empress, John Salter, Princess Teck, Queen of England, Miss Haggas, Lady Dorothy, Alfred Salter, Lord Alcester, and Hero of Stoke Newington. The Japanese were very strong, and comprised the following—Etoile de Lyon, Gloire de Rocher, Louis Boehmer, E. Molyneux, Condor, Gloriosum, M. Bernard, Madame C. Audiguier, Mrs. F. Jameson, Stanstead White, Sunflower, and Madame Baco. The second prize went to General Vials, C.B., Teddington House (gardener, Mr. Higginson), for good blooms, and the third to Mrs. Holberton, The Cedars, Teddington (gardener, Mr. W. Cave).

With twenty-four incurved, distinct, Mr. E. Coombs was first for excellent blooms of Empress of India, Violet Tomlin, Lady Dorothy, Golden Empress, Mrs. Heale, Empress Eugénie, John Salter, Miss Haggas, Perle Précieuse, Queen of England, Princess of Wales, Mrs. Shipman, John Doughty, Jeanne d'Arc, Baron Beust, Lord Alcester, Mrs. Coleman, Princess Beatrice, Alfred Salter, Princess Teck, Barbara, Emily Dale, Lady Hardinge, and Hero of Stoke Newington. Mr. Coombs also had the best twenty-four Japanese, but he was closely followed by Mr. W. Davies, Weir Bank Gardens, and Mr. Cave. For twelve incurved the prizes went to Messrs. Slade, Higginson, and Davies in the order named. In other smaller classes Messrs. Coombs, Slade, and Davies were the successful competitors, while for Anemones and Pompons, which were excellently shown, A. Nagle, Esq., Bijou Cottage, Surbiton (gardener, Mr. W. A. Clark), was the most successful. Noteworthy exhibits also came from Mrs. Howard, The Grove, Teddington (gardener, Mr. Osborn); T. F. Weymott, Esq. (gardener, Mr. F. Gregory); Mrs. Cowan, Park Lodge, Kingston; W. Cunard, Esq., Orleans House (gardener, Mr. R. Mitchell); and Mr. Sallows (specimen plants).

Some very tasteful floral decorations were contributed by Miss Furze, Miss Douet, Mrs. Birmingham, and other ladies; there was also an admirable display of Apples and Pears, together with vegetables. The non-competing exhibits included a beautiful group of Orchids from Mr. Tracy of Twickenham, and a collection of fruit from Messrs. J. Peed and Sons, Roupell Park.

#### WANTAGE.

THE historic town of Wantage made a horticultural departure last week by inaugurating a Chrysanthemum Show, and having made so necessary a beginning it is to be hoped that the interest thus awakened will result in a substantial advance during the coming year. It was somewhat late in the season before the Committee and officers of the local horticultural Society determined to make an effort in the direction of promoting a Chrysanthemum Show, therefore time did not permit very extensive preparations on the part of intending exhibitors. An idea was, however, conveyed of what can be accomplished in well-grown plants, and good blooms were contributed by several amateurs. Apples and Pears were well represented, but there will no doubt be considerable extensions in these classes another season.

To impart an additional educational importance and interest to the Exhibition, arrangements were made for two lectures, one on Chrysanthemums in the afternoon, and another on Fruit Culture in the evening;

and, with a programme of music, all the attractions that should be needed were furnished. The Committee with the Hon. Secretaries, Messrs. Ormond and Adnitt, deserve much commendation for their efforts and every encouragement for the future, and it may be fairly expected that some of the many wealthy residents in the district will readily afford the necessary pecuniary assistance to ensure a continuance of the work and an extension of the Society's scope.

The Show was held in the Corn Exchange, nearly facing the handsome statue of King Alfred, which adorns the market place of that celebrated monarch's native town. The building is a convenient one for the purpose of an exhibition, and it presented a very bright appearance when the arrangements were completed. The groups and plants were arranged around near the walls, the cut flowers and fruit occupying central tables. The first class was for a group of Chrysanthemums arranged for effect, unrestricted as to space it should occupy. The premier honours were adjudged to J. Taylor, Esq., who had a most effective tastefully arranged group in which Japanese predominated, a good margin being formed of smaller plants and Ferns. Mr. C. O. Walter was second, his plants being good blooms, but the finish was not so satisfactory in front. Mr. Haines was third with a bright, fresh, but small group. The plants were not the strongest feature in the Show, but some of them had well developed blooms, and with a little experience several of the exhibitors will be well able to hold their own. The chief prizetakers were Messrs. Clark, Walter, Brooks, and Gibbons.

The cut bloom classes provided incurved and Japanese, also two for a collection of any variety. In these (both open and for amateurs) Mr. C. O. Walter was the most successful, while in other classes Miss Garraway, with Messrs. R. Pumfrey and Taylor, took the leading prizes.

For a collection of twelve dishes of Apples (six dessert and six culinary) Mr. G. Brewer was first, showing fine examples of Ribston Pippin, Cox's Orange, King of the Pippins, Fearn's Pippin, Hollandbury, Blenheim Pippin, Dumelow's Seedling, Warner's King, and others. Mr. Clark was second, his best dishes being Scarlet Pearmain, Court Pendu Plat, Cox's Orange, King of the Pippins, and Golden Noble. For six dishes of Apples Messrs. Harman, Walter, and Haines were successful, while in the class for Pears equal first prizes were awarded to E. Ormond, Esq., and Mr. R. Pumfrey for excellent fruits.

The non-competing exhibits included a handsome basket of most tastefully arranged Chrysanthemums from Mr. R. Bennett, a stand of Japanese Chrysanthemums from Mr. R. Owen, Maidenhead; a group of Ferns from Mr. T. R. Barnby, and some extremely fine Onions from Mr. Arthur Bell.

#### DISS.

UNCONVENTIONAL in all ways was the bright Exhibition of Chrysanthemums held in the quaint old town of Diss, in Norfolk, last week, and the Committee, with their distinguished horticultural Secretary, the Rev. F. Page Roberts, of Scole Rectory, had ample reason to be satisfied with the result of their efforts. It is not to be supposed that they will be content to rest on their laurels, but rather it will be a stimulus to them to still farther improve the character by their show, and this could be readily accomplished by providing some additional attraction in one class for cultivators at a distance. The Show was held in the Corn Hall, a light and convenient structure for such a purpose.

The cut blooms were very good, and the competition was close in several classes. With twenty-four Japanese, not less than twenty varieties, Mr. R. C. Notcutt, Broughton Road Nursery, Ipswich, was placed first, a position which he gained by a few points. His flowers were very fresh, bright, and even, the following being the varieties—Stanstead White, Madame Baco, Triomphe de la rue des Châlets, Sunflower, Vivand Morel, Lady Lawrence (2), A. H. Neve, Gloriosum (2), E. Molyneux, Sarah Owen, Etoile de Lyon, Madame C. Audiguier, G. Daniels, M. Bernard, Boule d'Or, Puritan, Condor, Gloire de Rocher, and Mr. H. Cannell. R. Burrell, Esq., Westley Hall, Bury St. Edmunds (gardener, Mr. Alfred Bishop), was a very close second, staging capital blooms of many varieties; the Rev. H. G. Hawkins, Beyton Rectory, was third, and an extra prize was awarded to the Rev. F. Page Roberts.

For twenty-four blooms, twelve Japanese and twelve incurved, distinct, Mr. Alfred Bishop won first honours with a creditable collection, comprising fine blooms of Japanese—Ralph Brocklebank, Duchess of Albany, Thunberg, Carew Underwood, Maiden's Blush, Belle Paule, Mr. H. Cannell, Madame Baco, Pelican, Baronne de Prailly, G. Daniels, and Mrs. Cannell; incurved: Lord Alcester, Golden J. Salter, Antonelli, Lord Wolseley, Miss M. A. Haggas, Prince Alfred, Queen of England, Princess Teck, Faust, Golden Empress, Violet Tomlin, and Barbara. Mr. Notcutt followed for the second place, and the Rev. Page Roberts was third.

With twelve Japanese the Rev. Hugh Berners, Harkstead Rectory, Ipswich (gardener Mr. G. Jordan), was first, showing fine blooms of Carew Underwood, Madame Baco, Condor, Madame J. M. Pigny, Boule d'Or, Sarah Owen, E. Molyneux, E. H. Carrière, Japonaise, Etoile de Lyon, Baronne de Prailly, and Puritan. Mr. F. T. Smith, Palgrave, was second; and Mr. Bunnington third. In other classes for cut blooms there was good competition, the chief prizes going to Messrs. Bishop, Smith, Bunnington, Bird, Notcutt, and Huggins.

The best group came from the Rev. Page Roberts, an effective arrangement, chiefly consisting of Japanese and single varieties. J. T. Frere, Esq., was second for a very tasteful group, and an extra prize was awarded to Mr. Bolton. Messrs. Smith, Frere, and Bolton were the prizetakers for specimen plants, some of which had excellent blooms.

Mr. J. Tudor Frere of Rydon Hall showed a collection of well grown

Apples, Pears, Grapes, Plums, and other fruits. Mr. Alfred Bishop also had forty-six dishes of extremely fine Apples and Pears of excellent colour, and for both these exhibits extra prizes were awarded.

#### GRIMSBY.

THE second annual Exhibition of the Grimsby and District Chrysanthemum Society was this year held in the Town Hall, and was opened by the Mayoress, Lady Bennett, with some very pleasing remarks. The capacious hall was well filled throughout, and the arrangements were carried out in the most satisfactory manner, Mr. A. Mountain, the Hon. Secretary, deserving every credit for the management of so large an exhibition.

Cut blooms formed the most important feature of the Show, some excellent blooms being staged. The principal class was that for forty-eight blooms, twenty-four to be Japanese, and the remainder incurved, in not less than eighteen varieties in either section, for which a silver cup, value 5 guineas, and £2 in money were offered. There was keen competition, and the place of honour was won by Mr. W. Welton, gardener to Mr. G. A. Carr, Waltham Grove, with the following varieties. First on the stand was a handsome bloom of Mrs. Alpheus Hardy which measured 8 inches across and 4½ inches deep. It won the special prize, and well deserved it. It was a credit to Mr. Welton to exhibit such a bloom. The following were the other blooms staged—Condor, Baronne de Prailly, Sunflower, Mrs. F. Jameson, Belle Paule, J. M. Pigny, Carew Underwood, very good; Madame C. Audiguier, Puritan, Coronet, good; Mrs. J. Wright, Val d'Andorre, Avalanche, T. Stephenson, W. Holmes, Criterion, and Comte de Germiny, all most excellent blooms. The incurved were composed of the following varieties—Golden Empress, Lord Alcester, White Empress, Lord Wolseley, Emily Dale, Barbara, Jeanne d'Arc, Violet Tomlin, Jardin des Plantes, Queen of England, Princess of Wales, Bronze Queen of England, Guernsey Nugget, Empress Eugénie, Lord Derby, Alfred Salter, Nil Desperandum, all excellent blooms, not large, but well finished. The second position was taken by Mr. G. Burrows, gardener to Sir Henry Bennett, The Westlands, after a close competition. His blooms were very good, and the principal amongst them were Etoile de Lyon, E. Molyneux, Puritan, Stanstead White, Vivand Morel, very good; Avalanche, Sunflower, Lord Alcester, M. R. Bahuant, very fine indeed; Alfred Salter, Earon Beust, Violet Tomlin, and Mrs. Heale, all neat well finished blooms. The third place was gained by Mr. W. H. Clark, gardener to Mr. G. Smith, The Elms, after a close competition, only three points dividing the second and third stands. The incurved were all good.

In Class 2 for twenty-four blooms, twelve Japanese and twelve incurved, Mr. E. Wright, gardener to David Wilson, Esq., Park House, Cottingham, was an easy first. His blooms showed very good cultivation. They were sound, deep, heavy blooms. The following were the most noteworthy:—Condor, Fair Maid of Guernsey, Puritan, Alberic Lunden (very good), Album Fimbriatum. Incurved: Prince Alfred, Lord Wolseley (the champion incurved bloom of the Show, measuring 6 inches by 3½ inches, a magnificent bloom). The second place was gained by Mr. Clark, gardener to Colonel James Reed, Westland Corner, with some fine blooms well finished, especially the incurved. The Japanese were a trifle light, but very bright. The third place was occupied by Mr. Walker, gardener to Mr. Granville Southwell, Waltham Hall. The most notable bloom was Louis Boehmer, a grand bloom, but not fully out. Its measurement was 8 inches by 3 inches.

For twelve Japanese the premier prize was gained by Mr. G. Burrows, gardener to Sir Henry Bennett. Second honours went to Mr. W. Welton. With twelve incurved in not less than nine varieties Mr. Walker was first for a stand of beautiful blooms, large, solid, well finished, and indicating the best cultivation. The reflexed classes were not very well represented, but some good blooms were shown. Anemones were well represented, especially in the first prize stand, shown by Mr. G. B. Burrows, Jeanne Marty being much admired.

In the amateurs' classes there were some fine blooms shown. Mr. A. Mountain, the Hon. Secretary, had good blooms, indeed they were equal to those in the open classes. The cottagers also showed well, the principal honours resting with Mr. Jos. Cook and Mr. C. Wilson; the last named took the special prize with a good bloom of E. Molyneux.

In the classes for groups the principal prize was a cup value 5 guineas, and £2 added, which was won by Mr. Fred. Isle, gardener to Capt. E. L. Grange, for a good group. Mr. J. Clark, Cromwell Road Nurseries, and Mr. C. Colebrooke, Royal Nurseries, were second and third with good groups. The classes for fruit were well filled, the examples being good. Mr. Mobbs, gardener to Henry Josse, Esq., took the first prize for dessert Pears with five fine fruits of Pitmaston Duchess, each fruit averaging a pound in weight. The Apples also were very good. Taking the Show all round it was a great success, considering it is only the second year. Every credit is due to the Secretary and Committee for the way in which they have worked the Show up to its present standard. Next year it will probably be a greater success than it has even been this season. It will be difficult to surpass the quality of the blooms shown.—J. DOBBS.

#### BRADFORD, NOV. 6TH AND 7TH.

THE fifth annual Show was held in the Technical College. This was the earliest fixture in the north, and in past years it has been the meeting place of some of the best growers in the Midlands, and around Liverpool considerable interest was evoked as to the quality of the flowers likely to be shown during the current year. For some unexplained

reason only two entries were made in the class for forty-eight, twenty-four Japanese and twenty-four incurved, Mr. George Burdon, Birkenhead, having an easy success with good flowers staged as follows:—Japanese, back row: Etoile de Lyon, Mdlie. Lacroix, E. Molyneux, Sunflower, Avalanche, Mrs. Jameson, Stanstead White, and E. Molyneux. Second row: Staastead Surprise, W. W. Coles, Stanstead White, Marsa, Jeanne Délaux, Belle Paule, Stanstead Surprise, and Sarah Owen. Front row: Puritan, M. Bernard, M. Marrouch, Avalanche, Madame Baco, Sunflower, Gloire de Rocher, Puritan, Sunflower, Jeanne Délaux, and Avalanche being specially fine. Incurved, back row: Queen of England, Empress of India, Emily Dale, Improved Jeanne d'Arc, Emily Dale, Improved Lord Alcester, Empress of India, and Queen of England. Second row: M. Bahuant, Jardin des Plantes, John Salter, Golden Empress of India, John Doughty, Jeanne d'Arc. Front row: Lady Hardinge, Sir S. Carey, Mr. Bunn, Princess Beatrice, Miss Haggas, Refulgens, Mr. Bunn, Prince Alfred. The second prize was taken by Mr. W. Boston, Manor Farm Nurseries, Calthorpe, Bedale.

In the local class Messrs. H. Clark, Rodley, won the Mayor's cup for twenty-four varieties, staged as follows:—Incurved: back row, Jeanne d'Arc, Queen of England, Bronze Queen, Lord Alcester; middle row, Golden Empress, Empress of India, Lord Wolseley, Nil Desperandum; front row, Miss Haggas, Violet Tomlin, Mr. Bunn, and Princess of Wales. The second prize went to Mr. T. Torrelvel, Lightcliffe; and third prize to Mr. J. Gordon, Lightcliffe. All the other classes in this section were well filled and keenly contested, making altogether a fine and attractive show, being generally considered an advance on previous years. Groups of Chrysanthemums and ornamental foliage plants were staged by Messrs. Thos. Bell, Frizinghall; Mr. Butter, Calverley; Mr. Utting, Manningham, the prizes being awarded in the order named. The second prize collection was made up of remarkable fine well-grown and valuable plants, but marred by too stiff an arrangement and a multiplicity of thick white stakes brought prominently into notice, this fault being not uncommonly committed by inexperienced exhibitors who, relying on the quality of their plants more than upon the best use which may be made of them, and having only a loose interpretation of the conditions laid down in the schedule, meet with disappointment, and in some cases meet it in bad spirit, when the Judges give effect to their convictions by adhering to those conditions. Bouquets and ladies' sprays were an interesting feature of the Show. A fine display of black Grapes was also brought together in competition for prizes offered by Messrs. Thompson of Cloufords, Mr. G. Carter, gardener to — Bottomley, Esq., taking the first place with two magnificent bunches of Gros Colman, and Mr. W. Butters was second with fine Alicante. Mr. Thos. Horsman, nurseryman, Bradford and Ilkley, showed, not for competition, an imposing group of ornamental foliage plants of high quality and in vigorous health.—T. GARNETT.

#### ECCLES, PATRICROFT, AND PENDLETON.

THE fifth annual Exhibition of Chrysanthemums was held on Friday and Saturday, the 13th and 14th inst., at the Town Hall, Eccles, and was in every respect the best ever held by the Society. The display was of a delightful character, and the groups of Chrysanthemums and miscellaneous plants were magnificent. The cut blooms were also of a superior quality and showed a great improvement. The classes numbered fifty-seven, distributed over three sections; the first being open to all England, the second to amateurs, and the third was reserved to amateurs in the district who do not at any time employ a professional gardener.

In section I the exhibits were highly meritorious, especially the groups of Chrysanthemum plants, which were most tastefully arranged. They were composed of fine plants with foliage down to the pots. In this class Mr. G. H. Leigh of Swinton (Mr. Jos. Belshaw, gardener), was awarded the first prize and silver medal of the National Chrysanthemum Society; and for twenty-four cut blooms, twelve incurved and twelve Japanese, Mr. John Walker of Stockport received the first award, together with a silver medal of the National Chrysanthemum Society. Two charming groups of miscellaneous plants were exhibited by Mrs. Thos. Agnew (Mr. W. Elkin, gardener) and Mrs. H. Winterbottom (Mr. A. Torve, gardener), for which the former was awarded the first prize.

The principal prizewinners in section I were—for plants, Mr. G. H. Leigh, Swinton; Mrs. H. Winterbottom, Pendleton; Mr. Jos. Belshaw, Swinton; Mr. H. H. Howarth, M.P.; Mr. Fritz Reiss, Mr. C. S. Chatwood, and Mr. J. G. Groves. For cut blooms—Mr. John Walker, Stockport; Mr. J. Hanning, J.P., Leyland (J. Hickman, gardener); and the Right Hon. the Earl of Lathom, Ormskirk (J. Hathaway, gardener). Much praise is also due to the exhibitors in the amateur classes, which were well filled. The premier prize, together with a silver medal from the National Chrysanthemum Society in section II, for twelve cut blooms (six incurved and six Japanese), was won by Mr. Thos. Morton of Eccles; and in section III the silver medal, together with the first prize, was awarded to Mr. James Smethurst of Winton.

The principal prizewinners in sections II and III were Mr. H. Huber, Winton; Mr. James Smethurst, Winton; Mr. Thos. Morton, Eccles; Mr. A. B. Wimpary, Eccles; Mr. J. Benj. Wroe, Patricroft; and Mr. James Royles, Swinton.

The certificates of merit from the National Chrysanthemum Society were awarded for the best cut bloom in section I to Mr. John Stanning, Leyland, for one bloom of Vivian Morel, and in the amateur sections to Mr. J. Benj. Wroe for a very good grown bloom of Avalanche.

Messrs. W. Clibran & Son, Oldfield Nurseries, Altrincham, exhibited a collection of fine cut Chrysanthemum blooms, and Messrs. Dickson

and Robinson, and Messrs. Dickson, Brown, & Tait of Manchester showed each a very fine collection of miscellaneous plants. Each of these three exhibitors were highly commended by the Judges.

#### WOKINGHAM.—NOVEMBER 18TH AND 19TH.

A VERY attractive Show was held by the Wokingham Chrysanthemum Society in the Drill Hall on the above dates, and although there was a slight falling off in some classes the competition was extra keen in others.

The leading prize for a group of Chrysanthemums arranged for effect brought some remarkably well grown plants, and Mr. Bungay, gardener to Sir W. Moorshed, Forest Lodge, Binfield, easily won the first prize. Second, Mr. Wilks, gardener to B. E. Cammell, Esq., Folly Court. Third, J. M. Wescott, Esq., Easthatch. In the class provided for a group of Chrysanthemums not disbudded Mr. Goddard, Mathew's Green, took the first place, followed by Mr. Townshend, gardener to Sir W. J. Farrar, Sandhurst Lodge.

Good flowers were shown in the cut bloom classes, and for twelve incurved varieties, distinct, Mr. Lane, gardener to Miss J. D. Smith, Kings Ride, Ascot, took first honours with clean even blooms of Lord Alcester, Lady Dorothy, Lord Wolseley, and others. Mr. Godfrey, Ribsdon, Bagshot, second; and Mr. Poppie, gardener to Sir A. K. Stepney, Bart., M.P., Woodend, Ascot, third. In the class provided for twelve Japanese, distinct, Mr. Trinder, gardener to Sir H. Mildmay, Bart., Dogmersfield Park, Winchfield, took the first prize for very fine blooms of Sunflower, Louis Boehmer, Avalanche, Mrs. E. A. Carrière, Mrs. Wheeler (which also took the special prize as the best Japanese in the Show), Etoile de Lyon, and Stanstead White. For reflexed Mr. Godfrey was first, his best blooms being of the Christine family, Cloth of Gold, and Cullingfordi. The next class was for twelve cut blooms, distinct, any varieties to be shown, with not less than 9 inches of stem above the board; Mr. Trinder was again first, his best varieties in this stand being Mrs. Wheeler, Sunflower, Mrs. Alpheus Hardy, and Louis Boehmer; Mr. Godfrey was a close second, and Mr. Lane third.

For a group of flowering and foliage plants, staged for effect, 6 feet by 4 feet, Mr. Bungay repeated his success with a tastefully arranged group. Mr. Woodgate, gardener to Colonel Harvey, Ambaran, Ascot, was second, and Mr. Townshend third. For six table plants Mr. Lane came in first, Mr. Ashman, gardener to C. T. D. Crews, Esq., Billingbear Park, second, and Mr. Woodgate third. For six Primulas Mr. Goddard was first, and Mr. Bungay second.

Apples and Pears were shown in quantity, and of good quality too. For four dishes of dessert Apples Mr. Godfrey was placed first with good Ribston Pippin, King of the Pippins, Cox's Orange Pippin, and Blenheim Orange; followed by Mr. J. House and Mr. Townshend. For four dishes of cooking Apples some wonderfully fine fruit were shown. Mr. Godfrey was again placed first, Mr. Ashman second, and Mr. Townshend third. Pears were also numerous and fine. Mr. Trinder was first with good Pitmaston Duchess, Beurré Diel, Beurré Clairgeau, and Durondeau. Second, Mr. Godfrey, third, Mr. Townshend. Grapes were poorly shown. Mr. Cooper, The Vineries, Sunninghill, was placed first, Mr. Ashman second, and Mr. Townshend third.

In the classes provided for amateurs some excellent groups were shown, the chief prizewinners being Mr. M. A. Lemaire, Peach Street, and Mr. Caiger; and for table decorations, Mrs. Goddard and Mrs. Bedford.

Special prizes for collection of vegetables were offered by Messrs. Sutton & Sons, Messrs. Sale & Sons, Wokingham; and Messrs. Daniels Bros., which brought over twenty competitors, the chief prizewinners being Messrs. Bungay, Ashman, Turner, Hawkins, and Kcep. A very fine group of well-flowered plants of Chrysanthemums, not for competition, was exhibited from The Vineries, Wokingham.

(For other Shows see page 454.)

EVENTS OF THE WEEK.—The Chrysanthemum Shows are now concluded with the exception of the National Chrysanthemum Society's early winter Exhibition, which will be held on December 9th and 10th. In the current week there is little of importance, with the exception of the National Chrysanthemum Society's annual dinner, which will take place at Anderton's Hotel, Fleet Street, E.C., on Tuesday, December 1st, at 6 for 6.30 P.M. The tickets are 3s. 6d. each, a first-class musical entertainment will be provided, and the chair will be taken by R. Ballantine, Esq., Chairman of the Committee.

— ROYAL HORTICULTURAL SOCIETY.—We have pleasure in announcing that, by the kind permission of the Treasurer and Benchers, the great summer Show of the above Society will be held in the Inner Temple Gardens on June 1st and 2nd, 1892, when a display as extensive, rich, and diversified as before may be confidently anticipated.

— OAKDENE, GUILDFORD.—We are requested to announce that this estate has been purchased by the Marquis of Sligo, and that Mr. W. H. Aggett remains in charge as head gardener.

— RAISING CHRYSANTHEMUMS FROM SEED.—Is it possible to ripen the seed of Chrysanthemums in this country? If so, what is the mode adopted, and how are the flowers hybridised?—STANSTEAD SURPRISE.

— KINGSTON CHRYSANTHEMUM SOCIETY.—We are informed that the Committee of the Kingston and Surbiton Chrysanthemum Society have decided to hold their next Exhibition on November 8th and 9th, 1892, and that judges are being engaged for the occasion.

— LECTURES IN HORTICULTURE.—We are informed that Mr. G. Jordan, gardener to the Rev. Hugh Berners, Harkstead Rectory, Ipswich, has been appointed by the County Council of Suffolk to deliver twelve lectures on horticulture in the neighbourhood of Ipswich.

— THE second CHRYSANTHEMUM SHOW AT ELLESMERE (Salop) appears to have been very satisfactory, for the numbers of entries as compared with last year show an advance from 73 to 113. The President is Mr. Brownlow R. C. Tower, who gave an interesting address on the Chrysanthemum in the afternoon.

— BIRMINGHAM GARDENERS' ASSOCIATION.—A well-considered exhaustive paper on the Culture of the Melon was read at the last meeting of the Birmingham Gardeners' Association by Mr. William Comfort, The Gardens, Knowle Hall, near Birmingham. A lengthened discussion followed, and a very hearty vote of thanks was awarded.

— GARDENING APPOINTMENTS.—Mr. Henry Osman, having resigned his engagement at Harefield, has been appointed gardener to Mrs. Miller, Brentby House, Westbury-on-Trym, Gloucestershire. The following appointments have been recently made through Messrs. J. Laing & Sons, Forest Hill:—Mr. G. Yoell, late of Colley Lodge, Reigate, as head gardener to W. Watkins, Esq., Fairfield, Lee, S.E.; Mr. Beckett as head gardener to F. Behrens, Esq., Worleston Grange, Nantwich; and Mr. C. Stocking as head gardener to the Earl of Aylesford, Packington Hall, Coventry.

— THE works of the LATE MR. HIBBERD.—Messrs. W. H. & L. Collingridge, the proprietors of the *Gardeners' Magazine* (the editorship of which was under the late Mr. Shirley Hibberd) have purchased of the receiver of the estate of Messrs. Groombridge & Son, Limited, the whole of the stock, copyright, engravings, and stereotype plates of the well known gardening books by the late Mr. Shirley Hibberd, and will in future supply the trade. Many of the books are at present out of print, new editions of each are in preparation.

— ALTHOUGH MIGNONETTE is a great favourite with most people, and much frequented by bees, it is not cultivated to the extent as it might be, nor in a manner to prolong its flowering. Treated as a hardy annual it is seldom seen in bloom before the end of July, but when treated as a biennial it may be had in flower from the end of April or the beginning of May in the open ground, just as the plants have been treated. I used to preserve the plants in frames, and sometimes in dry sheltered positions the whole winter, and when spring came had only to plant them out in any vacancies in the flower garden.—W. T.

— MR. ALBERT KOEBELE, the American entomologist, is travelling in the Australasian colonies for the purpose of studying the ENEMIES OF INSECT PESTS. In introducing him to the Wellington Philosophical Society at a meeting on September 23rd, Sir James Hector recalled the circumstances connected with a memorable service which Mr. Koebele lately rendered to California. In 1888, when on a visit to South Australia in search of a small fly (*Testophonus*), a parasite on that dreadful pest *Icerya Purchasi*, Mr. Koebele discovered a single ladybird (*Vedalia*) preying on the pest. He found a second specimen in New South Wales, and then on his arrival in New Zealand he found that the *Icerya* about Auckland was also being destroyed by something, and this, too, turned out to be *Vedalia*. He at once saw that here was the thing he sought, and he was fortunate enough to be able to collect several thousands of *Vedalias*, which he afterwards liberated in California. Up to that time California had been so eaten up by *Icerya* that the damage was estimated at twenty millions of dollars annually. Yet, in twelve or fifteen months after the liberation of *Vedalia* in April, 1889, the State was practically free from the dreaded pest. Sir James Hector rightly characterised this work of Mr. Koebele as one of the grandest things in the interest of fruit and tree-growers that have been effected in modern times.—(*Nature*.)

— THE WOODBRIDGE HORTICULTURAL SOCIETY.—The Committee of the above Society show in the financial statement of their Floral and Musical Fête, held in the Abbey Grounds on July 9th last, a balance in their favour of £39 5s. 9d. In consequence of the fire which occurred in the Tan Yard, by which the whole of the working plant was consumed, it was necessary for the Committee to have new stands made which cost a considerable amount, besides various other materials which have not all been replaced yet, the Committee feeling the expense too great to incur in one year, but they trust that all friends will rally round the old Society so that next year the whole of the working stock may be obtained. The town having taken up the question of allotments so warmly, the Committee hope to be able to offer more encouragement to allotment holders in future. The next Show is fixed for July 7th, 1892, and a £25 cup is offered for twenty-four Roses (open), a remarkably liberal prize.

— PROF. G. L. GOODALE, of Harvard University, has recently paid a visit to the MUSEUMS AND BOTANICAL GARDENS IN THE TROPICS AND IN THE SOUTHERN HEMISPHERE, and has contributed an interesting description of them to the *American Journal of Science*. In the number for October we find an account of the Technological Museum at Sydney, which contains a very complete collection of the economic vegetable products of Australia, and which is largely visited by the working classes; of the two Botanic Gardens at Brisbane, one of them under the management of the Society of Acclimatisation; the Botanic Gardens at Geelong, Dunedin, Christchurch, and Wellington; the Museums at Dunedin, Christchurch, Wellington, and Auckland; and the small but excellent local Museum and Garden at Hobart. Prof. Goodale notices, with commendation, the tenacity with which all the Australian Museums cling to rare specimens of archaeological and ethnographical interest, instead of utilising them for exchange.

— THE TEIGNMOUTH AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION held a non-competitive Show in the Assembly Rooms on Friday, November 20th. The object of the Show was to start a fund for a library in connection with the Association. Some very effective groups were arranged most creditable to the gardeners of the neighbourhood, as it is only five weeks since this Show was suggested. H. Hammond-Spencer, Esq. (the President of the Association) sent a fine group of miscellaneous plants, Orchids, a fine *Adiantum farleyense* over 5 feet across, with fourteen dozen cut blooms of Chrysanthemums; Miss Fripp sent some fine cut blooms and fruit; Mrs. Marsh-Dunn, Carlton Lodge, had a very good group of Palms and Chrysanthemums, as also did H. Leah, Esq., — Atkins, Esq. F. Wheatly, Esq., Endfield, Shaldon, sent some beautiful Orchids in splendid condition; the Rev. A. Simms, Newton Abbot, showed good cut blooms of Chrysanthemums; Messrs. Hannaford & Son, nurserymen, displayed a fine bank of miscellaneous plants, &c.; Mr. Stamp, nurseryman, Bishops Teignton, also had a small group. The Show was a great success in every way, after all expenses are paid there will be a balance in hand of £15.

— A FURTHER NOTE ON THE KINGSTON SHOW.—The furious gale of Wednesday, November 11th, accompanied with the drenching rain, seriously affected the receipts on the second day of Kingston Show. Fortunately, the Society has a good reserve fund, and in the evening of the second day the prize money was paid to the successful competitors to the amount of £130. A most interesting feature of the Exhibition, which we were unable to note before, was the class for twenty-four blooms, twelve incurved and twelve Japanese, the first prize a cup value £5 5s., given by Messrs. John Laing & Sons, Forest Hill, which brought six magnificent collections, so even and fresh that each collection would have done honour to any first-class show. Mr. R. Cawte received the premier distinction with massive blooms of Lord Leicester, Violet Tomlin, Jeanne d'Arc, Alfred Salter, Queen of England, Miss M. A. Haggas, Prince Alfred, Golden Empress, Brookleigh Gem, Princess of Wales, Mrs. Coleman, and Lady Hardinge; Japanese Avalanche, Mons. Bernard, Condor, Edwin Molyneux, W. W. Coles, Stanstead White, Jeanne Délaux, Ralph Broeklebank, Mrs. H. Cannell, Stanstead Surprise, Puritan, and Carew Underwood. Mr. Woodgate ran the first prize collection very close, and received the second award; Mr. R. Coombe was third, and Mr. J. Wilkins fourth. A finer display of reflexed has probably never been seen, and Mr. J. Carpenter was deservedly awarded the first prize with the following:—Amy Furze, Cloth of Gold (two), Cullingfordi (two), King of Crimson, Golden Christine, Pink Christine, and Mrs. Forsyth (two). There were six competitors, all staging grand collections. Large Anemones, Pompons, and Anemone Pompons were alike all extraordinarily fine, and brought

several representatives, as well as the classes for eighteen distinct (six Japanese, six incurved, and six Anemone), and for twenty-four distinct (eight Japanese, eight incurved, and eight reflexed), and brought a very keen competition, which was much admired. The maiden classes were also well filled, as were indeed all the special classes, and Kingston has once more held its own amongst the foremost exhibitions of 1891.

— THE CORRIDOR AT CLEVELEY, ALLERTON.—A beautiful display of Chrysanthemums has been recently provided at the above place. A bank was arranged running the whole length of the corridor, 120 feet. Of Japanese Etoile de Lyon, Gloire de Rocher, G. Daniels, Madame Laing, A. H. Neve, Belle Paule, Sunflower, Condor, W. W. Colcs, and many others were represented in the best possible manner. In the incurved the Princess of Wales types were very fine. On a stage at the opposite side were scores of plants of *Salvia splendens*, carrying abundance of flowers, and affording a fine contrast to the Chrysanthemums. To view the whole from either end was delightful. On the back wall beautiful trusses of *Plumbago capensis* and *alba* were still showing, and the waning flowers of the *Bougainvillea* showed bright in several places. This corridor is one of the many places I enjoy when visiting Cleveley, and Mr. Cromwell, the gardener, seems to make it an ever-changing scene.

— DOUBLE MIGNONETTE.—Whilst visiting the nursery of Mr. W. Treseder, Cardiff, a few days ago, I was shown what was termed a "White Mignonette." Its whiteness I found was due to the fact of its being double and having all the stamens suppressed. The variety is consequently sterile, and can only be propagated by cuttings. The best of the plants had nearly finished flowering at the time of my visit, but even then the perfume from the few remaining flowers was delightful. Mr. Treseder informed me that it was a splendid variety for winter and spring work. He said that a single cutting would develop into as compact and bushy a plant as could be desired. One peculiar and valuable character of this double Mignonette is, that from the empty capsules, fresh racemes spring forth, giving the inflorescence the appearance of a compound raceme. The variety was discovered two years ago in a large bed of ordinary Mignonette, and although there was but one plant of it, the density of its racemes attracted attention, and when found that it did not bear seed, cuttings were at once taken, and a good stock gradually worked up.—W. W. PETTIGREW.

— SOME time ago the Department of Agriculture in New South Wales included in its list of economic plants suitable for cultivation in the north-eastern portion of the colony the "AVOCADO" or "ALLIGATOR PEAR" (*Persea gratissima*, *Gærtn.*). Several inquiries about it having since been made, Mr. F. Turner provides an account of the plant, with an illustration, in the August number of the *Agricultural Gazette* of New South Wales. Unless it is grown in very sheltered situations, the climate of Sydney is too cold for its successful cultivation as a commercial crop; but Mr. Turner thinks that on the northern rivers of New South Wales it should bear fruit as prolifically as it does in Southern Queensland. Some years ago, in the Brisbane Botanic Gardens, a fine Alligator Pear tree bore annual crops of very fine fruit, and it may do so still. When Sir W. W. Cairns was Governor of Queensland, he often asked Mr. Turner for some of the fruit when it was in season, and Mr. Turner kept him well supplied, for at that time no one seemed to care much for it. His Excellency told Mr. Turner he was very fond of the fruit for breakfast, and he used to eat it spread on bread and butter, with pepper and salt added to give it zest, and in various other ways. Mr. Turner did not care for the fruit at first, but afterwards became as fond of it as his tutor. So we are not unlikely to hear of the Alligator Pear by-and-by as a popular Australian product.

— THE ROYAL METEOROLOGICAL SOCIETY.—The first meeting of the present session was held on Wednesday evening, the 18th inst., at the Institution of Civil Engineers, Mr. Baldwin Latham, M.Inst.C.E. (President), in the chair. Eleven new Fellows were elected. Mr. R. H. Scott, F.R.S., gave an account of the proceedings of the International Meteorological Conference, which was held at Munich from August 26th to September 2nd. The following papers were also read:—1, "Account of an Electric Self-recording Rain Gauge," by Mr. W. J. E. Binnie, B.A. This is a very ingenious instrument, and has been constructed on the assumption that all drops falling from an orifice or tube are identical in weight, as long as the dimensions of the orifice are not varied." 2, "On Wet and Dry Bulb Formulæ," by Prof. J. D. Everett, F.R.S. This is a criticism of the methods investigated some years ago by Mons. August and Dr. Apjohn for determining by calcula-

tion the maximum vapour tension for the dew point from the temperatures of the dry and wet bulb. Prof. Everett also criticises the values adopted by Regnault, and says that in presence of the uncertainty as to a rational formula he thinks that Mr. Glaisher did wisely in constructing his table of factors, which give the dew point approximately by the most direct calculation which is admissible. The inherent difficulties of hygrometric observation and deduction are great, and have not yet been fully overcome. 3, "Results of Meteorological Observations made at Akassa, Niger Territories, May, 1889, to December, 1890," by Mr. F. Russell, F.R.G.S. This is in continuation of a former communication respecting the same place. After detailing the results of the various observations the author says this period was very unhealthy, and the year 1890 especially so. The weather was exceptionally dry, with small pox and phthisis amongst the native population. The west coast reports generally were also unfavourable in reference to the condition of resident Europeans, and at the principal ports quarantine regulations were put in force consequent upon an outbreak of yellow fever in places situated to the south-west. At Bonny ten deaths occurred from November to February out of a population of some sixteen Europeans.

## CHRYSANTHEMUM SHOWS.

(Continued from page 452.)

### SCOTTISH HORTICULTURAL ASSOCIATION'S SHOW AT EDINBURGH.

THIS large Show was held in the Waverley Market on the 19th, 20th, and 21st inst. The Managing Committee, encouraged by the great success of the two previous exhibitions, had again procured the services of the Grenadier band, under the leadership of Mr. Dan Godfrey, and in addition to the heavy item of bringing this celebrated band over 400 miles, they this year introduced the electric light for the three evenings of the Exhibition. The bareness of the huge building was somewhat covered by means of coloured drapery and a free use of evergreens, and the pillars being wreathed with these and studded with incandescent lamps, a pleasing effect was produced at night.

As a Chrysanthemum Show this was undoubtedly the best yet held by the Association, the cut bloom division being well filled, and in the Japanese section the blooms were of exceptionally fine quality. In the incurved section were also some notable examples of high class culture, but these as a rule were wanting in size. In the division for plants the improvement was most marked, many extremely well grown examples being staged. The few groups that were arranged formed one of the poorest sections, though the large group of Messrs. Methven & Sons was undoubtedly one of the leading features of the Show.

The blue ribbon of the several classes was the £20 cup offered by the Corporation of Edinburgh for forty-eight blooms, Japanese, in thirty-six varieties, the Association adding several substantial prizes to the less successful. The struggle for this coveted prize was engaged in by twelve competitors, several of whom had capital stands. Mr. Parker, Impney, and Mr. Machattie, Newbattle Abbey, had a close fight for the cup, but notwithstanding the massive proportions of the Staffordshire blooms, the fresher and younger flowers from Newbattle gained the day, and to Mr. Machattie, gardener, the cup was awarded for the second time. The blooms were remarkably even, and just at the right stage, neither too young nor too old. Extra fine were the following:—Viviand Morel, Condor, Boule d'Or, Etoile de Lyon, Elaine (two grand blooms), Gloriosum, Lillian Bird, M. Bernard, Avalanche, Mdma. Audigui, Puritan, George Atkinson, Coronet, and W. H. Lincoln. Mr. Parker, as indicated, was second; and Mr. Macher, gardener to R. Mudie, Esq., Broughty Ferry, with a very fresh but somewhat uneven lot, obtained third place. Fourth, Mr. Carruthers, gardener to Mrs. Fleming, Hillwood, Corstorphine, a grand bloom of Viviand Morel in this stand being selected as the best Japanese bloom in the Show. Fifth, Mr. A. Milne, gardener to Thos. Balmain, Esq., Hardington House, Lamington.

For the Scottish challenge cup, open to gardeners in Scotland only, for twenty-four blooms, incurved, the competition was not exciting, M. A. Wall, Blackhouses, Skelmorlie, secured the cup with blooms a little rough; second, Mr. Mathieson, Dhaling Mohr, Kirn; third, Mr. J. Clark, gardener to Mr. Roberts, Bannerfield, Selkirk. The stand included a good Empress of India, which was awarded the prize as the best incurved bloom in the Show.

The following were open to all gardeners and amateurs. Twenty-four blooms, twelve incurved, and twelve Japanese: first, Mr. Parker, Impney Hall, Droithich, for a very fine lot—Robert Cannell, Miss Haggas, Princess of Wales, and Lord Alcester being particularly fine in the one section, and Florence Davis, W. H. Lincoln, Etoile de Lyon, and Triomphe de la rue des Châlets in the other; second, Mr. Foster, gardener to Mrs. Roberts, Wellwood Park, Selkirk, and third Mr. Burden, gardener to G. Cockburn, Esq., Lingdale Lodge, Birkenhead. Twelve competitors. For twenty-four Japanese there were ten competitors: Mr. Kyles, gardener to Lady Q. Foulis, Corstorphine, was first with very fresh and bright blooms; second, Mr. Machattie; third, Mr. J. Beisart, Castle Huntley, Longforgan. For twenty-four incurved Mr. Jellicoe, gardener to F. H. Gossage, Esq., Camp Hill, Woolton, Liverpool, was first with a very good stand, Golden Empress being extra fine; also noteworthy were the blooms of Princess of Wales, Miss M. A. Haggas, Prince Alfred, Lady Dorothy, and Princess of Teck; second,

Mr. Burden; third, Mr. Clark, who had in this stand a perfect Golden Empress, to which was awarded the prize for the best bloom in the Show. Fifteen competed in the class for twelve Japanese, Mr. Parker being first with a stand of very fine blooms. W. H. Lincoln, M. M. Hoste, Mr. A. H. Neve, Triomphe de la rue des Châlets, and Etoile de Lyon being extra good; second, Mr. Geddes, gardener to G. Elder Esq., Knock Castle, Largs, bloom of a bright and fresh colour; third, Mr. Machattie, this was a fine class. For twelve blooms, six of each, Mr. Geddes was first with a very fresh lot, Mr. Machattie second, and Mr. Matthieson third. For six Japanese Mr. Beisant was first, Mr. Clarke second, and third Mr. Jellicoe. Fourteen entries.

In the class for six Avalanche ten competed, Mr. Geddes being first

least not decorative. The third lot contained Japanese, large blooms, which were decorative. There seems to be still a good deal in a name, and it would appear that this decorative class might be worth defining with clearness.

The classes for pot plants were well filled, and, as already stated, the plants were generally very good. Mr. D. Cavanagh, gardener to Mrs. Oliver, Murrayfield, Mr. Copeland, gardener, Orwell Lodge, and Mr. Cowan, Dunedin, took the chief prizes. An interesting exhibit was that of two standard Chrysanthemums, grafted, each with several varieties. Mr. Machar had the one, and Mr. Copeland the other. Mr. Petrie, Westerlea, Murrayfield, had the best group. Prizes were also given for various flowering and foliage plants, including Zonal Pelargoniums, Primulas, and others.

FIG. 85.—A VIEW IN THE GARDEN AT PREGNY, NEAR GENEVA. (See Page 446.)

with deep perfect flowers. Second, Mr. Kyles. Mr. Geddes was again first for six Stanstead White, with extra fine blooms. Second, Mr. Beisant. For six Boule d'Or, Mr. Kyles was first. For six E. Molyneux, Mr. Watt, gardener to J. Stewart, Esq., Blackhouses, was first, very good fresh blooms. Second, Mr. W. Lillie, Railway Station, Selkirk. For twelve incurved, Mr. Jellicoe was first with fresh but not over-large blooms. For six incurved, Mr. Nicoll, gardener to G. W. Bell, Esq., Rossie, Longforgan, was first with notable examples of the Queen family. For six Lord Alcester, Mr. Nicoll was again first with large but somewhat flattened blooms, and again for six Golden Queen. For six Empress of India, Mr. Watt took first, as also for six Golden Empress. The first prize for twelve reflexed varieties was secured by Mr. Watt, blooms small. For twelve trusses, decorative, there were three competitors, the first and second prizes being awarded to stands of small flowered varieties and Pompons which might be anything, but were at

Fruit was a rather poor show. Some good Pine Apples were exhibited by Mr. Dunn, Dalkeith Palace; and Mr. McIntyre, The Glen, was first for respectively one and two Pine Apples. Mr. Murray, Parkhall, Falkirk, had the best four bunches of Grapes, Mr. Leslie the best Muscat of Alexandria, Mr. Murray the best Alicante, Mr. Young, Peebles, the best Lady Downe's. There was a fair lot of Apples and Pears staged, but nothing calling for remark.

Vegetables were very largely shown. Some excellent collections of thirteen varieties, and single dishes of Cucumbers, Cauliflowers, Tomatoes, Leeks, Celery, &c., in great numbers, and of the most excellent quality. Miscellaneous exhibits included the group from Messrs. Methven & Sons already referred to, another from Dickson and Co., Waterloo Place, and collections of fresh blooms of Chrysanthemums up to date from Mr. Jones, Lewisham, and a sale stand of plants and flowers in favour of the Gardeners' Orphan Society.

## SWANSEA.—NOVEMBER 11TH AND 12TH.

THIS, the second of the above Society's ventures, proved, from a horticultural point of view, a splendid success, being on the score of quantity and quality a very marked advance on that of last year, all the open and limited classes being well filled, and in the former class—notably in the forty-eights, the competition was of a very high order of merit. The first and second lots were the finest stands I have seen so far this season.

The first prize for forty-eight was secured by Sir Charles Phillips, Bart., Picton Castle, Haverfordwest (Mr. Dumble, gardener). His best Japs were Sunflower, Avalanche, Meg Merrilies, Fair Maid of Guernsey, Annie Clibran, W. W. Coles, Ralph Brocklebank, Puritan, Madame C. Audiguier, M. A. E. Carrière. Incurred: Empress of India, Queen of England, Miss Haggas, Lord Alcester, Violet Tomlin, Jeanne d'Arc, Princess of Wales, John Doughty, indeed the incurred throughout were a perfectly even and clean lot. The second blooms, only less meritorious than the above, came from Sir H. H. Vivian, Bart., Singleton Park (Mr. Ireland, gardener), and in his incurred the Queen family were notably fine, but the stand on the whole had not the evenness or finish of the first lot. His Japs, however, were exceedingly good; among them were splendid blooms of Mr. A. H. Neve, Volunteer, M. Pigny, Miss A. Hartzhorn (a glorious flower), Mr. E. W. Clarke, &c. Mr. Hardy, gardener to J. C. Richardson, Esq., Glanbrydan, was third with pretty and fresh blooms. For twenty-four varieties, twelve Japs, twelve incurred, the same order was maintained in the first and second with similar quality to above class. Right Hon. Earl of Lisburne, Crosswood Park (Mr. Williams, gardener), taking third with a very creditable stand. For twelve, six Japs, six incurred, Colonel Wright, Gowerton (Mr. Weaver, gardener), was a good first; Mr. Dumble taking second place; and third, Mr. J. Harding, Guiscedwyn House.

There was a very strong competition, too, in the distinct classes, Mr. Ireland taking first for an excellent group of Chrysanthemums; Mr. D. Jenkins second; and Mr. Hammond, gardener to B. Evans, Esq., third. In the plant classes the prizetakers were Messrs. Ireland, Hammond, and W. Walters.

For twenty-four blooms, twelve Japanese and twelve incurred, Mr. Ireland was first; Miss Talbot, Penrice Castle (Mr. Milner, gardener), second, with very fine quality; and Mr. E. Gwyn, Neath, third. With twelve incurred Mr. Ireland was again first, and Mr. Hammond second. For twelve Japanese Mr. Milner was first, Mr. Ireland second, Mr. Weaver and Mr. E. Stuck equal thirds. With six reflexed and six Anemones Mr. Ireland had matters his own way. For thirty-six blooms (eighteen Japanese, eighteen incurred), open to Wales and Monmouthshire, Mr. Dumble again scored, closely followed by Mr. Weaver; Mr. Muir, Margam Park, taking the third place. For table plants Mr. Morgan, gardener to A. Gilbertson, Esq., Pontardawe, took the first place, Mr. Ireland being second, and Mr. Tom Barron, florist, third. Mr. Morgan was also first for Cyclamens and third for Primulas, Mr. Buckmaster taking first and Mr. Ireland second. Mr. T. Barron and Mr. Davidson took honours for bouquets and wreaths in the order of their names.

Fruit was very indifferently shown, but vegetables were excellent, as may be imagined when a Shrewsbury veteran enters the lists. Mr. Milner of Penrice Castle had a magnificent collection in competition for silver cup and prize given by Messrs. Parsons & Co., seedsmen of Swansea, with which he took first, and Mr. Ireland of Singleton, with a grand collection also, taking second. There were other competitions in vegetables for prizes given by the Committee and by Mr. James Harris of Swansea, but all were overshadowed by the collections above mentioned. The amateurs' and cottagers' classes were filled with very excellent exhibits, and the Chrysanthemum fever might be said to have caught on in the district. In addition to special prizes mentioned Mr. Ireland won that offered by Messrs. Garaway for best six Japanese blooms; and Mr. Hammond won the silver cup, offered by B. Evans, Esq., for six specimen plants.

Trade exhibits were staged by Mr. J. Harris, Black Pill, Swansea; Messrs. Parsons & Co., Swansea; Farrant, Swansea, miscellaneous tables of plants, &c.; Mr. Roberts, Uplands, Swansea, a pretty exhibit of Apples; The Neath Potteries, their specialities; and Messrs. W. Clibran & Son of Altrincham stands of cut blooms, new and rare varieties, also their new Fern Pteris Clibrani.

## HITCHIN.—NOVEMBER 13TH.

ALTHOUGH this Society does not boast of such wealth as many of the Societies existing in more populous districts, it can produce a Chrysanthemum Show second to very few indeed. The classes number only forty, but the Committee do not believe in offering a large number and small prizes; rather would they have restricted number of classes, and substantial prizes, and keen competition. The arrangements were under the direction of Mr. W. G. P. Clarke, a hardworking secretary and enthusiastic amateur. The Corn Exchange was a suitable building for the Exhibition, and viewing the hall as a whole the scene was magnificent. The entries were quite up to the average, and without doubt the quality was in every way superior. The classes for trained specimens and bush plants produced numerous entries, which were a strong feature in the Show. In the former class Mr. W. Springham, gardener to J. H. Tuke, Esq., secured premier honours, closely followed by Mr. James Upchurch, gardener to F. Lucas, Esq., Hitchin, and Wm. Millard, gardener to William Ranson, Esq. The first prize for bush plants was taken by the three very bright specimens of Mr. G. Harwoods, gardener

to A. Ransome, Esq., Hitchin, the second falling to Mr. E. Butler, gardener to F. Selbolmn, Esq., Hitchin, and the third to W. Springham.

The first prize for forty-eight blooms, twenty-four incurred, not less than eighteen varieties, or more than two blooms of one variety, twenty-four Japanese, distinct, was won by Mr. J. Kipling, gardener to Mrs. Osgood, Knebworth Park. The blooms were a picture of neatness throughout, as well as being of large form. Amongst these blooms being—Incurred: Golden Empress, Alfred Salter, Princess of Wales, Bendigo, Lord Alcester, Queen of England, J. Doughty, Miss M. A. Haggis, and Empress of India. Japanese: Stanstead White, Mons. Berard, Etoile de Lyon, E. Molyneux, Madame J. Laing, Sarah Owen, M. C. Audiguier. The second prizewinner, Mr. A. Hornett, gardener to G. B. Hudson, Esq., of Proginone Lodge, Hertford. The Japanese were good, but the incurred were past their best. The third prize was awarded to Mr. Anning, gardener to Capt. Pringle, R.N., Digwell, Wclwyn. The twelve incurred in Section I were of fairly even character. Mr. E. Cotton, gardener to A. W. Lines, Esq., and W. Millard gaining first and second respectively. The Japanese in the same section were of excellent quality, the order being reversed, and W. Millard gaining first with Mr. E. Cotton second, and W. W. Pepper, gardener to G. Burnand, Esq., Tewin Water, as third. A silver medal and 10s. as first prize, bronze medal and 5s. as second for eighteen blooms. Nine Japanese distinct and nine incurred distinct brought a good number of competitors. Of course with Mr. W. G. P. Clark (Secretary) exhibiting it would be expected that he would be first, for it is well known that his name has appeared in prize lists all over the country, his blooms were very creditable, and were specimens of what an amateur can do. The bronze medal fell to Dr. O. H. Foster, Hitchin.

Messrs. A. Hornett and R. Sharp now followed in the next three classes as first and second prizewinners respectively. For six incurred, Mr. John Anning was third. The first prize stand of Mr. Hornett's was a fine display of Queen of England. His Stanstead White, in competition for the prize for six Japanese one variety (white), were so good that they were awarded a first-class certificate by the National Chrysanthemum Society. Mr. R. Sharp was a good second and Mr. E. Cotton third. But it was in the class for six Japanese, one variety (coloured), Mr. Hornett's exhibits were particularly good. The stand of Mons. Berard was in such splendid condition that probably they are the best ever put on an exhibition table. Again Mr. Clark far outdistanced all competitors with three Mons. Berard and three Empress of India, the stand being awarded a first-class certificate, and one of the latter blooms being the premier incurred bloom in the Show. It is worthy of notice that the same variety was the best bloom of the class in both Watford and Luton Shows. Mr. Osman was second in this class, and Mr. Sanders third.

The Pompons were poor, and in saying this it may not be out of place to say that it was the only exhibit of which it could be said they were below the average. The winners were Messrs. George Moules, Hitchin; G. Harwood, and C. R. Smith. The groups were very fine indeed, and were quite a feature of the Show. The space occupied was 30 feet, the entries numbered five. Between the first three there was little to pick, the blooms being about equal, and the arranging such that it was with difficulty the Judges decided. Mr. Osman's was, however, slightly better arranged, and following him were Mr. E. B. Lindsell, Hitchin, and Mr. Richard Sharp. The cottagers' classes were well represented, the principal prizewinner being Mr. George Sanders, Hitchin. The fruit, bouquets, vases of Chrysanthemums, and table decorations all tended to make a successful Show.

## CUCKFIELD.

THIS Society held their annual Show in the Talbot Hotel Assembly Rooms, Cuckfield, on the 17th and 18th inst., and it was fairly successful. Unfortunately there was a great falling off in the number of groups, which has always been the best feature of this Show, only two being staged. This is to be regretted for two reasons. In the first place it is not in accord with the object of such societies that a main feature should become a minor one; and secondly, it shows either a lack of perseverance on the part of local growers at better cultivation and greater skill in tasteful arrangement, or an unwillingness on the part of their employers to show them. That the latter is the case if the matter was placed before them in the proper light cannot be believed after such good results in past years. Mr. George Stringer, gardener to R. A. Bevan, Esq., Horsham, was awarded the first prize; and Mr. J. Mitchell, gardener to Mrs. Moberly, Myttons, was second, both with good groups of well grown plants, the former being specially clean and bright. Specimen plants were not numerous, but good; Mr. Mitchell and Mr. T. Burtenshaw, gardener to W. Pagon, Esq., Hatchlands, being the only exhibitors. Primulas were very good. Mr. Burtenshaw was first for the Society's prize for six plants; but the keenest contest was for Messrs. Peed & Son's prizes for a similar number. Mr. J. Mitchell here was first, followed by Mr. J. Lingley, gardener to Mr. T. W. Best, Harvest Hill; and Mr. Manton, gardener to Mrs. Clifford, Borrer Bolney. The latter was first for six Solanums; and Mr. R. Inglis, gardener to T. T. C. Lister, Esq., was the only exhibitor of Cyclamens.

There were good entries in the cut bloom classes. For twelve incurred, open to the county of Sussex, Mr. S. Horscroft, gardener to — Potter, Esq., Ardingly, was first with fresh smooth blooms. They were Miss M. Haggas, Violet Tomlin, Princess of Wales, Empress of India. Second row: Alfred Salter, Jardin des Plantes, Barbara, Mr. Brunlees. Front row: Baron Beust, Cherub, Mrs. Heale, and Mrs. W. Shipman. Mr. T. Venn, gardener to W. Sturdy, Esq., Paxhill, Lindfield, and Mr. J. Voss, gardener to W. Savill, Esq., Finches, Lindfield, followed in the order named. In a similar class for twelve Japanese

Mr. Voss took the first place with the following:—Back row: Etoile de Lyon, Boule d'Or, Baronne de Prailly, and Pelican. Middle row: Mrs. F. Jamson, Condor, George Daniels, and W. G. Drover. Front row: Belle Paule, Ralph Brocklebank, Stanstead White, and Madame Baco, all fine blooms. He was closely followed by Mr. J. Coles, gardener to — Nichols, Esq., Highley, Manor, Balcombe, and Mr. T. Venn. In the local classes for twelve Japanese Mr. Coles was first in a good competition. Mr. R. Inglis was placed first for twelve incurved, and Mr. J. Lingley for twelve reflexed.

The show of fruit was good, but it must suffice to name those taking first places. Mr. R. Inglis, for black Grapes; Mr. G. Warren, gardener to B. Hankey, Esq., Balcombe Place, for white Grapes; dessert Pears, Mr. Stringer; stewing Pears, Mr. J. Sands, gardener to T. Banister, Esq., Haywards Heath. The latter was also rightly placed first for six dishes of Apples in a competition that will not soon be forgotten at Cuckfield. The Judges placed the successful competitors in the following order:—Mr. W. Manton (second); Mr. J. Harding, gardener to B. B. Hodson, Esq., Bolney; Mr. G. Warren, and Mr. Geo. Stringer. Most of the above-named gardeners also staged Apples and Pears not for competition, as did Messrs. Peed & Son, who showed fifty dishes of fine fruit, and Mr. J. Lingley, altogether making a fine display of Apples of high quality.

This Society is thoroughly popular with the people, and it is they who chiefly enable the balance to come on the right side of the books. But it must be admitted that unless Major Moberley, the President of the Society, can prevail on his lady friends of Cuckfield to take up the question of giving some entertainment during the afternoon, as they so successfully do at Lindfield, for instance, there is but little prospect of the Society being able, however much they may wish it, to provide anything really worthy of the neighbourhood. Mr. J. Tugwell efficiently discharged the duties of Secretary, and Mr. Umpleby that of Superintendent.

#### LIVERPOOL.—NOVEMBER 17TH AND 18TH.

PERHAPS at no previous Show in connection with the Liverpool Horticultural Association has so much interest been manifested as at the one held last week in St. George's Hall. The reason is easily explained when, in addition to the ordinary prize schedules of former years, there was another silver cup and substantial money prizes offered. These latter have both been presented by Messrs. R. P. Ker & Sons, Aigburth Nursery, and they deserve the greatest compliment it is possible to pay them for the broad and liberal policy they have pursued. The gift comes at a time when the Association stands in need of it, for on several occasions lately large inroads have been made into their funds which they could ill afford. We believe there are many more amongst the wealthy inhabitants of Liverpool and the neighbourhood who would be willing to provide classes in the schedule for next year. The magnificent Exhibition of last week surpassed all previous efforts, and considering the unfavourable season through which we have just passed the exhibits must have astonished all who attended. Before entering on the awards, may we call the attention of the Committee to Rule 10 of the schedule, where it is stated that no specimens will be received after 9.30, and every exhibitor must retire at eleven, and that this rule will be strictly enforced? We do not know who was responsible for it, but the rule was not enforced. The Judges of cut blooms were there early, and if they could have commenced their duties at the time specified there would have been no need to be carrying on the work after the public had been admitted.

The cut blooms amounted to over 2000, and beautiful they looked, arranged on tables running the whole length of the hall. The groups and miscellaneous plants were arranged in banks on each side, while the staging in front of the orchestra was devoted to orchids, bouquets, and a magnificent collection of Cyclamens from Messrs. Ker & Sons, Aigburth Nursery, arranged with the admirable taste which they always evince in whatever they undertake. The highest prize in the Show for cut blooms was that presented by Messrs. Ker, viz., a silver challenge cup value ten guineas, and ten guineas in cash each year, until finally won, for thirty-six cut blooms, consisting of twelve incurved distinct, twelve Japanese distinct, and twelve reflexed in not less than six varieties, open to all within a twelve miles radius of the Liverpool Exchange, to be won twice consecutively or three times in all. Should the cup be gained by three different exhibitors, then only these three shall be entered for the final competition. This brought six competitors, and the Judges awarded the prize to Mr. A. R. Cox, gardener to W. H. Watts, Esq., Elm Hall, Wavertree, who won more especially by the superiority of his incurved blooms, which were remarkably fresh and solid, and consisted of Empress of India, John Lambert, M. R. Bahuant, Mrs. Coleman, Mrs. Heale, Violet Tomlin, John Salter, all very fine; Golden Empress, Lord Alcester, Miss Haggas, Princess Teck, and Princess of Wales; Japanese—Sunflower, Bouquet des Dames, Lilian B. Bird, Belle Paule, Etoile de Lyon, Mr. A. H. Neve (grand), Condor, E. Molyneux, W. W. Coles, Avalanche, and Madame C. Audiguier. Reflexed—King of Crimsoms (2), Mrs. For-yth (2), Christine (2), Golden Christine (2), Cullingfordi (2), Chevalier Domage (2). The second place was taken by Mr. Donald Forbes, gardener to A. Holt, Esq., Crofton, Aigburth, who also had a splendid stand, containing remarkable blooms of Etoile de Lyon, W. W. Coles, Lilian B. Bird, and Mdle. Marie Hoste. Third, Mr. Geo. Eaton, gardener to W. H. Shirley, Esq., Allerton House, Florence Davis being a great attraction in his stand. Fourth, Mr. T. Foster, gardener to J. Brancker, Esq., Greenbank, Wavertree.

In the class for forty-eight cut blooms, twenty-four incurved and twenty-four Japanese (first prize 10 guineas and a silver cup value £5),

there were seven stands staged, the premier position being gained by Mr. George Burden, gardener to Geo. Cockburn, Esq., Lingdale Lodge, Oxtou, by two points only. Mr. Burden's incurved were especially good, and consisted of the following:—Back row: Queen of England (2), Empress of India (2), Alfred Salter (2), John Lambert, and Lord Alcester. Second row: Golden Empress (2), Violet Tomlin (2), Mrs. Heale (2), Miss Haggas, and Robert Cannell. Front row: John Salter, Mrs. N. Davis, Princess Teck, Jardin des Plantes, Lady Dorothy, Hero of Stoke Newington, Mrs. S. Coleman, and Princess of Wales. Japanese.—Back row: Etoile de Lyon (2), fine; M. E. A. Carrière, E. Molyneux (splendid), Pelican, Puritan, Vivian Morel (very fine), and W. W. Coles. Second row: T. Stephenson, Boule d'Or, Stanstead White, Mrs. Wheeler, Mrs. F. Jamson, W. H. Lincoln, Mons. Bernard (grand), and W. W. Coles. Front row: E. Molyneux, Marsa, Japonais, Mons. Bernard, Mrs. Irving Clarke, Mrs. F. Jamson, Avalanche, and Boule d'Or. Second, Mr. R. C. Townsend, gardener to J. R. Greatorex, Esq., Mytton Hall, Shrewsbury, who was a shade weaker in Japanese, but good in incurved. Third, Mr. J. Gould, gardener to R. N. Dale, Esq., Bromborough Hall, Cheshire. Fourth, Mr. C. Osborne, gardener to H. J. Robinson, Esq., Aymestry Court, Woolton. Of eighteen incurved eight stands were staged; Mr. J. Haynes, gardener to Mrs. B. C. Nicholson, Oswaldcroft, Wavertree, being first with a well-finished stand, the best being Mrs. Coleman, Jardin des Plantes, Miss Haggas, and Golden Empress. Second, Mr. R. C. Townsend. Third, Mr. J. Brantingham, gardener to W. Radcliffe, Esq., Roselands, Aigburth. There were two classes for twelve incurved, the first being won by Mr. H. Howard, gardener to A. S. Mather, Esq., Beechwood, Aigburth, Mr. T. Foster second; and the next by Mr. J. Edwards, gardener to Henry Tate, jun., Esq., Allerton Beeches, Mr. Townsend being second. In the class for six incurved Mr. J. Watson, gardener to T. S. Hannay, Esq., was first; Mr. T. Eaton, gardener to John Parrington, Esq., Roby Mount, Roby, second. In the corresponding classes for Japanese Mr. T. Healey, gardener to Col. Wilson, Hillside, Allerton, was placed first with fine fresh flowers, notable being Stanstead White, Etoile de Lyon, Avalanche, Volunteer, and W. W. Coles. Second, Mr. J. Gould, having Sarah Owen, Condor, and Etoile de Lyon, good. Mr. Geo. Eaton was third. For twelve Mr. T. Elsworthy, gardener to A. R. Gladstone, Esq., Court Hey, Roby, was first with a splendid stand; second Mr. T. Foster. Another twelve—Mr. H. Howard first, Mr. J. Edwards second. In the six Mr. J. Williams, gardener to C. J. Proctor, Esq., Birkenhead, first.

In the class for twelve blooms from those who have not won a prize previously, Mr. Coates, gardener to W. H. Verdin, Esq., J.P., Darnhall Hall, Cheshire, was a good first. Anemones were not numerous, but good in quality, as were the Pompons and the reflexed, the prizes going respectively to Mr. W. Wilson, gardener to H. Cunningham, Esq., Gorse Cop, Gateacre; Mr. R. Foster, gardener to S. H. Thompson, Esq., Thingwall Hall, Broad Green; and Mr. Sivess, gardener to S. Smith, Esq., M.P., Carleton, Princes Park. In still another class for six blooms, any kind, for those who do not employ a gardener, the prize was won by Mr. W. Mackarell, Freshfield.

Groups were very bright, and contained flowers of excellent quality. Mr. T. Winkworth, gardener to R. Brocklebank, Esq., Childwall Hall, was awarded the chief honour for a capital display. Second, Mr. J. Harrison, gardener to Mrs. W. G. Bateson, New Heys, Allerton. Third, Mr. Johns, gardener to J. Revill, Esq., Hill House, Wavertree. Mr. Johns was first for one untrained and second for six untrained, the first going to Mr. J. Lowndes, gardener to S. S. Parker, Esq., Sudley Road, Aigburth, who was second for one large flowered. Trained plants were poorly shown. For three large flowering, Mr. T. Wilson, gardener to C. H. Williams, Esq., Fulwood Park, Aigburth, was the only exhibitor. Mr. Wilson was also first for one large flowering, one Pompon, second for three Pompons and one pyramid. Mr. Thomas Gowen, gardener to J. A. Bartlett, Esq., Mossley Hill, was first for one standard, one pyramid, and an extra first for six untrained. Mr. T. Robinson, Mossley Hill, first for three Pompons; Mr. Winkworth was second with a standard on which some seven varieties were grafted.

In the miscellaneous plant classes the chief were secured by Messrs. Jellicoe, gardener to F. H. Gossage, Esq., Camp Hill, Woolton, A. R. Cox, T. Healey, T. Gowen, C. Osborne, T. Wilson, T. Foster, R. Pinnington (gardener to Edward Banner, Esq., Backlow House, Roby), J. Harrison, T. Hitchman (gardener to Arthur Earle, Esq., Childwall Lodge), and H. Wright, gardener to C. MacIver, Esq., Yew Tree House, Allerton.

Seldom has fruit of such excellent quality and quantity been seen in Liverpool. In every class the competition was of the keenest character. For a collection of six dishes there were seven exhibitors. Mr. T. Elsworthy was placed first for splendid Alicante and Muscat of Alexandria Grapes, fine Hero of Locking Melon, Marie Louise and Durondcau Pears, and Cox's Orange Pippin Apples. Second, Mr. J. Bennett, gardener to the Hon. C. H. Wynn, who had also a grand collection. Third, Mr. J. Barker, gardener to J. W. Raynes, Esq., Rock Ferry. For two Pine Apples Mr. P. Blair, gardener to Duke of Sutherland, Trentham, was the only exhibitor.

The most successful exhibitors in other classes for fruit were Messrs. Elsworthy; J. Hollingsworth, gardener to J. F. Campbell, Esq., Woodseat, Uttoxeter; W. Oldham, gardener to Joseph Beccam, Esq., Ewansville, Huyton; Sivess; Fergusson, gardener to Mrs. Paterson, Rock Ferry; McMaster, gardener to Sir Ughtred Kay Shuttleworth, Gawthorpe Hall, Burnley; Middleton, gardener to R. Pilkington, Esq., Rainford Hall; J. Downham, gardener to E. H. Harrison, Esq., Eastham; J. Broome, gardener to T. Harrison, Esq., Belle Vale, Gateacre; J. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derby;

S. Barlow, Stakehill, Castleton; Rev. L. Garnett, Christleton Rectory, Cheshire; and J. Davis, Bodenham, Leominster.

Certificates of merit were awarded to Messrs. R. P. Ker & Sons for a splendid group of Cyclamens; to the Liverpool Horticultural Company for groups of Orchids, Ferns, and miscellaneous plants; to Messrs. Clibran and Son, Altrincham, for new Chrysanthemums with capital blooms of the following Japanese: Annie Clibran, Aida, Alberic Lunden, Cesare Costa, Elliott F. Shepherd, Eynsford White, Sugarloaf, Vivian Morel, Louis Boehmer, Mrs. Levi, P. Morton, Coronet, Mr. A. H. Neve, Mdle. Marie Hoste, W. H. Lincoln, and Gloire du Rocher, the same firm having also a splendid stand of single Chrysanthemums which were much admired; and to Mr. R. Owen, Maidenhead, for new seedling Chrysanthemums, three of which were certificated—viz, F. W. Flight, G. C. Schwabe, and Mrs. Robinson King. Mr. Carling, gardener to Mrs. Cope, Dove Park, Woolton, showed a pure white sport from Etoile de Lyon. A special certificate of merit was awarded to Messrs. J. Williams & Co., Manure Manufacturers, 62, Mount Pleasant, Liverpool, for Williams' Garden Fertiliser.

Cultural certificates were awarded to Mr. W. Kipps, gardener to W. Crosfield, Esq., Walton Lea, for three fine Pine Apples; to Mr. R. C. Townshend for a fine dish of Onions; to Mr. R. Pinnington for a capital basket of Grosse Calebasse Pears; and to Messrs. Dicksons, Limited, Chester, for some fine fruit taken from young pyramids growing in their nursery. The attendance was not so good as last year, but still it was satisfactory, and was visited by all the leading families in the neighbourhood, including the newly appointed Mayor and Mayoress (Mr. and Mrs. J. de Bels Adam) who opened the Exhibition, the Chairman, Secretary, and Committee having every reason to be proud of such a beautiful Exhibition.

#### SALISBURY.—NOVEMBER 17TH AND 18TH.

THE annual Exhibition of Chrysanthemums, fruit, and flowers was held in the County Hall on the above dates, and although there was a decrease in the number of entries, there was certainly no falling off in the quality of the exhibits staged. The decrease was more noticeable in the cut bloom (open) classes, and may be accounted for by the fact that the three previous years—thanks to the energy of Dr. F. W. Coates, a generous supporter of horticulture in and about Salisbury—four silver cups were offered to be competed for, and three of these having been won for the third time in succession last year, none had been offered in their stead to be competed for this year.

Groups of Chrysanthemums and of miscellaneous plants made a good show, the winning ones being efficiently and tastefully arranged. The principal class, and one which evoked much local interest, being that in which the £10 10s. challenge cup, together with a small money prize constituted the premier awards; the plants to be arranged in a semi-circle of 10 feet by 6 feet, the cup to be won three years in succession before becoming the property of any one exhibitor. Mr. Frank Pearce, Crane Street, Salisbury, was a good first for well-grown plants, clothed with rich green foliage from the pots and most tastefully arranged, gradually diminishing in height until the outer row of plants barely showed about the edging of Maidenhair Fern which gave finish to the whole. The blooms, too, were uniformly large, even, and fresh, and the colours well intermixed. This is the second year that Mr. Pearce has won the trophy in succession. Mr. A. Robey, gardener to Captain Greenwood, Harnham Cliff, Salisbury, was second, and if he had had some dwarfier plants for the two outside rows and an edging of Maidenhair Fern instead of *Panicum variegatum* he would have stood a good chance of being first. Alderman Lovibond, St. Anne Street, Salisbury, was a creditable third. Mr. Haskins, Poultry Cross, Salisbury, was an easy first in the amateurs' class, his plants being dwarf, and capitally grown and efficiently arranged, being a bright and attractive group. Mr. W. H. Pearce, New Street, was second.

Three groups of miscellaneous plants were arranged on a space covering the same area indicated above. Two of these were very close to each other in point of merit, and took the Judges some time to determine their relative positions; the premier position being ultimately accorded to Mr. Curry, gardener to Col. Pepper, Milford Hill, Salisbury, for a most tastefully arranged and highly effective group. Brightly coloured Crotons and Dracenas and variegated narrow-leaved plants and small Palms set at intervals in a carpeting of Maidenhair Fern (*Adiantum cuneatum*), among which the pale green leaves spotted with white of *Caladium argyrites* showed off to great advantage. An edging of *Panicum variegatum* and *Isolepis gracilis* and the arching fronds of a healthy Palm (*Kentia Fosteriana*) occupying a central position at the back gave an imposing finish to the whole. Mr. A. Robey secured the second prize for a capital arrangement, the plants employed being similar to those used in the first prize group, except that the variegated-leaved plants, which gave it such a light effect, were absent. In his arrangement were a few good plants of *Oncidium crispum*, one having a very fine spike of well developed flowers; *Cypripedium Lawrenceanum*, C. Lowi, and *Cattleya Bowringiana*, which had due weight with the Judges. Mr. Frank Pearce was a decent third.

Specimen plants were not well shown, neither was the cultural skill displayed of a high order. With four plants Mr. A. Robey was first, and Mr. James Chalk, gardener to George Read, Esq., Westwood, Wilton Road, Salisbury, was second. For two specimen plants of Chrysanthemums (open only to those not keeping a regular gardener), Mr. John Kaines, Twyford, Winchester, was first with dwarf, healthy, and well flowered plants of Berthe Rendatler and Cloth of Gold; Mr. W. H. Pearce, New Street, Salisbury, being second. The same exhibitors occupied like positions in the single specimen (open) class; Mr. Chalk

being third; Mr. Kaines staging a nice compact plant of Barbara, having good sized, solid, even, and fresh flowers.

Cut blooms were not shown so extensively as in previous years, but the quality of the exhibits was quite as good. The chief class was for thirty-six blooms, eighteen Japanese and eighteen incurved, to include not more than two of any one variety. Mr. Neville, gardener to F. W. Flight, Esq., Twyford, Winchester, was first, staging large, solid, even, fresh blooms of fine finish, the incurved being Princess of Wales (two), Mrs. S. Coleman (two), Princess of Teek (two), Lady Dorothy, Miss Haggas (two), Violet Tomlin (two), Mr. Brunless (two), Hero of Stoke Newington, Queen of England (two), Alfred Salter (two); Japanese—Etoile de Lyon (two), Thunberg (two), Triomphe de la rue des Châlets, W. W. Coles (two), Meg Merrilies, Mrs. Jesse Clarke, Gloriosum, Leon Track, Mrs. Wheeler (two), Sarah Owen, Ralph Brocklebank, Edwin Molyneux (two), and Bertha Flight. Mr. W. Robinson, gardener to Lord Chief Justice Lopes, Heywood, Westbury, was a good second, his best blooms being Etoile de Lyon (two), George Maelure, Louis Boehmer, Lord Alcester, Princess of Wales, Violet Tomlin, and Golden Empress of India. The third prize going to Mr. George Inglesfield, gardener to Sir John Kelk, Bart., Tedworth, Marlborough, for good all-round blooms.

In the class for eighteen blooms of not less than twelve varieties (open to amateurs only) Mr. W. Follen, gardener to J. D. Willis, Esq., Bapton Manor, Codford, near Warminster, was first with blooms of Thunberg, Edwin Molyneux (two), Etoile de Lyon (two), Christine, Boule d'Or (two), Louis Boehmer (two), Triomphe de la rue des Châlets, Mrs. J. Wright, Sarah Owen, Lord Alcester, Alfred Salter, Miss M. A. Haggas, Violet Tomlin, Jeanne d'Arc, and Barbara. Mr. J. Voce, gardener to Alfred Williams, Esq., Fisherton, Salisbury, was second; his best blooms were Mrs. F. Jameson (two), Etoile de Lyon (two), and Mr. H. Cannell. The third going to Mr. W. Batten, of Basingstoke. In the class for twelve blooms, not less than six varieties (open only to those not employing a regular gardener), Messrs. John Kaines and W. Batten took first and second in order, both showing creditable blooms.

With twelve incurved, not less than eight varieties, Mr. Neville was first, staging good blooms of Princess of Wales (2), Mrs. S. Coleman, Miss Haggas (2), Hero of Stoke Newington, Queen of England (2), Empress of India, Golden Empress, and Mrs. Heale. Second, Mr. W. Robinson, his best blooms being Princess of Wales, Queen of England, Hero of Stoke Newington, Mrs. Norman Davis, and Lord Alcester. Mr. G. Tucker, gardener to Major W. P. Clarke, Bellfield, Trowbridge, was a good third. Twelve Japanese.—Mr. W. Robinson led the way with a very good stand, staging, amongst others, excellent blooms of Etoile de Lyon (2), Edwin Molyneux, Mrs. E. W. Clarke, Ralph Brocklebank, Condor, George Maelure, Thunberg, and Avalanche. Mr. George Irfield was a capital second, and Mr. Neville was a good third. Twelve blooms reflexed.—First, Mr. W. Robinson, his best blooms being Peach Christine (2), Golden Christine, Elsie, Cullingfordi (2), Mrs. Forsythe (2), Dr. Sharpe, and Cloth of Gold. Mr. G. Tucker was second. Only two lots were shown. Messrs. W. Robinson and G. Tucker were first and second in that order for twelve blooms of Anemone varieties with two good stands.

Ladies' classes were well represented. Vase of flowers for table.—First, Miss Agnes Flight, Twyford, Winchester, for an arrangement consisting of Chrysanthemums, Maidenhair Fern, and Grasses disposed to good advantage, with a shoot of *Ampelopsis Veitchi* with its brightly coloured leaves depending from the top of the centrepiece. Miss Lovibond, St. Anne Street, Salisbury, was second for an arrangement which, had a few more flowers been used in its composition, would have obtained a higher award. Miss Elsie L. King of Little Durnford, Salisbury, was third. For a basket of flowers, foliage, berries, &c., Miss Agnes Flight was a capital first with an exceedingly bright, fresh, and tasteful arrangement. Miss Ethel Mary Waters, Stratford Sub-Castle, Salisbury, was second; and Miss Elsie M. King was third. For three shoulder sprays Miss A. Flight secured first place for medium-sized neat arrangements, one—the middle one—being composed of Marie Louise Violets and small autumn leaves, with a base of *Adiantum cuneatum*, and the other two of small Tea Roses. Miss C. A. Mathews of Highfield, Salisbury, was second for rather too large arrangements, consisting of very suitable flowers—Roman Hyacinths, Niphetos Roses, and such like. Miss E. Burt of Winterbourne Daunstre, near Salisbury, was a capital third; her middle spray prevented her taking a higher award. For six buttonholes the prizes went to Miss C. A. Mathews, Miss Hodges of Dean, and Miss B. Flight, Winchester, in the order in which their names appear for good arrangements.

Fruit was shown well, but in very limited numbers. Mr. H. W. Ward, Longford Castle, Salisbury, was the only exhibitor in the class for a collection of six kinds, staging Black Alicante and Foster's Seedling Grapes, Webb's President Melon, Queen Pine, Beurré Clairgeau and King of the Pippin Apples. Mr. Chalk was the only competitor in the classes for Muscat of Alexandria and Black Alicante Grapes, staging large, well coloured bunches in both cases, the Muscats being particularly good. In the any other black class Mr. Ward took first with well coloured bunches of Lady Downe's; Mr. Chalk taking second with Gros Maroc. Mr. Ward was also first in the any other white class with Trebbiano. Apples and Pears were well shown by Mr. Thomas Hall, gardener to T. Montague, Esq., M.P., South Stoncham House, Southampton; and Mr. Fred Smith, gardener to the Bishop of Salisbury, The Palace, Salisbury, who took first and second in that order in the classes for three varieties of dessert and a like number of culinary Apples and dessert Pears. The three varieties of the latter staged by Mr. Hall were Pitmaston Duchess, Duchesse d'Angoulême, and Beurré

Diel. The six fruits of the latter were simply grand, being of immense size, uniform, and perfect in shape and colour. The Apples shown were (dessert) King of the Pippins, Cox's Orange Pippin, Harvey's Golden Russet; kitchen, Wellington Pippin, Flower of Kent, and Alfriston. Mr. Smith showing very fine fruits of Blenheim Orange, Lord Derby, and Warner's King.

Messrs. Keynes, Williams & Co. contributed a group of Chrysanthemums, &c., which added greatly to the general effect.

#### YORK.—NOVEMBER 18TH, 19TH, AND 20TH.

AN excellent Show was the twelfth autumn gathering, held, as usual, in the Fine Art Exhibition Building. It was in every way a success, the competition in most classes being keen, and the arrangements were admirably carried out by Mr. Lazenby, the Secretary.

Cut blooms were staged in large numbers. The principal class was for thirty-six, eighteen incurved, not less than twelve varieties, or more than two blooms of one variety, and the same of Japanese, and for which a first prize of £10 was offered. This was won by Mr. P. Blair, gardener to the Duke of Sutherland, Trentham, with medium-sized examples of the following—Lord Alcester, Alfred Salter (2), Golden Queen of England (2), John Salter, Empress of India (2), Golden Empress, Empress Eugénie, Mrs. Robinson King, Queen of England, Mrs. S. Coleman, Violet Tomlin, Princess of Wales, Novelty, Mrs. Heale, and John Doughty. Japanese: Etoile de Lyon (2), Mrs. C. Wheeler, Vivian Morel (2), Sunflower, M. E. A. Carrière, Avalanche, W. W. Coles, Puritan, Stanstead White, Golden Dragon, Baronne de Prailly, Mr. Ralph Brocklebank, Beauty of Castlewood, Vice-President Audiguier, Condor, and E. Molyneux. Second, Mr. W. H. Hotham, gardener to W. Robinson King, Esq., North Ferriby, Hull, with an even stand of blooms. Third, Mr. Folkard, gardener to Sir J. Walker, Sandhutton.

For twenty-four distinct, twelve to be incurved and the remainder Japanese, there were eight competitors, the best coming from Mr. Blair, —even blooms of Golden Empress, Empress of India, Mr. R. King, Queen of England, Prince Alfred, Golden Queen of England, Princess of Wales, John Salter, Mrs. W. Shipman, Camille Flammarion, Mr. Brunlees, and Refulgens. Japanese: Puritan, Mrs. C. Wheeler, Stanstead White, Etoile de Lyon, Madame J. Laing, Coronet, E. Molyneux, Sugarloaf, Stanstead Surprise, Thos. Stevenson, Madame Bac, and Avalanche. Mr. C. Lawton, gardener to Col. Broadley, Welton House, Brough, second, not well arranged. Messrs. Longton & Sons, Malton, third.

Four competed in the class for twelve incurved, the best blooms coming from Mr. Hotham; Mr. Folkard second; and Mr. G. Anderson, gardener to A. Milnthorpe, Esq., Tower Hill, Cattal, third. The best of six lots of twelve Japanese, distinct, came from Mr. Hotham, a bright lot. E. Molyneux, Puritan, Sunflower, Avalanche, Mrs. J. Wright, Etoile de Lyon, M. J. M. Piguy, Val d'Andorre, Sarah Owen, W. H. Lincoln, Madame J. Laing, and Boule d'Or. Mr. Short, gardener to A. Pease, Esq., Hummersknot, Darlington, second. Mr. Ketchell, gardener to C. H. Simpson, Esq., Moor Top House, Ackworth, third. The best six blooms any one variety came from Mr. Blair, fairly good ones of Avalanche; Mr. Ketchell second with Madame Bac; Mr. Short third with Puritan. The best reflexed in six distinct varieties were staged by Mr. Blair, solid high coloured blooms of leading kinds; Mr. Folkard second; Mr. Ketchell third. Single varieties were best shown by Mr. Ketchell. Anemone blooms were well represented in the first prize stand from Mr. Blair, followed by Mr. Ketchell and Mr. Short in the order given.

Six staged in the class for twelve bunches of cut flowers other than Chrysanthemums, the best coming from Mr. C. H. Letts, gardener to the Earl of Zetland, Aske Hall, Richmond, comprising *Cypripedium Spicerianum*, *Vanda coerulea*, *Vanda Amesiana*, and *Pancratium fragrans*; Mr. Blair second. Bouquets and baskets of Chrysanthemums were but moderate, and call for no further comment.

Plants were numerous, and the quality left little to be desired. For a group of Chrysanthemums and foliage plants arranged in a circle there were six collections, which produced a very fine display. Mr. Dawe, gardener to Dr. Baker, The Friend's Retreat, York, was placed first with a bright assortment; Mr. McIntosh, gardener to J. T. Hingston, Esq., Clifton, York, second with a somewhat crowded arrangement; Mr. G. Slater, gardener to the Right Hon. The Lord Mayor, third. For a group of Chrysanthemums only, to which may be added a margin of foliage plants, Mr. Everard, gardener to Mrs. Crutch, Holgate Lodge, York, was first with a solid bank of plants carrying good blooms and foliage; second, Mr. W. Boston, Calthorpe, Bedale.

Japanese Chrysanthemum plants were well shown, being well flowered and not too stiffly trained, the best four coming from Mr. S. Smith, Beverley; especially good was Val d'Andorre, Madame de Sevin, Etoile de Lyon, and Sunflower. The second position was occupied by Mr. Everard. The best two varieties were Dr. Macary and Val d'Andorre from Mr. S. Smith, Mr. Everard second. Reflexed varieties were also well shown by Mr. Vear, gardener to Miss Steward, Bishopthorpe, York, who obtained the premier award. Incurved kinds were here better seen than in many exhibitions, being freely grown and well flowered. The best four distinct kinds coming from Mr. Everard were Lord Wolsley, Mrs. G. Rundle, Jardin des Plantes, and Prince Alfred; Mr. S. Smith second. Pompons were well shown by Mr. S. Smith, being freely flowered and not stiffly trained.

A class was provided for six plants in 7-inch pots, suitable for decorative purposes, and excellent specimens were staged by Mr. Everard. Primulas were numerous and good. The following class was for ladies

only. The best dressed table of 8 feet by 4 feet with Chrysanthemums and any foliage created much interest. Miss Blanchet, 3, Muser Street, York, was awarded premier honours for a lightly arranged table. Mrs. Nutbrown, Nunnery Lane, York, second.

Fruit was sparingly staged but of good quality, Grapes being the chief feature. For six bunches in three varieties Mr. C. H. Letts won easily with grand examples of Muscat of Alexandria, Gros Guillaume and Alicante. Second, Mr. D. Dickinson, gardener to W. B. Richardson, Esq., Elm Bank, York; Mr. McIntosh third. For two bunches of black, any variety, Mr. G. Lee, gardener to Sir J. Cowell, Bart., Clifton Castle, Bedale, first with Gros Colman, Mr. Dickinson second with Alicante, nine competing. The last named had the best white Grapes in two bunches of Muscat of Alexandria, Mr. J. Smallwood, gardener to H. Leetham, Esq., Burnholme, having the second award.

The Show was attended by 10,000 persons, the receipts at the doors being nearly £240.

FIG. 86.—*DESMODIUM PENDULIFLORUM*. (See page 446.)

#### BRISTOL.—NOVEMBER 18TH AND 19TH.

AN excellent all-round display was made at this, the twenty-eighth annual Exhibition of the Clifton Chrysanthemum Society, and it was altogether a great success, the Colston Hall being taxed to its utmost to provide room for the exhibits without unduly encroaching upon the space required for the thousands of visitors who patronised the Show.

Trained Chrysanthemum plants are not so extensively shown as of old, but there was enough of them, good cultural skill being displayed by several growers. Mr. J. Ayres, gardener to T. W. Gibson, Esq., was successful with Chrysanthemum plants generally, taking among other prizes firsts for six large flowered incurved varieties, three Japanese varieties, three standard large flowered varieties, and for several single specimens. He also secured the silver medal of the N.C.S. for a grandly flowered specimen of incurved Mrs. Dixon. Messrs. T. M. Miller, Atwell, J. West and H. St. Vincent Ames were also successful with trained plants. Mr. J. Dale had a first prize for a highly credit-

able group of Chrysanthemums, Mr. J. Saunders being second. Equal first prizes were awarded to Messrs. Ayres and H. St. Vincent Ames for a group of Chrysanthemums arranged with fine-foliaged plants and Ferns, Mr. T. M. Miller being third. There was also a class for a group of miscellaneous plants arranged for effect, Chrysanthemums being excluded, and in this instance Mr. Ayres was first, his plants being prettily arranged though of far less value than the second prize group shown by Mr. J. Crispin. The last named had some grandly flowered Orchids in his group, but these sadly wanted a good groundwork of Ferns. Various other classes were provided for flowering and fine-foliaged plants, all of which were remarkably well filled, the principal prizewinners being Messrs. T. Tagart, T. W. Gibson, H. St. V. Ames, J. H. Lockley, J. B. Bain, J. Crispin, G. White, A. W. Summers, J. Saunders, R. Cripps, and W. K. Waite.

The show of cut blooms was one of the finest ever seen at Bristol, but Messrs. Drover of Fareham must have sadly damped the hopes of numerous exhibitors, as they took the first prizes in all the principal classes. The premier class, or that for forty-eight blooms, to consist of equal numbers of Japanese and incurved varieties, the first prize being £10, only attracted three competitors—viz., Messrs. Drover, G. Runnales, and J. Austin, Witley Court, who took the prizes in the order named. Messrs. Drover's blooms were remarkable for their great depth and solidity. The Japanese were Etoile de Lyon (2), Lady Lawrence, C. W. Lincoln, Sunflower, W. W. Coles, Stanstead White (2), Condor (2), Mrs. Wheeler (2), M. Bernard (2), Mrs. J. Clarke, M. E. A. Carrière, E. Molyneux, Boule d'Or, Sarah Owen, Mrs. Cannell, Carew Underwood, Louis Boehmer, and Mrs. F. Jameson; while the incurved consisted of Alfred Salter (2), Golden Empress (2), Violet Tomlin, Lord Alcester (2), Mrs. S. Coleman, Princess of Wales, Robert Cannell, Empress of India (2), Lady Dorothy (2), Mrs. N. Davis, John Lambert (2), Princess of Teek, Beauty, Miss Haggas, C. Gibson, Hero of Stoke Newington, and Jeanne d'Arc. In Mr. Runnales' stand were fine blooms of Japanese Louis Boehmer, F. A. Davis, A. H. Neve, Condor, and E. Molyneux. Mr. Austin also had a capital lot of both Japanese and incurved varieties. Messrs. Drover were well first for twenty-four incurved blooms, not less than eighteen varieties, these comprising John Lambert, A. Salter, Empress of India, Golden Empress, Lord Alcester, Princess of Teek, Nonpareil, C. Gibson, Mrs. N. Davis, Lady Dorothy, Violet Tomlin, Beauty, Robert Cannell, Mrs. S. Coleman, Princess of Wales, Lord Eversley, and Hero of Stoke Newington. Mr. Runnales was again a good second, and Mr. G. H. Copp third. In a corresponding class for Japanese varieties the competition was very keen; but Messrs. Drover were irresistible, and were first with fine blooms of Etoile de Lyon, Pelican, Baronne de Prailly, Sunflower, Mrs. C. W. Wheeler, Meg Merrilies, Stanstead White, M. Bernard, Mrs. F. Jameson, E. Molyneux, A. W. Lincoln, Carew Underwood, Lady Lawrence, Boule d'Or, W. W. Coles, Mrs. J. Clarke, Condor, and Louis Boehmer. Once more Mr. Runnales was a good second, and Mr. A. Cole was third. The best twelve blooms of Japanese varieties were shown by Messrs. Drover, Mr. Copp being second, and Mr. T. P. W. Butt third—a good class. For twelve blooms large flowered varieties Mr. Copp took the lead, Mr. T. P. Butt being second, and Mr. J. Baylis third. Mr. A. G. Hayman was first for six incurved varieties, Mr. W. P. M. Baker second, and Mr. J. Daw third. A special prize offered for six blooms of Mrs. Alpheus Hardy was won by Messrs. Drover, who had a beautiful stand of this delicate variety, and they were also the winners of a special prize for Louis Boehmer. Mr. J. Aplin, Gloucester, showed well in the latter and several other classes.

Bouquets, sprays, wreaths, and vases are always well shown at Bristol, the competition being remarkably close and good this year. Mr. C. Winstone, Clifton, was very successful in these classes, as also were Messrs. E. S. Cole & Son, Bath, other prizewinners being Messrs. E. T. Hill, F. W. Haskins, and A. Deedes. Special classes were provided for amateurs, and several of these distinguished themselves, not only with baskets of flowers, but also with cut blooms of Chrysanthemums, Mr. H. W. Gillingham being particularly successful with the latter in this his first attempt.

Fruit was capitally shown, a large number of classes being provided for everything in season. Mr. W. Nash, Badminton, was well first for a collection of six varieties, having good Alicante and Muscat of Alexandria Grapes, a Melon, Medlars, Pears, and Apples. Mr. J. Lloyd, Langport, was a very good second. Grapes were particularly well represented, the quality throughout being good, though much better Muscats were shown last year. The prizetakers were Captain Bayley, Mr. A. Cole, Mr. T. Jones, Mr. W. Marsh, Mr. W. Iggulden, Mr. J. Gibson, Mr. W. Nash, Mr. J. Down, Mr. J. Lloyd, Mr. J. Dole, and Mr. T. H. Hill. In other classes Messrs. A. P. Vivian, W. G. Pragnell, Sherborne Castle; J. Gibson, H. St. V. Ames, W. Nash, J. Bradner, E. Hall, Runnales, Pragnell, J. H. Virgo, and Deedes were the prizetakers. The most successful with vegetables were Messrs. Ames, Evry, E. T. Hill, D. A. Thomas, and J. C. Wall.

There were several noteworthy non-competitors' exhibits, foremost among these being some grand Chinese Primulas contributed by Messrs. Sutton & Sons, Reading. All their varieties were well represented, including the novel Moss Curled Advance, and Double Lilae. Messrs. Suttons also had a remarkably good display of Potatoes, many novelties, as well as older varieties of their own raising. Messrs. Garraway & Co., Durdham Down Nursery, Clifton, sent a large number of Palms and other plants, and also exhibited a fine collection of hardy fruit. Messrs. Parker & Sons, Clifton, gained much credit for a capital display of wreaths, bouquets, and baskets of flowers, the arrangement of these being somewhat novel.

#### HULL.—NOVEMBER 18TH AND 19TH.

ALTHOUGH, as in the case of many exhibitions this year, the tables were not quite so crowded with cut blooms as on the last occasion, yet the Hull Show lost nothing in effect on that account, while in high average quality it fully equalled, and probably exceeded, any previous display held in the busy town. It may fairly be called a town of Chrysanthemum lovers, as it would be difficult to find such a numerous and influential company assemble elsewhere immediately the doors are open to the public. The Exhibition was opened by the Mayor, who said "he felt sure that, under the able management of the Chairman and various officials, the Chrysanthemum Society would continue to be what it was at the present time—one of the standing institutions of Hull."

The compliment paid to the officials was well merited, for the Committee is composed of strong men who work zealously, harmoniously, and successfully. Everything was ready for the Judges at ten o'clock, and about 2 P.M. each was presented with a copy of the programme and awards neatly bound, with his name inscribed in gilt letters; and no doubt Messrs. G. Gordon, E. Molyneux, and J. Wright will preserve the copies as pleasant mementoes of a pleasant gathering, and as examples of what can be done by prompt action on well-considered lines.

It is only the record of a simple truth to say that the Hull directorate stand right in the forefront as expert managers of Chrysanthemum shows, and thus set an example that might with advantage be followed by several societies in the kingdom. Lateness in commencing the work of judging necessarily involves too rapid action, and this is the cause of more mistakes and disputations than everything else put together. At the Show in question not a hitch occurred, and even the losers of prizes were satisfied, well and worthily as they competed. With true Yorkshire persistency they intend, if possible, being in the charmed circle next time, and it will be no easy task to keep some of them out of it.

*Groups.*—The judging commenced with the groups arranged in semi-circles, occupying a space of 100 square feet. The first prize was a challenge cup, value 20 guineas, presented by a generous Vice-Chairman of the Society, George Bohn, Esq., with £6 added, the remaining prizes being £5, £4, and £2 respectively. The competition was splendid, three out of the five groups being of superlative quality. Foliage plants are admissible with the Chrysanthemums, and contribute materially to the beauty of the arrangements. Last year Mr. Geo. Wilson, gardener to James Reekitt, Esq., Swanland Manor, Brough, made a departure from the formal method of association, and easily won the first prize with a picturesque arrangement. No doubt thinking his idea would be followed, he struck out another this year, and won again, against strong opposing collections. He has only to win once more to retain the trophy, and he will have to do his best to succeed. His method of arrangement consisted in a steeply arranged background of Chrysanthemums, ranging from 7 feet in height down to about 18 inches, leaving a space from the latter of nearly 3 feet to the margin of the group. This was occupied with tall single-stemmed Crotons at wide intervals, so that their full beauty was displayed. Bright Dracaenas were also tastefully employed, and a groundwork of procumbent foliage plants, with a few very dwarf Chrysanthemums in moss. The tall Chrysanthemums were remarkable for rich foliage and magnificent blooms, and the interspersed of Palms and Eulalias was in the best of taste. There was a total absence of crowding, and the whole group represented a masterpiece in the artistic association of plants and flowers. Mr. G. Cottam, jun., Alma Gardens, Cottingham, was, after much consideration, adjudged the second prize. It was what may be termed a twin group, the recess which extended back nearly to the wall being furnished with low foliage plants and very dwarf Chrysanthemums, the margin being neat, and well finished with Isolepis and Panicums. Mr. E. Wright, gardener to D. Wilson, Esq., was an extremely close third. His plants were arranged in a less broken and more formal style, but with great taste and they were of superb quality. It was the best group of its kind seen at Hull, and in its way would be difficult to excel. Mr. G. Coates, gardener to W. Wheatley, Esq., Anlaby Road, Hull, was the remaining prizewinner, and well deserved the position he won.

Now that groups of plants are under notice a charming contribution of Orchids and Poinsettias mainly, by David Wilson, Esq., may be appropriately referred to. The Cyripediums were of rare excellence, while valuable Cattleyas, Oncidium, and Odontoglossums lent richness to the display, Calanthes contributing elegance, Poinsettias brilliancy; the whole being displayed to the best advantage by the relief afforded by Isolepis and Ferns. This group was a great centre of attraction in the hall, and having regard to the high quality of the plants, and their effective arrangement by Mr. E. Wright, the Judges felt they could do no less than recommend the award of a silver medal.

*Specimen Plants.*—At the first Hull Show the plants exhibited were perhaps the worst prizewinners in the kingdom, but the trained incurved that win prizes there now certainly rank amongst the best that are seen anywhere. Mr. J. S. Graham, gardener to G. Lawson, Esq., Newland Grove, was the first prizewinner in all the classes, and his plants were superb. Besides the money prizes he won three medals and deserved them all. Mr. J. Hemming, gardener to E. Leatham, Esq., was the next most successful competitor; Mr. W. Mason, gardener to Major Dibbe following. Very fine bush-grown plants were shown, in one class the prizes falling to Mr. Thomas Smith, Beverley, Mr. Hemming and Mr. H. Taylor in the order named; in another class, Messrs. A. Clarke, R. Falconer Jameson, and H. Harland occupying the same relative positions. For cut-back plants, the first prize, including the N.C.S. medal, was well won by Mr. J. P. Leadbetter, gardener to A. Wilson, Esq.,

Tranby Croft. The remaining plants must be passed or there will be no space to refer to the next important section of the Show.

*Cut Blooms.*—These were handsomely provided for in the twenty-five classes set apart for them, and a splendid display was the result. This year a change was made in the composition of the classes, but it did not increase the competition. Previously the principal class was for incurved and Japanese varieties combined, but this year first prizes of £10 were offered in each section. For twenty-four blooms, the incurved were to be in not less than eighteen varieties, and not more than two blooms of one variety; in the Japanese section all were to be distinct. In the incurved class five competed, the winner of the first prize being Mr. H. Shoesmith, gardener to M. Hodgson, Esq., Shirley Cottage, Croydon, by the narrow majority of two and a half points. The blooms were not extra large, but solid, fresh, and well staged. The varieties were Golden Queen of England (2), Mrs. S. Coleman (2), Golden Empress of India (2), Lord Alcester (2), Queen of England, Miss M. Haggas (2), Alfred Salter, Princess of Wales (2), Jeanne d'Are, Empress of India, Lady Dorothy, Barbara, Princess Teck, Mrs. N. Davis, John Salter, Hero of Stoke Newington, Mrs. Shipman, and Princess Beatrice. Mr. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derby, was second with larger blooms, but not so solid nor so well staged. Mr. J. P. Leadbetter, gardener to A. Wilson, Esq., Tranby Croft, Hull, was a close third. In the Japanese class five competed, the best coming from Mr. G. Wilson, gardener to James Reekitt, Esq., large, solid, fresh blooms, staged in capital style, the stands being a trifle larger than the ordinary size, which added to the appearance of the blooms. The names were Vivian Morel, M. Bernard, Boule d'Or, Criterion, Stanstead White, W. W. Colcs, Puritan, Mrs. C. Wheeler, Etoile de Lyon, Mrs. F. Jameson, Sunflower, Mdme. C. Audiguier, W. H. Lincoln, Avalanche, Edwin Molyneux, Golden Dragon, Meg Merrilies, M. J. M. Pigny, Mdme. Laing, Sarah Owen, J. Délaux, G. Atkinson, Mdme. Baco, and Coronet. Mr. Shoesmith was a close second; and Mr. E. Wright, gardener to D. Wilson, Esq., a good third.

For twelve incurved, distinct, four competed, Mr. F. Thornton, gardener to C. E. Marfleet, Esq., Boothby Hall, Lincoln, was a somewhat easy first with well staged blooms of Alfred Salter, Lord Wolseley, Lord Alcester, Prince Alfred, Golden Empress, Miss M. A. Haggas, Cherub, Jardin des Plantes, Golden Beverley, John Salter, Nil Desperandum, and Mr. Brunlees. Mr. Shoesmith was second, and Mr. Leadbetter third. For twelve Japanese, distinct, Mr. F. Thornton was placed first with a capital stand of blooms of the following varieties:—Condor, M. Bernard, Ralph Brocklebank, Etoile de Lyon, Sunflower, Avalanche, Madame Baco, Sarah Owen, Madame J. Laing, J. Délaux, Criterion, and Mdme. Lacroix. Second, Mr. G. Wilson. Third, Mr. Shoesmith. Class 5 was for twelve blooms, Japanese, to be staged with not less than 8 inches of stem above the stands, and with foliage as grown. The seven competitors made a capital display. Mr. G. Wilson was an easy first, the blooms being large, of good form, the foliage excellent, and staging neat. Mr. E. Wright was second, and Mr. Leadbetter third. An interesting display was made by the five competitors in the class for twelve blooms of any white variety, but not more than three blooms of one variety. Mr. G. Appleton, gardener to C. H. Johnson, Esq., The Hall, Thorngumbald, Hull, received the premier award for the following in good order:—Fair Maid of Guernsey, Stanstead White, Avalanche, M. J. M. Pigny, Mdme. Lacroix, and Bouquet de Dame. Second, Mr. W. Welton, gardener to G. A. Carr, Esq., Waltham Grove, Grimsby. Third, Mr. Goodacre.

Anemone-flowered varieties were staged by eleven competitors, the bulk of them in first-rate condition. Mr. G. E. Smith, Floral Cottage, Paull, was first, the following being the principal varieties:—Lady Margaret, Margaret Solleville, Gladys Spaulding, Acquisition, Sabine, Madame Robert Owen, La Marguerite, Gluck, and J. Thorpe, jun. Second, Mr. R. Walker, gardener to Colonel Stacey Clitheroe, Hotham Hall, Brough. Third, Mr. F. Mason, gardener to G. Bohn, Esq., Tranby Park, Hessle. A special certificate was awarded to the first prize stand, so good were they in point of quality. Reflexed varieties were well shown, eight competed. Mr. G. Appleton was first (also granted a certificate) with Cloth of Gold, King of Crimson, Felicity, Cullingfordi, Irene, Zelia, Peach Christine, James Carter, Golden Christine, and Mrs. Forsythe. Mr. G. E. Smith second; and Mr. Robert Dalby, gardener to A. B. Beckett, Esq., Westwood, Beverley, third. Class 9 was devoted to varieties possessing the most scent. Mr. H. Harland was first, Mr. A. W. Stanley second, and Mr. R. Walker third. Pompons were fairly well shown. The best twelve bunches with foliage, in not less than six varieties, were contributed by Mr. G. E. Smith; second, Mr. J. Hemming. Single varieties were moderately well staged. Mr. G. E. Smith had the best stand; Mr. H. Harland closely following.

The following classes were open to those not competing in previous classes. For twelve incurved, distinct, there were six entries. Mr. G. Appleton was a good first; Mr. W. H. Clark, gardener to Lieut.-Col. James Reed, Westland Corner, Bargate, Grimsby, second; and Mr. W. Welton third. For twelve incurved, in not less than nine varieties, Mr. J. Appleton won the first place with medium sized blooms. Mr. R. Walker second; Mr. Weldon third. In the class for twelve Japanese, distinct, Mr. G. Appleton was easily first; Mr. G. B. Burrows, gardener to Sir H. Bennett, Westlands, Grimsby, second; and Mr. R. Walker third. For twelve blooms, Japanese, in not less than nine varieties, Mr. G. Appleton succeeded in taking the premier award. Mr. J. Bridle, gardener to R. F. Jameson, Esq., Hessle, Hull, second. Amateurs staged a wonderfully fine lot of blooms in the classes set apart for them.

The prize for the best incurved bloom in the Show was won by Mr. R. Falconer Jameson with a firm symmetrical example of Lord

Alcester; the best Japanese being W. W. Coles, but we have no record of the name of the exhibitor.

*Ladies' classes.*—A piece of challenge plate was offered, in addition to the first prize of £4 4s., for a dessert table 8 feet by 4 feet, laid out for six persons with Chrysanthemums and any kind of foliage; six competed. Miss Lily Wheatley, 7, Milton Terrace, Anlaby Road, Hull, was adjudged premier honours for a table harmoniously arranged; Miss Muriel Ayre, The Cottage, Hessle, second; Mr. Frank W. Jameson, Runswick House, Prince's Avenue, Hull, third. Miss Lily Wheatley was the most successful exhibitor of a hand bouquet of Chrysanthemums with a pleasing arrangement; Miss Elsie Todd, Tranby Park, Hessle, following. Miss P. Munby, Spring Villa, Anlaby, Hull, had the best arranged dress spray, and Miss E. M. Harland the most tasteful arrangement of cut blooms of Chrysanthemums.

The N.C.S. silver medal was offered, along with £3, as first prize for a table 12 feet by 3 feet of bouquets, wreaths, sprays, and buttonholes, or other floral arrangements with Chrysanthemums and any kind of foliage or grasses; seven entered, making a magnificent display. Messrs. Perkins & Sons, Coventry, easily secured the leading position with one of their best exhibits; Mr. C. Colebrook, Royal Nurseries, Grimsby, second; Mr. G. Cottam, jun., Alma Gardens, Cottingham, third.

We learn that the total number of cut blooms staged at the Show was 2311; the total number of visitors over 10,000, including 737 charity children with their teachers, admitted free on the invitation of the Committee. The receipts at the doors slightly exceeded those of last year.

A meeting was held on the evening of the first day of the Show, Mr. J. Wright presiding. Mr. E. Molyneux read a practical and pithy paper on growing and showing Chrysanthemums, which was highly appreciated. The attendance was very large, the discussion instructive, and the gathering a distinct success.

#### GRASSENDALE AND AIGBURTH.

THE second Exhibition in connection with this newly formed Society was held on Saturday last in the Grassendale Parish Room. This is the first year of the Society's existence, but from the persevering way in which the President, A. L. Jones, Esq., and the Committee are working, it will be hard to say to what dimensions it may assume in the future, as funds are readily forthcoming.

The schedule contained twenty-nine classes, fourteen for plants, six for cut blooms, and nine for fruit. The plants were arranged round the room, and the fruit on a table in the centre of the room. Chrysanthemums in pots were only moderately shown, the first for three being taken by Mr. J. Madeley, gardener to W. C. Atkinson, Esq.; Mr. J. Lowndes, gardener to S. S. Parker, Esq., Aigburth, second; and Mr. J. Bounds, gardener to A. L. Jones, Esq., Oaklands, Aigburth, third. For a single plant Mr. J. Lowndes was first with Val d'Andorre. There were sixteen entries for cut blooms, which were scarcely up to the standard. For twelve incurved and twelve Japanese, Mr. J. Agnew, gardener to Mrs. Watts, was first, the best being Japanese Etoile de Lyon, Stanstead White, Avalanche, Sarah Owen, and Sunflower, whilst of the incurved the Queen family were the best. Mr. J. Lowndes was second, but the flowers were not staged satisfactorily.

In other classes the prizetakers were Messrs. J. Bounds; Jenkins, gardener to E. Tinne, Esq.; Peers, gardener to C. E. Terry, Esq.; Kelly, gardener to R. Singlehurst, Esq.; J. Harrison, gardener to Mrs. W. G. Bateson, Allerton; C. Evans, gardener to W. Maxwell, Esq.; J. Lowndes, and W. G. Davey.

Grapes were of very fair quality; Mr. Kelly first, Mr. W. G. Davey second, Mr. J. Bounds third, all staging Alicante in the class for black, and Mr. J. Bounds and Mr. W. G. Davey in the white with Museat of Alexandria. Mr. J. Lowndes was first for four dishes of Pears with Beurré Diel, Beurré Clairgeau, Pitmaston, and Marie Louise. Second Mr. J. Kelly, the latter being first for a dish of stewing Pears and Mr. W. G. Davey for dessert; Mr. Davey winning for one dish of dessert. In other classes the prizes went to Messrs. Lowndes, J. Bounds, Kelly, J. Agnew, and W. G. Davey. Messrs. R. P. Ker & Son were highly commended for a group of plants, as was also Mr. J. Bounds. Extra prizes were given to Mr. J. Bounds and Mr. J. Lowndes for groups of Chrysanthemums, &c., and Mr. J. Kelly for Cyclamens. The President, A. L. Jones, Esq., has signified his intention of presenting a silver cup, value 10 guineas, for cut blooms next season, when the entries will no doubt be considerably increased.

#### SUTTON COLDFIELD.

THE Royal old town of Sutton Coldfield has a history of its own, it having been a long number of years ago a residence of one or more of our earlier monarchs, and the centre of their hunting ground, for in the very extensive forest in those days the wild boar and other objects of the hunter's regard were to be found.

Sutton Park, with its fine woods and host of British plants, is now a great resort for the Birmingham people, and its 800 acres is now under the care of Mr. Morewood, who was formerly the head gardener at Canwood, a fine old place near to Sutton Coldfield, which is but a few miles run from Birmingham. A gardeners' Association exists here, an offshoot from the Birmingham parent Society, and it holds its annual Chrysanthemum Exhibition in the Town Hall. This year the Show was very attractive with some admirable groups, plants, and flowers.

In the class for larger groups three lots were staged, the first prize being well won by Mr. E. Pears, gardener to Mrs. Jerome, with a really superb group of well-grown and well-flowered plants, in which the colours were artistically arranged in small groups. The second and third prize groups were fine also. Smaller groups with foliage plants were staged in another class, and made an attractive display.

Plants in pots, of which there was a good assortment, were all "cut-backs" trained upright, and not at all formally; some were quite 3 feet through, admirably grown, dwarf, and well flowered. They were much preferred to the old system of tying the plants down closely into a formal shape. Mr. Henry Warren, gardener to G. H. Lloyd, Esq., Sutton, was first, and Mrs. Jerome second, both lots being exceptionally good. In the class for twenty-four cut blooms, twelve incurved and twelve Japanese, Mr. J. Padbury, gardener to F. Cooke, Esq., was first; Mr. Jeff, gardener to H. E. Yates, Esq., second; and Mr. Phillips, gardener to the Right Rev. Bishop Ilesley, third. The other classes for cut blooms were also well filled. Mr. Yates's first prize twelve *Primula*s were the finest ever seen at the Sutton Shows, well-grown plants of the Birmingham varieties. A. W. Wills, Esq., J.P., sent a collection of plants, including good specimens of *Cypripedium Spicerianum* and *Oncidium prætextum*, some excellent specimen *Eucharis*, a fine *Anthurium crystallinum*, and a stand of fine *Chrysanthemum* blooms. Mr. T. B. Grove, nurseryman, also sent an excellent group of plants, filling the stage across the hall.

WE again find it impossible to publish the whole of the reports of *Chrysanthemum* shows which have been obligingly sent, and two or three which arrived late must be held over till next week.

#### FRUIT FORCING.

**FIGS.—Earliest Trees in Pots.**—To have ripe fruit at the end of April or early in May the trees must be started early in December; therefore dress them with an insecticide, applying it with a brush to every part, care being taken not to rub off the immature fruits, nor damage the points of the shoots. The trees should be placed on loose brickwork pillars, so that they may not settle with the fermenting material, which being placed in the pit and brought up about the pots will afford a genial warmth, but the heat about the pots must not exceed 65° until the trees are fairly in growth. The top heat may be 50° to 55° at night, and 65° by day, the trees and house being damped in the morning of fine days, and again early in the afternoon, but it must be done sufficiently early to allow of the trees to become fairly dry before night. Water must be given at the roots to keep the soil thoroughly moist and about the same temperature as that of the heat about the pots. Avoid a very close moist atmosphere, the moisture arising from the fermenting material, with an occasional damping of available surfaces, as paths, &c., will be sufficient on dull days.

**PINES.—Successional Plants.**—Span or three-quarter span-roofed pits or small houses properly ventilated are the most suitable for small stock, which at this season often suffer irreparable injury from being kept too close and warm, the plants being drawn and weakly. A temperature of 60° at night and 65° in the daytime will keep all young stock gently progressing, admitting a little air at 65° at the top of the house leaving it on all day, but not to lower the temperature below that point, and when the sun raises the temperature to 75° a free circulation of air should be allowed. The bottom heat should be kept steady at 80°. Avoid anything approaching to a damp atmosphere, moderate humidity only is needed at this time of year. Apply water only when the plants become dry, and then afford a thorough supply of weak liquid manure. It is essential that the plants be kept well up to the glass and be given plenty of room.

**Suckers.**—Those ready for starting now should be kept until March, and if there is likely to be a scarcity of suckers any recently potted may be retained in 5-inch pots, affording them a light position in a rather moist pit, with a temperature of 55° at night and a slight bottom heat, keeping them rather dry. Take every opportunity of collecting leaves whilst dry, Oak and Beech being the best, and whenever a favourable opportunity offers push forward whatever may be necessary in the renewing or augmenting the fermenting beds, effecting this without giving a check to the plants.

**CUCUMBERS.**—Winter fruiting Cucumbers are frequent failures, and due to a deficiency of heating surface combined with an arid atmosphere. Sharp weather necessitates brisk firing, which, where there is little piping, dries the atmosphere, causing excessive evaporation from the foliage, and it becomes crippled in consequence; the fruits also are stunted and swell indifferently, and where the pipes are in close proximity to the roots the soil is dried too much, and the growth is consequently not healthy. Heat radiated at a high temperature is not good for vegetation, and when the water in the pipes has to be kept near boiling point failure is almost inevitable, besides it is highly wasteful of fuel. Admit air very carefully, yet afford a little whenever a favourable opportunity offers, excluding it, however, when the external air is sharp and cold, turning off top heat when the sun is very bright and likely to raise the temperature much over 80°. In bright weather damp the house morning and afternoon, closing early, but be careful not to wet the embryo fruit, for water hanging from it will cause decay. Water will be needed at the roots about twice a week, always affording it equal in

temperature to that of the bed. Maintain a night temperature of 60° to 65°, 5° less on cold nights, and 70° to 75° by day, advancing 5°, 10°, or 15° from sun heat, and endeavour to enclose as much sun heat as safe.

The plants from the August sowing planted out in September have covered the trellis and are fruiting, but this must be allowed very moderately if the plants are expected to afford full supplies at a later period, and unless there is undue vigour in the plants they should not be allowed to fruit for a few weeks, especially if they are wanted to supply fruit plentifully at the new year and forward. Attend frequently to stopping and thinning, also tying the shoots, avoiding overcrowding, as stout foliage better endures the trying ordeal of wintry weather. Canker is best held in check by lessened moisture and quicklime rubbed well into the affected parts. Removing old useless leaves is good for the plants, and may keep off attacks of red spider; but if that pest appears sponge the infested leaves carefully with a solution of soft soap, 2 ozs. to the gallon of water.

Mildew may be kept under by dusting the infested parts with flowers of sulphur, or brushing the pipes with sulphur brought to the consistency of cream with skim milk. Bisulphide of calcium and sulphide of potassium, half ounce to a gallon of water, destroys mildew, but has the disadvantage of discolouring the paint and causing a disagreeable smell. Carbonate of copper, 1 oz. to 12½ gallons of water, destroys mildew and other fungi, using it as a spray only, and keeping agitated whilst being applied. Aphides succumb to fumigation with tobacco, but the smoke must be cool and the fumigation repeated two or three times on consecutive evenings.

**Strawberries in Pots.**—A start must be made early in next month to have fruit ripe early in March. La Grosse Sucrée has been our standard early forcing variety for many years, but John Ruskin promises to lead in the matter of early forcing, and it is recommended for trial. Vicomtesse Hericart de Thury usually shows and sets abundance of fruits, and these, if well thinned, attain a good size. Princess Frederick William has almost disappeared from cultivation, from not being satisfactory outside; but for early forcing it has done excellent service, being a capital cropper, bright in colour, and with a pleasing aroma. Noble and Auguste Nicaise have fine looking fruits, and brought on slowly may be started with the preceding varieties, assigning them positions on shelves in Peach houses. The others to fruit at the time mentioned will need forwarding in a Strawberry house. The plants to be introduced to the Strawberry house, vinery, or Peach house should have the drainage seen to, rectifying it if defective, making sure that it is free, removing the loose surface soil, and supplying a top-dressing of horse droppings rubbed through a half-inch sieve, adding a good handful of steamed bonemeal to every peck, then watering it with a rose watering-pot, so as to bring into a moist state, and consolidate the material, otherwise it washes off in watering the plants. Pots may then be placed in position after removing the decayed leaves only, taking care to keep the soil moist, for dry soil causes the loss of roots; therefore rap the pots, and if any ring dry—a practised hand readily detecting by the sound which plants are needing water—afford a thorough supply.

#### THE KITCHEN GARDEN.

**SEAKALE.**—This again is in great demand during December and throughout the rest of the winter and spring months. Strong young roots ought always to be bought in, or, better still, prepared for lifting, the preference in all cases being given to the improved variety known as the Lily White, this having no purple tips, being also the most mildly flavoured. Mushroom houses are of the greatest service in forwarding and blanching Seakale; but at this early date progress is slow, high temperatures not being maintained, as these are most injurious to the Mushroom beds. They ought, therefore, to be depended upon for producing successional crops, only one or more scores of roots, according to the resources or demands of the place, being bedded in thickly in rich soil and kept moist, warm, and dark. In order to have Seakale more quickly lift a number of straight young roots, lightly shortening the coarsest thongs, and then pack them thickly in large flower pots, the crowns only just peeping through the surface of the soil, and which ought to be somewhat moist and rich that is used. Two or more of these pots may be set at a time either on or close up to hot-water pipes in a forcing house, inverting other large pots over them and closely stopping drainage holes and crevices with moss so as to effectually exclude the light. When the soil is getting somewhat dry moisten with warm water, or, better still, liquid manure, and thus well treated, all the crowns may be cut over twice, a good and early return for the trouble taken. Strong roots grouped for covering with pots or boxes where they now are and forced by means of a well-prepared hotbed of manure and leaves placed over them, move very slowly at this early date, but they usually produce extra fine and very succulent well-blanching growths. Such heaps of heating material, enough being got together to cover several pots at one time, must be watched very closely, being liable to get quite cold in cold windy weather, and to become dangerously hot in warm muggy weather.

**RHUBARB.**—Mushroom houses and warm cellars are very handy for forcing Rhubarb, but it can be brought on more rapidly in confined chambers or near to hot-water pipes in forcing houses. Lift large clumps of early varieties, and surround these with good moist soil, the latter precaution being most necessary where a dry heat is kept up and least needed in cellars. Extra fine stalks are more surely if more slowly obtained by forcing the clumps where they now are. Cover with inverted cement or flour tubs, substituting lids for the ordinary bottoms, and mound up several of these at a time with heating material, taking away from or adding to this according to the rise and fall of the heat.

## PLANT HOUSES.

*The Forcing House.*—Where large quantities of plants are forced into flower it is necessary to devote a structure for this purpose. Where practicable select one in which a hotbed of litter and leaves can be made, for the gentle moist heat that rises from these materials are beneficial to the plants, and bring them forward rapidly into bloom. The materials for this purpose should be composed of about equal quantities of leaves—Oak or Beech are best—and litter, the former to be perfectly dry. They may be mixed together outside and thrown into a heap, so that if wet weather follows it will not penetrate any depth into the material. If turned two or three times while outside it will soon be in condition after it is placed in the house for standing plants upon. Be careful, however, not to stand upon it plants that might be injured while strong ammonia is being thrown off. When the bed is ready the house may be filled with the plants required. Employ no fire heat at first until the plants are starting, when the temperature may be gradually increased.

*Azaleas.*—A few plants of early flowering varieties may be introduced into the forcing house as soon as it is ready for them. Do not plunge the pots of these plants, but merely stand them on the top of the fermenting material. Syringe lightly with tepid water each morning when fine.

*Lilacs* that have lost their leaves and have been exposed to light frost may be plunged into the fermenting material. These plants will bear brisk heat. If the plants have been confined in pots, and are well ripened, they will be ready for starting by the time the forcing house is ready for them. Lift *Rhododendron præcox*, *Early Gem*, early-flowering hybrids, *Ghent* and *mollis* *Azaleas*. Until the house is ready leave them outside, and if they are exposed to a few good frosts in the meantime they will start all the better.

*Lily of the Valley.*—The earliest single crowns may be started now. Plunge the pans or boxes in brisk bottom heat, and cover the crowns with about 1 inch of cocoa-nut fibre refuse. Those for succession may be placed amongst leaf mould, cocoa-nut fibre or light soil in pans, boxes or pots, and left outside until they are wanted.

*Dutch Hyacinths.*—Early varieties that are green, and display signs of growing, may be stood on the surface of the fermenting material until they are growing freely, when they can be arranged 10 inches or 1 foot from the glass. After these plants start growing they come forward rapidly in the moist heat of the forcing house. For this purpose *Homerus* and *La Tour d'Auvergne* are most suitable.

*Tulips.*—White *Pottebakker* and *Scarlet Duc Van Thol* in pans and boxes must be ready for pushing forward into bloom. These will bear more heat than *Hyacinths* in their early stages. Neither these nor *Hyacinths* can endure dry atmospheric conditions, and if the boxes are stood on the fermenting material they will soon display signs of growth, and are not long before they come into flower. Good supplies of these before the close of next month will be found invaluable. Few flowers are more effective for dinner table decorations towards the close of the year than *scarlet Tulips* arranged in small vases with their own foliage and a little wood moss between to keep them in their proper position.

*Dielytra spectabilis.*—Lift quantities of these and place the roots in 5 to 7-inch pots, leaving them outside for a few weeks. When lifting all weak crowns should be reserved for planting again. Those that were forced last season and laid in may be divided and planted for another year in rows 15 inches apart; bury the crowns about 1 inch below the surface.

*Gladiolus The Bride.*—These are very useful in 5 and 6-inch pots. Good supplies must be potted without delay. Drain the pots liberally, and place the roots as thickly as possible in the pots, covering with 1 inch of soil. After potting plunge them in ashes outside until they start into growth. Those that flowered early this season will have started into growth, and may be removed from the plunging material to a frame. Keep them shaded until their growth is green, when they may occupy a position in the greenhouse. These plants do well in sandy loam and one-seventh of decayed manure.

*Epiphyllums.*—These are showing their flower buds freely, and will soon come into flower if arranged in an intermediate temperature. In no position, perhaps, do they look so well as amongst *Adiantums*, and well elevated above them. Be careful to allow them a sufficient supply of water at their roots, it is a great mistake to keep them dry. Place young stock that has only been worked a few months in a temperature of 50°. Established plants that are not needed in flower may be kept perfectly cool.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### WINTER WORK—WAX RENDERING.

To a great many bee-keepers this is a source of great annoyance, and the difficulty of extracting it thoroughly from the combs; also it sometimes forms into granules, and will not become solid. This last state I have never been quite able to understand, but I believe certain kinds of pollen is a cause, as is also the water when in a state favourable to granulation. Pouring the wax while hot

into cold water produces it. Lime and other alkaline substance destroys the compactness of wax. Rain water that has not been in contact with these substances should be used in all cases of rendering wax.

Exposure to the sun and air is the best and safest method of bleaching wax to white. The purity and clearness of wax is best effected by melting it in a double-sided vessel, glue-pot fashion, and keeping it a long time in a liquid state undisturbed, so as to allow all sediment to fall to the bottom.

Nitric acid in early times was much used to purify or bleach wax, and is preferable to sulphuric acid more recently used in bleaching wax. I cannot recommend either, further than if the vessel for melting wax is iron, it might be cleaned beforehand with dilute sulphuric acid, iron having a tendency to darken wax.

Tin or copper vessels are the best for that purpose. The most satisfactory method of extracting wax.—Put the combs into bags of open texture, such as the best scrim or of cheesecloth; tie them single knot, and put one or more into the sieve of tinned wire cloth or one of wicker work, so that no part of the bag touches the outer boiler, which the sieves must also clear. Care must be taken that the wax does not boil over, for, in addition to loss, it is very inflammable. When boiling, press the bag gently to help force out the wax, and when seen on the top either skim or let it off by a spout about 4 inches or so from the top of the outer vessel. When this is done, draw the bag and place it in a sieve or form under the press, which will press out all the wax. Meanwhile, as the hot bag is lifted from the boiler, replace it with another bag of combs.

The above process answers either for a large or small quantity of combs, and as the boiler is never much below boiling it is a continuous, speedy, and cleanly method of extracting wax, as combs become infested with acari soon after being taken from the hive which consume the wax. Neither these nor moths should be allowed to harbour amongst them, but melt at once.

The sieve should be of a fair size, not less than 12 by 12, which necessitates the boiler to be about 14 or more inches wide by 16 or more deep, which is also used to hive bees. Either near the ground or attached to the telescopic pole when the bees ascend to trees I have used such an arrangement for many years. I sometimes use a light lid so that it may be closed when the bees are shaken into it, so that it does not kill them. If the day is very warm a light piece of cloth may envelope the hiver. When practicable I prefer to hive the bees at once into their permanent hive, but this sometimes cannot be done; full sheets of foundation prevent inversion or rough handling of the hive, and flighty queens forbid shaking in front or top of hive. To obviate all this, and reduce labour to a minimum, I use a bag the same size as the sieve; the wax bag will do, but it is well the material be light. This bag is fastened to the bottom rim or mouth end of the sieve, and the bag is drawn taut to the close end, and fastened several places, so that the bag is kept distended the full size of the sieve. When the bees are secured in the sieve carry it to the hive to be tenanted, which ought to have a cross (made with two pieces of wood, a little less in size inside measure than the sieve) upon the top of the hive. Now place the sieve upon the hive over the cross, and unloose the fastenings. The bees will, as the cloth presses upon them, retreat to their permanent hive below without any fuss or risk whatever.

It will be observed that when round sieves are used the bees if they choose could escape at the angles, the openings there should be closed. Or to obviate all trouble have square tin sieves and hivers, which latter may be of wood. The inner bag in this case should have a stiffish wire or wooden rim to keep the bag distended, and dools of wood or iron will keep it in its place.

There are other things to prepare, but think the foregoing sufficient for the time being for bee-keepers to study and get ready in time before the vernal sun reveals the charms of the apiary and garden.—A LANARKSHIRE BEE-KEEPER.

## TRADE CATALOGUES RECEIVED.

Hogg & Wood, Coldstream and Duns, Scotland.—*Catalogue of Nursery Stock, 1891-92.*

Harlan P. Kelsey, Linville, North Carolina, U.S.A.—*Catalogue of Trees, Shrubs, and Herbaceous Plants.*

Thomas. Rivers & Son, Sawbridgeworth.—*Fruit Trees, 1892-93.*

George Phippen, Reading, Berks.—*Carnations, and How to Grow Them.*

James Walters, Exeter.—*Catalogue of Roses.*

Lévêque et Fils, Ivry-sur-Seine, near Paris.—*Roses and Other Plants.*

James Carter, Dunnett & Beale, 237 and 238, High Holborn, London.—*Illustrated Wholesale List of Novelties for 1892.*

"Lambert's," 12, Dover Street, Borough, London.—*List of Novelties.*

W. Cooper, 751, Old Kent Road, London, S.E.—*Illustrated Price List of Conservatories, &c.*

\* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Stands for Chrysanthemum Blooms (H. O.).**—Thanks for your letter; the height should be 3 inches in front, as you suggest.

**Double Lilac Primrose (S. D.).**—Yes, there is a double variety of *P. acaulis*, which is quite hardy, and can be had from any dealer in hardy plants.

**Papers on Peaches (G. N.).**—The numbers you require are not in stock, but several other good papers have appeared since then, to which we can refer you if desired.

**Name of Chrysanthemum (Amateur).**—We have no record of the bloom to which you refer, but if you write to Messrs. Perkins & Son, they will, no doubt, supply the name readily.

**Christmas Roses (G. Twyford).**—They are very good. A letter has been posted to you. If the address you gave is insufficient inquire at the post office.

**Gloucester Show (G. Tidman).**—If you will point out the precise inaccuracies in the report, and supply the necessary corrections, they shall be inserted if your letter reaches us not later than Tuesday morning next.

**Roman Hyacinths (T. F.).**—The Hyacinth bulbs are sound and good and the roots healthy. You should have described briefly your method of culture, and the position in which you grow the plants that fail. We suspect that those you have sent will flower satisfactorily with us.

**Species of Fruit (W. Gale).**—The class in the schedule is thus worded: "Collection of fruit, six species, distinct." You showed Grapes, Plums, Pears, Apples, Currants, and a Melon, and was therefore within the terms of the schedule. Another competitor showed two varieties of Grapes and two of Pears in his collection of six dishes, thereby placing himself outside the prescribed terms, and he ought to have been disqualified by the judges, no matter how good his fruit might be.

**Sport from Cullingford Chrysanthemum (J. T. Ebbutt).**—Yours is not the first sport of this nature; but whether it is the best or not we cannot tell, as unfortunately half the florets fell out of the most incurved example on removing the bloom from the box. It is worth preserving with the object of determining its true character by the methods adopted by leading exhibitors. The chief defect at present is bristliness of the florets, as is often seen in Jeanne d'Arc. Try it again, and send younger blooms another year.

**Chrysanthemum Sport (G. Hawkins).**—The paler bloom, which we should have thought the younger, is very fine indeed. It is pearly white with a faint blush tint, with broad smooth florets, the bloom being full and deep. Several florets fell out of the more cream coloured bloom which you refer to as the younger, and many were withered. If the characters of the first-named were fixed and constant, the variety would be an acquisition; but the second detracts from the merits of the sport. Give it further trial.

**Gansel's Seckle Pear (B. D. K.).**—It so happened that Mr. Rivers called here the same day your letter and sketches arrived. He has no doubt the No. 2 Pear is Gansel's Seckle, of which he has fruits at the present time. He considers it inferior to the true Seckle. So do we. It was raised by Mr. Williams of Pitmaston by crossing the Seckle with Gansel's Bergamot. We should imagine the Seckle was raised from seed, not as a sport. Dana's Hovey is a delicious little American Pear of the same nature, but ripens about Christmas. If you like small rich Pears you should try it.

**Stocks for Medlars (J. W.).**—Seedling Medlars are sometimes used, the seeds being sown as soon as the fruit is ripe; they usually take two years to vegetate. The young plants must be tied to stakes, have the side growths pinched, and kept in an upright position to secure stems for grafting, or preferably budding at the right height. Medlars are also worked on Pear, Whitethorn, and Quince stocks. The Pear stock answers well for grafting or budding standard high, and has the advantage of succeeding in most soils. The Whitethorn is employed because it is readily obtained, and succeeds on sandy and dry soils. The Quince is considered the best when the Medlar has to be grown in moist situations, as it roots near the surface, and the trees are dwarfed and produce finer fruit. Seedling Medlars are the best stocks in good soils.

**Apricots (Inquirer).**—Oullins Early Peach and Powell's Late are two good Apricots, having the quality of Moor Park, but much hardier constitutions than that fine variety. Kaisha is also an excellent Apricot, much less in size than the preceding, yet when well thinned attains to a good size and is delicious in flavour. It is a most abundant bearer, and not so liable to gum as many varieties. The Pears cracking and spotting is no doubt due to the wet season, which has been favourable to the spread of the fungus, causing their disfigurement, one of the worst being Louise Bonne of Jersey. Try the remedies named in last week's Journal, page 421.

**Saddle Boiler Furnace not Drawing (J. B.).**—Either the setting is defective or surrounding objects cause a down draught. We presume you have an ash pit not less than 1 foot deep and the length of the furnace bars, and this enclosed on the two sides and far end so that air must pass through the bars or door opening to the furnace. Then the side flues should have their bottoms at two-thirds the height of the furnace, calculating from the furnace bars to the crown of the boiler. This will give the fire and smoke a jump from the furnace into the side flues, and if those are taken over the top of the saddle in one flue to the chimney, and all properly separated and constructed, it is difficult to see why the fire will not draw. Consult a bricklayer who understands boiler setting.

**Gypsum as Manure (G. H. H.).**—Gypsum as advertised for manure differs from the plaster of Paris used by builders in being purely ground or powdered sulphate of lime (gypsum), whilst plaster of Paris of the builders contains a small quantity of lime, causing the plaster, when moistened, to set into a hard marble-like substance, otherwise pure plaster of Paris and gypsum (ground) are identical. You cannot form gypsum by taking lime and sulphur and mixing them in the manner you describe; besides, sulphur is one of the worst possible substances to apply to the soil. Sulphur, combined with lime (hydrated calcic sulphate,  $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ ), is very different substance from the same components used separately. Procure the gypsum from the manure dealer or make sure that the plaster of Paris contains no "setting" substance.

**Heating Arrangements (J. B.).**—You may cut a piece out of the flow and another out of the return pipe, and fix a two-way branch on each where you propose, with a syphon at the end of the run of piping, where there must be a pipe or tap at the highest point of each syphon to let out the air, but it seems that you will have to heat the greenhouse at the same time as the house you wish to keep warmer, which is a bad arrangement, as the warmest part should be nearest the boiler, so that it could be heated without unnecessarily heating the greenhouse. It would be better to so arrange the pipes so that each house could be heated independently of the other, having valves on each for regulating the heat. This may, perhaps, be arranged in the manner you describe by heating direct from the boiler. You may get diminishing sockets from the horticultural builder who supplies the pipes if you describe what you require.

**Flowers and Seeds (J. W.).**—The essential parts of a flower are the stamens and pistil, and without these seed cannot be produced. The term "flower" includes both calyx and corolla, which are not essential to seed production, though they are present in a very large number of flowers, and serve both as protection to the more delicate essential organs, and as a means of attraction to insects. Seed, however, is often produced without calyx or corolla being present, and some might, therefore, erroneously think there was no flower. Some flowers, termed cleistogamous, also produce seed without expanding, as in some of the Viola family, and when these pods are observed it might be thought they had been produced without flowers. Without ovules to be fertilised by pollen, through the medium of stigma and style, or without their aid (as in the Conifer family), it is impossible to produce seed; therefore our decision is in favour of B.

**Guano for Asparagus (Francis).**—"Guano copperas," consisting mainly of porous sulphate ( $\text{FeSO}_4$ ), more or less ammoniated, is useful as a manure and may be used for Asparagus as a top-dressing. A small quantity is most beneficial, say half to 1 lb. per square rod, or quarter to half oz. per square yard. A large quantity is injurious. It should be applied early in spring, always when the ground is wet. Asparagus contains a large per-centage of iron, and succeeds best on siliceous soils, especially alluvial, which always contain iron. Iron sulphate is well known to increase the leafy or pulpy parts of plants, but it must be used discriminately, taking care not to give an overdose. "Ichthemic guano" is not so good as the nitrogenous guanos for Asparagus, yet valuable. Non-nitrogenous guanos, however, are more durable in effect, and may be used with advantage in soils deficient in lime.

**Packing Fruit (F. S., Buenos Ayres).**—There is always a market in England for choice garden produce of all kinds, especially at those seasons when it has not to compete with continental consignments and home-grown produce. "Very fine, first-class Pears in the months of March, April and May" are sure to realise good prices, provided the fruit

## LAVENDER FOR PROFIT.

I SHOULD like to give a few hints on the formation of plantations, as I have had considerable experience in this work. Where the situation and soil are of a suitable character many land-owners might do worse than turn some of their—at present—unprofitable land to account by growing Lavender. I am positive that a fair return may be realised by so doing. Where Lavender is cultivated with a view to distilling the flowers for the oil, the wet month of August was very detrimental to a good yield; the best weather is that which is hot and dry. Sold in a green state Lavender will pay £5 per acre for the first year's cutting, and often more can be realised. The fourth year's harvest sometimes realises £40 per acre, which cannot be considered a bad investment, and this sold in a green state, which dispenses with the trouble and cost of distilling.

Although Lavender plantations in some districts suffered to a great extent by the long and severe winter of last season, strange to say in a plantation established the year previous we did not lose a single plant. They look remarkably well, and yielded a good crop of flowers this season. No doubt the position favoured these plants somewhat. The ground slopes gently to the south, and is sheltered on the eastern side as well as the north. Although the land is retentive and heavy, it cannot be termed a wet soil; there are too many flint stones among the soil to admit of the water remaining long in it. The chalk lies fully 2 feet below the surface, and I think Lavender is as certain to succeed there as it is possible to do anywhere.

Some say that the soil must be poor to grow good Lavender. I do not think it is wise to have the soil rich at planting time, especially if cuttings are used instead of plants; but, like most other crops, a fairly luxuriant growth gives the best crop of spikes, and from these a better yield of oil is obtained than from small puny flowers, the result of poor, half-starved land. Soil of the character named, and which overlays chalk, is sure to be highly impregnated with this composition, rendering it quite of a calcareous nature, and the same plants will continue to bear freely much longer than where the subsoil is clay, and likely to be wet during the winter. Shelter from the east is most essential; the tender growth of the young shoots often receive a check in the spring by the prevalence of biting winds from that quarter.

In growing Lavender for profit the best variety must be secured. This is undoubtedly the English variety *spica*, or what is commonly known as the "Mitcham" kind, distinguishable from the French variety by its upright growth, larger flowers, which are deeper also in colour, as well as more numerous produced. The French kind is more spreading in its habit of growth, the leaves are larger, much more grey or "mealy" in appearance, fewer spikes are produced, these being considerably smaller in the flower heads, and less rich in oil producing, which is an absolute essential point to study in a commercial point of view. Intending planters ought to pay considerable attention to this phase of the undertaking, it being utterly useless to risk the planting of the inferior kind.

Propagation requires some consideration. Cuttings, or what is perhaps more correct, slips, are usually employed to increase the stock. I have tried both methods—cuttings and slips. Much the greater success is obtained by the latter. Pieces with three or four

growths attached are the best; these slipped off the plants by a sharp downward tug contain a small portion of old wood attached to the base, commonly called a heel. From this part roots are first formed. Some pull old plants in pieces, and with pruning shears or a small bill-hook sever the cuttings about 3 inches below the growth shoots from the main stems squarely across. In this case roots are first made from the sides of the cutting, not direct from the base, as in the case of the slips. The shoots formed at the top of the cuttings or slips are cut squarely across, which lays the foundation for a future bush growth. Opinions differ as to the best time for inserting the cuttings. I have tried the early part of October and also February; the greatest success has been obtained during the first named time, especially if the position is a sheltered one. The advantage of autumn propagation is, I think, considerable over spring, as so much more time is allowed for the plants to grow the first year, the sooner they make big bushes the better for their future success in producing a crop of flowers. Many of the Sutton and Mitcham growers of Lavender hold to February propagation, but I have noticed very long gaps in the rows the following summer, and have come to the conclusion that autumn inserted cuttings have an advantage.

The next question is, How shall the cuttings be inserted? The general practice is to dibble them in rows 1 foot apart, and the same distance from each other. The following October the plants are thinned, removing every other; the next year they will stand 3 feet apart, which is the usual distance for established plants. Where land is not of very great consequence and horse labour available the cuttings may be dibbled in rows 3 feet apart, the plants half that distance, the surplus cuttings required would be available for filling up any gaps which might occur in the rows. This plan saves the trouble of replanting from the beds into the permanent place, and does not entail any check upon the growth of the plants occasioned by removal. With the aid of a horse hoe a few acres of land is quickly cleaned, given suitable weather.

Where land is scarce, and labour for cleaning it also, I consider the best plan is to insert the cuttings in rows 1 foot apart, allowing but 4 inches between the cuttings, putting out the plants permanently at the end of September if the weather be showery. By this method less ground has to be kept clean and the risk in the permanent plantation is reduced to a minimum. The great point in getting the cuttings to strike and root freely is to make them thoroughly firm at the base, going over them a few times after severe frost, which raises them out of the ground somewhat, which is all against their making roots.

Directly 2 inches of new growth is made the point of each shoot should be pinched out with a view to induce side shoots to form, making a more compact and larger bush. If the shoots are topped twice the first year there will be a wonderful difference in plants so treated as compared with those which are not topped.

In preparing the ground for the plants it ought to be well worked, ploughing it 6 inches deep if possible, following with a subsoil plough in every trench, afterwards crossing the top spit to break up the clods. The better the land is worked and pulverised the greater will be the success the first and subsequent years. In the case of impoverished soil a dressing of farmyard manure should be ploughed in previous to putting out the plants from the cutting bed, but where they are dibbled direct into the land at the full distance I consider manuring the whole space is partly lost. In this latter case I prefer a dressing of dissolved bones or blood manure sprinkled about the plants early in April during showery weather, forking it in afterwards, repeating the application each succeeding spring. The ground should be kept well stirred about the plants, and free from weeds at all times; nothing effectually answers so well as a combined drag and horse hoe. While in the cutting bed the plants are not allowed to flower, but induced to make growth freely.

In some districts—wet ones—it is a good plan to slightly earth

up the plants with the plough on each side of the rows, which is again levelled down with the horse hoe in the spring.

The age at which the plants require renewing depends entirely upon circumstances. Sometimes they are the best at four years old; in some cases they will last ten years. Directly they show signs of decline they ought to be destroyed. If some cuttings are taken every year the supply will be maintained efficiently.

Harvesting is done when the flower heads are fully developed. A properly made Lavender hook is employed, which differs somewhat from an ordinary reaping hook by being narrower and more bent in the middle. An expert person will clear a whole plant with one sweep. The hook is employed to collect the flowers into a bundle in the centre of the plant, where they are held fast in the left hand, and severed from the plant with the right; the flowers are then in correct order for tying in bunches if sold in a green state, but for distilling they are laid straight on large mats of the ordinary Russian type.—E. MOLYNEUX.

## HARDY CLIMBING PLANTS FOR NORTHERN DISTRICTS.

(Continued from page 447.)

### JASMINES.

THE next climber to consider is the Jasmine. The white sweet-scented variety, *Jasminum officinale*, very commonly met with, is a beautiful climber when fairly well treated, but it requires annual attention in regulating its growth, as it is a rank and rapid grower. When, however, it has too much of its own way it makes a dense head of interlacing twining growths very difficult to liberate. The flowers on such plants are few and scattered, simply from the reason that the shoots have not had the chance of getting properly ripened; therefore regulate the main growths, and there will still be abundance of room for a free growth of a fair number of unrestricted lateral shoots which ought to bloom profusely. *Jasminum nudiflorum*, the winter Jasmine, bearing yellow flowers in January and February on the whole length of young shoots of the previous summer, is also a free grower, and well adapted for town gardens. The flowers are borne on the naked or leafless shoots, and therefore every flower is conspicuous. After the flowering period growth commences, and the foliage appears, covering a wall, trellis, or other support with verdure for the summer. Annually prune out the old wood, encouraging as much young wood as possible, and retain every shoot that happens to start from the base of a plant. These Jasmines are deciduous. *J. officinale* is a summer bloomer. Both varieties will grow in ordinary garden soil worked well and enriched liberally at the time of planting. Afterwards, when established, an occasional mulching of rotten manure may be placed over the roots in order to maintain the plants in a vigorous condition. Old established plants are benefited by good soakings of water or liquid manure.

### COTONEASTER MICROPHYLLA AND CRATEGUS PYRACANTHA.

These are useful evergreen climbers, which, moreover, when in good condition, bear very attractive red berries in winter. When these plants are much neglected they do not show themselves in their true characters. Too much old wood is in many cases allowed to remain, and the plants are not treated liberally at the roots. The *Cotoneaster* is a beautiful plant even without its berries, as its small Box-like leaves are so regularly and thickly set upon the branches. For very low positions and for horizontal training the *Cotoneaster* is an excellent plant. It flowers in May at the same time as the *Crategus*, and both bear white flowers.

### CLIMBING ROSES.

There are plenty of Roses adapted for climbing, and none better perhaps than *Gloire de Dijon* among the choice Roses. But for profuseness and freedom in bloom and growth plant the Ayrshire, the Banksian, the Boursault, and the Evergreen Roses. The Ayrshire Roses are slender, but very rapid growers. Little pruning is required, just cutting back the shoots which have borne the flowers immediately these fade, and cutting out crowded, very old, or useless shoots.

The Banksian Roses are vigorous and bloom in large clusters. Very slight pruning is necessary, as the flowers are produced on laterals issuing from ripened shoots of the previous year. It likes a warm wall, and the roots should be protected in winter with a mulching of littery manure. The Boursault Roses are also rapid

growers, blooming in large clusters. They may be treated similarly to the others.

The Evergreen Roses are useful, because they retain their foliage, which is dark green and glossy, throughout the greater part of the winter. They are very rapid growers, and will succeed in situations where many other kinds would die. The flowers are produced in clusters of white and pink flowers.

The soil for Roses on walls should be as good as possible, as upon this depends in a great measure their vigour and floriferousness, and to have them in this condition is a sure antidote against insect pests. There are Roses belonging to other classes also useful for walls, many of the H.P.'s being used in this manner, and also the Teas, but it is needless to say that the latter should have the most favourable situations, and have some protection in winter, by means of a mat hung in front of them during very severe weather, as it is most desirable that the stems should not be injured by frost, or the prospect of bloom the following year will be blighted.

For sweet fragrance in summer the Honeysuckle is a favourite plant, and should be planted in close proximity to the windows and entrances of a house. The best varieties to produce a display of flowers over as long a period as possible are the Early Dutch and the Late Dutch.

The Hop plant makes a grand summer climber almost in any position. It is deciduous, and may be cut down to the ground every winter. The following summer it will grow freely again and cover a large space.

Before concluding these notes I will give a short list of plants suitable for various aspects. For a south wall: *Gloire de Dijon* Rose, *Clematis Jackmani*, *Wistaria sinensis*, Ayrshire Roses, Honeysuckles, *Ampelopsis Veitchi*, variegated Ivies, Boursault Roses, *Jasminum officinale*. For a north wall or aspect: *Jasminum nudiflorum*; Ivies in variety, small and large green leaved; *Ampelopsis hederacea* and *sempervirens*, *Crategus pyracantha*, *Cotoneaster microphylla*, *Clematis vitalba*, *montana*, and *flammula*, *Humulus lupulus* (Hop plant).

For a west wall or aspect: Silver, golden, and small green-leaved Ivies, *Jasminum nudiflorum*, Banksian and Evergreen Roses, Honeysuckles, *Cotoneaster microphylla*, *Ampelopsis Veitchi* and *hederacea*, *Crategus pyracantha*.

For an east wall or aspect: Ivies in variety, mainly green-leaved kinds; *Ampelopsis hederacea*, *Crategus pyracantha*, *Cotoneaster microphylla*, *Jasminum nudiflorum*, *Clematis flammula*, *Humulus lupulus*, Ayrshire and Evergreen Roses. Whatever succeeds well on the north and east aspects will also succeed on the more favourable and sunny positions.

For very favourable districts and warmer positions there is a still wider range of plants suitable for climbing, but those which have been mentioned will succeed almost anywhere where the soil is good and vegetation thrives at all. There is little doubt that a more extended cultivation of climbing plants would enliven many districts, and do something towards forwarding a wider knowledge and love of gardening among all classes, for wherever climbing plants are used to embellish the walls of a residence and its surroundings they most certainly give an added charm.—E. D. S.

## INSECTS OF THE FLOWER GARDEN.

(Continued from page 262.)

CERTAINLY the commonest insects in our gardens are flies, of all sizes and hues. Even the entomologist cannot always distinguish amongst these the insects which belong to the large family of the ichneumon flies, and it is not to be expected every gardener should. Belonging to the same order as the bees and wasps, therefore possessed of four wings, a large number of them are much like the two-winged flies familiar to us both indoors and out. The name of ichneumon fly is not, perhaps, suggestive to some; it is taken from that given to a singular little quadruped which is stated to hunt for the eggs of crocodiles and snakes, thus putting a check upon their increase. The ichneumon flies act similarly, but only a few of them attack eggs; most of them prey upon insects in their larval stage, though some infest matured individuals. It is evidently a wise provision of Nature that exempts adult insects generally from such foes, and directs them to the destructive grub-caterpillar, which is then prevented from completing its changes. Great is the dexterity shown by the mother fly in depositing its eggs when the larva it is seeking is, more or less, hidden from view. By some sense unknown to us the ichneumon flies detect grubs that are feeding in wood, and discover a cranny into which the eggs of the parasitic larvæ can be placed so as to reach their object. Other flies manage to deposit eggs in the nests of wild bees, and escape unmolested, and a curious instinct sends one kind actually into the water, where they attack aquatic grubs.

Probably we have about 1100 species of these flies in our

islands, and many of them are haunts of flower gardens where their presence should be welcomed. We cannot estimate with exactness the benefits we receive from them, as their victims cannot be numbered, but no doubt these natural enemies of our garden pests accomplish results which would contrast favourably with the destruction of insects brought about by human agency. One notable circumstance in their economy is that by a sort of adjustment, if caterpillars or grubs are particularly abundant, Nature brings rapidly into existence in most cases a proportionate number of their destroyers. This was very observable in what some people called the "caterpillar year," viz., 1887, when the warm dry summer much favoured these insects. Of many species there must be several broods during each season; but we notice the flies chiefly while the sun is shining, as they not only hover about; it is also their habit to run rapidly over plants, constantly vibrating the antennæ. Some of them extract honey from flowers, only, however, in small quantity; they do not seem to need much food while in the fly state.

Amongst the ichneumon flies we find great differences of size. Several are large, like *Ophion*, which is almost an inch in length and moves with a hum, the bulk are of moderate size. Some, and these of considerable use, are very small, having also short wings; they might be taken for little ants upon the twigs or leaves. Generally, we might say these flies are examples of lightness and strength. The thorax is stout, the abdomen long and slender, usually attached by a stalk, in the females having an egg placer; the wings are delicately veined, often large, and the slender antennæ show keen sensibility to touch; it has been supposed they may be also organs of hearing. Some of the ichneumon flies deposit but a single egg on each victim, and some fasten upon it a number, even seventy or eighty have been counted. When full fed some of the larvæ (which are all maggot-like, only they have six minute legs) change to pupæ within the carcase of their victim, from which they emerge as perfect flies. Most quit it and spin a cocoon of silk; this is sometimes beautifully banded with colours, a peculiarity observable by a moderate magnifying power. One species of *Microgaster* is seen to form its cocoons in tiers, the larvæ working together when they have fattened on some caterpillars, twenty or more cocoons being joined so as to resemble a honeycomb in miniature. Another *Microgaster* groups the cocoons together irregularly; these are like tiny half cheeses, and the larvæ spin about them a sort of grey wool, possibly to keep off enemies. Then there are cocoons which are swung, and some that are called jumping cocoons, because they leap or jump about from the contortions of the pupa enclosed; this may be because it is itself attacked by another insect, for there is ample proof that ichneumons are themselves often preyed upon by other lesser parasites, fulfilling a familiar saying.

Many a plump caterpillar, which has devoured the leaves and tender stalks of our garden flowers, holds within it the larvæ of an ichneumon fly, by which its farther advance is arrested. We have a well-known instance in that of the small white butterfly, which is a feeder upon Cruciferous and other plants in our flower beds from spring to autumn. It is attacked by more than one ichneumon fly, notably by a species of *Microgaster*, allied to that, which first slays the common caterpillar of the Cabbage butterfly, then covers it with a mass of golden cocoons. It is the habit of the grubs or larvæ to feed within the caterpillar they infest, and manage to avoid a vital part till they have nearly become adult, when they finish it off, leaving but the shrivelled skin as a relic. The caterpillar of the gamma, which feeds upon a variety of herbaceous plants, is checked in its increase by an ichneumon fly; so too is the abundant caterpillar of the Currant moth, which occasionally pays a visit to our flower beds. Hairy caterpillars do not escape, such as those of the garden tiger and the common ermine. In spite of their clothing the flies succeed in placing eggs, and the larvæ burrow into the skin. The repulsive sawfly grubs, so hurtful to the Rose and to other favourite plants, have their diligent foes of the genus *Paniscus*. Even the tiny caterpillars that disfigure our shrubs by rolling their leaves have no power to elude these flies, which, by means of the egg-placer, reach them in their green hiding place.

In the *Ophion* group we have the singular circumstance that the eggs are laid upon the footstalks, not inserted in the skin, and the grub when it enters carries in a thread which keeps it attached to this stalk till it is adult. Some of the caterpillars infested by *Ophion* grubs succeed in making their cocoons, but they do not enter the pupal state, the parasites' cocoons being spun inside—the caterpillar's dying effort. Then there is a large tribe of these flies called the *Braconidæ*, and their occupation is different. They hunt up a variety of beetles, and deposit eggs on their hard wing-cases, but the larvæ manage to pierce in, and through them many beetles that gnaw leaves or nibble our flowers die off speedily. Great, too, is our obligation to another group, the *Aphidi*. These tiny flies

deposit one egg upon the body of every aphid they attack, and diminish the numbers of one of our most troublesome insects. Each fly is parent of many larvæ.—ENTOMOLOGIST.

### LILY OF THE VALLEY FOR FORCING.

A FEW sprays of Lily of the Valley during the winter months are much appreciated by all lovers of flowers, and especially when flowers are required for working into sprays for ladies, or for buttonholes. Although the Lily of the Valley is a hardy plant, it requires a high temperature to force it into bloom by Christmas and the following two or three months. We grow, and greatly prefer, single crowns for early forcing, as they come into bloom earlier and are more certain than clumps, although these are useful for later use. Many people have failed with crowns; but when failure occurs it is due to their being allowed to become dry before potting, or keeping them too dry during

FIG. 87.—FORCING LILIES OF THE VALLEY; A POT OF SINGLE CROWNS.

forcing. If procured from a respectable nurseryman the crowns are sure to be well ripened and in a fit state for potting on arrival.

If it is not convenient to pot them at once cover them over in damp cocoa-nut fibre refuse in the open air until the desired time arrives. We place sixteen crowns in a 5-inch, or 48-size pot, and insert them very firmly, arranging them equally over the pot with the tips of the crowns protruding through the soil. Some people find a difficulty in arranging them in the pot, but by placing the required number in the hand with layers of soil between they can be dropped in and the rest of the soil worked in amongst them.

After potting, plunge in damp cocoa-nut fibre refuse in a cold frame, or in the open air. Although they may be introduced for forcing directly after potting, we do not place ours in heat until two or three weeks afterwards, when they are introduced as required. From three to four weeks generally elapse from the time of placing them in heat until they come into bloom, if the course of treatment is pursued that will be here indicated. A moist bottom heat of 90° is required, and a position where they may be kept quite dark.

We have a small frame placed over the pipes where they enter the house, and this is kept covered up so as to keep the interior dark. When

ready for forcing, the pots should be brought into the house, and receive two or three waterings with warm water so as to thoroughly soak the soil. Plunge in the frame, or wherever they are to be placed, up to the rims of the pots, and cover the surface of the pots over with moss. Every morning water each pot with warm water, and until the crowns have grown about 2 inches keep them in the dark, then gradually inure them to the light, keeping them well watered.

After the crowns have grown 3 inches or so, stand them out in the house, but where the temperature does not fall lower than 70° or 75°, and take care to keep them well supplied with water; indeed, this is the main requisite for insuring success. If the above treatment is followed foliage as well as flowers will be produced at the same time. If clumps are used for later batches, a lower temperature can be allowed. Fig. 87 represents a pot of Lily of the Valley treated as described, the engraving having been prepared from a photograph.—A. YOUNG.

## SWEET WILLIAMS AND THE LATE MR. THOMAS HASTIE.

THE Sweet William may be called everybody's flower, as, being easily grown and cheap, it is within the power of the poorest cottager to have a bed of it. The heads are somewhat stiff, it is true; but then for cut flowers its rigidity is valuable to keep up flowers with weak stems, while its glowing colours set off the quieter looking blooms to advantage, and from a bed many varieties in colours are obtained. It has been grown for many generations, but, strange to say, never seems to have been made the subject of anyone's peculiar care until almost our own day. Seeds were sown with regularity, but little seems to have been done to improve the flower by careful selection of the good and resolute destruction of inferior kinds. Fully thirty years ago, when I began to get fairly interested in flowers, "Hastie's" Sweet William was commended most highly in the West of Scotland. Many seasons passed ere I knew who Mr. Hastie was; but still, wherever I went and chanced to see a good strain of Sweet William the proud possessor would explain the reason of its excellence by saying, "Yes, it's very fine, it's Mr. Hastie's." At length, escorted by a mutual friend one autumn afternoon, I found myself in Strathavon, Lanarkshire, some fifteen miles south-east of Glasgow.

About a mile beyond the curious old town the beautiful River Avon is crossed, and just at the bridge, on the east bank, Craigmill stands. The owner, Mr. Thomas Hastie, joyfully gave us welcome with true florist's delight, showing us over the fine garden and greenhouse, which he had planned and brought to rare perfection up in the moorlands. Thinking only of his interest in Sweet William, it was quite an astonishment to see a great square entirely filled with many hundreds of the finest Roses in cultivation, and again, another great square of late Phloxes, marvellously well grown, and all carefully named. Then the very long border of choice herbaceous plants, where many a gem graced this upland Eden. Between the Roses, and at the back of the hardy flower border, a narrow path divided, and along this were very fine Delphiniums, ranging from 3 to 8 feet high, and of every shade of blue. Here, strange to say, the *Gunnera scabra* was growing with magnificent spreading leaves as big as umbrellas, and a cone flower over 18 inches in length. All the protection given in winter was a great square of turf (grass side turned down), laid over a little leaves or straw about the crown of the plant. *Eryngium amethystinum* shone with a steel-blue glitter and a profusion of spikes, which I have never seen equalled elsewhere.

In a large bed were what I had come to see, his famous Sweet Williams, but almost out of bloom, only a warm invitation to come and see them next year, and meanwhile I noted the few flowers still appearing, which for colour were dazzlingly bright, the deep blood red being kept apart to preserve the strain. Among the varieties were very light reds set off with pure white eyes and white edges. Deep carmines were, however, the finest of all, and when seen the following summer with immense heads of bloom in sparkling sunshine gave an idea of what careful cultivation could do to what had hitherto been left to the mercies of bee-fertilisation and careless growing.

Mr. Hastie said that years before he had tried to save seed only from the best, but always poor sorts would assert their presence till he ruthlessly drew them out whenever their common ragged character appeared. By continuing this practice he eliminated all the tooth-edged sorts as well as those with the colour run into the white. Every year he had a new bed of seedlings to scan, from out of which some would come almost perfect. These he carefully saved, taking cuttings from them as well as saving the seed.

After many years he attained to the standard of perfection, the white lacing smooth and unbroken by rays of run colour, with the

outmost edge uncut or rose petal like; saw-like edges were not tolerated. Then the band of colour was solid, as if drawn with a brush, and the richer the colour the better. The centre or eye was pure white, while the heads were very large, being grown on rich soil. For years I had the pleasure of seeing the blaze of colour far superior to a bed of Stocks or Asters, while otherwise the garden was always beautiful.

In spring the Primroses of all shades and varieties, the Daffodils *Horsfieldi*, *Sir Watkin*, and other fine sorts, with *Lychnis viscaria* fl. pleno, &c., made a picture not often seen, even in gardens situated in warmer localities, or superintended by skilled gardeners, with assistants to boot. For a long time the rage for double flowers of every description was quite shutting out the improvement of single blooms. The fashion for single Daffodils, *Marguerites*, &c., has now set all the other way. Many double Sweet Williams have arisen, most of them neither showy in colour nor pretty in themselves. Exception to this general condemnation must be made in favour of Murray's double dark crimson, which is superb in colour—a dark rich velvet, and of good form and dwarf habit. It was raised by the late Mr. Murray, Superintendent of Paisley Cemetery, and for a ribbon border of a permanent kind is unsurpassed. To see it on a bright day puts all other flowers into the shade, while a patch of it a yard across makes any garden look much above the common. Of course, propagated by cuttings.

A fine bed of Columbines were an especial delight, as the single varieties *chrysantha*, *cœrulea*, *Witmanni*, &c., had been crossed by the bees, and innumerable varieties had resulted and were perpetuated. Go where you pleased, the large garden was in fine order, the vegetables, Cauliflowers, &c., splendidly grown, while every week visitors came long distances to see something or other in bloom. Hospitable in the extreme, without fuss, Mr. Hastie gave most willingly to those he esteemed cuttings and plants of all the rare things he had collected in a long lifetime. When he visited others he expected the same treatment, and was not pleased when he did not receive it. In his youth he was very active, of a spare habit, but untiring as a worker. Fully 6 feet in height, he thought nothing of walking out twenty miles to see a friend's garden, have a "crack" and walk away home again, proud of any new thing he had obtained. Latterly he became somewhat deaf, and friends had to speak loud to enable him to hear.

Once, while admiring the blaze of his greenhouse, with Fuchsias, *Pelargoniums*, &c., of which he had a large and expensive collection, I asked how he managed to keep everything in such order. He answered that his "better half" did the better half of it, and it was true, as in Mrs. Hastie he had a helpmeet indeed. But for her, Peaches and Grapes would not be the grand crop they were, as now he could not take enough patience with them. Then, when he would go to the Kipe Hill, several miles to the south, where he had grouse shooting, everything might be scorched ere he returned.

Three years before his death he bought many pounds' worth of stage Auriculas, which he set out in a long brick frame, eschewing pots, and certainly the blooms of them were extraordinary, and for size of trusses unequalled. One drawback, however, existed in this planting-out in open frames: the plants could not be lifted to the eye and examined at leisure. As a set-off, the reduction of trouble in watering was very great, while poor growers, as Lancashire Hero, became vigorous, and he delighted in a well-grown plant.

Born in 1808, in Forland, Dalserf, his father shortly thereafter took an orchard farm near Carlisle, and here, while but a boy, his strong taste for flowers, manifested itself. He used to laugh over his first attempt at grafting, as it arose over seeing the operation performed while he was very young on the farm orchard. He imitated the process on an old Cabbage stalk, and great was the mirth of the household over Tom's ingenuity.

In the year 1832 he came to Craigmill as a miller, and carried on the business for fifty-six years. He transformed the whole place, rebuilding and extending, planting trees, laying out the garden, and building greenhouses, &c. He spent some hundreds of pounds on Roses alone, and no finer or more extensive or better grown collection could one see in a private garden. All he grew had to be first-class, and I remember well taking a Highland friend once in to call as we passed up the riverside, when the *Pelargoniums* were at their gayest, and the utter astonishment of the kilted gentleman was delightful to us all, while Mr. Hastie said, "They could grow more than Heather and Grass up in the moors."

He kept several bee skeps, and here the "Lanarkshire Bee-keeper" was always welcome, but for new fangled ways of keeping bees in boxes Mr. Hastie would prefer the old straw methods of his fathers. Even a visit to his friend, the "Renfrewshire Bee-keeper," where the Stewarton octagon system improved was seen at its perfection, could not alter his preference for straw skeps.

"I may try boxes for summer, but for his *could kintra* the straw was safest to winter in." He died in July, 1887, of heart disease, and was buried "on the windy hill" which shelters Strathavon from the east, with many a life-long friend laid beside him. His widow maintains the greater portion of the plants in undiminished beauty, Roses and hardy border flowers being even finer than ever.

What a contrast this to the garden of Mr. Hastie's old friend and fellow grower of Sweet Williams—viz., Wm. Campbell of Woodfield, Dunoon. For years these two friends exchanged floral courtesies, comparing their choicest seedlings of Sweet William, and esteeming each other's success to the full. No jealousy disturbed the calm friendship or interfered with their visits. "If Mr. Campbell has the finest Sweet William as to form I have it in colour," said Mr. Hastie to me on one occasion, and it was the exact truth. Mr. Campbell took up the raising of Sweet William, and for ten years worked patiently and with all the skill and "gumption" which used to mark our old Scottish gardeners ere that mastery of all outdoor cultivation became lost in the too much glasshouse knowledge of our present time. He sold his stock of Sweet William to Messrs. Downie & Laird of Edinburgh, and now it is scattered everywhere, but our busy little friends the bees are so laborious in their efforts that it is almost impossible to retain the strain pure. One bad plant in a garden will effectually ruin a whole bed of the finest flowers, as I have experienced frequently. Hence the scarcity of the true strain of Hastie's or Campbell's to be found in even carefully kept gardens where Sweet William is appreciated. It has not died out, as this year in September I had as lovely a head of it as I ever saw, and a friend grew a whole large bed as pure as Mr. Hastie ever had.

Many now proclaim that the finest strain is theirs, and certainly the culture goes forward by many skilled seedsmen, but, like the other good things of the world, what was at first contemned has been sought after; what was of no value when it was Mr. Campbell's or Mr. Hastie's is now to be lauded to the skies because it is other people's.

"Once in a golden hour  
I cast to earth a seed,  
Up there came a flower,  
The people said, a weed."

To those pioneers, however, let us award the praise, and while we continue to grow the flowers which their patience and skill improved so much, let us not forget the—alas! now desolate garden at Dunoon, where the late Mr. Campbell did so much to carry forward the good work begun at the still beautiful garden at Craigmill, for from these gardens we all obtained the seed.—ALEXANDER SWEET.

### AMERICAN APPLES.

#### AN ARBITRATION CASE BETWEEN SHAW AND RONALDSON.

Before MR. JUSTICE MATHEW and MR. JUSTICE CHARLES.

THIS was a remarkable case illustrating how disputes arise between mercantile men upon shipments of cargoes, especially of a tender and perishable nature as fruit, and their deterioration by reason of delay in their shipment after they are packed; and the settlement of such disputes by arbitration. The case had arisen out of the shipment of a cargo of 12,000 barrels of Apples from Nova Scotia to London; the shipper's complaint against the shipowner being that, by reason of his delaying the shipment for fourteen days—the Apples being already packed—many of them were rotten and the rest seriously deteriorated in value when they arrived in London.

On October 3rd, 1889, Benjamin Shaw, a fruitbroker of Hull, wrote to Thomas Ronaldson (trading as Thomas Ronaldson & Co.), ship and insurance broker, of Leadenhall Street, London, "I hereby guarantee to ship by the 'Damara,' 'Ulunda,' and other equally good steamers you may load of your line, from Horton or Annapolis, in the Bay of Fundy, a minimum of 10,000 barrels or a maximum of 12,000 barrels during the last half of November of this year, the same to be delivered to me at Hull or London in the usual docks, &c. The rate of freight to be 4s. per barrel if the entire shipment is taken delivery of at one port, but if I require you to deliver at both Hull and London, the rate of freight then to be 4s. 1½d. per barrel all round. Freight to be paid on the usual line terms." To which Ronaldson wrote an acceptance, promising to advise Shaw as early as possible what vessels he should nominate for the purpose, and mentioning the "Roehampton," which, however, left Halifax on October 15th without any Apples from Shaw, and the two vessels named were to be at Halifax within a few days. The "Scandinavia" was then proposed, but the "Gallina" was not mentioned.

A correspondence took place between the parties as to the vessels to be chosen for the shipment, which were to be equal to the vessels named "because Apples are tender and require very fast steamers, and if an unsatisfactory boat were given the consequences would be serious." This was on October 31st, and on November 1st Shaw wrote again, "I am very anxious about the Nova Scotia Apples" and that ventilation of the cargo was very important. On November 1st, 1889, Ronaldson wrote

proposing the Gallina, which was chartered to load the Apples at Annapolis, which was described as equal to the Damara and would bring the Apples home in the best condition. Shaw, however, wrote that he did not consider the Gallina equal to the Damara, but the shipment of the Apples took place in the Gallina. There was an earlier vessel, the Scandinavia, which reached London earlier than the Gallina. Six thousand three hundred and fifty barrels of the Apples were shipped on December 13th in the steamer Gallina, and another quantity of 5650 barrels was also shipped by that vessel, making up the 12,000 barrels, which arrived on December 28th, having been kept packed at the port in Nova Scotia for fourteen days until so shipped; the Apples not having been shipped by the Scandinavia, which arrived in London on December 16th, 1889.

Immediately after the arrival of the Apples in the "Gallina" Shaw wrote to Ronaldson—"Price of the Apples, 3s. per barrel lower than when the 'Scandinavia' arrived," and upon that fact made a claim for compensation for not having shipped the Apples by the "Scandinavia," a claim which Ronaldson at once repudiated. Shaw, however, made a claim for compensation for damage caused by the failure to ship by the "Scandinavia" or some ship which would have brought the Apples to London in good time for the Christmas market; and also for the deterioration of the Apples through their having been kept packed for fourteen days prior to the shipment, whereby it was said many of them were made rotten and required to be repacked; it being, it was said, of the nature of Apples so to become rotten if kept packed, and the only means of preventing it being to unpack them and then to repack them. Disputes arose in respect to these claims, which in August, 1890, were referred by agreement to arbitration, and the claims of Shaw were then formulated in "particulars" as follows:—

Loss of 2s. 2d. per barrel on half cargo of 11,300 barrels of Apples, which should have come by ss. "Scandinavia" (arrived in London December 16th, 1889), but which came by ss. "Gallina" (arrived in London December 28th, 1889), 5650 barrels, at 2s. 2d. ..	£612	1	8
To loss on 6350 barrels (making shipment agreed for 12,000 barrels), which should have been shipped in last half of November, and delivered in London in due course, about 15th December, but which were not shipped until December 13th, and not delivered until December 28th, by ss. "Gallina," at 2s. 2d. per barrel ..	687	18	4
Broken barrels, &c., ex ss. "Gallina," as per broker's catalogue ..	140	19	0
To loss through Apples having to be repacked and waste in consequence of being detained in Nova Scotia fourteen days ..	193	11	11
	£1634	10	11

The two last items of claim, however, were abandoned. The arbitrators sat for two days and heard Mr. Shaw's case, and it was supposed that it was substantially closed. Upon an adjournment, however, his solicitor set up a right under the first two heads of claim to show deterioration in the quality of the Apples, and for that purpose to take evidence in Nova Scotia, and to have in the meantime a further adjournment, and during such adjournment Mr. Shaw's solicitors applied to the Judge at Chambers in the vacation (Mr. Justice Collins) to order a Commission to take evidence in Nova Scotia. The learned Judge, however, declined to make such an order. Mr. Shaw now appealed against that decision, but the appeal was dismissed.—(*Times*, November 24th.)

#### THE DECORATIVE VALUE OF THE CHRYSANTHEMUM.

THERE has been a tendency to imply that the chief merits of the Chrysanthemum consist in its adaptability for exhibition purposes and competition for money or other prizes in public, but great as is its value in this way it has qualities fitting both plants and cut blooms for decorative purposes, equalling in general utility the other characters, and likely to lead to a more enduring popularity. We have no plant to approach the Chrysanthemum in its importance for house decoration during the months of autumn and early winter, and it rivals some of the best in the whole year. In its comparatively easy culture for such work, abundance of flowers, gracefulness of form, and variety of colours, it stands as pre-eminently and unquestioned the queen of autumn as the Rose holds undisputed reign in summer. How we could now dispense with the Chrysanthemum it is difficult to imagine, for we have nothing to take its place.

Commercially, also, this phase of its character is very important, as many cultivators have proved, or are proving. The demand for the flowers in the market and at the florists is increasing every year, and some nurserymen who have made a specialty of these plants say that they can make larger returns from the sale of flowers at certain seasons than they could formerly from the cuttings or plants of new and established varieties. The brightly coloured Roi des Préoces, a small early Japanese, has, to my knowledge, brought one grower an astonishing return for the flowers sold. Source d'Or is another which has sold well in the same way, and numbers of others could be named equally useful, the pure white, bright red, and bronze or orange, and golden-tinted varieties being the favourites, the small, or not above medium size, and of light graceful appearance.

Quite recently I had an opportunity of observing what enormous

quantities of these plants and flowers are grown for market purposes. When paying a visit to Mr. Edward Rochford's great establishment at Cheshunt I was shown, in addition to the scores of vineries and the tons of Grapes, a series of houses was devoted solely to Chrysanthemums. Amongst them were three span-roofed houses, each 260 feet long and 30 feet wide, filled with Fair Maid of Guernsey, presenting a perfect foamy sea of white flowers such as probably few have seen. It would be impossible to estimate the number of flowers and buds. It seemed quite safe to talk about millions with such an array before us. Then, too, there were other houses of Source d'Or, Boule de Neige, Belle Jaune, and Lady Trevor Lawrence, enough, as one might well suppose, to stock the world. Yet this is only one of three in the same district, and some of them have even more than this. It is referred to here chiefly with the object of showing what a wonderful demand there must be, because market growers cannot afford to waste time and space on plants that will not sell readily.

So many methods of employing Chrysanthemums are available that it will only be possible to touch upon a few of the principal, and first amongst them is the grouping of the plants for conservatories, rooms, or at exhibitions, and the general arrangements at the latter. Admirable as many of the shows are, there is a certain uniformity, becoming almost monotonous to those who visit many shows, that cannot be entirely avoided; but it is strange that so few attempts are made to introduce anything novel in the classes or arrangements, with the exception of a few challenge vases.

A correspondent has favoured me with the description of a Chrysanthemum Show in New York. The arrangement of the Chrysanthemum plants with backgrounds of crimson-tinted Oak trees, Hemlocks, Spruce, and Irish Junipers, was extremely tasteful, suitable, and effective. From the balconies of Cosmopolitan Hall to the floor these trees were spread out in a trellis, and at intervals platforms were raised, on which the bush plants were placed—those of the Chinese type one side of the hall, and the Japanese opposite. Through the centre of the building were large oval parterres of plants, with specimen Palms and other decorative foliage massed in a large bed near the west end of the building, where the Japanese garden was laid out. As viewed from the balcony above, all the effects in the hall were irregular and informal; there were no straight paths, but it seemed a maze of the fleecy blossoms—a zig-zag of patterns—a crazy quilt of colour and confused devices.

One of the best features of the exhibition was the entire transformation of the hall by the changing about of the plants. A re-arrangement of the foliage plants was the first move made. They were taken from their massings and placed singly among the Chrysanthemums, or in small groups; the effect was to heighten and add a fantastic grace. When the Judges had made their decisions and there was no longer a need for keeping the classes of plants together, the competitive arrangement was changed to a grand ornamental display. All the golden Chrysanthemums were massed in the centre of the hall. The amaranth-tinted ones were put together, and so were the whites, the crimsons, and the red-and-yellow variegated lot that looked like burning bushes, so flame-tipped were the petals. The electric lights were lowered, so they rested like meteors among the plants. An exquisite effect was made with *Draænas*, lifted above white flowers, with a ball of light which seemed tossed up from its fountain-like leaves.

This arrangement, which is the system adopted at most continental shows, is scarcely practicable here, but groups of similarly coloured varieties might be employed. Here is another suggestion from the same source. The choicest standard plants and the new Japanese seedlings were arranged in the Japanese garden, where there were two bamboo summer-houses profusely hung with curios—fans, parasols, umbrellas, scrolls, and panels. Flowering plants were twined in and out of these structures, and each side of them were quantities of cut flowers, baskets richly filled with bloom, and pots of growth on which but one flower had been brought out. The latter flowers were of enormous size and remarkable shapes and colours. Most of them were named after Japanese celebrities. A native Japanese sat in each summer house, where he painted fans and screens, which were sold at reasonable prices.

In grouping Chrysanthemums in conservatories or houses it is seldom that attempts are made to form the smooth even surfaces of blooms too often seen at shows, the only merits of which are the variety and richness of colour and handsome blooms they present to ready inspection. Arranged with some freedom beautiful effects can be produced, and it has been well shown at Brighton that when classes are provided for this style a good competition can be obtained, and a most pleasing break from the uniformity so prevalent in such groups.

Dwarf plants are indispensable for groups of all kinds if only for the front rows, and Mr. Orchard was at one time so successful in this that I quote his system of culture as communicated to my "Chrysanthemum Annual":—"Many cultivators adopt a style of pinching the young plant after it is established in a 60-pot, which checks the height, and then they pinch again in June. That is a good plan to get medium-height plants from 3 feet 6 inches to 7 feet. Others strike them later and pinch once, but the objection to these two plans is—in the former case the young plant is checked just at a time when he ought to be making roots to establish a good foundation; and to the latter, the plants never gain substance enough in a short season of growth from the cutting to the flowering.

The only way to get the plants dwarf is to cut them hard back from 3 to 6 inches the first fortnight in June, beginning with the later flowering varieties, doing a few every day. It requires some boldness to do it at first. It seems such a sacrifice, for up to that time they should have

had the care and attention of plants required to be grown on. To be successful, it is necessary they should be then strong, healthy, and well-established in 48's or 32's, with plenty of good healthy roots. They will bleed a little, but by being kept rather dry a day or two beforehand, and only a slight sprinkling afterwards, they will not lose much.

Care will be necessary to thin the shoots to the required number, and support them with thin sticks, or they will be easily broken. Transfer them into their largest pots as soon as the growths are fairly started, say from 4 to 6 inches long, and feed with liquid or artificial manure as soon as the roots reach the sides of the new pot and are properly established. Take the first bud that shows, and the height of the plant then corresponds with the natural growth from break to break.

Formal banks of beauty are not so desirable as light free arrangements, and when other plants are utilised for the groundwork or margin Chrysanthemums can be employed to excellent purpose for conservatories or in any similar way. As cut flowers the value of the Chrysanthemum is extremely great; in wreaths, bouquets, sprays, baskets and vases charming results are readily produced when a little taste is exercised, and the tendency to form heterogeneous mixtures of colours is avoided.

Whenever Chrysanthemum flowers are employed in this way the shades of one colour should be associated as far as possible. Pure white is best alone in some cases, but yellow, orange, and bronze go well together. Bronze and light and dark red, the various shades of pink and pale red or crimson harmonise, and delicate pink tints also go well with white. The Japanese varieties are generally superior for this purpose, the incurved of the Mrs. G. Rundle type, when not disbudded, produce charming little flowers that can be utilised in many ways.

At most shows prizes are offered for hand bouquets, to be composed solely of Chrysanthemums, with their own foliage and Fern fronds, but very rarely are any to be met with that could honestly be admired. They are far too flat and closely packed to be pleasing, and in many instances a most extraordinary mixture of colours completely spoils the effect. If those who make them would be content to use fewer colours and not wedge the blooms together in a mass, that would be a step in the right direction. Plenty of moss worked in among the stems prevents the flowers from crowding together when bound, while showing up between the latter there ought to be some healthy Chrysanthemum foliage, as well as neat sprays of the Pompon Snowdrop springing up well above the rest. Wire frameworks are objectionable, and there is no reason why presentable bouquets cannot be made without them. Much that has been advanced about bouquets also applies to the class for vases.

Arched stands and small flat dishes with tiny trumpet centres are altogether unsuitable for the purpose, it being hardly possible to effectively fill them with Chrysanthemums. What do answer well—and those who use them never fail to win a prize—are tall, trumpet-shaped vases, without any dish of any kind at the base. This ought to be boldly filled, that is to say, only fine blooms, with long stems and an abundance of good foliage attached should be used, the incurved varieties being quite as effective as the Japanese. Large Fern fronds, intermingled with wreaths of Ivy trailing down, completes a noble vase. In order to be able to lightly fill these large vases it is frequently necessary to fill them with short sprays of Box, this serving to hold the flowers in any position.

It has been urged against the Chrysanthemum that it is either scentless or possesses such an unpleasant odour that it cannot be used in rooms. To meet these fastidious declaimers, it has been discovered that certain varieties possess a slight delicate and agreeable fragrance. Some of the best of them are Progne, a purplish reflexed, the scent of which has been not inaptly compared to Violets; Dick Turpin, an Anemone Pompon, with rosy red ray florets and a yellow centre; and Mrs. Langtry, single, of a pale blush or pinkish colour, one of the most useful decorative varieties that can be grown. The single varieties are all very valuable, and yield such an abundance of choice, varied, graceful flowers, that they ought to be extensively grown wherever cut flowers are required in large numbers.

Perhaps I shall be expected to say something about Chrysanthemums for exhibition, but this subject has been so frequently and fully treated upon, and Mr. Molyneux's excellent little book is within everybody's reach, so I shall confine myself to a few general hints. One very important point at starting is to secure sturdy, well developed, but not too luxuriant cuttings, as they lay the foundation of sound plants. It often happens that novelties are so rapidly propagated that the cuttings become much weakened unavoidably, and the grower will find it a difficult matter to restore vigour to such plants. One friend of mine always has stock plants out of doors from which to obtain his cuttings (except in severe weather), simply because he has proved that these hardy though small shoots, provided they are not stunted, usually develop into the best plants. From the middle of December to the middle of January is a good time for striking the cuttings, but the actual time to a week or so is of less importance than the subsequent treatment.

With the Chrysanthemums, as with everything else, the man who has the greatest interest in his work, the most persistent perseverance to overcome difficulties, and who exercises the closest observation respecting all details, is the one who is most likely to succeed, and success with such a useful plant is something of which anyone may well be proud.

#### SINGLE-HANDED GARDENERS.

In your impression of November 19th a writer asked why I showed in the single-handed gardeners' classes at Putney, and my reply is that anyone can show in the classes above him. A cottager can show in the

amateur section or gardener section, and an amateur can show in the gardeners' classes, and a single-handed gardener can show in the gardeners' classes. If, however, the single-handed gardeners are afraid of the amateurs and cottagers, surely they ought to be placed below the cottagers. Mr. Shea showed in the open class at the Aquarium Show, but I did not see the name of his gardener on the card. I have for years past shown in the single-handed gardeners' classes at Putney with the permission of the Committee, and not without success.

The whole question of competitors wants revision. No gardener who sells cuttings, other than seedlings of his own raising, ought to be allowed to show except in the classes set apart for nurserymen, and no one ought to be called an amateur if he employs any help of any kind, size, or shape in his garden.

No one would object to the exhibitors being allowed to show only in their respective classes, but if a cottager or an amateur is not allowed to show in the single-handed classes or the gardeners' classes, neither should the single-handed gardeners be allowed to show in the gardeners' classes, or the gardeners in the nurserymen classes.—DR. GEO. WALKER, *alias* THE WIMBLEDON AMATEUR.

#### CONFUSION AT EXHIBITIONS.

ON visiting the Bristol Chrysanthemum Show I was surprised to see such a confusion in the arrangement of the exhibits. There did not seem to be a fixed place arranged for any of the classes. The Committee did not seem to have calculated beforehand what space certain exhibits would take; therefore when the exhibitors came to stage their fruit or flowers, as the case may be, no one seemed to know the proper place for them. First one thing had to be shifted, then another, to make room for the exhibits, causing waste of valuable time; whereas if the number of exhibitors had been ascertained in each class, there would have been little difficulty in finding space for the whole of the exhibits. Some little time ago I had occasion to visit one of the National Chrysanthemum Society's exhibitions at the Royal Aquarium, and it was quite pleasing to see how well the arrangements were carried out by the Secretary, Mr. R. Dean. Places were assigned for each class, shown by a large card, and the direction in which the exhibits were to be staged, to the right or left, was indicated. Not the slightest confusion occurred, and the staging went as smooth as clockwork.—EXHIBITOR.

#### NEW CHRYSANTHEMUMS—FLORENCE DAVIS AND VIVIAND MOREL.

I THINK the past season will bear very favourably with any previous ones for thoroughly good new varieties that have been staged at the different exhibitions, especially in the Japanese classes, and I should like to say a word in praise of two which have proved everything that could be desired with me, and grand acquisitions in every way.

Florence Davis was strongly recommended to me last season by that good grower and judge, Mr. N. Davis of Camberwell, and I must say all he then said in its favour fell short of its great beauty and general merits. I have watched the reports of all the shows, but only in one or two places have I seen it mentioned. Such a grand variety should not be kept in the dark, and I strongly recommend all growers who have not already secured it to do so at once. From four plants I secured twelve exhibition blooms, which speaks well for its freedom—in fact, it is as free as Avalanche in producing grand blooms. I staged two of these at Birmingham, where it took "the eye" at once, and was duly noted down by all who "know what they are about." (I should like to mention here in your report of this Show you call it in one place Fanny Davis, which might be taken for F. A. Davis—Jeanné Delaux). The habit is good, growing about 4 feet high. The blooms before expanding are of a light green, which develop into pure white, with long drooping florets, the tips of each slightly curled, which gives it a very pleasing appearance. I should say it is a late variety, and as the flowers are very large (8 inches broad and 10 deep) and slow in opening it should be housed early rather than hurry it with fire heat.

I do not think it necessary to say so much about Vivian Morel, as this has been shown well and frequently, and also referred to in the Journal, only that I can bear out all the good things that have been said in its praise, and intend growing plenty of it next year, at the expense of some of its taller neighbours. One or two others I hope to refer to later on.—RICHARD PARKER, *Impney*.

#### DWARF EXHIBITION JAPANESE CHRYSANTHEMUMS.

I AM surprised that so excellent an authority as Mr. R. Owen should give a list of dwarf exhibition Japanese Chrysanthemums and not include such varieties as the following:—Mrs. Falconer Jameson, Vivian Morel (a great acquisition), Condor, George Daniels, Gloire de Rocher, W. W. Coles, E. Molyneux, and M. Bernard; not to mention less notable varieties seldom seen in exhibition stands. I am pleased to say several firms have varieties (new) on trial intended to add to this list. One (not yet named) only 2 feet high, sent me by Messrs. Clibran of Altrincham promises to be an addition to the limited number of excellent late varieties.—W. J. MURPHY, *Clonmel*.

#### CHARLES GIBSON.

I HEREWITH enclose a bloom of Charles Gibson showing hairy florets. There were two blooms on the plant, but very few of the florets were bristled on the other bloom. I have grown three plants of Charles Gibson this year, and the blooms have been quite smooth on two of them. Has this been experienced with other Chrysanthemum growers?—SUBSCRIBER.

#### FUNGOID DISEASES.

THROUGH the courtesy of the Editor of this Journal I have had the opportunity of perusing "The Journal of Mycology," published by the United States of America Department of Agriculture, vol. vii., No. 1, 1891, edited by the Chief of the Division of Vegetable Pathology, Mr. B. T. Galloway, and assistants. Among other interesting and valuable matter appertaining to fungoid diseases, the "Journal of Mycology" contains description of experiments in combating, and hints for the avoidance of Sweet Potato black rot (*Ceratocystis fimbriata*, *Ell. and Harkn.*), by Dr. B. D. Halsted and Mr. D. G. Fairchild, with plates, showing the "rot" on the tubers, and the life history of the fungus.

This may concern growers in this country but limitedly, still the results obtained have an important bearing on fungoid diseases generally, and are instructive and useful in treating similar pests. The results of the experiments or cultures are found to be:—1, Mycelium present in the diseased roots planted infects the young shoots. 2, Infection may take place either through the medium of spores, or by the growth of mycelium from the diseased areas themselves. 3, Diseased sprouts planted in the field produce diseased roots, which may spread the disease to other hills, either through the soil directly, or by means of the numerous fibrils from other plants. 4, These infected areas, although perhaps inconspicuous at first, grow steadily in diameter, not being checked by digging, and when the Potatoes are stored for keeping continue to grow in the root, and at the same time to produce the various forms of spores. 5, These reproductive bodies, when supplied with sufficient moisture, are capable of infesting, unaided, sound Potatoes through their eyes. 6, Thus one diseased Potato when stored in a bin of healthy ones is capable of infecting all those in the bin, and causing them to rot in a short time.

Those are valuable data, and it is further shown that it is not unlikely that the parasite may inhabit different stable manures, and that a passage through the digestive canal would not kill the spores. In the way of preventives it is recommended:—1, To plant only perfectly healthy seed. This is most essential; as diseased seed will give diseased sprouts, which in turn will grow a crop of worthless Potatoes. 2, Use copper fungicides, keeping the shoots green with it till pulled. 3, Fields impregnated with disease should be added to the regular rotation, that is, not kept under the same crop year after year, thus allowing the infective material to burn itself out. 4, Decaying roots, and the refuse after digging should be carefully removed from the field and burned, as such debris adds to the food of the parasite. 5, Large quantities of farmyard manure probably favour the development of the trouble, since it greatly adds to the decaying vegetable matter of the soil. Where the use of commercial fertilisers can be made to take the place of manures it will certainly be desirable to make the change. 6, It is probable that the spread of the disease in the bin may be checked by dipping the roots in one of the copper mixtures, preferably the ammoniacal solution, before storing for the winter. What effect tobacco smoke or the fumes of sulphur would have in checking the disease in the bins remains to be ascertained.

The foregoing particulars are taken from the "Journal of Mycology," and, though having special application to Sweet Potato (*Batatas edulis*), they are appropriate to tuberous esculents liable to fungoid disease, and should be borne in mind by growers of Potatoes.

Then follows a very important paper by the Editor, Mr. B. T. Galloway, entitled "Experiments in the Treatment of Plant Diseases." The first treats of Grape diseases, and contains results of experiments conducted at Greenville, South Carolina; Vineland, New Jersey; and Neosho, Missouri, the work having special reference to "black rot, which is everywhere recognised as being the most destructive of all Grape maladies." The investigations were conducted with a view to ascertain the value of fungicides, which cannot fail to interest readers of the *Journal of Horticulture*, therefore we extract the following:—

"I.—A comparison of the fungicides given below as regards cost, efficiency, and effects on the healthy foliage and fruit.

"(a). Bordeaux mixture, prepared in accordance with the usual formula—i.e., copper sulphate 6 lbs., lime 4 lbs., and water 22 gallons.

"(b). Bordeaux mixture, prepared the same as a, then allowed to settle, after this has taken place drawing off the clear liquid and drying the sediment, the latter being simply mixed with water when used. The object in using this preparation was to determine if possible whether the Bordeaux mixture prepared in advance was as effective as that made in the usual way. The question has considerable practical importance, as there is an increasing demand for a mixture ready for use. This demand is mostly from small growers who do not care to go to the trouble of buying the copper and lime and making their own mixture.

"(c). Modified eau celeste, containing copper sulphate 4 lbs., aqua ammonia 3 pints, carbonate of soda 5 lbs.

"(d). Copper carbonate in suspension, 3 ozs. to 22 gallons. This being a much cheaper preparation than the ammoniacal copper carbonate solution, it was thought best to give it a thorough trial.

"(e). Simple milk of lime, made by dissolving 3 lbs. of lime in 25 gallons of water.

"(f). Copper acetate, 2 lbs. to 22 gallons.

"(g). Mixture No. 5, consisting of equal parts of ammoniated copper sulphate and ammonia carbonate. Used at the rate of 1 lb. to 25 gallons of water. Mixture No. 5 is practically eau celeste in dry concentrated form.

"(h). Ammoniacal copper carbonate solution, 3 ozs. copper carbonate dissolved in 1 quart of ammonia, and diluted with 22 gallons of water.

"II.—The value of a mixed treatment, consisting of three early treatments of the Bordeaux mixture, and three late sprayings of the ammoniacal solution.

"III.—The value of early against late sprayings. By early is meant the first treatment when the buds begin to swell, and by late the first treatment when the Grapes are the size of bird shot."

Full accounts of the experiments are given with diagrams. From the extended particulars relative to the experiments we gather the following remarkable facts, but it will be necessary to observe that the experiments were conducted at Greenville, South Carolina. "The vineyard chosen by Mr. Howell (who carried out the work) for the experiment was one which had been well cultivated and cleared, but had never before received any treatment for Vine disease, and for three years had regularly lost from 50 to 75 per cent. of its crop by black rot. Besides this it had been invaded by downy mildew and anthracnose." It may be as well to state that none of these fungi have appeared in this country, except it be downy mildew (*Peronospora viticola*) and that not making much headway in our vineries.

reduced the amount of rot to less than 1 per cent., while on the untreated Vines the loss averaged 40 per cent. This was much less than in an ordinary season on account of the dry weather. In such cases about 75 per cent. would have probably been lost. The present season was not one, either, that furnished a good test of fungicides. If more rain had fallen there is little doubt that there would have been more rot on the treated plats, more striking differences in the degrees of efficacy of the different fungicides, and more Grapes actually saved—that is, the difference between the amount lost on the treated and the untreated plats would have been much greater.

"As to the comparative value of the fungicides, the ratios found in the figures as given can scarcely be considered such as will hold for other seasons and in different climates. This season's work has shown that a difference in locality affects the action of fungicides on foliage. For example, the copper acetate, which proved very efficacious with Mr. Howell of South Carolina, burned the foliage so badly in Missouri as to ruin the crop for the year."

The experiments at the other places were practically the same as

"The variety selected for experimental treatment was the Concord, because of its regular habits of growth and fruitage, and its unvarying susceptibility to rot." The vineyard was divided into plots:—"Three plots of fifty Vines each, containing no sub-plots; eleven main plots containing fifty Vines each, having in the centre a sub-plot of eight Vines each." The diagram given in the work shows the arrangement of the plots, but suffice for our purpose to state that the variation in regard to the plots was for the purpose of bringing out the value of early spraying as will be shown later." "The first spraying was made ten days before blooming, and would have been applied earlier but for a delay in some of the chemicals. The weather had been dry for two weeks and no disease was showing on the leaves. The next day, however, a rainy spell set in, lasting five days. The second treatment was also given on a clear day, and the first traces of black rot had been discovered the day before. There were rains on May 18th, 19th, 20th, and then none until June 1st. The day after the fourth treatment there was a light rain (June 15th), and this was followed by a drought, which put an end to any infection of black rot for the season.

In order to get a fair estimate as to the value of the various treatments the diseased and the healthy berries on both the treated and untreated plats were carefully counted and weighed. The weight of diseased fruit was estimated by counting, in several cases, the number of berries in a pound of sound fruit, obtaining an average number and dividing the number of diseased berries by it. The result of this work is shown in tabular form above.

The foregoing table explains itself. "Seven of the fungicides used

those given in detail in the preceding notes, and the entire work is summarised as follows:—

"I. All things considered the Bordeaux mixture still heads the list as a preventive of black rot.

"II. The Bordeaux mixture prepared in advance, according to the directions already given, is not satisfactory, and is therefore not worthy of further use.

"III. Copper carbonate in suspension and milk of lime are comparatively useless as preventives of black rot and other Grape diseases.

"IV. Copper acetate has fungicidal value, but in most sections it is likely to injure the foliage.

"V. The cheapest and most effectual remedy for black rot and downy mildew (*Peronospora viticola*), taking everything into consideration, is the ammoniacal solution of copper carbonate. Next to this is a mixed treatment, consisting of two or three early sprayings of Bordeaux mixture and the same number of late treatments with ammoniacal solution.

"VI. Mixture No. 5, while possessing value as a fungicide, is likely to injure the foliage. Until this difficulty is overcome its use on a large scale cannot be recommended.

"VII. Early sprayings are absolutely necessary to insure the best results in the treatment of black rot."

Although the experiments relate to black rot and other Grape diseases little, if at all, prevalent in this country, they are valuable as showing the importance of proper, efficacious, and early treatment of fungoid diseases generally.—G. ABBEY.

(To be continued.)

**EVENTS OF THE WEEK.**—A meeting of the Linnean Society takes place to-day, December 3rd. On the 4th there is a meeting of the Dundee Horticultural Association, and on the 5th of the Preston and Fulwood Horticultural Society. On Tuesday, December 8th, there will be a meeting of the Royal Horticultural Society at the Drill Hall, Westminster, when there will be a lecture and discussion on Hellebores. The annual meeting and dinner of the National Rose Society take place on the 9th. The December Show of the National Chrysanthemum Society will be held at the Royal Aquarium, Westminster, on the 9th and 10th. Bulb and plant sales take place nearly every day at Messrs. Protheroe and Morris' rooms, Cheapside, and at Messrs. Stevens' rooms, Covent Garden. There will be an important sale of *Cattleya labiata* at the former place on the 4th by order of Mr. F. Sander.

— **NATIONAL ROSE SOCIETY.**—The annual general meeting of this Society will be held at the Horticultural Club, at three o'clock on Wednesday, December 9th, and the annual dinner at six o'clock the same evening at the Hotel Windsor. The Very Rev. the Dean of Rochester will preside on the occasion.

— **THE "HORTICULTURAL DIRECTORY."**—This extremely useful publication is now ready, and can be procured from the publisher of the *Journal of Horticulture*, 171, Fleet Street, London, price 1s., post free 1s. 3d. It contains a vast mass of valuable information to all interested in gardening, including calendar, postal and other tables, useful garden recipes, certificated plants, the names and addresses of British and continental seedsmen, nurserymen and florists, country seats, names and addresses of gardeners, horticultural builders, horticultural societies, and a considerable amount of miscellaneous information.

— **NATIONAL CHRYSANTHEMUM SOCIETY.**—The early winter Exhibition of Chrysanthemums, which takes the place of the midwinter Show formerly held in January, will take place at the Royal Aquarium on Wednesday and Thursday, December 9th and 10th, and the Floral Committee will meet at 2 P.M. on the first day.

— **MESSRS. JAMES CARTER & Co.** write:—"When reading the very interesting HOLIDAY NOTES on page 445, by Mr. Castle we are gratified to observe special mention made of the lawns upon Baroness Rothschild's estate, and which have been produced exclusively with our Invieta Grass seed, especially prepared for this particular purpose."

— **CHISWICK GARDENS.**—A new span plant house has recently been erected at Chiswick Gardens, and is worth going to see. It was built by Messrs. J. Weeks & Co. of Chelsea, to whom the Council of the Royal Horticultural Society have accorded a special vote of thanks for its "economy and excellence."

— **HULL CHRYSANTHEMUM SHOW.**—Mr. H. H. Taylor informs us that he was the winner of the fourth prize in the group class, and not Mr. Wheatley, as stated in our report last week.

— **PEAR-SHAPED APPLE.**—Mr. Spence King sends us from Ipswich a true Pear-shaped Apple of full size. It was gathered from an espalier tree in the gardens of Mr. Alfred Wrinch, of the well known firm of Wrinch & Sons, horticultural engineers. An Apple of the normal type sent from the same tree resembles the Bedfordshire Foundling. The cause of the change in shape is not known, and may, or may not, occur again on the same tree. Three years ago a tree at Ipswich bore several Pear-shaped Apples, one of which we figured, but has since satisfied itself by producing ordinary round fruits.

— **DOUBLE MIGNONETTE.**—Mr. W. W. Pettigrew refers to a Double Mignonette in your issue of the 26th ult. His description appears to correspond with a plant sent out by Mr. Balchin in 1881, which I described in a paper read before the Linnean Society, December 1st, 1881. It is a proliforous state, so Mr. Balchin named it *Reseda odorata alba prolifera*. Whether it is still in the market I do not know. I enclose a copy of my paper for your acceptance.—G. HENSLOW.—[The paper contains an excellent botanical description of the plant referred to, and the illustration represents a branching spike which differs from ordinary varieties of double Mignonette we have seen grown in gardens. It has been sent to Mr. Pettigrew.]

— **GRIMSBY CHRYSANTHEMUM SHOW.**—Mr. Chas. Colebrooke, nurseryman, Great Grimsby, notices that he is mentioned in the *Journal* as having taken third prize for a group of plants, whereas it should be second.

— **GARDENING APPOINTMENTS.**—Mr. A. Burgess, for the last six years head gardener to Major Browne, Doxford Hall, Chathill, Northumberland, has been appointed head gardener to M. Walton, Esq., Grove Park, Kingsbury, Middlesex. Mr. W. Mabbott, foreman at Ewenny Priory, has been appointed head gardener to E. P. Martin, Esq., Gwernllwyn House, Dowlais, Glamorgan, South Wales.

— **WE** are sorry to hear of the death on the 22nd of November of Mr. FRANZ KRAMER, head gardener to Herr Legationsrath Rucker-Jenisch of Flottbeck-Hamburg. Mr. Kramer had for about thirty years charge of one of the most renowned continental Orchid collections, that of the late Senator Jenisch. He was well known in English horticultural circles, and generally esteemed both for his character and abilities as a gardener. The situation having been held by his family for several generations, is likely to be filled by his eldest son.

— **CANADIAN AND AMERICAN APPLES.**—The transatlantic Apple trade has assumed great proportions this year. The imports in Liverpool for the season were 369,880 barrels, as against 96,628 barrels during the corresponding period of last year. The principal portion of these supplies has been Canadian, the prices of which range from 15 to 20 per cent. more than for those of the United States. The fruit is described as of exceptionally fine quality, well-packed, and the supply, great as it is, by no means exceeds the demand. A barrel contains a 140 lbs. or a hundredweight and a quarter, the prices ranging from 10s. to 20s. a barrel last week in Liverpool. Evidently the home supply of high class marketable fruit is quite inadequate to consumptive demands.

— **NOVEMBER WEATHER IN HERTS.**—The following report of the weather during November, 1891, from observations taken at Hamels Park, Buntingford, by Mr. E. Wallis, gardener, is sent for insertion. The weather during the past month has been of a very sunless character, and a fair amount of rain has fallen, which has kept our heavy soil in an unworkable condition. Tree planting and such work has been at a standstill. There has also been almost a total absence of rain. Rain fell on seventeen days during the month; maximum twenty-four hours being 0.50 on the 10th; minimum 0.02 on the 11th. Total for the month, 2.37; against 2.66 in 1890.

— **RAINFALL IN SUSSEX.**—The total rainfall at Cuckfield, Sussex, for November was 3.75 inches, being 0.8 inch above the average. The heaviest fall was 1.0 inch on the 10th. Rain fell on nineteen days. The maximum temperature was 54° on 1st and 10th; the minimum 23° on 25th. Mean maximum 47°, mean minimum 35°, mean temperature 41°. A mild, damp, sunless month. The latest formed runners on Strawberries were in bloom when cleared out. Such has never been observed before. The heavy rain on the 10th stopped all work on the land, and it has been almost impossible to get such work as earthing Celery, lifting Seakale, and other crops accomplished.—R. I.

— **GROWING VEGETABLES.**—Mr. A. Watkins sends us a copy of his "Amateur's Guide" on the above subject, and asks us what we think of it. We think that some of the best teaching is on salads, and the following paragraph is a citation from the pages:—

— **SALAD AND SALAD DRESSING.**—"The vegetable ingredients of a salad need not be many. They may consist of all Lettuce or all corn salad, or all Endive, &c., &c., with the addition of a little sliced Beetroot and Chervil (very little of the latter), and a few leaves of Tarragon, with a few spring Onions to taste; or there are twenty or thirty different vegetables suitable for making salads of, but the great secret rests in the way these articles are prepared. If washed, they should be most carefully dried with a cloth—every leaf separately; or instead of washing, clean all grit off with a slightly wet cloth, then tear up (not finely) with the fingers instead of cutting up with a knife, then add the dressing, which should consist of three parts finest Lucca oil; this should be quite smell-less and tasteless, and one part vinegar, a little made mustard, and salt. For a salad, say for three or four persons, consisting of an ordinary salad bowl two-thirds full of Lettuce, &c., take a large eup, into which put half a good teaspoonful of salt, and same of made mustard, then one tablespoonful of vinegar, and mix all up

together well with a wooden or silver fork, after which add three table-spoonfuls of best Lueca oil, beating this well up with the vinegar, &c. The dressing now made can be poured over the Lettuce, &c. The writer trusts that as many of his countrymen who read this will bear in mind that a salad is worth eating for health sake, and is worth making and dressing properly, when it becomes a palatable and enjoyable food, the first and most important thing to remember being to have the component vegetables dry, and to use the very best oil. All other things are secondary, and, in conclusion, a salad should be made and eaten at once, as soon as the dressing has been added."

— **DOUBLE MIGNONETTE.**—We are much interested in your remarks last week concerning White Mignonette, but would take the liberty to remind your readers that the true White Mignonette is always double, and though sterile in consequence of the stamens being developed into petals, these beautiful flowers may be easily raised from the seed of the few single flowers always present in a carefully selected strain. We have for many years cultivated a stock of Mignonette which produces a large percentage of these beautiful double white flowers, and although it is of course impossible to get them all true in the same way, as it is impossible to get double Petunias all true from seed, it is a strain well worth growing. These lovely flowers can then be propagated from cuttings if desired.—**SUTTON AND SONS.**

— **PRIZEWINNERS AT SHOWS.**—As an old reader of the Journal "from my youth up," and to which I owe many useful hints, kindly allow me to make an addition to your excellent report of the Bradford Chrysanthemum Show (page 451-2). I took the first prize in the open classes for two bunches of white Grapes with Muscat of Alexandria, and was first for two black with Gros Colman in competition with seven other exhibitors. May I also add that I was first and third for white and black Grapes in the local class at Leeds, five and seven entries (page 435 of Journal)? This is my first time of showing Grapes, and to be not reported in each case appears to me at least rather peculiar.—**TOM NEWBOULD, Cragg Royd Gardens, Rawdon.**—[We congratulate "Tom" his success, and, at the same time, explain that it is impossible to read the names of even half the prizewinners in the multitudinous shows at November shows.]

— **AT the annual dinner of the Highgate and District Chrysanthemum Society, Mr. H. R. Williams, the President, congratulated the members on the large number of friends they had present at their gathering. In reference to the late Exhibition which they had held, he was of opinion from his own knowledge that it was an excellent Exhibition, and of the best that he had seen in connection with societies that he knew of, and he hoped that the future shows would not only rival those that had passed, but would surpass them. He remembered the circumstances under which Chrysanthemums had been grown during the year, and he believed that gardeners would know they needed what was termed "a damping off." He believed there was at the present time 2400 or 2500 varieties of Chrysanthemums. He had seen a large number of varieties in connection with their late Show. It was his privilege, as he believed it was that of many others, to see the large Show at the Aquarium, and that gave them some idea as to the number of Chrysanthemums that were grown. Mr. Williams proceeded to enter at some length into the growth of fruit, and said we should not be so much dependant upon the foreigners as we were at present. So far as he could see there was nothing to prevent English Apples from being cultivated and kept into April and May, when they could be sold at a moderate price. In connection with the Show at Highgate recently, it did not only the Committee but others a great credit, and the neighbourhood was quite exalted by it. He called himself a Hornsey man, but as they knew, that included Highgate, for the latter was part and parcel of the same place. He considered it his duty, and the duty of everyone who resided in that particular neighbourhood, to uphold the dignity of the parish in which he lived, and he believed there were few parishes like the parish of Hornsey. He believed in its health, and he believed in a variety of causes which helped to make the place a most enjoyable one in which to reside. It was his privilege to congratulate them upon their success with the growth of the Chrysanthemum, and also the cottagers for the splendid exhibition of vegetables which they had got together. During the evening the President presented the amateurs' silver challenge cup (for the second time) to Mr. D. B. Crane, and a like honour was bestowed on Mr. C. Halsey, who exhibited in the cottagers' class. The President's medal was presented to Mr. J. Brooks, gardener to W. Reynolds, Esq., J.P.; whilst Society medals were also awarded to Mr. T. Tuck, T. Gillman, and D. B. Crane.**

— **WINTER AND SPRING FLOWER BEDS.**—If the beds are to be filled with hardy and spring flowering plants, shrubs and bulbs, advantage should be taken of the first dry time to complete this work. In many cases a thorough cleaning of the beds is all that is necessary, digging doing more harm than good. There is quite a wealth of flowering plants available, but these ought always to be well prepared for transplanting. Polyanthus are particularly good, the strains being greatly improved of late years. These are to be seen at their best in moderately large beds, masses being more effective than single lines, and if they can be given some good fresh loamy soil they will flower grandly next spring. Primroses again are much improved, and either beds or double lines of these are very showy. Masses of Myosotises, Wallflowers, Alyssums, Saponaria calabrica, Virginian Stocks, and Gypsophila elegans, appropriately edged by either Daisies, Violas, Aubrietias, Arabises, Nemophila insignis, and Silenes are also very showy during their flowering season. Much, however, depends upon the size of the plants put out, and they ought to be arranged rather closely together, as many of them will not increase in size. Small, coloured Beet, Golden Pyrethrums, variegated Thyme, Stachys lanata, and other hardy plants used in the summer arrangements may well be retained in their present positions or planted afresh, and single pieces of Yucca recurva and small clumps of Iris foetidissima variegata, are of good service for dotting. Most of the foregoing will require to be moved carefully so as to preserve a good ball of soil with the roots, and to be replanted firmly. Not many of the beds will require to be watered this season, but if there are any dry spots well water in the plants filling them.—**SOMERSET.**

— **EYNSFORD HORTICULTURAL SOCIETY CHALLENGING KENT.**—An interesting account is forwarded us of the proceedings at the dinner given to members of the Eynsford and District Cottage Gardeners' Society at the "Five Bells Inn," by Messrs. Cannell & Sons of the Swanley and Eynsford Nurseries. An invitation had been circulated among the members of the society to bring to the dinner each a dish of hot cooked Potatoes, and the first business consisted of "sampling" some twenty-five dishes of the vegetable and deciding on their various merits. After a careful test, the palm was awarded to a new variety raised by Mr. Robert Cannell, and known as "Our Seedling," the next in order of merit being Cannell's Victory, followed by White Beauty, Snowdrop, and American Rose, in the order named. After the tables had been cleared, Mr. H. Cannell occupied the chair, and Mr. J. D. Abbott, Sir W. Hart-Dyke's gardener, the vice-chair. The Chairman, after expressing the pleasure it gave him to meet the members of the society, said he had decided to offer £6 in prizes at the Society's show next year, and it was for those present that night to decide the terms of the competition. The Vice-Chairman, in proposing "That the best thanks of the Society be given to Messrs. Cannell for their generous offer," said he was sure that every member would agree with him that it was a great honour for them to have such eminent horticultural authorities as Messrs. Cannell among them, and he was sure the Chairman's able address would stimulate them to further efforts than they had yet made. It was eventually decided that the competition should take the form of a collection of eight varieties of vegetables, selected from the exhibits of the Eynsford Society on the day of the Show, matched against a similar collection of eight varieties exhibited by any other similar society in Kent, the prizes to be divided as follows:—First prize, £3; second prize, £2; and third prize, £1; the proviso being inserted that no one society should take more than one prize. The particulars of the special prize competition will be forwarded to all neighbouring societies, and it is hoped that a good show on August 17th next will result.

#### AMERICAN COWSLIPS.

SOME of the members of the Dodecatheon genus have been introduced into this country from the western hemisphere more than a century, and the American Cowslips are among the handsomest of hardy flowers. Why they are called by this fanciful name is not so easily understood. Certainly they belong to the same family as the Cowslips, but they have no resemblance whatever to the latter flowers. They belong to the Primulaceæ, and in growing them it is most beneficial to associate them with such plants as Primulas, Soldanellas, and Cyclamens. Where any of these genera will flourish they are equally happy.

If a bed is set apart after due preparation for Primulas the Dodecatheons may be depended upon to flourish as well. It is necessary that the position selected should be a moist and shady one. We have

seen Primulas planted in sunny positions, and unless constant and copious supplies of water are given them during a dry season they are literally baked. They succeed remarkably well on the rockery, planting

soil. With that treatment, however, we do not agree, knowing well that although they thrive in light peat soil, at the same time the result of experience is greatly in favour of employing light loamy soil

FIG. 88.—AMERICAN COWSLIPS.

them in shady places, readily establishing themselves, and flowering very freely.

Some growers recommend for their successful culture light peaty

leaf soil, and sharp sand, which is also an excellent soil for most of the Primulas. Planted on the rockery in a small portion of that soil they will succeed well and the result will be satisfactory.

The typical forms of *Dodecatheon* are all natives of North America; some of the varietal forms of *D. Meadia* may have originated in our gardens, or have been introduced as natural varieties, since, like almost all the genera of *Primulaceæ*, they are easily worked upon either by artificial or insect agency. They are all perennials, easily increased by division of the rootstock or from seed, although the seed if sown in spring is frequently slow in germinating—in fact we have had it germinate after being in the pots twelve months. The seed should be sown as soon as ripe, but if purchased from a seedsman it is as well not to discard it until all probability of its germination is past.

The plants produce erect racemose spikes of pendulous *Cyclamen*-like flowers during the early summer months, with the segments of the corolla sharply reflexed. The generic name assigned to these plants by Linnaeus is very absurd, as it literally means "twelve divinities," and like a multitude of other names the similarity or associations of the subjects in question with those represented only rests in a very remote region of the imagination. Below are enumerated some attractive species and varieties.

*Dodecatheon integrifolium* is widely distributed over North America, varying to some extent; it grows from 9 to 12 inches high, producing numerous spikes of bright crimson flowers, which last a considerable time in beauty. This is as handsome and durable as any of them.

*D. Jeffreyanum* is a more recent introduction than the last; it varies in height from 1 to 2 feet, usually growing about 18 inches high, producing strong scapes of bright rosy purple flowers, which are also rather larger than those of the last.

*D. Meadia* is the most common of the series, and is frequently known as the "Shooting Star of the West." It is very widely distributed throughout North America, and there is a large amount of variation, which has originated the establishment of many varietal forms. The typical form produces scapes about a foot high, bearing several flowers of lilac or rosy red colour. It is a very valuable species, and will thrive well in ordinary borders if a select position is given to it and a little attention. For growing in pots it is valuable, and the cultivator is well rewarded.

Varieties of this species worth growing are *album*, which is similar in all respects to the type, but has white flowers. *Elegans*, a charming variety; the flower scapes are freely produced, bearing several large, bright rosy lilac flowers. This is also a vigorous grower. *Carneum*, with very delicate blush flowers, produced in very large umbels. *Giganteum*, a tall-growing variety 18 inches high; the umbels large, bearing dark rose-coloured flowers. The American Cowslips represented in the illustration (fig. 88) were grown by Mr. Ware at Tottenham.

### INSECTIVOROUS PLANTS.

BEFORE a large audience at the weekly meeting of the Richmond Athenæum in the College Hall last week, the Rev. Professor Henslow, M.A., F.L.S., delivered a lecture on "Insectivorous Plants." The Rev. Astley Cooper presided. The Lecturer said that the subject was of extreme interest, and as in many similar cases they were indebted to Mr. Charles Darwin for a large amount of information on the subject. Very little had been added to the information given in his book on "Insectivorous Plants," and those who desired further information on the subject he referred to that book. In former days it was supposed to be the great distinction between animals and plants, that plants lived upon the mineral kingdom and animals lived upon the vegetable. A very large number of plants lived upon the mineral kingdom, water, gases, and things dissolved, but many can also catch flies and insects, and sometimes seeds which happen to drop upon them, and devour them. This opened our eyes to the fact that the process by which they do it must be very much like what animals and we ourselves do. The insectivorous plants were found in all parts of the vegetable kingdom. Botanists divided up plants into families, and considered all plants in one family to have a certain amount of affinity. They believed that they all came down from some ancestral form and were related. But the insectivorous plants were scattered all over the vegetable kingdom, and had no other affinity at all. The process by which they secured their prey was sometimes something like a rat-trap, sometimes a tube into which insects crawled and could not get out, sometimes a little box with a kind of lid, while others secreted a gummy fluid. These methods were found scattered about through the different families, one family adopting one method, one another, and sometimes it was found that a method adopted in one family reappeared in another. That opened out the question how had all these things arisen? The general idea was that this power had arrived somehow or other to be the common property of all plants of the vegetable kingdom; that there was in every plant a living matter called a protoplasm, which had the power of acquiring carnivorous habits under certain conditions. This would show that there was unanimity running through the whole of the vegetable kingdom. Most of the insectivorous plants were thousands

of times larger than their prey, but there was a large number of insectivorous plants which were much smaller than their prey. In that case they ate them in a different way, and these were called parasites.

The little "Sundew," which would be found growing on Hampstead Heath, was an insectivorous plant. It was found in boggy places, growing amongst the bog moss, where it was very wet, and had scarcely any roots. It produced round leaves upon long stalks, and ultimately flowers. On a bright sunny day the leaf, which is green, is covered all over with what looks like very stout hairs. Mr. Darwin suggested the term tentacles, as they were not strictly the same as hairs upon plants. Every one of them terminated with a globular head, which secreted gum. This glistened in the sun, and they thus got the name of Sundew. That was its condition when it was ready to catch flies. It was unknown what attracted insects, but insects were constantly found on them. If a person took a minute fragment of hard-boiled egg or little bit of meat and laid it on the top of one of these long tentacles, the food immediately sank through the gum and reached the gland, as botanists called it, and in a very short time a curious phenomenon took place. The tentacle began to secrete, the gummy fluid became acid, and the tentacle began to bend in slightly towards the middle, carrying the particle of food which had been placed upon it into the centre of the leaf. The glands instantly began to pour out the acid as well, and what was still more remarkable, though none of the other tentacles had been touched, they all knew that there was something to eat in the middle of the leaf, and would slowly bend over until every one of them had placed its gland upon the bit of meat that had been put there. All began to pour out this acid, and they did it before they touched the meat—their mouths began to water, to use a metaphorical expression. It was a kind of reflex action caused by the irritation set up. The same effect was caused, said the Professor, when a human being began to eat anything. After everything had been digested which the plant could digest the plant resumed its normal habit, what remained of the fly, or whatever it was, is thrown off, and the leaf is ready for another prey. It had been asked what was the use of this food? could not the animal live without it? Dr. Francis Darwin, with a view to testing this, experimented with two lots of insectivorous water plants. One lot he fed regularly, and the other lot he gave nothing to but the water they grew in. The plants that were fed looked much better than the others. The weight of their seed was as 157 to 100, the number of their seed was as 141 to 100, and the number of capsules produced was as 194 to 100. This showed that the great effect lay in the reproductive process. Parasitic plants, such as Broom Rapes, Dodders, and others lived on their hosts, and while they never made any green leaves always abounded in an enormous quantity of seeds. The benefit in the fed plants was in the reproductive process, the foliage part became terribly degraded and vanished altogether.

A curious thing was that what was indigestible to a human being had the same effect on a plant. If a piece of cheese was put on the leaf the plant would pour out an enormous quantity of acid in order to manage it. It was the same with them. They took cheese as a rule after dinner, when the fluid secreted to digest the cheese attacked the other food and left the cheese undigested. He next dealt with a plant which was found abroad called "Venus's Fly-trap." Each leaf was fitted with a kind of winged stalk. There were prominent bristles on the inner face of each half of the blade. On the slightest touch the blades collapsed and went together like a rat trap. They did not at first close very tight, and a small insect might escape; but if a blue-bottle got in the more it struggled the tighter the blades closed, and it could not possibly get out. This action bore some analogy to the action of a human muscle. Having described the action of the Sensitive Plant when touched he passed on to a little plant which lived much in water—the Aldrovanda. It had a large quantity of bristles all over the middle, covered with glands, and groups of four cells. If the plant had got any little water prey the glands secreted. Then there was a little water plant generally found in muddy ditches. It had little black knobs that were once supposed to be floats, but were now known to be traps for catching insects. The little hollow bladders with hairs protruding made something of a hollow cone. When insects got into the hole it was impossible for them to get out again, as there was a flap which covered the hole, which they could not lift up. That plant had got no glands with which to secrete the digestive fluid, but instead was covered all over on the inside with quadrid process. Nothing it was now known could decay without the bacillus or microbe to do the work. Those microbes, of which we heard so much, set up a ferment. Thunder weather was a very favourable condition for the aggregation of microbes, and thus it was that the milk went sour so much more quickly. Of those insectivorous plants some required microbes to bring out putrefaction in the animal, and those quadrid processes absorbed the decayed food. Another plant was one called the Bladder-wort, and another the Butter-wort. They were found abundantly in the west of England and in Wales. The leaves were covered all over with glands, and the glands looked like complicated buttons under a microscope. Their cells radiated from a centre, and the crimped-in edges stood on a little pedestal or stalk. If a fly or anything else fell upon it the margin of the leaf began to roll over, and enclosed the insect.

The fermenting glands were the next things in plants. Very often they secreted oils, as in Lavender, and they were believed by botanists in other plants to be the means of easting off excretions which the plant did not require. There was a foreign tree called the Papaw, and it was a common habit to take the leaves of this tree in which to wrap tough meat. The plant had a power of secreting a nitrogenous ferment, which,

coming into contact with the meat, made it tender. It was just the commencement of digestion by the plant. The tree was now made use of in what were called Papaw pills for indigestion. There was a family of plants called the *Sarracenia*. On examining the interior it was found that the ledge was covered with hairs. Then there was a number of little glands which secreted honey and attracted the insects. As soon as the insect got on the hairs these gave it no foothold, and it had to go downwards. Under certain atmospheric and other conditions insects and flies got caught in such enormous numbers that they died, decayed, and the whole pitcher rolled to pieces. There was also what was called the true Pitcher-plant. *Nepenthes* was the name of it. It was found in the Malay Islands, where it abounded. It secreted water, and the insect was drowned. The insects got caught in great quantities, and there was no doubt whatever that the plant absorbed them. With respect further to the ferment process, it was the same which we saw in operation in seeds which were sown in the spring or in the winter. It was a wonder to many how a seed with no root could remain in the soil without nourishment. But it did not go without nourishment. A grain of Wheat possessed the vital principle in a granule at the end. The rest was that upon which this vital principle was sustained and which caused it to send forth roots downwards, and to sprout upwards into the sunlight and air. The lecturer then gave the principal components of Wheat, and pointed out that the least nutritious part was that which went to form white bread. Our digestive organs did exactly the same thing as the embryo in a plant. When we called ourselves human beings there was no essential difference. There was unity with diversity running throughout the whole.

Much interesting discussion followed the lecture, and a cordial vote of thanks to Mr. Henslow concluded the proceedings.

GOOD VARIETIES OF ROSES.

ALTHOUGH the lateness of the season deprived us of outdoor Roses in quantity till the middle of June, we have had no reason to complain of either the quantity or quality of the blooms at our disposal since that time, as we have been able to cut a continuous succession up to the present time (October 23rd), and it would be hard indeed to find any other hardy plant, shrub, or tree which would yield such a long succession of fine flowers. It is therefore no wonder that the Rose still maintains such a firm hold on the affections of the British people, combining as the flowers do in so eminent a degree the three essential qualities which all flowers require to enable them to approach a high standard of perfection—viz., a pleasing scent, good colour, and fine form. The scent of the Rose is acknowledged to be perfect, the colours of some of the varieties are among the loveliest, and the half-opened buds of many kinds of Teas are such models of exquisite form, that no one could suggest an improvement. Add to these good qualities the hardiness of the plant which bears these floral beauties, and there seems no reason to doubt that the Rose will still remain the queen of flowers. Here Roses are great favourites, and are preferred to all other flowers for the embellishment of the breakfast table, and for placing in small specimen glasses to be arranged in groups according to their colours. In consequence of the great demand for them we grow them extensively, and give them special attention. All varieties are prized, and many old kinds that are seldom met with are cherished here for the wealth of bloom they produce or for some special quality they possess. Although old Roses are grown in quantity and well cared for new varieties are not neglected; the aim is to get plenty of Roses and plenty of variety among them, and being favoured with many warm sheltered spots, where climbing kinds can be trained against walls, we manage to have a long season for Roses in the open air. Even now we have quantities of fine Teas in positions so sheltered that they will require very sharp frosts to injure them. Now that the planting season has arrived a few remarks on some sterling kinds may be of service to readers of the Journal who contemplate planting.

Among Hybrid Perpetuals A. K. Williams has with us produced some exceptionally fine flowers of good form, and being a vigorous grower should be in every collection. *Boule de Neige*, though only a small flower, is the purest white Rose among this section that I am acquainted with, and produces quantities of flowers throughout the summer, and is also a good late bloomer; flowers are even now opening daily on bushes in an open and exposed position. Captain Christy is a very free-flowering kind of a soft flesh colour, but unfortunately the flowers with us do not open well, the outer petals becoming slightly browned before they are fully developed, while other varieties growing beside them thrive remarkably well. *Queen of Queens* and *Madame Marie Verdier* produce flowers of an exquisite rose colour, which seem to be always admired, and deservedly so, their colours appear so fresh and pleasing. *Dupuy Jamain* and *Fisher Holmes* are fine deep coloured flowers of good form. The finest of all crimson scarlet flowers with us this season has been *Mrs. Harry Turner*, being good alike in size, form, and colour; it has given us the best blooms of the season. That old favourite, *Général Jacqueminot*, still attracts great attention, and surpasses many more

recent introductions. John Hopper is one of the most abundant bloomers, the flowers being of a pleasing shade of rose. Jules Margottin has both a peculiar and pleasant scent, and a bright cheerful colour; and the beauties of *La France* are so well known as to need no farther comment. *Louis Van Houtte* is conspicuous and beautiful on account of its fine broad petals and good form. *Marquise de Castellane* is an unique Rose, of a bright rose colour, tinted with silver.

*Merveille de Lyon* is the grandest of all light coloured Roses, the flowers being of extra large size, well formed, and the growth made being very vigorous. Other fine varieties are *Pride of Waltham*, flesh colour; *Prince Camille de Rohan*, dark crimson; *Sénateur Vaisse* and *Thomas Mills*, both bright red; and *Ulrich Brunner*, flowers very large, cherry red.

#### TEA-SCENTED.

Although the flowers of the many varieties in this section are not so showy as the Hybrid Perpetuals, their delicate, waxy-looking petals, which possess so many beautiful tints of colour, and their delicious scent cause them to be more highly prized than their hardier companions.

*Anna Olivier* is a large and beautiful flesh coloured flower, the petals of which are particularly smooth and glossy. *Catherine Mermet* is a grand variety, bearing light, flesh-coloured flowers. To grow them to perfection they require the protection of a wall, or a position under glass. Climbing *Devoniensis* is a very strong grower, and on that account is extremely valuable for covering high walls, and few creamy white flowers are more beautiful than those which this fine variety produce. *Duc de Magenta* has very sweet flowers of a salmon-rose colour, and is especially suitable for growing as bushes. *Innocente Pirola* is a lovely flower, both in its pure white form, and also when, as is sometimes the case, a pink tint is present. *Ma Capucine*, W. Allen Richardson, and *L'Ideale* are three very attractive varieties, the flowers of which are various shades of coppery yellow. It is a wonder they are not more generally grown. Of the three I prefer the first named, which is a seedling from *Ophirie*. *Ophirie* is also an excellent Rose for covering walls, as it produces great numbers of medium-sized blooms of a peculiar rose colour. It is a very old Rose, but it is highly prized here. *Madame Lambard*, being of a bright red colour, is perhaps the most striking among Tea Roses, its form also in the bud is perfect. *Madame de Watteville*, white-salmon tint, is both remarkable and beautiful. *Marie Van Houtte*, pale yellow, is one of the gems of this section of Roses.

*Niphetos*, and its climbing form, are indispensable white varieties. *Perle des Jardins* is another fine yellow Rose, especially in soils where the flowers attain that desirable canary yellow colour. *Reine Marie Henriette* in habit and vigour of growth resembles the well-known *Gloire de Dijon*, but the colour is red, and as may be supposed, is a most useful and beautiful kind. *Safrano* and *Madame Falcot* are apricot and pale yellow in colour respectively, and delightful Roses in the bud, and are well adapted for training against walls. The *Bride*, a new American sport from *Catherine Mermet*, resembling its parent in all points except the colour, which is ivory white.

Where Roses are planted in beds or against walls they well repay special attention in the preparation of the soil. This should be dug to a depth of at least 2 feet, and in damp positions have 6 inches of broken bricks or old mortar rubbish placed at the bottom to provide drainage. It is not everyone that can obtain good turfy loam for placing upon Rose beds, but where such can be had there is no question about the fine results which may be obtained by using it, and if only a small quantity can be spared for the purpose, this should be placed in immediate contact with the roots to induce quick and healthy root-action. A good layer of soot and wood ashes in equal quantities should be mixed with soil as the work of digging proceeds. The soil should also be enriched with well rotted manure. This should, however, be kept away from the roots at planting time.—D. W. C.

#### CHOICE ROSES FOR GENERAL CULTIVATION.

I AM not at all surprised that "W. R. Raillem" does not consider the list of Roses I recommended for general cultivation at the end of my last analysis to be as perfect as it should be. The fact is, no two rosarians, however experienced, would recommend for this or any other purpose precisely the same varieties.

As your correspondent justly says, "It is indeed an awkward task to make out a list of a certain number of best Roses suitable for all and sundry." In the first place soils and climates differ greatly, so that we occasionally come across varieties which are easy enough to manage in one locality, but which refuse to grow in others. For instance, I have eight-year-old plants of *Horace Vernet* on three different stocks, including the *Manetti*, which still continue to thrive and flower well; whereas *Xavier Olibo*, which "W. R. R." finds "not more difficult to grow" than *Horace Vernet*, I failed to keep alive on any of these three stocks; indeed, after persevering with this beautiful H.P. for five years I was at last reluctantly compelled to discard it from my collection.

Then, again, it is not the number of reliable Roses which puzzles the compiler of a selection of this kind, but their scarcity. He is, therefore, obliged to introduce a good many varieties which for some quality or other do not come up to the ideal standard he has set up for his guidance. For example, no choice selection would be considered complete without a few "dark velvety crimson" Roses, and yet I do not myself know a single variety of this colour which I could thoroughly recommend for ordinary garden cultivation. In my opinion such a Rose should be a good grower and certain flowerer. It should have a sound and hardy constitution and be little subject to mildew, while its blooms should be

sufficiently good to bear critical examination. The only dark velvety crimson Rose in my collection which comes sufficiently near this standard is Louis Van Houtte, which unfortunately in many localities is looked upon as but a miffy grower.

This year, almost in despair, I inserted Prince Camille de Rohan as being at all events more reliable than most dark Roses, although in other respects much below the above standard. And now "W. R. R.," in his good humoured way, pounces down on this poor *dernier ressort* of mine, with the cutting remark that "Prince C. de Rohan is lucky to find a place." If we only had a number of Roses in different colours as sound in constitution and as vigorous in growth as Ulrich Brunner, bearing flowers as freely as La France and as perfect as A. K. Williams, all our difficulties would at once disappear, and anyone with the least knowledge of the subject might be entrusted with the task of drawing up a select list which would satisfy even so practical and experienced a rosarian as W. R. Raillem himself.—E. M., *Berkhampstead*.

### THE VALUE OF HORTICULTURAL EXHIBITIONS.

A MEETING was held on the 18th inst. in the Guildhall, of the Devon and Exeter Gardeners' Mutual Improvement Association. Mr. G. D. Cann was unanimously voted to the chair, and he was supported by Messrs. A. Hope and T. E. Bartlett (Joint Secretaries), Franklin, J. E. Ebbutt, W. Vicary, W. Andrews, A. George, S. Radley, G. B. Lansdale, W. Webber, J. Gidley, F. Stone, J. Beazley, McCormick, James, &c.

The Chairman said that he had great pleasure in acceding to the request made to him that evening. No one was more capable of reading a paper on "Horticultural Shows" than Mr. Bartlett, who was a practical gardener, had been a large exhibitor, and now rendered great assistance to the Horticultural Society. The Gardeners' Improvement Association was greatly connected with the Horticultural Society, and this fact gave him (Mr. Cann) great pleasure in supporting the former.

Mr. T. E. Bartlett then read a paper on "The Value of Horticultural Exhibitions." He said:—Exhibitions, or flower shows as they are more commonly called, provide great pleasure and instruction to great numbers of people. The lovers of plants and flowers look forward to the show as the great event of the season. I wonder how many, when they go to these Shows, consider the value and benefit of them to the people of this country and its commerce. I hope, in this paper, to show a few of the benefits and advantages derived from exhibitions. Take, for example, the Chrysanthemum. Could they have attained their present state of perfection without the annual shows held in almost every town in the country? It is the same with the Rose, in fact everything, no matter whether flowers, fruit, or vegetables; since exhibitions have become so popular the improvement is truly amazing. Mr. Powell has given us a very able paper on the Apple and its culture, and I feel sure it will be a stimulant to every member of this Association. There are many things we know all about, or think we do, but we are so liable to be indifferent and careless, we want quickening up sometimes. I feel sure that next year we shall see the result in the way of finer fruit, better quality, and more exhibitors. The "Apple and Pear Fairs," held in the Lower Market, did a great deal of good in the classification of fruits and in showing the grower how necessary it is to keep the different varieties separate, and send to the market unmixed fruit.

To be successful at an exhibition should be the aim of every gardener. It is the stepping-stone to success in this life. If a man wishes to be a judge at some neighbouring show, what greater recommendation can he have than that he has been a successful exhibitor? He will soon be wanted. He must make a name for himself before he can expect to be placed in a position of confidence. It is no slight matter to judge between competitions, for there will be much judging going on afterwards by visitors, when every man will consider himself a good judge, and talk largely, if not wisely. Woe betide the judge if he has made a mistake. Public opinion will be against him, which no man can stand against, and is a very difficult thing to live down, and then there is the feeling of having wronged someone. But to gain a name requires great ambition and perseverance, and what is there to equal a show in fostering ambition?

The old order of things is fast passing away, but people must still be amused. The old-fashioned country fairs are now almost a thing of the past—and a good thing, too, for the morals of our young people. Now exhibitions take their place in a great measure, and where would the dividends of the railway companies be without them? All through the summer months they are running excursions to some exhibition or other, and I will venture to say that if you stop exhibitions the railways will cease paying such big dividends, and shareholders, in turn, will stop paying gardeners, and gardening would stand still to a certain extent.

From a gardener's point of view the advantages derived from exhibitions are very great, especially the prize money. As a rule, gardeners are very poorly paid considering the ability, skill, and tact that has to be brought to bear in the discharge of their duties. The prize money means a good deal; sometimes a new dress, a new bonnet for his wife, some new boots for the children, a trip to the seaside, or, perhaps (which I hope doesn't happen very often), to pay a doctor's bill. What chance would a man have of seeing the different parts of the country without exhibitions, for then there would be no cheap excursions or prize money to pay the necessary expenses.

Exhibitions are of great advantage to cottagers; not so much for the value of the prizes for which they compete as the better cultivation

of their gardens. When I have been judging "allotments and gardens" I have always found that those of the competitors are far better in every respect than their neighbours who do not compete. To a cottager nothing is more profitable; it takes up a deal of time, we know, but would he be doing anything else during the summer evenings which would be half so profitable? Moreover, it gives him something to think about, keeps him out of bad company, and gives him greater self-respect, and enables him to do well in life.

I have endeavoured to show the value of exhibitions in a few ways, and claim for it the lead of most of the industries of the country, and will now proceed to show the advantages gained by employers. Their gardeners go to the show and learn many things, make comparisons between different exhibits, and go home and look over the gardens under their charge. They see whether they could compete with those things at the show, with the result that when they are behind they work the harder to pull up, and try to grow things equal to those at the shows, which must be a great gain to their employers. I think I cannot close my essay without adding the Hon. H. G. Eastman's very excellent advice to the students of Eastman's Business College:—"My students, you are the architects of your own fortunes. Rely on your own strength of body and soul. Select some specialty for your life's work, and adhere to Paul's precept, 'This one thing I do.' Let your star be industry, self-reliance, faith, and honesty, and inscribe on your banner 'Luck is a fool, and Pluck is a hero.' Earnest effort in one direction is the surest road to health and high position. Don't take too much advice, keep at the helm, steer your own ship, and remember that the great art of commanding is to take on yourself the largest share of the work. Don't practise too much humility. Think well of your own self. Strike out. Assume your own position. It is the jostlings and joltings of life that bring great men to the surface. Turn a raft of logs down a millrace and the largest come to the top. Put Potatoes in a cart over a rough road and the small Potatoes go to the bottom. Rise above the envious and jealous. Fire above the mark you intend to hit. Energy, invincible determination, with a right motive, are the levers that move the world. Don't drink, don't chew, don't smoke, don't swear, don't deceive, don't read novels. Be in earnest, be self-reliant, be generous. There are two sides to every balance, and favours thrown in on one side of the scales are sure to be reciprocated on the other. Be civil, be a gentleman. It is a foolish man that does not understand that molasses will catch more flies than vinegar. Read the papers, they are the educators of the people; advertise your business. Make money and do good with it. Love God and your fellow men. Love truth and virtue. Love your country and obey its laws."

### A VISIT TO SLOUGH.

A FEW days ago I had the pleasure of going round the Royal Nurseries, where good things of many sorts are always to be seen well grown. The popular Chrysanthemum is there in great numbers, three large houses being devoted to the plants. Many varieties are grown, the object being not particularly large blooms, but dwarf sturdy plants with a profusion of flowers. The collection contains all the leading sorts, but I will name a few of the best only. The well known and much appreciated Avalanche was to be seen in splendid form; Belle Paule looked charming. Of the yellows Mr. H. Cannell and Mrs. Norman Davis were undoubtedly the best. Mons. Freeman was one of the most beautiful, the silvery rose coloured flowers being very striking amongst such darker varieties as Edwin Molyneux, Mons. Bernard, Mons. Garnier, Mons. W. Holmes, all of which are too well known to need any description here.

One of the houses, a long span-roof, was filled entirely with Princess Teck planted out in the border, and, though later than the other groups, the plants were showing some thousands of fine buds, and the blooms will be valuable in due time. Another variety very largely grown is Mons. Vivand Morel, the flowers of which are large and almost white; it is at Slough considered one of the very best for cutting purposes. A striking variety is Louis Boehmer, but these hairy-petalled sorts do not appear to be very popular, though they are effective when introduced into a group.

The Pelargoniums were next visited. They were in the best of condition, and will no doubt uphold the high reputation the firm has so deservedly gained as growers of them.

Of the Carnations and Picotees, there were many of the perpetual flowering sorts to be seen just now, amongst them Andalusia, one of the best for winter flowering, the primrose yellow-fringed flowers being very beautiful. Herald, a crimson, is a charming variety; as also is A. H. Kennedy, bright scarlet. Amongst the pure whites it would, I imagine, be difficult to find one superior to Vesta. Germania is one of the best of the yellows, and is consequently in great demand. Mrs. Reynolds Hole has also many admirers. All the plants are looking remarkably healthy, a credit both to the firm and to Mr. John Ball, the able and genial grower.

The Auriculas are also in excellent condition, and promise an abundance of splendid flowers. The Ivy-leaf Pelargonium Souvenir de Charles Turner arrested attention. For bedding, or in fact any other purpose, it stands pre-eminent; its very deep rose-coloured flowers, on each petal of which is to be seen a dark blotch, are very large, double, and freely produced, having a most pleasing effect.

Out of doors, amongst the thousands of fruit trees, all was bustle and life; enormous packages and bundles being sent away daily. After

a short chat with Mrs. Chas. Turner, I journeyed homewards, having passed one of the most pleasant hours amongst the flowers one could wish to experience.—AN AMATEUR.

## TWENTY-ONE WINTERS IN LONDON.

THE meteorological correspondent of the "Daily News" writes:—There lies before us a detailed record of the weather experienced in London during the past twenty-one winters. There have been seasons, like the last of the series, in which the winter has been attended by a serious amount of frost, of fog, and of snow; and there have been others in which the season has come to us on the wings of mild breezes wafted from the Atlantic, and in which cold weather, fogs, and snowstorms have been almost unknown. Take first the question of temperature—the most important element of all in the weather of the winter—and see how great has been the difference between the conditions prevailing in various seasons. Compare, for example, the weather of last winter, when hard frost prevailed in London throughout the whole of fourteen days, and when the thermometer sheltered in a screen fell to the freezing point or below on no fewer than sixty-five nights, with the mild season of 1876–77, when the maximum temperature of the coldest day was as high as 38°, and the number of frosty nights was only sixteen; or with the season of 1883–84, when frost occurred in the screen on nine occasions only. No less striking a contrast is afforded by the absolute minimum for the winter which, in the season of 1880–81, was as low as 9°, and in 1870–71 as low as 10°, but which in the winter of 1883–84 was as high as 28°. But no matter how cold the winter the temperature in London almost always succeeds in rising to 55° or more, and in three seasons out of the one-and-twenty it rose above 60°. It is not a little strange that notwithstanding the long-continued frost of last winter the thermometer at the close of the season reached a maximum of 62°, a reading which had only one equal in the winters of the previous twenty years.

Fog—another very important element in our London weather—also shows great variation in its prevalence. Last winter the number of days with fog was fifty, or just twice as many as the average for the previous twenty seasons. The cold season of 1879–80 came next with forty-three days of fog, but in the winter of 1871–72 there were only ten such days, and in that of 1876–77 only nine. Last winter we had, in short, nearly six times as much fog in London as we had in the winter of 1876–77. We find some explanation of the clearness of the latter season in the fact that with one exception gales were more numerous than in any other winter of the series. In the season of 1875–76, and again last winter, there were only two gales in London, and neither of them was severe; but in 1876–77 and in 1884–85 there were as many as thirteen gales, while in the seasons of 1882–83 and 1883–84 there were no fewer than eleven. The greatest number of severe gales occurred in the winter of 1883–84, when there were four occasions on which the wind reached force 10, or what is known among sailors as a "whole" gale. Snow also shows great variation in frequency and amount. Last winter the number of days on which snow fell was twenty-two, as against an average for the previous twenty years of twelve. It was, however, equally prevalent in the winter of 1887–88, and far more so in the seasons of 1878–79 and 1870–71, the number of days in the last-mentioned period being thirty. Against these we may set the winter of 1883–84, when there were only four days with snow; the season of 1876–77, when there were only three; and the still more remarkable season of 1881–82, when snow fell on two days only. The worst snowstorm of the whole twenty-one years was undoubtedly that of January 18th, 1881; but the storm which occurred on Boxing Day in 1886 was almost as severe, and far more disastrous in its effects, the damage to the telegraph wires in the latter case being the most serious and widespread ever recorded in this country. The amount of sunshine registered in the metropolis also varies greatly in different winters. The records of this element only cover fifteen winters, but in this space of time we have had one season (that of 1887–88) with a total of only sixty hours, while there has been another (that of 1886–87) with a total of 129 hours. In the former period the sun shone on an average for rather less than three-quarters of an hour each day, while in the latter case the daily average amounted to nearly an hour and a half, the nominal amount for fourteen winters being just one hour per day. Last winter there were forty-eight days without so much as a gleam of sunshine, while in the season of 1876–77 there were as many as fifty-nine sunless days, but in 1879–80 there were only thirty-nine.

The amount of rainfall shows variations quite as large as those exhibited by the other elements. Last winter and also in that of 1873–4 the aggregate fall in London was only about 2½ inches, but in the mild season of 1876–7 it amounted to over 12 inches and a quarter, and was nearly five times as much as in the two dry seasons just mentioned. The number of days with rain was rather more than twice as great in the wettest as it was in the driest seasons. The heaviest fall recorded in London on any one day in the course of the twenty-one winters occurred on Boxing Day, 1886, in connection with the great snowstorm to which we have already alluded. The snow was preceded by a somewhat heavy fall of rain, and the combined amount collected in the gauge was as much as 1.82 inches. In the storm of January, 1881, the snowfall was quite as abundant, but its consistency was far lighter, and the gale which accompanied it served to bring about great variations in the depth. In London the amount when melted in the gauge yielded only 0.3 inch of water. In conclusion it may perhaps be asked, "What guide is afforded by the twenty-one years' record as to the weather which is likely to

prevail during the coming winter?" And to this question there can be only one answer. The most qualified authorities are unanimously of opinion that in the matter of weather precedents count for nothing. A bad winter is more often than not followed by an inclement summer, and of that we have had a very forcible illustration during the present year. A hard winter is, however, by no means indicative of another equally bad season; and although such winters often run in pairs the frequency of such a combination is not sufficiently marked to admit of any forecast.

## SMALL SEEDS IN SEED PANS.

I THINK perhaps the raisers of plants from small seeds in seed pans may wish to know how I have got over all the difficulties in saving the young plants from their various enemies. In adopting my plan the delicate plants are perfectly free from the following destructive creatures—viz., worms, slugs, snails, woodlice, frogs, toads, or mice; whereas formerly my success was much hindered by them. The sketch accompanying shows one of my seed pans, about 12 inches in diameter, plunged in a warm bed in my vinery, varying in temperature from 60° to 70° Fahr., the usual drainage holes being corked up to prevent worms entering. I am careful, of course, not to overwater the pans. The pan has a channel round the upper edge for holding water that no small creatures may gain access to the plants, such as woodlice, slugs,

FIG. 89.—IMPROVED SEED PAN.

or snails. A handlight placed over prevents mice from scratching the soil and eating Marrow or Cucumber seeds, and toads or frogs from burying themselves and disturbing the seeds. These precautionary measures give a fair chance to the young plants. The handlight may be shaded by paper or whiting when the sun is too strong. The seed pans may be plunged or not, may be indoors or out, according to the season. I have one pan full of Auriculas from choice seed, lately come up, and plunged in a gentle hotbed. I can leave it a day or two without attention, feeling sure that it will be quite safe and right in my absence. During the last spring and summer I have used these pans with perfect success.—WM. MOODY BELL, *Cheltenham*.

[This seed pan appears to be good, and if made for sale would probably find purchasers if advertised.]

## CHRYSANTHEMUM SHOWS.

WOKINGHAM.—NOVEMBER 18TH AND 19TH.

This Society held their seventh annual Show in the Drill Hall on the above dates, and was a fairly good one. Most of the classes were open. For twelve incurved, distinct, Mr. W. Lane, gardener to Miss J. D. Smith, King's Ride, Ascot, was first with an even stand. Back row: Golden Queen, A. Salter, Queen of England, Lord Alcester. Second row: Lady Dorothy, Miss Haggas, Lord Wolseley, Golden Empress. Front row: Mrs. Heales, Angelina, Beauty, Barbara. Mr. H. Godfrey, Ribsdon Hill, Bagshot, was a very close second.

Twelve Japanese, distinct, brought a very fine display. Mr. Trinder, gardener to Sir H. Mildmay, Bart., Dogmersfield Park, was a good first with very heavy blooms, consisting of Sunflower, Condor, Louis Boehmer, Stanstead White, Carew Underwood, Etoile de Lyon, Boule d'Or, Madame J. Laing, Avalanche, Mrs. F. Jameson, M. E. A. Carrière, Mrs. C. Wheeler, a grand bloom, selected for the prize for the best Japanese bloom. Mr. Lane was second, and Mr. Godfrey third.

For six reflexed, distinct, Mr. Godfrey was first with fine blooms of Cloth of Gold, Cullingfordi, Pink Christine, White Christine, Golden Christine, and Fred Hart. Mr. Poppel, gardener to Sir A. K. Stephney,

Wood End, Aseot, second. This exhibitor also took the prize for the best incurved bloom—a fine Lady Dorothy (very deep). Class 6 was for twelve distinct, any varieties, to be shown with 9 inches of stem above the board, and here Mr. Trinder was again first, showing all Japanese, amongst them being a very fine bloom of Mrs. Alpheus Hardy. Mr. Godfrey was second with mixed incurved and Japanese. Mr. Lane third.

Groups do not call for special comment. Mr. Bungay, gardener to Sir W. Morshead, Forest Lodge, Binfield, was first. B. E. Cammell, Esq., Foley Court, Wokingham, second. Mr. Bungay was also first for a miscellaneous group. Mr. Lane had the best table plants. Mr. Cooper, The Vineries, Sunninghill, was first for Grapes, having good Alicante. Mr. Ashman, Billingbear Park, second. Mr. Godfrey had the best kitchen and dessert Apples, and Mr. Trinder was first for four dishes of Pears. Messrs. Sutton & Sons offered prizes for vegetables; Messrs. Lane, Bungay, Ashman, and Popple taking the prizes in the order named. The arrangements of the Show were excellent, and reflect great credit on Mr. T. Bedford, the Hon. Secretary, and Committee.

#### CARDIFF.

THE fifth annual Show was held on the 18th and 19th in the Park Hall, and, all things considered, the venture was highly satisfactory. We believe the Society will be enabled in the future to extend their list of prizes, and thereby induce some of the larger growers to enter the lists in the open classes. The Society is affiliated to the N.C.S., whose certificate was given for best twenty-four blooms, but on account of the earliness of the season in the district the exhibit winning the coveted parchment was not such as would rejoice the heart of a Tunnington or Molyneux. We believe that a fortnight ago the same exhibitor would have been able to stage very different blooms. A great improvement was noticeable in the groups this year, both in the open and amateurs' classes; some of the latter indeed might have entered with advantage in the former class, so even were their merits.

The largest class was for twenty-four distinct blooms, for which the N.C. certificate was given, Mr. W. Treseder, Cardiff, being first. T. J. Masters, Esq., Lanelly (Mr. Howe, gardener), was second; and Mr. F. Case, Cardiff, third. For twelve incurved, distinct, Mr. Howe was first with clean blooms of some of the leading varieties, followed by Mr. W. Treseder and Mr. F. Case, second and third. Twelve Japanese, distinct, brought out some very fine blooms, Mr. Hawkins, gardener to Colonel Turberville, Ewenny, being first; Messrs. Treseder and Case being again second and third respectively.

First and second for groups in the open class were taken by Mr. W. Treseder and Mr. F. Case. For groups in the amateurs' division Dr. Wallace, Howard Lodge, was first; Colonel Page, Llandaff (Mr. Hockey, gardener), second; and Mrs. Thomas, The Heath (Mr. Fisher, gardener), third; Dr. Wallace also taking the N.C. silver medal.

In the amateurs' division, cut flowers, for twelve blooms, Japanese, six varieties, Mr. Hawkins staged the best blooms in the Show, his Belle Paule, Mrs. Beale, Avalanche, Sunflower, Mr. H. Cannell, and Etoile de Lyon being splendid examples. Mr. Hockey, Llandaff, followed second with nice blooms, and Mr. Howe third. J. A. Orr, Esq., of Canton, was first for twelve Anemones, six varieties. Mr. Prosser, gardener to W. S. Ogden, Esq., Hatherleigh, Maindee, second. Twelve incurved, six varieties, Mr. Ryder, gardener to M. Gunn, Esq., Canton, was first; Mr. Hockey second; and Mr. Howe third. The competition for single specimen was good, but the same can hardly be said of the specimens themselves as such.

Table plants were numerous and good. For best six, Mr. Curry, gardener to E. M. Hann, Esq., Aberdare, took first, Mr. G. Clark second, and Mr. Hockey third. For four stove and greenhouse Ferns, Mr. Seott, gardener to J. Howell, Esq., was first; Mr. Clark, gardener to Colonel Hill, C.B., M.P., second, and Mr. Malpass, gardener to C. E. Jenkins, Esq., Penglan, third. For six Ferns, distinct, in 6-inch pots, Mr. Hockey first, A. Duncan, Esq., second, and Mr. Clark, Llandaff, third. Foliage Begonias were a feature, Mr. Ryder, Canton, as usual being first, Mrs. Kelly, Llandaff Road, second. Special prizes given by Mr. W. Treseder for twelve Chinese Primulas were taken by Mr. J. P. Jones, Penarth, Mr. Clark, Llandaff, and Mrs. Kelly, Llandaff, in the order named. Mr. Fisher, Heath Gardens, took the prize for best blooms of Mrs. Alpheus Hardy Chrysanthemum, and also the N.C.S. certificate for the same bloom. For six Chinese Primulas Mr. S. Grey, Canton, first, Mr. Fisher, The Heath, second, and Mr. A. Duncan third. Whilst for four double ditto, Mrs. Kelly, and Mr. Duncan took first and second.

The fruit exhibits were exceedingly fine in all classes, Apples and Pears particularly so. Mr. Hawkins was first for collection and Mr. F. Case second. Mr. Prosser first for two bunches black Grapes, Mr. Hawkins second, and Mr. Malpass third. Mr. Hawkins being first for two white, Mr. Ryder second, Mr. Davies, Aberaman, third. The principal prizetakers in hardy fruit being Mr. Rex, gardener to C. Waldron, Esq., Llandaff, Mr. Kelly, Mr. Pugsley, gardener to General Lee, Dynas Powis, Mr. Julian, Llandaff, Mr. Hawkins, Mr. Ryder, Mr. Malpass, and Mr. Hockey. The latter's collection of Apples, twelve dishes, six dessert and six culinary, were indeed a splendid feature, as were also a single dish of Peasgood's Nonesuch.

The vegetables also were good, chief awards going to Mr. G. Shewring, Llandaff; Mr. Geo. Clarke, Canton; and Mr. Pugsley. In looking at the collections staged by Mr. Malpass and others, we felt that the Committee might do well in future to make a separate class for market growers, private gardeners being necessarily handicapped in competition

with such. Mr. G. Clark, Mr. Hawkins, and Mr. Case took the awards for Tomatoes with extra fine dishes, and Mr. Hockey for best basket of salad. Messrs. Case and Crossling divided the honours for bouquets and wreaths in the open, Messrs. Hockey and T. Malpass doing likewise in the amateurs' class. The Committee are to be congratulated on the result of their efforts in the encouragement of floriculture among cottagers; the fruit, plants, and cut blooms exhibited by these were highly creditable to all concerned. Trade exhibits were confined to W. Treseder, Cardiff, stand of sundries; and Messrs. Clibran of Altrincham, stands of newest varieties of Chrysanthemums, for which the Society awarded a certificate of merit.—MUM.

#### BRENTWOOD.—NOVEMBER 19TH.

THE above-named Show was held in the Drill Hill, Ongar Road, Brentwood, and proved to be one of the best the Society has yet had. The groups were numerous, and the quality a great deal in advance of what has been seen previously at Brentwood. The cut blooms made a grand show, the competition in all the classes being very keen. Fruit was well shown. Particularly noticeable were the six dishes of culinary Apples exhibited by Mr. W. Goaring, gardener to C. J. H. Tower, Esq., Weald Hall. Messrs. Cheal of Crawley staged a magnificent collection of Apples and Pears not for competition, so also did Mr. Goaring. Mr. Breenes of Warley and Mr. Winter of Kelvedon Hatch exhibited splendid honey. The attendance was most satisfactory, and the arrangements were most carefully carried out by Mr. Thos. Haws.

The leading exhibitors in the groups were Messrs. T. J. Saltmarsh and Son of Chelmsford; Mr. P. Perry, gardener to H. Tasker, Esq., Middleton Hall, Brentwood; Mr. G. Nicholls, Brentwood; Mr. J. Preece, gardener to H. Wilmot, Esq., Warley Place; and Mr. Crook, gardener to J. Baxter, Esq., Hutton Hall.

In the open class for twenty-four cut blooms Mr. A. Ocock, gardener to Mrs. McIntosh, Havering Park, was placed first, only beating Messrs. T. J. Saltmarsh by a few points. The best blooms in the first stands were Empress of India, Lord Wolseley, Lord Alcester, Golden Empress, Lady Dorothy, and Barbara. In the incurved Japanese were Mrs. F. Jameson, Etoile de Lyon, Sunflower, Condor, J. Délaux, Fair Maid of Guernsey, W. H. Lincoln, Japonais, and Madame C. Audiguier. In the class open only to amateurs, eighteen distinct varieties, Mr. Ocock was again first, Etoile de Lyon, E. Molyneux, Condor, Gloriosum, Mrs. F. Jameson, W. H. Lincoln being all good. The best incurves were Empress of India, Empress Eugénie, Golden Empress, and Lord Wolseley. Mr. Brazier was a good second, and Mr. J. Brown third. For twelve incurved Mr. Brazier was a capital first, his blooms being very solid and large. The best were Empress of India, Queen of England, Mr. S. Coleman, Golden Queen, and Miss M. A. Haggas. Mr. Ocock was second, and Mr. Crook third.

For twelve Japanese Mr. Ocock was first, having Mrs. F. Jameson, Japonais, Etoile de Lyon, and Condor, very fine; Mr. Brazier was a remarkably close second, and Mr. Tullett, gardener to G. Alexander, Esq., of Warley Lodge, was third. For six Japanese, Mr. Bolingbroke of Chelmsford was first; Mr. Preece, gardener to F. Willmott, Warley Place, second, and Mr. F. Brown third. For six incurved Mr. F. Brown was a good first, Mr. Bolingbroke second, and Mr. Tullett third. For six incurved, one variety, Mr. Brown was first with a grand lot of Empress of India; Mr. Ocock second with Miss M. A. Haggas; and Mr. Brazier third with Empress of India. For six Japanese Mr. Ocock was first with Japonais, followed closely by Mr. Goaring with Madame C. Audiguier; Mr. Brazier was third. Six table plants, Messrs. Saltmarsh were first, Mr. Perry second, and Mr. Preece third. Bouquet of Chrysanthemums, Mr. Burley, florist, Brentwood, was first; Mr. Perry second; and Miss Haws third. Table decoration, Mr. Burley was first, and Miss Haws second.

Six dishes dessert Apples, distinct.—Mr. Green, gardener to the Ven. Archdeacon Johnson was a good first. His best dishes were Cox's Orange, Ribston, King, and Blenheim. Mr. Goaring was second, and Mr. Jolly third. For six dishes kitchen Apples Mr. Goaring was an easy first, his Blenheim Orange, Peasgood's Nonesuch, Queen, and Warner's King being particularly fine and very clear. Mr. Goaring was first for three dishes dessert Apples, Mr. Jolly second, and Mr. Palmer of Romford third. Mr. Goaring was also first for three dishes kitchen Apples, Mr. Palmer second, and Mr. Burgess third. For three dishes dessert Pears Mr. Ocock was first, having Pitmaston Duchess, Duchesse d'Angoulême, and Doyenné du Comice in good condition. Mr. Tullett was second, and Mr. Preece third. Three dishes stewing Pears.—Mr. Tullett was first, Mr. Carver second, and Mr. Barnard third. Mr. Ocock was first for black Grapes, Mr. Green of Harold Wood second. Mr. Ocock was also first for white Grapes, Mr. Green second. For six sorts of vegetables Mr. Ocock was first, Mr. Tullett second, and Mr. Perry third.

#### SOUTH SHIELDS.

THE very successful Show held in the Royal Assembly Hall, South Shields, on Wednesday and Thursday, the 25th and 26th, was the outcome of the resuscitation on very vigorous lines of the South Shields Chrysanthemum and winter flower Show. Previous Exhibitions held by this Society have not been very successful. The last was held in 1882. Since then the Society apparently hibernated, to wake up during the past summer with new life and increased vigour. Having reorganised a very able and efficient executive and working Committee, it proceeded to work on such broad and liberal lines as seem likely, if persisted in, to cause it speedily to become the most important Show of the kind in

the North of England. To this end the present Society possesses several very important advantages. Firstly, they have in the magnificent new Assembly Hall that is probably the finest building for such a purpose to be met with out of London. It is of large size, beautifully proportioned, most lavishly, and yet chastely, decorated, illuminated throughout with incandescent electric lights, is connected by elegantly fitted corridors with a very popular and sumptuously furnished hotel, and is within five minutes walk of the railway station—a combination of advantages not often met with and to be proportionately valued. Secondly, this appears to be practically the only Show of the kind now held in a wide and populous district, comprising several large and important towns around which Chrysanthemums are largely cultivated; and thirdly, and not of the least importance, is the fact that it possesses a large and rapidly extending list of subscribers, who furnish the sinews of war which will enable the Committee to provide a very liberal schedule of prizes, to invite the best growers throughout the country to compete for them, and they had better look out in good time for next season's schedule of prizes.

The Show now in question was by far the largest ever held in South Shields, the number of entries for the previous one having been 719, whilst the number on this occasion was 1560. The exhibits filled not only the large hall, but also a room of the same size below, termed the basement, and this being comfortably warmed and lighted by electricity formed an additional and attractive promenade for visitors.

The first class in the schedule was one for thirty-six cut blooms, eighteen incurved and eighteen Japanese, not less than twelve varieties of each, and not more than two flowers of each variety. This brought five competitors and a fine display, the Japanese especially being generally good and bright in colour. Many of the incurved varieties on nearly all the stands were slightly too old, showing that the last week in November is somewhat too late a fixture even for a district so far north as this. The first prize in this class was very well won by Mr. G. E. Smith, Floral Cottage, Paull, near Hull. The varieties in his stand were—Incurved: Golden Empress (2), Miss Haggas (2), Barbara (2), Princess of Wales (2), Golden Queen (2), and one each of John Lambert, A. Salter, Mrs. Norman Davis, Violet Tomlin, White Beverley, Lord Alcester, Mrs. Heale, and Mrs. Shipman. Second, Mr. James Coultas, Darlington; third, Mr. F. Boulton, Blaydon; fourth, Mr. T. J. Wheeler, Newcastle. The names of the Japanese varieties were accidentally omitted.

Class 2 in the schedule was for eighteen Japanese, not less than twelve varieties or more than two of each. In this and the next following class there was also good competition, the first prize going to Mr. James Coultas, gardener to Alderman Hardinge, Hollyhurst, Darlington; second, Mr. R. F. Jameson, Hess'e, Hull; third, Mr. James Pringle, The Gardens, Benton Hall. The varieties in Mr. Coultas's stand were Etoile de Lyon (2), Avalanche (2), Mons. Bernard (2), Stanstead White (2), Puritan (2), and one each of A. H. Neve, Sarah Owen, E. Molyneux, Sunflower, Elaine, Golden Dragon, Criterion, and Jean Délaux. In the corresponding class for eighteen incurves (class 3 in schedule), not less than twelve varieties or more than two blooms of any one variety, Mr. James Coultas was again first; Mr. G. E. Smith, second; and Mr. George Walker, Gateshead, third. The varieties in Mr. Coultas's stand were Queen of England (2), Empress of India (2), Golden Empress (2), Lord Alcester (2), and one each of Emile Dale, Barbara, Refulgens, Lady Hardinge, John Salter, Mrs. Heale, Mrs. Coleman, Mrs. Wilberforce, Nil Desperandum, and Violet Tomlin.

For twelve Japanese, distinct varieties.—First, Mr. John Short, Darlington; second, R. F. Jameson, Hull; third, Mr. G. E. Smith. Twelve incurved, distinct.—First, Mr. G. E. Smith; second, Mr. R. F. Jameson; third, Mr. James Pringle. Twelve bunches of Pompons (foliage as grown, three stems to form a bunch).—An interesting class. First, Mr. G. E. Smith; second, Mr. F. Bolton. Twelve large Anemone flowered Chrysanthemums.—This class brought some good competition, and some very fine stands of flowers. First, Mr. G. E. Smith; second, Mr. John Short; third, Mr. T. J. Wheeler. Six incurved.—First, Mr. W. Partridge, Cleadon. Six Japanese.—First, Mr. W. Partridge.

Bouquets, epergnes, ladies' sprays, and buttonholes were shown in large numbers, and, as a rule, of high quality. Messrs. Perkins & Sons, Coventry, took the first prizes in each of the classes with some beautiful exhibits; Mr. J. Battensby, Blaydon, being second in each case with bouquets; and Messrs. Clark & Co., North Shields, second in each case, with sprays and buttonholes. Epergne for dinner table.—A fine competition. First, Mr. J. Battensby; second, Mr. J. Punton; third, Mr. F. Bolton. Epergne of Chrysanthemums.—First, Mr. G. Webster; second, Mr. J. Battensby; third, Mr. T. Berwick, Westoe.

In the class provided for a group of Chrysanthemums and other foliage and flowering plants arranged for effect there were four competitors, the first and second prize groups being both excellent arrangements of finely grown plants. The first prize went to Mr. J. Wood, Gateshead, his group containing a good bank of Chrysanthemums as a background, a large and fine central plant of Cocos Weddelliana, and in the foreground some fine highly coloured Crotons and Dracaenas, with a goodly number of healthy well-flowered Orchids, including several pans of Cypripedium insigne and Spicerianum, two finely flowered plants of Oncidium Rogersi, a good Oncidium varicosum, some Lælias, &c. The second prize was obtained by Mr. F. East, Westoe, his group being especially commendable for the high quality of the Chrysanthemums it contained, which had very fine flowers and good foliage.

Twenty classes were provided in the schedule for plants in pots, and each of these classes brought a good and healthy competition, forming in the aggregate a fine display which well filled the large basement floor. Mr. P. Blanchard, Jesmond, Newcastle, was first in the classes for six and three large flowering, for four Pompons, also six Japanese, three Japanese, and one Pompon, in each case with well-grown dwarf and well trained plants having good foliage and flowers. The second and third prizes in these classes going to Messrs. F. East, A. Purvis, N. Mothersell, W. Partridge, and Thomas Bird. For one large flowering Chrysanthemum Mr. T. Bird was first; second, Mr. N. Mothersell; third, Mr. A. Purvis. Two Anemone flowered: First, Mr. W. Partridge; second, Mr. P. Blanchard. One plant, any variety: First, Mr. N. Mothersell; second, Mr. W. Forsyth, Jarrow; third, Mr. A. Purvis.

Foliage plants and exotic Ferns were very finely shown, the numerous specimens being mostly of large size and in good condition, the principal prizewinners being Messrs. W. Forsyth, W. Partridge, James Wood, T. Berwick, T. J. Wheeler, and R. Barnes. Black Grapes were also well shown. First, Mr. D. P. Bell, Alnwick, with one bunch each of Gros Colman and Alicante, both large bunches and berries, and well coloured; Mr. J. Wood second, and Mr. T. J. Wheeler third, each with very good examples.

A most beautiful specimen of flower painting on silk, being a long spray of Maréchal Niel Roses with foliage, and interspersed with bronze Japanese Chrysanthemums, occupied a small table near the orchestra, and was greatly admired. It was the work of Mr. Hodge, art designer, 163, Livingstone Street, South Shields, and was given by him as a special prize for amateurs. A fine case of carvers, also given as a special prize by Messrs. Stocton & Tompkinson, Sheffield, occupied a place on the same table.

The orchestra was tastefully decorated by Messrs. Wm. Fell & Co., Fellside Nurseries, Hexham. We must not omit mention of the splendid music discoursed by Amer's exhibition band, which is well known throughout the northern counties, and proved an immense attraction, causing the large building to be crowded with the élite of the town and district during the afternoon and evening of the first day, and abundantly proving that really high-class music at such gatherings, although costly, is in the end a good investment.

The highest praise is due to the Hon. Secretaries, Mr. Bernard Cowan and Mr. H. Hinde; to the Treasurer, Michael Graham, Esq.; and to the excellent working Committee for the vigorous manner and broad-minded spirit in which the whole arrangements of the Show had been conceived, and we are pleased indeed to know that success has crowned their efforts.

#### HARDY FRUIT GARDEN.

**WALL TREES.**—Peaches and Nectarines tied to wires should now be loosed, the branches tied together and secured to the wall so that none of the wood touches the wire, or serious injury will probably occur to the branches in the event of severe frost. Where nails and shreds are used do not unloose the trees at present, but fasten the points of any shoots that may be projecting in order to get as much protection from the wall as is possible during the winter.

**PLANTING.**—Have this completed as soon as possible; it is always a good plan to have a few young trees coming on to fill up the places of any that fail. It is not always necessary to grow these on south walls. In many gardens they will grow well on a west aspect, and will make good trees for removing to better positions; but except in the most southern counties it is useless to expect good fruit unless they are on a south wall. In planting give a little fresh soil to start the trees if none has been added to the border lately, and a little chalk or lime rubbish mixed in the soil is very beneficial to Peaches and Nectarines, especially in old gardens. Do not use any manure amongst the soil; young Peach trees are apt to grow too fast when fresh planted. Plant firmly, but if the soil is wet do not tread it in. Give a good mulching of litter afterwards to keep frost from the roots, and fasten the trees very loosely to the wall, so that they can settle down with the soil. The best varieties of Peaches for open walls in their order of ripening are—Alexander, Hale's Early, Rivers' Early York, Dymond, Stirling Castle, Crimson Galande, Violette Hâtive, Bellegarde, Princess of Wales, and Late Admirable. These will give a succession of fruit from the middle of July to the middle of October in favourable seasons.

**NECTARINES.**—Lord Napier, Stanwick Elruge, Dryden, Rivers' Orange, Pine Apple, Victoria—the latter variety should only be planted in the warmest districts; fan-trained trees are the best. Some nurserymen run them up to one central stem, this is a bad practice except for rider trees. The main stem of dwarf trained trees should not run more than 18 inches from the surface, and should consist entirely of the stock.

**APRICOTS.**—A deep alluvial loam is the best soil for these, but it must be well drained and must contain a fair amount of limestone or chalk as for other stone fruits. Canker, or the dying off suddenly of large portions of the tree, is very troublesome in many places. The

variety called Moorpark is unfortunately more subject to this than the other kinds, and should not be extensively planted where there is reason to anticipate failure from the above cause, otherwise it is one of the very best kinds. Other good varieties, which are stronger in constitution and not so liable to disease, are Royal, Hemskerk, Kaisha, and Roman. A south aspect is not so essential for Apricots as it is for Peaches and Nectarines. They will succeed in the warmer counties on west and south-west aspects provided other conditions are favourable. They should be trained on the dwarf fan system.

**PLUMS.**—The choicer kinds of these deserve the next best position to Peaches and Apricots, which will vary according to locality. In bad situations Plums should take the place of the above fruits. A long succession of choice dessert fruit may be had by planting a good selection. They may be grown either as cordons or as fan-trained trees; the former cover the walls quickest and give better returns, although costing more in the first instance. Plums on walls are apt to get unsightly and fail to give satisfaction through the spurs growing too long and projecting from the wall; the grower should always be watchful about this, especially at pruning time. The following are good varieties for a succession of fruit:—Dessert, July Green Gage, Oullins Golden Gage, Green Gage, Prince Englebert, Kirke's, Jefferson, Coe's Golden Drop, Reine Claude de Bavay. Kitchen—Early Rivers, Early Orleans, Czar, Victoria, Pond's Seedling, Pershore Monarch, Grand Duke.

**SUCKERS.**—In planting all kinds of stone fruits it is necessary to carefully remove every appearance of a sucker or bud on the roots. Some stocks produce these much more freely than others, and are very troublesome when they get older; they may generally be known in the nursery by the knotty appearance of the stem and should be carefully avoided.

**PEARS.**—The best varieties of these should always find a place on the walls of the fruit garden. No matter how well they succeed as pyramid trees, &c., it is impossible to obtain such fine clean fruit as trees on walls will give. In good localities Pears will succeed on any aspect if other conditions are suitable, but north of London they should not be planted on north walls, and only the hardiest and earliest varieties will succeed there in the south. As a general rule the west aspect will be found the best of all. Cordon trees are preferred by many to the old horizontal style, which takes such a long time to cover a wall properly, and only continues in full prosperity for a few years after gaining its full size. By growing cordons also it is possible to grow more varieties on each aspect, and thus prolong the season of many of them. The following varieties will give a succession of good fruit:—Beacon, Jargonelle, Williams' Bon Chrétien, Beurré d'Amanlis, Seckle (must have a warm position), Fondante d'Automne, Emile d'Heyst, Marie Louise, Louise Bonne of Jersey, Pitmaston Duchess, Doyenné du Comice, Winter Nelis, Passe Colmar, Glou Morceau, Easter Beurré, and for the south Beurré Rance may be included also.

**NORTH WALLS.**—Generally speaking these are most profitably occupied by Morello Cherries, dessert Gooseberries for late use, and Red or White Currants. A good arrangement is to plant the Cherries as dwarf fan-trained trees about 15 feet apart, and grow the other varieties between as upright cordons, eventually reducing the latter to three cordons between each Cherry when these get to their full size. The Red Warrington Gooseberry is most useful for this purpose, as it keeps longer and better than any other variety; but if others are required, Thumper, Leveller, Husbandman, Crown Bob, and Lancashire Lass are good ones. Victoria is the best Red Currant for late use, and White Dutch should also be grown.

#### FRUIT FORCING.

**VINES.**—*Houses Started Early in November.*—Whether the Vines are in pots or planted out in inside borders the temperature will need to be increased to 60° at night in mild weather, 55° in severe weather after the buds break, gradually increasing it from that stage to 60° at night when the Vines are in leaf, 65° by day in severe weather, and 70° to 75° in mild weather. Ventilation should begin at 70°, just a little to insure a change of atmosphere, increasing it with the sun heat, having it rather free at 75°, and above that temperature, for it is important that the foliage be well formed and solidified. Avoid, however, sharp and drying currents of air, as that cripples the foliage, stunting the growth. Sprinkle the Vines in the afternoon of fine days, and damp the floors and other available surfaces twice a day according to external influences, avoiding a saturated atmosphere on the one hand and a dry one on the other. If there be evaporation troughs charge them with liquid manure, the clear drainings of stables and cow byres, but avoid those of pigstyes. Guano, 1 lb. to 20 gallons of water, is suitable for filling the troughs, also for watering Vines in pots or planted out, the liquid being applied at the same temperature of the house. Disbudding should not be practised until the bunches show in the points of the shoots, but the Vines should be tied in position as soon as growth has well commenced, and before the shoots are so long as to be liable to be damaged in the operation.

*Houses to Afford Grapes in May.*—The Vines that are to afford Grapes for table at the time stated must be started at once, these having had a few weeks' rest after being pruned and the house cleansed, and everything put into proper order. To insure a good break the atmosphere must be kept moist; nothing insures this better than a bed of leaves and stable litter properly sweetened, placing the materials on the floor and turning daily, adding fresh as requisite. Outside borders should have the needful protection from cold rains and snow; two-thirds of leaves and one of stable litter afford a less violent

but more lasting heat than manure, but it is not desirable to use fermenting materials on outside borders unless they can be properly attended to afterwards in removing the spent, and replenishing with fresh as required; then they are useful, not otherwise. Where outside borders were covered with leaves, bracken, or litter in early autumn, so as to throw off the wet, the temperature will be considerably warmer than that of borders exposed, and in the case covering with fermenting material may be dispensed with, but where the roots of Vines are wholly outside a covering of warm litter is preferable. Such Vines, however, are not suitable for early forcing, as for that purpose the roots should be inside mainly, if not wholly; the outside border, if any, being properly protected from cold and wet. Inside borders must be brought into a thoroughly moist state by applying water in a tepid state. Weakly Vines, and the border in a proper state as regards texture and drainage, may have liquid manure supplied at 90°. Maintain a moist atmosphere by syringing two or three times a day in bright weather, occasionally only in dull, avoiding excessive moisture and a close atmosphere, as these excite the emission of aerial roots from the rods. The temperature should be 50° at night in severe weather, 55° when mild, and 65° by day, except the weather be severe, then maintain at 55°, not exceeding those figures until the Vines commence growth. Young Vines will need the rods depressed to the horizontal line, or below it, to insure the regular breaking of the buds; without this they push growths from the upper buds only.

*Midseason Houses.*—Prune the Vines directly the leaves have fallen. This is advantageous in securing complete rest. Thin-skinned Grapes keep better cut and placed in bottles of clear rain water with a piece of charcoal in each than on the Vines, especially under a leaky roof, and where plants are in the house. In a suitable room the Grapes have a more equable temperature than is possible in vineries, and they keep longer and quite as plump. Keeping late Grapes on the Vines to mature after the leaves have fallen certainly improves those having a coarse earthy flavour, such as Gros Colman, and the Grapes from their leathery skins are not so liable to injury from damp as the thin-skinned Grapes, therefore they are left until the new year, or later, before cutting and bottling; but in the case of midseason Vines it is well to prune them directly all the leaves are down, and cut and bottle any Grapes at that time remaining. Thoroughly cleanse the house, dress the Vines, top-dress the border after removing the loose surface soil, and keep the house as cool as possible.

*Late Houses.*—Take every possible precaution against damp. Drip is fatal to late Grapes, a single drop of water getting inside a bunch being sufficient to spoil it, as the decay spreads rapidly. Drip is often caused by keeping the house closed and the pipes cold, so that moisture condenses on the glass and falls from the rafters or sash-bars on to the Grapes. This is common when early ventilation is neglected on fine days. A little air and gentle warmth in the pipes dissipates the moisture and prevents decay in the berries, but too much heat and too dry air causes the Grapes to shrivel; seek therefore a dry, cool, and equable temperature, 40° to 45° being sufficient, keeping the house closed in damp weather, and when clear admit air freely. Remove all leaves as they become ripe, avoiding sweeping, as dust greatly impairs the appearance of Grapes.

**CHERRY HOUSE.**—The trees must now be pruned. Full-grown trees, properly attended to in stopping during growth, will require very little pruning now. Any summer shoots that have grown considerably should be cut back to about an inch from the base, and the worn out spurs may be shortened or removed as required. Cut out dead spurs and thin those which are crowded, always reserving sufficient for producing a crop. The terminal shoots in the case of trees extending must not be shortened, but when they reach the extremity of the trellis they will need shortening, always to a wood bud. Young trees will require to be cut back as may be necessary, the central shoots being shortened so as to originate others for filling the space regularly, but it is not desirable to start them too closely together, as that may cause the branches to press against each other, and this is a common cause of gumming. Fan-training is unquestionably the best for Cherries, as it admits of replacing any branch that may fall a prey to gumming. Thoroughly cleanse the house—the woodwork with soapy water and a brush, lime-wash the walls, using fresh burned lime, with a sixth of flowers of sulphur and a little dissolved glue to cause it to adhere firmly. Wash the trees with soapy water, and afterwards dress them with an insecticide, being careful not to injure the buds. Remove the loose surface soil, and supply fresh loam. The roof lights being off they need not be replaced until the time arrives for starting the trees, which to have Cherries ripe early in May should be at the middle of this month. The very early varieties will ripen sooner, such as Early Rivers and Belle d'Orleans, these being well in advance of Black Tartarian and Governor Wood. These divergencies in ripening must be kept in mind in forcing Cherries, and it is necessary not to bring them forward too rapidly, especially when forcing them for the first time. Trees under fixed roofs should be well supplied with water if necessary to keep the soil moist. Fixed roofs, however, are mistakes in the early forcing of Cherries.

**FIGS.**—*Forcing Planted-out Trees.*—The earliest house should be closed in December to have ripe Figs in May. Where, however, the earliest Figs are obtained from trees in pots, starting the trees in borders may be deferred until the new year, so as to afford a succession. Planted-out trees, even with the roots confined (as they should be for early forcing) to inside borders, will not ripen the fruit so early as pot trees, and if started at the same time they will afford a close succession

to that from the pot trees. Assuming the soil has become dry, apply water in a tepid state to the roots at frequent intervals until the soil is thoroughly moistened. Sweetened leaves and stable litter in ridge form introduced into the house will produce a moist genial condition of the atmosphere, and induce gentle excitement, as well as economise fire heat. Start with a temperature of 50° at night, 55° by day, and 65° from sun heat, syringing the trees and every available surface in the morning and early in the afternoon, unless the weather be dull and cold, when morning syringing need only be practised in the morning. Ventilate moderately whenever the weather is mild, closing the house with sun heat at 65°, or if it exceed that with full ventilation close the ventilators when the sun heat begins to decline.

*Succession Houses.*—When the foliage has fallen prune the trees. Shoots which have attained the limit of the trellis must be cut back to where the succeeding shoots start in order that they may occupy their places in the ensuing season. Cut away all elongated spurs, reserving, however, as there is room, a few of those which are short-jointed and fruitful. Loosen the trees from the trellis, thoroughly cleanse the wood-work with soap and water, the glass with clear water, limewash the walls, adding a little sulphur, and wash the trees with soapy water with a brush and afterwards with some insecticide, avoiding, however, pigments that contain gas tar and other substances deleterious to the bark. Tie the trees to the trellis, leaving sufficient space in the ligatures for the swelling of the branches. Lightly point the border, remove the loose material, supply a little fresh loam with a sprinkling of bonemeal, and mulch with a couple of inches thickness of lumpy, partially decayed manure. Ventilate fully in all mild weather, only closing when frost prevails.

#### PLANT HOUSES.

*Poinsettias.*—After the bracts have fully developed they continue in good condition for a very long time in conservatories or other structures where the temperature is not allowed to fall below 50°. To prepare the plants for this purpose they must be carefully and gradually hardened if developed in strong heat, or the leaves will turn yellow, and thus destroy the appearance of the plants. While in a lower temperature the atmosphere should be kept as dry as possible, and care taken not to overwater the plants. Water of a lower temperature than the house must not be given to them. For all plants of this nature it is a good plan to use tepid water. Euphorbias that are in bloom should be subjected to the same treatment.

*Calanthes.*—These may be placed with advantage while in flower in conservatories or other houses where the temperature ranges about the same as advised for Poinsettias. Damp is the greatest enemy; in a moist atmosphere and moderately low temperature the flowers quickly become spotted, while in the conservatory little or no water will be needed. Few plants are more effective than Calanthes when they rise well above other plants and the pots and pseudo-bulbs are hidden with Ferns or other decorative plants.

*Gloxinias.*—Those that have enjoyed a good rest may have the old soil shaken from their tubers and started into growth in brisk heat. They may be laid in boxes amongst leaf mould, and when they have well started potted into various sizes, according to the size of the tubers.

*Begonia semperflorens carminia.*—Plants that are not required in bloom for some weeks may have their points removed. This will induce them to branch freely from near the base, and thus form a good succession to those allowed to flower now. Young plants that have been pinched and started two to four shoots may be placed in larger pots.

*Crotons.*—Good heads on plants that have become leafless towards the base may be partially cut through and mossed. These in a temperature of 60° to 65° will soon emit roots, and if well cared for will be in excellent condition for taking off early in the new year. After they are severed from the old plants slight bottom heat and a close frame should be provided for them until they commence rooting freely. Good heads started early in the year quickly make handsome plants. Dracaenas of various kinds may be subjected to the same treatment.

*Gardenias.*—Young plants, well established in thumb pots, may be transferred into 3-inch. Keep these in stove heat and they will grow steadily. Cleanse established plants from scale and mealy bug. No time is better than the present to get these pests under proper control. Sponge the plants, and then give them occasional applications of petroleum and water in a weak state. Strong stimulants and strong insecticides must be avoided after the flower buds are formed; they are liable to check the plants, and deformed flowers are the result. Do not keep the plants in a low temperature or apply cold water to their roots.

*Coleus.*—These are useful in small pots, but the cuttings should be inserted singly, and distinct bright colours selected. A good dark form will be found most useful for dinner table decoration if the plants are dwarf and well furnished with large leaves at the base. For this purpose the tops of shoots that have grown strongly should be chosen. Coleuses soon draw up too tall for a variety of purposes even when confined in small pots, and therefore some should be rooted at intervals of every three weeks during the winter. Although they do not last so long as Crotons they are distinct from those plants, and their highly attractive appearance during the winter renders them invaluable.

*Allamandas.*—The earliest plants may be pruned back and repotted in a compost of loam, sand and one-seventh of manure. If the pots are afterwards plunged where they can receive gentle bottom heat, growth will commence quickly. Clerodendron Balfourianum may also be started, but do not pot these until they have made little growth.

## THE BEE-KEEPER.

#### AN EXPLANATION.

IT has come to our knowledge that the publication of a statement which appeared on page 442 in our issue of November 19th was inserted under a misapprehension, and that the information supplied to us that "there was no mention of the Punic bees in the *Record* of June, 1890, nor has there been any allusion to them, either editorially or by any of its correspondents," is not in accordance with facts. Here are the facts:—

On page 74 of the *Bee-keepers' Record* for June, 1890, a question is asked by Guillaume, Wigtownshire, N.B., "What kind of bee is the Punic?" to which the editorial reply is, "According to 'A Hallamshire Bee-keeper' the Punic bee comes from North Africa. It is dark in colour, and from our limited experience of it is a good worker and a prolific sort."

It will be seen that "Punic bees" are twice mentioned there, and that a reply is given founded on "experience." Yet in the *British Bee Journal* for August 27th, 1891, on page 381, the same Editors, in reply to "Inquirer," say, "We know nothing about the so-called Punic bees, and can give no information as to their value."

We were induced to publish the statement last week in reliance on the accuracy of the matter furnished, and with a desire to be just to the conductors of our contemporaries; but we must also be just to our correspondent "A Hallamshire Bee-keeper," who has placed in our hands evidence which justifies us in making this explanation; and, we would add, our long experience has led us to regard him as an accurate correspondent.

#### BEEES AND SEDUMS.

I HAD not forgotten my promise to make careful observations of the effects of the Stonecrops upon bees. Unfortunately I have been baffled by the weather during the latter part of the season, and, like "A Lanarkshire Bee-keeper," have been unable to notice anything so definite as to be worthy of notice. The earlier Stonecrops do not seem to be much frequented by the bees, and some of the others appear to be only attractive to the humble bee, which does not seem to be affected in the same way as the others. I think the subject should be investigated over a wide area, as it is evident that in some districts where there are different sources of honey supply certain Stonecrops may not be frequented by the bees, while in others the contrary may be the case. This is quite a Clover district, and several Sedums bloom at the time when there is a good supply of honey from the Clover. I shall return to the subject shortly, but am at present very busy.—S. ARNOTT.

#### STANDS AND FLOORS.

I AM in receipt of many letters in praise of my style of hive and ventilating floor, which I think, after upwards of forty years' experience with it, and with its latest improvement, cannot well be improved upon. It is simply a square box of the same dimensions as one of the divisions of my storifying hive (it may be an inch shallower). The back portion is in two pieces, the upper being about 3 inches broad, having a wooden button in the centre of the bottom edge, the under piece about 1½ broad, which leaves from 1 to 1½ inch space to admit the withdrawal of the wooden shutter kept in its place by a fillet all round above it, which keeps it close to the aforesaid button at the back and held up in the front by a fillet each side, lowered at the back and the shutter when down falls flush with the bottom back rail, so that it is kept in place when in transit. This arrangement permits the easy withdrawal of the shutter for cleaning the *débris*, and the two-angled fillets permit it to be easily replaced. The feet should not exceed 8 inches long by 2½ by 1½. They should be checked

so that five-eighths may be left projecting and nailed firmly to the sides of the stand, leaning as it were 2 inches for the feet proper. The alighting board may either be hinged with brass butts or wire dools. The ladder, 9 inches broad, may be fastened by two bell-wire staples, forming a hinge, and one near each end.

The stand is fixed to the hive by a piece of brass or galvanised iron, or any non-corroding metal, about 4 inches long by one-sixteenth thick, having four holes in a line; and better if brass screws be used, and the sheet of perforated zinc seven holes to the inch should have one tack in the centre of the front only. I hope these details, although in some respects a repetition, will enable anyone to make their own stands and floors, which form in a double sense the basis of a good hive.

I have just observed water trickling from the floors of some of my hives, which, had they solid boards or floors, would by this early time been drenched with damp, which is the main cause of bees dying within their hives, to be dragged out with a crooked wire so as to insure the safety of the few that may have survived for a time till disease contracted through damp ends their days. Keep a sharp look-out for damp; do not let it have a place in or on the hive from either respiration or rain, and keep the bees in a comfortable state so that the heat from them will repel the humidity of the atmosphere.

#### STRAW HACKLES.

In order to show visitors the utility and economy of these over both double-cased hives and exposed single-cased ones, I have had several made, and every experienced bee-keeper who sees them is simply delighted, as much as the bees ensconced within their protection will be benefited, and the bee-keeper ultimately rewarded.

If bee-keeping has to be a paying concern in the future, economy in all the details of the apiary must be studied and acted upon accordingly. In order to hasten the desideratum, bee-keepers should fraternise more with one another, giving and taking ideas in a friendly spirit, so that all would, by friendly discussions, be the better of them intellectually and financially. — A LANARKSHIRE BEE-KEEPER.

#### TRADE CATALOGUES RECEIVED.

Thomas Rivers & Son, Sawbridgeworth, Herts.—*Catalogues of Fruit Trees, Ornamental Trees and Shrubs, and Roses.*

\*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Seedling Apple** (*J. Jeffrey*).—We think the Apple is worth sending to the Fruit Committee of the Royal Horticultural Society, and you can obtain the requisite particulars for forwarding a dish (one fruit being insufficient) from Mr. A. F. Barron, Chiswick Gardens, London.

**Address** (*D. D. D.*).—The address you require is 171, Fleet Street, London, E.C.

**Pipe Sockets Splitting** (*J. R.*).—Have you written to the firm who supplied the boiler and fixed the pipes for an explanation? Their reply might perhaps indicate to us the cause of the evil. We fail to see that any of your suggestions satisfactorily accounts for it, except faulty packing.

**Inarching Vines** (*L. C.*).—Black Alicante is more easily grown and more certain to produce heavy crops than those you propose to displace, but is relatively inferior in quality. Assuming the Vines are healthy and the border in good condition, strong fruiting rods could be had sooner by inarching young Vines to them than by planting the same young Vines. Spring is the time for inarching, and it is desirable that the young Vines be kept cool, so that the growth of the stocks may be somewhat in advance of them when the operation is performed. We have not tried the effect of establishing the Black Hamburgh on a stock of Mrs. Pinee.

**Chrysanthemum Mrs. Robinson King** (*H. T. S.*).—We think if you write to the Secretary of the National Chrysanthemum Society, Mr. R. Dean, Ranelagh Road, Ealing, you will find that this variety has been certificated by the Floral Committee of that Society. It was exhibited at Hull last year as Golden Queen, and as that name was insisted on the judges refused to admit its accuracy, and they were right. The owner was told if he would show it as a new sport it would be admitted as such, but as he refused his stand was disqualified. He subsequently found out it was distinct from Golden Queen, and we believe sold the stock to Mr. R. Owen. We shall shortly publish notes on this and other new varieties by Mr. E. Molyneux.

**Adiantum Fronds Browed** (*W. M. B.*).—The fronds are seriously scorched and disfigured, having the unpleasant smell indicative of the destruction of vegetable tissues by obnoxious fumes. The scorching appears such as results from fumigation with tobacco or other substance. Though you do not say that fumigation has been practised for the destruction of the black aphid frequently infesting the Cucumber plants, yet the appearance of the fronds point to some deleterious fumes having been employed. The vapour arising from troughs charged with liquid manure or guano water would also cause the fronds of Ferns to scorch, the ammonia vapour destroying their tissues, especially when soft, as appears to be the case with those scorched. Deficiency of air would not cause the scorching unless the sun acted powerfully upon them whilst wet. The close atmosphere and warmth would certainly cause soft tissues, and water resting on the fronds for any length of time cause their decay; but it is not a question of damp, but of scorching by fumes destructive of the tissues.

**Roman Hyacinths** (*T. F.*).—We removed one pot, and the roots in that had not reached the drainage and were fresh and sound; but on examining the roots of the more advanced plants we find that on these entering the drainage they appeared to come in contact with deleterious matter and were destroyed. This would affect the whole system of the plants, including the roots in the soil above the drainage, which become discoloured in consequence. Correspondents do not "trouble" us by asking questions; but, on the contrary, we are glad to receive questions when any answers we can give may be useful. You are fully at liberty to write again if you wish. You observe the bulbs admittedly sound have had the "usual treatment." You must permit us to say they have not had the treatment in respect to soil, drainage, watering, and position assigned, under which the best results are achieved by successful cultivators. It is certain there has been a departure in some respect, but without the requisite details it is impossible to indicate with greater precision how the mishap has been brought about.

**Salading for Winter** (*G. Brown*).—Too much wet and moderately severe frosts are alike injurious to Endive, causing the outer leaves to decay, the hearts soon following. Timely precautions must therefore be taken in the matter of either storing or protecting where the plants now are, or the bulk of the supply will be over long before midwinter arrives. Advantage should be taken of a fine dry day to tie up a few dozen fully grown plants, the outer leaves well enclosing the hearts, and if these are further enclosed by inverted flower pots with their drainage holes stopped the blanching will be more rapid and perfect, and a certain amount of protection also afforded. Blanching can also be readily effected by means of boards and slates, or even hay laid over two or three dozen plants at a time, fresh plants being covered every fortnight or rather oftener rather than covering up many at a time, and which will not keep long after they are blanched. Much may be done towards protecting a good breadth of Endive by means of side and end boards kept in their places with strong stakes, these supporting either lights or mats or both in severe weather. Endive nearly or quite fully grown transplant readily, and before they are injured by frosts they can if necessary for the purpose of getting them well together be lifted and packed somewhat closely in either pits, frames, or cool vineries and Peach houses. Tie them up prior to moving them, lift with a good ball of soil about the roots, replant in rich moist soil, and open them out again. Being duly protected from severe frosts and much moisture they will keep for several months, and a few at a time can be blanched for use as required. Late and nearly fully grown Lettuces should also be taken good care of, as they will be handy for mixing with well blanched Endive. If there is a good bed of them have rough frames ready for protecting or also transplant to frames as advised in the case of Endive. The Cos varieties blanch best when tied up. Mustard and Cress are the best of the small saladings, and should now be grown under glass. Sow every week or ten days separately in boxes, using fresh rich soil each time, and thickly on a level surface, pressing the seed well in and covering the Mustard only, and that very lightly with fine soil. Place in gentle heat and keep uniformly moist and perfectly dark till the stems are nearly 2 inches long, then transfer to lighter and cooler quarters. Grown in this manner the stems are well blanched and the salading of superior quality accordingly. Tender

WHEN considered as a merely mechanical operation, the pruning of Vines is a simple and easily acquired branch of the gardener's art, but viewed in its true light, as a necessity of cultivation, and a means by which we are enabled to control the quality of the crop and the size of the bunches produced, and also to rejuvenate apparently worthless Vines, few, if any, of the gardener's multitudinous duties will so well repay thoroughly thinking over before a single shoot is cut. The condition of the Vines to be operated on, their behaviour during the previous season, the peculiarities of different varieties, and the purposes for which they are grown, all come in for due consideration. Take the case of Vines which have become weak and debilitated, and which therefore produce unsatisfactory crops; a surprising improvement may be made in one season by ignoring all hard-and-fast methods of pruning, and leaving plenty of young wood, so as to be able to have a number of shoots to select from at disbudding time. Instead of cutting back to one or two eyes, as so frequently recommended (without any qualifying conditions being given) prune to wherever the best bud can be found, whether it happens to be 2 inches or 2 feet from the point it was last pruned to. With old Vines in a bad state, this often makes the difference between a very poor crop and a creditable one. I do not say that any system of pruning will make up for deficient root action, or the evils of an unsuitable border. These are matters which should also have proper attention, but if half the Vines in the undesirable state described were pruned closely, and the other half left as recommended, a second trial would not be necessary. Neither do I advise old Vines to be kept when they are so unsatisfactory, but there are hundreds of cases in which gardeners have no choice but to leave them, and in such instances, with the roots attended to and the long-spur system of pruning adopted, many might surprise even themselves with the result. It will be urged how unsightly these long spurs must be, but this need not be the case, as a shoot can always be retained at the base when the disbudding is done, and later on be stopped at a couple of leaves, so that the spurs may be cut back to that point at successive prunings.

My remarks thus far are intended to apply to Vines in an unsatisfactory state. In the case of those in a sound healthy condition the character of the crop may be greatly varied by the method of pruning adopted, and before this is determined it must be distinctly understood that close pruning means comparatively small bunches. Therefore, where Grapes are grown for home use alone, and large bunches are not particularly prized, cut back to one or two eyes, and fairly good bunches will result, such as are extremely useful for keeping up a continuous supply. One great point in favour of medium sized bunches is they are generally cut and used while in a perfectly fresh state, while larger bunches are not unfrequently dished up many times in succession till their appearance is not inviting.

Those who grow for market find, that except for special occasions, medium sized bunches weighing from 1 to 2 lbs. are in much greater demand than those of larger size, although a limited number grown to an imposing size are in constant demand for exhibiting in the windows of high-class fruiterers' shops, and command a higher price per pound than those of less bulk. The majority of Grapes grown for market, however, pay best when

large numbers of moderate sized bunches are produced, and pruning to one or two eyes is found to answer best with most varieties. Lady Downe's seems, however, to be an exception, and it is too much inclined to produce very small bunches, or to produce them too sparingly if pruned closely year after year. It is therefore always advisable to leave three or four eyes when pruning this variety, then at disbudding time when the back buds are promising they may be retained in preference to the terminal ones.

Two other varieties of Grapes which succeed much better when pruned on the long rod or the long spur system are the Muscat of Alexandria and Gros Guillaume; the former never appears thoroughly satisfactory for any length of time if closely pruned annually. It is really little short of marvellous the difference in the produce of closely pruned and closely stopped Vines of this variety; but the spurs should be kept a greater distance apart than most others require, and a shoot always retained at the base of the spur, so that after a couple of years the long spurs may be cut back to that point. Gros Guillaume should be treated on the long spur system for two reasons—first because much larger bunches are produced, and also because it is not generally a free fruiter if pruned back closely.

Having now given a few hints on the pruning of Vines to produce bunches of moderate size, and also pointed out those which I consider should never be pruned closely, I now come to the course to be followed in cases when exhibition bunches are wanted, as there can be no doubt that the greatest achievements in cultivation are attained where each variety is grown (and perfectly coloured) to as large a size as possible. To accomplish this there should be at least three or four eyes left at pruning time, so that a good selection of shoots can be made when the bunches are visible. Only a few gardeners, however, grow their Grapes from a purely exhibition point of view, so that all the Vines need not be treated on this long spur system. If some are pruned to one or two eyes and the rest allowed a couple of extra buds, and when a very promising shoot is found still longer, bunches of a great variety of sizes will then be the result, so that there may be abundance for home consumption, and a few extra good ones for exhibition purposes.

After a perusal of these remarks, the question will naturally arise in the minds of some growers as to what effect the various methods of pruning enumerated will have on the colouring of the Grapes produced, as there is a general belief that, with close pruning, Grapes, as a rule, colour the best. This is true to a certain extent, but the matter requires careful observation before a reliable opinion can be formed; for instance, it is a well-known fact that small bunches invariably colour the best. It is not an unfrequent occurrence to see a few small and medium sized ones (on Vines where every spur has been pruned closely) coloured perfectly, while the remaining bunches are far from being in that desirable state; and most growers know that the larger the bunch the longer the colouring process takes to complete. It is, therefore, reasonable to suppose that with a given number of large bunches and the same of small ones the latter would produce the larger percentage of perfectly finished examples; but, if only a relatively small number of really fine bunches attain that high standard of perfection, this would in reality be a greater achievement in the art of Grape growing than the production of double the number of bunches of a size met with frequently enough to merit the definition of commonplace. It seems to be an unerring law of Nature that the highest degree of excellence is only reached by a sacrifice of minor considerations, and those cultivators who thoroughly think out their methods of procedure, and under the constant guidance of their reason and observation strike out a bold course, are invariably rewarded with the greatest amount of success in Grape growing, as in most other matters connected with horticulture, and indeed, with life in general.—H. DUNKIN.

## HARDY FLOWER NOTES.

THE year is hastening to a close, December's short and dreary days are upon us, and frost, which came with laggard footsteps, has come and gone again. Dahlias lingered on until the last week in November, when a sharp night destroyed for the season many of Chloris's tender subjects. The Grecian nymph has, however, still some of her subjects left to render her their homage. Not least attractive at present are the Monthly Roses, which here show a few blooms well nigh throughout winter. One of these it might well be of which Hartley Coleridge speaks thus :—

"The patient beauty of the scentless Rose,  
Oft with the morn's hoar crystal quaintly glassed,  
Hangs, a pale mourner for the summer past,  
And makes a little summer where it grows."

I do not know that we have as yet fully realised the usefulness of these little Roses. We run too much after the exquisite blooms of the Hybrid Perpetuals, and neglect the little flowers which would brighten our gardens in such gloomy days as these. The "little summer" by their aid would abide, not only in our gardens but in our hearts, were these dainty flowers more widely grown. With these pretty China Roses before one's eyes we are disposed to protest against one of the expressions of that true lover of flowers—Shakespeare, who says :—

"At Christmas I no more desire a Rose  
Than wish a snow in May's new fangled mirth,  
But like of each thing that in season grows."  
—("Loves Labour Lost," Act I, Scene 1).

In ordinary winters the China Roses flower here for months at a time and are ever welcome at any season. This seems a favoured spot for Anemones, as while my friends a short distance inland have none in flower here they are again flowering away, and within the last few days a frame has been placed over some so that they may flower unchecked throughout the winter. The single varieties will be found the more suitable for this purpose. The day of named Anemones seems almost over, for the present at least, unless they experience a revival of taste such as is beginning to be experienced with the named Tulips. I do not know of any one in this country who makes a speciality of growing named double Anemones. I believe the late Mr. Carey Tyso was one of, if not the last in England. I was a little surprised the other day on looking up Justices' "Scots Gardener's Director" (1759) to find, that at that time the price of Anemones was £5 per 100. Unless in the case of someone who was particularly desirous of having a choice collection it is needless to purchase named sorts, as a packet of seed will produce many fine colours at a small cost. Although at this season the flowers do not open well outdoors, if cut when in bud and placed in water they will open in the house. There are few finer sights in May than a bed of Anemones with their beautifully cut foliage of bright green and their fine flowers of many colours, white, pale blue, deep blue, purple, crimson of various tints with various rings and markings, all ornamented with the black central boss which enhances the beauty of this classic flower. Classic flower I say advisedly, for few flowers are more alluded to in ancient works. I have previously quoted one of the legends of the origin of the Anemone, and another may be found in Folkard's "Plant Lore, Legends and Lyrics," p. 215, by Rapin, according to which the Anemone was originally a nymph beloved by Zephyr. This is perhaps an explanation of the name of the flower, which is derived from *anemos*, the wind. This "fairest flower" of Rapin is one which we would fain see more widely grown; and as tubers are cheap and may be planted from now onward till March, it is surely not too much to hope that they may again find their way into favour. They do very well in sandy soil here planted about 3 inches deep. One would gladly say more about these exquisite flowers, but others claim attention.

Protected from the storms by a little handlight is one of the latest of those flowers which seem to have stored up the summer's sunshine, that they might give it forth to brighten gloomier days—the Colchicums. The species now in flower is named *C. Decaisnei*, and is assuredly a valuable acquisition to the hardy flower garden. It has fine bright light purple flowers with broad well-rounded petals, and is said to be a native of the Anti-Lebanon. It is newly introduced, and is said to have narrow leaves. It produces a number of flowers from each bulb, and is from its late-flowering habit well deserving of notice. Poisonous as are the Colchicums or Meadow Saffrons, their beauty and value in the garden should cause them to be more widely cultivated. Speaking of their poisonous qualities, Gerarde recommends anyone who has eaten Colchicums to "drinke the milke of a cow, or else death presently ensueth." Nor are the Crocuses (like the Colchicums herbs of the sun, as the old astrologers tell us) unrepresented in

the garden even in December. *C. longiflorus* and *C. Fleischeri* still bloom under small handlights (specially useful for such flowers as these), and a new species (*C. hyemalis*), is in bud and will keep up the succession.

One becomes weary of pointing out the distinctions between the Crocus and the Colchicum, but it seems necessary to repeat them again and again. The broadest distinction, and the best probably for all practical purposes, is that the Crocus has only three stamens, while the Colchicum has six. On rockwork and in border various species of Crocus are peeping through the soil, holding out the hope of the time when they will open their glowing cups to the vernal sunshine, and glittering with radiance enchant us with their charms. But long dark days will pass before the yellow Crocus opens its burning flowers, which inspired Tennyson with the words :—

"And at their feet the Crocus brake like fire."

And the hues of changing and dying leaves meantime must needs temper our hope with sadness. This sadness is, however, almost drowned with admiration as we look upon these tints. The forest has its glowing autumn tints, and in a lesser degree our garden flowers give us a vision of beauty of a similar kind. In the dying foliage are shades of brown, of saffron yellow, and of bright crimson.

Perhaps the brightest shades of the latter colour are afforded by the dwarf *Polygonum Brunonis*, the Indian Knotweed. This is not a free flowerer with me, my soil being too dry, but in autumn it atones for this fault by the brilliancy of its leafage. Some of my friends consider it "weedy," but the epithet is hardly applicable to such a close dwarf habit of growth. It grows from 6 to 12 inches high, is a native of the Himalayas, and was introduced in 1845. I have observed it catalogued as synonymous with *P. affine*, which seems to have been introduced from Nepal in 1822. I am not an adept at describing plants, and the briefest description I can find is that given in Sutherland's "Hardy Herbaceous and Alpine Flowers," page 260. It is as follows—"This plant is creeping in habit, with numerous close-lying stems clothed with lance-shaped toothed evergreen leaves, tapering sharply at both ends on longish stalks. The flowers are deep rose, in dense but irregular spikes, supported on stems about 9 inches high; they appear rather late in the summer, and continue late. Pink, changing to deep rose, would perhaps be a better description of the colour. I have never seen this plant flower so well as at Edge Hall and at Blacklow House, Roby, the plant at the latter place being particularly fine. The mention of *P. Brunonis* reminds me of a dwarf species of earlier habit, and with sharper pointed leaves, which remain green. I saw this in an old garden last summer, but was at a loss to identify it. I find, however, it must be the one figured in Maund's "Botanic Garden" (Mr. Niven's edition), vol. ii., plate 57, and there named *P. viviparum*—the viviparous *Polygonum*. I do not see this catalogued anywhere, but although not showy it is particularly interesting from the growth upon its flowering stem of its little viviparous progeny of bulbs or buds. The flowers are whitish, of the same character as the other dwarf Knotweed, and are produced on a flower stem 3 to 6 inches high, and, as is stated in the "Botanic Garden," "at the same time as its flowers become, from their small green buds, more and more developed, the growth of a distinct progeny will be proceeding below them from the same stem. These consist of a number of brown or reddish buds or bulbs, as seen in our figure, each of them not only capable of forming a distinct plant for perpetuating its species, but capable of that development whilst on its parent stem." Although a native plant, *P. viviparum* is so interesting as to be worthy of a place when the peculiarities of plants receive notice.

This note on this curious Knotweed is a digression, but it serves to bring me back to my subject of the garden in December by reminding me of the curious appearance of *Mesembryanthemum uncinatum*, the only hardy Fig Marigold or Noon Flower with which I am acquainted. I have grown it for several years, and it is perfectly hardy here, but is only valuable from its curious gnarled-looking growth. I cannot get it to flower, but would by no means have it absent from my garden. It is said to have a pale purple flower, and is a native of the Cape of Good Hope, whence it was introduced in 1725. Haworth is, I believe, the authority for the specific title, but I have been unable to obtain much information about the plant. It is, at all events, interesting in the rockery at all seasons.

But the length of my MS. reveals to me that I have written too much. Verdant Mossy Saxifrages with their kindred with encrusted foliage, mounds of grey-leaved alpine Pinks, trailing sheets of variegated Arabis, with the many evergreen plants, and the Heaths of the rock garden still attract our eyes, and would inspire my pen. A small plant of *Ionopsidion acaule* still exhibits its gem-like flowers in the border, and appeals for notice ere the

year is done, for soon it shall be said of this little beauty in the words of Shakespeare—

“Death lies on her like an untimely frost  
Upon the sweetest flower of the field.”

—S. ARNOTT.

### PANCRATIUM FRAGRANS.

THIS beautiful West Indian bulbous plant seldom meets with the attention it deserves. Though its floral segments are not so long as those of some of the other species, its fragrance and the ease with which it is grown renders it one of the most useful of the genus. Seldom do we find any attempts being made to propagate it in private establishments, the stock being generally limited to one, or at most to a few bought plants. It is propagated readily by offsets, also by seed. The former may be pulled away from the parent plant with a few roots attached, the better way being to shake the plant clear of the soil, when the young bulbs may be removed intact. An occasional shake out in this manner is beneficial to the old bulbs, and allows of their being placed in smaller pots.

For potting a compost of fibrous lumpy loam and peat in equal parts, with sufficient coarse sand to make the whole porous, suits them. It is not desirable to use manure in potting or to employ stimulants after, except in the case of old and well established plants whose pots often contain more roots than soil. These latter would be better for a little liquid manure or clear soot water once or twice a week during the period of growth. Being a native of a tropical climate it requires stove temperature during the spring and summer when growth is active. During those seasons it should be afforded plenty of water at the roots. As the year declines less water should be afforded, and where practicable be removed to cooler quarters, a Cattleya house temperature being the best where it can be given.

It must not be forgotten that this *Pancratium* is an evergreen, and should therefore never be allowed to become quite dry, distress from this cause being evident by the flagging of the leaves. In *Cattleya* temperature they require very little water during winter, and if examined once a week there need be no anxiety on their account. March is the best time to remove the side bulbs, when both young and old plants should be removed to the stove or other equally warm house. The latter flowering in May or early in June if not shaken. Those plants from which all soil is removed require at least a month longer to flower than those left undisturbed. For decorative purposes this *Pancratium* is excelled by no bulbous plant, though many are better understood and cared for.—W. R. WILLIAMS, *Gt. Marlow*.

### CRINUM AMABILE, Don.

#### CRINUM SUPERBUM, Roxb.

WE have pleasure in offering you for publication a photo of *Crinum amabile*, Don, which, it is said, is one of the largest plants in Europe, and is well grown in one of the stoves of Messrs. Ant. Roozen & Son at Overveen, near Haarlem. The plant itself is, even without flowers, a picture of health and beauty; but in flower it is most lovely. It is about 2½ yards in diameter, the leaves are 4 feet long and 5 inches broad, lorate, tapering gradually to a point. The flower stalk or scape is 3 feet long, with an umbel of thirty to thirty-five flowers, which are very fragrant. The colour is white suffused with crimson, dark purple beneath. The perianth tube is bright red, cylindrical, 3 to 4 inches long; the segments the same length, spreading or revolute; the stamens 1 inch shorter than the segments. The bracts are 8 inches long and 7 inches broad; the circumference of the stem (neck of the bulb) is 16 inches, and the height above the tub 48 inches.

Like most other species, *Crinum amabile* being from Sumatra, likes a stove temperature with plenty of light and water. Some of them prefer a rest in winter time, but as far as I know *C. amabile* does not require that, at least the plant of which I speak, at Messrs. Ant. Roozen & Sons' nursery, never has any rest. All the *Crinums* can be raised from seed, but I never saw any seed on *C. amabile*. I have often tried to fertilise this, but never with any success. The propagation is effected by means of offsets and is very slow; when the offsets have attained sufficient size take them off, and grow them separately. We do that at any time. Last year this beautiful plant flowered four times, in January, May, August, and November. There is a figure of it in the “Botanical Magazine,” tab. 1605.—J. K. BUDDE, *Haarlem, Holland*.

[The necessary reduction of the large photo for engraving could not do justice to the stately plant in question.]

### CONFERENCE PEAR.

A CORRESPONDENT sends us what he calls a “picture” of this Pear, and asks if “all the fruits are like it?” He can judge for himself from our engraving of a typical specimen. The following is the description of this Pear:—Fruit oblong pyriform, from 4 to 4½ inches long, rather uneven on the surface, being somewhat undulating and bossed. Skin entirely covered with cinnamon coloured russet, through which the yellow ground colour appears in freckles; stalk long, stout and curved, inserted in a small round cavity; eye open, set in a slight depression; flesh buttery and smooth in texture, salmon-tinted throughout, and richly flavoured. In use during the end of October and beginning of November.

This is a seedling raised by Mr. Rivers of Sawbridgeworth, to whom

FIG. 90.—CONFERENCE PEAR.

we are indebted for specimens of the fruit from which our figure was taken. The tree is very hardy, and a great bearer. As an orchard fruit it is a valuable acquisition, and will be much in request as a market Pear. It received the name of “Conference” from obtaining a first-class certificate at the Pear Conference held at Chiswick in 1885.

### SIXTY YEARS OF HORTICULTURAL PROGRESS.

(1760—1820).

(Continued from page 301)

Now and then in our perambulations we come across a fairly preserved good old greenhouse of the reign of George III., and when we survey such a relic we wonder how it was that in those days gardeners succeeded as well as they did. Any sort of glass seems to have been thought quite good enough to glaze a hot-house with, and many of them were covered by small panes of green glass of the commonest kind; also, for the sake of cheapness,

nurserymen often glazed their buildings with fragments, and there were occasional gaps, while deposits of dirt settled in the interstices. Quantities of putty were used to fill up the laps, which, in connection with other obstructions of the light, often gave to the houses a very gloomy aspect. The construction of most was severely simple, whatever might be the size; a high back wall, generally 2 feet higher than the roof, a low front wall, or parapet as they called it, the sides of glass and wood. To avoid the necessity of shifting the sashes on the roof, some of the houses were built with openings in the back or high wall for the purpose of ventilation, these were usually closed by wooden shutters. It was about the year 1780 that someone suggested the employment of a leaden lap instead of putty for holding the glass in sashes, but an objection was made to this after a time, as the water running down the outside of a roof accumulated on the upper edge of each band of lead, and by degrees worked its way inside to drop on the plants. An improvement was made by the use of a very thin lap of lead, the glass being also secured with putty, but after a few years both modes became unpopular. The copper lap was a later invention, attributed to Mr. Stewart, who employed it in his large conservatories at Woodlands, near Blackheath. Gardeners, however, objected to the drip from this, which occurred unless the roof had a considerable slope, as this was said to be impregnated with copper, also to some extent the light was diminished.

By the middle of George III.'s reign, the open fireplaces first used for heating greenhouses were almost discarded, and the yet more objectionable plan of sinking the building and of warming it by a surrounding of decomposing manure had been quite given up. All houses, nearly, were now heated by stoves and smoke-flues; the stove, or furnace as they called it, being outside the structure and mostly placed behind the higher wall out of view, though some, for good reasons, preferred to have the flue enter the house at the front. It was carried round three sides in small houses and then brought back to the point where it entered, but in large houses it was made to return down the middle of the building. Coal was burnt, not coke or charcoal as a rule, and a variety of schemes were tried to avoid the necessity of going out to feed the stoves during the night, such as by a wheel which would revolve when the fire went down, but they were not successful. About 1775 we find mention of can-flues, so styled, a Dutch invention, known long before then in Holland. These were earthen pipes laid in portions and joined by cement; the objection to these was they heated rapidly but cooled down as soon. On the introduction of cast iron flues, rather later, these were also opposed by many, because it was thought difficult to prevent their being overheated, and some coated them with a mixture of clay and sand. Flued walls for fruit trees appear to have been introduced about this period. These were built of brick, occasionally of stone, and, of course, hollow pipes being carried from the base of the wall to within 1 or 2 feet of the coping; the stove was not placed in close contact with the wall, to avoid the diffusion of too much heat. A wooden or wire trellis was sometimes put in front of the side used, and some nurserymen had these walls covered with glass.

The poet Cowper amuses us by his description, given both in prose and in verse, of the trouble he took to raise "the prickly and green-coated Gourd." Evidently from what we read about his period the Cucumber was attaining an important position. Many new methods for its forcing and cultivation were tried. Indeed, McPhail remarks that almost every mechanic had a bed of Cucumbers in his garden, and he appears to have originated the method of raising plants by cuttings and layers as well as from seed. The gardeners now managed to produce Cucumbers all the year round by forcing in frames or stoves. Large quantities also began to be raised under handglasses; the seeds were sown in April or May for a summer and autumn supply. The majority of growers used dung chiefly for forcing, sometimes combined with vegetable mould or top-spit earth. Abercrombie gave his brethren many valuable hints, pointing out the importance of a steady heat, not allowed to fall much at night, also the need of due ventilation, which had been rather neglected, and he advised the application of sulphur as a remedy for mildew.

Before 1760 there were not more than six nurseries of any consequence in Scotland; but twenty years later showed a marked increase when the cannie Scots found that money was to be made, not only by the productions of the garden, but by raising seedlings of hardy and half-hardy trees and shrubs, some of which were found to succeed better in the air of Scotland than in that of England. A taste for flowers rapidly developed itself amongst the weavers of Paisley, which extended to other districts. Florists' societies were formed, and competitions took place, which led to the exhibition of new varieties of the Pink, Carnation, Tulip, Ranunculus, and other species, some of which were deemed superior to those obtained in the south. At this time the cultivation of the Strawberry had

increased more in Scotland than in England, also of Gooseberries and Raspberries, these being much in demand for making British wines. Some of the pupils of the famous garden-planner, Brown, made their way into Scotland, but did not attain to much success there. A man named Ramsey, however, improved upon some of Brown's methods, and became eminent there towards the end of that century.

In England a stimulus to the cultivation of choice and new plants was given by the publication of Curtis's "Botanical Magazine," commenced in 1787. Before that date, however, we read of William Curtis as the publisher, in 1777, of a "Flora Londinensis," and about that date he took up the subject of horticulture practically, for having secured a plot of ground in Lambeth he formed a collection of plants, medicinal, useful, and injurious, all arranged scientifically, to which he admitted the public by subscription. He was assisted by Barrington and White, and subsequently removed to Brompton. We have, it seems, to thank Lord Bute for introducing the Dahlia, a flower which caused much excitement, the seeds being sent from Mexico to Madrid in 1789, and his Lordship secured England a few of these. It is curious that some persons were anxious to name it Georgina, after Georgi, a Russian botanist, but it received an appellation from Dahl, the Swede. The first perfect blossom is said to have been raised in the French garden of Holland House, after many failures, and its history is illustrative of a common error amongst gardeners then, they supposed that because a plant was an exotic it must want a high temperature and a stuffy atmosphere. Mignonette (first grown, 'tis said, in Chelsea Botanic Garden, had become common about the London windows by 1775, and one of its cultivators prophesied that it would so increase as to grow along our hedgerows; but this does not appear likely to occur. Some good work for horticulture was done unobtrusively by men comparatively unknown, such as Nathaniel Rensch, whose family for two centuries held a nursery at Southfields, Fulham. He died in 1783, at the mature age of 100, and in the same room where he was born. This Rensch produced many variegated evergreens, and some think he introduced the Moss Rose.—J. R. S. C.

## FUNGOID DISEASES.

(Continued from page 474.)

THE following subject has special interest to growers of fruit in this country, inasmuch as it treats of Apple scab, *Fusicladium* (*Cladosporium*) *dendriticum*, *Fckl.* The work was conducted by Prof. E. S. Goff, and at the same station as last year, to which reference was made in this Journal; but a brief outline of the circumstances under which the experiments were pursued are imperative:—"The fruit farm of Mr. A. L. Hatch, on which the experiments here reported were conducted, lies three and a quarter miles south-east of the village of Ithaca, Richland County, Wisconsin. It crowns the summit of a hillock, and is not far from 1000 feet above sea level. The soil is a light clay loam, underlaid by Potsdam sandstone, and is in a good state of cultivation." The location is a wet one, and corresponds in many respects with the climate of this country, especially in a wet season; hence the experiments have special significance, because Apple scab and cracking in Pears is most prevalent in wet seasons, and runs rampant in cold soils and wet localities.

"The weather during the early summer," states Prof. Goff, "proved excessively rainy, and the effects of some of the applications were undoubtedly destroyed by copious showers soon after the treatments. It was sometimes necessary to postpone applications from day to day owing to the very frequent rains." Three fungicides were tested this season (1891), namely:—I. Copper carbonate dissolved in ammonia and also in suspension. II. The sulphur powder, so-called, introduced by Mr. E. Bean, of Jacksonville, Florida. III. The compound of ammoniated copper sulphate and ammonium carbonate—namely, mixture No. 5, before described.

The objects of the experiments were to ascertain the most efficacious materials and the best methods of using the fungicides. Prof. Goff observes that "It was found in 1889 that the ammonia, unless very largely diluted, endangers the foliage, and gives the fruit a rusty appearance. It also dissolves the arsenic of Paris green or London purple when used for the codlin moth at the same spraying, and this indirectly causes injury to the foliage." This is in accord with our experience of ammonia applied to the foliage as we have done for many years for the destruction of parasites. Treatment was followed on two trees with copper carbonate dissolved in ammonia, and two others with the same material simply stirred in water, as we apply Paris green, and the crops of these two pairs of trees were compared with each other, and also with those of the check tree. The treatment also had regard to spraying before the opening of the flowers, deferring it until after bloom, and the number of times necessary to give best results. Some trees were sprayed two, others four, six, and eight times respectively, and the crops of the different trees compared with each and with check trees not sprayed at all.

"The strength at which the fungicides were used. The copper carbonate was in every case of the precipitated form, and when applied in the

diluted ammoniacal solution was used at the rate of an ounce of the salt to 25 gallons of water. One ounce was dissolved in a quart of ammonia (strength 22° Baumé) and the solution added to the water just before the treatment at the rate named.

"When the copper carbonate was applied in suspension, an ounce was first stirred in a small quantity of water, and the mixture thus formed was added to 12½ gallons of water.

"The sulphur powder was used according to the directions on the package, *i.e.*, 10 lbs. were added to a barrel (50 gallons) of water, and allowed to stand a few hours before use. The yellow coloured liquid resulting was employed without dilution. As the barrel became nearly empty it was again filled with water, and the solution used as before.

"The mixture No. 5 was used as suggested by you (Mr. Galloway)—*viz.*, 12 ozs. to 22 gallons of water in the first two treatments, but owing to injury to the foliage it was diluted one-third in the later sprayings.

"The trees selected for the experiment were of medium size, and all promised a full crop of fruit, though all did not mature a full crop. None of the trees used in the experiment in 1889 were employed in the experiment here reported. The first treatment was given on May 5th, and others were made May 13th, 31st, June 5th, 16th, 28th, July 14th, 25th, August 6th, 19th, and September 2nd. Of course all the trees were not treated at all these sprayings. The treatment of June 5th was intended to supplement that of May 31st, much rain having fallen between the dates. As the Apples showed indications of maturity the entire crop on each of the trees selected for the experiment was gathered and assorted into three qualities as follows:—

1. Fruits free from scab.
2. Fruits showing scab spots, but not of sufficient size or number to distort the Apples.
3. Fruits more affected.

"In assorting the crops only the scab was considered, size and insect injury being ignored. Some of the fruits placed in the first quality were badly distorted by insect injuries, and were very small in size. In like manner some fruits of comparatively large size were of necessity placed in the third quality."

Tables follow showing the number of trees sprayed, with the number of times and dates of spraying, from which we glean that one tree of Canada Peach Apple sprayed with suspended copper carbonate two times before bloom, two after bloom; dates, May 5th, 13th, and 31st, June 5th, gave 257 fruits; first quality, 16.34 per cent.; second quality, 77.43; third quality, 6.23. One tree of the same variety sprayed with suspended copper four times after bloom, dates May 31st, June 5th (extra on account of rain), 16th and 28th, July 14th, gave 175 fruits; first quality, 5.71 per cent.; second quality, 72.57; third quality, 21.72.

One tree of Fameuse Apple treated with suspended copper carbonate six times—*viz.*, May 31st, June 5th (extra), 16th, and 28th, July 14th and 25th, August 16th, produced 633 fruits; first quality, 3.79; second quality, 41.71; third quality, 54.38 per cent.

Spraying with ammoniacal copper carbonate six times, dates as last given, fruits, 1.027; first quality, 2.32; second quality, 32.91; third quality, 64.27 per cent. One tree sprayed two times, May 31st, June 5th (extra) and 28th, produced 1161 fruits; first quality, 3.16; second quality, 37.15; third quality, 59.69 per cent. One tree sprayed once before bloom, three after bloom, May 7th and 31st, June 5th (extra), 16th, and 28th, bore 912 fruits; first quality, 20.61; second quality, 56.47; third quality, 22.92 per cent. Bean's sulphur powder, six sprayings, May 31st, June 5th (extra), 16th, and 28th, July 14th and 25th, August 6th, fruits, 1359; first quality, 1.18; second quality, 28.18; third quality, 75.64 per cent.

Mixture No. 5, eight sprayings, May 31st, June 5th (extra), 16th, and 28th, July 14th and 25th, August 6th and 19th, September 2nd, fruits, 1096; first quality, 18.70; second quality, 52.56; third quality, 28.74 per cent. One Canada Peach Apple tree, check, not sprayed, fruits 865; first quality, 0.36; second quality, 68.98; third, 30.66 per cent. One Fameuse tree, fruits, 258, first quality, 1.16; second quality, 22.87; third quality, 75.97 per cent.

In addition to carefully compiled tables, from which the preceding are taken, diagrams are given showing the results of the treatments in black and white, and shaded lines representative of qualities. White first quality, diagonal lines the second, and the black portion the third quality. From these it appears that the mixture No. 5 was considerably the more efficacious; that the sulphur powder actually appeared to increase the amount of scab, and that there were little difference in the results obtained by using copper carbonate suspended in water and in ammoniacal solution. In spraying the Canada Peach Apple with suspended copper carbonate before and after bloom, the benefit from the treatment before bloom is very perceptible, which indicates that this method of using copper carbonate is capable of giving good results. The value of spraying once before the flowers have opened and three times after the petals had fallen is apparent from the fact that it is more efficacious in preventing Apple scab than four sprayings made after the fruit is set. Eight treatments gave only slightly better results than four, but four gave considerably better results than two. It must be noted that the first two sprayings succeeding the fall of the petals gave no results, the rains then prevailing washing off the fungicide, and rains simply promote the growth of the fungus, for the June 28th and July 14th sprayings proved beneficial, because the weather was less wet; and it is evident that treatment made after midsummer are of doubtful value, as stated in the subjoined summary.

Prof. Goff states that the experiments suggest the following conclusions:—"I., That in seasons of excessive rains in early summer

the scab on badly infested trees cannot be wholly prevented by the treatments given in this experiment. II., That of the substances tested the mixture of ammonium carbonate and ammoniated copper sulphate (designated as mixture No. 5) was most efficient. III., That the precipitated copper carbonate applied stirred in water, as we use Paris green, is nearly or quite as efficient as when one-half the amount was applied dissolved in ammonia, a point which, if confirmed by future trials, is important, as it will render possible the use of Paris green for the codlin moth at the same spraying with the fungicide. IV., That early treatments, and especially at least one treatment previous to the opening of the flowers, is extremely important."

It is stated that the cost for spraying one tree once with ammoniacal copper carbonate is, including labour of preparing, about 6 cents. (3d.); that of spraying one tree with suspended copper carbonate, using double the amount as in the above, is about 4.2 cents. (2d.), the mixture No. 5 costing practically the same as the ammoniacal solution. "V., That sprayings after midsummer are at best of doubtful value. VI., That on trees badly infested with scab the fruits that develop may be so far reduced in size by the fungus as to diminish the crop nearly 20 per cent., but this is doubtless but a small part of the injury actually produced."

Professor Goff, in concluding an extremely valuable report, advises that in future experiments a larger number of trees be employed as duplicates. Additional notes on the experiments in treating Apple scab (*Fusicladium dendriticum*) are given by Mr. Hatch, on whose fruit farm the experiments were conducted, and having an important bearing on the use of fungicides in some essential points they are subjoined:—"It is my opinion that the first spraying for the Apple scab should be made much earlier than the time usually selected for the first spraying for the codlin moth. The foliage is then pretty well formed, and the past season we found well developed scab spots upon the leaves at that time. The few scab spots found later in the season that appeared to have been killed by the treatment warrants the conclusion that the chief benefit of spraying comes through the destruction of the spores that have gained lodgment upon the fruit and foliage. The results in the case of the trees treated before blooming also points in this direction. I think it possible that a treatment before the buds have commenced to expand would be productive of much good. The extremely heavy rains of June and the first part of July rendered the season very unfavourable for the work, and resulted in loss of the benefits of spraying my main orchards for both Apple scab and insects. Still, by persistent efforts I think we have some valuable results. At least we have done all possible to make them successful, and our thanks are due to Professor Goff for his aid at various stages of the work. My loss from Apple scab has been very serious, not only in fruit but also in foliage, and the magnitude of its injury warrants still further efforts in combating it. We found mixture No. 5 very persistent upon the foliage, but apparently too strong in ammonia. Its caustic effects were so apparent that for some of the later sprayings we reduced the quantity one-third. The solution of carbonate of copper, although diluted 100 parts with water, had similar effects, and I would suggest that it may possibly be found equally efficient if diluted even 200 times. We used strong ammonia (supposed to be 22° Baumé) to make a saturated solution (about 1 oz. to 1 quart). In using carbonate of copper in water alone I think we used too little. There would have been no harm to the foliage if used several times as strong, nor indeed is it likely to prove injurious in any degree."

The use of precipitated carbonate of copper in suspension is really worth all the experiments. It not only proves the possibility of one treatment answering the purpose of a combined fungicide and insecticide, proves that precipitated carbonate of copper does not injure the foliage and fruit, and may be used with perfect safety, but it establishes the fact that the surfaces coated with a thin film of copper carbonate are practically invulnerable to attack by the fungus, and that its germinal tubes are destroyed by the copper at the point of contact. In fact, fungoid diseases must be treated early—in advance of the germination of the spores. If allowed to germinate and the mycelium have penetrated beneath the epidermis no treatment does more than arrest the disease, if that, whereby trouble and loss is entailed, which by early treatment might have been prevented.

The "Journal of Mycology," as will be seen from the foregoing extracts, of which we are heartily ashamed to have made such copious use, but it is justified, for in this country we absolutely do nothing to prevent the spread of fungoid disease but let whole fields of Potatoes rot before our eyes. On this subject, Potato disease, the "Journal of Mycology" is not silent, but contains some very cogent notes on experiments conducted by Prof. Goff on Mr. Hatch's farm, which I hope to allude to on a future occasion.—G. ABBEY.

#### PACKING THE JOINTS OF HOT-WATER PIPES.

THERE are many complaints of the bursting of sockets that have been packed with iron filings. The cause is unquestionably the use of too much sal ammoniac amongst the borings. The too free use of this is rapidly bringing iron joints into bad repute. They are without doubt the best and most durable that can be made, provided the necessary care is exercised in mixing the materials. Excess of sal ammoniac destroys the properties of the metal, and the sockets are certain to burst sooner or later. They fail when the rope placed into the joints begins decaying. The sockets often burst during the time the fires are not employed, or almost directly after they have been restarted or heat turned on to the pipes. The length of time the sockets last after these

salts have been used too freely depends a good deal upon the amount of rope or similar material employed.

Sockets packed with iron filings and sal ammoniac often burst through carelessness in mixing the ingredients—ignorance in not knowing the destructive properties of sal ammoniac or laziness. When used in excess the filings become pasty and are much easier to work, the joints requiring less hammering up than when the right portion only is used, thus being made easier and quicker.

Split sockets may sometimes be kept together for years by placing an iron band round them. Long thimbles are the most satisfactory after cutting off the socket. Practically new rope or hemp that has been loosely twisted should be used, and this should be liberally coated with white or red lead, half filling the joint, then finishing with Portland cement. Joints made with rope and red lead only have stood for years.—O. M.

#### AMATEURS AND SINGLE-HANDED GARDENERS.

DR. WALKER'S letter in last week's Journal is surely one of the most quaint productions that has ever appeared in its pages. Force of habit appears to be too much for him, and while attempting to defend himself in an illogical position, he wanders off into a sort of prescription by saying "the whole question of competitors wants revision."

When an amateur is found winning prizes in an amateurs' section, and in one reserved for single-handed gardeners as well, it will be admitted by every reasonable person that the Doctor is right, and that revision is indeed sadly wanted; the striking thing in this particular case, however, is that it is he himself who creates the special case for revision. He appears to be working on the good old principle, "Do not do as I do, do as I tell you." As a medical man "the Wimbledon Amateur" is accustomed to giving advice. Probably he could not help it if he tried, but in the present instance some persons may be inclined to think that he should be content with receiving instead of giving it.

One might imagine from Dr. Walker's eagerness to connect someone else with him that he felt by no means sure of his ground in this matter. He turns upon Mr. Shea with the threadbare old "you're another" apology for an argument, and tries to link the latter with himself, but it signally fails to hold good. Mr. Shea is not "another." He stands on different ground altogether. Instead of copying the magnanimous example of showing in a small reserved class, in which there is no credit to be won beyond that of depriving hard-working gardeners in small places (earning 18s. or 20s. a week perhaps) of a little prize money, he enters in an "open" class against the most powerful competition in the country, and achieves a most brilliant and creditable victory. Does the "Wimbledon Amateur" really think that in the eyes of the Chrysanthemum world he, winning a few shillings from those poor fellows in a class that was reserved for them at a local show, and Mr. Shea, bo'dly throwing down the gauntlet to the strongest exhibitors in an unreserved class at one of the largest shows in the kingdom, occupy the same position? And while he is answering this question perhaps he will also tell us whether, since he uses the word "afraid," he exhibited in the leading classes at Wandsworth Show, as well as in the small ones reserved for single-handed gardeners. If so, well and good; if not, was it because the opposition was too strong for him? and if so, will he say who it was that was really "afraid?"

That he had the sanction of the Committee only proves that the latter, by making two distinct sections for different classes of exhibitors, and then allowing the one to mix with the other, stultify themselves. It is to be hoped that they will in future seasons give due weight to Dr. Walker's opinion that the "question of competitors wants revision," and act accordingly. Justice, like charity, should begin at home.—THE JOURNAL REPORTER.

#### AMATEURS EXHIBITING IN GARDENERS' CLASSES.

I HAVE no wish to enter into this controversy, but I notice that in your last issue Dr. Walker imports my name into the matter by remarking that I, an amateur, showed and took a prize (first) in the "open" class (forty-eight Japanese) at the November Show at the Royal Aquarium, and that no gardener's name appeared upon the card. I may be allowed to point out that the fact alluded to scarcely appears to bear upon the question at issue, which, as I understand it, is whether amateurs may rightfully compete in classes nominally reserved for gardeners. I have never showed in these classes, but have considered, what I should have thought no one would be disposed to question, that the "open" classes, as the word suggests, are "open" to all the world—nurseryman, gardener, and amateur. How, therefore, the fact of my competition in the "open" class can affect one way or the other the question of the right of one clearly outside the nominal terms of a reserved class to compete therein I must confess that I am unable to see.

A gardener's name does not appear on my card for the simple reason that it is one of my many hobbies to grow and attend to my plants "from cutting to show board" myself. I observe that Dr. Walker

assumes as a principle that "anyone may show in a class above him." How this may be I do not know, nor am I aware that it has ever been laid down that any one class is "above" another. Suppose, for the sake of argument, that an unexpected accession of amateur skill, coupled with the greater time devoted to the one particular flower by the amateur, brought about the result that amateurs were stronger at the show tables than the single-handed gardeners, would the latter be then entitled to compete in the amateurs' classes on the ground that they were "above" the single-handed gardeners' classes in the only sense that I think it can be suggested that the latter are now "above the former?" If not, where stands Dr. Walker's argument?

I do not think that the suggestion of one class being "afraid" of another should be used as an argument, if for no other reason that it goes dangerously near inviting the retort that if the ambitious amateur is also so very fearless, he has it always in his power to avoid the question raised in the case of Dr. Walker by showing in the "open" classes. If he will do this I think that I may promise the Doctor the same immunity from criticism which has attended the practice which I have hitherto made of confining my exhibits exclusively to that class.

Of course anyone who knows Dr. Walker must also know that he acted with the most perfect conviction that he was right in the view he took, and he has certainly achieved one result, and that is that he has made out a case for legislation upon the point—say by the Committee of the National Chrysanthemum Society.—CHARLES E. SHEA, *The Elms; Foot's Cray.*

#### NEW CHRYSANTHEMUMS.

CULTIVATORS for exhibition know well the advantage of being in possession of the new varieties as soon as they are obtainable, as improvements in any section always score a point or two more than inferior sorts. Apart from their value as exhibition varieties, it is the constant change in form and colour that maintains so great an interest in the Chrysanthemum. Even to those who do not make exhibiting a feature, the introduction of a new variety is of interest. As all growers have not an opportunity to inspect the novelties of the season, and as the descriptions in catalogues are at times a little puzzling, I have transcribed my notes of those which I consider worthy of a place in the revised lists of 1892. The descriptions of some may differ from catalogues for the reason that I fail to find the colours in the flowers as represented in some instances.

INCURVED varieties are introduced so sparingly that any which are really meritorious are sure of a hearty welcome, and are perhaps more eagerly sought after than any other section, therefore deserve a first notice. The present season has been somewhat remarkable for the introduction of several French varieties which possess merit, but as a rule the best are the result of English sports, therefore do not add to the list in variety of form, as they retain the form of the parent in every respect. The colour is the only point in which to expect a change-taking place, hence so many complaints are heard about the lack of variety in this section. With very few exceptions French raised seedlings cannot compare with those from sports, there is such a want of the true incurved form in the former as judged from the English standard; the florets have such a tendency to stand erect instead of incurve correctly.

*Mrs. Robinson King.*—This is a sport from Golden Queen of England, raised by Mr. Hotham, gardener to W. Robinson King, Esq., North Ferriby, Hull. It appears to me to have a greater likeness to Golden Empress than to its parent, having exactly the slightly serrated floret which is at times found in Golden Empress. In any case it is a decided acquisition in point of colour, which is one shade lighter than Jardin des Plantes, and as the latter is not often seen in good condition the new "Queen" sport is sure to become popular amongst exhibition growers; as it will give them another "back row" flower. I have seen blooms measuring 5½ inches in diameter and of proportionate depth, which size at once places it in the front rank as a distinct exhibition variety.

*Madame Darrier* is one of the few varieties in this section of French origin of sufficient merit to receive a foremost position in the section to which it belongs. Although not destined to be a back row flower it will do well for a middle or front row, and for this reason is a valuable introduction, being really wanted more than those for the back rows. Well-grown blooms are nearly upright at the sides, which shows what a solidity of petal and "build" it has; add to this its great depth, and we have qualities desirable in the section to which it belongs. The colour is nankeen yellow with a bronze suffusion; some say it is striped purple, but this colour I fail to find until it shows in the florets with age. This variety produces flowers of two distinct colours, that previously described when developed from crown buds, while the terminals give blooms much flatter, with a distinct purple shade of chestnut. The florets are narrow and pointed, which in the case of crown bud flowers are desirable to make a perfect incurved bloom.

*Ami Hoste* is another of French origin, and worthy of a place. The florets are narrow and pointed; in well-grown blooms they incurve neatly. The colour reminds one very much of Cherub, with perhaps a shade of carmine and gold tipped points of the florets. As a front row flower it should be useful.

*M. R. Bahuant* has been much praised and described. At present it is much too early to be of use to exhibitors at the ordinary November shows. About the middle and end of October it was very fine, but if it is not amenable to treatment to retard its development it will quickly drop out of the lists. Throughout the whole season I did not see it shown in its true character. The blooms lacked depth, which was proof of its earliness, the lower florets having decayed. It has the broadest

florets of any incurved variety we have, quite of the Queen type in habit of growth, probably a seedling from that family. The colour is carmine rose with a cerise shading.

*Brookfield Gem*, a sport from Jeanne d'Arc, is most peculiar in its colouring, being a kind of slatey lilac, having the same properties in the build as its parent; it is sure to be much sought after when more known.

*Madame Frederick Mistral* is of French origin, light violet rose with salmon tips; it incurves neatly, and as such will be valuable as a front row flower in large collections.

*Madame Pierre Louis Blancard* is also of French origin, white with carmine shade; each petal is tipped with gold; is of the Princess of Wales type, though smaller; as a front row flower it should prove useful.

I have seen several more of promise, some seedlings from Princess of Wales, but as they are not to be sent out until 1893 I will refrain from describing them.—E. MOLYNEUX.

(To be continued.)

#### CHRYSANTHEMUMS FOR CUTTING DOWN.

"NORTH COTSWOLD" makes inquiries at page 450 about the best twenty-four varieties of Japanese Chrysanthemums for the above purpose, and as I have had some experience I offer my assistance by naming the following, which will probably suit your correspondent:—

White: *Avalanche*, *C. Wagstaffe*, *Bouquet des Dames*, and *Stanstead White*, while *Mrs. Wright* is very attractive. Blush or delicate pink: *Etoile de Lyon*, *Madame Marie Hoste*, *Miss Anna Hartzhorn*, *Madame J. Laing*, and *Puritan*. Pink and rose: *Madame Baco*, *Vivian Morel*. Crimson: *W. W. Coles*, *Wm. Holmes*, and *Miss Esmeralda*. Purple: *Neptune*, *M. Bernard*, and *Alberic Lunden*. Yellow: *Sunflower*, *President Hyde*, *Mrs. Clinton*, *Martha Harding*, *W. H. Lincoln*, and *Sarah Owen*.

"North Cotswold," no doubt, is well acquainted with cutting down; however, I will remind him that *Stanstead White* and *W. W. Coles* should be cut down early, while *Puritan*, *Neptune*, *Mrs. Clinton*, *President Hyde* and *Sunflower* should be cut down about the 1st of June, and those not mentioned ten days later.—J. PITHERS.

#### READINESS AT EXHIBITIONS.

I WAS an exhibitor in a small way at the Bristol Chrysanthemum Show, and can bear out "Exhibitor's" remarks as to the backward character of the arrangements. Having exhibited at Bath, where, so far as I could see, every class was marked out and cards denoting the class fixed everywhere, it was easy to place my stands in their classes and I might have gone off at once. Mark the difference at Bristol. Getting there about nine o'clock, I found one side of the room, for the larger classes of cut blooms, partially occupied and persons busily engaged in setting up. Beyond the one or two larger classes Chaos reigned supreme. At last I saw an official and asked where my class room was. Oh, he could not possibly tell. I moved my boxes into a corner and waited. Later on I appealed again, and then had a part of the staging marked out, where I had better put them "for the present." This I did, but had I not watched them with the feverish love of a juvenile at the game, the little beauty they possessed in other eyes would have been ruined by the unceremonious shower of plant exhibitors on the more raised portion of the staging. Then I found these plant exhibitors of *Poinsettias*, *Palms*, &c., just as particular about every leaf on their plants as we Chrysanthemum bloom exhibitors on our petals. Jump up on the staging, and put this leaf above that one, down again and criticise. No; won't do. Up again and shift this pot round, and put that leaf over this one. Down again; and so the game went on. Meanwhile, the staging never being very firmly foundationed, the box containing my blooms had sustained sundry shakings, not improving their general appearance. Then the said official—I do not know his name, but willingly testify to the hard work he performed on that memorable morning—told us that where I had put my boxes would surely be wanted for other classes and I had better get the other side of the room. So from pillar to post and post to pillar, the morning wore on, and about 11.30 or 11.45, just an hour or so after the time that the Exhibition was ready, or should have been, for the Judges, we began to see a possible solution to our difficulties, and about twelve I was able to escape from the room.

Now at a splendid exhibition like that of Bristol this is not quite the treatment that exhibitors expect to receive, and the only sort of excuse that can be made for it is that the exhibition seemed unfortunately to have been without a mainspring—without a secretary at the date—and therefore without the official on whose head all errors of omission and commission are sure to fall.

The official in that portion of the Exhibition, I have already said, worked hard, very hard, in trying to bring the state of chaos into order; but should he read these lines, I would say to him, his work would have been easily performed overnight—say Class 25, forty-eight blooms, suppose five entries, that will take so much space, and so on—the staging might have been all marked out the previous night, and this is what it should be.

I do not wish to grumble, but having to stay three hours in a room when half an hour was sufficient is rather a trial, even to one who on that occasion was able to call himself a—SUCCESSFUL EXHIBITOR.

#### HAIRY CHRYSANTHEMUMS.

THESE appear to have been unusually prolific this year, judging from what I have seen and heard. It is nothing unusual to see blooms of the Teck family carrying a few hairs, and especially the variety

Charles Gibson, as alluded to by "Subscriber" (page 473). Cullingfordi has in many places shown the same peculiarity in a few of its florets. Violet Rose is another variety exhibiting the same peculiarity; but perhaps the most remarkable sort in this respect, apart from Mrs. A. Hardy and the newer Louis Boehmer, is *Lalla Rookh*, a carmine buff coloured Japanese, but unfortunately it has no other point to recommend it beyond the hair-like growths so freely covering its florets. By-and-by we shall expect to see a class formed for these varieties.

#### REVISION OF LISTS OF VARIETIES.

Cultivators of Chrysanthemums in any form, those who have been exhibitors in the past season, and those who purpose entering the lists, will now need their lists of varieties revising. Additions are so numerous made in some sections, Japanese especially, that a yearly revision is quite a necessity if cultivators wish to keep pace with the times, and if exhibition is a point of study the new varieties must be added and inferior ones dispensed with. My object in writing this note is to impress upon beginners the great mistake made in overcrowding limited space with varieties merely for the sake of numbers. Far better is it to cultivate an extra plant of a well-tried kind than to burden oneself with those which may turn out worthless for the purpose for which they are required. I am also aware that nowadays there is a great craving amongst Chrysanthemum cultivators for novelty, and although this may prove interesting it is not always remunerative. Many of those which were but a very few years since looked upon as ideal blooms appear worthless beside the newer varieties. I find that the list needs much annual revision. Except in the matter of personal taste, or a weakness for some particular variety for some private reason, such varieties as *Baronne de Prailly*, *Meg Merrilies*, and more of those which are notable for their width only should make room for such as *A. H. Neve*, *W. W. Coles*, *Vivian Morel*, and *Sunflower*. These are the types of flowers which cannot fail to please even those who sometimes object to large blooms. Varieties like those first named are but thin at their best as compared with the newer sorts last quoted. We do not require sorts through which the green boards can be seen when the blooms are staged. Such stretched-out examples do much towards making the cultivation of Chrysanthemums for cut blooms unpopular with those who profess to see no beauty in such huge flowers.—E. M.

#### CHRYSANTHEMUM FLORENCE DAVIS.

IN the note, page 473, on this variety, Mr. Parker says:—"The flowers are very large (8 inches broad and 10 deep)," which is not, to say the least of it, something wonderful. It is not the breadth that I think so much about, but a Chrysanthemum bloom 10 inches deep sets one thinking that a slight error has crept in somewhere in the measurement. Previously I thought 6 inches deep was large for even a Japanese, but to add 4 inches to that makes one wonder how big the new varieties of the future will be. I saw blooms of *Vivian Morel* this season which measured 9 by 6 inches. I thought them extremely large and in grand proportion, but it appears these were a long way off the size attained by the variety which forms the subject of this note.—E.

THE few growers who have been fortunate enough to procure a stock of this grand new variety would not be much surprised to see the note by Mr. Richard Parker on page 473. I do not know that I can say much more in its favour than your correspondent; but growers may be a little mistaken in reading it, seeing that the buds are green, and may be led to think that it is another *Mrs. Alpheus Hardy*, but it is not so. The buds when opening are almost a sea green, but as they expand become the most lovely white. It is a seedling raised by Mr. Norman Davis of Camberwell. Your correspondent seems to be limited to a few plants; but I have had the pleasure of not only growing it myself, but seeing a quantity of the same growing in pots, and in no case have I seen it refuse to open; and I shall be greatly mistaken if we do not see it as freely shown next year as *Avalanche* and *Stanstead White*. It will certainly rank as high as either. I should like to hear what other growers have to say upon this variety.—W. A.

#### CHRYSANTHEMUM CHARLES GIBSON.

HAVING noticed "Subscriber's" query respecting the disposition of this variety to produce hairy florets, I may say that one of my plants last year had some of its blooms rather thickly covered with these appendages, and the cuttings taken from that plant have this year "hirsute" qualities considerably in excess of that of their parent.—WELTON DALE.

NOTICING "Subscriber's" remarks, page 473 in last week's Journal, of his Charles Gibson showing hairy florets, I may add that I have experienced the same with one of my plants. It had six fair-sized blooms on the plant, and all of them showed hairy florets, three in particular, quite as much as *Mrs. Alpheus Hardy*. The colour of all the blooms was of a much deeper bronze, and wider in the florets. I am sorry they are too old to enclose one for your inspection.—S. K.

#### THE OLDFIELD NURSERIES.

TRAVELLING to Broadheath Station, L. and N.W.R., a walk of about ten minutes brought me to the above-mentioned nurseries. Unfortunately the day was of the most miserable description, but as I had journeyed with the intention of giving to the readers of the Journal some little information regarding this enterprising firm that I did not mind the

weather, and after inspecting some thirty-six large houses I felt amply repaid, for bad as the weather was outside I was the greater portion of the day in a congenial atmosphere. The firm of Messrs. Clibran & Son has made rapid strides of late years. Their first catalogue was a small eight page list of 250 copies. This year they have sent out over 80,000 copies, well printed and full of valuable information. In 1872 the Oldfield Nursery consisted of one greenhouse, £20 a year being paid for rent. Now they have over 3 acres of glass alone, and over 100 acres of land, the rental being raised to over £1000. The employes number over 150, and £7000 is paid annually in wages alone. I was fortunate in finding Mr. Clibran at home, and we set out together to inspect the great area of glass. His first greeting was, "I hope you have not come with the intention of seeing a show place. Ours is not so in a sense; it is rather a large plant manufactory;" and I was soon reconciled to the fact that he was right. All the houses are of the plainest description—span-roofed, but excellent for their purposes. It would be quite impossible for me in the space at my command to pretend to give a detailed description of everything I saw in each of the thirty-six large houses, and it could not be expected of me to enter into such minute details, but I will as far as possible deal with some of the more important stocks of plants grown.

#### STOVE PLANTS.

Seldom have I seen such quantities and in such clean condition. Splendid healthy Dipladenias of all the best forms—Brearleyana, amabilis, ornata, Thomas Speed, boliviensis, Lady Louisa Egerton, and insignis, with Ixoras amabilis, Colei, conspicua, Dixiana, Duffi, Morsci, sanguinea, Westi, and Williamsi. Fine plants of Stephanotis were noted, including a very free-flowering variety, and one which will stand the temperatures—viz., Cole's variety. All the above plants were represented in various sizes, and in capital growth. Of Allamandas all the best varieties are grown, one especially, magnifica, surpassed the others by its free flowering and the excellent substance of its large clear yellow flowers. Stigmaphyllon ciliatum (Golden Vine) was charming on the roof of one of the houses. The foliage is extremely pretty, and the flowers suggestive of Oncidium flexuosum. Schubertia grandiflora had pure white flowers, nearly 2 inches across, produced in trusses; they last a long time, and have a delightful almond-like fragrance. These are two plants which can be thoroughly recommended; there are also Bignonias, Tabernæmontanas, Thunbergias, Toxicophleas, Rudgeas, Luculias, Rondeletias of which they have a very fine form, surpassing the ordinary types. Gardenias by the hundred, Dracenas, Anthuriums, Crotons, Clerodendrons, Æschynanthus, Alocasias, Euphorbias, Hoyas, and many other choice stove plants are also included.

#### GREENHOUSE PLANTS.

All classes are to be met with, but the most noticeable were the Bouvardias. Thousands were in full bloom, the sorts largely grown being Vulcan, President Garfield, Purity, President Cleveland, and Mr. Robert Green. There is a great demand for these as young plants, and when in flower for wreaths. Cyclamens were in equal abundance, but not then at their best; Azaleas, the most useful variety being Deutsche Perle, of which some 2000 are forced each year; Calceolarias, Cinerarias, and Primulas were in all stages and pictures of health; Richardias on every hand, and nearly all grown on the single crown system. The variety grandiflora has large spathes, and is altogether a finer growing variety than the old form, while Little Gem is what its name implies, only being about 9 inches or a foot high. Ficus elastica variegata I never saw better. Camellias in all sizes are represented by healthy plants. Clematises were there in thousands, comprising a large number of Jackmani, indivisa, and indivisa lobata, Jackmani alba, and the beautiful double variety Duchess of Edinburgh. The new variety Smith's Snow White is likely to become a favourite. Clanthus magnificus is a far finer acquisition than Dampieri and was flourishing in abundance. Lapagerias in all varieties formed a splendid stock, and the beautiful greenhouse Rhododendrons were also noted in many sizes. In one greenhouse a grand display of Lilium lancifolium album and auratum were in full bloom. About 2000 of the former are grown each year, and 2000 of the latter are imported. Some 1500 L. candidum are forced each year, and 6000 imported. There was a fine houseful of Fuchsias, from 12,000 to 15,000 being sold each spring. Passiflora Watsoniana was unique in the large collection of Passion Flowers.

#### TUBEROUS BEGONIAS.

The Begonia house is 150 feet long and 34 feet wide. Although a little late there were many fine varieties left as witness of what the show had been. Flowers of the finest substance in shades of salmon, pink, crimson, yellow, and all the intermediate shades, and the Picotee-edged were clearly defined. The seedling doubles were extremely beautiful. About 15,000 had been bedded out, and I was informed that notwithstanding the adverse season they had done remarkably well.

#### SOLANUMS.

A house 210 feet long is devoted to the cultivation of these beautiful berry-bearing plants. They are grown in three successions. The first plants were just finishing, the second changing colour, and a third just swelling. Every plant will find a ready sale. This house is heated by steam, and Mr. Clibran says it is excellent for forcing purposes, and is used for forcing Lily of the Valley, Hyacinths, and Tulips; 50,000 Romans, 35,000 large flowering Hyacinths, and 150,000 Tulips are grown annually.

#### ZONAL PELARGONIUMS.

A house 150 feet long is in full bloom at the present time, and a magnificent display they make. No inferior sorts are grown, only the

best varieties are to be seen, and some of the seedlings are very promising. A few of the best are Oldfield Surprise, Jessie Clibran, Lady Vernon, Lady Egerton, Mr. H. Barlow, Mr. T. W. Killick, Oldfield Gem, Rev. Dr. McKennal, Sir Wm. Cunliffe Brooks, and Willie Clibran. Other promising seedlings are on the way. A new bedding variety certificated at Liverpool last August will be sent out by them next season under the name White West Brighton Gem. It has a well-defined leaf and a dwarf habit, and ought to be in large demand. Speaking of new plants, I wish to say a word in praise of the new Tropæolum Mrs. Clibran. As a bedding variety it will become as popular as anything yet sent out. With a wet season like the present it has only grown about 6 inches high, and the clear yellow flowers glisten like gold. It is to be sent out next season, and has been thoroughly tested in every respect.

#### FERNS.

Three or four houses each 150 feet long are set apart for these, the demand being so extensive. Everything old and new is kept in stock. Beautiful young plants of Adiantum farleyense in 5-inch pots were noticeable for the fine fronds they carried. Adiantum Waltoni was decidedly superior to the old A. cuneatum. They were growing side by side, and it is so fine as to warrant a most extensive propagation, and only requires a closer acquaintance to have a large sale. Many thousands of Palms in all sizes are to be seen, amongst which were numbers of the somewhat scarce Kentia Canterburyana.

ROSES.—The principal Rose house is 150 feet long and 28 feet wide, and is filled with Roses in pots packed closely, and nowhere can be found a trace of mildew. They were in rude health, the climbing varieties being especially well grown. Thousands of plants might be counted in various other houses, all bearing the same healthy appearance.

CHRYSANTHEMUMS.—I was a little early for these, but there was sufficient evidence that their cultivation is well understood. They were arranged in a large span-roofed structure in three divisions, the first being filled with large flowering sorts, the others with plants grown specially for cut flowers. In the first I noticed Mr. R. Bahuant, well illustrated in the Journal recently. It is a most pleasing shade, and, as I saw it, must find many admirers. Alberic Lunden has large flowers, after the Stanstead Surprise style; colour a beautiful carmine crimson, with white centre. Coronet.—The largest buds of any in the collection of a light bronzy yellow, globular in form. Mr. A. H. Neve.—Silvery blush, rosy purple centre, long drooping florets, a lovely variety. Gloire de Rocher, Louis Boehmer, and Robert Cannell all gave promise of excellent blooms, and Mr. W. H. Lincoln was charming.

Caladiums had been a splendid show, a few of the best at the time of my visit being Mrs. Harry Veitch, L'Aurore, Ibis, Rose, L. Lorrain, Comte de Germiny, Oriflamme, and Lymington. Orchids are being taken in hand, and a house containing amongst others a fine pan of Cælogyne cristata alba 3 feet across, fine pieces of Dendrobium nobile nobilium, and some choice Cypripediums and Cattleyas. An improved variety of the edible fruiting Passion Flower is here, superior in every respect to the old variety, and is to be sent out very shortly.

The collection of herbaceous plants is extensive and well grown, and of Dahlias the same remark will apply. Shrubs and fruit trees are excellent clean examples. Many other things I could dwell upon, but space forbids. Messrs. Clibran are busy erecting new stables, and other improvements are in contemplation. In addition to the Oldfield Nurseries they have the Stamford Nurseries, Bowdon; and Principality Nurseries, Deganwy, Llandudno. The latter they intend to devote chiefly to the cultivation of fruit trees and Roses. The Roses were doing exceedingly well.—VISITOR.

#### ORCHIDS AND CHRYSANTHEMUMS AT KING'S SCHOOL, WARWICK.

WHAT a fascination both these popular classes of plants have for the majority of those who become interested in their cultivation, and to keep a garden gay throughout the year the best of all methods to adopt is to grow successional supplies of well-selected plants, and make a speciality of them. This is the plan pursued in the garden of the Rev. J. P. Way, who is an enthusiastic horticulturist, and whose gardener (Mr. W. Rouse) manages so admirably all the plants which he takes in hand. At the present time Chrysanthemums are the chief attraction, and a bright varied show they make in the two houses in which they are arranged. Most of the best varieties are grown, as well as many of the older kinds which have been ousted from many collections on account of their not being large enough for exhibition. A notable flower which is not often seen now is Madame de Sevin, which is a useful decorative variety. Mrs. Alpheus Hardy was in good form, almost equal to a fine bloom I saw a few days after at the Birmingham Show. Louis Boehmer was also in fairly good condition, and is certainly a good companion to its hirsute pioneer. Sunflower, Etoile de Lyon, Mrs. F. Jameson, and Stanstead White were conspicuous among the Japanese; and in the incurved section The Queens, Lord Wolseley, Prince Alfred, Violet Tomlin, Refulgens, and Barbara were especially good. The plants throughout were in excellent health, though only grown for providing a good home display. Many of the flowers would have given a good account of themselves if placed upon the exhibition boards.

The Orchid houses were filled with healthy plants of Cattleyas, Odontoglossums, Dendrobiums, Oncidiums, Vandas, and Cypripediums of a useful size for supplying cut flowers, and thereby creating much interest and delight, as the varied markings of flowers of so many types are constantly unfolding some fresh beauty, and stirring up the

imagination to speculate upon the form and markings of others yet unopened.

The *Cypripediums* in themselves made quite a show of quaint beauty. *C. callosum* was carrying several fine flowers; the beautiful *C. Schlimi* was also flowering freely; *C. barbatum superbum* and the well-known and useful *C. insigne* were numerous and good; *C. Fairrieanum* was also in good condition and producing flowers freely. Many good and widely different types of *Oncidium crispum* were in flower; the peculiar bronzy marking of these *Oncidiums* make them especial favourites during the autumn months. The diminutive flowers of *O. ornithorhynchum* were graceful and effective when arranged among those of bolder type. *O. incurvum* was producing many long flower stems which give promise of a quantity of miniature flowers later on. Among *Cattleyas* in flower, *Bowringiana* and *guttata* were the most conspicuous. Several good varieties of the ever popular *Odontoglossum Alexandræ* were in full beauty in one of the cool houses.

The effect produced by this well-managed collection was greatly enhanced by the admirable manner in which the stages and plants were arranged. Instead of the usual straight stages a curving walk was formed through the centre of the house, and the stages fitted to follow the windings of the walk, the edges of them being faced with virgin cork, over which *Fittonias*, *Isolepis gracilis*, and *Panicum variegatum* were growing in careless profusion, thus forming a pleasing finish to the green leaves and bright colours behind them.—D.

**ROYAL BOTANIC SOCIETY.**—The arrangements for 1892 are as follows:—Floral Exhibitions—Wednesdays, March 23rd, April 27th; May 18th. Special Floral Fête, Wednesday, June 22nd. Evening Fête, Wednesday, July 6th, 8 to 12 P.M. Rhododendrons, during June. Musical promenades.—On the Wednesdays in May, June, and July, exhibition and fête days excepted. Lectures.—Fridays in May and June at 4 o'clock. General meetings, for election of new Fellows, scientific discussions, &c., Saturdays at 3.45 P.M.—January 9th, 23rd; February 13th, 27th; March 12th, 26th; April 9th, 23rd; May 14th, 28th; June 11th, 25th; July 9th, 23rd; November 12th, 26th; December 10th. Anniversary, Wednesday, August 10th, at 1 P.M.

— **DEATH OF M. AUGUSTE FRANÇOIS HARDY.**—Many readers will learn with much regret that M. Hardy of Versailles died on the 24th ult. As the able director of the National School of Horticulture in that town M. Hardy was principally known to British horticulturists; but he was also a prominent member of the French National Horticultural Society, and he assisted materially in the promotion of all objects bearing upon horticulture.

— **ACCIDENT TO MR. W. J. GRANT.**—It is with deep regret, a regret which I think will be shared by many of the readers of the Journal, that I have to record a sad piece of news which has just reached me. Mr. W. J. Grant, so well known to most rosarians, in crossing the railway near Monmouth was struck down by an engine and received most severe injuries, including a fracture of the base of the skull. Little hope is entertained of his recovery.—D., Deal.

— **GARDENING APPOINTMENTS.**—We learn that Mr. George Hemming, late head gardener at Beechfields, Doncaster, has been appointed superintendent of the various public parks in Sheffield belonging to the Sheffield Corporation. Mr. Hemming is well known in Leeds, Doncaster and Sheffield, as an able and experienced gardener, and will doubtless by his works justify his selection for so responsible a post. Mr. R. C. Townsend, Mytton Hall, Shrewsbury, Salop, has been appointed head gardener to Colonel Lloyd, Aston Hall, Oswestry, Salop. Mr. H. Prosser, late gardener to the Right Hon. Lord Heytesbury, has been appointed head gardener to H. J. Miles, Esq., The Knoll, Wimborne, Dorset.

— **ROYAL METEOROLOGICAL SOCIETY.**—At the ordinary meeting of the Society, to be held at 25, Great George Street, Westminster, on Wednesday, the 16th inst., at 7 P.M., the following papers will be read:—"Report on the Thunderstorms of 1888 and 1889," by William Marriott, F.R.Met.Soc. This paper will be illustrated by a number of lantern slides. "On the Prevalence of Fog in London During the Twenty Years, 1871-1890," by Frederick J. Brodie, F.R.Met.Soc.

— **CHRISTMAS ROSES.**—A Totnes correspondent sends us some of the finest samples of Christmas Roses we have seen, most of them exceeding 4½ inches in diameter, and bearing two blooms on a stem. They are, moreover, very pure, and therefore valuable for decorative purposes.

— **NATIONAL CHRYSANTHEMUM SOCIETY** held its annual dinner at Anderton's Hotel, Fleet Street, last week, when Mr. R. Ballantine presided, and about 120 members and friends were present. The evening was a very pleasant one, and proved highly satisfactory to all who attended.

— **FINE CYCLAMENS.**—Mr. William Mowbray, gardener to the Hon. H. C. Legge, Fulmer, Slough, sends us some Cyclamen flowers and leaves for inspection. The plants are now in 24-size pots. The plants were raised from seed sown in October, 1890. They are from 15 to 18 inches through the foliage. Last year eight dozen blooms were gathered from one plant at one gathering, and the same good results are expected this year. The leaves are remarkable for their substance, and the flowers for their size, brilliancy, and purity. We have seen few samples to equal and none to surpass the specimens before us. The able grower of them would do good service to many by sending details of his methods of culture for publication.

— **LYCIUM AFRUM.**—At the latter end of November I was at Armatage, near Rugeley, Staffordshire. Between the station and Armatage is a most conspicuous shrub in full berry. The berries are of an oblong shape, and bright scarlet. The shrub is trained over a cottage door. I never saw this shrub in fruit before, and I beg to ask, Does this shrub flower in many parts of England? A gentleman writes me from Armatage to say the name is *Lycium Afrum* or Box Thorn, an African tea tree, and a native of Good Hope.—R. H. D. [The *Lycium* is frequently seen in some parts of England, more especially in the south.]

— **IVY INJURIOUS TO WALLS.**—At page 447 "E. D. S." says, "Some assert that Ivy causes dampness to buildings against which it is grown, but I have no hesitation in saying it is a false idea." I quite agree with "E. D. S." when he says that Ivy "throws off the rain that falls upon them." But it does more; it prevents evaporation, which appears to be an essential to Ivy, and walls clothed with Ivy are in a constant and chronic state of dampness (if the latter word can be allowed), and such constant dampness is more injurious to health than if water ran in a constant stream down the walls. Lime and stone also crumble and decay more quickly under Ivy than when exposed, which I have learnt from experience.—W. T.

— **THE WEATHER LAST MONTH.**—November was very foggy, with much showery weather also, and remarkable for the very low reading of the barometer (28.32) on the 11th at noon. We had ten bright days. Wind was in an easterly direction the first half of the month, and mostly westward during the remainder. Barometer was highest—30.65—at 9 A.M. on the 5th; lowest, 28.32 at noon on the 11th. Highest shade temperature 57° on the 18th; lowest, 24° on the 8th; lowest on grass, 20° on the 8th and 28th. Mean of daily maximum temperatures, 48.40°; mean of daily minimum ditto, 35.40°. Mean temperature of the month, 41.90°. Total rainfall, 3.14 inches, which fell on twenty days. The greatest daily fall being 0.81 on the 15th. The garden spring ran 30 gallons per minute on the 30th.—W. H. DIVERS, Ketton Hall Gardens, Stamford.

— **THE CHINESE ARTICHOKE (STACHYS TUBERIFERA).**—As this delicious vegetable seems to be so little known in this neighbourhood I have been induced to send an account of my experience in its cultivation to your valuable paper, trusting it may be interesting to some of your readers. I think that when it becomes better known it will be largely grown, as it comes in for use at a time when choice vegetables are very limited. I selected full-sized tubers, and planted them on the 24th of April last on a piece of rich ground well pulverised. Six rows 30 feet long were planted 18 inches between the rows, and about 9 inches apart in the row, covered about 3 inches with soil. The hoe was run through two or three times at intervals in the early part of the season; but the plants soon covered the ground, forming neat bushes about 15 inches high, branching freely, and they kept down all weeds. We commenced lifting them for use on the 7th November. The tubers range from 1 to 2½ inches in length, and about three-quarters of an inch in diameter at the thickest end, and are produced in immense numbers. When cooked by boiling or steaming, and served with melted butter in the same manner as Jerusalem Artichokes, they make an acceptable

dish, and I hope that by lifting them before severe weather, and storing the bulk of them in a pit the same as Potatoes, I shall be able to keep them in good condition for use through the present winter.—  
JOS. PUNTON, *Benwell Dene Gardens, Newcastle-on-Tyne.*

— WISTARIA SINENSIS SEEDING.—At a meeting of gardeners in a Sussex village two or three years ago the question of special prizes for a local Show was being discussed, when a veteran offered to give a prize of 5s. to the man who could produce a pod of seeds of the *Wistaria sinensis*. This, seemingly, is rather a hard nut to crack; for though there are several fine specimens of this climber in the neighbourhood the prize has never been claimed. The old gentleman told his hearers that he had himself produced seed pods, and that they were at the time laid before Dr. Lindley, and duly chronicled by the Press. This incident was brought to mind on reading "E. D. S.'s" note on this fine hardy climber in your pages of November 19th (page 424). Can any of your correspondents give instances of its having produced seeds in this country? And also can any reason be assigned why it should not produce seeds except on rare occasions?—R. I.

— THE following is the WAKEFIELD PAXTON SOCIETY'S programme of meetings for the fourth quarter—Session 1891-92. The meetings are held at the Society's Rooms, Saw Hotel, Westgate, each Saturday evening, commencing at 8 o'clock prompt:—Dec. 5th, "The Amateur Gardener," Mr. J. Haigh, Sheffield. Dec. 12th, "Brusse's Sprouts" (exhibition of specimens), Mr. W. Hudson. Dec. 19th, "Hardy Perennial Plants, their Habits and Culture," Mr. John Wood, Kirkstall. Dec. 26th, Bank Holiday. Jan. 2nd, Musical evening. Jan. 9th, "Agricultural—Soils, their Formation, Character, and Cultivation," Mr. J. Metcalfe. Jan. 16th, "The Evolution of Plant Life," Mr. T. Tate, F.G.S., Leeds. Jan. 23rd, "A Selection of Vegetables Suitable for this District," Mr. E. Fenner. At this meeting an election will be made of the most suitable varieties of vegetables, all growers are desired to take part in the same; papers will be supplied by the Secretaries. Jan. 30th, "Earthquakes and Volcanoes," Mr. H. J. Martin, Rothwell. Feb. 6th, "Decorative Use of Flowers," Mr. W. Wardman. Feb. 12th (Friday), "The Florist *Ranunculus*," Rev. F. D. Horner, Kirkby Lonsdale. Feb. 20th, "The Peach," Mr. C. Fletcher. Feb. 27th, "A Prolific Bloomer," Mr. B. Whiteley. March 5th, Annual Meeting.

— DOUBLE MIGNONETTE.—I am unable to send you a good specimen of the double Mignonette about which I wrote a short note recently. The small pieces sent with this give quite an inadequate idea of the flower, both with regard to its peculiarity and its value as a commercial plant. I feel much indebted for Mr. Henslow's paper, which I duly received. The Mignonette figured and described in it is almost identical with the one I wrote about. I was much struck with the similarity of the origin of both, in each case having been discovered in the seed beds of nurserymen. The only difference between these two Mignonettes that I can observe is that the one mentioned by me is more compact in the panicle than the one described by Mr. Henslow, which the figure represents as having a lax inflorescence and a rather slim peduncle. Why is the name *alba* given to this proliferous variety, seeing that the petals of the normal type of *Reseda odorata* are white? With regard to Messrs. Sutton & Sons' remarks anent this variety bearing seed, I can only say that Mr. Treseder informs me that he has never yet discovered a fertile flower on any of the plants, and he has had them under his close observation for two years.—W. W. PETTIGREW. [The specimen sent had very full pure white and extremely fragrant flowers.]

— SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, 56 feet above mean sea level, November. Mean temperature of month, 41.1°. Maximum on the 18th, 55.5°; minimum on the 30th, 25.2°. Maximum in the sun on the 2nd, 97.4°; minimum on the grass on the 30th, 17.8°. Mean temperature of the air at 9 A.M., 40.2°; mean temperature of the soil, 1 foot deep, 43.6°. Nights below 32°, in shade eleven, on grass twenty-one. Total duration of sunshine, thirty-one hours, or 12 per cent. of possible duration. Thirteen sunless days. Total rainfall, 2.48 inches. Rain fell on twenty-two days. Average velocity of wind, 8.1 miles per hour. Velocity exceeded 400 miles on one day, and fell short of 100 miles on seven days. Approximate averages for November:—Mean temperature, 41.7°; rainfall, 2.04; sunshine, fifty hours. A dull and calm month, rather wetter and colder than the average. The barometric depression of the 11th is the lowest recorded, except that of December, 1886, but the gale did no damage of any consequence here.—J. MALLENDER.

— WEATHER AT RIPLEY, YORKS, DURING NOVEMBER.—The past has been a dull sunless month, only one bright day occurring. Rain fell on twenty-one days, total for the month being 2.95 inches, of which 0.89 fell on the 10th. The soil is in a very saturated condition, which sadly impedes work on the land. Frost was recorded on sixteen days, the most severe being 13° on 28th, and 12° on the 30th. At 9 A.M. on the 5th the barometer stood at 30.85; mean reading of barometer, 30.64; mean maximum temperature, 45.9°; mean minimum temperature, 31.9°; mean temperature, 38.9°. The total rainfall recorded here from July 1st to November 30th, inclusive, is 15.92 inches. Up to to-day, 8th, December has only yielded us one fine day, and as I write the rain is falling heavily. The River Nidd gives promise in a few hours of overflowing, and, on the whole, things look anything but cheery.—  
J. TUNNINGTON, *Ripley Castle Gardens, Yorks.*

— PEAR MARECHAL DE COUR.—Of November Pears there are few to rival the above named in quality, and being of a free bearing disposition, intending planters ought to secure at least one tree if the variety is not already represented in sufficient numbers. Unlike many sorts it does not decay at the core immediately it is fully ripe, but remains in fine condition a good time after maturing. I have had this variety sometimes as late as Christmas, but the season has such varying influences on Pears that it must not be planted with the view of securing its fruit at that date. It forms a good pyramid, and has quite a distinct but somewhat spreading style of growth, and bears freely almost every year. Under good cultivation the fruit grows to a large size, which is an additional point in its favour, but the dense russet coloured skin does not present the same attraction on the exhibition table as the clear coloured varieties. This, however, is of but small moment for home use, quality and good size sufficing for general purposes, and on the exhibition dish competent judges will estimate its sterling qualities as being above that of many of the more handsome in appearance. Dr. Hogg in his "Fruit Manual" describes it as one of the finest Pears in cultivation, and many could, if it was found necessary, bear out the Doctor's excellent testimony. It is also known by the title *Conseiller de la Cour*, but the correct name, I believe, is that which heads this note.—W. S.

— THE HORTICULTURAL ATTRACTIONS AT THE WORLD'S FAIR, CHICAGO, in 1893, are increasing. The following are the latest announcements. The Agricultural Department of the Government will make an exhibit of fac-simile casts of all of the 200 varieties of edible Mushrooms which grow in the country. Hugh Price, one of the Wisconsin Commissioners, has made arrangements for securing for the World's Fair a mammoth Cork Pine, a tree which is growing rare in his State. It is 24 feet in length, and will scale 2500 feet. One plank is 16 feet long, 3 inches thick, and 44 inches wide, without a knot or blemish. The native flora of each State and Territory will be shown at the Exposition, under the direction of Chief Thorpe, who has enlisted the Lady Managers to undertake the collection of specimens. On the roof of the Horticulture Building, around the central dome, an elaborate display of roof-gardening will be made. It is expected that this will not only be pleasurable to visitors, but will afford valuable suggestions that will be utilised by persons who live in large cities and are deprived of door-yards and lawns. In the centre of the Horticulture Building will be a miniature mountain, 70 feet high, upon which will grow giant Tree Ferns and Palms, and other vegetation, finding there a congenial home. A mountain stream will dash from one declivity to another and play hide-and-seek with the foliage. Beneath this rock mountain will be a cave, 80 feet in diameter, and 60 feet high, brilliantly lighted by electricity, where, during the whole six months of the Exposition, the experiment will be tried whether plants will grow under electric light as well as under sunlight. Chief Thorpe, of the Floriculture Division, originated the plan.

— PROFITABLE FRUIT CULTURE IN AMERICA.—Mr. M. A. Thayer, who has demonstrated practically that small-fruit culture can be made profitable in Wisconsin, has just published a report from his fruit farms at Sparta which, from his careful method of keeping accounts and the generous spirit manifested, seems worthy of commendation. Five years ago the question of growing small fruits there was doubtful, and he therefore gives a full account of his outlay and income. The first year he planted 8 acres of Blackberries, 7 of Raspberries, and 2 of Strawberries, at a total expense of 1618 dollars with no income. The second year he added 8 acres, and his total expenses were 2462 dollars, and his income was 926 dollars. The third year he set 10 acres more to small fruits; his expenses were 3394 dollars, and

his receipts 4432 dollars, or considerably more than 1000 dollars profit. The fourth year, or 1891, the expenses were 4500 dollars, and the receipts 8846 dollars, with a profit of 4346 dollars. The receipts and expenditures are itemised, and the report concludes with advice to beginners to go slow, doing only as much as can be done well, since nothing but the best production will pay, and it may safely be estimated that, besides the land, every acre of small fruit properly prepared, planted, and brought to a bearing age will cost from 125 dollars to 150 dollars, or their equivalent in honest work at 1.25 dollars a day. Mr. Thayer's

It is one of his informal low standard trees, of which he has so many, and which produce an abundance of large and luscious Peaches and Neectarines every year. The crops never fail under the light roof of this large house with boarded sides, and just one hot-water pipe to temper the cold when needed.

He has other houses and other trees of varied shapes and sizes, the handsome pyramids from 4 to 10 or 12 feet high being pictures of beauty, both when laden with blossom in the spring and ripening their rich, crimson, and many-tinted fruits in the summer.

FIG. 91.—MR. T. FRANCIS RIVERS AT HOME.

concluding counsel is: "Begin modestly, subscribe liberally to good papers, increase your plantation as experience is gained," and he promises to answer questions on particular points by mail or otherwise, or send short, plain instructions for growing small fruits, free, to any one who will send his name.—(*American Garden.*)

#### MR. RIVERS AT HOME.

"QUITE at home," it will be admitted Mr. T. F. Rivers is, as in a characteristic mood he appears as if studying one of the trees in his orchard house, and possibly counting its fruits.

Mr. Rivers is emphatically a Peach and Neectarine man, the raiser of more new varieties than any other person, and is a consummate cultivator.

The tree he is examining is not one of those which supply 40s. a dozen fruits early in the season, but is one of his old favourites, which represents Peach-growing made easy; no training, no pinching, the simplest possible pruning, and always plenty of fruit in its season. When we came across the photograph we at once thought it appropriate for reproduction, and the chief figure in it will, perhaps, be a little surprised when he opens his Journal to-day. His mood will then change to either a frown or a smile, and a smile we shall hope it will be.

## NATIONAL ROSE SOCIETY.

THE annual meeting of this Society was held in the Horticultural Club Rooms, Hotel Windsor, on Wednesday last, Dec. 9th, when the Very Rev. Dean Hole presided over one of the largest gatherings the Society has ever had, over fifty members being present, representing all the principal districts. It was also one of the most interesting, for never has discussion been so vigorously conducted at these meetings. After the reading of the Report the Rev. W. Wilks, who occupied the chair until the arrival of the President, proposed its formal adoption, which led to considerable discussion as to the desirability of altering the date of the Crystal Palace Show. Ultimately, however, the wording given in the paragraph below referring to the arrangements for 1892 was that adopted.

A much more important matter was, however, raised by the following proposed new regulation—namely, that “At the two principal exhibitions of the Society amateur exhibitors shall be required to show according to the number of plants of ‘exhibition’ varieties grown by them.” This was proposed by Mr. C. J. Grahame, seconded by the Rev. F. R. Burnside, and supported by several prominent rosarians, though it was also opposed by others. The subject was discussed very thoroughly, and after the disadvantages under which the smaller amateur growers labour when in competition with those who grow large collections had been duly argued, it was adopted with some dissentients as a recommendation to the Committee who have to consider in what way the regulation can be best applied.

Amongst other resolutions carried were the following:—“That the report and financial statement be adopted, printed and circulated; that the best thanks of the Society be communicated to the Horticultural Club for the use of their Rooms during the past year; that the thanks of the Society be given to the officers and other members of the Committee for their services during the year, and that Regulation I. be altered so as to read, “The Society shall hold one, or more, metropolitan shows in each year, and provincial shows when practicable.”

## REPORT OF THE COMMITTEE FOR THE YEAR 1891.

SELDOM have Rose growers, Rose exhibitors, or Rose exhibitions had such a difficult year to contend against as that of 1891. Taking the country throughout, very great injuries were inflicted on Rose plants generally, and especially upon the Teas, by the severity of last winter, and the aggregate losses must have been considerable. The spring and summer also proved unseasonably cold and backward; in fact, so much so, that none but the earliest districts were well represented at either the Tea and Noisette Show at Westminster, or at the Metropolitan Exhibition. The first of these shows, although a small one, contained several stands which were surprisingly good considering the season. The Crystal Palace Exhibition proved as extensive as usual, but from the causes referred to above the general quality of the flowers was necessarily below the average. On the other hand, the Exhibition held at Hereford nearly a fortnight later proved in every way a great success, and was, with one exception, the largest provincial show the Society has yet held. The thanks of the Society are due to the Committee and Secretaries of the Hereford and West of England Rose Society for the admirable manner in which the arrangements in connection with this Show were carried out, and also to the Mayor of Hereford for the hospitality shown by him to all members attending the Exhibition.

The Society still continues to make steady progress, and to extend its influence in all matters relating to the exhibition, culture, and improvement of the Rose. The number of members and of affiliated societies is well maintained, and quite recently an application for affiliation has been received from a horticultural society in Tasmania.

## FINANCIAL STATEMENT.

This the Committee cannot but regard as very satisfactory, considering that three exhibitions have again been held, and that a larger sum has been expended in prizes than in any previous year. The total receipts have amounted to £677 18s. 11d., and the expenditure to £637 18s., leaving a balance for the financial year of £40 0s. 11d. The Society has now been established fifteen years. During the first five years the average amount received annually in subscriptions was £229, in the next five years £283, and in the last five years £333.

THOMAS BURT HAYWOOD, *Hon. Treasurer.*

Audited with vouchers and found correct,

J. D. PAWLE,

F. T. WOLLASTON, } *Hon. Auditors.*

## ARRANGEMENTS FOR 1892.

The Tea and Noisette Exhibition will again be held under the auspices of the Royal Horticultural Society, at their Drill Hall at Westminster, on Tuesday, June 21st; while the Metropolitan Exhibition will take place at the Crystal Palace on the first Saturday in July. At the request of the Mayor and Corporation of Chester the Society's Provincial Exhibition will be held in that city on Thursday, July 14th. The central position of Chester, the interest attaching to the city itself, and the great facilities of railway access from most parts of the country, together with the assistance promised by the leading rosarians of the district, all combine to make the Committee hopeful that a most successful Exhibition will next year be held there.

## AFFILIATED SOCIETIES.

The Committee are of opinion that definite instructions should be drawn up and forwarded each year to the secretaries of the affiliated societies as to the terms on which medals are supplied, and also as to how far the Society's regulations are binding on these societies. Some of the schedules issued by affiliated societies during the past year contained little or no reference to the regulations of the parent Society.

## MEMBERS' PRIVILEGES.

Subscribers of £1 will, as in previous years, be entitled to two private-view tickets for the Society's Exhibitions at the Crystal Palace and Chester, and to four transferable tickets admitting at the same time as the general public; while subscribers of 10s. are entitled to one private-view and to two transferable tickets. Each member will also receive one ticket of admission to the early Exhibition of Tea Roses at Westminster. New members will be entitled to a copy of the Society's illustrated catalogue of exhibition and garden Roses, and of the supplement to this catalogue issued in 1890. Members alone are allowed to compete at the Society's exhibitions.

The Committee, following a now established precedent, desire in conclusion to tender their best thanks to their local Secretaries, to the donors of special prizes, and also to all those who have in other ways assisted in helping forward the work of the Society. Their thanks are especially due to Mr. C. J. Grahame for obtaining for the Society during the past year a large number of new subscribers.

## SEASONABLE NOTES ON ROSES.

TRANSPLANTING ROSES.—The immature condition of the young wood on Roses generally has, or ought to have had, the effect of delaying transplanting considerably. Moved when the foliage is fresh and the wood still very green and growing, shrivelling is almost certain to take place. It is scarcely possible to lift Roses with a ball of soil about the roots, and not a few of those transplanted in October have suffered badly from this over-hasty proceeding. The end of November would appear to be nearer the proper time for moving Roses this season, and should the present mild moist weather last fresh root fibres may yet be formed before midwinter. Now, weather permitting, is therefore a good time to move young plants to where they are more required, and also to lift and replant apparently worn-out old standards and bushes, replanting in quite fresh soil putting new life into these. It is next to useless planting Roses in either lumpy or very poor soil, and if the ordinary soil of the new site is either poor or unworkable quite fresh compost should be substituted, nothing answering better than fresh loam, fibrous or otherwise, and a liberal addition of decayed manure and burnt garden refuse. In any case that which comes into contact with the roots should be moderately fine and rich, thus favouring an early and strong root action. Nor ought Roses to be transplanted while the ground is in a sodden state. They must have the soil well refixed about the roots, and the necessary trampling of wet soil would amount to puddling, than which nothing could well be more injurious.

PLANTING YOUNG ROSES.—Much of the foregoing also applies to the work of planting either home-raised or newly purchased Roses where they are to remain for some time. If the latter, when received, cannot be planted properly owing to either the very wet, or, it may be, badly frosted ground, they ought to be laid in singly, yet closely together, where they can be temporarily protected with mats or litter, the roots being first lightly pruned, and then well interspersed among fine good soil. They may have to remain in this for several weeks or months to come, and the aim should be, therefore, to both promote the formation of fresh root fibres—and which heeled-in plants are very prone to do—

and also to take good care of these same delicate fibres. Very few of the latter will be lost in moving them out of tight, fine soil, and plenty of the latter, as before hinted, ought always to be used in planting Roses. It may be asked, Why order Roses when there is not much likelihood of their being finally planted for some time longer? But it must be remembered that there is every probability of the nurserymen's stocks being early exhausted this planting season. Orders have already been largely received, and the stocks are far from being up to the average in numbers. Standards of both Hybrid Perpetuals and Teas are the first to suffer from severe frosts, and frequently fail badly where dwarfs have succeeded well. For beds wholly given up to Roses, standards might well be interspersed among dwarfs, the latter being disposed not less than 2 feet apart each way, and be the most extensively planted. Dwarfs are also the best for massing in borders or the kitchen garden. Own-root Roses are to be preferred to any worked on stocks of any kinds, but these cannot be bought. If, however, the point of union of scion with stock is buried 2 inches below the surface the good fresh soil surrounding will usually cause the former to emit roots freely, so that it soon amounts to their being own-root Roses. To raise the Manetti stock above the ground is fatal to good progress, an early death being far more likely to occur. They must, therefore, be buried below the ordinary border level. Standards on the Briar stock and bushes raised from cuttings ought not, however, to be deeply planted, the collar being kept just up to the surface. Too often Roses are planted and then left to take their chance till pruning time arrives. Not a few are furnished with one or two extra strong shoots, and it is largely owing to these that the roots are being constantly loosened, and a good sized hole formed by the oscillating stems. If these strong shoots were materially lightened, or say, made into cuttings at once, the wind would have far less power over the bushes; but whether this light pruning is done at once or not, there should be no delay in staking standards. Wooden stakes are to be preferred to iron ones, the latter being cold-conducting and injurious to the stems accordingly. Much exposed dwarfs ought also to be supported by stakes, and all should have the benefit of a loose mulching of strawy litter, this being added or loosened up considerably so as to protect the lower portion of the bushes whenever severe frosts are imminent. This may be the means of saving the lot, the loss of the upper portion of dwarfs not greatly impairing their usefulness, but rather the contrary.

**TEA AND OTHER ROSES.**—Teas and some few of the Noisettes succeed fairly well in the open as standards and more often as dwarfs, especially if protected during the winter with a heavy mulch of either bracken or strawy litter as just suggested for newly planted Roses generally. It is against warm garden and house walls and fences that they are most at home, and they ought to occupy all such sites to the utter exclusion of Hybrid Perpetuals generally. Even these will do but little good if starved at the roots, but if given the benefit of a fairly deep and rich loamy root run, it is really surprising what grand blooms will be forthcoming, the season extending from May to November inclusive. It is only those starved at the roots that are addicted to mildew; therefore plant in wholly fresh and fairly rich loamy compost. Teas and Noisettes were rather hard hit by frosts last winter, but they recovered better than expected. It would pay well to cover strong trees with mats, or even to protect with branches of Spruce or other Firs during the prevalence of severe frosts. China and the Hybrid Bourbon and China Roses, are also well worthy of a place against sunny fronts of dwelling houses, the first-named being almost continuous flowering, and are better known as the "Old Monthlies."

**OWN-ROOT ROSES.**—Many of the Hybrid Perpetuals strike root nearly as readily as Gooseberries, the cuttings being formed of well-ripened young wood. Late in October or early in November is a good time to insert these cuttings, but this year the wood is in a very backward state, and still largely clothed with green leaves. Long and strong shoots are more abundant than usual, and it is not yet too late to make the attempt to strike many of these. Prepare a good open border by well working it, mixing in a little old Mushroom bed manure or leaf soil. For cuttings select the best ripened shoots, and if it can be done without injury to the bush cut them off with a small slice of old wood—that is to say, a heel attached. The latter, though, is not indispensable, lengths of firm young wood cleanly cut to a joint answering nearly as well. All should be about 12 inches long, and cleared of thorns, but not buds, and be inserted directly they are made. Open a straight trench 6 inches deep with a spade, put in the cuttings 9 inches apart, return half the soil, trample this firmly against the cuttings, and then level over the ground prior to opening the next trench 18 inches apart from the first. Mulch over the surface with either short manure, leaf soil, or ashes. Most of the cuttings will strike root and flower next summer, and will require to be thinned out the following planting season.—A SOMERSET GROWER.

### THE CHEMISTRY OF GARDEN CROPS.

IN the fifth edition of Messrs. Sutton & Sons' excellent work, "The Culture of Vegetables and Flowers from Seeds and Roots," are several new chapters of great interest and importance to cultivators, one of which we take the liberty of reproducing. As an illustration of the appreciation in which this work is held, it may be stated that 18,000 copies have been sold of the four preceding editions, and of the fifth no less than 10,000 have been printed.

A CONSIDERATION of the chemistry of the crops that engage attention in this country will afford an explanation of one great

difference between farming and gardening. And this difference should be kept in mind by all classes of cultivators as the basis of operations in tillage, cropping, and the order and character of rotations. The first thing to discover in the cropping of a farm, is the kind of vegetation for which the land is best adapted to insure in a run of seasons fairly profitable results. If the soil is unfit for cereals, then it is sheer folly to sow any more corn than may be needful for convenience, as, for example, to supply straw for thatching, and oats for horses, to save cost of carriage, &c., &c. On large farms that are far removed from markets, it is often necessary to risk a few crops that the land is ill fitted for, so as to satisfy the requirements of the homestead, and to save the outlay of money and the inconvenience of hauling from distant markets. But everywhere the cropping must be adapted to the soil and climate as nearly as possible, both to simplify operations and enlarge to the utmost the chances of success.

In the cropping of a garden this plain procedure cannot be followed. We are compelled certainly to consider what the soil and climate will especially favour amongst garden crops, but notwithstanding this, the gardener must grow whatever the household requires. He may have to grow Peas on a hot shallow sand, and Potatoes and Carrots on a cold clay, and Asparagus on a shallow bed of pebbles and potsherds. To the gardener the chemistry of crops is a matter of great importance, because he cannot restrict his operations to such crops as the land is particularly adapted for, but must endeavour to render his land capable of carrying more or less of all the vegetables and fruits that find a place in the catalogue of domestic wants. That in certain cases he must fail at certain points is inevitable; nevertheless his aim will be, and must be, of a somewhat universal kind, and a clear idea of the relations of plants to the soil in which they grow will be of constant and incalculable value to him.

We are bound to say at the outset that a complete essay on the chemistry of vegetation is not our purpose. We are anxious to convey some useful information, and to kindle sufficient interest to lead those who have hitherto given but slight attention to this subject to inquire further, with a view to get far beyond the point at which we shall have to quit the subject.

Plants consist of two classes of constituents—the inorganic, which may be called the foundation; and the organic, which may be considered the superstructure. The first alone concerns us now. A plant must derive from the soil certain proportions of silica, lime, sulphur, salt, phosphates, alkalies, and other minerals, or it cannot exist at all; but given these, and its manufacture of fibre, starch, gum, sugar, and other organic products will depend very much upon the action of light, heat, atmospheric air, and moisture upon it, for these have to be produced by chemical (or vital) action within the structure, or, as we sometimes say, the tissues of the plant itself. To a very great extent the agencies that conduce to the elaboration of organic products are beyond our control (though not entirely so), whereas we can directly, and to a considerable degree, provide the plant with the minerals it more particularly requires, first by choosing the ground for it, and next by tilling and manuring in a suitable manner. A clay soil, in which in addition to the predominating alumina, there is a fair proportion of lime and silica may be regarded as the most fertile for all purposes; but we have few such in Britain, our clays being mostly of an obdurate texture, retentive of moisture, and requiring much cultivation, and containing, moreover, salts of iron in proportions almost poisonous to plants. But there are profound resources in most clays, so that if it is difficult to tame them it is also difficult to exhaust them. Hence a clay that has been well cultivated through several generations will generally produce a fair return for whatever crop may be put upon it.

Limestone soils are usually very porous and deficient of clay, and therefore have no sustaining power. Many of our great tracts of mountain limestone are mere sheep walks, and would be comparatively worthless except for the metals that may be extracted from them, or the lime that may be obtained by burning. On the other hand, chalk, which is a more recent form of lime, is often highly productive, more especially where, through long cultivation, it has been much broken up and has become loamy through accumulation of humus. Between the oldest limestone and the latest chalk there are many intermediate kinds of calcareous soils, and they are mostly good owing to their richness in phosphates, the products of the marine organisms of which these rocks in great part and in some cases wholly consist. For the growth of cereals these calcareous soils need a certain proportion of silica, and where they have this we see some of the finest crops of Wheat, Trifolium, and Peas and Beans in all these islands. If we could mix some of our obdurate clays with our barren limestones, the two comparatively worthless staples would probably prove remarkably fertile. Although this is impossible a consideration of the chemistry of the imaginary mixture may be useful, more especially to the gardener, who can in a small way accomplish many things that are out of the region of practice on a great scale.

Sandy soils are characterised by excess of silica, and deficiency of alumina and phosphates. But here the mechanical texture is as serious a matter as it is in the case of clay. The sand is too loose as the clay is too pasty, and it may be that we have to hold the estate as it were in our hands to prevent it from being blown away. It is especially worthy of observation, however, that sandy soils are the most readily amenable of any to the operation of tillage; and if we cannot take much out of them we can put any amount into them, and must always calculate nicely where the process of enrichment is to stop. It is not less worthy of observation that sandy soils can be rendered capable of producing

almost every kind of crop save cereals and pulse, and even these can be secured where there is some basis of peat or loam or clay with the sand. The parks and gardens of Paris, Versailles, Haarlem, and Berlin are on deep sands that are blown away when left exposed for any length of time with no crop upon them to prevent direct contact of the wind with the soil; and not only do we see the finest of Potatoes and the most nutritious of herbage produced on these soils, but good Cauliflowers, Peas, Beans, Onions, fruits, and big trees full of sound timber. It would be inaccurate to say that any soil is beyond improvement, for the plough has found its way to the foot of Stonehenge, where only a hundred years ago cultivation was declared impossible, and on the granite of Dartmoor we may now see a fine grass sward where not long since the only vegetation comprised lichens and mosses. The farming and gardening at Prince Town owe their success in great part to the judicious use of sewage, and thus illustrate the immense importance of the subject before us.

Garden soils usually consist of loam of some kind, the consequence of long cultivation. Natural loams are the result of the decay and admixture of various earths, and they are mostly of a mellow texture, easily worked and highly productive. They are, as a rule, the best of all soils, and their goodness is in part due to the fact that they contain a little of everything, with no great predominance of any one particular earth. Cultivation also produces loam. On a clay land we find a top crust of clayey loam, and on a lime or chalk land a top crust of calcareous loam, where cultivation has been long pursued, for the staple is broken and manures are put on, and the roots of plants assist in disintegrating and decomposing, and thus there is accumulation of humus and a decomposition of the rock proceeding together, and a loam of some sort is the result. Hence the necessity of caution in respect of deep trenching, for if we bury the top soil and put in its place a crude material that has not before seen daylight, we may lose ten years in profitable cropping, because we must now begin to tame a savage soil that we have been at great pains to bring up to cover a stratum of a good material prepared for us by the combined operations of Nature and Art during, perhaps, several centuries. But deep and good garden soils may be safely trenched and freely knocked about, because not only does the process favour the deep rooting of the plants, but it favours also that disintegration which is one of the causes of fertility. Every pebble is capable of imparting to the soil a solution—infinitesimal perhaps, but not the less real—of silica, or lime, or potash, or phosphates, or perhaps of all these; but it must be exposed to light and air and moisture, to enable it to part with a portion of its substance, and thus it is that mechanical tillage is of the first importance in all agricultural and horticultural operations.

The principal inorganic or mineral constituents of plants are potash, soda, lime, sulphur, chlorine, silica, and phosphates of lime and iron. Clays and loams are generally rich in potash, sulphur, and phosphates, but deficient in soluble silica and lime. Limestone and chalk are usually rich in lime and phosphates, but deficient of humus, silica, sulphur, and alkalies. Sandy soils are rich in silica, and are rarely deficient of lime, but are generally poor in respect of phosphates and alkalies. Therefore, on a clay or loam, farmyard manure is invaluable, because it not only contains ingredients that all crops appreciate, but is helpful in breaking up the texture of the soil. The occasional application of lime also is of importance, and not seldom this produces an almost magical effect on an old garden soil that has been heavily cropped and liberally manured. Calcareous soils are greatly benefited by a free application to them of manure from the stable and cow-byre; but it would be (generally speaking) like carrying coals to Newcastle to dress these soils with lime. Clay may be put on with advantage, and nothing benefits a hot chalky soil more than a good dose of mud from ponds and ditches, which supplies at once humus, alumina, and silicates.

In the manuring of sandy soils great care is requisite, because of their absorbing power. In the bulb-growing districts of Holland manure from cow sheds is worth the enormous price of 1s. per barrow-load for digging into loose sand for a crop of Potatoes, to be followed by bulbs. This is an exceptional case, but it illustrates the subject usefully. As a rule sandy soils are deficient of phosphates and alkalies, and hence, instead of employing manure, which may often be more advantageously bestowed upon the loamy pieces and reserved for special purposes, it will be found that kainit (a rough form of potash) and superphosphate of lime will conjointly produce the best results, more especially in raising Potatoes, Onions, and Carrots, which are particularly well adapted for sandy soils. Probably one of the best fertilisers is genuine farmyard manure from stall-fed cattle, for it contains phosphates, alkalies, and silicates in available forms and suitable proportions. Artificial manure should be selected by analysis, and with a view both to correct the deficiencies of the soil, and to satisfy the requirements of the crops to be grown on it.

For the present purpose the principal garden crops may be grouped in two classes, in accordance with the predominance of certain of their mineral constituents. The figures show the average proportions of the several minerals per cent. in the ashes that are left after burning a sample.

In class 1 phosphates and potash predominate. This class includes the following:—The Pea, containing phosphates, thirty-six; potash, forty. The Bean, phosphates, thirty; potash, forty-four. The Potato (tubers only), phosphates, nineteen; potash, fifty-nine; soda, two; lime, two; sulphuric acid, six. The Parsnip, phosphates, eighteen; potash, thirty-six; lime, eleven; salt, five. The Carrot, phosphates, twelve; potash, thirty-six; soda, thirteen; sulphuric acid, six. The Jerusalem Artichoke, phosphates, sixteen; potash, sixty-five.

In class 2 sulphur, soda, and salt predominate. This class includes the following:—The Cabbage, phosphates, sixteen; potash, forty-eight; soda, four; lime, fifteen; sulphuric acid, eight. The Turnip, phosphates, thirteen; potash, thirty-nine; salt, ten; lime, ten; sulphuric acid, fourteen. The Beet, phosphates, fourteen; potash, forty-nine; soda, nine; salt, twenty; lime, six; sulphuric acid, five.

As a matter of course Lentils and other kinds of pulse agree more or less with Peas and Beans in the predominance of phosphates and potash. So, again, all the Brassicas, whether Kales, Cauliflower, or whatever else, agree nearly with the Cabbage in a predominance of lime and sulphur, ingredients which fully account for the offensive odour of these vegetables when in a state of decay. Fruits as a rule are highly charged with alkalies, and are rarely deficient in phosphates. Moreover, stone fruits require lime, for they have to make bones as well as flesh when they produce a crop. As regards the alkalies, plants appear capable of substituting soda for potash under some circumstances, but it would not be prudent for the cultivator to assume that the cheaper alkali might take the place of the more costly one as a mineral agent, for Nature is stern and constant in her ways, and it can hardly be supposed that a plant in which potash normally predominates can attain to perfection in a soil deficient in potash, however well supplied it may be with soda. The cheaper alkali in combination with salt may, however, be usually employed in aid of quick-growing green crops; and more or less with tap-roots and Brassicas. As regards Potatoes, it seems worthy of observation that they contain but a trace of silica, and yet they generally thrive on sand, and in many instances crops grown on sand are free from disease and of high quality, although the weight may not be great. The mechanical texture of the soil has much to do with this, and when that is aided by a supply of potash and phosphates, whether from farmyard manure or artificials, sandy soils become highly productive of Potatoes of the very finest quality. On the other hand, Potatoes also grow well on limestone and chalk, and yet there is but little lime in them. Here, again, mechanical texture explains the case in part, and it is further explained by the sufficiency of potash and phosphates, as also of magnesia, which enters in a special manner into the mineral constitution of this root.

Thus far we have not even mentioned nitrogen or its common form of carbonate of ammonia, nor have we mentioned carbon or its very familiar form of carbonic acid. These are important elements of plant growth, and they account for the efficacy of manures derived directly from the animal kingdom, as, for example, the droppings of animals, including guano, which consists, in part at least, of the droppings of sea birds. The nitrogen in these substances, however, is of an evanescent character, and rapidly flies away in the form of carbonate of ammonia. Hence, a heap of farmyard manure left for several years loses much of its value as manure, and guano should be kept in bulk as long as possible, and protected from the atmosphere or its ammonia will disappear. One difficulty experienced by chemists and others in preparing artificial manures is that of 'fixing' the needful ammonia, so that it may be kept from combining with the atmosphere, and at the same time be always in a state in which it can be appropriated by the plant. We cannot supply plants with nitrogen directly, but in all good manures there is a certain proportion of it in combination, and in many instances the per-centage of nitrogen is made the test of the value of a manure.

The importance of humus—the black earthy substance resulting from the decay of vegetation—in a soil is that it contains in an assimilable form many of the ingredients essential to plant life. Humus is also highly charged with carbonic acid, which decomposes the crude minerals in the soil and renders them available as plant food. When vegetable refuse is burned the nitrogen—one of the costliest manures—is dissipated and lost. But by burying the refuse the soil gets back a proportion of the organic nitrogen it surrendered, and something over in the way of soluble phosphatic and potassic salts; and as this organic nitrogen assumes the form of nitric acid it is assimilated by the growing plant to the great benefit of whatever crop may occupy the ground.

The practical conclusion is that in the treatment of the soil a skilful gardener will endeavour to promote its fertility by affording the natural influences of rain, frost, and sun full opportunity of liberating the constituents that are locked up in the staple, by restoring in the form of refuse as much as possible of what the soil has parted with in vegetation, and by the addition of such fertilising agents as are adapted to rectify the natural deficiencies of the soil. Thus instead of following a process of exhaustion, the resources of the garden may be annually augmented.

## ROYAL HORTICULTURAL SOCIETY.

DECEMBER 8TH.

COMPARATIVELY small table space sufficed to contain the exhibits at the meeting on Tuesday last, yet the display was interesting, especially of Orchids, which formed the greater part of the floral arrangement, though Chrysanthemums also added to the attractions, the new English and American seedlings receiving much attention.

FRUIT COMMITTEE.—Present: P. Crowley, Esq. (in the chair), and Messrs. J. Lee, R. D. Blackmore, Harrison Weir, G. W. Cummins, C. Ross, A. H. Pearson, W. Warren, T. J. Saltmarsh, A. Dean, W. Bates, W. Denning, G. Wythes, J. Hudson, H. Balderson, F. Q. Lane, J. Smith, G. Bunyard, J. Cheal, and P. C. M. Veitch, Dr. R. Hogg, and Rev. W. Wilks.

Some dwellers in the low-lying and damp districts of Mitcham, Merton, or Morden would have been surprised to see the display provided at this meeting. No less than fifty-two dishes of extremely fine

fruits were shown by G. Hatfield, Esq., Morden Hall, and the silver medal awarded was well merited, for such creditable samples are not the result of chance, but show that the gardener, Mr. Alderman, knows exactly what the trees require and how to provide it. In many parts of England more favourable than that at Morden Apple growing has been said to be impossible, or so unsatisfactory as to be not worth the trouble; yet in the collection under notice were included as fine fruits as we have ever seen shown at the Royal Horticultural Society's December meeting. Another interesting exhibit on the same occasion was from Mr. A. Verdon, the Greyhound Ho'el, Carshalton, and consisted of a dish of large Apples, said to have been gathered from a tree more than 100 years old, which still bears freely, and the fruit keeps well until March, the tree being of dwarf compact habit. It was suggested that if it were deemed worthy of a name it should be termed "The Greyhound Seedling," but while the Committee did not express any definite opinion on the matter it was thought to resemble Withington Fillbasket. In any case it seemed to be an Apple of some merit.

Three magnificent Pine Apples from J. A. Rolls, Esq., The Hendre, Monmouth (gardener, Mr. T. Coomber), gained as a well-deserved honour a silver Banksian medal. They were grandly developed specimens of Charlotte Rothschild, weighing 9 lbs. 14 ozs., and two Smooth Cayennes, weighing respectively 8 lbs. 4 ozs. and 9 lbs. 14 ozs. each. Very rarely are such Pine Apples seen now, either in gardens or at exhibitions.

A dish of the Croft Angry Apple from Miss Macknight, Malden Lodge, Wallington, excited some interest, and it may be remembered that the history of this Apple was given in the Journal recently (page 431). The specimens were small and greenish, and did not possess any marked characteristics (vote of thanks). R. G. Lakes, Esq., Trevarrick, St. Austell, Cornwall, exhibited numerous fruits of *Benthamia fragifera* (vote of thanks). Mr. C. Turner, Slough, sent four fruits of Apple A. F. Barron.

Mr. E. S. Wiles, The Gardens, Elgacote Park, showed some Onions. Mr. Gilman, Ingestrie Gardens, sent a new Melon. Mr. A. Colbourn, Woolhampton, Berks, sent a small yellow Apple from Germany; and P. Crowley, Esq., Croydon, showed two fine Citrons, which were well grown at Waddon, and a preserve prepared from this fruit. Messrs. W. Paul & Son, Waltham Cross, sent a collection of Pears (vote of thanks). Messrs. Paul & Son, Cheshunt, showed a handsome seedling Apple named Captain Sanders; and Mr. Whiteley, Hillingdon (manager, Mr. Godfrey), showed excellent fruit of Improved Hackwood Park Tomatoes (cultural commendation).

**FLORAL COMMITTEE.**—Present: W. Marshall, Esq. (in the chair), and Messrs. J. Laing, H. Herbst, B. Wynne, R. Dean, T. Baines, H. B. May, F. Ross, W. C. Leach, C. Jeffries, G. Phippen, C. E. Pearson, J. Walker, J. H. Bennett Poë, H. Turner, C. Noble, W. H. Williams, H. Cannell, G. Paul, A. W. Furze, and Rev. H. H. D'Ombrian.

Mr. Robert Owen, Maidenhead, had eight stands of *Chrysanthemum* blooms, representing numerous new English and American varieties, conspicuous amongst these being Robert Owen, an incurved Japanese, raised at Maidenhead from a cross between Sarah Owen and an American seedling. The one bloom shown was  $7\frac{1}{2}$  inches across and  $4\frac{1}{2}$  inches deep; the florets broad, tapering to an acute point, and strongly incurved, forming a deep massive bloom of a rich bronzy yellow tint, very distinct and striking. Other notable varieties were Lizzie Cartledge, rosy purple, a Japanese of American origin, rosy purple to white in the centre, the florets recurving neatly (award of merit). Mr. J. S. Fogg is a bright golden Japanese variety of American origin, very rich in colour (award of merit). Of the English raised Japanese seedlings the best were Peter Blair, bronze yellow; J. P. Kendall, deep crimson; Thomas Selwood, large yellow, incurving (award of merit); A. J. Booker, deep crimson, large Anemone; and Henry Perkins, a reddish bronze, incurved (award of merit); and Rivelyn, also an incurved, with broad florets, forming a compact bloom, reddish salmon, tipped amber (award of merit).

Mr. W. Wells, 8, High Street, Redhill, exhibited an interesting collection of *Chrysanthemums*, comprising many of special decorative value, incurved, Japanese, and singles. The white incurved Miss Maréchaux was well represented by numerous blooms (vote of thanks). Mr. G. Wythes, gardener to the Duke of Northumberland, Syon House, Brentford, sent flowers of the white Japanese *Chrysanthemum* Duchess of Northumberland. Mr. Rochford, Turnford, Broxbourne, sent an *Adiantum* named Rochfordi, with large fronds and broad pinnules. Mr. C. Turner, Slough, had a dozen heads of *Poinsettia* major, with broad and brightly coloured bracts (vote of thanks). Mr. W. Iggulden, Marston Gardens, Frome, showed heads of a seedling *Poinsettia*, very bright in colour and early.

Messrs. Paul & Son, Cheshunt, showed flowers of the peculiar bright orange coloured *Leonotis leonurus* and *Canna* President Hardy, which has large flowers streaked with reddish orange. Messrs. Cannell and Sons, Swanley, had two new *Primulas*, Duke of Clarence and Prince George, the flowers large, and the colours rich crimson. Mr. W. Whiteley sent a group of *Chrysanthemum* flowers, Princess Teck and Mrs. Norman Davis being the varieties (bronze Banksian medal). Mr. T. S. Ware, Tottenham, contributed a group of *Hellebores*, with *Narcissus monophyllus* and *Iris Histro* in pans and pots (bronze Flora medal). A collection of *Hellebores* also came from Messrs. R. Veitch & Son, Exeter, and choice greenhouse hybrid *Rhododendrons*, with *Begonia* Winter Gem from Messrs. J. Veitch & Sons, Chelsea.

**ORCHID COMMITTEE.**—Present: H. J. Veitch, Esq. (in the chair), and Messrs. J. O'Brien, Ballantine, H. M. Pollett, J. Douglas, G. Hill, S. Courtauld, and T. B. Haywood.

One of the most beautiful groups of Orchids ever seen at a winter

meeting of this Society was that from Sir Trevor Lawrence, Bart., M.P., Burford Lodge, Dorking (Orchid grower, Mr. White), for which a silver Flora medal was awarded. It consisted of the numerous handsome hybrid *Calanthes* which have been raised at Burford Lodge, and arranged as they were with Ferns and *Oncidiums* at the back, the effect was extremely good. A collection of varieties of *Cypripedium Lecanum* was also included. M. S. E. Cooke, Esq., Kingston Vale, sent some cut Orchid flowers with a fine *Laelia alba*; and Messrs. Collins & Collins, Willesden, showed a group of *Cypripedium* insigne varieties (bronze Banksian medal).

Messrs. Pitcher & Manda, Hextable, Kent, had a remarkable group of *Cypripediums*, comprising nineteen varieties of *C. insigne* and twenty-seven other species. Many very beautiful forms were included. Messrs. H. Low & Co., Clapton, sent a plant of *Cypripedium Leeanaum* claptonense, a variety with a broad dorsal sepal and broad white margin. Mr. Prewett, Hammersmith, sent a plant of *Dendrobium superbiens* with a long raceme of dark crimson flowers. Messrs. Lewis & Co., Southgate, had a small group of Orchids, including a very handsome variety of *Cypripedium Curtisi*, remarkable for the dark colour of the lip.

Messrs. F. Sander & Co., St. Albans, contributed a large and varied group of Orchids, including many fine *Cypripediums*, of which *C. Leeanaum excellens* is remarkable for the nearly pure white dorsal sepal, and another variety *giganteum* secured an award of merit. Other notable plants were *Cypripedium Niobe*, *Cattleya dolosa*, *Cattleya Holfordi luteola*, *Cypripedium Pollettianum*, *Trichosma suavis*, and the yellow *Oncidium cheiroporum* (silver Flora medal).

C. Ingram, Esq., Godalming (gardener, Mr. T. W. Bond) exhibited several interesting Orchids, amongst them being the remarkable white *Dendrobium Macfarlanei* and hybrid *Cypripediums*, one named *Cynthia* being from C. Chantini and C. Harrisianum, a large effective flower in the way of the latter parent. C. W. Lea, Esq., Hallow, Park Field, Worcester (gardener, Mr. Catt), showed a raceme of *Odontoglossum coronarium* bearing about twenty-four of its polished reddish-brown flowers (cultural commendations).

#### CERTIFICATED PLANTS.

*Schomburghkia Sanderiana* (Baron Schröder).—The members of this genus are not very abundant in cultivation, though *S. tibicinus* is

FIG. 92.—SCHOMBURGHKIA SANDERIANA.

occasionally seen as a curiosity. The new species, of which a flower is represented in fig. 92, appears, however, likely to be a useful addition to the list of cultivated forms. The flower is about 3 inches in diameter, the sepals lanceolate, half an inch apart at the widest part,  $1\frac{1}{2}$  inch long, and pale rosy purple. The petals are broader and less tapering, the same length as the sepals, but deeper in colour. The lip is  $1\frac{1}{2}$  inch long, the centre lobe rounded, an inch across, and slightly cut at the margin, rich crimson-purple, like the lateral lobes, which are folded over the column, and the white blotch in the throat brings the colour into bold relief. In general appearance the lip is suggestive of a small *Sobralia*. The plant produces hollow pseudo-bulbs like its relative, the "Cow Horn Orchid," as *S. tibicinus* is sometimes termed, and it is supposed that these cavities are utilised for a similar purpose by the ants of the districts in tropical South America, where the plants are found. The flowers are produced in short racemes of four or five each; but it is said to be very free, and its colour will render it a favourite. The plant was introduced a few years ago by Messrs. Sander & Co., St. Albans (award of merit).

*Cypripedium Masereelianum* (Pitcher & Manda).—A beautiful hybrid in the style of *C. Leeanaum superbum*, the dorsal sepal very broad, pure white, and deeply spotted with purple; the petals undulated, dark; the lip neat and polished (award of merit).

*Zamia integrifolia* (Pitcher & Manda).—A compact and elegant

plant, with leaves 18 inches to 2 feet long, with short narrow dark green pinnae (first-class certificate).

*Cypripedium Lecanum giganteum* (F. Sander & Co.).—A variety remarkable for the great size of the flowers, the dorsal sepal  $2\frac{1}{2}$  inches across, with a broad white margin, dotted purple in the centre, and veined with green at the base. A handsome flower.

*Cymbidium pulcherrimum* (Sir Trevor Lawrence and F. Sander & Co.).—A species with long narrow graceful dark green leaves, and pendulous racemes of medium-sized flowers, the sepals and petals narrow, white, with a central line of dark crimson, and a small crimson-edged lip.

*Calanthe versicolor* (Sir Trevor Lawrence).—A charming hybrid with large flowers, white, with a reddish tint at the base of the lip; very free and graceful (award of merit).

*Chrysanthemum Mrs. H. Simpkins* (Mr. Simpkins, gardener to R. J. Measures, Esq., Camberwell).—A peculiar variety with small globular blooms, clear lemon yellow, the narrow florets curiously forked and cut. It was said to have been imported from Japan in 1889 (award of merit).

*Chrysanthemum E. G. Hill* (J. R. Pearson & Sons).—A large deep yellow or bronzy Japanese, with hard substantial florets, forming a full bloom (award of merit).

*Vriesia cardinalis* (C. Duval, Versailles).—A hybrid from *V. Krameri* and *V. brachystachys* with a broad triangular head, the bracts deep red with a wax-like shining surface. The flowers yellow. The leaves are plain green, and the habit is compact.

*Chrysanthemums Henry Perkins, Rivelyn, J. S. Fogg, T. Selwood, Lizzie Cartledge, and E. G. Hill* (R. Owen).—Awards of merit were granted for all these, which are described in the preceding report.

#### FRUIT FORCING.

**PEACHES AND NECTARINES.—Earliest Forced House.**—Trees started early in December, or at an early date in previous years, swell their buds promptly without much incitement from artificial heat, but those forced for the first time are slower in starting into flower. These must not be hurried, and with the buds swelling and advancing for flowering the atmosphere must not be kept nearly so close, as it is important that the blossom advance steadily and have time to develop a strong flower, perfect in all its parts. When the atmosphere is kept close and too moist the flowers are drawn and weak if the temperature be high, if low little progress is made, and the organs are stunted and effete. Admit a little air constantly at the upper part of the house, and above  $50^{\circ}$  it should be increased correspondingly with the temperature, but not allowing a decline below  $50^{\circ}$  in the daytime, sufficient artificial heat being employed for that purpose, and with sun heat an advance may be allowed to  $65^{\circ}$ , closing for the day before the temperature has receded  $55^{\circ}$ . A temperature of  $40^{\circ}$  to  $45^{\circ}$  is ample at night, or in mild weather  $50^{\circ}$ . When the flowers are advanced so that the anthers are showing cease syringing, but afford a moderate amount of air moisture by damping the borders, paths, and walls in the morning and early afternoon. Avoid a close moist stagnant atmosphere at any time, but especially at night with a high temperature. Examine the inside border, making sure that there is no deficiency of moisture. If necessary afford a thorough supply of tepid water or liquid manure. The surface soil is often deceptive, being kept moist by syringing, therefore supply enough to moisten the soil through to the drainage, for surface moistening does very little good. Trees often have weakly blossoms and fail to set in consequence of moisture being given to the tops of the trees instead of to their roots. If there is a superabundance of flower buds remove those on the under side of the trellis by drawing the hand the reverse way of the growth. This will materially assist the swelling of the remaining buds. If there be any trace of aphides fumigate the house on two or three consecutive evenings before the flowers are much advanced in colour, always before the petals unfold, and the atmosphere must be dry, or the moisture will be condensed on the cooler surfaces of the flowers, and they will be discoloured and injured by the tobacco smoke.

**Second Forced House.**—If the trees are very early varieties, as Alexander, Waterloo, and Early Rivers, with Advance Nectarine, fruit may be had in late April or early May by starting at the new year, but if the trees are such as Hale's Early, Stirling Castle, or Royal George Peaches, with Lord Napier Nectarine, the fruit will not ripen until May is well advanced or early in June. This must be taken into consideration by growers. In either case the house must be closed at once, fire heat only being used to exclude frost, the trees being sprinkled occasionally, or on fine days in the morning and afternoon, allowing time for them to become fairly dry before night. Keeping the trees constantly dripping with moisture, especially at night, enfeebles the blossoms, and is provocative of wood bud rather than blossom bud development. Do not allow the temperature to exceed  $50^{\circ}$  in the daytime without full ventilation. Supply water or liquid manure to inside borders, and protect outside with a little litter or dry leaves. Spare lights are an advantage in throwing off rain and snow.

**Succession Houses.**—Where the roof lights are movable it is much the best plan to remove them, and expose the trees to the elements for the winter, the wood being thoroughly ripe. This is inimical to many insects, and the trees are insured rest and thorough moistening of the border. Even the latest and unheated houses are best treated in that way, often having the effect of causing trees to retain their buds which cast them under fixed roofs, and the blossoms are generally finer than on trees that are kept constantly evaporating from the young wood through the time they are at rest under fixed roofs, or when they are subjected to alternating rests and excitements where plants are grown in the house. The fogs and damp of winter, with the drenching rains and snow, suit Peaches in well drained soil, the trees being invigorated and the soil enriched. If the houses have fixed roof lights, ventilate to the fullest extent in all but very severe weather. Proceed with the pruning, bringing matters in respect of cleansing the house and trees to as speedy a conclusion as possible.

**PINES.—Young Stock.**—Growing plants are liable to become drawn and weakly at this time of year by keeping them too close, moist, and warm, the damage often being irreparable, and not unfrequently arises from improper structures being employed. Well ventilated pits or small houses properly heated are most suitable for young Pine plants, as they can be kept near to the glass, and should be given plenty of room. Maintain a night temperature of  $55^{\circ}$  to  $60^{\circ}$ , which, with  $65^{\circ}$  in the daytime, will keep all young stock gently growing, admitting a little air at the top of the house at  $65^{\circ}$ , leaving it on all day, but do not let the temperature fall below that point, and when the temperature advances to  $75^{\circ}$  from sun heat a free circulation of air must be allowed. The bottom heat may be kept steady at  $80^{\circ}$ . Avoid a damp atmosphere, an occasional damping of available surfaces will suffice. Water only when the plants become dry, then afford a thorough supply of weak liquid manure.

**Plants to Ripen Fruit in May and June.**—This is a very important time to have Pine Apples ripe, as fresh ripe fruit is not over-plentiful, and they are a great ornament at dessert, far transcending imported fruit in appearance, and are juicier and more richly flavoured, besides having a much more pleasant aroma. Where a supply is required at the time named, and plants are not showing fruit, it will be desirable to select from those started in March last, which have completed growth, and are now in a state of rest, such as show a stout base—the best indication of starting into fruit when subjected to a higher temperature both at the roots and in the atmosphere. The plants are best placed in a structure to themselves. Where this cannot be afforded they must have a light position in the house where the fruiterers are swelling. Maintain a night temperature of  $65^{\circ}$  in the fruiting department,  $5^{\circ}$  less in the morning of cold nights, and  $70^{\circ}$  to  $75^{\circ}$  by day, but in very severe weather a few degrees lower is preferable to extra sharp firing.

**CUCUMBERS.**—The weather has been wet and cold, and the growth suffers more than when there have been some bright intervals, light being very important in all forcing operations, especially in winter, therefore the glass should be kept as clean as possible both inside and out. Use warm sweet soil and not very wet for earthing over the roots as they show at the sides of the ridges or hillocks. A few sweetened horse droppings spread on the surface will attract the roots and afford nutriment to them when watered. This is preferable to liquid manure, unless the plants are growing in limited borders, boxes, or pots, then copious supplies will be necessary. Always apply it weak and tepid, and not too often. Sufficient moisture will be secured by damping available surfaces other than the plants in the morning and in the afternoon of fine days, but avoid excessive moisture, and do not supply water to the roots till the soil is becoming dry, then afford a soaking. Look over the plants at least once a week for stopping, removing bad leaves, thinning as required, but stopping and thinning will not be much needed, yet it must not be neglected, as crowding is one of the greatest of evils in the growth of winter Cucumbers. Overcropping is a still greater malpractice, and allowing the fruits to needlessly hang after they attain a size fit for cutting serves only to weaken the plants and prevent other and younger fruit swelling; but when large enough, the fruits keeping several days if the heels are inserted in saucers of water in a cool place but safe from frost. Ill-shaped and superfluous fruit should be removed as they appear, and tendrils and staminate blossoms answer no useful purpose, therefore remove them, but sometimes it is necessary to fertilise the pistillate flowers to make sure of the fruits swelling, and, though this may cause a "knobby" fruit, it is better than none at all. Plants from old seed and those enfeebled by attacks of eelworms sometimes fail to swell unfertilised fruits, but fertilisation is seldom necessary for healthy plants raised from fresh seeds.

Mildew is sometimes troublesome. It may be combated by dusting the affected parts with flowers of sulphur, and the atmosphere should be kept drier. A light brushing over the pipes with a cream of sulphur and skim milk is useful against mildew, also red spider. This pest appears after a spell of sharp firing, and spreads with amazing rapidity. Sponging the first discoloured patches on the leaves with a solution of softsoap, 2 ozs. to a gallon of water, is the surest, and, all things considered, the safest remedy. Thrips are best destroyed by similar means, or fumigation with tobacco. Tobacco powder dusted on green and black aphides destroys them, and fumigation on two or three consecutive evenings moderately eradicates these pests. The foliage at this time of year is tender, therefore care must be exercised in fumigation, not giving an overdose.

## THE KITCHEN GARDEN.

**PREPARING FOR FROSTS.**—A change from mild wet weather to sharp frosts and colder days and nights may take place any time now, and unless a few precautions are taken much harm may be done. Globe Artichokes are not perfectly hardy, and will not survive extra severe frosts unless the clumps are protected by either strawy litter, bracken or ashes. Whichever material is used, it ought to be well mounded up to the plants, not sufficiently so to smother them, but about half the length of the strongest suckers may be buried. Thus treated, the severest frosts will not permanently cripple Globe Artichokes, and a row or breadth of plants usually pay well for being taken good care of.

Jerusalem Artichokes are rarely if ever injured by frosts, but if the tubers are wanted regularly or in all weathers, a portion of the crop ought either to be lifted and stored in sand or fine soil, or a breadth of ground should be covered with a good thickness of strawy litter, as this admits of the Artichokes being dug during the prevalence of severe frost.

Parsnips keep best where grown, and if the ground about these is also heavily mulched there will be no difficulty in getting at the roots any time. Leeks are perfectly hardy, but cannot very well be dug when the ground is badly frosted. It is advisable therefore to either mulch a portion of the bed, or else to lift and lay in closely a few dozen plants. Main crop Carrots ought to have been lifted and stored some time since, but any sown in June or July may well remain where they are, young Carrots being much the most tender and sweet when used direct from the ground; still later Carrots will continue to grow whenever the weather is mild, and that is another good reason for leaving them where they now are. They are seldom injured by frost, but it is advisable to have a heap of strawy litter in readiness for covering a portion at least of the beds whenever severe frosts are imminent, and the roots can then be drawn whenever required.

The tops of Beet are harder than the roots, and it is possible for the former to be uninjured by frost, and yet the roots be spoilt for eating. Lifting and storing is the best way out of the difficulty and ought to have been attended to some time since. Turnips are rather scarce this season, the late sowings failing in many places, while those early raised are somewhat coarse. Those not half grown may well be left to take their chance, and, unless a severe winter be experienced, will give acceptable tops next spring. Orange Jelly, White Stone, Red Globe and Chirk Castle Black Stone are all fairly hardy, but no risks ought to be run where the crops are small. A portion or all of the largest roots may well be pulled and trimmed, then placed in a heap in a cool, dry place and covered with straw heavily faced over with soil. Thus treated they will keep well, especially if turned once or twice during the winter and cleared of all young shoots.

Turnip-rooted Celery is now quite large enough for storing, and will keep best if treated as advised in the case of Turnips, or, if preferred, the roots can be heavily covered with leaves or litter faced with soil. An ordinarily severe frost will not injure either Celery or Celeriac, and it is the extremes that have to be prepared for. The weather for some time past has been all against moulding up Celery, but unless this important work is persevered with the chances are much injury may be done before midwinter by a severe frost. If only partially earthed, frost will seriously damage the exposed stalks, the decay consequently spreading downwards and to the hearts very rapidly. Heavily earthing so as to leave only the tips of the leaves protruding is the best protection against frost, and unless this is done the plan of covering with boards nailed together in the form of a V and inverted over the rows in frosty weather, or the more objectionable practice of covering with strawy litter ought to be resorted to. When moulding up finish off neatly and smoothly so as to throw off as much water as possible, and see that there is a good outlet for all that accumulates between the ridges.

Parsley has grown very strongly in the autumn, and will cut up badly if we have severe frosts during the winter. It is not yet too late to lift a considerable number of roots, removing the larger outside leaves from them prior to packing the plants closely in deep pots or boxes filled with rich loamy soil. If placed in a warm house of some kind, newly started Peach houses or vineries answering well, top growth will soon be fairly strong, and a difficulty probably avoided. Also cover up as much as possible with spare frames and handlights, abundance of Parsley being a pleasurable surprise to the cook.

## PLANT HOUSES.

**Chrysanthemums.**—Cuttings of early flowering varieties will be ready for insertion. When these are grown solely for purposes of decoration boxes 5 inches deep are filled with light sandy soil, after placing a layer of leaf mould at the base, the cuttings being inserted moderately close together. If well watered after insertion and then covered with squares of glass very few if any will fail to root. The boxes should be stood in any cool house. Plants that are raised under cool treatment grow sturdily from the first. As soon as the cuttings are rooted the required number may be placed singly in small pots, or two or three may be placed together in 3-inch pots. This is only necessary where very large bushes are needed. Those required to produce exhibition blooms may be inserted as far as cuttings can be obtained. These should be placed singly in small pots and stood in handlights in a cool house. There are various ways of raising these plants, and all may be practised with success. Stools that have not yet produced cuttings may be placed by themselves where they can be kept a little closer until they show signs of pushing. Be careful not to give too much water to the old stools, especially those that have not displayed signs of

growth. Plants for flowering at Christmas require abundance of air, as the present mild weather will bring them forward rapidly. Fogs and damp are the greatest enemies to these; to avoid them becoming spotted ventilate early in the day after the house has been closed at night.

**Hydrangeas.**—Tops that were rooted early and developed flower buds may, if well ripened and the foliage has dropped off, be potted as opportunity offers. For these 5-inch pots are the most suitable. One good crock should be placed at the base, and the compost may consist of old Cucumber and Melon soil, if loam has been the principal ingredient for them. A little soot may be mixed with the soil. In potting, the soil may be pressed moderately firm, and the flower bud left just above the surface. After potting, the plants may be returned to a cold frame or any cool structure where they can be kept in an intermediate state of moisture without having recourse to the water pot. Plants that were rooted later may be kept on a shelf in the greenhouse or any cool house where they will be safe from frost until they have thoroughly matured their foliage. This is necessary if they are to do well; do not allow them to become dry.

**Hydrangea paniculata.**—Although this variety will not bear forcing it is invaluable in pots for purposes of decoration. Plants that have been well established and made good growth outside should be lifted and placed in 5 to 7-inch pots, according to their size. These may be pruned close back and stood or plunged in cold frames. When the plants have not been established in pots they should be allowed to break into growth in the frames and then given greenhouse treatment.

**Zonal Pelargoniums.**—Plants that have flowered may be stood in a vinery or Peach house and kept perfectly dry, so that they can be cut back in a few weeks and started again into growth.

**Freesias.**—Those that have made 1 or 2 inches of growth should be placed on a shelf near to the glass in the greenhouse, to prevent their drawing up weakly. These plants are often ruined by an attempt to force them into flower. Later supplies may be potted and stood in the greenhouse, where they can be covered with a little cocoa-nut fibre refuse until they have started into growth.

**Gladioli The Bride.**—Keep those on a shelf in the greenhouse that were potted early and have made some inches of growth. These plants do remarkably well under greenhouse treatment. A good number for late use may be potted at once, 5 and 6-inch pots being the most suitable size, placing the bulbs thickly in the pots.

**Lilium lancifolium.**—Where these have been standing outside, and the old flower stems are dead, they may be cut away and the plants placed under cover until the soil is in an intermediate state of moisture. They should then be turned out and repotted. It is often necessary to break up the balls and sort them, for they increase rapidly under pot culture. If left too long before potting is commenced new roots are formed, and then it cannot be done properly without considerable injury. In potting use the soil in an intermediate state of moisture, place them in a frame, and cover the surface with ashes or cocoa-nut fibre refuse, which will prevent evaporation until they commence rooting and growing.

**Fuchsias.**—A few plants may be pruned and started into growth in a vinery or Peach house that has been closed for starting. If the soil is very dry a little water may be given, and then if well syringed they will soon start into growth.

**Primula obconica.**—Young plants in 3-inch pots may if required for spring flowering be placed into 5-inch pots. They will do well on a shelf in any position that is cool, and where they are safe from frost.

## APIARIAN NOTES.

## THE WEATHER.

DURING the past week the temperature varied from 52° to 19°, calm and fine, to stormy. Several of the hives took advantage of the mildness and aired themselves; most of them, however, remained quiet. So far, neither death nor disease manifest their presence.

## PERFORATED ZINC FLOORS.

Amongst my correspondence I have a letter from "F. McC., Annan," which is interesting, and I give part of what he says to your readers. He seems alive to the risk bees run of dying when they leave the cluster of bees and descend to the floor. This is also our experience; hence the reason we advocate the combs to be within the reach of the bees when upon the floor; the space between the two should be the distance bees elect to leave. Of the floors he says, "After experience of perforated zinc floors I am quite satisfied that they are good. They are perfectly clean in spring, and all the dirt is below, having fallen into peat moss which is below. I find the peat moss a favourite place for moths and their

eggs, but I change this frequently, and always subject the material before using it to as great a heat as it will stand without burning; it destroys the moth eggs and other insects, but it is strange how soon the moths find it out." The above is the testimony of a gentleman who is reliable, and who tests things before he recommends them to others. He is in short the friend of the cottager and of the industrious, hence the greater the value of his testimony, and of the effectual way to destroy insect pests.

#### GOVERNMENT AID.

There has been for a considerable time past much clamour to influence County Councils to allow portions of the grants to bee-keeping that has been allocated for technical instructions on rural matters. I am informed this has already to some extent been granted. Public money should be disbursed by responsible individuals for the benefit of the public, and in a judicious and economical manner. Bee-keeping can be carried on successfully by comparatively few, and it never will be as great a national industry, as bee-keeping is associated with horticulture, and cannot be well separated from it. So that whatever grants are procurable let them go for horticultural and agricultural purposes, of which bee-keeping is but a part. It is to be hoped that County Councils will think the matter over as seriously as they possibly can before they grant any aid to bee-keeping separated from horticulture and agriculture.

#### AN EXPLANATION AND CORRECTION.

I, in common with many others, were well pleased with your admission of a supposed fault, as we were equally so with the correction made by you at page 485, as decidedly called for by the circumstances of the case.—A LANARKSHIRE BEE-KEEPER.

#### TRADE CATALOGUES RECEIVED.

J. Carter & Co., 237 and 238, Holborn.—*List of New Chrysanthemums for 1892.*

Norman Davis, Lilford Road Nurseries, Camberwell, S.E.—*Catalogue of New and Old Chrysanthemums.*

Dicksons & Co., 1, Waterloo Place, Edinburgh.—*Catalogue of Forest Trees.*

\*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Cutting Down Something** (*A Subscriber*).—If you will be so good as to make clear what you desire to cut down your question shall be answered. No one here can decipher the word on your postcard, and printers can decipher almost anything.

**Pipe Sockets Splitting** (*J. R.*).—You will no doubt find the cause of the mishap indicated in a short article on page 493 from a correspondent who has had great experience on the subject on which he writes.

**Chrysanthemum Mrs. Norman Davis** (*H. Prosser*).—Your blooms arrived just as we were preparing for press. The florets are distinctly bristled, like many we have seen of Charles Gibson. Those additions, in our opinion, deteriorate from the merits of incurred blooms.

**Seed Pans** (*W. P. Dennis*).—We have no doubt your seed pan is very good, but it seems to us that if the water trough were glazed, as you suggest, its utility as a slug barrier would be destroyed. Manufacturers who wish to increase the sale of meritorious goods keep them before the public in the usual business way that has proved so profitable to many.

**Chrysanthemum Etoile de Lyon** (*W. D.*).—We have seen scores of blooms nearly white like those you have sent, the consequence mainly of variation in the character of the buds; but we believe there is one, if not more, white sports of the variety established. Yours may either be a natural sport or artificial production, and next year's experience will determine the point.

**Emigrating** (*H. J.*).—We would not advise you to go to either America or Australia to seek work in gardens if you have no friends to go to, or without testimonials from well known nurserymen and horticulturists, recommending you to persons who would be likely to assist you in your object. In reply to your question for an address that will enable you to obtain information, the most reliable we can give is that of the Secretary Emigrants' Information Office, 31, Broadway, Westminster.

**Forcing House** (*W. P.*).—The illustration cut from Mr. W. Cooper's catalogue represents a very useful house indeed, and numbers of gardeners would be glad to possess one. It is not ornate nor costly in character, but essentially serviceable, and one of many such houses in which are raised and grown thousands of plants of various kinds and

FIG. 93.—FORCING HOUSE.

sizes sold in Covent Garden. Such structures are moreover just as suitable for growing Cucumbers, Melons, and Tomatoes as ornamental plants; indeed, not a few persons grow such crops as those in the summer, and different kinds of plants in winter and spring.

**Anemone blanda from Seed** (*L. R.*).—The Anemone you name can be raised from seed, and if the seeds you had were properly matured they should, if the soil and situation were suitable, have germinated before this. If sown too deeply, or in a dry exposed place, they may be lost, but seeds of the Anemone family vary greatly in the time required for germination, and it is possible that some young plants will appear in the spring. If you have any seed now sow some in pans of light soil, and place them in a cool moist frame, or any position where they can be protected from frost and rain. Flowers would probably be produced the following season.

**Hæmanthus, Pancratium, and Eurycles** (*J. T.*).—Hæmanthus Katherinæ belongs to the same section of the genus as *H. multiflorus*, and is easily cultivated. It requires a stove temperature, and no doubt like others of its relatives would flower at different periods, which could be regulated by starting the bulbs at intervals. If it is potted now and placed in heat growth would shortly commence, and flowers might be expected in the spring months. The most suitable compost consists of peat and turfy sandy loam in equal parts, with a small proportion leaf soil and a little sand added if the loam be heavy. Good drainage will be needed, and plenty of water during growth, gradually reducing the supply afterwards, and placing them in cooler quarters for the resting period. *Pancratium Sickenbergi* is a native of the desert region of Egypt and Arabia, and Mr. Baker describes it as possessing "the leaves of *Pancratium tortuosum* with the flowers of *P. maritimum*." Try the effects of a good season of rest, possibly this may assist the production of flowers. The *Eurycles* should be treated similarly to the *Pancratiums*—namely, grown in a stove temperature, employing good loam as the basis of the compost, supplying water freely during growth and flowering, and a little assistance with liquid manure may be beneficial.

**Aralia Veitchi** (*T. S.*).—The stock upon which *Aralia Veitchi* is grafted is *A. reticulata*, which is freely increased from cuttings. Plants that have grown tall should be cut up into lengths of about 2 inches, and inserted singly in small pots. January is a good time to cut up the stems, which soon form roots in sandy soil if they can be placed in a close propagating frame, where they can enjoy moderately brisk bottom heat. We have inserted pieces of *Aralia reticulata* rather longer, and when well rooted have applied the grafts of *A. Veitchi*. But we prefer to allow the stocks to be well established, and have grown some few inches in length. These are then cut nearly close to the base, and the scions of *Aralia Veitchi* placed on to them. Side shoots from a large plant from which the top has been removed soon become united to the moderately soft wood of the young stocks. By this means few grafts can be applied at once, and therefore cut up the stem of *A. Veitchi* into lengths of nearly 2 inches, and join them to stocks with firmer wood. Side grafting is the best to adopt, and they can be worked as near the soil as possible, so that after the stock and scion have united and the plants are placed in 5-inch pots the union will be practically buried in the soil, so that the young plant of *A. Veitchi* will be furnished from the base. The scions should be tied on in the usual way, and then kept practically air-tight by the aid of grafting wax. As the stocks are grafted they should be returned to the propagating frame, and kept close shaded and moist until they are united and have commenced growth, when they must be gradually hardened.

**Malmaison Carnations Diseased (T. S.).**—The "grass" is badly infested with a fungus, probably *Puccinia Arenariae*, which forms small brown masses, often in irregularly concentric groups on the leaves of many Caryophyllaceous plants. The masses on Malmaison Carnation "grass" are larger than on Pinks, and are more disastrous to cultivated than wild plants, for this fungus infests a number of wild as well as garden plants of the class named; and, unless the fungus is very abundant the host plant is not materially damaged or hindered in its growth. The spores are pale yellowish brown and slender. They are abundant, and the mycelium of the fungus is unusually vigorous in the "grass" you sent. There is no remedy for these internal parasites, except by the removal and destruction of the infested growths; but the disease can be prevented by early treatment with copper, and bad as your plants are we advise your spraying them with precipitated carbonate of copper in suspension at intervals of seven days twice, and afterwards at fortnightly or three weeks' intervals. Use 1 oz. to 12½ gallons of water, merely covering the "grass" each time with a mist-like but even water film on both surfaces.

**Young Apple Trees Cankered (J. R.).**—There is always danger of canker intervening in transplanting trees from level ground, and substantial soil to light soil, and a position facing south and rather exposed, as they are not only checked by the removal but by the different climatic conditions, and the bark becomes hardened, the trees showing dark patches in places, and dying forms wounds, which may or may not be infested with the fungus—*Nectria ditissima*. If mere wounds they will soon heal naturally, but if infested with fungus they will enlarge, and ultimately destroy the branch attacked. Evidently the manure you have applied has no effect on the canker, therefore we assume the trees are infested with fungus. In that case the only remedy is to cut out the affected parts and burn them, dressing the wounds with grafting wax or grafting clay if any cankered patches are removed on the stem or large branches with a knife. This will certainly arrest the spread of the disease, and it will be to a great extent prevented by promoting growth in the trees, mulching the roots with partially decayed stable litter, and top-dressing with phosphatic and potassic manures. Canker is caused by various conditions of soil, climate, and management; but there cannot be any canker resulting of fungus without wounds and the presence of spores. We therefore advise your cutting off the heads of the old trees badly affected with canker and burn the tops, grafting the trees with free-growing sorts such as Lord Grosvenor and Bramley's Seedling, at the proper time. We should be glad if you would name the varieties that are most infested with canker, also those most free and longer resisting its attacks in your light soil.

**Names of Fruits.**—*Notice.*—Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. *In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing.* The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (J. S.).—The Pear was a poor specimen, but it is probably Nouveau Poiteau. (H. E. Arnatt).—Broompark.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (A. B.).—As you may see clearly stated above, we do not undertake to name varieties of florists' flowers. Possibly you may be right in your surmise. Why not send it to the person from whom you obtained your plants?

#### COVENT GARDEN MARKET.—DECEMBER 9TH.

HEAVY consignments of Nova Scotia and Canada Apples to hand, considerably depressing the English market. Trade generally quiet.

#### WINTER KEEPING.

PASTURES were hoary with frost; trees, too, were equally hoary, for the fog was dense and the air keen and biting as we were driving to Melton Mowbray in the early morn of a real November day. As we passed through Great Dalby we saw the title of this paper in large type on a placard announcing the sale by auction of the right to graze cattle on certain pastures during winter. Nearer Melton we saw cattle of all sizes, from sturdy stirks downwards to small calves, out on the frozen pastures, whence they have to obtain bare subsistence during winter. Some cake may be given them daily; but foddering with hay will hardly begin while "winter keeping" continues so abundant. As the "fog" becomes scarce some hay will be taken out on the pastures once daily, and the hungry beasts will eagerly consume every scrap of it.

Upon the face of it such treatment may wear the guise of true economy; we invite those who follow the practice to consider if it is so in reality. "Fog," we may inform the uninitiated, is a comprehensive term, embracing all long herbage found on pastures now; much of it is yellow or brown with age, a sure indication of the loss of nutriment. Its consumption is a certainty, as the cattle are driven to eat it by hunger. The pasture is cleared and is bare enough of herbage before spring. Bare, too, are the ribs of the half-starved cattle; all are in low condition, many of them being so weak that they succumb to any ailments. Losses mount up, especially among young stock, yet it does not appear to occur to the graziers to attempt any new departure in management. Cattle so obviously suffer severely during winter from a low dietary and exposure to wet and cold, that it cannot be difficult to see how very possible and desirable a better system of management is.

Blind faith in custom brings to auction sales of winter keeping plenty of eager competitors, the time of outlying pasture now for store beasts being as common in the midlands as is that of summer grazing in southern counties. Marsh flock masters withdraw the sheep from their native fat pastures and send them to upland farms during winter, because they know the sheep would suffer—would not thrive, in fact, on the low damp marshes. They evidently are aware that animals do suffer from exposure to cold and wet, and instead of looking on with the supine indifference of a midland grazier, they bestir themselves, and the sheep are all "over the

hills and far away" long before the soft, alluvial, marsh land becomes sodden by the heavy downpour of an average autumn. No doubt the comparison of good and bad practice, of wisdom and folly, is odious, but it is necessary. Repeatedly have we reminded our readers of the low temperature and heavy rain of October, in order to induce them to be ready with shelter for cows and store cattle, for all of them and not for a favoured few.

Shelter, and how to obtain enough of it, is the second, not the first difficulty in the way of reform. The primary stumblingblock, the chief hindrance to a change for the better, is the obstinate adherence to custom, notwithstanding the heavy loss involved. Why, the value of the beasts lost from disease resultant from exposure would go very far to supply ample means of shelter. We are aware that very many farms are deficient in cattle-sheds or hovels, both in corn and grazing districts. A wise landlord will not hesitate to set right so great a wrong, affecting himself as well as his tenants. Enable a tenant to help himself by thus affording him the means of doing so, and thus indirectly prevent the losses which give such colour and force to his plea for rent reductions.

Bad enough was it for Essex landlords when so many farms were thrown upon their hands, and when the men of Ayrshire came to negotiate for those farms a low rent was a certainty; yet even that could not be obtained without an undertaking to considerably enlarge the homesteads. The shrewd Scotchmen saw the rock on which the old tillers of the soil had split. Not for them the corn-growing that had led to bankruptcy; they intended dairy farming and nothing else; they also intended having suitable yards and lodges to winter their cows in; they have got them. In this instance it was not the setting right of a great wrong. The former tenants had not the stock to require more shelter, they were content, having no cause of complaint till beaten by hard times. Nor has the midland farmer always a just plea for the hovels of which he has such urgent need. Many an instance is known to us where a man has begun with a small holding and sufficient buildings, more land has been hired—often from another landlord—the herd of stock is enlarged till there is no possibility of housing it in winter. The cattle have to rough it out in the open, under the very trying conditions of winter keeping.

#### WORK ON THE HOME FARM.

Ewes timed for lambing early in the new year must now be kept off heavy arable land either in a park or meadow, where they run no risk of worrying by stray dogs, or any sudden fright or disturbance. Let shepherds be alert always to protect their charge, especially if there is a pack of hounds in the neighbourhood. So many people from a distance ride to hounds now that reckless riding among sheep is by no means uncommon. The shepherd should, of course, be there to prevent it. As a general rule he ought not to be long absent from his flock at any time now. Twice recently have we found ewes cast—that is to say, they had rolled upon their backs and could not get up. We were in time to save the lives of both, but one could hardly stand when set upon its legs, so exhausted was it from its prolonged struggles.

The ewes have plenty of grass, and a little trough food consisting of chopped Barley straw and a pint of crushed Oats per head daily. This tends to keep them in sound condition, and corrects any undue tendency to scour. We want strong healthy lambs, and to obtain them must have strong, healthy, well-fed ewes. Very little fear is there of abortion among ewes so cared for and fed with heat-giving, nourishing food. Compare such treatment with that of ewes out in folds with watery Turnips for food, and mud so deep that it is difficult for the sheep to walk at all. Every time a leg is withdrawn from the mud the effort is so great as to put a severe strain upon the body. Surely it is no wonder that abortion and foot-rot are rampant among such sheep. Never should ewes be placed in such folds before lambing. Hoggets may and do thrive in them, but we never allow ewes to have Turnips before the lambing. Afterwards, when ewes and lambs are doing well, a field of late-sown Swedes is a great boon, especially if the winter has been mild and the tops are green. The lambs run forward and eat off the tops and very much of the bottoms as they gain size.

Timely attention should be given now to having plenty of dry food at hand in case of snow. A good stock of sweet chaff and crushed Oats, with a stack of Pea straw (for the sheep to have in racks), near an upland meadow well sheltered from cold winds, is a guarantee of good feeding, whatever the weather may be. Do not wait till the snow comes, but have all in readiness now, and so be practically independent of the weather.

#### ROOT AND SEED STANDS AT ISLINGTON.

THE annual Exhibition of the Smithfield Club in the Agricultural Hall, Islington, is particularly interesting this year, and the entries are

much larger than in the two past years. Cattle, sheep, and pigs, as usual, occupy the greater portion of the ground floor, and the galleries are devoted to the lighter forms of agricultural machinery, together with the imposing stands of roots and seeds from the various large firms which make a special feature of the farm seed business. To the latter we must, in accordance with our custom, devote a few words.

Turning to the right after ascending the stairs near the offices, the first stand which attracts attention is that of Messrs. Sutton & Sons, Reading, which is arranged in a very effective manner, semi-circular mounds of handsome Swedes and Mangolds occupying the upper part, with samples of seeds below in tasteful cases, and examples of the chief specialties in other departments with some of the honours they have secured. Among the Swedes the variety which principally attracts attention is Crimson King, a tankard-shaped purple Swede, introduced in 1883, and which has lately come into such great prominence as a prizewinner and an enormous cropper. Champion Swede still maintains its reputation which it has borne since it was first sent out by the Reading firm in 1857 for general cropping. The roots are slightly smaller than the Crimson King, very hardy, growing well into the ground. Good roots are also exhibited of Sutton's Stubble Swede, a valuable variety which often succeeds well when sown after the corn crop has been removed. Among the Turnips Purple-top Mammoth, Imperial Green Globe, Snowball, and Favourite, a variety which gained the Highland Society's gold medal in 1877 as the best new or improved root, are represented by fine specimens. Of Mangolds the Golden Tankard seems to improve year by year in their quality, shape, and in depth of golden flesh. Crimson Tankard is also a great acquisition. It has all the useful qualities of the Long Red with the advantage of a tankard-shaped root, which is much easier to remove, and the roots are less fibrous-rooted than those of the Long Red. Yellow Globe is also a favourite Mangold. Disease-resisting Potatoes and samples of Maize ripened in England are also shown.

Next to be noticed is the handsome exhibit from Messrs. Carter & Co., High Holborn, which is as full of interest as ever, and the roots shown are remarkable for their clean even appearance. Very conspicuous is a central mound of the Elephant Swede. It is said that thirty valuable cups have in a few years been awarded to this variety, including the Gloucester county cup, value £21, two years in succession; the Duke of Grafton's prize cup, £20; the Ledbury Hunt cup; Gloucester City Corporation, £10 10s. cup, two years in succession; Messrs. Proctor's first prize of £15 15s. in 1890; and Lord Wantage's prize of £5 5s. in Berks the same year. It is also said that last year it was grown by 20,000 cultivators in various parts of England, Ireland, and Scotland. Messrs. Carter devote an important area to the exhibit of enormous specimens of the select stocks of Warden Prize, Mammoth Prize Long Red, Golden Tankard, and Golden Intermediate Mangolds. There are also to be seen excellent examples of some of the most popular varieties of white and yellow-fleshed Turnips, the latter being more especially identified with the business of the colonial flock-master, with whom these Turnips are deservedly popular. Additional interest attaches to the examples of grass seed for laying down land for permanent pasture, illustrating their well known and successful system.

Upon the opposite side of the gallery Messrs. Webb & Sons, Wordsley, Stourbridge, have one of their characteristic displays of excellent roots and seeds, a rather different system of arrangement being adopted than with the other stands, the roots being placed in deeper and nearly perpendicular slopes. They represent the special varieties which have gained so many prizes, such as Imperial and Giant King Swedes, Mammoth Long Red Mangold, and Invincible Turnip, all, with many others of well proved merit. Kinver Chevalier Barley is conspicuous amongst the grains, but several other fine Barleys, Oats, and Wheats are included. Potatoes and other vegetables are well shown, with grass and flower seeds of all kinds.

#### REMARKS.

- 29th.—Wet till 9 A.M.; overcast and damp day.  
 30th.—Wet fog early, and dense yellow fog from 10 A.M. to 11.30 A.M.; then showery or drizzly, and fog again in evening.  
 1st.—Bright morning; overcast afternoon; damp evening; wet night.  
 2nd.—Wet till 7 A.M.; bright and fine after 8.30 A.M., and bright night.  
 3rd.—Overcast throughout.  
 4th.—Damp early; bright fine day.  
 5th.—Overcast early; cloudy day.  
 A mild and damp week. Temperature about 5° above the average, and nearly 9° above that of the preceding week.—G. J. SYMONS.

OWING to the heavy and almost continuous rain, the planting of fruit trees has been checked considerably, especially in strong soils. Autumn planting is admittedly desirable; but it is better to wait a little time than to force trees into the ground when it is in a very wet adhesive state. Still, when it is in suitable condition from now onwards, it is better to continue the work than to wait till next November.

Since so much public attention has been directed to the production of hardy fruit and the shortcomings of our home supply a great extension in planting trees and shrubs has followed, and not before time. It would have been well if the work had begun sooner, and many persons who established young plantations in suitable soil a few years ago and tended them well have been so satisfied with the results that they have extended their operations, in some instances very considerably. Teaching in the form of practice such as that indicated is the most effective of all, and the most cogent reply to those who teach by their reasoning faculties alone that the planting of fruit trees is being overdone.

If there is one thing more certain than another as bearing on the fruit of the future it is that the market supply will, in a very few years hence, be afforded almost exclusively by the produce of young trees growing healthfully in good soil. Why? Because so many young trees are now established, and affording fruit so much superior to orchard veterans, that it follows as the good increases in bulk there will be no demand for the inferior, and the time is not far distant when only the meritorious will be "looked at" by purchasers. It follows, therefore, that according to the law of competition those who desire to share in the production of fruit cannot possibly do so profitably in relying on trees that have had their day and done their duty.

New generations of trees should and will be provided to meet the demands of new generations of consumers of fruit, and if the trees are not planted in this country they will be most assuredly planted in others. Time is almost vanquished by electricity, and distance is of little object in these days of express trains and fast steamers. The state of the markets of the world is flashed to those who can supply them, and all voids are quickly filled where even small profits can be made on transactions; and small profits on hundredweights, or barrels of Apples for instance, sent in large consignments amount to substantial sums in the aggregate.

How extensive these consignments are is shown incidentally in the report of an Arbitration trial which may be found on page 471, and in which it will be seen that one provincial fruit broker alone undertook to ship to one firm in London 12,000 barrels of Apples in a fortnight. We may take that to be a mere item in the trade of the parties concerned, and they are only two out of many who are competing in the same way. The rivalry of brokers, merchants, and shipowners stimulates the producers to grow more and more fruit, and if home growers intend to hold their own in fruit production they must plant young trees in soil prepared as for high class garden culture, and keep it well charged with fertility. Nor is that all, for the trees must be rationally managed, so that the virtues of the soil are not only appropriated by the roots, but converted into sound wood and

fruit-producing matter by the leaves for storing in the stems. If this is not accomplished soil fertility is wasted. For preventing this waste we must have clean growths so thinly disposed that every leaf can develop under the full, free and direct action of sun and air. There is no other way in which the virtues of the soil, the food of fruits, can be turned to profitable account.

Every good leaf, or leaf perfect in structure, is a strengthener of the tree, and contributes to its fruit-producing power; every bad leaf is a weakener of the tree, and an exhaustor of the soil. Leaves grown in the absence of light, in overcrowded trees, are exhausters, as are those on long, strong, and sappy growths, which are allowed to extend rampantly throughout the summer, as if for no other purpose than to enable a great show to be made by pruning in the winter. Young trees, therefore, must not only be well planted in a suitable medium, but the common evil of overcrowding them in summer by injudicious pruning must be avoided. Useless soil-exhausting growths must be prevented, and only those encouraged and retained that are essential to health, form, and fruitfulness. Far more good can be done by the thoughtful use of the fingers and thumb in disbudding in spring than by wholesale slashings away with the knife in winter of parts that ought never to have been permitted to grow.

But to return to the supply of fruit. The inability of home cultivators to meet the home demand for Apples at the present is indicated by the circular of a fruit broker. It is there stated that the imports of Apples into Liverpool alone this autumn up to the 18th ult. amount to 331,646 barrels, or at 140 lbs. a barrel, no less than 3,616,460 stones (14 lbs.) of fruit. The prices quoted generally range from about 10s. to 15s. a barrel, and it is stated the demand is active and prices firmer. This activity in the demand and firmness in price is attributed to the "specially good quality of the fruit offering." That ought to be specially noted, for it is one more example of the commercial fact, that the supply of anything distinctly good creates a demand. There can scarcely be a doubt that fruit would have a larger share in the diet of the nation if the produce generally was more tempting in appearance. Clean, bright, uniform samples are alluring, the trashy and unsightly repel the public, who readily purchase the more tastefully displayed fruits sent from the Continent and elsewhere.

It has been stated before, and will have to be stated again, that as the trashy crops, "all rind and core," deprive the soil of more of its fertility—mineral wealth—than do the largest and most coveted fruits, it follows that these can be grown and sold profitably at prices usually paid for the inferior. That should be the aim of cultivators, because it is the best possible way of making new customers for their wares. Raise the standard of fruit and purchasers will be bound to increase, the consumption of fruit will be greater year by year, and the general health of the nation be improved in consequence. The imports referred to show how great is the demand, and another fact shows that it is increasing—namely, that although our Apple crops were better this year than last, yet the increase in imports this year over last amounts to no less than 240,145 bushels, or more than 2,000,000 stones of fruit.

No doubt there are persons in this country who are honest in the belief that home-grown Apples cannot equal in public estimation the consignments referred to. Arguments are lost on persons holding those views, but facts cannot be ignored, and one of my friends has at the present time no difficulty in selling his Apples in a midland town at nearly or quite twice the current price of the best stocks that have had a journey across the ocean. They are uniform in size, speckless, and bright, and are preferred because of the greater briskness and piquancy inherent in British Apples than pertains to those grown under the more tropical sun in other lands, and so it will ever be.—J. WRIGHT.

## PLANTS AND FLOWERS FOR CHRISTMAS.

At this season we all wish to have plenty of flowers and plants. All need the former for home use and some over to send away, while many have in addition churches to supply and to decorate with flowers and plants. I do not think that a general review of what may or can be done would be so helpful as particularising what I do myself. No doubt many with better means of production will find little or nothing new, but those who are less happily situated I hope may derive some benefit.

Taking first of all the requirements of the home establishment, there no difference is made in the flowers or plants used in apartments except in cases where dinner parties occur at this season. The plants in general use are various Palms, notably *Cocos plumosus*, *Kentia Belmoreana*, and the common Fan Palm, *Latania borbonica*, three essential species. Green and variegated Indiarubber Plants, several *Aspidistras*, green and the variegated *Pandanus Veitchi*, Maidenhair Ferns, and *Isolepis* are the chief foliage plants.

Flowering plants comprise *Chrysanthemums*, *Marguerites*, *Bouvardias*, *Richardias*, the earliest Lily of the Valley, sometimes crimson *Duc Van Thol* Tulips, *Narcissus præcox* and *pallidus*, and a few *Hyacinths*. For extra table work *Crotons Johannis*, *Mrs. Dorman*, *Angustifolius*, *Dracæna Mrs. Freake*, *Cooperi superba*, variegated Pine Apples, variegated Indiarubber and Palms are among the best. For the private chapel *Richardias*, *Pandanus Veitchi*, *Aspidistras*, *Panicum variegatum*, Maidenhair Ferns, *Odontoglossum Alexandræ*, *Poinsettias*, *Calanthe Veitchi* and *C. vestita*, and a few Palms are used, sometimes adding a *Croton* or two if to spare.

The cut flowers in use for apartments generally are late *Chrysanthemums*, the varieties in flower, as a rule, at this time being *Val d'Andorre*, *Peter the Great*, *Guernsey Nugget*, *Fair Maid of Guernsey*, *Princess of Teck*, *Lady Margaret*, *Miss A. Lowe*, *Ethel*, *Mrs. J. H. Jones*. These are sorts to be depended on with the treatment we give them, but there are always others which are rather erratic in their behaviour, sometimes flowering too early and sometimes at the period wanted. Lily of the Valley, which is much thought of; *Cyclamens*, Chinese *Primulas*, *Pelargoniums*, *Richardias*, quite a host in themselves; *Cypripedium insigne*, *Calanthes*, *Odontoglossum Alexandræ*, anyone with fifty to a hundred plants may have a few spikes of this now; *Odontoglossum Rossi majus*, a most useful species; *Cytisus filipes*, *Heaths*, *Bouvardias*, a few *Roses*, *Carnations Germania*, *Miss Joliffe*, and *Pink Malmaison*. Then there are generally odd flowers coming in at this time, besides bought bulbs such as *Roman Hyacinths* and *Tulips*.

For a series of dinner parties the table is varied thus:—The first evening *Chrysanthemums* in variety laid on the cloth and lightly veiled with Maidenhair, the same in silver vases, and one tall *Croton* as a centre. The next evening no vases but an arrangement of *Coleus* leaves and shoots, the varieties used being *Recamier*, a very rich dark variety, and *Gil Blas*, a veined variety with much crimson in its composition. Two Palms in silver pails were in the centre of the table with a branched candlestick dividing them, and two of the latter at each end of the table. Pink shades were used, and a good deal of gold and silver plate, the effect being very good. Other good *Colcuses* for this purpose are *Tête d'Or*, *Vesuvius*, and *Rising Sun*. Of course all these must be particularly well coloured.

Another evening red *Chrysanthemums* were used, *Val d'Andorre* cut with stalks 10 inches long, and five to six arranged in vases so loosely as to allow every spare bloom to be seen. Well-foliaged shoots of the deep yellow *Croton interruptus aureus* were disposed under the blooms. The plants used were two brightly coloured variegated Pine Apples. The effect in this instance was bright and striking. For a special dinner party in the same series nothing except *Cypripedium insigne* was used along with *Asparagus tenuissimus* as a slight veil. The flowers were laid pretty thickly all over the table save round the narrow ledge devoted to plates. The plants employed in this instance were two tall specimens of variegated Indiarubber. Yellow shades were in use for the candles, and the plate was gold. It would be difficult to excel this arrangement in soft beauty, yellow and green being the predominating shades. Of course it requires a large number of plants to yield sufficient *Cypripedium* flowers, but those who have much decoration to undertake would do well to grow a number in order to have a winter supply. For other purposes this is a most useful flower.

Upon one occasion the change was of the most decided nature. No plants were used, but three large cups were loosely filled with common *Rushes* intermixed with a few of the very smallest *Bull-rushes* it was possible to obtain. *Browned Fern fronds*—*Athyriums* and *Pteris aquilina*—were added, and a few branches of *Beech* with copper-coloured leaves. On the cloth more brown Ferns were sparingly used, with a good many branches of wild *Rose* covered

with red heds, the only flowers used being flowering sprays of the common *Strawberry Tree*. The evening next to this white *Chrysanthemums* alone were used. The plants were two tall deep-coloured specimens of *Dracæna superba*. The middle of the cloth alone was covered with the flowers, and the method of arrangement was what would have been "heavy" if any other but a white variety had been used, and that variety one of the "paper shaving" class. Good sized shoots were cut—the stems had not been disbudded—and laid thickly, but not too thickly, on the cloth, so as to make the candlesticks and various vases and cups appear to be rising from a bed of flowers. The foliage used was *Jasminum gracillimum*, *Cissus antarcticus*, and a few sprays of *Cytisus filipes*.

For church decoration the best cut flower is undoubtedly the *Richardia*, and it is well to grow a quantity of this most useful continuous-flowering plant. In the parish church, in addition to these in pots we also use *Chrysanthemums* banked round the pulpit and organ, lightly grouping *Richardias*, Palms, Ferns, cut foliage, and panicles of *Pampas Grass*, *Rushes*, *browned Fern fronds*, *Cyclamens*, *Honesty*, and indeed anything of no great value. The best material I have tried for wreathing pillars or windows is common *Box*; it is so quickly fixed, and looks better than anything else. Light wreaths of *Variegated Holly* are useful; green *Holly* boughs with berries are employed for dressing brackets, window ledges, and for covering pots where specimen plants are used singly in conspicuous positions. Simplicity in material and boldness in design are the chief factors in securing a well-decorated church. Where several parties are engaged in carrying out details it is exceedingly difficult, if not impossible, to secure this; but if a gardener has the charge and possessed sufficient judgment to know where to begin and where to stop then there ought to be no interference with his designs. Much better have an insufficiency than to have every nook and bare portion overloaded with so-called decorations.—B.

## STANDARD TRAINED FRUIT TREES.

I HAVE known the time when trained standard fruit trees could not be bought, while now there is small demand for them. One reason probably for this is the fact that they are naturally more costly than are dwarf trained or maiden trees, and in these days of enforced economy every item has to be studied. Then, again, they are more difficult to pack, and may not at all times travel quite so well as desirable. Moreover, modern fruit growers are not so particular about maintaining a very perfect form of dwarf trained tree, and more often than not the latter is allowed to "have its head," so to speak, the principal aim being to furnish a wall with bearing wood as quickly as possible. A more widespread trial of cordons or trees, with from one to four main fruiting branches trained uprightly, has also been another factor in the case, such being planted where in bygone days "riders" or standard trained trees were located.

The question now to be decided is whether this departure from a time-honoured custom is altogether for the best. That such may be the case, as a rule, with *Pears* and *Plums*, I think there is no disputing, both kinds of fruits, if given fair play, furnishing wall space very rapidly. Only in the event of extra high walls being bare of trees is it particularly advisable to plant standard trained trees of *Pears* and *Plums* midway between others with low stems; but when we come to consider what is best to be done in the case of *Peaches*, *Nectarines*, *Apricots*, and *Morello Cherries*, opinions will most probably be less decided. That garden and other high walls and fences cannot well be too quickly furnished with fruiting trees all will agree, and if the quickest method of accomplishing this is the most expensive in the first instance, it may yet, and most probably will, be the most economical in the end. Walls cost so much to build, and are of such good service to the fruit grower, that they cannot well be kept too closely furnished with trees, and, with such abundance of second-rate fruit now likely to be forthcoming annually, none but choice varieties should be selected for the walls. No time ought to be lost, therefore, in the matter of furnishing blank spaces or in the re-arrangement of trees already in possession of the best places, and standards might with advantage be employed in either case. For instance, they could be planted midway between dwarf trees that are either nearly worn out or of a comparatively worthless variety, the latter being cut away according as the standards require more room. If this fresh move is made with healthy trees, these having well developed clear stems, a good sized hole and perfectly fresh loam provided for the roots, progress will be satisfactory in every way.

It must be borne in mind that some of the best trees to be seen in the country have long clear stems, say from 4 feet to 6 feet in length, being originally planted as "riders." Not a few of the standards that were planted with the view either to transplanting

or cutting them away, according as the dwarf-trained trees between them require more space, have been found to do so well that these have been retained and the dwarfs gradually cleared out. In some instances nothing but half-standards were planted at the outset, and well balanced heads on these furnish a wall from top to bottom, a lapse of several years still finding them in a fairly vigorous and most productive state. Sixteen years ago I helped to plant a number of Morello Cherries against two long high garden walls, dwarf-trained trees being disposed 20 feet apart, with the 4 feet standards midway between them. At the present time not one in twenty of the dwarfs are left where planted, the standards having done so much the best from the first. Why the latter should succeed better than dwarfs in some cases and not in others is not so difficult to decide as may appear at first sight. Being trained at a good height up the walls they derive greater benefit from the warmth, light, and air than do the low trained trees; those against north walls being the most improved. The branches are nearly also more depressed in training, this checking extra strong growth, and on the whole it is not particularly surprising that standard or half-standard trees should have better balanced heads, better ripened, more durable wood, and produce crops more surely than the less favourably located dwarf-trained trees. I do not urge superseding the latter, but only suggest that we may be too hasty in deciding wholly in favour of either one or the other, the happy medium being most commendable.—W. IGGULDEN.

### GLOXINIAS FROM SEED.

IN olden times Gloxinia culture used to be rather a tedious business, but of late years the strains have been so much improved that few people, I suppose, now trouble to propagate these plants by means of leaves. Some years ago a writer gave a hint in the pages of the Journal as to planting Gloxinias upon hotbeds, and I adopted the plan, which should be more generally tried, as much finer tubers can be had for the following year than in any other way. We grow the erect kinds only, as they suit our requirements the best whether for cutting purposes or for general utility. My mode of procedure is as follows.

The seed is usually sown about the first week in February in the following manner. Take a shallow pan 9 or 10 inches in diameter, thoroughly clean and thoroughly well drain, covering the drainage with a little sphagnum or common moss. Fill within half inch of the rim with a mixture of brown peat well rubbed through the hands, adding enough sand to make it sparkle. Make it quite level, then very carefully open the seed packet, as the pinch of seed is so small that unless care is exercised it will be lost altogether. I have found it a good plan to get half a sheet of note paper—an old letter will do equally well—upon which I place about two or three thimblefuls of very fine sand, then pour out the seed on this, and well mix together, as it can then be sown much more evenly over the pan than by attempting to sow it out of the packet. I then water through a very fine rose, and do not cover with soil, but place a piece of glass over the pot, and cover the glass with moss to keep the seed dark, and place it in a warm moist house. Although the seed is so very small it is some eight or nine days in germinating. Keep a close watch, however, and as soon as the seedlings are visible gradually remove the moss, but take care the pan is shaded from the direct rays of the sun. I rarely give any water from the time of sowing till the seedlings appear, and then keep them covered with the sheet of glass for some time, as they grow away much faster than without it. Occasionally wipe off the condensed vapour, and gradually remove the glass as the seedlings put forth the rough leaves. I generally remove the glass by night at first, and though some will say I am too particular, I find they pay for any little attention.

As soon as they can be handled prick them out into shallow well-drained pans of peat, with a handful of old, sweet, and rather dry Mushroom bed refuse well rubbed through the hands, but not sifted, with enough sand to make it sparkle. I usually prick out the seedlings rather thick at first, as I fancy they do better, and as they become large enough they are again transplanted into shallow boxes, and grown till they are about 4 inches across, when they will be ready for planting into the frames or pits. They prefer a steady lasting warmth, afforded by half-spent leaves and manure mixed. I usually grow Alternantheras and similar plants upon the beds, first merely giving it a turn, just adding a little fresh material as the work goes on, making a firm bed. Upon this I place Cucumber frames, filling with from 6 to 9 inches of soil, about half loam and peat or the refuse from other pottings with a little sand, as they obtain their chief sustenance from the gentle ammonia vapours of the hotbed.

All being carefully levelled the plants are placed out carefully about 10 inches or 1 foot apart, or they would be better with even

more space than that. One good supply is given of warm water, and care is exercised that the sun does not play directly upon them. I usually shade the lights rather thickly with summer cloud before planting, as I once had one frameful completely spoilt while we were at dinner. They will only need attention in watering occasionally, with cautious ventilation, and if the nights be chilly throw a mat or two over the frames; they will grow luxuriantly, and give hundreds of magnificent flowers for cutting, which I have never been able to obtain in any other way. They will continue flowering until quite late in the autumn, and make fine heavy, fleshy tubers for the following year. They should be induced to retain the leaves as long as possible, as I find the tubers swell considerably after the leaves cease growing. About the middle of November we take them up, pack them thickly together in shallow boxes, covering with cocoa-nut fibre refuse for the winter, and place them under the stage of a greenhouse where the temperature does not fall below 45° for any length of time. It may be necessary to fresh line the hotbeds a time or two during the summer and autumn. I have on some occasions lifted tubers considerably over a half a pound weight. They must be well secured against drip when under the stage of the greenhouse. I always take the precaution to tilt a large pane of glass or slate over them, as if a drip falls upon them decay commences at once.

In preparing for the second year we usually make a start about the middle of February. We adopt what may be called a warm greenhouse treatment. The house is span-roofed, 24 feet by 12 feet. I make a point each year to empty it for a short time to give a thorough clean out, washing the woodwork and every part with hot water and petroleum, as if Gloxinias once become infested with thrips or bug it is all over with them, for they cannot be sponged, and to fumigate sufficiently to kill thrips is ruin to the plants.

We sort the tubers into two sizes. The largest are placed in 32-size pots, and the smaller of them into 48-size thoroughly clean. The drainage is as complete as it can be made. The compost used consists of equal parts of brown turfy peat and loam, with some sweet Mushroom bed refuse and a good dash of coarse silver sand. We mix the whole thoroughly, but leave it rough, using some of the turf over the drainage. The tubers are usually covered an inch or so, but always leaving an inch of space to hold water, as the tubers swell considerably. We press rather firmly, arranging them close together on one of the side stages, which is of slate and covered with shingle. They at first only occupy one-half of one of the stages, the other part of the house is generally used for newly potted bedding Pelargoniums that require a little extra warmth. We give one thorough watering, and no more until the soil appears to be dry, and the greatest care is exercised until they have filled the pots with roots. The temperature is kept about 55° to 60° by night, rising considerably by sun heat. Their progress should be steady, the air of the house being kept fairly moist, but not enough to promote long sappy foliage. Spread out the plants as the foliage reaches the sides of the pots. At first we usually give them the whole length of one side of the house, placing each pot upon an inverted one, as in time they will completely cover their own pot and the one they stand upon. The house should be ventilated, but never open the side lights, as they will not endure draughts. If a crowd of small shoots appear we thin them to about three or five, which is ample to make a thoroughly good plant. Many of them will need a little attention in this way, and as they grow they will again require further thinning until the house is filled.

Watering is one of the chief points in connection with their culture. The best soil and the best house are useless if the watering be trusted only for a short time to an inexperienced hand. As soon as they have filled their pots with roots and have commenced to show their flower buds freely I commence feeding them with guano water. I have tried all sorts of manures, but nothing ever gave so much satisfaction as good guano. I place about a pound into a 4 gallon can, and if I want to use it at once I fill it with warm water, and with this about three such lots are made, or twelve gallons. I water them with this three times a week until they are in bloom, when all stimulants are discontinued. I often find it necessary to supply water twice a day, as when they become a mass of foliage and flowers it will be readily understood they require a great deal, and often the pot becomes so completely covered it is difficult to find a place to apply the water. Let the supplies from the commencement be thorough, and do not get into that half-hearted way in giving it by dribblets in their early stages. It is always better to err on the side of giving too little than too much; but in the later stages they can be freely watered without fear of injury.

As I said at the commencement they must have some shade. We use milk and whiting with some green powder added till about the thickness of cream, and apply when the glass is

thoroughly dry and hot with the sun. It will remain on all summer. The floors of the house must be kept damp in hot dry weather, in damp cloudy weather a little heat in the pipes will prevent the plants suffering from damp. They are always seen at their best in the early morning or just before sunset. If the tubers are wanted to be kept over another year they should be cared for after the flowers are over, and not hastily dried, I have heard of people drying them and starting them again the same autumn, but I have never found the practice satisfactory; nor do I save seed, as this exhausts the tubers. I therefore prefer to purchase seed, and that is much better left to experts. Enough to furnish a fair size establishment can be had for 2s. 6d.—C. EDWARDS.

### CORDON GOOSEBERRY TREES—BRAMBLES.

THESE trees I find are coming more to the front every year. I was pleased to see the notice and sketch given in the Journal for the 12th November. Some people may think the drawing exaggerated, but with careful planting and training anyone will soon be satisfied with the fine crop these produce every year; and with a careful selection of kinds, both of early, middle, and late, they could be had from Whitsuntide to September. We have a double trellis here about 100 yards long. This was placed over some young trees four years old. This trellis is about 4 feet high, opening out on the top 20 inches, like the letter Y. The trees were planted 2 feet apart, and three branches each side were trained to it, which leave them about 8 inches apart. This I find is wide enough, except for a few strong growers, such as Early Sulphur, which require a space of 12 inches between the branches. The supports are made of iron, they are 10 feet apart, and four wires are stretched on each side from end to end. The supports are fixed to blocks of oak.

We carefully watch for the first attack of the caterpillar. These should always be taken or picked off the leaf as soon as they are hatched, and never allowed to destroy the foliage before anything is done to prevent them. I find a good dusting of soot or lime under the trees is a great preventive, two or three times during the year, and lightly pointed in. The red spider, another enemy, should be kept in check by syringing with lime water or soot water two or three times in the early spring, just before the buds swell. It is desirable also to keep the ground well mulched with good manure, and give two or three soakings of liquid manure during the growing season if a dry one.

Birds are sometimes troublesome in taking the buds, and also the fruit when ripe. Trees can easily be protected with the garden netting, which can now be bought very cheaply. I find I have one more enemy than I bargained for, that is the wasp. I find the only way to save the berries is to gather them before they crack, as I never find the wasps begin to take them till then. I often think a slight covering, such as feather-edge boards, as soon as they are ripe, would prevent cracking and prolong the time for gathering. I have gathered good fruit up to the second week in September. Some I have kept for a month after gathering by laying them out singly on a tray.

I am pleased to see the *Whinham's Industry* so highly spoken of. I find this a good early and free bearing handsome fruit, with a good bloom when ripe, but is not the earliest with me. We have a large smooth one that always comes in before any other. I never knew the name, although I have seen it for over forty years.

We always begin to thin from the trellis a week or so before Whitsunday, and by leaving the best fruit about 1 inch apart on the branches we have plenty of fine Gooseberries for table; and by planting about ten or twelve varieties we keep up a succession all through the season. When ripe we begin with *Early Sulphur*; following with *Whitesmith*, the large white smooth; and *Crown Bob*, *Lion's Provider*, *Honeydew*, *Dewdrop*, the old *Warrington*, *Whinham's Industry*, old *Rough Red*, and *Red Champagne*; the two last are small but good. I have tried several of the Lancashire prize sorts, but am inclined to rely on the old favourites for flavour and good keeping qualities. I find the birds do not take either the buds or fruit if any of the larger kinds are near.

White and Red Currants bear excellent crops if trained in the same way as the Gooseberries.

We have had an excellent crop of Blackberries, and the weather being mild, they ripened well up to the end of October. The best here is the old *Parsley-leaf Bramble*. The one secret about them was taken from the Journal—namely, to treat them the same as Raspberry canes in cutting out the old wood, and the young wood will come stronger every year. We have a few Brambles collected from the hedgerows. These have done well, but the *Parsley-leaved* is the finest and best flavoured, but not so early as the common English one. These I think if planted on a

ridge of ground about 10 feet apart in the rows and trained on a wire about 3 to 4 feet from the ground in rows about 6 feet apart, when once established would produce a good paying crop, and one to be depended upon every year.—GEORGE CLEMENTS, *Gardener, Haseley Manor, Warwick.*

### HORTICULTURAL LECTURES.

THE above subject is one of the many good works that is being placed by the County Councils before the public, and the thought which immediately strikes one is, Do the public in general appreciate their usefulness? At one place that I have attended in Surrey the lectures are arranged to be held on Saturday mornings for the convenience of school teachers, as a knowledge of horticulture is to form one of the future teachings in our national schools, but anyone has the privilege to attend by paying 2d., and I can assure all who can do so that the time will be profitably spent. The great drawback in this particular instance is that the lectures are given at midday, a very busy time with the amateur gardener, who is often a man of business, and an awkward time for the under gardener to be spared. For such, and many others, the evening arrangement is a great boon. No doubt there are some young gardeners, and some, perhaps, not young, who would not trouble to enter the doors were they close at hand. That class of man, as the old saying goes, "will not be worth his salt." With no determination to excel, and no love for his calling, he is not worthy the ancient and honourable name of gardener. The anxious and persevering man has nothing to fear from such a neighbour, only that in a few instances the easy-going one will, by some family influence or other cause, get placed in position that he is unable to fill with credit to our craft into which he has found his way.

Then, again, let any observant man look through either the cottagers' or gardeners' exhibits at our Shows and see for himself which of the two have the better exhibits. Without doubt the man who is eager to gain all the information possible, and who looks for his gardening periodical as regularly as he looks for his meals.

Another point that I venture to think worth recommending, and which I feel sure would be encouraged by the lecturer as well as giving the audience faithful ideas of what good culture will produce, that is honorary exhibits, and good specimens of either hardy fruits or vegetables grown in the locality. Though the lecturer may be well provided with good charts and faithful representations of various objects, showing the effect of good and bad management, yet I believe living specimens would be both helpful to the lecturer and stimulating to the audience, and it might be the means of inducing some at least to try and do likewise.—J. FRIEND.

[The lectures referred to at Red Hill are held on Saturday mornings, because at no other time could schoolmasters and teachers attend. Some of them travel long distances for gaining knowledge, in order that they may be better able to teach horticulture in schools, and we believe in some the teaching has already commenced. Mr. J. Wright has been fortunate in securing Mr. Edward Luckhurst for delivering these morning lectures, which cannot fail to have good and far-reaching results. Mr. Friend's suggestion is an admirable one. He has brought produce to the meetings of first-class quality—Onions to one, Endive to another, Seakale to a third, and so on; while Mr. Green, schoolmaster, Horley, has exhibited excellent Apples of his own growing. If owners and managers of gardens in localities in which meetings are held could see their way to send hardy fruit and vegetables, or examples of anything else that would be instructive, they would usefully share in carrying out the laudable object the County Council has in view. The whole of the Surrey meetings are held at night with the special exception referred to, and on the termination of the series at Red Hill a similar series will be held on Saturday mornings in another centre, and possibly night meetings as well for the general public, therefore in this respect Mr. Friend's desire will be realised.]

### LARGE PEARS.

It is not often that such examples of Pears as those staged and which gained the first prize in the single dish class at the late Bath Show are seen, and they accordingly proved a source of considerable interest among exhibitors and visitors alike. The variety was the now popular one at November shows, *Pitmaston Duchess*. Happening to know the exhibitor of the fruit under notice I was curious enough to inquire the extent of the crop, and I learn that, although the tree is only a comparatively young one, it carried quite four dozen fruits, none of which was less than a pound in weight. The dish of eight fruits staged at Bath weighed

10½ lbs., the largest turning the scales at 26½ ozs, another 23 ozs. The competition was unusually keen, no less than thirty-two dishes being put up; among them, too, were several fine exhibits of the same variety. The tree occupies a position on a lofty wall, having a west aspect, and being worked on a Pear stock it grows so freely as to require frequent root manipulation. Though but a young specimen, it has been removed to fresh stations twice; but the secret of its well-doing, I presume, lies in the fertile nature of the soil and the excellent attention bestowed at all seasons. Its roots are protected by a thick mulching applied in early spring, and this, together with frequent supplies of clear liquid manure in dry weather, promotes a vigorous, though at the same time fruitful, growth, for I am told it has never yet failed to yield a crop since it began to bear. By leaving them on the tree as long as possible the supply of this sort is kept up till the end of November this year, which for the variety, and taking into account the unfavourableness of the season, might be considered late.

I never remember witnessing the value of water, as applied to open-air trees, more strictly exemplified than in this case, and though many growers would prefer to have perhaps twice the number of fruits of a more useful size than fewer of a sensational character, yet great credit attaches to the cultivator who can secure a first prize from among so many as thirty-two competitors, all of whom staged superior produce. The grower referred to is Mr. J. Gibson of the Draycot Gardens, Chippenham.—W. S.

#### NATIONAL CHRYSANTHEMUM SOCIETY.—DEC. 9TH AND 10TH.

THE early winter Show of the above Society was held last week in the Royal Aquarium, Westminster, and takes the place of the one which for some years past been held in January. It seems likely to develop into an extremely interesting and popular exhibition; and the one referred to was so decided an advance upon the January gatherings that the Society has ample justification for continuing the experiment. October, November, and January are essentially the Chrysanthemum months, and it would be well if the displays could be confined to that period. One point was very evident at last week's meeting, and that was the freshness of the blooms shown—a character in which the January exhibits have too often been deficient. The competition was also very keen in several classes, the first and second prizetakers in particular in most classes showing blooms so nearly equal in merit that the Judges had much difficulty in determining their relative position.

For twelve blooms of the Princess Teck type several good stands were contributed, the best being from Mr. Shoesmith, gardener to M. Hodgson, Esq., Shirley, Croydon, who had excellent solid fresh neat blooms of Princess Teck, Charles Gibson, Hero of Stoke Newington, and Lady Dorothy. Mr. Peter Blair, The Gardens, Trentham, was a good second, Lord Eversley and Mrs. N. Davis being notable in his box, Mr. W. G. Gilbert, gardener to B. Le Neve Foster, Esq., Senwick Hall, Guist, Norfolk, was third.

In a class provided for a collection of Chrysanthemum blooms unrestricted as to number of varieties, freshness being one of the chief features to be considered, Mr. H. J. Jones of the Ryecroft Nursery, Lewisham, was awarded first honours for a most tasteful arrangement of blooms set up in bunches, with Ferns and Palms to form a bank. This was a valuable exhibit in several ways, for it showed what charming effects could be produced by a well chosen departure from the orthodox methods of staging Chrysanthemums. Mr. Wells, Earlswood Nurseries, Redhill, was placed second for a number of well selected varieties; the same exhibitor securing the first prize for twenty-four bunches of Japanese Chrysanthemums. The leading stand of twelve bunches came from Mr. Cane, gardener to Miss Smith, King's Ride, Ascot, very fine and fresh; Mr. C. J. Salter, gardener to T. B. Haywood, Esq., Woodhatch Lodge, Reigate, being a close second; and Mr. Gilbert was third. For six blooms Mr. A. Newell, gardener to Sir Edwin Saunders, Fairlawn, Wimbledon Common, was first with admirable examples of Ralph Brocklebank, Etoile de Lyon, Stanstead White, and Madame Audiguier. Mr. W. A. Searing, The Gardens, Oak Lodge, Sevenoaks, was second; and Miss R. Debenham, St. Peter's, St. Alban's, was third; Mr. F. Taylor, gardener to Sir John Lubbock, Bart., High Elms, Farnborough, Kent, had the best twenty-four blooms particularly beautiful; Mr. C. J. Salter contributed the finest twelve blooms, and other successful exhibitors were Messrs. C. Cox, Shoesmith, Wells, and Brown.

Cyclamens were well shown by Mr. T. May, Twickenham, who gained first prize in the large collection class. In the amateurs' section for Cyclamens and Primulas the prizes went to Messrs. D. White, J. Bateman, C. Ings, and A. Newell. Messrs. Cutbush & Sons, Highgate, gained premier honours for a group of foliage and berried plants, well arranged.

The non-competing exhibits included a handsome display of choice

Primulas and Chrysanthemums from Messrs. Cannell & Sons, Swanley (silver medal). Mr. R. Owen, Maidenhead, had a collection of new Chrysanthemums, similar to that at the Drill Hall on the previous day (silver medal). Messrs. Pitcher & Manda, Hextable, sent numerous fine Chrysanthemum blooms, including several novelties; they also sent a group of Cypripediums (silver medal). Mr. N. Davis, Camberwell, contributed some choice late Chrysanthemums. Mr. W. Walker, gardener to A. Hearn, Esq., The Elms, Upper Tooting, secured a bronze medal for some well grown specimen Chrysanthemums; while high commendations were awarded to Mr. Newell for plants of *Epiphyllum truncatum*; and to Mr. J. Waldie, gardener to J. Bigwood, Esq., Twickenham, for fine blooms of *Etoile de Lyon* Chrysanthemum.

#### NEW CHRYSANTHEMUMS.

##### JAPANESE.

(Continued from page 495.)

THE Japanese section afford so much more variety in form and general beauty that they are undoubtedly the most favoured. So many people object to the round, close ball of the incurved. Besides, the Japanese are so much more useful from a decorative point of view, that no wonder they are appreciated more outside of the exhibition world. What I am pleased to note about the present year's introductions is their improved form. We obtain more flowers now of the Belle Paule type, which is at once full and graceful in its build. Such varieties as *Baronne de Prailly* and *Meg Merrilies* are fast being crowded out of the lists in a competitive point of view. We do not require sorts that have extreme width only to recommend them. We need those that are full and solid, that cannot be seen through when placed on the stands, and this quality we have in the new kinds now offered. What is equally important is the habit of growth. Such sorts as *Madame C. Audiguier*, which reach the astounding height of 14 feet, we do not want repeating. I am especially pleased to find that the bulk of this year's sorts are under 5 feet, which is a step in the right direction.

*Vivian Morel* (fig. 95).—This is so noteworthy that I have no hesitation in placing it at the head of the whole Japanese section, new or old, which may be considered by some a bold step. The blooms possess all the requirements which go to make perfection even in a race of flowers which contains so many forms of beauty. Even objectors to large blooms cannot but admire *Vivian Morel* in spite of its dimensions. I have seen blooms which measured 9 inches in diameter and 6 inches deep, and this without unduly spreading out the florets. The florets droop at the points exactly as they do in *Belle Paule*, but the great charm is in its massiveness, which is devoid of any coarseness, such as quilled or unevenly formed florets, as in the case of *Etoile de Lyon*, for instance, sometimes. Some of the florets in *Vivian Morel* are split or forked, which increases its value rather than otherwise. The colour is rather difficult to describe. Some call it blush mauve, while blush suffused and striped with rose would not be wrong. One thing is necessary to guard against in securing the best coloured blooms, and that is not to be too eager to "take" the earliest formed buds, or the petals will be nearly white. It is from later set buds that the finest coloured flowers are obtained. The habit of growth is of the right kind—3 feet 6 inches only, plants this height giving flowers of the size quoted. It is not an extra strong grower either. I have, I fear, covered considerable space in describing this charming variety, which has already been awarded premier prize as the finest Japanese in the show many times this season, which speaks well of it; therefore I could not do it justice in a meagre description. Another point in its favour is the free manner in which it throws up cuttings, which is totally unlike many varieties.

[The illustration was prepared from a photograph furnished by Messrs. J. R. Pearson & Sons, Chilwell, and faithfully depicts the chief characters of the variety. Mr. N. Davis, Camberwell, who has had some fine blooms of the variety, and has helped considerably to bring it into public notice, states that it was raised by M. Louis Lacroix, and formed one of his set sent out for 1890. Messrs. J. Laing & Sons, Forest Hill, exhibited fine blooms at the Royal Horticultural Society's meeting on October 28th, 1890, when it received an award of merit, and it was also honoured at the National Chrysanthemum Society's meeting on the following day.]

*Mlle. Marie Hoste*.—Next in point of quality comes this variety. It has broad flat florets, quite of the reflexed type of Japanese, but considerably too large to be strictly classed as one of that section, which in my opinion ought to take *Elaine* as a type. Flowers of *Mlle. M. Hoste* measure quite 8 inches across when fully developed, and is quite full and solid in its build. When developing the points of the florets curl up a little, which passes off with age; the colour is creamy white, with the faintest tinge of blush.

*Florence Davis*.—An English seedling from Mr. N. Davis of great promise; the florets are long, strap shaped, exceptionally even in width their whole length; the points incurve slightly until fully expanded. As the flower develops the green centre passes to lemon, and finally to white, which is the natural colour when fully expanded. It is a full solid flower, and deserving of extended cultivation.

*Gloire de Roche*.—As is now well known this is a seedling raised in Algiers from an English plant of *Val d'Andorre*, which it resembles in its growth. I regard this as most promising; the habit is dwarf with stout foliage, the blooms large, and with great depth and solidity; the colour—bright orange amber, flushed crimson—is pleasing.

*Albrie Lunden*.—A Japanese reflexed order, being full and solid. The colour is remarkable—deep crimson amaranth—and for brightening the stand this variety is quite first rate.

*James Dibbens.*—This I noted at the Kent County Exhibition. An English seedling; should be classed with the incurved Japanese, the points of the florets, which are broad, eurling just a little. The colour is a gold base with a purple and bronze suffusion; quite a distinct and desirable addition to a class very much appreciated and encouraged. This variety, I note, has since then received a first-class certificate from the N.O.S.

*Marquis de Paris.*—Of French origin. I lately saw it in Mr. H. J. Jones' Ryecroft nursery. The florets are broad, flat, and slightly pointed, the colour pink, ground mottled, and edged white. A flower of promise, the colour being so striking.

*Mrs. Libbie Allen.*—After the Grandiflorum style the petals extra broad for a flower of that class, and rather pointed at the tips. A very fine bold flower of a pleasing colour, soft yellow. F.C.C.

*Vice-President Audiquier.*—This reminds one of the Val d'Andorre style of flower, but much larger, of a flat spreading habit. The colour is especially pleasing—a kind of a delicate rose, which changes to white at the tips of the petals. Growers of exhibition blooms would do well to make a note of this.

*Miss Lilian Cope.*—A pure white sport from Etoile de Lyon, which originated in the hands of Mr. Carling, gardener at Dove Park, Woolton, two years since, where I then saw it. Even the smallest buds from side shoots come pure white. The general character of the flower is of the style of its parent, although perhaps more refined, the petals not being so long. As a large-flowered white variety it ought to receive considerable attention at the hands of exhibitors, and for producing late blooms in a bush state it should prove valuable, it being well known that its parent is amenable to this form of culture.

*Cléopâtre.*—Sent out by Lacroix as an improvement on Fair Maid of Guernsey, which it closely resembles, but is fuller in the centre, a deficiency which the older variety certainly has, except under exceptional circumstances. The florets are of medium width, pointed and folded, of a semi-drooping character. It is a promising variety even among so many whites.

*Advance.*—Here we have a new style of flower which may be too formal as a Japanese for some, but is sure to meet with many admirers. The petals are narrow and evenly incurved, but still belongs to the Japanese section. The colour much resembles that of Madame C. Laing, perhaps more inclined to full pink; a large and showy variety. Majestic is one of Mr. Owen's seedlings, the florets of medium width, flat or strap shaped, with a semi-drooping tendency; the colour a warm brick red, with a gold reverse.

*W. Tricker.*—If this variety can be so managed to flower a little later than it did this season it will become a popular exhibition variety. Even if it does not do that it is sure to be largely grown when its merits become more known. In my opinion it possesses the most striking colouring of any yet introduced of that shade of silvery rose, with just enough of the former to tone down the warmth of the rose. The form is slightly incurved at the tips of the florets, which are irregularly folded and serrated, which give it a somewhat coarse ragged appearance; still for its colouring it is a charming variety.

*Madame Mezzard* is large flowered and of dwarf growth; the florets are strap leaved, the colour is pleasing, the faintest blush on a pure white ground, which change to white with age. The plant is furnished with stout green leaves, which add to the beauty of the flowers.

*Mohawk* is one of the right type, carrying large flowers on plants not more than a yard high, maroon crimson with silvery reverse; the tips of the florets curl up a little, which adds to the novelty in appearance.

*Mrs. J. S. Foag.*—Narrow florets, some of which are split; a full flower, quite of the right type; colour golden yellow.

*Lord Brooke*, one of Messrs. Pitcher & Manda's seedlings, belongs to the incurved type of Japanese with broad florets; the colour is striking, centre of florets mahogany, outside an edging of gold, the entire inside of the florets gold, making altogether a deep, full, and bold flower, quite distinct from any other variety.

*Miss Alice Brune.*—Flat florets, bright crimson, fine.

*Yellow Avalanche.*—Whether this is to be the future name or not I cannot say, but certainly the variety is desirable, being an exact counterpart of the type except in colour, which is bright yellow. I am not quite certain on this point, but fancy it is in the hands of Messrs. Pitcher and Manda. In any case when obtainable it is a desirable variety to cultivate, the type being too well known to need further comment.

*Kate Mursell* is a primrose sport from Lady Lawrence, having all the characteristics of that fine variety in form and build; the colour being so pleasing it is sure to become a great favourite.

*W. A. Manda* is the new yellow hairy variety received from America. It is likely to prove the best in this section; the colour is pleasing, being of a deep hue, and altogether promising.

*F. W. Flight* belongs to the reflexed class of Japanese; the florets are bright crimson on the upper surface, with gold reverse.

*Madame Darquier* reminds one of Margot in colour; the florets are broader and flat, while in the case of the older sort they are tubular and pointed.

*Pearless* belongs to the incurved class of Japanese, with somewhat narrow florets for that type of flower, which adds rather than otherwise to its attractions. The colour is one of those soft yet deep yellows which is so much appreciated; the inside of the florets is a full shade deeper than the outer, therefore in inspection reveals two different tints of yellow. The foliage and growth remind me very much of Peter the Great. Another peculiarity of this variety is the manner in which the outer florets recurve and are pointed, rolling the two sides

inwards, thus revealing the inner surface of the florets, which exposes the richer yellow, the centre remaining as usual—incurved.

*C. Wagstaffe* is pure white, narrow florets, which are rounded at the edges; a full flower, and possessing much merit.

*Yellow Mdle. Lacroix* (Mr. Charles E. Shea) is a sport from the well-known white Mdle. Lacroix, which it resembles in every respect except colour, and that is a pleasing shade of light yellow. It will no doubt prove valuable for cutting.—E. M.

(To be continued.)

#### NEW AMERICAN CHRYSANTHEMUMS.

THE new varieties from America seen this autumn at the exhibitions, and in collections of Chrysanthemums in nurseries and gardens, prove conclusively that we may now look year by year to the American florists for some important introductions, for several of their recently introduced varieties are taking a very high position with us as exhibition flowers. Such flowers as W. H. Lincoln, W. W. Coles, Puritan, Ada Spaulding, Coronet, Lilian B. Bird, E. G. Hill, Mrs. E. W. Clarke, and others from the American raisers may well lead us to expect some other fine varieties this coming season.

Mrs. Alpheus Hardy for a year or two after its introduction was a disappointment this side of the Atlantic, but its necessary treatment seems now to be better understood, and some good blooms of it have been seen both at exhibitions and elsewhere. I saw some superb blooms in one collection of plants, and I was informed that the plants had been flowered in a little warmth, and that the cultivator intended growing a dozen or more plants of it next year. Louis Boehmer is disappointing so far. I saw at the Birmingham Show two good blooms, but differing in shade. I saw also at the Chrysanthemum Show at Bilston, near Wolverhampton, a box of blooms from a great Chrysanthemum grower in the south, the greater part of which had large green centres, and the flowers were flat and very uninteresting. I think this variety also wants a little warmth to develop it, and that like its predecessor, Mrs. Alpheus Hardy, it will yet be seen good another year. It has been caught in good condition this season, but I am speaking of its general character so far. Even at the New York Exhibition recently it was not favourably viewed. In a notice of the Toronto Chrysanthemum Exhibition the *American Florist* correspondent, in reporting of Louis Boehmer, observes, "I have yet to hear of a favourable opinion as to colour. 'Dull,' 'muddy,' 'no good for market,' seems to be the verdict. 'Big' and 'hairy' are its good points."

The *American Florist* of November 12th gives a lengthened report of the New York Chrysanthemum Show, the great Chrysanthemum Exhibition of America, and a very large number of seedling Chrysanthemums were staged. "Here," says the report, "was the cream of the whole exhibition. There were fully 600 of them, many being decided advances, and the following is a list of the most promising varieties, with awards received by several of them."

Edward Hatch, pink, awarded the Whitney cup and a certificate; also described as in grand form at the Philadelphia Chrysanthemum Exhibition, and as a truly magnificent flower. Colonel W. B. Smith, light orange, awarded the Bird cup. H. F. Spalding, old gold colour, awarded the Ladenberg cup and a certificate. E. Hitzeroth, yellow, awarded the Winslow cup and a certificate. Harry May, orange, awarded the Lanier cup and a certificate. Emily Ladenberg, deep Jacqueminot colour. (The H.P. Rose Général Jacqueminot is largely grown in America for its blooms). Awarded the Oelrichs cup and a certificate. Miss Mabel Simkins, large globular white, awarded the Clews cup.

The following fourteen varieties were awarded certificates:—O. P. Bassett, a fine commercial variety, form of Cullingfordi. C. B. Whitnall, crimson maroon. Maude Dean, La France colour. Roselyn, a shade of Syringa. Mrs. Wm. F. Dreer, a great improvement on Source d'Or. Roy, incurved pink. Marguerite Graham, creamy white, form of Henry Cannell. Mrs. W. J. Kimball, white suffused with pink. Hicks Arnold, orange, and very bright. Mrs. E. D. Adam, white (also at the Philadelphia Exhibition, and described as an immense white, with a faint lemon tint, and as very fine). Oasis, yellow. Bryden Junior, fine yellow. Joseph H. White, pure white, form of Elsie. Charles J. Osborne, bronzy yellow.

The following varieties are amongst those selected as acquisitions from the very great number of seedlings staged at New York:—Mrs. Robert Craig, pure white, globular. Mrs. Anthony J. Drixel, deep carmine. Mrs. Louis C. Madeira, splendid golden sphere. Mrs. Maria Simpson, yellow, an improved Coronet. Judge Hoith, a fine incurved silvery pink. Mrs. Dr. Williams, red and gold. Mrs. Robert C. Ogden, deep pink, reflexed. American Flag, an improved Marvel. Chicago, striped earmine and white. Christopher Columbus, a Japanese incurved. Mrs. J. M. Schley, shell pink.

W. A. Manda, resembling Mrs. Alpheus Hardy in form and hairiness, but the colour is a rich deep yellow. This variety is thus described in the *American Florist*, but not as being seen at the New York Exhibition.

Thinking that notes of these new American varieties may be of interest to your readers I send them on to you, but incurved and Japanese are evidently mixed up in the list, and we must wait the issue of the catalogue of our leading English growers to see what class these varieties belong to.

I note also that at this great Exhibition there are classes for twelve blooms each of certain varieties, cut with long stems and staged in one vase. There were in the class for whites eight exhibitors, and the

twelve blooms of Mrs. Alpheus Hardy which won the first prize were stated to be undoubtedly the finest twelve blooms of this variety seen in America.

A distinct feature of the New York Exhibition was the enormous display of cut blooms in vases, as will be seen from the following extract from the report of the Exhibition:—"The display of vases, with cut blooms with stems not less than 18 inches, was the most gorgeous feature of the Show. That this superiority over the flat displayed blooms was understood by the public was very evident from the crowds that surrounded the tables on which they were displayed. The tables were unfortunately too high to show the flowers to the best advantage. The vases provided for their reception were of the most beautiful and costly ware, and some idea of the magnitude of the display will be gained by considering that nearly 3000 of these valuable vases were used for the reception of Chrysanthemums, Roses, and Carnations, in addition to the glass ware used."

The question arises, Can we not do something in this way to add a new feature of interest to our Chrysanthemum shows, and also in other ways showing examples of the use of the Chrysanthemum in indoor decorative work? There is certainly a great formality about our present style of showing all Chrysanthemum blooms; and whilst it may still be desirable to keep to the old system for exhibiting the prize blooms, very much may yet be done to greatly interest so many who know little or nothing about the individual merits of a flower, but who do take an interest in any artistic work in floral decorations.—W. D.

#### SEEDLING CHRYSANTHEMUMS AT THE FLORAL NURSERY, MAIDENHEAD.

ON paying a visit to Mr. Owen a few days ago, I was surprised to find such a variety of English raised seedlings still flowering in his houses. Mr. Owen has the past year or two proved most successfully the possibility of raising beautiful new Chrysanthemums from seeds of his own growing, and on the day of my visit I found him busy distributing the pollen amongst his plants, which for seeding purposes are grouped together in a specially warmed and dry house. Out of one thousand seedlings of last year several were selected and grown this season to prove their true character. The variability of the Chrysanthemum from seed is very peculiar. For instance, a seedling from the incurved John Lambert was a beautiful yellow Japanese; and a seedling from Sarah Owen, probably crossed with some other kind, produced an incurved, which appeared likely to prove a rival to Pink Venus.

One of the best then in bloom was a Japanese seedling of this year. It carried but one flower of large proportions, about  $7\frac{1}{2}$  inches in diameter, the florets broad and incurved, twisted and hooked at the points. The colour is of a deep reddish bronze, the florets lined with yellow, with yellow tips. It was a seedling from Sarah Owen, and has been provisionally named Robt. Owen, and if on propagation it continues constant to its present form it will be a great acquisition in this class.

In Viscountess Hambleden we have a pink blush Japanese, already certificated, a seedling from Miss Anna Hartzhorn. Mrs. T. A. Spaulding is another Castle Hill seedling from E. Audiguier, rosy carmine with white ground, shading off to nearly white with age. William Tunnington, of which there were several flowers open, is a large and distinct Japanese of a reddish chestnut colour, with a golden centre, the back of florets lined yellow. Atlantic, a seedling from Mrs. Falconer Jameson, long strap-shaped florets, yellow splashed with red. Budget is another distinct seedling from Mrs. Falconer Jameson, reflexed, florets yellow and bronze, striped with crimson on the upper side.

Beauty of Castlewood and Sarah Owen are free seed-bearers, and several seedlings promise to be distinct, and will be grown another year. Yellow Avalanche, a seedling from Avalanche, good yellow shading to primrose with age, the growth and foliage the exact counterpart of its parent. Another seedling from the same is of a blush pink, the growth and habit similar to Avalanche. A beautiful white seedling of last year is very similar to Florence Davis, also having a slightly green centre before it is fully expanded; it promises to be even finer than that good variety as they appear growing side by side.

Of American varieties Miss Lizzie Cartledge was in good form, flower large, with long reflexed florets of a deep purplish-pink colour, with a silvery reverse; it has been certificated this season by the N.C.S. President Harrison and Mrs. F. A. Spaulding are two incurved Japanese, the latter bright nankeen yellow, the reverse of the florets rosy salmon, very distinct and pretty. Mrs. J. S. Fogg, a reflexed chrome yellow, with long florets and good dwarf habit.

Of incurved varieties Matthew Russel, a sport from Princess of Wales, was certainly distinct from Mrs. Coleman as seen growing alongside that variety, the lower part of the bloom being of a deep rose colour, with a pale yellow centre. Rivelyn, a sport from Mrs. N. Davis, which originated here, is another of somewhat similar colour, golden bronze, with a shade of rose, centre of flower clear yellow.—C. H.

#### DATES AND SCHEDULES FOR 1892.

FROM the advertising columns of the Journal I learn that several societies have already fixed the dates of their exhibitions for next year. This is a step in the right direction, as it affords other societies an opportunity to make such arrangements as to avoid clashing with their neighbours in the fixture. Nothing is gained by deferring the settlement of dates for some months after the new year has been ushered in, as I note some societies do. I shall hope to hear of the early issue of the prize schedules which would be a commendable step and one to be

appreciated by exhibitors, especially where any society contemplates making great changes in the composition of their prize list. Cultivators then have no excuse to make if their arrangements are not satisfactory when the exhibition season of 1892 comes round. I have seen classes scantily filled where previous schedule arrangements had been much altered and no notice given of such to the regular exhibitors until within three or four months of the date when the prize lists were issued. How can exhibitors possibly cope with such dilatory proceedings on the part of committees? The principal classes may necessitate obtaining additional varieties of Chrysanthemums to compete on equal terms with others. I am aware that some societies are dependent upon circumstances over which they have no control before they can allot the amount of their prizes. Where committees are not hampered in this way they will earn the thanks of competitors if they make early arrangements to issue their prize list, and they will themselves have the satisfaction of knowing that, should failure occur, the fault is not in the late issue of their prize schedules.—E. M.

#### CHRYSANTHEMUM MRS. SIMPKINS

THIS is a peculiar variety, and though it is not likely to possess much value to exhibitors, it will prove an interesting addition to many

FIG. 94.—CHRYSANTHEMUM MRS. SIMPKINS.

collections where Chrysanthemums are grown for home use. When shown at the December meeting of the Royal Horticultural Society by Mr. Simpkins, gardener to R. I. Measures, Esq., Cambridge Lodge, Camberwell, it attracted some notice, and an award of merit was granted for it. The blooms are globular in form, of the size shown in the engraving (fig. 94), the florets being pale lemon yellow, very narrow, and curiously cut and forked near the points. It seems to be of compact habit and free.

Mr. Simpkins writes:—"This Chrysanthemum mentioned was not sent to us direct, but we had it with bulbs and Japanese Maples from Mr. William Gordon of Twickenham. The flowers have been very

much admired both last year and this year; hence we decided to send it to the last meeting. The plant sent had been in rather a warmer house than I like, but with care it may be had at its best about Christmas."

**ROYAL HORTICULTURAL SOCIETY'S MEETINGS IN 1892.**—The following are the dates of the Committee Meetings and Shows for the coming year:—January 12th. February 9th, annual general meeting. March 8th and 22nd, April 12th and 19th (Auriculas and Primulas). May 3rd, 17th, 25th, and 26th (Temple Show). June 7th and 21st (Rose Show). July 12th and 26th (Carnation Show). August 9th, 23rd, and 24th, Conference and Exhibition at Chiswick, Begonias, Apricots, and Plums. September 6th and 20th. October 4th and 18th. November 1st and 15th. December 13th. The titles of lectures, &c., will be published in the arrangements, to which a list of Fellows will be added.

— **THE MIDLAND COUNTIES CARNATION AND PICOTEE SOCIETY** has just issued a report of their proceedings for the current year, giving a full list of the winners, together with the names of the flowers each exhibited at the August Show in the Botanical Gardens, Birmingham. The report is admirably printed, and is a neat useful little book for amateurs. We are informed that the Committee have already met to prepare the new schedule for 1892, which will shortly be issued.

— **HORTICULTURAL CLUB.**—The usual monthly meeting was held at the Club rooms, Hotel Windsor, on the 8th inst., when there was a good attendance of members. The chair was occupied by Mr. John Lee, and there were present the Rev. W. Wilks, the Rev. F. H. Gall, Messrs. Soper, H. J. Pearson, C. E. Pearson, A. A. Pearson, Cousens, Druery, Cheal, &c. The discussion was opened by the Rev. W. Wilks, who gave a most interesting lecture on fruit trees in pots, and in order to illustrate it gave a description of what he had done himself. He first described the house which he had built for the purpose; he then described the soil which he used; and also the manner in which the potting was done, how the trees were treated during the growing, blooming, and fruiting season, and how they were treated afterwards. In fact, it was thoroughly practical. There was not a point connected with their culture that was not explained; and in the interesting discussion that followed it was more than once stated that it would be impossible for anyone following these instructions to fail. It was also most regretted that owing to its having been delivered from notes it was impossible to give a report of it.

— **SCOTTISH PRIMULA AND AURICULA SOCIETY.**—The annual general meeting of the Scottish Primula and Auricula Society was held recently at 18, Reform Street, Dundee, Mr. J. D. Ker, Douglasfield, in the chair. After the election of office bearers and a Show Committee the Hon. Secretary read the Committee's report on the Exhibition which took place in May last. The report stated that, notwithstanding the inclemency of the weather in spring, the quality of the exhibits forward was quite equal to that of former Exhibitions, and that, taking the Show as a whole, it was perhaps the best the Society has yet held. The Treasurer then read his report, which, although the attendance at the Exhibition and the subscriptions were somewhat less than in 1890, showed a good balance at the credit of the Society. After some conversation Mr. W. Straton, Annfield, Broughty Ferry, agreed to continue to act as Hon. Secretary and Treasurer for another year. Hearty votes of thanks were passed to private and nurserymen exhibitors, and to the Chairman. The date of next Show was fixed for May 6th and 7th, 1892, to be held in Dundee.

— **THE BIRMINGHAM GARDENERS' ASSOCIATION.**—At a meeting on the 2nd inst., Mr. Charles Bick, gardener to Walter Chamberlain, Esq., read a paper on Evergreen Trees and Shrubs for Town Gardens, speaking of the kinds he had from his long experience of Birmingham found to do best; and on the 9th inst. Mr. John Bluck, gardener at The Henburys, Birmingham, read a paper on the Camellia, its varieties and cultivation, and described his treatment for several years of the famous specimen Double White under his care; giving also a list of a few select varieties, and the cultivation of Camellias generally.

— **THE MIDLAND COUNTIES PANSY SOCIETY.**—With a small balance in hand from the first Exhibition, held in June last, the Committee have decided upon issuing the schedule very early in the new year, with more open classes added, and a goodly list of extra prizes offered by friends. The Society appears to be established on a strong footing, and Mr. W. Dean, Sparkhill, Birmingham, is again the Hon. Secretary.

— **A HINT TO CONTRIBUTORS.**—I have previously stated how desirable it is that correspondents should name the district to which their remarks apply. I was much pleased with the article on Roses by "D. W. C." on page 479 until I came to the end of it. He says "here" Roses are cherished, &c. What I am often at a loss for is "where" the "here" is. If only the county were named it would greatly add to the value of such communications. I trust you will be able to give this hint to your able correspondents.—A. M. STANLEY, *Hull*. [We often supply the omission in question, but failed to add Midlands to the communication referred to.]

— **RAINFALL RETURNS.**—I am just preparing to send blank forms to all persons that are known to me as keeping a regular and accurate return of the fall of rain. I know that there are some readers of the *Journal of Horticulture* who do not yet help me. I know it because sometimes they mention the depth of rain, and yet give vague addresses and sign only with initials, and of course it is impossible for me to communicate without a full address. We are just finishing an exceptional year. I should like my account of it to be as nearly perfect as possible, and therefore I shall be glad if every reader of this paragraph who has a rain gauge and attends to it will send me his name and address, so that I may send him suitable forms.—G. J. SYMONS, 62, Camden Square, London, N.W.

— **HELIANTHUS DECAPETALUS** is without a doubt the most free flowering of the whole family, commencing in July and continuing till the end of September. No plant that I know in the whole catalogue of hardy plants increases as fast as this variety of Helianthus, or, as some call it, *Heliopsis laevis*. It grows about 6 feet high and the stems are particularly wiry and much branched at the top. The pale yellow flower heads with dark centres are cupped in form, which is perhaps the only reason why they are not so valuable in a cut state, being more difficult to arrange than those which have recurring florets.—E.

— **TO PRESERVE FLOWERS.**—To preserve delicate flowers take very fine sand, wash it perfectly clean, and when dry sift it through a fine sieve into a pan. When the pan is deep enough to hold the flowers in an upright position take some more sifted sand and carefully cover them. A spoon is a good thing to use for this, as it fills in every chink and cranny without breaking or binding the leaves. When the pan is filled solidly leave the flowers to dry for several days. It is a good plan to warm the sand in the oven before using it, as the flowers will then dry more thoroughly. Pansies preserved in this way will keep their shape and brilliancy of colour all the winter. Ferns when preserved in this way have a more natural look than when pressed, and the Maiden-hair Fern looks almost as well as when it is freshly gathered.—(*International Journal of Microscopy and Natural Science*.)

— **JAPANESE PINKS (DIANTHUS HEDDEWIGI)** are not cultivated nearly so much as they ought to be. They provide an extensive range of colouring, from pure white to intensely dark shades of crimson. Those who are fond of flaked and striped flowers may have them to their heart's content if they cultivate approved forms of Dianthus. The plants are dwarf, from 9 inches to 1 foot high, are well suited for massing; in fact, that is about the best style of arrangement. If anyone objects to the level compact mass when so grown in a bed by themselves this is easily obviated by planting two or three *Acacia lophantha*, *Grevillea robusta*, or *Sonchus laciniata* to give relief. Single or double flowers can be had at will, therefore there is no reason why those who prefer one kind to another may not have their choice. To my mind the single forms are much the best, and are more lacinated than the double variety. Where many persons make a mistake in cultivating these Pinks is in the spring, giving them too much heat; the plants are liable in that way to be weakened, and do not give the same satisfaction as when sown in a cold frame about the middle of March, pricked off into rich sandy soil, grown sturdily, and planted out towards the end of May with a good ball of soil attached to their roots. In this manner the plants receive no check, but start freely into growth, and with a reasonable amount of sun heat they commence flowering early, and continue well into the autumn.—E. M.

— THE ROYAL CALEDONIAN SOCIETY.—Mr. Charles Stewart, Hon. Secretary of the above Society, informs us that the following are the dates of the Shows of this Society, to be held in 1892 :—6th and 7th April, 13th and 14th July, and 7th and 8th September.

— GARDENING APPOINTMENTS.—The following appointments have been recently made through Messrs. J. Laing & Sons, Forest Hill :—Mr. A. Porteous as head gardener to E. H. Watts, Esq., Devonhurst, Chiswick, and Mr. Carpenter as head gardener to Mrs. Dewhurst, Highfield, Eastbourne.

— THE following are the dates of the BRIGHTON AND SUSSEX HORTICULTURAL ASSOCIATION'S SHOWS FOR 1892 :—Spring Show, March 29th and 30th ; summer Show, June 29th and 30th ; autumn Show, August 24th and 25th ; Chrysanthemum and fruit Show, October 25th and 26th. Mr. Edward Carpenter, 96, St. James's Street, Brighton, is the Secretary.

— SPIRÆA CALLOSA is one of the best of the shrubby species of a rather extensive family. Its rosy red terminal flat corymb-like flowers are showy during the latter part of the summer as they are earlier in the year, which is an advantage, as it does not come into flower all at once and then remain flowerless for so long again. Another advantage in this Spiræa is that it may be safely hard pruned every year, therefore it can be kept low and useful as a shrubby plant. Even then it does not fail to flower profusely every year.—S.

— THE DAHLIA.—In your last issue (December 10th, 1891) reference is made in a very interesting article by "J. R. S. C." to the introduction of the Dahlia into this country, "The first perfect blossom is said to have been raised in the French garden of Holland House." It may be interesting in this connection to recall the graceful lines addressed to his wife about 1844, by the Lord Holland of that day :—

"The Dahlia you brought to our isle  
Your praises for ever shall speak  
'Mid gardens as sweet as your smile,  
And in colours as bright as your cheek."

—A. C.

— GERMANIA CARNATION.—In conversation with a leading Carnation grower the remark was made that all yellow varieties were wanting in scent. When I reached home I tried Germania and induced others to do the same, and it was found to possess a distinctly sweet primrose odour. I have seen other yellow Carnations recommended as the best, but in my own experience no variety comes near this one. It is sweet-scented, the flower is of the most perfect form, of free flowering habit, strong growing, easy to increase, and as easy to cultivate as the commonest. True, the shade of yellow might be somewhat more intense, but as we have not any dark yellow near Germania in any other good quality, we may consider ourselves very well off in possessing a large flowering stock of this first class variety.

— I HAD sent me a few seeds of the LETTUCE "BLOND BLOCK-HEAD," about which there was some discussion in spring. Those who are fond of a large Cabbage Lettuce will find this a good one. It is a large grower, is a very pale green, and stands heat well. I made one sowing only, and that for trial. It appears to be a much enlarged Drumhead inclining to the Neapolitan type. I do not like the flavour so well as the small growing Cabbage varieties, nor nearly so well as a good Cos, but for those who have a liking for the class, and to others who have a large demand, no doubt, it is most useful, and I should be inclined to place it among the best.—B.

— PRINCIPAL J. L. THOMPSON, of the Hawkesbury Agricultural College, New South Wales, has no doubt that the climate and much of the soil of Australia are well suited for the CULTURE OF THE OLIVE. All that is needed, he thinks, is an adequate supply of labour. He himself has been very successful in preserving green Olives ; and in a paper on the subject in the August number of the *Agricultural Gazette* of New South Wales he gives the following account of the system adopted. The Olives are very carefully picked from the trees when about full grown, but perfectly green. They should be handled like eggs. If they are bruised in any way, they will become black and decompose. In the green state Olives contain gallic acid, which gives them an acrid taste. To remove this they are first of all steeped in alkaline water, made either of wood ashes, lime water, or washing soda ; of the latter, about 3 or 4 ozs. to the gallon of water. As soon as the lye has penetrated through the pulp, which is usually in from eight to ten hours, they are put into clean water and steeped until all acrid and alkaline taste has been removed. During that time the water is changed every day. They

are then put into brine, composed of 1 lb. of salt to each gallon of water, and kept carefully covered with a thick linen cloth, for if exposed to the air they will turn black. They are finally put up in air-tight jars.—(Nature.)

— SCARCITY OF VIOLETS.—It is not often that Violets are so scarce during a mild autumn as they have been, and still are, this season. We have several hundred strong plants, some planted this year, and still more two years ago, and principally of the Czar, but all we get from these are three fairly large bunches every week. Not only do the Russians fail to flower satisfactorily, but the Marie Louise in pits is also less free than usual, and these failures are general in this neighbourhood. Violets, though moisture-loving plants, evidently do not like too much of it. More sunshine than we had last summer is needed to develop good foliage and to build up strong crowns, and I am afraid that the plants will cut up badly in hard weather.—M. H.

— HÆMANTHUS KATHARINÆ.—Though this plant may grow and even flower in a stove it acquires much finer proportions, forms larger and finer heads of its brilliant flowers, and increases much more quickly when grown all the year round in a cold house from which frost is excluded, but no more, and in which Indian Azaleas and Camellias would ordinarily thrive. I had clear evidence of this when recently visiting the Royal Botanic Gardens at Glasnevin, near Dublin, when I was shown by the Curator of that most interesting and well cared for establishment an exceedingly fine specimen of the fine form of this plant, known as H. Katharinæ superbus (which I had presented to the Gardens some three or four years previously), which though grown altogether in the cold house for the previous year was in every respect finer than I had ever seen it when grown in a stove.—W. E. GUMBLETON.

— RAINFALL IN HAMPSHIRE.—The continuous rain of the past week or two has brought the total above the record of the last eight years. The greatest amount registered in any year during that time was 34.8 inches in 1886, when rain fell on 141 days. At Droxford, a village situated 1½ mile east of Swanmore, and lying in a valley, I find in 1882 36.10 inches was registered, this was before a register was kept here. I also find that Droxford usually registers slightly in advance of what we do here, more thunder showers appearing to fall in the valleys than on the hills, the altitude of Droxford being but 180 feet, while this station is 390 feet above sea level, therefore we may calculate that the previous highest total at Swanmore was in that year also. Even then we seem likely to considerably surpass that ; in fact, we have up to December 8th registered 35.66 inches. During the night of December 1st in nine hours 1.15 inch rain fell. Of 342 days 141 have been wet, the present year being remarkable for excesses in the number of days, wet and dry continuously. On strong land it has now become serious for farming operations, but for planting trees of any kind we have not had too much. It is surprising in our heavy soil how little water is to be seen on the surface or anywhere in the soil. Land not previously having the surface broken for some few months is in splendid order for working, owing no doubt to the presence of so many flint stones in the soil.—E. M.

— AT a large gathering of the CROYDON GARDENERS' AND AMATEURS' MUTUAL IMPROVEMENT SOCIETY recently Mr. W. Gunner presided, and Mr. Joseph Cheal delivered a most instructive lecture on "Our Conifers: Their History, Introduction, Uses, and Something of Their Native Habitats," illustrated with map, photographs, and drawings. He said at the beginning of the present century no more than twenty varieties were known in England, and now we have so many that we hardly realise that such rapid progress should be made. He first mentioned the sorts that are indigenous to this country, and concerning the Scotch Fir (yellow deal), it was also to be found in Norway and Asia, and the Spruce Fir (white deal) grew in vast forests in Sweden, Russia, and he had been in large forests of it in Norway, where he walked for days and days in stillness and dense shade ; and when on reaching the clearing he saw the Norwegian sunset over mountains of snow, it was such a truly magnificent sight that he should never forget it. From these forests alone 85,000,000 cubic feet of timber was annually cut. The root fibre is used for making cords and coarse ropes. He paid graceful tribute to the memory of David Douglas, to whom we are indebted for introducing so many valuable Conifers. It was he who first sent over *Abies Menziesii* from the Pacific coast, and the one named in his honour *A. Douglassii*. This is one of the best timber trees, being so full of resin. He mentioned the flagstaff at Kew in the Royal Gardens, which was cut from the Douglas Fir. Its height is 59 feet, 22 inches in

diameter, measuring 67 cubic feet, and weighs 3 tons. Turpentine is obtained from the Silver Fir (*Picea grandis*), which bears heavy cones. Arbor Vitæ wood made excellent posts and fences, lasting for fifty years. He dealt fully with the historical Cedar of Lebanon, *Araucarias*, *Cupressus*, *Junipers*, *Larch*, *Wellingtonia*, and *Yews*, &c. There was a good discussion, and several points of great interest were touched upon. A hearty vote of thanks to Mr. Cheal for his lecture was accorded. At the close of the meeting the members resolved to wind up the season by having a dinner, and they invited the horticultural and the *Chrysanthemum societas* to amalgamate with them for the purpose.

### ROYAL HORTICULTURAL SOCIETY.

SCIENTIFIC COMMITTEE.—December 8th. Present: Mr. Morris in the chair, Mr. McLachlan, Mr. Michael, Dr. Müller, Rev. W. Wilks, Dr. Scott, Prof. Oliver, Rev. G. Henslow, Hon. Sec.; and M. H. de Vilmorin (visitor).

*Primula Forbesi*, Franchet.—M. de Vilmorin exhibited growing plants and cut blooms of this new species. It was discovered by Abbé Delanay in the province of Yunan, China, growing wild in marshes and Rice fields, where it is practically an annual. The plants were raised from seed received from the Abbé, and under cultivation proves to be a most perpetual bloomer. It much resembles *P. obconica* in the succession of flower stems, but otherwise is quite unlike it in appearance. The flower stems are very slender, and bear several (3-6) whorls of flowers, which, individually, resemble those of *P. farinosa*. It has produced but few seeds as yet, possibly requiring a high temperature. It does, however, well in a cool house. The specimens appear to be all of the long-styled form, which may possibly account for the paucity of seed. The growing plants were presented by M. de Vilmorin to Kew, and to the Horticultural Society. A vote of thanks was given by the Committee to M. Vilmorin for his interesting communication.

*Thelephora* sp. (?).—Dr. Müller exhibited what appeared to be some species of this genus growing round the stems of *Rhododendrons* in peaty sand. He thought it appeared to be parasitic. It was forwarded to Kew for further examination and report.

*Fog and Rain*.—Prof. Oliver asked M. de Vilmorin if he had experienced in Paris any ill effects of fog comparable to those familiar to growers in the neighbourhood of London. He replied in the negative, as a typical yellow fog is unknown in Paris. He observed that was sometimes a well-marked local increase of rain induced to fall, through condensation brought about by trees.

*Narcissus bulbs attacked by Merodon*.—Mr. G. Lee of Clevedon, sent bulbs with this well-known pest. The only methods of destruction are either to cut out the portions containing the grubs; soaking the bulbs in water to drown them; or else, by destroying the bulbs altogether.

*Benthamia fragifera*, fruit.—Mr. R. G. Lakes of St. Austell, Cornwall, sent some fine ripe specimens of the fruit of this tree.

*Citrons*.—Mr. P. Crowley, F.L.S., forwarded two fine fruits of *Citrus medica*, grown at Waddon House, Croydon.

### EXPERIMENTS WITH POTATOES.

MR H. CHANCELLOR of Chessington Hall, Surrey, occupies a recognised position as a scientific and practical cultivator of Potatoes and other crops. He derives much pleasure in conducting experiments, and the information he has thus gained has no doubt been turned to profitable account. His early training at the Agricultural College, Cirencester, where he was a successful student and prize essayist, impressed him with the importance of great exactitude in his various trials, and of these he keeps careful record. This year he tried the Bordeaux mixture as a disease preventive and found it beneficial; he also tried tubers of different sizes for planting, as well as the effects of artificial manures, and has favoured with the following report of some of his experiments during the present year:—

"The past season has proved to be quite exceptional and particularly unfavourable for testing experimentally the value of any special plan of cultivating the Potato crop. This applies in a marked manner to the application of different artificial manures, and in trying to ascertain the relative advantages from the use of minerals and nitrogenous manures together and separately I have been met with not a few of those contradictory results which are very generally found in any series of experimental plots. The heavy gales and rains which prevailed during the latter half of August caught the main crop of Potatoes in full vigour of growth. As the outcome of such violent commotion among the haulm, accompanied by a very low temperature and excess of moisture, the hitherto luxuriant foliage quickly merged into a mere forest of naked stems. This was very generally the case, the gales extending throughout the length and breadth of the country, and though the tubers continued to swell somewhat while the haulm kept green, still the Potato plants were unable to derive much further benefit from the artificial dressings lying at their feet. In venturing to give you a statement of returns from some of my experimental series, I would remark that I scarcely remember a season in which I have noticed so little proportionate gain in produce from the use of artificial manures. It might reasonably be expected that highly forced vegetation would suffer from such a sudden visitation of ungenial weather in this critical

stage of growth more than that growing under normal conditions. So, in all plots heavily treated with nitrate of soda or sulphate of ammonia, the returns are not at all commensurate with the increased outlay.

#### INFLUENCE OF SETS.

*Variety, Beauty of Hebron (early), all Whole Sets.*

	YIELD.
One rod, planted with 80 sets, averaging 1 oz. ...	115 lbs.
" " " " " 2 oz. ...	122 "

*The Bruce (late).*

One rod planted with 72 sets, averaging ½ oz. ...	112 "
" " " " " 1 oz. ...	135 "
" " " " " 1½ oz. ...	142 "
" " " " " 2 oz. ...	146 "

"The larger sized sets showing uniformly a better yield than the small. The shortness of the period of growth this season was against the smaller sets, the plants starting somewhat weaker. Some few rods were lifted, planted with small baker's chats (ninety sets per rod) and weighed against others planted with ordinary full seed size (seventy-two sets per rod), and in all cases the weight per rod was the same, and the proportion of ware to middings in the produce agreed.

#### INFLUENCE OF SOIL.

*Soil Sandy Loam.*

*Soil Heavy Loam.*

	YIELD.	YIELD.
Beauty of Hebron (early) 20 sets (2 lbs.) ..	44 lbs.	36 lbs.
Jeannie Deans (early) " " ...	53 "	44 "
Magnums " " ...	49 "	41 "
The Bruce " " ...	51 "	41 "
Reading Giant " " ...	52 "	47 "
Her Majesty " " ...	53 "	41 "
The Major " " ...	50 "	38 "

"The Potatoes were planted rather earlier on the light soil, and the weather favoured this description of land.

#### INFLUENCE OF MANURES.

*Mineral Superphosphate and Basic Slag (Phosphate Powder) Rate per Acre.*

	PRODUCED.
Mineral superphosphate, 5 cwt. 1 rod (80 sets) ...	112 lbs.
Basic slag, 5 " " " ...	128 "
Mineral superphosphate 5 " " " ...	140 "
and nitrate of soda, 1½ " " " ...	128 "
Basic slag 5 " " " ...	116 "
and nitrate of soda, 1½ " " " ...	106 "
Nitrate only, 1½ " " " ...	
No artificial, " " " " ...	

"Basic slag shows single-handed a gain over superphosphate, but when nitrate of soda is added the positions are reversed, and the basic slag shows better results than nitrate of soda.

"In another series gypsum showed a good return, but salt was uniformly unsatisfactory, as might be expected this wet season. Sulphate of potash alone very unsatisfactory, but with nitrate of soda better. Sulphate of magnesia well repaid outlay (slight cost). Basic slag alone generally gave better return than mineral superphosphate. Bonemeal about equal to basic slag.

*Nitrate of Soda v. Sulphate of Ammonia.*

	RATE PER ACRE.	YIELD.
Two rods lifted, nitrate of soda, ... 1½ cwt. ...	283 lbs.	
" " " " " 3 " ...	251 "	
" " sulphate of ammonia, 1½ " ...	276 "	
" " " " " 3 " ...	241 "	

"Soil, very stiff clay, variety Magnums.—The heavier dose of both salts showing a less yield of tubers. The foliage on the 3 cwt. plots was over-luxuriant, and suffered from heavy gales and rains. A longer and drier season and the heavy dressings would probably have given the higher returns.

*Nitrate of Soda v. Sulphate of Ammonia with Minerals.*

	RATE PER ACRE.	YIELD.
One rod, 70 sets, 2 basic slag		
2 superphosphate		
1 sulphate potash		148 lbs.
2 nitrate of soda		
One rod, 70 sets, 2 basic slag		
2 superphosphate		
1 sulphate potash		139 lbs.
2 sulphate of ammonia		

*Nitrate of Soda, Sulphate of Ammonia, and Soot.*

2 cwt. nitrate of soda, 70 sets (giants), produced ...	150
2 cwt. sulphate of ammonia, 70 sets (giants), produced ...	130
40 bushels of soot (sown in drills when planted) ...	146

"It will be seen that nitrate of soda has given a better return than sulphate of ammonia throughout this last series. The great difference in value between these soluble salts is also a consideration. Many of our leading growers of Potatoes maintain that sulphate of ammonia is

better suited to carry through the crop, and that the tendency to die off prematurely is lessened by applying it in place of nitrate of soda. This season, however, I have not found this to be the case.

"In the above series of experiments the cost of the different dressings

never reached a full age, and are consequently more or less (according to variety) wanting in flavour and general cooking qualities. The difficulty of raising the crop this autumn has probably beaten any previous record, especially on low lying and tenacious soils. Very

FIG. 95.—JAPANESE CHRYSANTHEMUM VIVIAND MOREL.

has not been entered into. The calculation is, however, easily made. As previously mentioned, the season has been far too capricious for placing much value on results. The growing period was far too short. As a natural result of this sudden cessation of growth the tubers have

many tubers are soft and quite unfit for keeping. It is to be feared that very many "elamps" or "pies" will be found unsatisfactory in the spring. The early varieties have already gone off very badly from disease and excess of moisture."

## SEASONABLE HINTS ON FLORISTS' FLOWERS.

**AURICULAS.**—So far as the winter has gone nothing could be more different from last winter, and consequently the thoughts of the grower ran in a somewhat different channel at this time last year. The second week in December the garden was covered with snow, the ground frozen hard, and our frames containing our favourites closely matted down, while those growers who had the advantage of fire heat kept their fires going. I say the advantage, because although I do not at all agree with forcing Auriculas so as to get them in time for exhibition, I think that in very severe weather, as well as in damp weather, it is an advantage to have the power of putting on a little fire heat. Last year our pots were frozen hard at this time, and although the Auricula is a hardy plant, yet the high breeding of the edged varieties makes them unable to endure what their Alpine ancestors pass through unscathed; we cannot (at least I cannot) grow them in the open. I have tried it with such strong-growing varieties as Colonel Champneys and Traill's Beauty, but it was a failure. Like many other alpins, the alternations of heat and cold, moisture and dryness, are too much for them; and besides the first hour of rain after the bloom opens completely destroys its beauty. Hence we must always grow them under cover, not only protecting the plants, but also saving the blooms from the injurious effects of frost, which is apt to distort the flowers. What we have to contend with this season, however, is not cold but moisture.

There is an expressive word used about here by our rustics, "peart," I suppose a corruption of *pert*. When the corn looks up straight green, they say it looks very "peart." This is the best word I can find to apply to the appearance of my small collection of Auriculas. I have never at this season seen them with so much foliage, the old leaves not having yet died off, and consequently instead of at this time having simply a black appearance, they are really good looking plants. One ought not to prophesy, but as I have all along thought that we should have a mild winter, so I think we shall have an early bloom of Auriculas. The great enemy to be avoided now is damp. When I went to my small pit the other day I found that the pots were just as if they had been dipped in water. Air was, therefore, more freely given, although unfortunately that air was laden with moisture. It will be necessary to carefully examine the plants now, take off all dead leaves, examine for the presence of woolly aphis round the collar (it is of little consequence elsewhere), examine the foliage for green fly, which is likely to appear during such mild weather, and if present carefully brush it off with a small brush. I find at this season of the year this is sufficient, and there is no need of fumigation. There must be for the present a withholding of water; it is not well for the plants to get thoroughly dry, but in a state just short of that is the best for them. Of course drip must be carefully looked after; there is nothing more fatal to the well-being of a plant, and when once the soil has become waterlogged and sour there will be no hope for the plant but repotting. Prevention is better than cure, and when a drip is discovered the pot should be at once removed to some other place in the pit or frame. I find this is more readily done in the pit, and have for this and other causes removed mine to the pit earlier than I have hitherto done.

**CARNATIONS AND PICOTEEES.**—The disastrous season of 1891 is not likely to be repeated this season, and, as in the case of the Auricula, it will be necessary to guard against damp. This shows itself on these flowers in spots on the leaves, which destroy their tissue, deprives the plant of its proper amount of nutriment, and if unchecked ultimately kills it. To prevent this it is necessary to give all the air possible, and when it does appear it is best to dust the plants with sulphur. As yet I see no appearance of it in the few plants I have. Those which were planted out in beds have so far had a favourable time. The one precaution necessary is to see that the plants are not dragged about by worms.

**GLADIOLUS.**—Of course the harvesting of the corms ought now to be completed, and they should be safely housed where they are free from frost. I do not, as I have often said, advocate the storing of the roots in bags, as there is a sufficient amount of moisture in the roots to encourage growth where the roots are in contact, for a very little induces them to put out roots, and this weakens them, so that I recommend that they should be laid on trays, made not solid but in strips. They may be fitted into a stand similarly made. By this means there is no contact and the corms get plenty of light and air. I grieve to say that my harvest is a very poor one, from what cause I know not, but I have lost more than one-half of my collection, and of those which I have saved many are very small. I had all mine in one part of my garden, and have, I suppose, shared the fate of those who put all their eggs into one basket. The portion of the garden is damp, and it may be that this moist season did not suit them, or it may be that there is now too much manure in the beds. I have endeavoured to remedy this defect for a year by taking out a good deal of the soil, and putting in a good quantity of turfy loam, and I have also prepared a bed in another part of my garden so as to have a double chance. Last autumn I lifted my fine corms, so that I imagine the season must have a good deal to do with it.

**PANSIES.**—The moist season has suited these very well. My plan is after they have bloomed to plant them out and then in autumn to divide them and pot them. I find this answers my purpose much better than taking cuttings, and I see no difference in the size and quality of the flowers produced by these plants. They are now looking remarkably healthy, and all that they will require will be to be kept free from damp, and should any mildew appear, which is, however, not likely at this

season of the year, they should be dusted with sulphur. Of course, air should be given at all possible times to the frames where they are wintered.

**RANUNCULUS.**—The Persian varieties are quietly lying in the autumn quarters, where they will remain for a couple of months longer; but so wet has the ground been that I have not yet planted the Turban varieties, which, however, I do not or cannot class as florists' flowers. They ought to have been planted in the middle of last month, but it has been simply impossible, and I shall have now probably to defer it to the spring.

**ROSES.**—The trees look remarkably well. The Teas are quite green, and showing an occasional bloom very different from their appearance last year at this time. If it has not been already done, I would advise the thinning out of the old flowering wood—in fact, treating them much in the way that we treat Raspberries; this gives free access of air and light, and saves work in the spring, when there is a good deal of all kinds of work to be got through. Nailing, if not finished, ought now to be completed, first drawing up some earth to the collar of the plant and then placing the manure over it. Under the present system of growing Roses, *i.e.*, as dwarfs, I do not think there is any need of protection even for Teas. It very often does more harm than good, and it is only in such very exceptional seasons as the last that losses for want of protection occur.—D., Deal.

## PRUNING VINES.

My experience with Muscat of Alexandria differs from that of Mr. Dunkin on page 489. For twelve years Vines under my charge have been subjected to close spur-pruning, and I think the bunches this season were larger and better than in any previous year. This was certainly the case near the base of the rods, and the crop is always towards the base than near the points of the canes. I attribute our success in this respect to a close method of pruning the leader in its early stages of growth. The first year only three buds were left above the lower wire for a pair of side shoots and a leader. The next year only a few more than that number were left. I think more young Vines are ruined by faulty pruning, especially the first and second year, than anything else. People seem to be too anxious to cover the root or trellis too quickly, particularly if the Vines are expected to give a full crop of fruit for twenty or thirty years. I am, however, straying somewhat away from the point.

I believe securing a full crop of this variety depends more upon how the wood is ripened every year than upon any method of pruning. If two and sometimes three shoots are allowed to grow from one spur I do not wonder at their requiring pruning on a method which is not close spur-pruning, but if one growth only is taken from each spur and the laterals reasonably restricted I think an annual crop of fruit will be guaranteed, and not very small bunches either. I am a great believer in training the summer growth of Vines thinly, but some gardeners do not practise this plan. My experience with Lady Downe's is just the same in every respect as that quoted for Muscat of Alexandria.

I quite agree with Mr. Dunkin in his advice about Gros Guillaume. For eight years this variety was pruned on the close spur system without a failure, the two following seasons were. Last autumn we tried the long spur plan, with the result that this year we had larger bunches than at any time previous. I suppose it was the extreme vigour the Vine contained which was the means for the first eight years of producing such good results, and as this became exhausted the bunches grew less, until the Vine failed to give a crop.—E. M.

## RESULTS OF EXPERIMENTS AT ROTHAMSTED ON THE QUESTION OF THE FIXATION OF FREE NITROGEN.

FROM the results of the experiments of Boussingault, and also of those made at Rothamsted under conditions of sterilisation and inclosure more than thirty years ago, Sir J. B. Lawes and the author had always concluded that at any rate our agricultural plants did not assimilate free nitrogen. They had also abundant evidence that the Papilionaceæ, as well as other plants, derived much nitrogen from the combined nitrogen in the soil and subsoil. Still, they had long recognised that the source of the whole of the nitrogen of the Papilionaceæ was not explained; that there was, in fact, "*a missing link!*" They were, therefore, prepared to recognise the importance of the results first announced by Prof. Hellriegel in 1886, and they had hoped to commence experiments on the subject in 1887, but they had not been able to do until 1888. Those first results showed a considerable formation of nodules on the roots, and coincidentally great gain of nitrogen, in plants grown in sand (with the plant-ash) when it was microbe-seeded by a turbid watery extract of a rich soil.

In 1889, and since, they had made a more extended series. The plants were grown in pots in a glass house. There were four pots of each description of plant, one with sterilised sand and the plant-ash, two with the same sand and ash, but microbe-seeded with watery extract, for some plants from a rich garden soil, for Lupins from a sandy soil in which Lupins were growing luxuriantly, and for some other plants from soil where the particular plant was growing. In all, in 1889 and subsequently, they had grown in this way four descriptions of annual plants—namely, Peas, Beans, Vetches, and Yellow Lupins; and four descriptions of longer life—namely, White Clover, Red Clover, Sainfoin, and Lucerne. Enlarged photographs of the above ground-

growth, and of the roots, of the Peas, the Vetches, and the Lupins, so grown, were exhibited. Without microbe-seeding there was neither nodule-formation nor any gain of nitrogen; but with microbe-seeding there was nodule-formation, and, coincidentally, considerable gain of nitrogen.

As, however, in this exact quantitative series, the plants were not taken up until they were nearly ripe, it was obvious that the roots and their nodules could not be examined during growth, but only at the conclusion, when it was to be supposed that the contents of the nodules would be to a great extent exhausted. Another series was, therefore, undertaken, in which the same four annuals, and the same four plants of longer life, were grown in specially made pits, so arranged that some of the plants of each description could be taken up and their roots and nodules studied at successive periods of growth: the annuals at three periods—namely, first when active vegetation was well established, secondly when it was supposed that the point of maximum accumulation had been approximately reached, and thirdly when nearly ripe; and the plants of longer life at four periods—namely, at the end of the first year, and in the second year when active vegetation was re-established, when the point of maximum accumulation had been reached, and lastly when the seed was nearly ripe. Each of the eight descriptions of plant was grown in sand (with the plant-ash), watered with the extract from a rich soil; also in a mixture of two parts rich garden soil and one part of sand. In the sand the infection was comparatively local and limited, but some of the nodules developed to a great size on the roots of the weak plants so grown. In the rich soil the infection was much more general over the whole area of the roots, the nodules were much more numerous, but generally very much smaller. Eventually the nodules were picked off the roots, counted, weighed, and the dry substance and the nitrogen in them determined.

Taking the Peas as typical of the annuals, and the Sainfoin of the plants of longer life, the general result was that at the third period of growth of the Peas in sand the amount of dry matter of the nodules was very much diminished, the percentage of nitrogen in the dry matter was very much reduced, and the actual quantity of nitrogen remaining in the total nodules was also very much reduced. In fact, the nitrogen of the nodules was almost exhausted. The Peas grown in rich soil, however, maintained much more vegetative activity at the conclusion, and showed a very great increase in the number of nodules from the first to the third period; and with this there was also much more dry substance, and even a greater actual quantity of nitrogen, in the total nodules at the conclusion. Still, as in the Peas grown in sand, the percentage of nitrogen in the dry substance of the nodules was very much reduced at the conclusion. In the case of the plant of longer life, the Sainfoin, there was, both in sand and in soil, very great increase in the number of nodules, and in the actual amount of dry substance and of nitrogen in them, as the growth progressed. The percentage of nitrogen in the dry substance of the nodules also showed, even in the sand, comparatively little reduction, and in soil even an increase. In fact, separate analyses of nodules of different character, or in different conditions, showed that whilst some were more or less exhausted and contained a less percentage of nitrogen, others contained a high percentage, and were doubtless new and active. Thus, the results pointed to the interesting conclusion that, in the case of the annual, when the seed is formed, and the plant more or less exhausted, both the actual amount of nitrogen in the nodules and its percentage in the dry substance are greatly reduced, but that, with the plant of longer life, although the earlier formed nodules become exhausted, others are constantly produced, thus providing for future growth.

As to the explanation of the fixation of free nitrogen, the facts at command did not favour the conclusion that under the influence of the symbiosis the higher plant itself was enabled to fix the free nitrogen of the air by its leaves. Nor did the evidence point to the conclusion that the nodule-bacteria became distributed through the soil and there fixed free nitrogen, the compounds of nitrogen so produced being taken up by the higher plant. It seemed more consistent, both with experimental results and with general ideas, to suppose that the nodule-bacteria fixed free nitrogen within the plant, and that the higher plant absorbed the nitrogenous compounds produced. In other words, there was no evidence that the chlorophyllous plant itself fixed free nitrogen, or that the fixation takes place within the soil, but it was more probable that the lower organisms fix the free nitrogen. If this should eventually be established, we have to recognise a new power of living organisms—that of assimilating an elementary substance. But this would only be an extension of the fact that lower organisms are capable of performing assimilation work which the higher cannot accomplish; whilst it would be a further instance of lower organisms serving the higher. Finally, it may here be observed that Locw has suggested that the vegetable cell, with its active protoplasm, if in an alkaline condition, might fix free nitrogen, with the formation of ammonium nitrate. Without passing any judgement on this point, it may be stated that it has frequently been found at Rothamsted that the contents of the nodules have a weak alkaline reaction when in apparently an active condition—that is, whilst still flesh-red and glistening.

As to the importance of the fixation for agriculture, and for vegetation generally, there is also much yet to learn. It is obvious that different Papilionaceæ growing under the same external conditions manifest very different susceptibility to, or power to take advantage of, the symbiosis. The fact, as shown by Prof. Nobbe, that Papilionaceous shrubs and trees, as well as herbaceous plants, are susceptible to the symbiosis, and under its influence may gain much nitrogen, is of interest from a scientific

point of view as serving to explain the source of some of the combined nitrogen accumulated through ages on the surface of the globe; and also from a practical point of view, since, especially in tropical countries, such plants yield many important food materials, as well as other industrial products.

In conclusion, it will be seen that the experimental results which have been brought forward constitute only a small proportion of those already obtained or yet to be obtained at Rothamsted, but they have been selected as being to a great extent typical, and illustrative of the lines of investigation which are being carried out.—(*Abstract in Nature of a paper read before the Agricultural Chemistry Section of the Naturforscher Versammlung at Halle a.S., by Dr. J. H. Gilbert, F.R.S.*)

#### THE NATIONAL ROSE SOCIETY.

THE following is the list of Committee and officers elected for the year 1892:—President: The Very Rev. the Dean of Rochester, D.D. Vice-Presidents: His Grace the Duke of Portland, the Mayor of Chester, R. N. G. Baker, Rev. J. M. Fuller, Rev. Lionel Garnett, T. B. Haywood, Robert Hogg, LL.D., M. T. Masters, M.D., F.R.S. Hon. Treasurer: Thomas Burt Haywood. Hon. Secretaries: Rev. H. Honeywood D'Ombain, Edward Mawley. General Committee: H. Appleby, J. Bateman, Rev. H. A. Berners, R. Bloxam, W. Boyes, G. Bunyard, Rev. F. R. Burnside, J. Burrell, B. R. Cant, F. Cant, Rev. A. Cheales, Captain Christy, W. F. Cooling, G. Dickson, Rev. A. Foster-Melliar, W. H. Fowler, T. W. Girdlestone, C. J. Grahame, W. J. Grant, R. Harkness, C. F. Hore, W. J. Jefferies, R. L. Knight, E. B. Lindsell, H. V. Machin, O. G. Orpen, Rev. F. Page-Roberts, G. Paul, J. D. Pawle, Rev. J. H. Pemberton, A. Prince, A. Slaughter, A. Tate, A. Turner, W. H. Wakeley, H. Wallis, R. E. West, E. Wilkins, Rev. W. Wilks, and F. T. Wollaston. Hon. Auditors: J. D. Pawle and F. T. Wollaston.

#### THOUGHTS ON THE N.R.S. ANNUAL MEETING.

WHAT a good meeting it was, to be sure. Fifty-seven good men and true present, and all intent upon business; and how good to have the reins held by the experienced hand of the ever-genial President, Dean Hole. I think it was the first time he has been at the annual meeting for twelve years. May it be very much more frequently that he shall "fill" the chair, as he facetiously remarked in acknowledging the vote of thanks at the close.

By-the-by, that vote ought to have been a "double-barrel," to include Rev. W. Wilks, Sec. of the R.H.S., for until the arrival of the President he discharged the duties of Chairman with a degree of *verve* that was most gratifying to those who prefer to have business done in a business-like manner.

What a pity, though, that the resolution fixing the date of the Metropolitan Show for the Saturday nearest to the 6th of July should not have been carried. The outlook for the past, the present, and the future all seem to point to the desirability of some such arrangement. Last Show day found Messrs. F. Cant and Harkness, each of whom has won the challenge trophy twice, both unable to stage, the former having only sixty sorts in bloom, and the other less than that. When the weather is so mild and damp that December 12th finds Roses still growing and blooming (I cut a nice bloom of Mrs. John Laing to-day), the reasonable presumption is that the next season will be a late one. The President, out of his great experience, asserted that it is simply impossible for the midland and northern growers to be ready before about the 7th of July, and yet the resolution which would have fixed the Show for the 9th instead of the 2nd was rejected. Well, perhaps, we shall have a repetition of the performance of Mr. H. May of Yorkshire, who, some ten or twelve years ago, cut his seventy-two blooms under glass, and so won the prize. Try again Messrs. Pemberton, Foster-Melliar, and Co.

But if a much-needed reform was refused, an even more needed one was adopted in the triumphant passing of Mr. Grahame's resolution, which requires that in future amateur exhibitors shall show in accordance with the stocks of exhibition varieties which they grow. This was warmly urged by the mover and his supporters, who pointed out some glaring abuses of the absolute freedom which the schedules have hitherto allowed, and the deterrent effect which these things have had upon small growers. Some two or three favoured a *laissez-faire* policy, but upon being put the motion was carried by a majority of fifteen. This is satisfactory, because a resolution passed by so substantial a majority may expect to receive the loyal support of all, even of those who dissent from its principle. The change has begun to bear fruit already. One exhibitor who had given up in despair says, "Now I'll have another try." One local Secretary has already received eight new subscriptions for next year because of the resolution, and another reports the enrolment

of a new member a week beforehand merely on the strength of the promised discussion.

But how very sad was the news Mr. D'Ombraïn had to impart—that Mr. W. J. Grant had met with so severe an accident! We were heartily sorry to lose him from the amateur ranks, but to miss him altogether from our gatherings will be a great calamity. Not only was he able to show some of the finest stands ever staged by an amateur, but he was ever ready to rejoice in the success of others, to acknowledge defeat, or to give a word of advice and encouragement to a beginner. Genial and hearty, "straight as a line," and a magnanimous opponent, he was a type of the class of exhibitor we can least afford to lose. May we all be ready to follow the example he so ably set us!—J. B.

### THE NEWCASTLE-ON-TYNE HORTICULTURAL SOCIETY.

THE annual meeting of the members of the Botanical and Horticultural Society of Northumberland, Durham, and Newcastle was held last week in Cross House Chambers, Westgate Road. In the absence of the President (Mr. Thomas Nelson) Mr. Benjamin Plummer occupied the chair. The Secretary (Mr. J. J. Gillespie) read the annual report, which contained the following:—

In previous reports the Council has invariably had to attribute the failure of the year's operations entirely to the wet weather which has prevailed at the shows, in spite of which they have struggled from year to year to keep the Society together, notwithstanding that there has often been a large deficiency in the funds. This year the Society commenced free from debt. The spring Show, held in April, was a financial success, and your Council looked forward with confidence to the autumn Show, which was likely to have been one of the best ever held, exhibitors having brought their plants from an area extending as far south as Wiltshire and as far north as Aberdeen. What happened is now a matter of history, as on the Council assembling in the early morning of the 26th August, at the Leazes Park, to place the exhibits, they found the tents had been totally destroyed by the violent gale of the previous night, and that considerable damage had been done to the plants already staged. After mature consideration your Council unanimously decided to abandon the Show, as it was impossible to re-erect the tents. After considering the claims sent in, and the available funds of the Society, it was found there was a deficiency of £335. Many of the local tradesmen having offered to reduce their accounts, and in some cases to waive them altogether, and letters having been received from several local gentlemen proffering subscriptions, your Council, though greatly disheartened, resolved to issue an appeal for financial assistance, believing that the sympathy of the public was with them. The Chairman of the Council and the then Mayor (Councillor Jos. Baxter Ellis) kindly undertook to sign the appeal, which appeared in the Newcastle newspapers of the next day. The response was at once both generous and hearty, and far exceeded the expectations of your Council. The result is that not only are the liabilities of the Society paid off, but that there is £560 to the good. Encouraged by the sympathy and help already given the Council will endeavour to uphold the status of the Shows by offering liberal prizes, giving the best musical entertainments, pyrotechnic displays, &c.; and whilst they will do their utmost to add to the surplus fund by keeping the expenditure within the income each year, they ask the subscribers to induce their friends to join the Society, so as to increase the ordinary revenue.

The Chairman moved the adoption of the report. He said that the unhappy experience they had in the autumn was not without its lessons. It brought them proof that the public had confidence in the Committee, or they would not have made such a generous response to the appeal that was issued for assistance. The Committee had worked hard, and so improved their shows that, as a matter of fact, an exhibit which would have taken first prize eighteen or twenty years ago would now only take the third prize or none at all. One of the lessons they might learn from the catastrophe of last autumn was the necessity of doing something further than they had hitherto done for retaining the confidence of the public, and sustaining their willingness to assist them in case of need. There were several ways of doing that. In a prize pamphlet on profitable fruit-growing was the suggestion that such societies as theirs might do something in the way of distribution of fruit trees, and he would ask them whether they could not do something in that direction. Another point that occurred to him was, could they not arrange to hold their annual meetings in the afternoon, and arrange for some competent person to address the society on some subjects bearing upon the objects of the society. The adoption of the report was seconded and carried.

The Chairman moved the re-election of Mr. Thomas Nelson to the office of President, and the motion being seconded by Mr. G. Nesbitt, was carried unanimously.

The Mayor of Newcastle was elected Vice-President, after which the meeting proceeded to the election of members of the Council.

### REVIEW OF BOOK.

*Travels and Adventures of an Orchid Hunter.* By ALBERT MILLICAN. Cassell & Company, Limited, 1891.

THE wish has often been expressed by plant-lovers generally that travellers who visit tropical and other distant countries in search of rare

or beautiful plants for introduction to this country would more frequently relate their experiences. As a rule, of course those engaged in this hazardous work are employed by nurserymen, and when competition is so keen it is not in their interest to describe all the localities and situations where certain plants are found. It might often be possible, however, to give useful particulars as to the local conditions that would serve as a guide to cultivators at home without indicating the exact geographical position. This is sometimes done, but usually in a meagre and unsatisfactory manner, and insufficient details in such matters are apt to prove more misleading than serviceable.

From the title of the work under notice, which professes to be "an account of canoe and camp life in Colombia while collecting Orchids in the Northern Andes," it might be expected that it would contain very much material of special interest to horticulturists, and this in a measure is true; but after a perusal of the book we are somewhat in the position of Oliver Twist—namely, we "want more," i.e., more of the interesting information of which we receive only a taste. The author dedicates the work to R. Brooman White, Esq. of Arddarroch, "whose wealth and love of Orchids have encouraged and supported me in the journeys described, and whose kindness has rendered the present publication possible." Mr. Millican further tells us that "the book aims at representing to the reader, and especially to the lover of Orchids, the circumstances under which these plants are found in the north of South America, as well as being a guide to the traveller." Later in the preface he informs us that "It is not a missionary's report, nor a traveller's diary, nor a student's compilation, but a narrative of things seen and experienced by me while travelling with natives through the forest, sharing with them the hospitality of the wayside hut, or the forest shelter and the camp fire, as well as the more agreeable life of hotels and towns. The information contained in this volume has been gathered over a period of four years, during which I have made five journeys to the Orchid districts of South America, the time occupied being generally from the month of October to the month of July."

The book comprises 222 pages, but up to page 114 we have little directly connected with Orchids, the first eight chapters being devoted to a description of the passage from Liverpool to the West Indies and South America, together with the journey "up country" from Barranquilla on the river Magdalena. Having reached Bucaramanga, the author states (page 110), "My journey was made in search of the fairy tribe of Orchids, and as up to the present I had not even seen a single plant of value, I was delighted to learn that the early botanists had found the gorgeous *Cattleya Mendeli* growing around here in profusion. Now, however, through the immense exportation of these plants, not a single one is to be found within many days' journey from here on mules." Starting on the journey, Mr. Millican notes in passing the town of Piè de Cuesta at about 3500 above sea level, with "a mild balmy air, which is never oppressively hot or disagreeably cold," that he found "the beautiful *Epidendrum atropurpureum* covering the walls around the houses, all flowering in profusion." Continuing the expedition beyond Piè de Cuesta, the author mentions an extensive plain, termed La Mesa de los Santos at a considerable elevation, and while "the vegetation consists of a tall rank herbage, with occasional scrub, intermixed with thousands of the beautiful *Sobrolia leucoxantha*, with rose and white flowers of the colour and substance of a *Cattleya Mendeli*, but so difficult to transport that very few of the plants are known in England." The description, however, scarcely corresponds with the *Sobrolia* known under the name given in collections here, for the flowers are yellow and white. At one side of this plain it appears are precipices over 200 feet high, and "on the ledges of these precipices, where the eagle and the condor make their home, the lovely *C. Mendeli* has grown in profusion since the memory of man. Even when the first plant-hunter arrived, these dizzy heights offered no obstacle to his determination to plunder. Natives were let down by means of ropes, and by the same ropes the plants were hauled up in thousands, and when I visited the place all I could see of its former beauty and wealth of plants was an occasional straggling bulb hung as if in mid air on some point only accessible to the eagles. I left the place impressed with the magnificence of the scenery, but disappointed in my search for plants."

After a prolonged search in a semi-tropical vegetation, consisting of Ferns, Selaginellas, Bamboos, Palms, and timber trees, the author was "rewarded with the object of my search in the myriads of Bromeliaceæ and Orchids which literally cover the short, stunted trees and the bare points of rocks, where scarcely an inch of soil is to be found. The most magnificent sight for even the most stoical observer are the immense clumps of *Cattleya Mendeli*, each new bulb bearing four or five of its gorgeous rose-coloured flowers, many of them growing in the full sun or with very little shade, and possessing a glowing colour which is very difficult to get in the stuffy hothouses where the plants are cultivated. Some of these plants, considering their size and the slowness of growth, must have taken many years to develop, for I have taken plants from the trees with 500 bulbs, and as many as 100 spikes of flowers, which to a lover of Orchids is a sight worth travelling from Europe to see. Apart from the few extraordinary specimens, the Orchids, as a rule, are very much crowded and mixed up with other vegetation. The photograph taken on the spot represents a tree growing in its natural state in the forest. The higher branches are covered with a long, white lichen; a little lower is an immense clump of *Tillandsias*; while the branch on the right hand is inhabited by some *Oncidiums*. The next plant, lower down, is a nice piece of *Cattleya Mendeli*. The whole of the mountains at the time of my visit were crowded with the famous parasite. Like most of my predecessors, I was tempted to bear away a large quantity of

the coveted plants, besides exploring the mountains and enjoying much of their beauty."

*Odontoglossum crispum* was the next special object, and this was to be sought in the interior of Colombia in the department of Cundinamarca, on the slopes of the Andes. "For five days' journey the track had run through the most miserable class of vegetation. Apart from the curious undulating tops of the mountains, which sometimes extend away into most glorious scenery, nothing is to be seen but a miserable scrub, and the eye becomes weary with the endless expanse of moss and short stunted shrubs. When we came to some wayside farm or plantation, the clumps of Orange trees, laden with their wealth of golden fruit, somewhat broke the monotony. A few flocks of sheep and stray cattle wandered about over the immense waste lands, but an almost entire absence of birds and other animal life gave the tops of the Andes an appearance of desert loneliness. As a rule, in the early morning and in the evening the tops of the mountains are enveloped in thick mist, and the track was scarcely visible. The rising sun gradually dispelled this from the peaks, only leaving straggling patches in the valleys. At the town called Puente Nacional I was delighted to find a somewhat better class of vegetation commence, and this seems to be the limit of the growth of the *Cattleya Mendeli*, and the commencement of the gorgeous-flowered *Cattleya Warsecwiezi*. In the mountains near to this town, in the flowering season of the plants, the display in the woods is most superb. High trees, in some places, are so hung with these glorious epiphytes that very little is to be seen but a blaze of purple and rose. A small *Epidendrum* with scarlet flowers makes up the finishing touch of colour."

Then the author describes his visit to the Pacho district, where so many fine varieties of *Odontoglossum crispum* have been found. After leaving there he proceeds in search of *O. odoratum*, and says: "The mist had scarcely risen from the top of the mountains when we came in sight of the valley and range of mountains on the other side, where I expected to find *Odontoglossum odoratum*, knowing that this variety is found growing at a lower altitude than the *Odontoglossum crispum*, although they are both often found at a high altitude growing on the same tree. By evening we had made the descent of the tortuous path to the village of San Cayetano, most of the journey being made in a blinding rain. This village is situated on the very edge of the *Odontoglossum* forests. I expected to find someone here who would help me to get plants in the woods; but the people were too indolent for me to persuade them to work for wages, so I rested here for the night, and then kept on the journey further into the woods to a place called El Ortiz. I was told that here I could find people who would be willing to work in the mountains. We had scarcely entered the forest on this side of the mountain when I remarked a difference from anything I had seen before. The trees here were so grown together that they made a thick wood, while every branch and trunk was laden with a heavy coat of trailing lichen, perfectly dripping with water, so much so that, riding under them, our clothes were quickly wet through. In these natural reservoirs the *Odontoglossums* find their home at an altitude of from 7000 to 8000 feet above the sea, with a temperature which often falls as low in the night as 50° Fahr., and I have never seen the thermometer rise above 59° Fahr. at mid-day. *Odontoglossum odoratum* is most conspicuous as well for its heavy branched spike of flowers as for its powerful smell, which fills the air until it becomes oppressive. The plants are almost hidden from sight in the trailing mass of lichen, and when they are not in flower they are difficult to find. I arrived at night at the hut called El Ortiz, after a toilsome ride, but the whole journey had been made through a wealth of Orchids. Being informed by the natives that the *Odontoglossum crispum* had all been taken away from here, leaving only the *Odontoglossum odoratum*, I was obliged to continue my journey over the top of the mountain-range, along a track which is too bad to describe, but, at the same time, the scenery is very beautiful. After three days' journey, passing on the way a lovely valley rich with patches of Sugar-cane and Maize, and also a small village called Buenavista, I struck into the forest, in the direction of the emerald mine. Here, at an altitude of about 8500 feet above the sea level, I found an abundance of plants, their magnificent spikes of flower looking doubly beautiful hanging from the branches of the trees, some high up out of reach of the native climbers, and others so low as to be easily pulled off by hand."

A journey is also related to the emerald mines of Muzo and to La Palma, where many Orchids were found. "On the top of one of the high mountains on the way, near a village called Cachiri, at a height of 10,000 feet above the sea level, I passed on the side of the track thousands of *Masdevallias*, chiefly of the *Harryana* variety. On another hill, two days' journey further along, but much lower, the trees are hung to crowding with the dainty little *Oncidium cucullatum*. Any future novice Orchid hunter in search of *Odontoglossum Pescatorei* will find it by leaving the town of Oeana, passing across the magnificent plains called La Savanna de la Cruz, and entering the chain of the Andes on the western side. Here, amongst the matted, moss-grown vegetation, *Pescatorei* is growing side by side with *Odontoglossum triumphans*, while the creeping rhizomes of *Odontoglossum coronarium* cover the roots of the same trees. I have seen the curious *Anguloa Clowesi* and the pretty *Ada aurantiaca* here as well, while in the cooler parts that choice little *Odontoglossum blandum* grows in profusion in a peculiar mist which reminds one of a continual Turkish bath. It is all very well to see this fastidious little Orchid in its natural beauty, but it is quite another thing to succeed in bringing it home to England alive. Many of the plants die before they leave the coast, many more before they pass the West Indies; a few reach the Azores, and fewer still arrive in England safely."

But the extracts given will afford an excellent idea of the character of the book, and it is not necessary to continue them farther. It must however be said that, in addition to the subjects of special horticultural interest, the work contains a variety of information respecting the natural history of the country, the chief towns, the customs of the people, and all that we look for in works of travel. It is admirably printed on fine paper, tastefully bound, and contains a large number of illustrations prepared from photographs taken by the author. A coloured frontispiece of *Cattleya Mendeli* var. *Empress of India*, a handsome variety collected by Mr. Millican, also adds to the attractions of a book that will no doubt find its way into many horticultural libraries.

#### A GRACEFUL ASPARAGUS.

SEVERAL species of *Asparagus* are now of considerable importance in gardens for decorative purposes, notably *A. plumosus* and the variety *plumosus nanus*, which are valuable as plants in pots and for cutting. Another form, of which a small branch is represented in fig. 96, was shown by Sir Trevor Lawrence, Bart., M.P., at the Chiswick meeting of

FIG. 96.—A GRACEFUL ASPARAGUS.

the Royal Horticultural Society on October 6th this year under the name of *Asparagus retrofractus arboreus*, when a first-class certificate was awarded for it by the Floral Committee. It is distinguished by the long hair-like bright green leaves, arranged in dense whorls, and not in the flat, frond-like manner of *A. plumosus*. Being free and strong in growth it will, no doubt, prove useful for many purposes.

#### JOINTS IN HOT-WATER PIPES.

YOUR correspondent "O. M." surmises pretty accurately as to the different causes which bring about the bursting of the sockets in hot-water pipes; and whilst I have nothing whatever to say against his method of making joints, I think I can give him "a wrinkle," and possibly a few others as well, in what I consider the best method of doing this work. By following my directions anyone may undertake to make a joint perfectly water-tight, even if the pipes are full of water, and pouring out in streams all round the socket. Now for the *modus operandi*. Take a piece of old ship-rope—the stiffer it has become with tar the better—untwist the strands, and with a caulking tool and hammer force the tarred rope into the joint as solid as possible, during the process adding a little cement, then more tarred rope, and finish the joint smoothly with the cement. You will then have a perfectly water-tight joint, and one that will never burst the socket. Another important matter is that joints made in this way do not take up more than half the time of those made in the old style.—WELTON DALE.

I USED to think that joints made with iron borings properly mixed with sal ammoniac were by far the best, but experience has taught me they

are not. The loss of time in picking out joints in case of accident during severe frost is a serious matter. When our hot-water apparatus was put down several years since, the joints were made with iron borings, sal ammoniac, and the usual hemp, named by the then fitters "gaskin." Not a single joint in 3000 feet of piping ever leaked or burst, so well was the work done, but the inconvenience of picking some of them out has been experienced, and I now consider nothing beyond red lead and "gaskin" is necessary to make joints good enough for any strain to which such pipes and joints may be subjected to. Portland cement I have not tried, nor do I think it is necessary, for the same reason that I object to the iron borings—difficulty in removing.—S.

### INWOOD.

It is worth anyone's while to visit Inwood, the seat of Mr. Merthyr and Lady Theodora Guest. From Onions to stove plants everything is grown to the highest state of perfection. The conservatory is one of the prettiest it has ever been my lot to see. Formed exactly in the shape of a horseshoe, 200 feet long, it has an intertwining walk, each bend of which opens up a fresh view different in its main features from the rest. It is in this conservatory that Mr. Wilkins and his able assistants gain their skill in the arrangement of groups of plants, which at the Salisbury Show this summer gained highest honours in two classes against great competition. Every foot of this great conservatory is arranged to give the best decorative effect to every plant. One stately *Latania borbonica* is a magnificent specimen; it measures 13 feet high, 27 feet through, and bears twenty-eight finely developed leaves. It stands alone to show its full magnificence, dipping its drooping leaves into a pool of water with which it is surrounded.

The houses abound in choice and rare specimens, which are seldom to be met with in this country away from Kew. In one huge house the luxuriant growth is tropical indeed. At the entrance was an immense *Brugmansia suaveolens*, planted in the centre of a bed. Its white trumpet flowers measured over a foot long, while its delicate perfume pervaded the whole house. It flowers three times a year, and bears hundreds of blooms. Immediately behind was a noble group of Bananas growing rampant with their mighty leaves and noble clusters of flowers and fruit. Fruit has been cut from these plants weighing 80 lbs. In the same house also growing and fruiting were the Custard Apple, the Guava from which 10 lbs. of Guava jelly has been made this year. *Monstera deliciosa* in fruit is also there; while clambering up the pillars and high overhead are *Allamanda*, *Ipomœa Leari*, the Giant *Granadilla* (*Passiflora macrocarpa*), all twining and flowering in happy fellowship.

Chrysanthemums were in fine exhibition form if only one could have persuaded Mr. Wilkins to show, but he generously thought he had won his share of prizes for one year. There are three Fern houses with some grand specimens of *Adiantum cuneatum* and *farleyense* 6 feet through, *Davallias* 8 and 10 feet, *Gymnogrammas* 6 feet, besides many others. The long range of vinceries contained fine bunches of *Alicante*, *Lady Downe's*, *Foster's Seedling*, and *Gros Colman*, averaging 4 lbs. to 5 lbs. each.

Lady Theodora Guest is devoted to her garden; in fact, to every part of it. Through her efforts so many beautiful and rare plants have been collected. The pleasure grounds were most tastefully laid out nine years ago under the direction of Lady Theodora Guest and Mr. Wilkins. A wild overgrown wood was converted into an immense pleasure garden. Here, again, the statuary is alone worth a visit. The lovely garden walks, the herbaceous borders, the rock gardens, are things to dream of but defy description. Being a Rose man though, I must just mention a *Madame Isaac Perriere* covered with blooms late in the year. This is a glorious Rose for very early and very late bloom. The Onions are as wonderful and perfect in their way as any of the more beautiful things mentioned. They are from Mr. Deverill's strain, and every one is a perfect specimen worthy of any exhibition table. Mr. Wilkins tells me he has not been beaten either this year or last with Onions, though he has exhibited far and wide, besides securing the gold medal this year at Edinburgh. In a quaint old tower, possibly a watch tower of the olden time, is the Onion room. Rather prosaic, is it not? but methinks they would well serve as cannon balls now, so smooth and hard and round are they. I never fell in love with an Onion before, but these giants had not even the smell of Onion upon them.

Every convenience seems to be at Mr. Wilkins' hands, and the skill he shows proves him to be one of those thoroughly good all-round gardeners who can only be found in such a place as this.

### IWERNE.

Now we speed away by strange ways and ever-changing roads to Iwerne Minster, where the baronial seat of Lord Wolverton is found. The noble park with clustering trees, bright in their autumn glory, were very handsome. Between groups of immemorial Elms there are some splendid young plantations some twelve years old. Just now few sights give more pleasure in a landscape than the judicious blending of Larch, Silver Beech, and Scotch Fir. The soil and situation are evidently well suited to these young trees, for the progress they have made is wonderful.

The gardens are reached after passing across the vast lawns and by the handsome modern mansion, on which it is evident no expense has been spared in order to secure comfort and refinement. It does one good to receive the sincere and hearty greetings of Mr. Davidson, than whom a more genuinely enthusiastic gardener it would be hard to find.

All true gardeners are gentlemen, and this is one of the true varieties, and a grand old specimen of his class. Mr. Davidson was a pupil of the late Charles Macintosh of Dalkeith Palace Gardens, and Editor of the "Book of the Garden." Mr. Davidson's forte seems to be Grapes, and many are the laurels he has won. In spite of the past unpropitious weather there was still a grand crop of Grapes hanging, among which were *Lady Downe's*, exceptionally fine in bunch, berry, and colour, also *Alawick Seedling*, *Mrs. Pearson*, *Alicante*, and *Mrs. Pince*. It is a pity Zonal Pelargoniums are not more universally grown as they may be seen here, lovely plants in 6-inch pots covered in rich blooms. With their strongly contrasting colours they make a grand display on a dull November day. Such varieties as our old favourites *Niphctos*, *Queen of the Belgians*, *Henry Jacoby*, *F. V. Raspail* seem exactly suited for this purpose.

The conservatory is a stately lofty building adjoining the house arranged with *Chrysanthemums*, *Palms*, *Poinsettias*, &c. The electric light in here at night must be very effective. Tea Roses seem to thrive here far better than Hybrid Perpetuals. The soil is a very heavy loam, and has been entirely remade by the addition of hundreds of loads. The natural subsoil is hungry chalk.

Many and quaint are the anecdotes our old Scotch friend has to tell, not the least interesting of which was that some years ago Mr. Gladstone visited the late Lord Wolverton. Mr. Davidson had the honour of showing him round the garden. Five years afterwards Mr. Gladstone again visited Iwerne. He remembered and asked for Mr. Davidson, and though that veteran statesman must have gone through more in those five years than most men go through in a lifetime Mr. Gladstone remembered the conversation of the former visit. It was late on a dark winter afternoon before I could tear myself away from my hospitable friends (for I must include Mrs. Davidson if she will allow me), and ride my thirty miles home.—W. H. W.

### SARRACENIA PURPUREA.

THE history of this curious plant is as interesting, probably, as that of any of our wild flowers. The pilgrims who landed in the "Mayflower" paid considerable respect to the *Epigœa*, if the ideas of our poets are to be trusted; but they did not seem to have noticed this, for John Josselyn, who styles his profession "Gentleman," and who wrote a work on "New England Rarities" in 1672, was led to "wonder where the knowledge of this plant hath slept all this while—i.e., above forty years." He gives a rough sketch of the plant and the following quaint description: "Hollow leaved Lavender is a plant that grows in salt marshes overgrown with moss, with one straight stalk about the bigness of an oak straw, better than a cubit high, upon the top standeth one fantastical flower, the leaves grow close from the roots, in shape like a tankard, hollow, tough, and always full of water; the root is made up of many small fibres, growing only in the moss and not in the earth, the whole plant comes to its perfection in August, and then it has leaves, stalks and flowers as red as blood, except the flower, which hath some yellow admixt." But even "John Josselyn, Gentleman," might exclaim "there is nothing new under the sun," for in spite of his wonder where the "knowledge had slept" till he discovered it, it was known to Charles de Clusius, who in a history of rare plants, published at Antwerp in 1601, describes it as a plant "allied to the Sea Lavender," which then, as now, was the common name of the *Statice Limonium*. In those days plants were grouped according to their external resemblances, and those who are familiar with the broad, thick, dark green leaves of our common Sea Lavender will not wonder that our early botanists saw in our Pitcher Plant a close ally, but with a hollow leaf. It may be interesting to observe that according to Mr. Tuckerman, who edited Josclyn's work, "Clusius' figure was derived from a specimen furnished to him by Mr. Claude Gonier, apothecary at Paris, who himself had it from Lisbon, whither we may suppose it was carried by some fishermen from Newfoundland coast." So that we may look back on near three hundred years since this remarkable plant was known to Europeans, and it was, perhaps, one of the first plants of our continent to make its bow to the lovers of plants in the Old World.

As a cultivated or living plant, however, it does not seem to have been further known till Dr. Sarrazin sent it to the Royal Garden at Paris, from whence Tournefort described it in 1700. It was about this time that the true relationships of plants were becoming understood, and Tournefort, seeing the distinctness of the plant from *Limonium*—the Sea Lavender—made a new genus, calling it *Sarracena*, after his friend Dr. Sarrazin. But we have no account of its culture in England till the time of Peter Collinson. In the notes he made of his garden, and which were published by Dillwyn under the title of "Hortus Collinsonianus," he says, "*Sarracenia canadensis*," which was Tournefort's name, the *i* being finally added by Linnæus, "has for some years flowered annually, being placed in large pots, and the roots set only in moss, and no earth, and the pots set in pans of water, kept always full; this makes an artificial bog, in which they naturally grow; the plants were sent to me from New York anno 1755." We can further trace these plants by the correspondence of Dr. Colden, published some years ago by Prof. Gray, in which a letter appears from Collinson to Colden, dated June 9th, 1755, in which he says "the *Sarracenas* you sent me are now in flower." Of late years the plants of the genus have been brought strongly before the general public through the impression that their singular structure was especially designed for catching insects, and this has led to a more general culture of our present species particularly than ever before. It has also been employed by the late

Dr. David Moore of Dublin, Ireland, as one of the parents in hybridising the various species of *Sarracenia*, of which numerous curious and interesting examples have been produced. The exact use of these pitchers of water in the economy of the plants has long been a subject of speculation, and one by no means satisfactorily settled. Philip Miller in the "Gardener's Dictionary," issued in 1758, saw no further use than as a provision to aid, and not as a lure to living creatures. He says "The English who first settled in North America gave to this plant the title of Side-saddle Flower, from the resemblance of the stigma to a woman's pillion; and some of the first writers who described the country have given imperfect accounts of this plant. They have taken particular notice of the leaves always having water in them; and one of them mentions his being often refreshed with this water in great droughts, when he was at a distance from any other supply." Of the lid at the top of the pitcher he says: "This top or ear is supposed in hot, dry weather to shrink and fall over the mouth of the tube, and serve as a lid to prevent the exhalation of the water; so that in the greatest droughts birds and other animals repair to these plants, where they always find water to refresh them."

The plant is often called "The Huntsman's Cup," and it is quite likely Miller's account is made up in imagination from the name. He was evidently under the impression that the cups were filled by rains, and that therefore the lids were to prevent evaporation, whereas it is now known that the pitchers are filled through the roots, and that the process goes on in dry as well as wet weather. Moreover, the plant never grows in dry ground or away from water in the driest time, so that living creatures could get all the water they needed without resorting to these. As to the Huntsman, who in a dry time was "refreshed," if he had attempted it, he would have seen that in the water were numbers of dead insects, and he would have been anything but refreshed by the draught. It seems to have been the custom with many writers in the past times to give their impressions for the facts, and is in striking contrast with the strict fidelity to facts demanded in the modern writer.

As already noted, insects, as well as water, are generally, and as far as the writer of this knows, always found in the pitchers; and modern investigators believe that their capture is the chief design of this wonderful structure, and that after capturing, the dissolved elements of the insects are used as food. In New Jersey, from whence the plant used in illustration was taken, the writer has never examined the leaves without finding living larvæ which, as well as the living plant were evidently feeding on the dead material, and in plants on tussocks of wet sphagnum moss, so surrounded by water that only winged insects could get there of themselves, others which could not have crossed the water of their own volition have been found in the pitchers. Sir James E. Smith has recorded that a gardener in the Liverpool Botanic Garden had seen larger insects, probably Ichneumons, carrying others into the pitchers, and he infers that most of the insects are thus placed there as food for its own larvæ.

Besides the common names already noted, Professor Douglass of West Point, who accompanied the Cass expedition to the Great Lakes in the summer of 1820, notes in the fourth vol. of Silliman's Journal, that he found the plant about the upper waters of the Mississippi, especially at Point Keewenaw on Lake Superior, and that it was known to the Indians as "Owl's Moccasin"—in their language, "Ko-Ko-Mokasin."

*Sarracenia purpurea* is the most northern of all the species, and grows over a greater extent of territory than any native species. It is found in Newfoundland and Hudson's Bay, and extends west to the Mississippi River, beyond which it has not been seen. Southwardly it reaches Florida. Generally preferring low lands, it is not, however, unusual to find it in swamps at high elevations. Pursh found it on the Pocono Mountain, as he records in his diary, and a correspondent of the second volume of the "Entomologist and Botanist," notes it in Northern Wisconsin, and the curious fact that wherever found it is always in the sub-carboniferous formation, as if that were the period when it was first created. It is generally uniform in its character, but varies in colour with the season. In early spring it is quite green, in the autumn dull brown. Our artist has taken it just as it is passing from the green to the brown. The flowers are generally always of a brown-purple; but sometimes these are produced as green as the leaves, and with some leaf variation in connection, and have suggested to some authors to make of the form a distinct variety as *Sarracenia purpurea heterophylla*. Mr. E. S. Miller once found a plant at Hampton, New York, with the flowers double.—(*Meehan's Monthly*, Philadelphia).

#### HARDY FRUIT GARDEN.

**PRUNING CURRANTS.**—Proceed with this as fast as possible whenever the weather is suitable. All kinds of fruit trees should be attended to in rotation. In places where Gooseberry bushes are apt to be denuded of their buds by birds they are sometimes left unpruned until

late in the season, while others prune them early and protect them; the latter is probably the best plan to follow in the majority of cases. All fruit bushes should be kept open in the centre, so that sun and air can reach both sides of the shoots.

**RED AND WHITE CURRANTS.**—These fruits bear freely from small spurs on the old branches; the young shoots may, therefore, be cut back closely to two or three buds, unless the leading shoots are required for further extension of the tree or to fill up vacant spaces, in which case they should be left about a foot in length. Clear all suckers away cleanly from the roots, and if any of the main stems are becoming weak from old age cut them back and bring young ones up in their place. These fruits do well grown as standards, and are easily trained on that system by pruning the young trees to a straight stem until they are 3 feet high, and then forming a head as in ordinary bushes. Trees on this system are much handier for gathering, for cultivation, and for netting for late use.

**BLACK CURRANTS.**—The finest fruit is borne on the young wood; the pruner should, therefore, endeavour to keep a continual supply of young wood in the trees by removing the old wood every year as much as possible, and bringing young shoots on in its place. Sometimes it is necessary to cut the bushes right down to the ground when they get old and do not produce young shoots freely. This causes the loss of a year's crop, but the trees throw up some fine growths if encouraged with a little manure, and the fruit is much larger afterwards. In pruning these do not take the points off the shoots, as is done with Red Currants, unless the trees are getting too tall, but thin out the wood so that all of it gets plenty of air.

**GOOSEBERRIES.**—Trees of this fruit bear from spurs on the old wood, and also from the young shoots; and as the latter bear the finest fruit, some of them which are of moderate strength should be left at intervals on the main branches, merely shortening them to about 6 or 8 inches, but none should be left for this purpose which are thicker than wheat straws, as they will only produce more wood instead of fruit. Pull all young suckers clean out by the root and the strong growths in the centre of the bushes if this was not done in the summer, which is the best time for it. Gooseberries are very apt to throw up strong shoots from the roots, and for this reason are best grown on a single stem to about 1 foot in height. The shoots of some kinds grow almost upright, while others form a curve, which gradually bends to the soil again. The latter kinds require to be constantly shortened back in the leading branches to a young shoot on the upper side, so as to keep the ends from getting too near the ground. All of them should be more than a foot from the surface when pruning is finished, or the weight of the fruit next season will soon bring them down farther; the fruit then gets spattered with dirt when heavy rains come, and is afterwards useless. In pruning the leading shoots of bushes with a drooping habit always cut to a bud that is on the upper side, as this will grow upwards for a time when it starts, and assist in keeping the branches away from the surface.

**PROPAGATING BUSH FRUITS.**—Now is the time to select cuttings of the various kinds as required, choosing the straightest and strongest shoots, and laying them in by the heel in a convenient place, to be prepared for planting in bad weather, when it is impossible to get on with outside work; they may then be taken into the buildings and cut into the proper form. Gooseberries and Red and White Currants should be not less than 1 foot in length; after taking out the terminal bud all the lowest buds should be removed, leaving only four at the top; they will then form bushes on short clean stems, and not throw up suckers. If standard bushes are required take off all buds except the terminal and the one nearest to it. These trees take longer to form than dwarfs do, but are preferred to them for some purposes. Black Currants need not have any buds removed, as they require a constant supply of young wood from the base, and suckers are therefore to be encouraged. The cuttings should not be left out of the soil longer than is absolutely necessary. When made they must either be temporarily heeled-in again or inserted into the nursery beds; there they may be planted in rows 1 foot apart and 6 inches apart in the row, pushing them well down to a depth of 4 inches, and treading them in firmly. Omit every seventh row, which will give beds 5 feet wide, with 2 feet alleys between them. These are convenient for cleaning and attending to the plants.

**PROTECTION FROM BIRDS.**—Bullfinches, tits, and sparrows often make sad havoc with the buds of Gooseberry bushes in severe weather, and if any danger is apprehended from this source some white knitting cotton should be strained over the trees by winding it round the tips of some of the tallest branches, and crossing it about in various ways. This cannot be done, of course, until all planting, pruning, and digging is completed.

**FIGS.—PROTECTION FROM FROST.**—North of London Figs cannot be depended on as to hardiness, especially as far as the next year's crop is concerned. The young Figs may now be seen as small buds at the joints near the extremities of the shoots. These are the most tender parts of the tree, and are sometimes damaged by frost enough to spoil the crops without killing much of the wood; but in winters like the last one we had the old also is likely to be killed. There are many ways in which they can be protected. One of the easiest and best is to loosen all the branches from the walls, tie them in bundles, and then thatch them with straw, beginning at the lower end, and tying each layer on with string, securing the bundle to the wall again when finished. All young Figs which are as large as marbles should be rubbed off before tying the shoots together, as they are useless. In mild winters it is possible for a few of them to survive and come to

maturity in the following summer; but they never make such fine fruits as those which make the whole of their growth in the next season.

#### FRUIT FORCING.

**VINES.**—*Early Forced Vines in Pots.*—If the pots are placed on pillars in the pits the fermenting materials will need frequent additions as the heat declines, bringing the material up about the pots so as to maintain a steady bottom heat of 70° to 75°. Much heat at the roots is injurious at this stage. A gentle warmth, however, accelerates root action and admits of higher feeding than when the roots are not incited into activity. The temperature of the house will have been gradually raised so as to have it 60° to 65° by the time the Vines were coming into leaf, allowing an advance of 5° to 10° by day, admitting a little air at 70° without lowering the temperature or causing an inrush of cold sharp air, and close early in the afternoon. Disbud as soon as the bunches can be detected, reserving the most promising. Stop the growths about two joints beyond the bunches, allowing a leaf or two more when there is room. Remove the laterals up to the bunches, and allow those beyond to extend as space permits without crowding, it being important that the foliage have full exposure to light and air, encouraging that only. Two or three joints of lateral extension are sufficient for fruiting Vines in pots, the crop preventing further extension. If the Vines show two or more bunches on a shoot remove the least promising before they flower, and do not allow more to remain than will be necessary for the crop, as a number of bunches allowed to remain until thinning time only lessen the size of the berries ultimately retained. Damp the floors and other available surfaces in the morning and early afternoon. Where, however, fermenting materials are employed the necessity of damping will not be so great as where the heat is solely obtained from hot-water pipes. In the latter case the evaporation troughs should be filled with guano water 1 lb. to 20 gallons of water, or clear liquid manure from stables or cow byres, and that may also be employed for damping the floors after closing the house or early in the afternoon. The liquid manure may be used occasionally in structures having fermenting beds, but the imperceptible vapour arising from those is in most cases sufficient, and care must always be taken to use the liquid weak, or an excessive supply seriously injures the foliage.

*Early Forced Planted-out Vines.*—These start less promptly, as a rule, than Vines in pots with gentle warmth at the roots, especially those which have not previously been subjected to early forcing, and they should not be hurried, time being allowed them to insure an even break and sturdy growths. The buds of those started last month are now moving, and another good watering must be given the inside border, unless already thoroughly moist, at a temperature of 85° to 90°, and in the case of weakly Vines supply liquid manure. Raise the temperature to 55°, and increase it a degree or two daily so as to have it 60° to 65° by artificial means when the Vines are producing their leaves. In forcing to time it is sometimes necessary to induce growth by a brisk moist heat of 70° to 75°, continuing it until the buds have fairly started growing, and then allow it to fall to 60° to 65°, with 5° to 10° rise in the daytime. This is important, a moderate temperature being essential to secure short-jointed wood and stout, well-developed foliage, but a close atmosphere is very prejudicial, and cutting currents of air equally disastrous; therefore ventilate carefully and early, seeking advancement and solidification of the growth under sunshine, closing early so as to husband the sun heat as much as possible. Outside borders must be protected against cold rains and melting snow. A 6-inch thickness of dry leaves with a little litter over them to prevent their blowing about are effective, especially when covered with spare lights.

**FIGS.**—*Early Forced Trees in Pots.*—Very early Figs are best secured from trees in pots, as they can be given a slight warmth at the roots, and be kept in steady progressive growth. There are numbers of varieties that force well. The earliest is Early Violet and Angelique (Madeleine). Those have small and medium sized fruit respectively; Black Marseilles and White Ischia also have small fruit, Brown Ischia and Pingo de Mel have medium sized fruits, Brown Turkey, St. John's, and White Marseilles produce large fruits. All force well when brought on gradually and not subjected to too much heat in the early stages. This is apt to occur with bottom heat, and the heat about the roots being 70° or more, during the early part of the forcing process the growth is too rapid. The embryo Figs also swell freely, but not having time for the proper development of the floral organs they are cast. This defect can only be avoided by thoroughly ripened growths, sparse or no second crops, and steady progressive advancement in forcing. Until the leaves are unfolding the heat at the roots should not exceed 70° at the base of the pots, then it may be increased to 75° or 80°, giving an atmospheric temperature of 70° to 75°. That is quite sufficient, the fermenting material being added to as required to maintain the heat regularly. The temperature of the house should be increased by degrees to 60° at night, 65° by day by artificial means in severe weather, 5° more in mild weather, 70° to 75° with sun heat and moderate ventilation, closing at 75°, but in mild weather a little air must be admitted at 60° to 65°, just a "crack" at the top of the house to let out pent up moisture and insure a circulation. In cold weather the pipes radiating heat will keep the air in motion, and the moisture will be condensed on the glass, therefore ventilation is not then required. Be careful, however, not to bring on the growth too rapidly, especially in dull weather, as foliage produced under such conditions is not of stout texture, but large and thin, possessing little elaborating power, and is very susceptible of external changes, often scorching and becoming infested with red spider.

Afford water whenever necessary, always in a tepid state. Syringe the trees in the morning and early afternoon so as to have the foliage dry before nightfall, but avoid excessive moisture, damping the house only in dull weather.

*Modes of Growing Figs.*—Those contemplating Fig culture under glass may find the following particulars useful, and it is not necessary to have a large house or a great number of trees to enjoy ripe Figs from June to September inclusive. Two methods are followed in cultivating the Fig—namely, in pots and planted out. The former is an excellent method, either for early forcing or growing in cool houses; but in the latter one crop only will be secured, and that ripening at the latter part of summer, whilst two crops are had by starting the trees early in the year. Pot trees become larger and more fruitful the longer they are grown, as the restriction of the roots and feeding them highly contributes to their fertility. The Fig is a light and heat-loving tree, therefore the house must be light and well ventilated, and the trees must not be crowded. Grown in pots for forcing they must be started early in the previous season, so as to make and perfect a growth and have time for rest before starting. When once subjected to forcing they commence growth, as the usual time of starting comes round in a lower temperature than trees that have not been subjected to the process.

Planted-out trees, however, afford the largest fruit. They are often very unsatisfactory, because the borders are too wide, and deep, and rich; consequently, the wood is long-jointed, the foliage large and thin, and the trees produce wood instead of fruit. The wood must be stout, short-jointed, and hard, the leaves thick and leathery; and to insure these the border must be narrow, firm, and well drained, and the growth being trained near the glass. A 3 feet width of border is ample to begin with, and in no case need the border be more than one-third the breadth of the trellis. This affording a favourable rooting medium, supplies of nutrition can be afforded as the growth and crop requires. A foot depth of drainage should be provided, and this must have a drain under to carry off superfluous water, unless the site have natural drainage as gravel or rock. As Figs like lime, a layer of old mortar rubbish or chalk 4 to 6 inches thick on the rubble will supply that substance, and prevent the roots becoming massed in the drainage. The soil may consist of any good loam, preferably tuify from a pasture on the limestone formation. If not calcareous and inclined to be light, add a fourth of clay marl dried and broken up small; if heavy add a fourth of road scrapings and a sixth of old mortar rubbish. Calcareous matter is almost a necessity for Figs, but they can also use silicious matter for much the same purposes as lime, and both should be provided. Bones are generally mixed with compost for the trees; but buried bones are slow in decomposing, and it has proved better to apply bonemeal or superphosphate to the surface. The whole of the materials must be well incorporated, and made up firmly when moderately dry. Two feet deep of soil is ample, allowing a few inches more for settling. Trees with single stems of the height necessary to reach the trellis are the only suitable ones. They will be in pots, and need not be planted until the time of starting, or they may be planted in autumn. Soak, and wash away all the soil; disentangle the roots and spread them out evenly, working the soil in amongst them and making quite firm about the collar, disposing the roots in layers, all within 9 inches of the surface, and covering the upper layer with 3 inches of soil. Give a good watering to settle the soil about the roots, and when soaked in and become dry so as to bear the pressure of the foot without elogging tread firmly, and mulch with a couple of inches thickness of short partially decayed manure. Fan training is most suitable, as it admits of cutting out the exhausted growths and keeping up a succession of bearing wood. The shoots should be trained about 1 foot from the glass, never crowding them, as light is very important, also air, to insure fruitfulness and high quality in the fruits. Trees against the back walls of lean-to houses are generally failures; but when the trees are allowed to extend and the shoots are trained down the roof they bear profusely, because the downward training concentrates the sap on every joint, so that they form fruit at nearly every leaf down to the base of the shoots, and the points of the shoots are ever pointing to the glass, so that the growth is thoroughly solidified as made, and the trees retain instead of casting their fruit.

## THE BEE-KEEPER.

### APIARIAN NOTES.

WINTER with its shortest days is now upon us, and for fully a month we shall be anxious for our bees to remain at peace within their hives; they should, therefore, be left undisturbed. If proper care has been taken to have them in a fit state for winter they will not be disposed to fly, even although snow lie about. Snow in December does not entice the bees out to their destruction, as it does after January. Where birds are troublesome to bees and buds of fruit trees they may be trapped; the sparrow and the blue titmouse are the only pests we have.

## SUPERS FILLED RAPIDLY.

Instead of waiting the prescribed two or three weeks after the bees have been hived I hive them into the supers, and if the day is fine (as it is only when the weather appears to be in a settled state I do this) I allow them to begin working in them a few hours. They are placed upon the hive they are to occupy, having a little comb, so as to induce breeding there, and so preserve the purity of the supers. By this departure from the common practice I have often secured supers of the greatest purity at times when they were not to be had otherwise.

## DIVISIONAL SUPERS.

These are very often used by me, although I am fully aware that full-sized supers are filled more quickly in proportion than small ones are. The latter are, however, more certain of being finished in a short spell of fine weather, and is one of the reasons supers are had from straw hives when not to be had from wooden ones.

In our variable climate it is a mistake to have much super space laterally. During a long continuance of fine weather bees will enter and store in supers placed anywhere about their hive, which, in the majority of seasons, they absolutely refuse to enter. Novices who have been favoured with a fine season or two at the start have not only misled themselves but many others who have followed the rules laid down for managing bees under their short but successful period, having had no knowledge or experience whatever of adverse seasons. The question of whether the nearly completed super should be raised on the top of an empty one, or the latter to be placed uppermost, has been fully discussed without everyone being convinced which is the proper way. Perhaps a little reflection on the bad seasons we have had will convince most that it is folly to interpose an empty super when there is no honey to gather, and that the more compact the comb is, and the more cosy the hive, the greater is the economy.

It is partly upon these lines I advise small supers, while they are much more easily handled in every respect than large ones. Small supers proper I have often commented upon. In this instance I refer to sections and section cases other than those which may be used in conjunction with division or dividing boards. For my hives I prefer cases that hold nine sections, whether they be 1 lb. or 2 lb. ones—that is, three rows running parallel with the combs below, and two of which cover the frames between the super protector, which gives double protection to the supers in protecting them from injury when in transit, and greater warmth by the double casing where it is most needed.

## HOW TO MAKE SECTION CASES.

This might serve as a pastime for amateurs during the winter evenings. Procure the wood, so that when seasoned it will stand nearly  $\frac{3}{8}$  inch broader than the height of the sections. For example, for  $4\frac{1}{4}$  inch by  $4\frac{1}{2}$  inch sections the sides should measure  $13\frac{3}{8}$  inches by  $4\frac{1}{2}$  inches bare by  $\frac{3}{8}$  inch thick, make a rebate in the bottom edge a  $\frac{1}{4}$  in and on; it is now ready to be nailed to the end, which must be of the same breadth by  $\frac{1}{8}$  inch thick by  $6\frac{1}{2}$  inches long. These are easily cut to length or breadth by laying a pattern on the top and cut by drawing an ordinary pocket knife round the pattern, lightly at first into the wood to be cut. Now nail with fine wire nails through the thin ends into the ends of the sides for bearers, pieces of wood the exact length to fill the rebate crossways by  $\frac{1}{2}$  by  $\frac{1}{4}$  inch full, and these nailed so as to catch the sections equally completes the case with the exception of end pieces to keep the sections square and tight to each other. They must be the length of the width of the case, by  $\frac{1}{2}$  by 3-16ths; four are required for each case one for the bottom at each end, and the other two for the top. The under ones should have a bevel on the face of the upper edge, so that the sections slip down easily and without hindrance. The top ones may be used to keep the sections firm endways.

The price of the wood for these cases, including two pieces 14 inches by  $6\frac{1}{2}$  inches by  $\frac{1}{4}$  inch, for covering top and bottom will cost about 2d. Heavier wood may be employed for the ends, but for an amateur would be more difficult to make. I used to have my cases made so that no nailing was required, but found that the foregoing plan was the most satisfactory, certainly the cheapest and readiest got at by the amateur.

When cases are employed of this style the small supers may be employed in conjunction with them, and when attention is paid to build them up to the bee's requirements, giving always plenty of room, but never much in excess, there will be, as a rule, few unfinished sections. When the bees have the two first cases well forward, lift the one on to the top of the other, and put the empty case or cases in their place. By doing this no vacuum is formed, and the bees being more concentrated work with vigour and satisfaction.—A LANARKSHIRE BEE-KEEPER.

\* \* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Preserving Orchid Flowers (W. V.).**—A method such as you require is described on page 516 this week.

**Everlasting Flowers (J. A. G.).**—You will find it difficult to remove any strong odour they may possess, but the majority are free from any scent of an objectionable character, and it would be wise to avoid using the strongest. Possibly if they were placed in boxes with Lavender or camphor for a time it might help to lessen the odour.

**Seedling Apple (J. B.).**—Your seedling is too much like the Wyken Pippin to be considered distinct, but the fruits you send are not equal in quality to the old favourite, which, like your variety, has "short stalks, and the fruit is not easily shaken from the trees by the wind." It is right to say, however, your samples were not in the best condition. We do not say the variety is identical with Wyken Pippin, but only that it closely resembles it, and is not so good.

**Hardy Climbers for Trellis (Northern Climate).**—Mixtures are seldom satisfactory, especially those comprising a number of varieties, and there are few climbers that will thrive in exposed situations on trellises, for they are always associated with other trees or objects from which they derive shelter as well as support. We advise you to have Honeysuckle and climbing Roses at the most exposed part, and these are very unsatisfactory in bleak situations. Clematis montana and C. vitalba are most likely to succeed. We had Honeysuckle (Caprifolium perelymenum) interspersed with Ayrshire and Boursault Roses on a similar trellis, and they were beautiful in June. The plainer the beds are for a mixture of shrubs and flowers the better. Those you sketch would answer very well.

**Coriander (W. W.).**—The leaves of this plant are used both in salad and in soups for their high and peculiar aromatic flavour. The seeds are used medicinally, and are considered soothing and stomachic. They are also sold by confectioners, encrusted with sugar. If required early the seed is to be sown thinly on a hotbed in February or March; and when 3 inches high the plants are ready for use. As they will soon run to seed another sowing must be made in April for a succession. This may be done in an open warm situation, in drills 6 inches apart, an inch deep, then covered over with light earth with a rake. When the leaves are 3 or 4 inches high, they may be gathered for use by cutting them off close to the ground. To have a supply all the summer a little should be sown every month, as it soon runs to seed. For winter use it may be sown in August and September on a warm border; and when cold weather sets in the plants must be hooped over and protected.

**Methylated Spirit for Destroying Scale (F. S.).**—This is not always safe to use, because it is mixed with spirit of tar, and in that state

may be injurious; but pure alcohol or spirits of wine is quite safe and effectual when carefully used. As a winter wash you could not have anything better than soft soap, 3 or 4 ozs. to a gallon of water, applied with a brush, dislodging the scale, and taking care not to rub off the embryonic figs, nor break off the points of the shoots. A solution of half an ounce of caustic soda and half an ounce of pearlash to a gallon of hot water may be applied with a brush in a tepid state, thoroughly washing every part, but not letting it run down, merely keeping the brush sufficiently moistened with the solution to insure the regular coating of the wood. These are for winter dressings only.

**Alnwick Seedling Grape Vine Unfruitful (A. M.).**—You do not say whether the Vine fails to show bunches, and is consequently sterile, or that showing fruit it fails to set properly for a crop. If the latter, as we suspect, the bunches should be brushed with a camel's-hair brush or plume of Pampas Grass when in flower, and after that apply pollen to the bunches from such free-setting varieties as Black Hamburgh, brushing them lightly with a camel's-hair brush charged from time to time with the pollen, which may be collected from Black Hamburghs when in full flower by holding a sheet of white paper beneath a bunch and gently rapping its footstalk with the finger. If the Vine does not show fruit we can only suggest that the wood be left longer in pruning—say, instead of pruning to one or two buds leave four to six, and always shortening to a plump eye on well-ripened wood.

**Tabernaemontanas (S. S.).**—The varieties of this useful plant produce their double white flowers nearly the whole year round. *T. coronaria* fl.-pl., is more adapted for spring and early summer flowering, while *T. camassa* produced its flowers in greatest abundance about August. This has been the character of large plants, and in order, if possible, to induce the first-named variety to flower during the winter cut it hard back, and after it had commenced growth it was pushed on rapidly, until a few weeks ago it was placed under a little cooler treatment. It is again in brisk heat, and has commenced showing a fair number of flower buds. Hard cutting back appears to suit them well, for our plants have made remarkable growth, and we intend to subject them to the cutting-back system annually, especially so if we can make them flower during the duldest months of the year by so doing.

**Pruning Young Vines (H., Surrey).**—As a rule young Vines do not make satisfactory progress when planted between others that have been long established in old borders, and are certainly less likely to do so when the canes are left their full length after planting. Those referred to ought either to have been shortened in the autumn, or the buds rubbed off them in spring down to a good one towards the best for encouraging strong growth. The best thing that can be done will be to cut down the canes at once to the best bud you can find not far from the ground. If you also remove some of the old soil from round the roots, and add fresh of a suitable character, you will have done what you can for the Vines, and if they do not succeed as is desired, you can scarcely be held responsible under the circumstances of finding them in the condition described. Your other question will be answered next week.

**Pruning Ipomæa Leari (M.).**—*Ipomæa Leari* is one of the best conservatory climbers; but it will be apt to suffer if the average temperature at night in winter be long below 45°, and especially if the main stem be near the glass of the roof, where it would be most quickly cooled by radiation on a frosty night. If the plant consist of one main strong stem, with flowering shoots coming from that main stem all the way, then each of these shoots may be pruned back now to within three or four joints or buds from the main stem. In spring, after winter is past, you may prune back to one or two buds, as it is from the shoots produced in summer from these buds that the flowering takes place. If the plant be not furnished with a stout main stem, it would be advisable to merely partly prune now and again in spring. Prune in such a manner as to leave a sufficient amount of buds to produce shoots regularly all over the plant; say, to produce a stout shoot, every 15 or 18 inches; and these will look best if allowed to grow downwards as dangles from the main stem and rafters. If your house be kept cool in winter it would be advisable to suspend the main stem 2 or 3 feet from the glass.

**Winter Treatment of Allamandas (R. S. B.).**—If they are required in bloom as early as possible in the season plants that have enjoyed a good rest in a temperature of 55° may be started. These plants may either be repotted before they are introduced into a warmer house or after they have broken into growth. We have potted them at both periods, and have found no appreciable difference in the results, and therefore prefer doing it before they are started. The plants should be turned out of their pots and the roots reduced, being careful to preserve as many fibry roots as possible. The soil should afterwards be soaked in tepid water and allowed to drain before potting. If the plants have been in large enough pots the same size may be used. If necessary to increase the size of the plants do not reduce the old ball so liberally, and transfer them into pots one or two sizes larger than they were resting in. They should be clean and liberally drained. The soil may be pressed as firmly as possible, and the plants then placed into a house with a night temperature of 65°. If they can be plunged in leaves or other fermenting material so much the better. The plants should be syringed twice daily, but no water will be needed at the roots before they start into growth. Use for a compost rich fibry loam and one-seventh of decayed manure. Plants that are growing in borders should have the surface soil removed and top-dressed with equal parts of loam and manure.

**Thinning Larch Plantation (T. W. R.).**—The Larch will now be suitable for stakes and various useful purposes, and the first thinning

should be effected as soon as practicable. The trees being planted so thickly, it will be necessary to cut away about one-fourth of the worst shaped and ill placed, or, if the trees are very vigorous and require more room for their healthy development, it may be necessary to thin out more freely, always bearing in mind that excessive thinnings are more injurious than beneficial; at the same time the thinning must be efficient, allowing top space for those that remain, so as to insure a sturdy growth. Where the trees have grown most they should be thinned most, and *vice versa*. At the next thinning, say in three years hence, the trees will be suitable for rails and general fencing purposes. Therefore it is not advisable to thin too severely at first, but whilst considering the ultimate good of the trees, keep in view the utility of the thinnings, as they may be of little use at first, but if left a little longer (without prejudice to those that would remain after thinning), their value would be considerably enhanced. Judgment must be exercised, removing in the first instance the most unsatisfactory in growth.

**Pereskia aculeata (R. P.).**—The plant of which you send a fragment is *Pereskia aculeata*, a member of the natural order Cactaceæ, and a native of the West Indies. It is chiefly grown as a stock for Epiphyllums, which are grafted on clean stems of the *Pereskia*, varying in height according to the uses for which the plants are intended. For plants in pots a height of 6 inches to 1½ foot is sufficient; but we have seen the stems taken to a height of 8 feet or more before grafting the Epiphyllums upon them. In this case the stems have been trained to the wall of a house, and the heads arched over a walk, the suspended Epiphyllums having thus a fine effect when in flower. The *Pereskia* itself is of little value except as a curiosity, and is easily grown, though seldom seen in flower. A compost of loam, sand, and small pieces of broken bricks, with a little well-decomposed manure, suits it well, and the temperature of a stove is the best fitted for it. Water must be carefully supplied during winter—indeed, very little will then be required; but whilst growing a larger quantity is needed. When your plant is large enough we should advise you to graft an Epiphyllum upon it, which you may easily do by cutting the stock to the required length, and then cut the upper part of the stem to a wedge-like point, taking a piece out of the base of the scion so that it will fit evenly saddle fashion upon the stock. This may be then secured with a piece of matting, and a union will soon be effected.

**Pear Trees Infested with Scale (S. S.).**—The scale will continue to spread, and ultimately will overpower the growth of the trees and render them unprofitable, and sometimes the insects kill the trees. The pests, however, sometimes disappear naturally, being destroyed by certain minute insects of the great division Hymenoptera, which are parasitic on the scale insects. Birds also destroy great numbers, the blue titmouse and long-tailed titmouse pecking off the "scales" and eating the eggs; but these "aids to cultivators" are not sufficiently numerous in gardens to prove of benefit, and the blue titmouse is too fond of choice Pears and Apples, pecking holes into them and destroying the best fruits, that its merits receive little consideration. Brushing the trees with whale oil when the trees are quite dry and at rest destroys the scale by closing the pores by which it breathes. That is a safe and sure method of destroying scale on Pear or Apple trees. Alkaline washes are also very effectual, especially the following:—Caustic soda and commercial potash (pearlash) half pound each dissolved in boiling water, then adding enough hot water to make 5 gallons of wash. This should be used as a spray on the trees whilst dry and when they are quite dormant, wetting every part thoroughly with the solution at a temperature of 100° to 120°. The trees, being against walls, are difficult to cover with spray on the under side of the branches; therefore unloose the trees and apply the solution with a brush, employing it weaker—that is, instead of diluting to 5 gallons dilute to 8 gallons, applying it hot, as before stated. This will bring off the scale, and if not used carelessly and excessively will not injure the trees. There is no need to prevent the trees fruiting for a year.

**Names of Fruits.—Notice.**—Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. *In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing.* The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (A. S. Brett).—We have recognised the box by your description. There was no letter in it. The Apple is not Worcester Pearmain, but Caraway Russet.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (J. R. S.).—A good variety of *Cypripedium insigne*, somewhat like *Maulei*. There are many named varieties of this species now, and it is not difficult to select over a dozen with well marked characters. (P. G.).—*Iris Histrio*. (T. W. B.).—1, *Oncidium cheiroporum*; 2, *Odontoglossum coronarium*; 3, *Trichosma suavis*.

## CHRISTMAS SUPPLIES.

COMPARED year by year at the same period the collective supplies in our large central markets do not vary so much as might be expected. It is true that the seasons have some effect upon certain classes of produce, but this is met to a great extent by the increased facilities and speed of communication, not only with other districts of the same country but with distant lands, which contribute so largely to our requirements. Scarcity or failure of any particular crop in one place only, therefore, seldom has any material effect upon the chief markets, and even in the course of a few days it is astonishing what a change can be produced by telegraphic and other communication. Thus, on one market morning there may be a great scarcity of some special article, yet the next market may be almost glutted with it. This characteristic, common in some degree to markets generally, is especially noticeable in Covent Garden, which is undoubtedly the most representative market of horticultural produce in the world. But notwithstanding the variations in supplies in ordinary weeks there is such a concentration of effort to meet the enormous Christmas demands that the supplies are always large, and at no time does the market present a more uniform or more animated appearance than a few days before the great festival of the year. It is not merely interesting as a spectacle either, but many an important lesson may be learnt there if those "who run would read;" and if many of those who supply the markets but depute the selling to others would pay a visit occasionally, they might by close observation gain innumerable valuable hints.

In glancing at the leading characteristics of the Christmas supplies in Covent Garden, and passing for the moment the decorative material which occupies so important a position at this time of year, the fruits demand a few words. One of the most striking features to a stranger is afforded by the numerous auction sales of imported fruit, and it is a matter for surprise first as to how such quantities can be disposed of, and secondly as to what becomes of the home-grown fruits. In the main portion of the market itself, and in the spacious Floral Hall, thousands of barrels of American Apples have been received, sold, and dispatched within the past few days—bright, even, well selected, and well packed fruits that would command purchasers anywhere, the Newtown Pippins and Baldwins being the favourites, the former realising from 15s. to 16s. 6d. at one sale per barrel, which is somewhat less than is usual for this variety, as it generally leads.

Side by side with the American Apples in the other portion of the market were bushels of English Apples, and the contrast was almost painful; irregular, unselected fruits seemingly shot into the baskets without heed or care—handsome fruits and rubbish intermingled, with the result that a very low average only could be taken. Certainly there were exceptions, in which every care was manifest both in packing and selection, but unfortunately they were only the "exceptions" that proved the rule was the opposite. It is the one great defect of home growers, and however the culture may be improved or extended it will never produce adequate results until these cognate important matters receive due attention, and it is surprising considering how much has been said and written on the subject that more

effect has not been produced. Mr. Thomas Meehan has lately referred to the American system of packing in these words:—

"It is interesting to note how a very small fact, when clearly perceived, will lead to great commercial results. No one knew better than the fruit grower that when an Apple was bruised it would rot. When, therefore, Apples first became an article of commerce, and were packed in barrels, they usually arrived at their destination rotten because of the bruises they received in transit; but when it was discovered that it was the action of the atmosphere on the bruised portion which caused decay, and that a bruise, if it did not expose the interior of the Apple to the atmosphere, was of no great consequence, then the transportation of Apples became a business. We may now take an Apple out of a barrel, squeezed into squares, hexagons, octagons, and all manner of shapes, without the Apple suffering any material injury, because the pressure causing the bruise is of such a character as not to crack the skin; in fact, the great success of Apple transportation consists in pressing them thus tightly into the barrels. It is the exposure to the atmosphere of the interior portion of the fruit, and not the bruise in itself, which causes decay. This principle may perhaps in time be applied to other fruits. Recently fruits have been separately packed in paper, but possibly a slight pressure to the fruit in the case, as given to the Apple, which will pack them tightly together without causing the outside coating to crack, would do just as well as the paper enclosure."

Thoroughly good English Apples have been realising substantial prices, and at this time it is impossible to obtain sufficient; but it cannot be expected that poor English fruits will be purchased in preference to good foreign samples. It is rarely that patriotism goes so far as this, and it would surprise some to have seen indifferent specimens of Cox's Orange Pippin displayed at 6d. per dozen in the middle of December. Pears are more restricted in quantity, but French and Channel Island fruits are represented by fine samples.

The Grape business is important and rapidly extending, large quantities of the finest black Grapes in the market now being home grown, and here we see something of the style that is wanting in the hardy fruit department, for the Grapes are carefully packed, neatly set up, and reach the consumer in a really tempting form. Channel Island Grapes are also abundant, and the supplies of Almeria Grapes this year are coming to hand in exceptionally good condition. There is thus a wide range of quality to select from, the prices from 1s. 6d. per lb. upwards, some professedly English Grapes being as low as 2s. per lb. Pine Apples have been in request, and they have been imported by thousands. Indeed, a few days ago one consignment of over 6300 was received at Covent Garden, many being grand fruits which would not disgrace the best of British cultivators, and that would some years ago have realised fabulous prices. Now this aristocratic fruit is within the reach of nearly all classes. Oranges are uncommonly good this season, affording a pleasing contrast with those of last year, and they are now coming into the market in abundance, as also are the Nuts of all kinds which constitute so essential a part of Christmas fruit supplies.

Green vegetables have been very plentiful this autumn, and even now there is an unusual supply for the time of year, while the prices have been fairly good, this being one department in which the home-grower has little to fear from foreign competition, except as regards the early salading and Asparagus. Cabbages, Savoys, and Brussels Sprouts are good, while the ordinary root crops—Carrots, Parsnips, and Onions—are similarly satisfactory; but a large portion of the latter are imported and sold as Bordeaux Onions. A small quantity of Asparagus and Seakale is noticeable, and the early forced Rhubarb is also fairly plentiful from Yorkshire and elsewhere. Around London the latter is being taken up more extensively than formerly, and one market grower in the Mitcham district recently received a consignment of ten trucks (4 tons each) of roots for forcing, and five others will be required to complete the season.

Amongst what may be termed the decorative material the

Holly and Mistletoe stand pre-eminent, but this season the supplies are not so extensive as usual. The Holly has in most cases a fair quantity of berries and is nearly all home grown; the Mistletoe, on the other hand, is almost exclusively French, chiefly from the Apple orchards of Normandy, where it is said to yield a substantial return and not to injure the trees in any appreciable degree. Some years ago the Rev. F. H. Arnold seriously suggested that the culture of this plant should be tried in the southern counties.

"If Mistletoe can be sold in London at Christmas at prices varying from 10s. to 25s. or 30s. per crate, it may be queried whether it might not be profitably cultivated at home, instead of our obtaining such large supplies from abroad. It may be asked why should we be mainly dependent on France for our supplies of Mistletoe. Why, if it can be cultivated there, should it not be cultivated here, in the Somerset, Sussex, and Hampshire orchards and hedges, from which crates of this valuable commodity could be so easily forwarded to town without the cost of the Channel transit. Were I to buy a sprig of Mistletoe, with its bright white glistening berries at Christmastide, I must say that I would prefer it of home growth, and not have of foreign production one of the most ancient amenities in our English folk lore, which from the times of the Druids to present day has always been a favourite with our ancestors, is still so with ourselves, and will doubtless continue to be so when 'a thousand years are gone.'"

For cut flowers, again, we seem to be largely dependent upon our continental neighbours who are sending us from the South of France and Italy large quantities of Violets, Roses, Roman Hyacinths, early Narcissi, and White Lilac. Of home grown produce in this department Lilies of the Valley, Richardias, Roses, Camellias, Eucharis, Chrysanthemums and Orchids constitute the chief items. In the plants, Palms, Ferns, and others valued for their foliage preponderate, but brightly berried Solanums, forced Tulips, Lilies of the Valley, and Hyacinths are conspicuous.—C.

### SOLANUM CAPSICASTRUM WEATHERALLI.

THOSE who have a good stock of plants of this fine subject will find them of immense value during the festive season of Christmas, provided they are carrying a good crop of well-coloured berries; but I fancy many will have some difficulty in getting the berries coloured by that date this year, where the usual plan of planting the young plants in the open air during the summer months has been followed. I hear from various quarters that few berries have set this season, and those were small at the time the plants were potted up. All things considered I think it a much better plan to plant out in a pit or frame; the cultivator can then to a great extent be independent of the weather. During bright weather the lights can be left entirely off, and throughout dull or very wet periods they may again be placed over the plants, which will then be kept steadily growing.

Another advantage derived by adopting the frame system of culture is, that when planted out the lights can be kept closed and shaded, and by so doing enable the plants to start into growth more quickly, which is a distinct advantage, the great point to be aimed at being to get a good crop of berries set early, so that they may ripen by the required time. I have proved this season Solanums will bear without injury a much greater amount of heat than I had previously considered they would do. Our plants when lifted from the pit they had occupied during the summer months were thickly studded with berries; they were potted up by the end of September, and placed in a pit, where they were kept close, but received no fire heat till well established. By the end of October I found I should require the berries to be perfectly coloured early in December, so heat was applied in such a way as to keep the hot-water pipes constantly warm, a little air being left on night and day. This treatment was continued for a couple of weeks, and a slight tinge of colour was beginning to be visible on the majority of the berries; but I considered the treatment they were then receiving would not effect the desired result. The temperature was then gradually raised till it reached 60° to 65° at night, with a rise of 5° in the daytime, air being kept on constantly. The tops of the plants were only 24 inches from the glass, and they were well syringed once a day. This treatment was persevered in, and we had the satisfaction of getting the berries well coloured by the end of the first week in December. While so much fire heat was given green fly gave considerable trouble, but this pest was eventually overcome by regular fumigations once a week, and occasional syringings with a solution of softsoap.

While being subjected to so great an amount of heat the plants grow very freely, and if allowed to go unchecked the abundant growth has the effect of retarding the ripening of the berries considerably, and also prevents many of them from being fully seen. It is, therefore, an excellent practice to pinch out the majority of the young shoots as soon as the berries commence colouring; the light and air is thus let in to every portion of the plant, which undoubtedly has the effect of accelerating the colouring process, and also enables the berries to be fully seen when wearing their bright scarlet colour. If this operation is performed at the time indicated other young shoots will be quickly formed, which, by the time the plants are ready for use, will furnish a sufficient number of leaves to show up the berries to advantage, and hide the parts to which the former shoots were stopped.

As soon as the berries show signs of shrivelling some of the most promising should be gathered and placed in a dry position, and when thoroughly ripe, which should be the case in about a fortnight, the seed should be removed from the husk, and after being spread out thinly for a few days may be sown thinly in shallow boxes and grown on in gentle heat till May, when if a pit or frame recently cleared of bedding plants can be devoted to them, with proper attention they will make fine plants, and be ready for lifting by the time the frame is wanted for bedding plants again in September. A good loamy soil with a little leaf soil added suits Solanums admirably. The great point is to give the individual plants plenty of room to develop into shapely plants without crowding each other, and with liberal treatment in the matter of watering they will require to be planted 1 foot apart each way. Although the seedlings may be small when planted out do not be influenced to place them closer together, or before the growing season is over any good cultivator will perceive the common mistake of planting too closely has been made.

A few of the old plants should be retained, as they make capital specimens for filling large vases. They should be pruned back as soon as the berries are past their best, so as to give them a long season of growth; and when the young growth is a quarter of an inch long shake out and re-pot in pots two sizes larger, and, of course, the plants should be kept in a close house or pit till they have recovered from this operation, after which, an ordinary greenhouse temperature will be found to suit them. Unless the summer is very hot the plants will well repay for being kept under glass throughout the year, although I have seen excellent specimens produced by placing them in the open air during the summer months.

The uses to which well grown plants of this showy Solanum may be put are manifold. For placing in vases they are thoroughly seasonable and attractive, and when associated with flowering plants they supply a colour not generally too plentiful in the depth of winter, and single berries with a small shoot attached look effective and novel when arranged with Roman Hyacinths in vases or shoulder sprays, and one of the most charming and suitable arrangements for a Christmas dinner table can be worked out by using Solanum plants of various sizes, standards and bushes being interspersed. The plants should be turned out of their pots and placed in saucers, the surface of the soil and the receptacle holding it being entirely covered with Lycopodium denticulatum. A gracefully curving scroll design should also be worked out with small sprays of the same Lycopod, and be dotted at intervals with Solanum berries. Although this arrangement will not require a single flower to be added, the effect produced will not be deficient in either beauty or brightness, and the cheerful scarlet of the glossy berries will instinctively remind each beholder of Christmastide.—H. DUNKIN.

### FRUIT GROWING IN COLORADO.

AT the Conference on the Culture of Fruit convened by the Royal Botanical and Horticultural Society of Manchester, held in Manchester on the 21st October, I see by the English papers that the Earl of Derby, who presided, said, as to fruit growing in England:—

"As to the return, no certain average can be taken where soil and climate vary so widely. The figures which I have obtained relate to Kent and come from good authority. Strawberries are taken as giving a gross return of £27 per acre and a nett return, after all expenses are paid, of between £6 and £7; Raspberries, £21 gross return and £7 nett profit; Currants, £30 gross, nett £11; Apples, Plums and Cherries, £25 gross returns, nett profit about £5. But these last, especially Apples, give no returns for five years at least. The average of several seasons has been taken, so as to allow for losses as well as for exceptional gains."

As the readers of the *Journal of Horticulture and Home Farmer* are naturally interested in fruit growing in other countries and the methods adopted and profits made, and perhaps some of

them are inclined to emigrate if they could only get reliable information as to some one fruit-growing district, I submit for their perusal the following particulars, collected during the past summer and autumn from practical fruit growers in Colorado, in each case giving the name and post office address of the fruit grower, and giving the amounts in English instead of American money, so that they can be more readily compared and contrasted with the figures quoted by Lord Derby. I abstain from any comment, as the particulars given speak for themselves.

Mr. C. J. Coombs, address 2,332 Fifteenth Street, Denver, whose orchard and garden is five miles west of Denver, has a splendid five-acre orchard of Apples, Pears, Plums, Strawberries, Blackberries and Currants, has sold his crop this year for £1200, the working expenses being £300.

Mr. J. Green, address, Villa Park Post Office, five miles west of Denver, has two acres of Strawberries which averaged this year 6000 quarts to the acre, average price per quart being 6½d. One acre of Blackberries brought him £75 this year. The balance of his five acres is in Apple and Pear trees set out three years ago, and one of his Ben Davis Apple trees had 200 Apples this year.

Mr. W. A. Benedict, P.O. address, Denver, has a Strawberry and Blackberry tract six miles north of Denver, which averaged him £100 per acre.

Mr. E. H. Sumner, Post Office address, Denver, has 7½ acres in small fruits, about six miles north of Denver; they yielded over 30,000 quarts last year, selling (in this market) for from 10d. to 1s. a quart. The Apples averaged him £85 an acre.

Mr. Elwood Easley, Golden, Jefferson County (twelve miles from Denver) says:—

"I have about 40 acres in cultivation, of which 20 acres are in fruit and vegetables, and took £900 nett from it last year; one acre of Cherries yielding £110 on sixth year from setting out."

Mr. David Brothers of Wheatridge, near Denver (an English farmer from Suffolk) who came here in 1868, says:—

"A man can make money farming on irrigated land in Colorado, if he can anywhere on earth. The resources of this State are wonderful enough when the truth is told; no need to exaggerate. I have a tract of about 25 acres Apples at my place, five miles west of Denver, from which I took £500 this year; but these are all young trees yet, and will increase, of course, as they grow older. Yes, I had rather raise fruit than farm; there will be more money in it."

Mr. C. T. Wilmore, also of Wheatridge, near Denver, an experienced grower of small fruits, assures me that his average nett returns per acre are—Blackberries £60, Strawberries £80, Currants £40, and Raspberries £60; selling his fruit retail in the Denver market direct to the consumer.

Mr. James Ackerman of Hygiene, Boulder County, writes that he is raising all the tree fruits except the Peach and Apricot, that his nett profits are £40 an acre, and that he gets most profit from Apples, Pears, Plums, Raspberries, and Currants.

Mr. W. B. Felton of Canon City, Fremont County, President of the Colorado State Horticultural Society, writes:—

"It is easy to ask questions which it would take a good deal of time and space to answer fully. For instance, 'At what age do trees begin bearing in Colorado?' Varieties differ in that regard so materially that the question could only be answered by one who had had experience with many varieties. With Apples, for instance, the Ben Davis will bear the fifth or sixth year as full a crop as the trees should be allowed to bear. It is the same as to Missouri Pippin. Wine Sops will bear, but not so full a crop, at the same age, while the Red Astrakan and Northern Spy will not bear a crop till eleventh or twelfth year; other varieties coming in between. But to answer the question generally as to Apples, I would say six years. As to Pears, there are dwarf and standard. The dwarfs, many of them, bear the next year after being set out, while standards do not bear for six, eight, or ten years, according to variety. Bartlett's, Clapp's Favourite, Sheldon, Beurré d'Anjou, Seckle, and other varieties (standards) gave me a good crop the seventh year, while I have some varieties that are full of fruit buds now for the first time, the eleventh season. For a general answer as to Pears (standards) I would say that they are from one to two years longer coming into bearing than Apples. Some varieties of Plums and Cherries commence bearing right away, while others are four or five years getting to it. The amount of fruit on a tree before it has been out long enough to attain size to hold a crop does not amount to anything as a crop. It is simply a curiosity. Therefore in speaking of trees bearing a crop it would be safe to say from four to ten years according to kind and variety."

"What do you consider a fair average yield per acre in money for a Colorado fruit orchard at mature age? That is a poser. Everything depends on the climate, varieties you have, the cultivation given, and the market. I can give you my experience. I have 10 acres of fruit that was set out ten years ago now—5½ acres Apples, 1½ acre Pears, about ½ acre of Peach, Cherry, and Plum trees, 1½ acre of Grapes, and about 1 acre of Strawberries, with a few Currants, Gooseberries, Raspberries, and Blackberries along the fences. In 1889 I sold the crop for a little over £1200, the expenses being about £480. In 1890, which was an off year for many varieties, the crop sold for £640, expenses £260. This year I have prospect for a £1600 crop. An orchard in bearing is

worth what it will pay—a profit of 10 per cent. on taking an average of two years. We never have two full crops of all varieties in succession. While the off years are not so marked in Colorado as in the Eastern States, yet there is a difference. I know of no diseases that affect our fruit trees here. We have the Codlin moth that makes wormy Apples and the leaf hopper that injures the Grape crop, but neither affect the tree or Vine. The conditions in the different fruit sections of Colorado are so varied that a general answer cannot be given as to what varieties are most profitable. Here at Canon City I believe the Apple to be the most profitable in the long run. Pears would be more profitable than Apples, but as they bloom earlier are more liable to damage from late frosts, and therefore are more risky than Apples. All kinds of fruit are profitable in Canon City except Peaches and Gooseberries. Peaches are not reliable. Gooseberries bear well, but do not sell well, and cost too much to pick. If an orchard is handy to express (parcel company) Strawberries and Grapes are good paying crops, also Blackberries and Black Raspberries. We do not raise Red Raspberries at Canon City because we would have to cover them in winter. They always pay well where they do well."

Mr. W. B. Osborn of Loveland, Larimer County, where he has a fine orchard, and who is the Vice-President of the Colorado State Bureau of Horticulture, writes:—

"In regard to the age that trees begin to bear in this country, &c., I answer, Earlier than in any fruit country that I have ever been in. It depends much on the variety of the Apple, Plum, or Peach. Some varieties of Apples will begin to bear at four years old from root grafts. Some varieties of Pears will do the same. Some varieties of Plums at two years old. I have them that did so."

"I believe a fair average yield per acre in money of an orchard well cared for at mature age might safely be put at £60; many acres more. The cost to produce that much from beginning depends upon the value of the lands, &c. As an investment per acre, I will answer in this way. Plant a healthy three-year-old tree this spring, and if it does well next spring you can count quite safely the tree to be worth 4s., the second year 8s., and so on until it is ten years old, £2. This can be done with well selected varieties with good careful cultivation. If eighty trees to the acre it brings it up to £160 per acre. Now deduct £40 per acre for unprolific trees and other disadvantageous things, and you have £120, which you might count on in a fruit season. An orchard, as an investment, can be made to be worth £60 per acre per annum."

"As regards diseases, or climatic influences that are liable to prevent a full crop, we have had a little touch of twig blight in Larimer County, which has done some damage, but there are more trees planted this year than ever before. The climate is all right. If locality has proved favourable for fruit by experience, that is the place to plant. To explain, the Peach is not at home with us in Larimer County, but the Apple, Pear, Plum, and small fruits are. So we need not plant the Peach; but in other localities in Colorado it is at home. Apples, Plums, Peaches, and Pears will, in my opinion, do as well in some localities in Colorado as in any State in the Union, California not excepted, and I am fully convinced that fruit trees bear younger and are more prolific in Colorado than in any fruit country that I have ever visited."

Mr. H. R. Brown of Arvada, Jefferson County, about six miles from Denver, writes:—

"In regard to the age at which Apples begin to bear in this district, I would say at from five to six years, occasionally sooner. As to the value per acre in money, that depends very much on circumstances, but I think, judging from the age and yield of my trees, 200 barrels, per acre would not be over-estimating it, and as the price ranges from 14s. to 24s. per barrel here, you can easily get at the approximate value."

"As to the cost of production that also depends very much on circumstances. Cultivation, pruning, watering, and picking would not exceed £15 per acre. As to the cost of marketing and barrels, that would depend on the nearness of the markets and facilities for reaching them. I would consider a bearing orchard anywhere near a good market very cheap at £200 per acre. I do not know of any fruit more profitable than the Apple for extensive culture in this district. I have great faith in the future of Colorado as a fruit-producing State, and believe in the near future it will be one of the leading fruit producers of the Union."

The orchards and gardens owned and operated by the foregoing gentlemen are all on the eastern slopes of Colorado, but the instances now quoted are all from the western slopes of the State.

Mr. C. W. Steele, owner of the Hopedale Fruit and Vegetable Gardens at Grand Junction, Mesa County, writes:—

"Some varieties of Apples bore a few specimens at three years of age. Notably the Missouri Pippin, Ben Davis, Rome Beauty, and Yellow Transparent bore at four years of age. My orchard at five years (four years from planting trees one year old) was profitable, though many varieties were not in fruiting. Peaches and Plums, Apricots and Nectarines, came well into bearing two years from planting. No trees in this valley have reached mature age. I have sold 100 lbs. of Peaches from a single tree of Hill's Chili Peach three years after planting, bringing in the Grand Junction Market 5d. per lb. The same trees this year, five years after planting, promise 200 lbs. per tree. Other varieties have done quite as well. Contracts are made for Peaches delivered in

Grand Junction at 24s. per cwt. At 150 trees per acre parties interested can do their own figuring. My Peach trees, six years from planting, are now full of bloom.

"The cost of planting varies greatly. For instance, Apples, fifty trees per acre, cost £6 6s., while an acre of Pears, 18 by 18, 134 trees at 1s. per tree, cost £6 14s. per acre for the trees alone. I make the product of the land, by cultivating between the rows, bear more than all expenses of interest, taxes, and care of trees until the orchard comes into bearing. An orchard of Pear trees should be worth at ten years of age £300 per acre, Apple trees £120, Peach and Plum at five years £120, Apricots and Nectarines at five years £100, Prunes at five years £160.

"This is the best all-round fruit country with which I am acquainted. No wormy Apples as yet, and I trust the fruit growers, by 'spraying' their orchards, if they should appear, will keep the codlin moth subdued.

"The great tendency of fruit trees with us is to overbear, and some varieties must of necessity exhaust themselves if thinning the fruit is not practised. I think the culture of the Pear for long shipment is to be specially recommended, and our dry climate offers superior facilities for drying fruit. I think the Apricot, and more especially the Prune, should be largely planted for open air drying.

"I have answered, in a general way, your questions. To tell all the profits of fruit culture in Grand Valley would not do. People must come and see for themselves to realise the great advantages we possess over California in freedom from insect pests and nearness to market, making, as I believe, a bearing orchard of ten acres in our district realise as much nett profit as a California orchard of forty acres of the same age and the same varieties."

Mr. G. B. McGranahan, proprietor of the Garnet Fruit Farm, near Delta, in Delta County, writes:—

"My orchard is not for sale. I have twenty-six acres now set to fruit, and £4000 will not buy it. I have never had a failure of any kind of fruits since old enough to bear. I had about ten tons of Grapes this season on 1700 Vines, 250 bushels of Peaches on ninety trees which brought from 3d. to 7½d. per lb. As there are no orchards that I know of being offered for sale, it is pretty hard to say what they are worth, but the Eastern and California criterion is that the land set to standard fruits is worth the third year after setting £1 per tree, which in Apples (fifty per acre) set 30 feet apart, would make a value of £50 per acre, in addition to the value of the intervening unimproved land. In Peaches (170 trees to the acre) this would be £170. I had Peach trees, set five years this season, that produced from £4 to £6 each.

"Mr. A. M. Olds, one and a half mile from Grand Junction, has ten acres of fruit in bearing, for which, I am informed, he refused this summer £1600. If fruit lands in California that bring a revenue of £40 per acre per year (fruit selling from £4 to £6 per ton) are estimated to be worth, and sell for from £200 to £400 per acre, does it not look reasonable that our lands are much undervalued, when we consider the fact that we in Colorado receive for our fruits from three to five times as much as the California growers receive for theirs?"

Such is the experience and testimony of practical fruit growers in Colorado, and as neither they nor the writer have any lands to sell, the only object of this letter is to show English readers what can be done here, and perhaps the interesting character of the information and the desire to be explicit, will excuse the length of this communication.—THOMAS TONGE, *Formerly of Manchester, England.*

### TWIN BOILERS.

WHERE opportunity occurs I should strongly advise everyone to put down twin boilers, especially where all the houses are heated from one stovehole. The boilers can be worked during alternate weeks, or jointly where necessary, in the case of sharp frost or continuous cold winds in the spring where the position is an exposed one. It is surprising what a difference two or three shovelfuls of fire will make in the second boiler to the heating of the whole hot-water pipes. Instead of the water becoming cold when returned into this boiler by the circulation from the one in use, the small amount of fire maintains it in a warm state; indeed by the economic use of two fires a saving in fuel is effected in spells of bad weather. More fuel is required to maintain the heat with one boiler than with two properly managed.

But my chief aim in recommending the use of two is in the case of a breakdown, such as we have just experienced. Our boilers, saddle with waterway back, were fixed thirteen years since; one of them a short time since developed a crack at the bottom, no doubt mainly caused by sediment from our chalky water settling there—the lowest place; and this leads me to say that all saddle boilers should have a draw-off tap fixed to each side, by which means the boiler can be thoroughly rinsed out at least twice each year. Many boilers of this pattern have but one such tap. The opposite side cannot then be cleaned thoroughly out. No matter how the water is rushed into the boiler by turning on the valves, a certain amount of sediment will remain at the bottom, which

prevents the water coming in contact with that part of the boiler, causing it to become unduly heated and burnt, and which in time develops a crack, which means removal.

The chief advantage gained by the use of twin boilers is that the heat can be maintained in the houses all the same while the necessary repairs to the other are being effected, which means a lot in some cases, and at this time of the year especially. All boilers of this kind should be provided with valves on both the flow and return pipes, which when closed will enable the remaining boiler to provide heat. Even when the flues which pass over each boiler, separate of course and connect at the back into the main flue which leads to the chimney, have to be interfered with, temporary arrangements can be made to admit of the fire being employed. In our case the fixing of a new boiler in the place of the defective one, by the aid of an iron pipe 6 feet long and 9 inches in diameter, we were enabled to construct a temporary flue, so that with the exception of a few hours one day while the last few joints were made, and the water had to be drawn off to enable the mains to be connected, we were able to maintain heat everywhere, which could not have been the case for at least four days had we not possessed twin boilers of the same pattern.—H.

### FEEDING PLANTS IN POTS.

THE solid (mineral) parts of plants, as shown by the analysis of their ashes, is very small, and the quantity of earth required by each tree or plant depends on the component parts of the soil in which the trees are grown. This was demonstrated by the researches of the younger Saussure, and taken advantage of by T. A. Knight, Esq., for growing fruit trees in pots for experimental purposes. The late Mr. Thomas Rivers, acting on the same lines, proved that fruit trees could be kept healthy and fruitful over many years in pots without change of soil, though he also practised top-dressing and partial renewal of the soil, as better enabling him to attain greater excellence in the fruit and increase of plant without enlarging the rooting area—shifting into larger pots. This system has been extended by his son, Mr. T. Francis Rivers, and is practised on a large scale at the Sawbridgeworth Nurseries, Herts, with almost every description of fruits calculated to afford interest, enjoyment, and profit.

The purpose of soil seems to be that of permitting plants to fix themselves firmly in the earth, to afford them a regular supply of water, and a sufficient quantity of organisable matter. This is proved by the rapid growth of plants in pots, the small quantity of turfy loam, or soil enriched with manure, leaf soil or other substance, sustaining them until it becomes exhausted. Thus a Vine eye, inserted early in the year, and the plant shifted into its largest pot in June, produces a cane in a 10 inch pot with firm, hard, ripe wood, and eyes like nuts by August, and capable of producing Grapes the following year of little less weight than that of the soil in which the Vine is growing when deprived of organic matter and water. Mr. Knight states that he "grew a seedling Plum stock in a small pot, which attained a height of 9 feet 7 inches in a single season, which is, I believe, a much greater height than any seedling tree of that species was ever seen to attain to in the open soil." This is conclusive proof that Mr. Knight used a much richer soil in potting his seedling than a similar one would have had in the "open soil," where supplies must be drawn from a large extent and depth, which is sufficient to account for the discrepancy. But be the soil ever so rich in available plant food the stores of it in a small pot must necessarily soon become exhausted; and the size of the pot, the increase of rich material would need to be frequent and considerable to sustain growth in the tree or plant equal in future seasons to that attained by it in the small pot in the first year, otherwise the plant must become stunted and dwarfed—a mere pigmy of the type. Soil exhaustion, however, is only relative, for the seedling Plum stock would only exhaust the soil of certain elements—potash, soda, magnesia, lime, phosphoric, sulphuric, and silicic acids, with peroxide of iron, some more than others, and of all some, causing the seedling Plum stock to languish, yet the soil is practically rich, fertile for another plant. All the same it is for ever rendered sterile as a soil for the Plum, and it can only be made fertile by restoring those substances to it which have been abstracted from it by the Plum, and become fixed therein—the wood and bark.

To sustain the soil in fertility manure is given in two forms—solid and liquid. There are two kinds of the former—1, bulky; 2, concentrated. The bulky comprises stable and farmyard manure, animal and fowl manure, alone or mixed with vegetable substances, as straw, hay, and moss litter; leaf soil, vegetable refuse, turf parings, and composts. These are used as a mulch or top-dressing to the larger-growing kinds of trees and plants,

especially fruit trees, quite as much for the purpose of encouraging surface roots and inciting the emission of active feeders as for enriching the soil.

The concentrated or artificial manures contain as much manurial matter and readily available plant food in as many pounds as is contained in as many hundredweights of stable or farmyard manure, and in a form productive of the best results in the current crops. This is because they are soluble in water and at once taken up by the roots, assimilated by the leaves, and stored in the fruit, wood, and buds for next year's crop. Suppose a quart of pigeon or fowl manure—the richest in ammonia—is applied to a square yard of ground, it at once absorbs moisture from the air, and the ammonia becomes volatile and takes to itself wings. If the application be followed by moist weather the manure will be saturated and its volatile matter be washed into the soil, and at once be available as plant food, the soil holding it until the roots abstract it therefrom. There is a great difference between applying manures to benefit the trees and using them so that their fertilising properties are wasted.

But instead of applying the pigeon or fowl manure in solid form it is formed into liquid—say  $2\frac{1}{2}$  gallons—ten times more than the solid; the whole of the ammonia is then placed in the soil without loss of time or waste of substance. One remarkable thing about these manures is that one kind pursued continuously produces a sort of surfeit, and changes, with alternations of clear water, are advantageous. It is a mistake to be always giving liquid manure and surface dustings, for it amounts to frittering away plant food.

The plantsman mixes phosphatic and potassic elements through the soil used in potting, and troubles no further about the plants as regards feeding until he wants to get enlargement and fix some desirable property in the flower. The fruit-grower makes sure of his crop as far as can be determined by promise in the shape of buds, and then applies manures that will act simultaneously with the feeders that are pushed to sustain the setting fruit, following this up with another dressing when the fruit is half swelled, whereby it is enabled to perfect, and thus secures a maximum of benefit from the smallest means, because given at the time when the trees display the greatest degree of health and luxuriance, and are most benefited by abundant food. Trees treated in this manner seldom give indications of over-feeding; but strewing phosphatic and potassic manures in highly soluble form when they cannot be utilised serves to produce sterility.—G. ABBEY.

## THE FLOWER TRADE IN PARIS.

[Notes at a Conference held at the Hall of the Association Française pour l'Avancement des Sciences by Mr. H. L. DE VILMORIN.]

(Continued from pages 90 and 157.)

If the flowers which are sent to the "Halles Centrales," and other special markets constitute the largest part of the daily arrivals they do not represent the whole quantity that reaches Paris, nor do they include all the best. Nearly all the choicest flowers and plants go direct from the producers into the hands of the shopkeepers. The latter now constitute a numerous class, increasing every day. The shop windows, so prettily and tastefully dressed, so attractive, particularly in the evening when brightly illuminated by the fairy electric lights which peep out of the flowers, contribute materially to embellish the streets and boulevards of the city. It is difficult to estimate the exact number of florists. A directory, which certainly does not include them all, mentions about 200, whereas it only named 104 in 1880, and forty-five in 1870. But if we judge the whole city by the Boulevard St. Germain, where at least eight florists are established and only one is mentioned in the directory, we may say, without exaggeration, that their number in Paris is about 500, and a proof that the business is yielding a satisfactory return is afforded by the fact that the number is annually increasing.

Is it not a delight to pay a visit to the charming, well lighted shops, where, on entering, a delicious odour strikes you? But the chief attraction is for the eyes. On every side of the windows, on shelves and stands, vases or hanging baskets are exhibited, fresh, bright, graceful and perfumed. The Palms and large Ferns, whose fronds reach the ceiling, shelter the handsome Azaleas and forced Rhododendrons, the Dracænas with their coloured leaves, the charming Bouvardias and Stephanotis, the Clivias with their broad ribboned leaves and orange flowers, and the Poinsettias so beautiful with their brilliant scarlet bracts. In the high narrow vases sprays of white Lilacs alternate with bunches of Safrano or Souvenir de la Malmaison Roses. In the windows between the small symmetrical Araucarias and Cycas are bunches of Hyacinths, Anemones, Narcissus, &c., according to the season, whereas a number of varied

receptacles, dressed with the most refined taste, contain the forced bulbous plants, Lily of the Valley and Cyclamens, Bromeliads, such as Tillandsias, Vriesias and Aechmeas, with Epiphyllums and Sedums or Begonias, garnish the hanging baskets. Everywhere are the beautiful and fantastic Orchids, which are taking first rank for floral decorations; and everywhere the greenery of the Selaginellas, Ferns, and Isolepis combine agreeably with the brilliant shades of the flowers.

Towards Christmas or New Year's Day is the time when the shops of the florists are in all their splendour. For the Parisian florists there is, however, no absolutely slack season. The whole year through there are birthday offerings and festivities, and receptions or entertainments afford opportunities for floral gifts, bouquets, baskets, and decorations of all kinds. In the spring and in summer the Iris, Gladiolus, Lilies, Pæonies, Foxgloves, perennial Larkspurs, and large Poppies furnish from the open ground a large contingent of flowers of grand effect. But the influence of the seasons is far less felt by the shopkeepers than by the street vendors. The former supply the wealthy, who willingly pay the prices of luxuries, and the money enables them to heat glass houses and hotbeds by means of which we can increase the productions.

As intimated above, the shop florists receive their supplies mostly direct from the producers, but they also secure their requirements at the Halles or in other markets. One of their principal duties is setting up the materials which are furnished by the gardeners or horticulturists. The taste and talent of the Parisian florist is seen in the arrangement, the combination and contrast of the colours, their light, thin, and neat disposal affording a saving of materials, give at same time a more graceful appearance to the whole. One should think that our bouquet artists know how at will to fix air amidst the flowers which they set up or group.

It is usually in the afternoon or in the evening that the flowers reach the florist from the producer's hands. They are immediately unpacked, sorted, and displayed either in the window or in other floral decorations. All are placed in water during the night, and employed the following day when duly refreshed.

The ingenuity by means of which they make up for what the flowers lack in sturdiness of habit, size of stem, and boldness of structure and growth are infinite. The reeds which lengthen, the imperceptible wires which support, and the small bundles of moss are all employed by turns or together. The more handsome flowers are the easier is the florist's work, so that in the costly or aristocratic bouquets the highest art is shown in the most perfect simplicity. The ribbons serve in a large measure as companion to the flowers, and if some florists make a too free use of them, yet with the majority Chevreuil's studies have evidently helped them to associate the colours tastefully and harmoniously.

Besides the sale of flowers and plants, the florists undertake for a sum agreed upon for the whole season to decorate apartments. They have numerous customers of that class, but most probably only a few who are disposed to pay £1000 for that service—a sum which, some affirm, not to be extraordinary in New York City.—(Translated by EUG. SCHAEFFEL, *Paris*.)

(To be continued.)

## MARECHAL DE COUR PEAR.

I WAS pleased to notice in your last issue a good word for Maréchal de Cour Pear. It is certainly one of the deceptive varieties while in the fruit room to those who are not acquainted with its exquisite flavour. This, with Winter Nelis, are two of the best Pears for flavour and bearing qualities with which I am acquainted. The Maréchal is perfectly at home either as a pyramid or against a wall; indeed, it makes one of the best pyramids I am acquainted with, bearing well nearly every year; but this time unfortunately it was overtaken by the memorable Whitsuntide frost, being at that time in full flower. Consequently we had a very light crop of fruit.

I am of opinion that this class of Pears will ultimately take the places which are at present occupied by Duchesse d'Angoulême, Pitmaston Duchess, Beurré Diel, and other fine looking Pears, but which have no other qualities to recommend them. On more than one occasion I have seen the Pitmaston placed before Marie Louise at exhibitions, but I fail to see why this should have been in most of these instances. Certainly the Duchess has been of enormous size this season, and it assumes a very attractive colour, but in my opinion most of its qualities end there. With me it is very gritty and devoid of flavour. Certainly public taste points to size and appearance in the present day. An instance of this has just occurred. Latterly we have had some rather large shooting parties staying here, and having some fine bunches of Gros Colman

Grapes hanging I was told to take these to the table while the company was staying at the house; and great was the praise, not only as to the appearance, but the flavour was pronounced to be first-rate.—ONE FOR QUALITY.

### HARDY GLADIOLI.

I HAVE seen, under this heading in two of the gardening papers, a description by Mr. W. E. Gumbleton of the new varieties introduced by M. Lemoine of Nancy, and as I think the designation "hardy" a misleading one, I think that my experience may serve as a warning to others who may have been under the same illusion as myself.

These Gladioli are of two sections—what are called the Lemoinei group, and the Nancianus, the former being the result of a cross between hybrids of *gandavensis* and *G. purpureo-auratus*, and the latter a more recent introduction, a cross into which *G. Sanderianus* has been introduced. With regard to the latter, although I have grown a couple of them, I do not wish to say anything, my experience not being sufficient to add any weight to my words. It is with the former, the Lemoinei section, that I am best acquainted. I have grown some of them for the last ten years, and have from time to time added a few, my last bulbs being those of the lot sent out in 1889, including *Dugeuslin*, *Lamarek*, *Etoile polaire*, and *Venus de Milo*; for as further acquaintance with them did not enhance my opinion of this beauty, I declined getting any more, and am very glad as the result proved that I refrained. Now although Lemoine heads his list of the varieties of the Lemoinei type with the word "rustique" or hardy, yet in the description of them which follows he recommends that they should be afforded a little shelter in winter, while MM. Vilmorin, Andrieux & Cie. in their catalogue of Gladioli describe them simply as "*Glaieuls à grandes macules*," without any reference to their hardiness. There was one of their recommendations that they could be left in the ground all the year, another was that they came into flower early in July before the hybrids of *gandavensis*, for in respect of beauty they, in my opinion, can never for one moment be compared with the *gandavensis* section. Take for example *Venus de Milo*, the best white that has been raised, as far as I know, in that section, and compare it with *Mont Blanc*, *Enchanteresse*, or *Burrell's Snowdon*, and I fancy that there would be little difficulty in an unprejudiced mind in deciding which was the more beautiful in length and closeness of spike. In purity of colour and size the superiority I think lies with the *gandavensis* flowers. The matter of hardiness is of course a relative character, but knowing how cold it is at Nancy, I concluded that if these hybrids could stand that climate they ought to be hardy in most parts of our islands. A plant or bulb may be hardy in the south of Ireland, in the south-west of Scotland, and in the Isle of Wight, and Devonshire and Cornwall, which loses that character in other parts of the kingdom, their other quality of being in advance of *gandavensis* section in point of flowering, seems in the newer varieties to be very questionable; in fact, I imagine that the more they are improved in the character of the flowers, the more, *i.e.* of the *gandavensis* blood they get into them, the more do they partake of the other characteristics of that section.

It has been, perhaps, somewhat hastily assumed that *G. purpureo-auratus* is itself hardy. I do not find it placed in any of the lists of hardy perennials, and as it is a native of Natal it is likely to be one of those provoking plants which are nearly hardy, but which, like many of the New Zealand plants, succumb to our winters. I should like to know whether anyone has found in the colder parts of our islands withstood last winter.

My experience of the two sections of Lemoine's hybrids has been this. I have some of them six or seven years, and others were added from year to year. They were never taken up out of the ground, the soil of my garden being of a rich, light, alluvial character. They flourished well, increased rapidly, and although, as I have already said, they did not appear to me so desirable for the garden as the *gandavensis* hybrids, yet they formed a pleasing variety, and I had determined to go on with their cultivation, but last winter completely altered my opinion. They, every one, succumbed to the severe frost, and although they had a good coating of snow for the greater portion of the winter, not a trace was left of them, and their supposed hardiness was a "mockery, delusion, and a snare." Some roots of the *gandavensis* section had also survived many previous winters, but they also fell a victim to last year's intense frost; in fact, as Mr. Kelway said to me, it is all stuff about hardy Gladioli, none of them will stand being frozen. When you get 2 or 3 inches deep of frozen soil they will not mind it, but when frost goes down 5 or 6 inches, then you must give them up. Such is my experience, and I can

only, in conclusion, advise all those who wish to grow these varieties that they must treat them in every respect as they do the hybrids of *gandavensis*.—D., Deal.

### DEATH OF MR. W. ALFRED DICKSON, OF CHESTER.

WE regretfully have to record the death of Mr. William Alfred Dickson, which took place at his residence at Newton Villa, shortly after seven o'clock on Thursday, December 17th. Mr. Alfred Dickson was fifty-four years of age at the time of his death. He was brother of Mr. Geo. A. Dickson, J.P., Mr. James Dickson, and Mr. Johnson Dickson, solicitor, whose father, Mr. James Husband Dickson, was a prominent citizen in a previous generation, and one of the foremost men in the horticultural world of his day. The name of Dickson has been so long and so honourably associated with the city, and the business with which the title is identified is of such historic interest, that we feel called upon to make something more than a passing reference to Mr. Alfred Dickson's death, for he bore his full share of responsibility in the direction of the business, having had the entire management of the nurseries during the whole period of his active business life. In the prime of early manhood few men showed more activity and indomitable energy. He never neglected the claims of his business; up to within a few months of his death he met his partners to go through the day's letters soon after six in the mornings, winter and summer. In the earlier years he travelled extensively, yet found time to pursue his favourite sport across country. Mr. Alfred Dickson was also well known in connection with the rifle volunteers. He was one of the oldest members of the corps, having joined in 1859 at the commencement of the movement. He passed through the various grades, and at the time of his death held the rank of Hon. Lieutenant-Colonel. He went into camp regularly each year, and in the earlier years he was regarded as an excellent marksman, having won the gold challenge medal for the year at a time when this was the chief prize of the yearly competition. The nature of his complaint—a phase of paralysis—was such that of late years his moving about became uncertain and difficult, and later he was compelled to assist locomotion by artificial methods, so that he did not take a prominent place beyond the range of his business, but in this he was actively engrossed to within a few weeks of his death.

As a nurseryman, very few men had such knowledge of trees and plants in relation to their history, their treatment, cultivation, and commercial values. The acquirement of knowledge was aided by a memory of marvellous retentiveness, and a mental grasp in every way remarkable. He had that quick discernment which enabled him to pick up a point which gave a characteristic distinctiveness and a determining feature to a particular plant, and which once seen seemed never to be forgotten. The tender regard he had for plants and flowers was manifested often to those who might be brought into contact with him at his offices in the nursery grounds. At such times when his attention would be given to some new variety which was shortly to add to the riches of horticulture, and with the introduction of which he was closely identified, one would find on his table, in front of him and about him, now a Daffodil, now a Rose, now a Carnation, or something of bright beauty, depending upon the season of the year when the call might happen to be made. This was placed so that it seemed to be more of a companion than a specimen to be critically examined for comment, for nomenclature, or for description.

As an employer he was firm without that sternness which seems inevitable to some men when brought into contact with the problems and trials involved in the employment of labour and in dealing with large masses of men. He was a strict observer of method and punctual discharge of duty. When he passed the word he expected the accomplishment of duty, and he was not slow to discern how far those about him could be trusted to carry out his instructions. We venture to say there is but one opinion amongst the hundreds of employés who to-day mourn his loss, and that is that a strong man with the mind of a man and the tender heart of a true gentleman has passed away from them.

For Mrs. Dickson and her young family of six children deepest sympathy is everywhere felt, and amongst the records of the deaths of this mournful year, of shadows and sadness now drawing to its close, few will touch the hearts of so many friends and acquaintances as that of Mr. Alfred Dickson.

The funeral took place on Monday.—(Condensed from the "*Chester Chronicle*," December 19th.)

### BENHAM PARK.

THIS well appointed residence, now occupied by Mrs. Myers, is most pleasantly situated on a gentle slope about three miles from Newbury, from the top of which a capital view can be obtained of Highclere Castle and the surrounding hills—one, especially, the "Beacon" being at a considerable altitude, standing no less than 900 feet above sea level. The house is a handsome squarely built structure, complete in every respect, the trim well-kept lawns and drives in front making a contrast to the light stone of which the house is built. The flower garden at the rear is unique, the numerous flower beds of large size being laid out on a steep slope in grass, and look remarkably well. The beds, at the time of my visit, were filled with the usual summer occupants, such as *Pelargoniums*; *Coleuses* especially being of capital colour. Sloping away from the beds are large

breadths of common Laurels, kept closely cut, forming an even surface of green, which served as a foil to the brightly coloured Pelargoniums in the beds. A long winding border, the centre of which is filled with choice evergreens, is ornamented in the front on both sides with useful summer and autumn flowering plants, such as *Anemone japonica* alba, Phlox, Pœonies, and so forth, in all making a bright display, and at the same time providing the means of filling the flower vases in the house. A capital effect was produced with *Clematis Jackmanni* growing over some tall and wide arches on which Roses were trained, the dark purple of the *Clematis* was fine in the extreme. A good sized conservatory adjoins the west end of the house in which is a fine plant of *Passiflora violacea* flowering in profusion. *Salvia Betheli* made a fine display; some good plants were in full flower, healthy Palms in the centre, and the usual flowering plants around the side stages were to be seen.

The kitchen garden and glass houses are situated some distance from the house, and, like the latter, are well appointed. There are numerous vineries, and serviceable crops of fruit had been cut or were hanging of well tried varieties. One range, span-roof, running east and west, contained the best examples I have seen of combined Grape and Peach culture. The latter were in perfect health, reaching quite to the ridge of the house, covering the whole northern side, and had borne splendid crops of fruit. The Vines were late kinds, a circumstance in favour of the Peaches. Substantial crops of fruit of the latter had been gathered from the trees in the regular Peach house, one Royal George giving sixteen dozen handsome fruits. Figs are well grown, a lean-to house being specially devoted to them, Brown Turkey and White Marseilles being the favourites. Pine Apples were represented by splendid fruits of Queens, weighing fully 5 lbs. each.

Benham Park has been long noted for Melons. This year large crops have been gathered. At the time of my visit some splendid examples of Countess were hanging. The flavour of this variety is excellent; it is also a good grower, and sets abundance of handsome fruit. Strawberries in pots were a feature. Next spring should be no exception to the rule. The plants now being grown look as promising as the most exacting could wish. The houses devoted to plants were filled with those best suited to house decoration, which is the main object in their growth.

The kitchen garden is spacious, having a gentle slope to the south, and is surrounded by a wall fully 14 feet high, a good part of it fitted with Parham's wall coping, which is found serviceable in procuring a full supply of fruit annually, especially of Apricots and Peaches. Sweet Cherries are not a success. Growing as they are against the eastern wall the trees look anything but happy, and they are gradually being supplanted by cordon Pears, which succeed satisfactorily, and so do the horizontal trained trees on west and north walls; the branches were exceptionally thickly hung with some sorts, Pitmaston Duchess especially so. Hacon's Incomparable had extra fine fruits. Full crops of Morello Cherries were borne by trees trained against a north wall. Plums were a heavy crop, particularly Coe's Golden Drop. The hardy fruit trees on the walls, with the exception of the Cherries referred to, are a credit to the planter and trainer. A fair sprinkling of Apples was to be seen, magnificent fruit of Tyler's Kernel were noted on a small bush tree. The highly coloured and popular Bismarck was fruiting freely, and so was Potts' Seedling as a half standard, an old tree, which had a full crop of fruit. The vegetable crops were all that could be desired, quarters well kept, and absolutely free from weeds. The whole garden reflects credit on its custodian, Mr. Howard.—A RAMBLER.

DENDROBIUM LEEANUM.

WITH the beautiful variety of *Dendrobium Phalænopsis*, named in honour of Baron Schröder, and which has attracted so much attention recently, Messrs. Sander & Co. of St. Albans succeeded in importing a plant from New Guinea of a distinct species of *Dendrobium*. This has been named *D. LEEANUM*, in honour of W. R. Lee, Esq., 33, Fountain Street, Manchester, who makes a speciality of *Dendrobiums*, and when a plant was shown at the Royal Horticultural Society's meeting on November 10th last a first-class certificate was awarded for it by the Orchid Committee.

*Dendrobium LEEANUM* produces pseudo-bulbs about 3 feet long, rather stout, somewhat compressed, and bearing gracefully drooping racemes near the apex. The flowers (fig. 97) are very pleasing in form and colour, the sepals and petals tapering white, white at the base, tipped and tinted with rich rosy crimson, somewhat deeper in the petals, which are also slightly narrower than the sepals. The lip is broadly margined with a similar colour, green at the base, and with three prominent ridges in the centre.

One excellent character possessed by the *Dendrobium* is the

length of time the flowers last, for the only plant received at St. Albans has been in flower for over six weeks, and the three racemes are still fresh. It will no doubt prove a useful and popular Orchid.

#### ORCHIDS AT PENLLERGARE.

ON a recent visit to the famous gardens of Sir John T. D. Llewelyn, Bart., at Penllergare, Swansea, the following were the most noticeable among the Orchids in bloom:—*Cypripedium Spicerianum*, several very good forms; *C. LEEANUM* and *C. L. superbum*, *C. callosum*, *C. Haynaldianum*, *C. Harrisianum*, *nigra*,

FIG. 97.—DENDROBIUM LEEANUM.

*C. insigne*, *C. insigne Chantini*, and *C. insigne punctatum*, *C. Arthurianum*, *C. Sedeni*, *candibulum*, and others. Of *Dendrobium superbiens* there were several fine plants. Why is this not more frequently grown? *Vanda cœrulea*, *V. Amesiana* were represented by healthy plants, only imported last spring. *Phalænopsis* in variety, showing plenty of robust spikes, and the plants in rude health—the exception now rather than the rule. A houseful of *Calanthes*, too, were very fine. They are especially well grown there, and amply do they repay the liberal treatment they receive.

In one of the stoves we found a very fine plant of *Nepenthes Rafflesiana*, evidently at home, and carrying a large number of its fine pitchers. *Odontoglossums* and *Dendrobiums* are promising a fine display later on; and in addition there are no end of stove and greenhouse plants to do duty in their several seasons in the production of floral treasures for those favoured to enjoy them. *Lapagerias rosea*, *superba*, and *alba* are at home on the roof of one greenhouse; and *Rhododendrons* of all classes, which are special favourites, need an article to themselves. Everything in his charge reflects great credit upon Mr. Warmington, Sir John's gardener, who spares no pains in bringing about such fine results.

#### CALANTHES AT THE HENDRE.

The *Calanthes* at The Hendre at present are particularly fine, *C. Veitchi* is handsome, *C. vestita* is also good, and the hybrid forms equally so. Mr. Coomber has been successful in raising some hybrids himself, which, whether distinct from others already in commerce or not, are at least really good and valuable additions to the collection. Mr. Coomber is equally successful in their culture as in the possession of good forms, the spikes large, and carrying a profusion of well developed blooms. Further, they are shown off to the best advantage in various positions. In a conservatory adjoining the mansion we find them arranged among Ferns and foliage in the recesses of a Fern rockery in a most graceful manner, and a house in the gardens is made exceedingly bright by an arrangement in which Ferns do duty as a ground, and the

various coloured *Calanthes* growing, as it were, out of the Ferns. Pots and bulbs are hidden, and the effect thereby, of course, is much improved.

A houseful of *Eucharis* we noticed was a sight to remember, and some fine *Pancratium fragrans*, one large plant having carried during one season no less than forty-three spikes. Among Orchids *Cypripediums* are doing well, and *Phalaenopsis* are a treat to behold. Mr. Coomber had not sent all his good things in the way of fruit to London, although the three Pines for which the R.H.S. awarded him a silver medal had been dispatched. Some very fine fruits remained at home, and trees and plants all promised well for equally good results to follow. J. A. Rolls, Esq., and Mr. Coomber have a similar enthusiasm in horticultural matters, and consequently the best possible results are obtained.—VISITOR.

### AN INTERESTING CASE.

IN the High Court of Justice (Chancery Division) an interesting case was tried before Mr. Justice Kekewich. It was an action brought by Sir Henry Bruce Meux, Bart., against Mr. Cobley, and the trial, which occupied the greater part of two days last week, raised a question of some interest upon the Agricultural Holdings Act, 1883. The object of the action was, in substance, to prevent the defendant, who was lessee of a farm under the plaintiff, from converting it into a market garden by erecting thereon glass houses for the cultivation of Tomatoes, Grapes, Mushrooms, and other market produce of that character. The facts were shortly these. By a lease, dated the 21st of January, 1889, the plaintiff, Sir H. B. Meux, demised to the defendant the Bulls-cross Farm, in Cheshunt and Enfield, in the counties of Hertford and Middlesex, adjoining plaintiff's mansion, Theobald's Park, and consisting of arable and pasture land, together with the messuages and farm buildings thereon, comprising about 152 acres, at a rent of £225, rights of sporting being expressly reserved to the lessor, and the lease contained a covenant by the defendant that he would in all respects cultivate and manage the farm and every part thereof "in a good, proper, and husbandlike manner according to the best rules of husbandry practised in the neighbourhood," and would at all times use his and their utmost endeavour to preserve the game on the demised premises and the nests and eggs of all partridges and pheasants. The plaintiff's complaint was that, without his consent, the defendant, in 1889, erected on the "arable" land of the farm two glass houses for the cultivation of Tomatoes and other hothouse produce for the London market, and that in 1890 he erected a third glass house, in spite of the remonstrances of the plaintiff's bailiff; also that he was intending to erect additional houses. The plaintiff contended that the erection of glass houses for the purposes aforesaid constituted such a change in the mode of cultivation stipulated for by the lease as to amount to a breach of covenant, and that the conversion of the farm into a market garden was "waste" on the defendant's part, and would cause loss to, and impose additional burden on, the plaintiff. The plaintiff accordingly claimed an injunction to restrain the defendant from committing the acts complained of. The defendant contended that he had the right to erect glass houses on the land, and that the same constituted an improvement to the farm and the inheritance thereof. He also pleaded acquiescence or consent on the part of the plaintiff. He also contended that the erection of the houses was authorised by the Agricultural Holdings Act, 1883, and that they were buildings which, having regard to the provisions of that Act, might be removed by the tenant at the expiration of his tenancy, or might be bought by the landlord.

MR. JUSTICE KEKEWICH said, "Much encumbered with rubbish" was the phrase he applied to this case twenty-four hours ago, and he deliberately applied the same phrase to it again. A great deal of the time occupied, and of the heavy costs incurred, was attributable to what His Lordship ventured to call the "rubbish" which had been imported into the case. If the case had been presented to the Court on its merits the whole of it might have been disposed of in two or three hours. One point urged by the plaintiff was that the buildings were an eyesore. His Lordship had never heard of a case in which a tenant could be prevented from erecting a building on his land, on the ground that it might be an eyesore or not agreeable to his neighbour. Then it was said that what the defendant had done or threatened to do would cause injury to the inheritance. In the first place, there was no evidence that growing market produce would throw a burden upon the inheritance. That was no increase of the burden. The only questions His Lordship had to consider were—first, whether what the defendant was doing was within the terms of the lease; and secondly, whether, irrespective of the terms of the lease, it was "waste" according to the common law. His Lordship came to the lease, and upon that there was a point of real importance—namely, whether, under a lease of what was called "agricultural land," the tenant was entitled to put up glass houses for the cultivation of non-agricultural produce, such as Tomatoes, Grapes, and the like. It was to be observed that, although this was a lease of a farm—that is to say, an agricultural lease—there was no prohibitive covenant against the lessee's doing things of this kind, and also no provision for a rotation of crops; therefore the lessee was left at large to cultivate the land at his discretion, the only restriction on that discretion being that he was to cultivate "in a proper and husbandlike manner according to the best rules of husbandry practised in the neighbourhood;" and he was also bound at the end of the term to yield

up in good condition not only the existing buildings, but all fixtures and other things attached to or set up on any part of the demised premises; so that the lease contemplated certain additions in the way of fixtures. Also it was to be observed that anything of this kind done was to be done at the tenant's risk. He could not compel the landlord to take it or pay for it, so that, after spending perhaps hundreds of pounds on the property, the tenant might be compelled to go out of possession without having got anything but a poor return for his expenditure, and possibly without getting anything back. This was so if the Agricultural Holdings Act, 1883, applied, except as to buildings erected with the landlord's consent.

Now, what was the tenant here doing which was not "according to the best rules of husbandry practised in the neighbourhood?" One must bear in mind the change of circumstances in the neighbourhood, and the mode of cultivation of land now adopted there. One must look and see what was going on in the neighbourhood, and not exclude the consideration which came within one's own extra-judicial knowledge that the wants of the metropolis and the neighbourhood were constantly extending and necessitated the increase of market gardens. Then there was the consideration that in the neighbourhood of this farm there were other market gardens and also other farms conducted on the principles which the defendant had adopted to his own advantage—namely, combining the farm proper with the market garden proper. His Lordship could not see that this was not using the land according to the best rules of husbandry practised in the neighbourhood. Construing the case according to the usages of mankind and the words of the lease, he saw no reason why the defendant should not erect such glass houses as he thought fit. His Lordship was of opinion that the defendant was entitled to use the ground as a market garden, and, if so, he was entitled to cover it with glass houses and derive advantage from it in that way. If that was expressly sanctioned by the lease, that could not be "waste." The tenant could not commit waste as against his landlord if the landlord had by special contract given him leave to do so. Was what had been done "waste?" Perhaps, technically, it was; but supposing it was, it did not follow that the plaintiff could recover damages, and if he could it by no means followed that he could get an injunction. His Lordship then referred upon that point to "*Doherty v. Allman*" (3 App. Ca., 709) and "*Jones v. Chappell*" (20 Eq., 539), and proceeded:—Then was there any injury to the inheritance? The evidence showed that to be an absurdity; and that, so far from the erection of these houses being an injury to the inheritance, it would be an advantage to the farm, the ground being in the neighbourhood of London. The only other point was as to the application of the Agricultural Holdings Act, 1883. In the view His Lordship took of the case it was unnecessary to consider what the meaning of the Act was; but the Act appeared to go a long way towards getting rid of the old common law doctrine of waste, and to be quite consistent with the two authorities above referred to. His Lordship felt inclined to hold that these houses were "improvements" within the Act—that is to say, improvements for which the tenant could get compensation; but he did not think it necessary to go further than that. His Lordship could not find a single point on which the plaintiffs succeeded, and therefore there must be judgment for the defendant with costs.

THE QUEEN AND HORTICULTURE.—The gold medal of the Royal Botanical and Horticultural Society of Manchester was awarded to Her Majesty the Queen for her exhibition of fruit at the recent show in this city. Mr. Bruce Findlay, the Secretary of the Society, proceeded to Windsor Castle and presented the gold medal. In acknowledgment, Mr. Findlay has received the following letter:—"Windsor Castle, December 16th, 1891. Sir,—I am commanded by the Queen to convey to the members of the Royal Botanical and Horticultural Society of Manchester the expression of Her Majesty's thanks for the gold medal which the Society has awarded to her for the fruit exhibited by Her Majesty on the occasion of the last exhibition there, and to express Her Majesty's satisfaction that the Apples and Pears sent from the Royal gardens should have been so highly approved of by the Society.—Believe me, yours faithfully, J. C. Cowell. Bruce Findlay, Esq. Secretary of the Royal Botanical and Horticultural Society of Manchester."

— THE WEATHER IN THE METROPOLITAN DISTRICT during the past few days has been very winterly, and keen frosts, accompanied by dense fogs, have been the rule. Temperatures as low as 14°, Fahr., have been registered in many places, and on several days the trees and shrubs have been rendered extremely beautiful by the abundant hoar frost lining every twig.

— **VEITCH MEMORIAL PRIZES.**—At a meeting of the Trustees of the Veitch Memorial Fund, held on Friday last, the 18th inst., at the office of the *Journal of Horticulture*, Dr. Robert Hogg in the chair, it was decided to offer Veitch Memorial Medals and prizes for the year 1892 as follows. At the Temple Show of the Royal Horticultural Society on May 27th a medal and prize of £5 for the best six hard-wooded greenhouse plants in bloom. At the special Exhibition of Orchids at the Royal Botanic Gardens at Manchester, to be held in June, a medal and prize of £5 for the best hybrid Orchid in bloom, already in commerce, and a medal and prize of £5 for the best hybrid Orchid in bloom not in commerce. These medals and prizes can be competed for by amateurs and their gardeners only. It was also decided to award a silver medal to Mr. William Watson of Kew, and a similar medal to Mr. John Heal of the Royal Exotic Nursery, as a recognition of their skill as hybridisers and cultivators.

— **FLORAL DECORATIONS.**—A very successful bazaar was held on Wednesday and Thursday last in the Shakespeare Room at Warwick Castle. The stall presided over by the Countess of Warwick was effectively decorated with wreaths formed of the coloured leaves of *Berberis aquifolia*, and long trailing shoots of "Traveller's Joy" (*Clematis vitalba*), over the centre a Prince of Wales' feather was formed of the same materials, with the addition of a few plumes of Pampas Grass, the whole being backed up with light sprays of Yew produced a novel and pretty effect, which was much admired. The downy substance formed on the seed vessels of the *Clematis* named renders it especially suitable for decorations at the present season. The conservatory adjoining the Shakespeare Room was converted into a refreshment stall, and presided over by the Lady Eva Greville. A charming effect was produced by draping the walls with art muslin and tapestry, and defining the doors and windows with wreaths, while the iron girders which supported the glass roof were entwined with Ivy, long trailing shoots of which hung down at irregular intervals, and Japanese lanterns and coloured lamps were freely used, the effect thus produced being especially striking when seen under artificial light.

— **CHRISTMAS ROSES AT WARWICK.**—A call on Mr. J. Kitley a few days ago revealed the fact that Malmaison Carnations are by no means the only plants he grows exceedingly well. On entering one of the houses a broad expanse of snowy whiteness compelled more than a passing expression of admiration. This fine effect was produced by 300 clumps of *Helleborus niger major*, studded with flowers as closely as they could be packed. The blooms were large, and beautifully fresh and clean, and no gardener with floral decorations to carry out at Christmas ought to be without a supply of these charming flowers, seeing that they are so easily grown. The plants are grown on a north border, where they are allowed to remain two and sometimes three years. About three weeks or a month before they are wanted in flower the plants are lifted with good balls of earth, and placed closely together on the floor of a vinery or any other cool structure, a little soil is worked around the roots as the work proceeds, and when completed the whole mass is given a thorough watering through a coarse rose. This washes the soil among the roots, and leaves the flower buds quite clean. As the buds begin to open, a little heat is applied to lengthen out the flower stems, as they are much more appreciated for decorative work when the stems are of good length. After flowering, the plants are hardened off, divided, and again planted in the open air.

— **LYCIUM AFRUM.**—In reference to "R. H. D.'s" inquiry (page 497) anent the fruiting of this shrub in this country, I beg to say that occasionally it does so, but very sparingly hereabouts, and there are several shrubs of it growing in the cottage gardens facing the streets of this—now annexed—suburb of the city of Birmingham. It grows rapidly against walls and over arbours, &c., and invariably produces a profusion of reddish violet blossoms. The shrub in question must indeed be an interesting sight. Its one drawback is its deciduous character, and consequently presents a naked appearance in winter. Regarding its cognomen, "Tea Tree," it would be interesting to know if its leaves are really used as a beverage in Africa, inasmuch as there is a tradition that its first introduction into this country was by the captain of a vessel, who was commissioned to bring a consignment of Tea plants (*Thea*) from East India, and lost them on the voyage before arriving at the Cape of Good Hope; but to get out of the dilemma he obtained plants of a shrub, the leaves of which he noticed were used by the natives there as a tea, and thus passed them off for the true Tea plants. The respective kind of plants, however, are of distinctly different families, the *Lycium* belonging to that of the *Solanaceæ*, and the *Thea* to *Ternströmiaceæ*.—W. G., *Harborne*.

— **DEATH OF MR. FLETCHER ROGERS.**—By the somewhat sudden death of Mr. Fletcher Rogers on Saturday last Liverpool loses one of its most prominent citizens and the Liverpool Horticultural Association one of its best supporters. To the latter the late Mr. Rogers had been Honorary Treasurer for a number of years, and it was a painful coincidence that his death should have occurred on the day of the annual dinner of the members of the Association, many of whom had hoped to look for his genial presence in the chair, a position he had held at all the previous dinners. At those gatherings his remarks always made a great impression on all present, his delight for all that was good and true in gardening being strongly emphasised in the excellent speeches he made. His kindly presence was a sure sign of encouragement, and when the Liverpool Horticultural Association has been passing through some of its darkest times, the late Mr. Rogers was always there with his cheering words to help the Committee and members to greater stimulation, with the hope that brighter times would dawn.

— **PANCRATIUM FRAGRANS.**—I can fully endorse the remarks by Mr. W. R. Williams, December 10th (page 491), for I have at the present moment a *Pancratium fragrans* in full bloom, four long fully expanded flowers on one stem; its fragrance is almost overpowering. Being ever-green I keep it in my Fern house, which has a stove temperature. It is in a 7-inch pot, and has not been disturbed for four years, the whole time I have had it, and has always each year flowered well and been a noticeable feature amongst my Ferns and Orchids, and with your correspondent I can say it does deserve worthy consideration by those who can give it the desired temperature.—ELLIS PALMER, *Salisbury*.

— **JERUSALEM ARTICHOKE.**—I do not think it is known to all growers of this useful vegetable that there is a white variety. Seeing it advertised by Messrs. Sutton I procured some of the tubers. They were planted by the side of the old purple variety; but now we have commenced to dig them the white is found to be far superior, being more prolific, quite double the quantity to a root, and of a much better shape, some of the tubers being perfectly round with very few eyes. When cooked they are also of a better flavour. It is a new introduction which will be much sought after when better known, especially amongst growers for market, as it should fetch a higher price than the purple, as there is less waste to them and it is more taking in appearance, which is one of the principal items with anything grown for sale.—E. TROLLOPE.

— **LIVERPOOL HORTICULTURAL ASSOCIATION.**—At the second meeting of the session, held in the lecture room of the Museum, William Brown Street, an excellent paper on "Deciduous *Calanthes*" was read by Mr. Hathaway, gardener to the Earl of Latham, Latham House, Ormskirk. Owing to the very inclement state of the weather the attendance was not so large as it might have been, but those present were highly gratified by the concise and lucid remarks from Mr. Hathaway, the paper showing him as one who thoroughly understood the cultivation of these beautiful winter-flowering Orchids. At the close a hearty vote of thanks was passed to Mr. Hathaway, and the hope expressed that he would at no distant date favour the members with another paper.

— **THE FIFTH ANNUAL DINNER** of the above-named Association was held on Saturday last in the large dining-room of the Adelphi Hotel, when about 130 persons sat down to an excellent repast. The chair was occupied by Mr. Thomas White, Chairman of the Association, who was supported by Mr. T. Powell (Vice-Chairman), and Mr. R. W. Ker, Aigburth Nursery. A gloom was to some extent cast over the proceedings by the announcement of the death of Mr. Fletcher Rogers, Hon. Treasurer of the Association, which had taken place that morning—a gentleman who had presided at all previous dinners. The Chairman feelingly referred to the sad loss the Association had sustained, and Mr. R. W. Ker made sympathetic reference to the death of Mr. Rogers. After dinner the usual loyal toasts were proposed. The toast of the "Liverpool Horticultural Association" was proposed by Mr. R. W. Ker, who in a brief speech pointed out the good work being done, and expressing an opinion that greater work might be expected in the near future. He also went on to urge the necessity of not only the gardeners themselves doing all in their power to lift themselves up to the highest position, but to secure the assistance of their employers to help forward in all things calculated to raise the tone of their profession. Mr. White replied. "The Horticultural Trade" was responded to by Mr. Andrew Ker. Mr. Blomily proposed that of the Chairman, to which Mr. White suitably replied. An excellent vocal and instrumental programme was performed.

— **GLENNY'S GARDENERS' ALMANACK.**—The leading article of the issue of January, 1892, is devoted to bush fruit and its cultivation. Among other matter are lists of new flowers, fruit, and vegetables as supplied by different seedsmen, florists, and nurserymen.

— **FOR** continuity of flowering throughout the summer the Tea Rose, *MADAME DE WATTEVILLE*, is one of the best. Either in bud or fully expanded it is appreciated, the fleshy-like pink of its colouring is so pleasing. The flowers last along time in a cut state in water. We grow it on a low south wall, and have good reason to be satisfied with it.—S

— **COPPER IN PRESERVED VEGETABLES.**—A correspondent sends the following cutting:—At a recent meeting of the Bavarian Society of Applied Chemistry, the subject of the "Presence of Copper in Preserved Vegetables" was under discussion. The discussion was epitomised in the "Chemiker Zeitung." One of the speakers, Director Kochler of Berlin, made a remarkable statement. He said that during a visit to the Strasburg Exhibition his attention had been attracted to the remarkably beautiful green of some preserved Beans, and upon inquiry as to how this colour had been imparted, he was told that it was a trade secret. Subsequently he had learned that during the boiling of these vegetables in a copper vessel an electric current was passed through the whole, the copper of the vessel acting as an anode, and that in this way a large quantity of copper was carried into solution, giving the vegetable a fine tint.

— **YORK FLORISTS' ANNUAL DINNER.**—The annual dinner in connection with the Ancient Society of York Florists was held at the White Swan Hotel, Pavement, York, when an excellent *menu* was laid before a large company of members and friends by Mr. and Mrs. Hornsey. Alderman Sir Joseph Terry presided, Mr. J. Lazenby (Secretary) being in the vice-chair. Amongst those present were the City Sheriff (Mr. Councillor L. Foster), Mr. Alderman Rymer, Mr. Alderman Clayton, Councillors Wragge, Purnell, J. S. Gray, the Vice-Presidents and Committee of the Society, and numerous others. Mr. Councillor Wragge said he was pleased to see that his Lordship had promised to give, at their summer series of Shows, a sum of £5, to be divided, at the discretion of the Committee, amongst the artisan class, for exhibits of their own culture. Mr. Councillor J. S. Gray referred to the great age of the Society, and was glad to see that it was now in a healthy, sound position. He thought the autumn Chrysanthemum Show had been a great success. The Chairman remarked that the Society had made grants to several of the charitable institutions of the city. They had granted the Hospital and Dispensary £7 7s. each, and also £10 10s. to the Benevolent Institution for Gardeners. Mr. John Fielden (Treasurer) said their income from all sources had been £472 12s. 2d., an advance of £81 2s. 7d. on the previous year. They had expended £444 3s. 7d., which was £101 9s. 11d. more than last year. They had given £25 5s. 8d. to various charities, and had a balance in hand at the bank of £171 15s. 8d.

— **ROYAL METEOROLOGICAL SOCIETY.**—The usual monthly meeting of this Society was held on Wednesday evening, the 16th inst., at the Institution of Civil Engineers, Mr. Baldwin Latham, M.Inst.C.E., President, in the chair. Mr. R. H. Hooker, B.A., Mr. A. B. MacDowall, M.A., Mr. E. G. Ravenstein, F.R.G.S., and Mr. R. Hedger-Wallace were elected Fellows of the Society. Mr. W. Marriott gave the results of the investigation undertaken by the Society into the THUNDERSTORMS OF 1888 AND 1889, which he illustrated by a number of lantern slides. Mr. Marriott gave the number of days on which thunderstorms occurred at each station, the number of days of thunderstorms in each month for the whole country, the number of days on which it was reported that damage or accidents from lightning occurred, and also the number of days on which hail accompanied the thunderstorms. In 1888 there were 113 days, and in 1889 123 days on which thunderstorms occurred in some part of the country. The number of days with damage by lightning was thirty-three in 1888 and thirty-eight in 1889, and there were fifty-six days in each year on which hail accompanied the thunderstorms. The tables of hourly frequency show that thunderstorms are most frequent between noon and 4 P.M., and least frequent between 1 A.M. and 7 A.M. Thunderstorms appear to travel at an average rate of about eighteen miles per hour in ill-defined low barometric pressure systems, but at a higher rate in squally conditions. The author is of opinion that individual thunderstorms do not travel more than about twenty miles, and that they take the path of least resistance, and are consequently most frequent on flat and low ground. The author believes that the thunderstorm formations are small atmospheric whirls, in all respects

like ordinary cyclones, and that the whirl may vary from one mile to ten miles or more in diameter. There are frequently several whirls near together or following one another along the same track. The numerous oscillations in the barometric curve are evidently due to the passage of a succession of atmospheric whirls, and it appears that lightning strokes are most frequent when these oscillations are numerous.

— **MR. F. J. BRODIE** read a paper "ON THE PREVALENCE OF FOG IN LONDON during the twenty years 1871 to 1890." The popular notion that November is par excellence a month of fog is not confirmed by the figures given by the author. The number of fogs in that month is, if anything, slightly less than in October or January, and decidedly less than in December, the last-mentioned month being certainly the worst of the whole year. The latter part of the winter is not only less foggy than the earlier part, but is clearer than the autumn months. In February the average number of days with fog is only 6.6, as against 8.9 in January, 10.2 in December, 9.2 in October, and 8.8 in November.

— **COBHAM PARK.**—In Smith's "Gravescend Almanack" we find an interesting description of walks and rides round Gravesend by our able correspondent, Mr. J. R. S. Clifford. We cite the following on Cobham Park:—"Cobham Park gives us a fine display of noble and ancient trees. It has large Oaks, though none of great age, avenues of venerable Limes and Chestnuts, handsome Pines and Firs, with many kinds we cannot enumerate, and it is remarkable for the show it makes in early summer of that grand exotic flower the Rhododendron. To the naturalist it is interesting as the resort of birds and insects, being the home of some both curious and rare. So, too, Shorne Wood, and others around Cobham; but as they are also preserves of game the stroller needs to be careful, for he may be suddenly 'warned off.' The Darnley Mausoleum in the Park, perched upon an eminence, is a conspicuous object; erected a century ago, it has never been used for the purpose of interment. Cobham Hall takes high rank amongst the family mansions of our nobility. Its centre is one of the memorials of the famous Inigo Jones. The wings, of date somewhat later, please the eye by their mullioned windows, quaint gables, and Tudor doorways, the deep hue of the bricks testifying to the fact that they are of the kind which stand the weather for centuries, now, alas! no longer made. Within the pile are splendid apartments and saloons, many of them filled with antiques and art treasures. (Cards to view that portion of the Hall shown to the public may be had from Mr. J. S. Caddel, King Street, also at the village post office. Admission is on Fridays, and the charge 1s., the proceeds being given to a charitable object.) Cobham itself is a pleasing specimen of the old-fashioned English village. At its Leather Bottle Inn many a traveller has enjoyed his lunch while he called up memories of Dickens' characters in his 'Pickwick Papers,' which have made this spot of enduring fame."

CHRYSANTHEMUM ROBERT OWEN.

ON several occasions during the past few weeks attention has been called to the remarkable seedling Chrysanthemum bearing the above name. The variety was first shown at the Royal Horticultural Society's meeting on December 8th last, but owing to there being only one bloom no award could be made for it by the Floral Committee. The same difficulty occurred at the National Chrysanthemum Society's Show on the next day, but there it obtained a special prize. Early in the season Mrs. Myers had offered two prizes of a guinea each for the best new Japanese and incurved Chrysanthemum of the year; but these not having been awarded, it was resolved at the meeting on December 9th to divide the amount into four prizes of half a guinea each. As only three novelties were found worthy of the prizes, two were adjudged to Mr. Owen for his namesake, and another for the incurved Henry Perkins.

Chrysanthemum Robert Owen is a seedling raised at Mr. Owen's nurseries, Maidenhead, and described as resulting from a cross between Sarah Owen and an American seedling. It is an incurved Japanese, the bloom shown being  $7\frac{1}{2}$  inches in diameter and  $4\frac{1}{2}$  inches deep; the florets broad, tapering to an acute point, and strongly incurved, forming a deep massive bloom of a rich bronzy yellow tint. The development of this variety will be watched with much interest another season, for it is one of the most distinct yet secured. The illustration (fig 98) was prepared from the bloom when shown at the R.H.S. meeting.

## CHRYSANTHEMUM VIVIAND MOREL.

FOR the last six years I have been growing Chrysanthemum Vivand Morel, which was described in the National Chrysanthemum Catalogue for 1888 as white lightened flesh colour, medium or large cup-shaped.

show flower. On receiving the *Journal of Horticulture* for 17th December, I find therein (fig. 95) Vivand Morel a totally different flower. Can nothing be done to prevent this confusion? Is it yet time to change the name of this new variety? We have two Duchess of

FIG. 98.—CHRYSANTHEMUM ROBERT OWEN.

This is a useful as well as beautiful flower of sturdy, vigorous dwarf habit. Seeing Vivand Morel very much praised, I naturally thought my old favourite was coming to the front in an extraordinary manner, for though a valuable variety it does not deserve premier place as a

Albany, surely it is not too late to prevent our being saddled with two Vivand Morels. When ordering a plant of the new variety what guarantee shall I have that I am not growing my old friend till the new plant comes into bloom? and, meanwhile, how am I to distinguish the

one from the other? for I do not intend to throw the old variety away. The old one like the new is extremely liberal in the production of suckers for propagation, a quality by no means to be despised. I would suggest that M. La Croix, the raiser, be communicated with forthwith, and that he be asked to rechristen his variety, say as Exeelsior.—J. EREAUT, *The Beeches, Jersey*.

P.S.—*Apropos* of names, the Strawberry Waterloo is neither more nor less than La Palmée, a variety I procured from Leroy, of Angers, in 1863.

#### CHRYSANTHEMUM MRS. ROBINSON KING.

THIS is a deep golden sport from Golden Empress, which originated at Mr. Robinson King's, North Ferriby, Hull (gardener, Mr. Hotham). It is, without doubt, one of the finest additions to the incurved class ever introduced. It possesses all the excellent qualities of its parent in florets, form, and size of flower, and is as deep in colour as Jardin des Plantes. I exhibited it at several shows this year, and it was the admiration of everyone who saw it. I have seen several spurious forms of Mrs. Robinson King, but much lighter in colour than the true variety. The entire stock has been acquired by Mr. Owen of Maidenhead, and will be distributed by him in the spring. Such a grand acquisition as this is sure to be eagerly sought after, and will find its way into many a prize stand next year.—PETER BLAIR, *Trentham Gardens*.

#### CHRYSANTHEMUMS AT SINGLETON PARK.

IT hardly needs an apology to write of Chrysanthemums at this season of the year, much less is it necessary to apologise for a note on those at Singleton, Sir H. Vivian's well known establishment at Swansea. The "fever" may well be said to have spread, as in the district generally, as evidenced by the very fine show provided recently. Many of the earlier sorts were over at the time of our visit, but sufficient were left to convince us that Mr. Ireland, the gardener, is in the front rank as a grower; indeed, some of his blooms were much the finest we have seen this year, notably the following—viz., Volunteer, Miss A. Hartshorn, and Mrs. Alpheus Hardy, all grown in 7-inch pots. The latter variety carried four fine blooms. Had not been treated in common with other varieties, but kept inside throughout the season, and not fed with stimulants. Mr. Ireland uses oyster shells freely for drainage, and finds the roots penetrate the scales of the shell, and doubtless derive nourishment therefrom, thus the shells answer a double purpose. Ground bones seem the favourite food, and Mr. Ireland feeds the plants in all stages; that is, as soon as the pots are filled with roots, whether in a small state awaiting potting, or in a more advanced state, a potful of roots is a signal for artificial feeding.

Personal attention, too, is the secret of much of the success here. Mr. Ireland doing himself what he wants done well. This is no reflection upon his young men either, who are ever anxious to assist; but ideas grow and cannot be transferred in a fully matured form from one mind to another in an instant, and the young men have a better chance of grasping the idea by witnessing the practical demonstration and watching the results.

About 300 plants are grown specially for large blooms, and an equal number for bush and cutting purposes. Pompons, too, are well cared for. We would like to note down other things, too, in passing through fruit and plant houses, but will reserve for another occasion with a mere mention of some very fine plants of *Adiantum farleyense* that are luxuriating in what many would think an enviable condition.—JOHN JONES.

#### NEW CHRYSANTHEMUMS.

(Continued from page 514.)

##### ANEMONES.

THE large or show Anemone class is by some very much appreciated since so many new varieties have been secured, the colour in consequence being considerably brightened, which was a drawback to the popularity of this section. The present season has been productive so far in bringing out several new varieties, the following being the more noticeable.

*Delaware*.—Centre or disc full, of a sulphur colour, the guard florets pure white.

*Enterprise*.—Sulphur coloured centre, with a complete row of tubular florets, rich pink in colour, form the guard florets.

*Miss Margaret*.—This must not be confounded with the old white variety of that name. The guard florets in this case being of a silvery pink shade, the disc, which is both full and high, sulphur or soft yellow.

*Gladys Spaulding*.—Brassy yellow, full centre.

*Duchess of Westminster*, so far, is the only new variety worthy of comment in the Anemone Japanese section, which is one of Mr. Owen's seedlings, in the way of Duchess of Edinburgh, but considerably better; in fact it ranks as one of the best in the whole section, having all the needful characteristics. The centre is exceptionally full of well formed florets, rosy bronze in colour; the long drooping guard florets silvery bluish.

*M. Charles Leboeuz* maintains the high opinion formed of it when it first appeared, and is now one of the most popular in that section. The colour is unique, a bronze ground with an old gold suffusion, deepening towards the tips of the florets. The centre or disc is full and neatly rounded, the guard or ray florets of that length which enhances the beauty of the flower as a whole.

##### REFLEXED.

Any worthy addition to the reflexed section is always welcome. So few are obtained to this class that any advance upon older varieties is

sure to receive a fitting tribute. So far as I am aware there are but two which are worthy of note. R. Smith, a sport from Dr. Sharpe, the colour being reddish, the florets flat, more so than in the parent, which at times are tubular, owing particularly to the selection of early buds for the development of the blooms; anyhow the addition is well worth a place in the too limited number of varieties.

*J. H. Bradbury* is in colour a warm brick red tipped and edged with gold, a full bold flower when well grown. I do not know its origin, but saw it for the first time at the Ascot Show, where reflexed varieties are perhaps better staged than anywhere else.

##### POMPONS.

Pompons are great favourites with many persons, but this section is seldom increased by really first-rate sorts.

*William Westlake* is a really splendid addition. The flowers are just of that size—neither too large nor the reverse—to fit it for either exhibition or home decoration. Some sorts when cultivated to bring out their fullest development are much too large and coarse to take a proper place in a stand of true Pompons. The colour is a rich golden yellow, with a faint suffusion of a reddish tint as it expands. The flowers are neatly formed and most freely produced; the habit of the plant is vigorous, running up to 6 feet when allowed freedom.

*Golden Marabout* is a sport from the well-known variety of the latter name, which is regarded as one of the best; white with a faint suffusion of blush, the florets serrated. The new form is exactly like the parent, except in point of colour, which is a pure gold tint.

*W. Saby*.—Chrome yellow, shaded orange; capital form, either when disbudded freely or allowed to develop in clusters.

Of all the newer introductions in the small-flowered sections, none is more valuable than the new Anemone Pompon Emily Rowbottom, which is a sport from Marie Stuart; pure white both disc and ray florets, and of capital form, quite one of the best, and for cutting a gem. The plant produces spikes of bloom fully 15 inches in length, and are charming for filling vases either alone with any suitable greenery, or in conjunction with spikes of its parent equally well flowered.

##### SINGLE VARIETIES.

In the south of England especially this charming race of Chrysanthemums receive much encouragement; their great beauty and usefulness is recognised and appreciated for either conservatory decoration, cut blooms in quantity, or cultivated to their full size, and staged at exhibitions in threes. At one or two of the northern shows they are to be seen in fairly good condition, but not nearly so well as their merits deserve. I am most partial to this section grown in any form, and am always looking out for any worthy addition, and am pleased to say there are several this season which, for the benefit of Journal readers, I will describe. By far the most successful cultivator of these varieties is Mr. Agate, Havant, who stages them in perfection at the southern shows, where they are always admired.

*Oceana* I regard as the best variety in existence. The blooms are of good size, and the florets are semi-drooping at the points; the colour is the palest pink—in fact, this variety has all the characteristics of a perfect single Chrysanthemum.

*Mrs. D. B. Crane* is quite alone in the matter of colour, a cerise pink. I know no variety with quite the same shade of colouring, the only fault is the upward tendency of the points of the florets instead of their drooping gracefully.

*Golden Star* is very striking. The colour has a great charm, a deep yellow without verging to orange; the flower is large, the florets making a perfect circle, rounded at the tips instead of being rather pointed as is generally the case. Those persons who appreciate single Chrysanthemums ought to add this one to their list.

*Miss A. H. Bates* is pure white, variety of much promise, with broad flat florets.

*Jenny Lind* has yellow flowers tinted with orange.

*Jessie Chignell*, very dark red, finely pointed petals, very distinct, and good.

*Ecquisite*, delicate blush, charming variety.

*Miss M. Wild*, medium size florets, circular in form as a whole; outer half of petals deep rose, lighter towards the centre, quite distinct and good. Charming has soft yellow coloured flowers which are not common in single Chrysanthemums. I know of no variety which is more free flowering when grown as a natural bush, allowing all the shoots which grow from the first natural break to develop all their buds. A most desirable kind.

*Florence*, blush white. The points of the petals recurve most gracefully; a pleasing variety, which should be in every collection.

*Yellow Jane*, the exact counterpart of White Jane, except in colour, which is a rich gold.

*Guernsey Sunset*, rich deep yellow, shaded with a tinge of carmine; large, very showy, and desirable in every respect.

*Nymphaea*, pure white, with a pleasing perfume.

*Milly Agate*, blush.

*Coquette*, rosy pink.—E. MOLYNEUX.

#### JOINTS IN HOT-WATER PIPES.

THERE appears to be some lack of knowledge regarding this matter. An ordinary labourer many years ago relaid the hot-water piping here, at the same time adding to and re-arranging it where necessary. The packing material used was sal ammoniac and iron filings. I showed him

how to proceed, and not one joint has given way or burst. Of late years we have not employed this material, but no doubt where permanent work is wanted, and more especially in cases where pipes are covered in, there is perhaps no better material going yet. "The loss of time in picking out joints" is commented on as being an unfavourable point against iron and sal ammoniac. Well, it is. I have a lively remembrance of a fitter spending many hours trying to dig out such a joint, and at last having to give up, at the same time that the patience of the proprietor was exhausted.

I do not know anything of pipes giving way during severe frost, but I have several times had to alter piping, and have had to add more to what was already down. The method of procedure was very simple. If we wanted to attach more piping to a house, the pipes were cut clean through far enough from the joints to allow the elbows or syphons to be used again. This of course requires to be done at each end of the house where the heating system enters and leaves, and at the further end where the flow returns. The necessary pieces are then fixed, short lengths of piping to make good that removed having been jointed before attaching to the main pipes. In a case of adding the heating system to a new house, the arterial pipes are cut so as to allow the two necessary tee-pieces to get in, a "thimble" piece jointing one end of each, and an ordinary spigot joint the other. A drawback, common alike to cement, vulcanite, and iron joints, has not been noticed by any of your correspondents. In all large systems of hot-water piping there is much expansion and contraction of the iron continually going on. Joints composed of the two former materials are the more easily ruptured, but in the case of the latter there is also risk. I have known several cases where no means of allowing the pipes to expand and contract had been provided, and where in consequence mischief followed.

I will now mention a joint which I employed for the first time this autumn, and which I imagine is well worth adopting. During summer I had an opportunity of visiting some of the large market-growing establishments near London, and, by the way, I may say they were worth visiting. In one of them men were busy, some bricklaying, others painting, others again at hot-water engineering. The latter attracted my attention at once, for they were making joints with a rapidity and ease quite novel to me. I turned to my guide for information, and I had everything explained verbally and by demonstration in less than five minutes. If I may again intrude another sentence here, it is to say how kindly the several growers I met explained anything that was asked, and how pleasantly they imparted information on cultural points. To return to our joints. I found they were simply indiarubber rings or washers, one of which formed a joint. The ring was first placed on the spigot end of one pipe, then the socket of another was pushed over it, when, with a jerk, the two seemed to go close together. I found the joint was efficient and durable; as I saw, easy to fix, the price very moderate, and the vendors the Thames Bank Iron Company. I had some work on hand a month or two previously which would have saved much trouble if these rings had then been known. Another was about to be started, and I quickly made acquaintance with the rubber ring, as one of the men said the joints were made like "winking." Of course there are other expansion joints, but they are expensive as compared with these, which I think are as cheap as anything that can be used for making joints.—B.

## THE ROYAL HORTICULTURAL SOCIETY'S JOURNAL.

THE most recent issue of this Journal (part 3, vol. xiii.) contains much interesting matter, including the papers and discussions at two of the Chiswick Conferences, together with the papers read at the ordinary meetings of the Society from June 9th to September 22nd. The reports of the Committee meetings also extend over the same period.

The subjects comprised in the part are as follows:—"Alpine Plants," by the Rev. C. Wolley Dod, M.A.; "Tea-scented Roses," by Mr. T. W. Girdlestone, M.A., F.L.S.; "Conference on Hardy Summer-flowering Perennials—'Wild Gardening in Meadow Grass,' by Mr. W. Robinson, F.L.S.; 'Some of the Summer Flowers of my Garden,' by the Rev. H. Ewbank, M.A.; 'The Picturesque Use of Hardy Summer Perennial Plants,' by Miss Jekyll—"List of Hardy Perennial Plants Suitable for Various Purposes;" "Conference on Small Hardy Fruits—'Strawberries for Private Gardens,' by Mr. W. Allan; 'Strawberries for Forcing,' by Mr. G. Norman; 'The Gooseberry,' by Mr. D. Thomson; 'Raspberries,' by Mr. G. Wythes;—"List of Small Fruits for Private Gardens;" "Early Peaches and Nectarines," by Mr. T. Francis Rivers; "Ornamental Stove and Greenhouse Plants," by Mr. James Hudson; "The Gladiolus," by the Rev. H. H. D'Ombraim, B.A.; "Hard Water and Bog Plants," by Mr. Geo. Paul; "Insectivorous Plants," by Mr. R. Lindsay; "Insect-catching Plants," by Mr. Lewis Castle.

From these we select for reproduction the following useful chapter by Mr. Geo. Paul.

### HARDY WATER AND BOG PLANTS.

MY paper was to have been on the subject of hardy bog plants, in the culture of which I have had some experience. The Secretary has, I find, coupled them with water plants, of which I know but little. My remarks, therefore, on these last must be confined to giving my limited experience with them, an enumeration of the difficulties I have had in planting them in somewhat difficult places and under exceptional circumstances, and to giving a description of a very pretty and successful, if a comparatively small, water garden which my friend Mr. M. F. Campbell has made at Hoddesdon. I will append a list of plants which

I have found to be useful. In the first place, I was led to pay special attention to hardy bog plants from possessing a small patch of natural bog, which, as a haunt of rushes and sphagnum, was an eyesore in an otherwise well cultivated garden. Such a patch is to be found in most large gardens and pleasure grounds situate on the hillsides of our valleys—a springy patch developing into a tiny marsh, and beautiful with masses of such flowers as the Yellow-rattle and the Cuckoo-pint, or covered with big Docks, Rushes, or Giant Hemlock.

Then turning to many of the moisture-loving perennials, such as the Spiræas, I was struck with their great beauty of development when by chance they found a moist and favourable spot, whereas when planted as usual in the mixed herbaceous borders one never saw their full beauty; with the setting in of dry weather they failed to finish their growth or to produce their flowers satisfactorily, and if subjected to two dry autumns consecutively many of them died out altogether. Here there were two things—a site wanting furnishing and plants seeking such a site, for there are few more lovely plants in their full beauty than the Spiræas, to name only one family of plants. From the common Meadow-sweet of our valley marshes all over England, through the beautiful Japanese forms, such as *S. palmata* and its white variety, up to the gigantic *kamtschatica* exhibited two years ago in this hall, with spikes 6 to 8 feet high of light feathery flowers, all are plants of great beauty when fully developed, and to attain this development a moist, boggy spot is essential.

There are several families of plants, which I will enumerate later on, which lend themselves to a like cultivation. I have made two bog gardens, both devoted to the growth of bog and mud plants. The first was a natural sphagnum and *Drosera*-producing bog on the Bagshot sand formation, which with some little difficulty was brought into cultivation, so that I may perhaps briefly describe the process.

It was a spongy piece of land about 12 yards square, about half-way down the slope of a hill, at the foot of a bed of gravel. It was treacherous walking to reach the little bed of Sundew, and the one difficulty in forming the garden was to make suitable paths. This slight difficulty was overcome by firmly driving in posts, and resting some long split trees on them; the split branches of the same trees were then nailed crosswise, thus forming what the Americans call a "corduroy" path. The top black soil was cleared away until we reached the clay or watery sand (in which we found an old Oak trunk fast passing into bog oak). The whole was then arranged in terrace beds by means of clay banks, on the top of which ran the corduroy paths. The water after use in the top beds was led in pipes through these clay banks to the next lower beds, and so onwards, varying the quantity of water according to the amount of moisture required in each bed.

A small pond, in which the Cape Pondweed flourishes, was made, and from it the water not required for the lower beds flowed into a narrow watercourse, along the sides of which, with their roots in the water, *Kämpfer's Iris* blossoms well. The highest bed is the wettest owing to the spongy water-spring, and just at this point the variegated *Iris pseudacorus* luxuriated. Other mud plants used were some varieties of *Caltha* or *Marsh Marigold*, which for nearly a month are sheets of yellow blossom; the variety in this family is more noticeable from the time of blooming than from the shape and variation of the flowers. On the sloping bank, above this bed, are naturalised masses of the beautiful *Fern Hypolepis millefolium*, while *Lily of the Valley*, which had originally grown on the bank, is preserved *in situ*; the *Blood-root*, the *Musk and Creeping Jenny*, both famous London window-plants, the native *Club-moss* (*Lycopodium clavatum*), two or three British kinds from Westmoreland, and the *Alpine Blackberry* (*Rubus arcticus*), which fruits, it is said, beneath the snow of the Arctic regions, were added.

Some curious instances of the travelling powers of plants have also occurred. From the drier part of this bed the *Iris* moved down into the water of the pond, whilst the *Trollius*, or *Globe Flower*, and the *American Fern*, *Onoclea sensibilis*, have gradually moved up on to the drier bank above.

The two next beds on a lower level were planted with the *North American Pitcher or Side-saddle Plants*, *Sarracenia purpurea*, *S. Drummondii*, and *S. flava*. The purple variety soon made itself at home, flowering and seeding and producing offsets abundantly. *Drummond's* variety exists, while *flava*, a native of the more Southern States, succumbed to the first hard winter. On this level the beautiful *Madeira Orchis*, *O. foliosa*, produces spikes of flowers 18 inches high, whilst I learn that it is almost extinct in *Madeira* from the effects of two or three dry seasons. The double white and pink *Ragged-robins* are beautiful in this place; the tall yellow *Meadow-rue*, and its purple and other forms, grow and flower freely, as do also the *North American Liatris*, with their noble spikes of dense purple flowers, and our *English Bog-bean*, or *Menyanthes*. Borrowing a hint from Kew, we planted the blue *Himalayan Poppies* (*Meconopsis*), which have not yet had time to flower, but evidently intend to do so next season. The finer sorts of *Iris Kämpferii* are here as well as on the margins of the brooks.

On the sides of the pond are varieties of *Osmunda regalis*, which have shed their spores in the interstices of the corduroy path; the *Alpine Willows*, and the fine big-leaved *Saxifrage peltata* and *Hirculus*.

The next lower beds soon became the home of the *Japanese Primula* and the *Himalayan P. rosea* and *denticulata*, which, once planted, seed freely after the manner of biennials. The *alpine Primula viscosa* and other water-loving kinds thrive here.

The lowest beds of all were made to hold the *Spiræas*, of which the most beautiful are *S. Aruncus*, *S. palmata*, the white *Spiræa Ulmaria plena*, and the newer *S. astilboidea*, with its better kind, *S. floribunda*.

The other kinds I give in a list at the end of this paper. The North American Lilies, such as *pardalinum* and its varieties, also *superbum*, give autumn flowers, mingled with the *Spiræas* in this bed. The double *Cardamine* is a weed here carpeting the ground, and the Zebra Reed (*Eulalia*) is most effective.

Some very pretty variegated Sedges (*Carex*) do well in these beds. I am getting sphagnum established on the wet top bed, on which no doubt the Sundew will also re-establish itself. I had forgotten one plant which I owe to Mr. Wilson, of Wisley—the large American Cranberry.

From these remarks I think it is evident that a bog garden may be made into a useful as well as a very bright and interesting spot, as my High Beech garden has been for some years. Now as to the second garden made on an entirely different site and strata, and in a different manner. I venture to think that such a place may be made in any of the damp, springy spots such as I spoke of as existing in most gardens, or indeed wherever the clean waste from a pump, a tap, or from the house-top can be led. I wanted soil to raise what my friend Mr. D'Ombraïn has facetiously styled "The Broxbourne Alps," and as I had only a flat surface to deal with, I formed a square pond at the foot of the line of one side of this projected hillock, using the earth for the hillock. I kept to the terrace formation, making about three levels, and into them I led the drains from the paths adjoining the nursery quarters, taking means also for artificially flooding them occasionally, in case of drought. After very heavy rains the beds on all three levels are entirely covered with water, which gradually sinks down into the pond-like hole in the centre, in which Bullrushes, the giant Dock, and the Water Iris flourish.

It will be noticed that the idea of the clay banks is preserved, to retain the water a short time in the upper reaches of the pond. This pond was carefully puddled, as the loam resting on gravel is thoroughly porous. All the beds were then filled up with black peat and leaf soil, into which the plants were put. Most of the kinds thriving at High Beech do well here, and have the advantage of more space. The bolder foliage plants, such as the Bamboos *Metake*, *viridis*, *glaucescens*, and the large *Polygonum sachaliense*, attaining 8 to 10 feet in height; the dwarf varieties *P. compactum* and *molle*, with their *Spiræa*-like blooms, are useful at this time of the year. Then two or three of the American plants, such as the *Andromeda pulverulenta* and the dwarf *Ledums*, are beautiful winter evergreens and love the moisture. *Primula farinosa* and *involucrata* or *Munroi*, *Asclepias tuberosa* and its pink form, are at home, and the *Astrantias* are almost too free. *Claytonia sibirica* becomes a weed. *Corydalis nobilis* and *lutea*, in the higher beds, form beautiful yellow patches, and the *Trillium* and *Cypripedium* do well in peat on the banks just above the water levels. *Dielytra spectabilis* assumes quite another form to that usually seen, and *Dodecatheon Jeffreyanum* is 1½ foot high. The Willow Herbs have to be banished, from their determination to monopolise all the space. *Euphorbia*, *Cyperus*, and *Stylophorum japonicum* make dwarf groups. *Helonias bullata*, a beautiful pink-spiked plant, wants the moistest place; and all the purple *Hellebores*, or *Lenten Roses*, thrive. *Iris aurea* is beautiful in June or July, and some of the *Mertensias* thrive well there. The Duck-foot, or *Podophyllum*, are also at home. *Senecio pulcher* takes wonderfully to the moist upper beds, and some few other plants which I have named in my list of bog plants. I am inclined to think that some such wet, peaty beds should surround all well-constructed rock-gardens. There are so many of the Alpine plants which love moisture at the root, with in some cases full exposure to the sun, and in others enjoying shade. Some of the Alpine *Primulas* would grow well in shaded bog. I have *Primula involucrata*, *nivalis*, and *Wulfiana* all doing well in such positions, as well as the *Dryas* and several *Campanulas*, which soon dry up on the higher shelves of the rock garden; and with the many North American and Himalayan plants, such as *Meconopsis*, which are likely to enrich our Alpine gardens, this is the secret of culture. Where water can be retained, all bog gardens should have their central or through-running pond, and here the culture of water plants can be judiciously and easily joined with that of bog plants. Such is Mr. Campbell's garden, which I will attempt to describe somewhat to you.

His water supply is the overflow from the house roofs, stored in two or three tanks of various kinds, to secure a constant supply in case of need. It is on the sloping side of a hill, and consists of a series of small basins, very artistically surrounded with small rocky banks, on which many Alpine plants succeed. Each part is devoted to one or two, or at most three, kinds of Water Lilies in the deeper part, while the rather shallower sides have some water plants which do not require any great depth of water. Thus the upper pool, 3 feet deep, is devoted to yellow Nuphars of various sorts. In the next is *Nymphæa tuberosa odorata*, with a red centre, and a very fine form of the white Water Lily; in the shallower water being *Arum virginicum*, the flowering Rush (*Butomus umbellatus*), and the three forms of Bullrush (*Typha latifolia angustifolia*, and *minor*). The third pool is full of *Aponogeton*, or the Cape Pondweed, the yellow Iris and a locally found white variety, the *I. Kæmpferi*, *I. foetidissima*, and *I. pseudacorus*, a variegated form of *Carex riparia*, and the Zebra Rush (*Juncus zebrina*). On the rocks close down to the water, looking north, Ferns seem to do exceedingly well. The Marsh Ferns, North American *Claytonia*, and even the two *Hymenophyllums* cover the rocks; while the *Spiræas* and other bog plants to which I have alluded clothe the banks. A little island of sphagnum rising out of the water on a clay hillock has *Pinguiculas*, or Grass of Parnassus, and the mealy Primrose of the Scottish moors. Altogether this picturesque little garden, filling what would be other-

wise a shady, damp corner, is, throughout the spring and summer months, one of the most interesting parts of the garden.

In Mr. Lynch's water garden at Cambridge there is a large central pond with narrower beds on either side, and a much more extensive collection of plants are there grown.

I understand he has all the newer and rarer of the hybridised Water Lilies, including, I believe, the pink one, which is now beautifully in flower in several of the Hertfordshire gardens. The *Sagittarias*, or Arrow-heads, with the beautiful double one, thrive well in such a water garden. The Marsh Plantain is a distinct and bold-looking plant. The Water Mimulus (*M. luteus*) on the margin of the banks makes glorious masses of yellow.

During the past year I have had great difficulty in planting pieces of water with suitable plants. One was a piece of water where, the bottom being cemented, there was no foothold for the plants. This difficulty was obviated by putting the water plants in paraffin tubs cut in half, and sinking them to the required depths. The plants succeeded admirably, and are easily kept free from weeds. The other was a swift-running stream, about 4 feet deep, through the chalk. Some large specially made drain-pipes, into which the plants had been put, had the lower ends worked into the chalk bottom, and some large burrs built up in a hollow manner round groups of three or five prevented the plants and pipes being washed away, and at the same time gave plenty of shelter to the trout with which the stream abounded. A small island formed in the same manner, and covered with *Calthas* and *Sarracenias*, has been successful.

### THE CULTIVATION OF THE TOMATO.

THE usual fortnightly meeting of the Devon and Exeter Gardeners' Mutual Improvement Association was held at the Guildhall under the presidency of Mr. D. C. Powell. During the meeting a specimen of the *Richardia africana compacta*, a kind of dwarf Arum Lily, was on the table for inspection by the members. The plant was one which had been exhibited at a meeting of the Royal Horticultural Society on the 27th October by Messrs. Robert Veitch & Son of Exeter, when an award of merit was unanimously accorded it. The ordinary business of the meeting having been transacted, the Chairman introduced Mr. W. Rowland, who had promised to read a paper on "The Cultivation of the Tomato" to the meeting.

Mr. Rowland said:—"My Experience with the Tomato," seems to me, on second consideration, a better title to my paper than "On the Cultivation of the Tomato." I intend to give my own personal experience, both with regard to my successes and failures. It is well known in the fruit department a failure with the Grape crop is about the worst thing that can happen to a gardener; the same, I think, can be said in the vegetable department with regard to the Tomato. One stands in amazement when he thinks of the rapid strides this vegetable has made in public estimation. Forty years ago it was practically unknown to the general public, and plants were only to be found in a few private gardens, where, as a rule, they were grown as much for their ornamental nature as for their use. Now everyone knows the difference. It seems uncertain at what date the Tomato was introduced in this country, but probably it was during the latter part of the last century. It belongs to one of the largest of our natural orders—viz., *Solanaceæ* (the same as the Potato), and is found wild in Brazil and on the coast of Mexico. The first Tomato plant I ever remember seeing was growing uncared for in the moist bottom of a gravel pit. Apparently the seed had been carried there by a bird in the same manner as we see the Gooseberry bushes growing practically wild in the woods. I remember the plant had a splendid crop of fruit, also the first impression I had on tasting the fruit. Since I have become better acquainted with this plant the remembrance of seeing it growing in such poor soil has shaped my own mode of cultivation to a certain extent.

### INDOOR CULTIVATION.

Now I will try to explain my mode of treatment year by year, since I have taken a special interest in Tomatoes, giving both the good and the bad results. About six years ago Mr. Brock had erected a span-roof house. The thought struck me it would be a capital house for Tomatoes. The house is 8 feet high, with a 3 feet path in the centre, and a bed on each side 4 feet wide. The beds are not heated, but were filled up to within a foot of the top with soil that was taken out of the path. About 2 inches of coal ashes are spread on top, on which stand *Bouvardias* and *Cyclamens*; in winter a 4-inch pipe flows round the house. Having procured plants of the old Large Red variety, and potted them in 5-inch pots and placed the pots in a line on the ashes about 18 inches apart, I covered the pots with a ridge of loam, top-dressing with loam. The result exceeded my most sanguine expectations. The plants began to fruit so low on the plant that they rested on the ground. As the fruit began to swell I gave them plenty of liquid manure to swell up the fruit, the result being very little foliage to cut away, and plenty of good fruit.

For two years I kept to the plunging-in-pot system and had good results. I may add that I kept to the Large Red, selecting the best fruit for seed. After this the Large Red variety began to get too common, and I started with other sorts. At the same time I gave up the plunging system and planted out in the usual way. The result was that the plants grew so rapidly and made so much gross wood that I had to stop the copious waterings I had been in the habit of giving. Then it was I first became acquainted with the Tomato disease, which made its

appearance directly I stopped the water supply. For the first time Tomato growing was a failure. Next year I tried the planting out system; again failure was the result.

In the beginning of this year I thought failure the third time would never do. I must return to my first plan. So I started very carefully with four sorts—viz., Sutton's Earliest of All, which I find very much like the old Large Red, Hathaway's Excelsior, Dedham Favourite, and a very fine variety I had from Winslade. Instead of one row of plants in each bed I planted two, taking care to plant the bed the north side of the house first, so that the plants gained the full light from the south side. Afterwards I planted, or rather plunged, the pots on the south side of the house, taking care not to let the plants starve before plunging. The thought of the dreadful Tomato disease came over me, so I determined to be very careful in airing. In fact, I left the ventilator open day and night; at night about half an inch at top and the same at the sides, so that the air was kept fresh and moving. The plants started capitally, and began to set freely at the base of the plants; when the fruit got the size of marbles I began to feed and water freely. I also top-dressed to make the soil level between ridge and ridge. The first manuring I gave was one of native guano, which I scattered plentifully between the plants; then with the hose I gave them a perfect deluge of water. The next time I used Thomson's Vinc manure, well drenching it in. The third and last manure I used was Peruvian guano, which I sprinkled about in the same manner as the other manures, but taking the precaution to have the hose running at the same time to prevent the guano burning the roots, which were by this time running luxuriantly. A friend coming in at the time exclaimed that I had ruined the house of plants, as all the roots must perish. Result—a better house of Tomatoes I never saw, and all free from disease.

#### OPEN-AIR CULTIVATION.

My experience in open-air culture has not been great. Several years I planted out, but I think owing to the lightness of our soil I could do nothing with them. This year, for the first time, I tried plunging out in pots. The result was that I cut from the open by the middle of August and have had a succession till October, not cutting a single Tomato to ripen in heat, as many have done this sunless summer. I give an extract from a correspondent at Manchester. He says, "Living not very far from Manchester, I cannot boast of having the largest share of sunny days, but for fog and smoke I believe we can vie with any district in the kingdom. Nevertheless, I generally succeed in getting a good supply of Tomatoes well ripened before autumn frost sets in. I propagate by cuttings, putting them in about the beginning of September, and propagating from them in the following spring. In this way plants bear and ripen sooner than those produced from seed. Now, my experience of plunging in pots is that I get the same result as propagating from cuttings. The great difficulty we have now in keeping cuttings through the winter is the disease."

#### DISEASES OF THE TOMATO.

The most common is the *Cladosporium*, which affects the leaves. Its first appearance is marked by whitish, woolly patches on the under-side of the leaves, which rapidly increase in size and number, at the same time deepening in colour till they are of a dark brown. Another disease—*cladosporium lycopersicum*—unlike the other form, attacks the fruit. Black spots are observed where a clean eye should exist. It rapidly spreads, and, by the time the fruit is ripe, it has become a mass of decay of a jet-black colour. I have never seen this disease in plants grown under glass. I had a few fruits attacked with it towards the latter part of the season in the open. *Dactylium roseum* appears in the form of a rose-coloured mildew upon the foliage. Though, fortunately, not very common, it is a most deadly disease, affecting plants in the open as well as under glass. *Peronospora infestans* is identical with the ordinary Potato disease; it attacks the Tomato both in the open air and under glass. It first appears in the stems and foliage, and in severe cases spreads to the roots, in which case the plant speedily dies. It is identified by the peculiar odour that is noticeable in a field of diseased Potatoes. A positive remedy for *Peronospora* is said to have been found in sulphate of copper, the Inspector General of Agriculture to the French Institute having recently reported that he had found a solution of six parts each of the sulphate and of lime in a hundred parts of water, the plants to be thoroughly syringed with the liquid twice or thrice in succession, watering at the same time with a solution of sulphate and ammonia and a little soot to enable the plants to grow out of the disease. My advice is, "Prevention is better than cure." Keep the plants in a perfect state of health by carefully looking after the airing and watering. Wherever the shutting up system is practised then the disease is invariably present, and since I have left the ventilators open a little night and day I have had no disease.

I think the only insect which attacks the Tomato may be said to be the aphid, or black or green fly, which may be dealt with by fumigation, or syringed with tobacco water. If red spider or thrips occur, it is in consequence of gross neglect.

#### VARIETIES.

The following I believe to be the best at present in cultivation:—Perfection for its solidity, Hathaway's Excelsior for sure-setting properties, Dedham Favourite for its handsome shape, King Humbert because it does well in the open air, Hackwood Park, the old Large Red, a sure and abundant cropper, and for a pretty yellow variety Golden Sunrise. Flying Dutchman, a new variety, sent out by Messrs. Veitch of Exeter is highly spoken of both for its fine flavour and free setting

qualities. Surprise, I have no doubt, will be caused by my leaving out Ham Green Favourite, but as I have not given it a fair trial I do not feel qualified to speak for or against it. From what I have seen of the fruit I should think it is of great merit. You will see by the plan that the house I grow Tomatoes in has not a long rafter, about 8 feet, I believe. It is necessary that the plants fruit low. By plunging in pots the plants are stopped from making that over-vigorous growth, and by the time the plants require more nourishment than they get from the soil in the pots, roots are parted from the stem above the pots, top-dressings of loam are given, and a good crop of fruit is secured from the base to the top of the plant. Mr. Bartlett was telling me he had been speaking to a gentleman who had seen Tomatoes grown largely in Spain. He says they are planted in trenches and flooded with water; and as it is a native of the seashore, I feel sure that plenty of water is one of the most essential elements for the Tomato.

In the discussion which followed, Mr. Lansdale said he had tried a good many varieties of Tomatoes for outdoor growing but had always found the best to be The Challenger. Mr. G. C. Crabbe (Prospect Park) endorsed Mr. Lansdale's remarks as to The Challenger variety. He said his first experience with this variety was when he had some, which were dead ripe, sent to him from his home in the eastern counties early in the second week in September. He thought that this showed that they were a good variety. Mr. Ebbutt (Winslade Gardens) said whatever variety of Tomato they grew the principal thing they would want was a firm solid loam to grow them in. With regard to disease he said he believed it generally came from indifferent management. As to water and temperature, he believed they could deluge Tomatoes and get fine fruit as long as they had good firm soil to start with. The temperature should not be less than 50°, and should be between that and 60°. Mr. A. George (of Heavitree, and late of Bickon Gardens), said by growing the plants in 10-inch pots and placing these on a hard surface they would get sure growth.

Mr. P. C. M. Veitch, Royal Nurseries, spoke as to the cultivation of outdoor Tomatoes. He had had experience in the Humbert variety. His method was to pot them hard in outdoor frames, and when they were set to plant them out in nothing but loam. This resulted in an extraordinary crop. There was not a sign of disease, he believed simply because the plants had no manure whatever about them. He thought under this system of growing the plants were very much less liable to disease out of doors. With regard to disease indoors, a good many had said it was due to stagnant air, and this was no doubt so to a certain extent; but he thought disease was also in a good many cases due to alternative temperatures at the roots. He had read of a method of curing Tomato disease. This consisted in putting the diseased plants into a temperature of over 80°. Mr. Hope said he had not heard anyone say whether one variety was subject to the disease more than another. As Potato varieties were thus subject, he thought it possible that the Tomato might be. Mr. Hope referred to the Old Red Tomato, and remarked that it was unfortunate that there was a prejudice against it among fruiterers, on account of its corrugated form, as it was one of the best varieties. The yellow Tomato was also one against which he believed there was a prejudice, but it was also a very good variety. Mr. Locke said he had heard that some people had altogether cured indigestion by eating the fruit. The meeting closed with vote of thanks to Mr. Rowland for his lecture, and to Mr. Powell for presiding.

#### BLACKLOW HOUSE, ROBY, LIVERPOOL.

THERE are many places round about Liverpool of great interest to the lover of horticulture, and on the occasion of a recent visit I had the privilege of visiting the gardens attached to Blacklow House, Roby, the residence of Edward Banner, Esq., and of making the acquaintance of the able gardener, Mr. R. Pinnington, who is a frequent contributor to the pages of the Journal.

A short run from Lime Street brought me to Roby station, and a few minutes' walk to the entrance to Blacklow House, and I at once saw that, although not extensive, the grounds and gardens had been laid out with great taste, and that every care was taken that they should be maintained in the best of condition. Near the entrance gate is one of the features of the grounds—a small but beautifully planned pond, spanned by a pretty rustic bridge and surrounded with rockeries filled with hardy Ferns and with walks spanned by arches of old-fashioned Roses, than which there is nothing better adapted for such a purpose. The pond and its surroundings formed a charming spot, and one which it was hardly to be expected would be found in such a place. Not the least of its charms was that it was so naturally constructed that it seemed as if Mr. Banner, when the house was erected nearly forty years ago, had chosen some natural pond and planted his house close by. It is not so, however, but the pond and a considerable portion of the ground adjoining was a marsh, and part was formed into a pond and the remainder reclaimed, thus making what would have been both unsightly and unhealthy into a thing of beauty. This art, which will not obtrude itself, is what should be aimed at in all such arrangements.

Passing on we come to one of the lawns in front of the house, where one of the first things which attracted my attention was one of the arrangements which are so natural and so beautiful that we are led to wonder we had not thought of it before—a bed of Roses carpeted with Musk. The bed is in a conspicuous position, and the "happy thought" which carpeted the bare earth beneath the Roses with a plant so neat in habit, pretty when in flower, and with so exquisite a perfume

deserves a special commendation. On the same lawn were beds of Pelargoniums, and a border filled with Asters, Chrysanthemum coronarium, and other useful flowers for cutting. Mr. Banner likes to have these in his garden, as, with the benevolence and kindly thoughtfulness for which he is distinguished, many flowers are sent to various charitable institutions in which he takes an interest.

Between one of the windows of the house and the conservatory was a small carpet bed, well planned and carefully kept, and although I make no secret of my general dislike of such formal arrangements I must confess that the bed was entirely in harmony with its position, and that it would be difficult to substitute a less formal arrangement which would be equally appropriate to its surroundings. The conservatory was filled with flowers in perfect health and beautifully in bloom, among them being Begonias, Fuchsias, &c., the roof covered with Passion Flowers and Tecomas. The Begonias were seedlings of Mr. Pinnington's raising from Sutton's well-known strain, and reflected credit on the strain and upon the cultural skill of the grower. Fuchsias in hanging baskets were very good indeed.

Passing from the conservatory to the early vinery we found the stage filled with well-grown Cockseombs, attractively arranged with a bank of Adiantums. Very fine here were two grand Ferns, specimens of *Goniophlebium subauriculatum*, a native of the Malay Archipelago. These specimens were splendidly grown. Caladiums were very good, and *Alocasia macrorrhiza variegata* was also very fine. The second vinery was also filled with plants such as Caladiums, Neriums, and a fine piece of *Cibotium Schiedei*. The Vines, which are young, were carrying fine serviceable bunches of Grapes, especially notable being Madresfield Court and Alicante. The object here is not to obtain monster bunches but those of good size for table purposes, and this is well attained, although plants are grown under the Vines.

With the fernery I was much pleased with its arrangements. Evidently the same taste which had laid out the grounds had been at work here also. Notable was the way in which a large number of Rex Begonias were grown in a group and not in the scattered "patchy" manner in which we see them so often in ferneries. A grand specimen by the little lakelet was that fine Fern *Angiopteris evicta*. This was specially noticeable. Many other good Ferns were to be seen, but space will not permit of entering into detail. The roof was covered with a fine plant of *Bougainvillea glabra*, one of those old flowers which will never be superseded. The walls were covered with *Ficus repens*, the dark foliage of which made a fine background for the graceful fronds of the Ferns. Curious, too, was the way in which this *Ficus* had taken possession of the door of the fernery. It had crept along and taken hold of the door, and, not content with covering the woodwork, had attached itself to the glass, and covered it closely with a network of rootlets and foliage. The opening and closing of the door did not seem to affect the *Ficus* in the slightest. I should like to know if a similar instance has been met with.

We then entered one of the most pleasing features of the garden, an avenue or pergola of espalier trained fruit trees. These form arches over the avenue which is 120 yards long, with side avenues of about 30 yards each. The framework, which is of iron, is substantially constructed, and is covered with the foliage of the trees, which are mostly about forty years old. Did they never produce fruit these avenues would be very attractive, but the crops produced are enormous. I was glad to learn that this is the rule with these trees, thus showing that, with judicious branch and root-pruning and ample feeding, even old trees can be made to yield large crops of the finest quality. Carrying grand crops were such as Williams' Bon Chrétien, Fondante d'Automne, Citron des Carmes, Hacon's Incomparable, Marie Louise, Easter Beurré, Beurré d'Amanlis, Beurré Capiaumont, Beurré Diel, Prince Consort, Passe Colmar, and several other equally good Pears. The orchard, which was filled with old standard trees, was what may well be termed a picture, so seldom are such good results achieved with old trees. Apples were a good crop also. Nearly 700 Strawberries are grown in pots; these looked well, having fine stout crowns.

Most of the fruit in the Peach house, which is 145 feet long, in two divisions, had been gathered, but the splendid fruits of Princess of Wales, Albatross, and Gladstone Peaches, and Pineapple Nectarine showed how successfully they were cultivated. Planted between the trees were Tomatoes literally roped with fruit, being such sorts as Sutton's Perfection and Golden Perfection, Hackwood Park, and a selected seedling. Then the stove was looked through, where were to be seen a number of plants for table decoration, Crotons, Calanthes, and some other Orchids, all well grown. Two other houses filled with miscellaneous plants were visited, and a very useful range of pits in five divisions, built only six months ago, some heated and others unheated, occupied some little time. These were filled with Cucumbers, Tomatoes, Cyclamens, Tuberous Begonias, which are here well grown, Cinerarias, Calceolarias, &c. A very large number of plants of the old double white Primula were here, and were pictures of health.

Time only permitted of a look through the vegetable quarters, which were stocked with vegetables of the most advanced varieties. Large quantities of Peas of various kinds are grown, and a succession is kept up over a long period. I find I have omitted the Chrysanthemums, which were evidently carefully attended to; and from their growth and luxuriant foliage gave the highest promise of grand flowers. Mr. Pinnington is no "rule of thumb" cultivator, but has taken many notes relating to the peculiarities of the varieties of the "Queen of Winter Flowers." It afforded me much pleasure to make his acquaintance, and to find that his practice is equally as good as his

cultural notes are valuable to the Journal, and I hope he will favour us with some of his observations of the Chrysanthemums.

It was pleasant to hear of the good relations existing between employer and employed. It is well for horticulture that it has such patrons as Mr. Banner, who has reason to be gratified with the results of his taste and expense.—S. ARNOTT.

### THE AMERICAN BUCKEYES.

THE North American forests are comparatively rich in Horse Chestnuts, or Buekeyes, as we are still apt to call them in America. The genus *Æsculus*, as it is now known, to which these plants belong, only contains thirteen species. Eight of these are American, if we include two little-known shrubs of southern Mexico and of the northern countries of South America, and another shrub of Lower California. Outside of America the genus is represented in south-western Europe, in the tropical forests of India, Assam and Burma, in northern and in central China, and in Japan. The different species fall naturally into two distinct sections. In the first the flowers are furnished with five petals, and the walls of the fruit, or pods, are thick and covered on their outer surface with sharp prickles. The common Horse Chestnut, which is a native of the mountains of Greece and which is now one of the most familiar of all ornamental trees, and the Indian species belong to this section. In the plants of the other the flowers have only four petals, and the fruit is smooth with thin walls; they are American, Chinese, and Japanese, and to them the name of Pavia was formerly given. The two sections are united, however, by one of our American trees, the so-called Ohio Buckeye, which has the flowers of the Pavias and rather thin-walled fruit, which, in its early stages at least, is covered with the prickles of the true Horse Chestnuts. And so it has seemed better to consider the Horse Chestnuts and the Buckeyes generically identical.

Five species grow naturally within the territory of the United States. None of these are so often planted here, however, as the European Horse Chestnut, and none of them, perhaps, are individually as beautiful as that tree, which surpasses all other members of the genus in the massiveness of its habit, in the density of its foliage, and in the magnificence of its great flower-clusters. But the massiveness and the formality of the head of the Horse Chestnut, while they make it a splendid object in some situations, render it a difficult tree to associate properly with other trees; and it usually looks out of place as an element in a picturesque landscape. Its value, however, for formal plantations, either in city streets or in the avenues of architectural gardens, was recognised in Europe two centuries ago, and no other tree has yet been found which surpassed it for such purposes.

If American Buckeyes are not equal to their Old World relative in breadth and solidity of head and in floral splendour they in their turn surpass it in grace and in their adaptability to harmonise with the other trees of the forest; and for general planting in this country they are, therefore, more valuable, especially the Sweet Buckeye, the *Æsculus octandra* of botanists, the largest, or, at any rate, the tallest of the American species. It is an inhabitant of the Alleghany region from western Pennsylvania to Georgia and Alabama, and of the Mississippi Valley. When it grows at its best, as on some of the slopes of the high mountains of Carolina and Tennessee, it is a noble tree, sending up a straight shaft 2 or 3 feet in diameter, sometimes free of branches for 60 or 70 feet, and often reaching a total height of 90 feet. The head is rather narrow and formal, and the branches are small and often pendulous. The leaves are of ample size, and are dark yellow-green and rather paler on the lower than on the upper surface. The flowers are peculiar in the unequal size of the petals, the limbs of the upper pair being much smaller than the others and borne on slender claws which much exceed the calyx in length. The fruit is pear-shaped, often 2 inches long, and is beautiful and conspicuous. There is a variety of this tree found in some parts of the southern Alleghanies and in Texas with red or purple flowers. The yellow and red-flowered varieties are both hardy as far north as New England, and they are both useful ornamental trees, growing rapidly in good soil and harmonising with the native trees of the north; and, unlike the Old World Horse Chestnut, they are not seriously injured by fungal diseases.

The so-called Ohio, or Foetid Buckeye, *Æsculus glabra*, is the second of the Horse Chestnuts of eastern America which grows to the size of a tree. It is not as large as the Sweet Buckeye, and it is unusual to find it more than 30 feet in height, although sometimes, under the most favourable conditions, it grows to fully twice that size. The trunk and branches are covered with dark bark, which separates readily into thin scales, and these make it easy to recognise the tree at a glance, even in winter and while still very young. The foliage is lustrous, dark yellow-green, and rather conspicuous from the yellow midribs and veins of the leaflets. The flowers are of a pale yellow-green colour, the petals nearly of the same length, although the lateral pair are much broader than the others. The Ohio Buckeye, which got its name from the fact that it was first known from the banks of the Ohio in Pennsylvania, belongs to the valley of the Mississippi; it is nowhere very common, and is even less common now than it was a hundred years ago. This is due in part, no doubt, to the fact that this tree always selects rich soil near the banks of streams or on river-bottoms, and has had to make way for the crops of the farmer. It is as hardy at the north as the Sweet Buckeye, but, from an ornamental point of view, is a much less desirable tree and hardly worth planting except as a curiosity.

The other Buckeyes of the east are inhabitants of the south, and do

not attain to the dignity of trees. The most common of these two plants and the type of the old genus *Pavia* is the Scarlet Buckeye, or *Æsculus Pavia*. This is sometimes a low shrub, producing its flowers when only a few inches high, and sometimes reaches the height of a dozen feet or more with many slender straggling stems. It is widely distributed and very common in all the coast-region of the Southern States, from Virginia to Texas, and west of the Alleghany Mountains, extending as far north as Kentucky and Missouri. The flowers are 2 or 3 inches long and bright red; they make a great show therefore, although individually narrow and placed rather remotely in narrow few-flowered clusters; they appear with the unfolding of the leaves and offer a warm and cheerful welcome to the traveller from the snow and ice of the north as he first reaches the south in early spring. Although this pretty plant cannot withstand the severity of our northern winters, the name is often found in the catalogues of nurserymen who confound it with some of the red-flowered varieties of the Sweet Buckeye.

The fourth species of eastern America is the rarest of all our American Horse Chestnuts, although, strange to say, it is more commonly planted than any of the others, and, therefore, perhaps the best known. It is the *Æsculus parvifolia* or, as it was once called, *Æsculus macrostachya*. It is an inhabitant of the foot-hills of the extreme southern Alleghanies, where the younger Bartram found it more than a hundred years ago, when he crossed from the sea-board to the head-waters of the Tennessee and saw, before any other educated man, the beauties of that marvellous region, covered then with one great forest, save where the Cherokee had made for himself a home by some swift-flowing river. The Dwarf Horse Chestnut, as the plant which Bartram discovered is now most often called, spreads in cultivation into a broad bush of compact habit, sometimes 20 or 30 feet across and 6 or 8 feet tall. From spring to autumn it is a handsome plant as it stands out singly on the lawn, and in early summer it covers itself with long narrow spikes of slender creamy white flowers, made conspicuous by their long exserted stamens and yellow anthers. Although it is a southern species, peculiar to a region whose plants are not, as a rule, hardy at the north, the Dwarf Horse Chestnut flourishes in all parts of New England, where it flowers abundantly, although the season is rarely long enough for the fruit to ripen.

The last of the North American Buckeyes is an inhabitant of California—the *Æsculus californica* of botanists. It is a low tree, sometimes 30 or 40 feet in height, with a short stout trunk, often much enlarged just above the ground, and spreading branches, which form a wide dense head; or more often it is a shrub with stems 10 or 12 feet high, forming dense thickets. It is widely distributed in all the foot-hill region of the Coast ranges and of the western slopes of the Sierra Nevada, from the northern almost to the extreme southern part of the state, lining the banks of many streams and the sides of innumerable canons. The flowers of the California Buckeye are more beautiful than those of the other American species; they are white or pale rose colour, an inch or more long, with broad spreading petals and long conspicuous stamens, and are produced in long, very compact, many-flowered clusters. The fruit, which is pear-shaped and rather larger than that of our other species, is also ornamental. The only drawback to the California Buckeye, as it appears in the valleys of California, is that the leaves, which appear early and are fully grown when the tree is in flower in May, ripen under the influence of the hot sun very early and often fall by midsummer, thus leaving the branches bare for a considerable part of the year.

The California Buckeye is not very often cultivated, although it was first sent to Europe nearly forty years ago and flowered in England as early as 1858. Unfortunately it is not hardy in the Eastern States, and probably outside of California it will never really flourish except in climates similar to that of the Pacific coast. It is well worth planting, however, in all the Mediterranean countries, and perhaps in Australia, as an ornamental plant, for it is one of the handsomest of the whole genus, and when in flower one of the most beautiful of all North American trees.—(*American Garden and Forest*.)

#### FRUIT FORCING.

**PEACHES AND NECTARINES.—Earliest House.**—The trees in the house closed early in December, and having been started at an early period the previous season, will now have the blossom buds well advanced towards flowering; but trees not previously forced will be several days later in showing colour in the flower buds. When this takes place syringing the trees must cease, but maintain a genial atmosphere in the house by damping the floors and borders on bright mornings and in the early part of fine afternoons. If the inside borders are found upon examination at all dry, give a thorough supply of water at a temperature slightly in advance of that of the house. Weakly trees may have liquid manure, supplying it rather thick after the soil has been made properly moist with water. Where there is a redundancy of

blossoms remove those on the under side or back of the shoots, and thin them elsewhere where too crowded. Admit a little air constantly at the top of the house, and this, with the warmth in the hot-water pipes, will keep the air in motion, and moisture will be deposited on the glass instead of on the blossoms, as frequently occurs in a close atmosphere to the prejudice of their setting fruit. The temperature may be maintained at 55° by day and 50° at night in mild weather, but 5° less in severe weather is more favourable to the trees than the higher temperature, and the setting is not prejudiced if the temperature fall to 45° at night, or in very sharp weather to 40°. Quick work is rarely good work, and it is necessary when the flowers show the anthers clear of the petals that the house be freely ventilated, avoiding cold draughts, and not exciting the trees by too much fire heat. To keep them, however, in steady progress, the temperature must be raised early in the day to 50°, and kept between that and 55° through the day with a little ventilation at the top of the house, and through the day a temperature of 60° to 65° should be maintained from sun heat. The aim should be to have stout blossoms, sturdy stamens well raised above the pistil loaded with abundance of pollen, well developed pistil and properly formed ovary. These all require time to develop, and aëration for their perfecting, then recourse can be had to fertilisation by shaking the trellis or brushing over the blossoms with a camel's hair brush on fine days after the house has been ventilated some little time. The pollen by either of those processes is distributed in a golden shower visible in the sunlight, and when this is the case, the set is generally a good one, even without artificial fertilisation, and sometimes the disturbance of the air by lightly syringing the trees serves to effect the setting in a satisfactory manner.

**Second Early House.**—To have fruit ripe at the close of May or early in June the trees must be started without delay, but it is desirable to merely close the house and only employ fire heat to exclude frost during the first fortnight, ventilating freely at and above 50°. This will gently incite the sap and buds. Afterwards, say at the new year, fire heat should be employed to maintain a night temperature of 40°, and to insure 50° by day, above which ventilate freely. This will bring the trees on sufficiently to insure sturdy blossom, and once they make a move it is necessary to keep them in steady progress. Sprinkle the trees and house on fine mornings and afternoons, but in dull weather omit the afternoon syringing, as keeping the trees constantly dripping with water has a softening and weakening tendency. If the house has had the roof lights removed the inside borders will have been thoroughly moistened through to the drainage, and not need water for some weeks, but where the roof lights are fixed the border may need a thorough supply of water, and if dry it will be necessary to repeat the applications, for nothing short of thorough moisture in the border ought to satisfy the Peach grower. Outside borders should be protected with dry fern or litter, a few inches thickness of dry leaves with a little litter over them answers admirably. Spare lights may be used to throw off heavy rains and snow, and for securing a more uniform temperature in the border.

**Succession Houses.**—The trees are best pruned and dressed after loosening them from the trellis. Cut out weak attenuated branches, and where crowded thin well, leaving sufficient of last season's growths for bearing, with space between them for training in those intended to displace them. Thoroughly wash the house, the trees with soapy water, and if necessary apply an insecticide, for aphides, red spider, thrips, and scale lurk about the trees in some form ready to become active and multiply when forcing operations are commenced. Secure the branches at once to the trellis, leaving spaces in the respective ligatures for the swelling of the branches and shoots. Remove the loose surface soil down to the roots without disturbing them, and supply good turfy loam in lumps from the size of a nut to an egg, with an admixture of about a fourth of well-decayed manure, not covering the roots more than 2 or 3 inches. If the trees are disposed to make long-jointed wood it is advisable to avoid nitrogenous manures, also potassic, especially in nitrate form, and supply bonemeal, which, furnishing phosphoric acid and phosphate of lime, will tend to promote sturdier growth, and where there is a deficiency of lime, sulphate of lime or gypsum may be used advantageously as a top-dressing. These substances are useful in the case of gummy affections, taking equal proportions of steamed bonemeal and gypsum, and applying it at the rate of half a pound per square yard before growth takes place in the trees. On the other hand, where trees make too little wood and are more prolific of fruit than desirable for attaining to a good size, the borders may be dressed with a combined phosphatic, potassic, and sulphatic manure, say superphosphate of lime two parts, nitrate of potash one part, and sulphate of lime two parts; mix, and apply at the rate of half a pound per square yard when the trees are starting into growth, or a little earlier in the case of weakly trees. These elements only benefit the trees in the year of application, except the sulphate of lime, therefore to be of service they must be applied when they can be appropriated and transformed into plant constituents. This is when the trees are in growth, and to benefit the fruits the manure must be available whilst they are swelling. Peach trees, however, require other manurial elements, as magnesia and soda. Not perhaps directly, but indirectly these substances contribute largely to the health of stone fruit trees, and without healthy trees useful crops are not forthcoming. Kainit supplies those elements as well as potash, and by using it along with bonemeal—two parts bonemeal to one part kainit—the trees are benefited in the year of its application and in the succeeding one, but the mixture must be applied in autumn or before growth takes place in the trees. The bonemeal and kainit mixture is

much cheaper than the other, and half the quantity suffices, or 4 ozs. per square yard. Carefully examine the inside borders, and supply a thorough soaking of water if dry, as dryness at the roots will cause the buds to fall later on. Keep the houses as cool as possible, so as to insure complete rest.

**STRAWBERRIES IN POTS.**—Plants introduced into the forcing house early in the month have commenced swelling their crowns, and the trusses of flowers showing, the temperature may be advanced to 60° to 65° with a free circulation of air, but avoid a high temperature by artificial means; 50° to 55° is sufficiently high at night, and on dull, cold days. Maintain a genial moisture in the atmosphere; syringe the plants lightly in the afternoon of bright days, but early so as to let the foliage have time to dry before nightfall. Look the plants over daily for water, and supply it to all those in need. Keep a sharp look out for aphides. They frequently cluster about the crowns, and should be subdued by fumigating on two consecutive evenings, having the foliage dry. More plants should be got ready for placing in Peach houses to be started at the new year. These are best placed in frames or houses from which frost is excluded, as the plants can then be drafted into the forcing structures as required. The dead leaves only should be removed, loosening the surface soil, removing it, and top-dressing with turfy loam containing a good handful of approved artificial manure to each gallon of soil, and afterwards feed with dissolved bone manure two parts, and nitrate of soda one part mixed, and take a pinch between the thumb and finger and sprinkle it on the surface of the soil, keeping it clear of the foliage and fruit. This must not be given until the plants are in growth. See to the drainage of the pots, rectifying it if defective, and wash the pots clean. Plants for introducing later are best in frames, except the late batches, which will be quite safe in their outside quarters plunged to the rim in ashes, and in sharp weather a light covering of dry fern or litter will make all safe, removing it whenever the weather is mild. If snow fall this will be quite unnecessary.

#### THE KITCHEN GARDEN.

**TOMATOES.**—The growth these make at this time of year is usually of a somewhat sickly character, and it is decidedly a mistake to force them much. On the contrary, the plants, whether in pots or ridges of soil, ought to be only just kept moving, a dry atmosphere being maintained with the aid of fire heat and a good circulation of air. Neither fruiting nor store plants thrive in a cool or rather damp greenhouse, an intermediate temperature best meeting the case. In order to have plenty of ripe fruit during the winter crops ought to have been set not later than September, a long succession then ripening during the autumn and winter. Any flowers that may show at this late period rarely open and set properly, the majority falling before expanding. It is yet advisable to keep healthy plants, whether young or old, as these will grow away more strongly directly the days become longer, the old plants breaking very freely, while all will produce good crops well in advance of any that may be raised or shifted into larger pots during January. Now is a good time to check the spread of disease and to exterminate the troublesome white fly or *Aleyrodes*. Fungoid diseases spread most rapidly in a moderately warm house and moist atmosphere, or such as cannot well be avoided in April. A strong dry heat is evidently the best preventive, subjecting the plants occasionally to a temperature raised by fire heat to 85° or more effectually destroying most of the germs. No kind of insecticide nor repeated fumigations are of much avail against the white fly, but what these cannot stand is an atmosphere well charged with sulphur. If the hot-water pipes are coated with a mixture of milk and sulphur, this being renewed occasionally, every time they become extra hot strong fumes will be given off, and ere summer arrives not a live *Aleyrodes* will be found in the houses so treated. The sulphur fumes are quite harmless as far as plant life is concerned.

**THE MUSHROOM HOUSE.**—While the mild weather lasts fire heat ought to be used very sparingly, or otherwise the crops will be brought on too rapidly, and be of poor quality too. The other extreme is not advisable, as without fire heat or sufficient fresh heating material in the shape of a newly formed bed to raise the temperature to about 55° the chances are late-spawned beds will not become productive till next February or March. Beds raised well clear of the floor are the most reliable at this time of year, these getting the benefit of any warmth going underneath. Directly over where the hot-water pipes or flues run the first Mushrooms are obtained, and beds may also be forwarded considerably by the formation of a brisk hotbed of leaves and manure directly under them. When the latter have had the effect desired they may, if desirable, be returned, watered gently if at all dry, freshened somewhat, and then formed into a square bed. Next enclose on the top of this, with the aid of stakes and deep boards, about 6 inches of well-prepared horse droppings, making these firm in the usual manner. Spawn this directly it is well warmed through, or directly there is no likelihood of a dangerous increase of heat, and soil over at then or any time during the next three weeks. This may be the means of obtaining very acceptable Mushrooms next spring.

Beds that have been spawned for some time, or say six weeks ago, and not yet showing Mushrooms should be examined, and if dry be given a gentle yet thorough soaking of lukewarm water. More likely than not this season they will be found too wet, and an excess of moisture is prejudicial to either the running of the mycelium or a satisfactory progress of the crops that show. Therefore be cautious with the use of the syringe, and also clear off all saturated mulching material, substituting some that is fresh, soft, and dry. Just now the Mushroom

house is of the greatest service in forcing Seakale, Rhubarb, and Swede tops, the latter only in the case of Seakale roots being scarce, Chicory also being forwarded and Endive blanched to perfection in these much darkened places. When there is a flue running through the house set pots or boxes filled with Seakale directly on this, and if the soil is kept thoroughly moist top growth will be rapid and fairly strong. As a rule about a dozen strong roots of Chicory are enough to introduce into the Mushroom house at one time, as they give heavy crops of leaves, of which not many at a time are mixed in salads. Blanched Endive keeps badly and it is unwise therefore to place many at a time in the Mushroom house, two dozen every week being ample for most establishments. Surround the roots with moist soil, dryness tending to make the tops hard and bitter.

**OPEN-AIR MUSHROOM BEDS.**—Those who depend solely upon these will most probably fare badly this season, the weather being altogether against them. The ordinary heavy coverings of strawy litter have been of little avail against such frequent and heavy storms of wind and rain. Tarpaulins, if securely fixed, would have kept off the rain and prevented the beds from being badly saturated, but even these are somewhat risky. Over-heating after spawning and soiling is the most frequent cause of partial or complete failures with ridge-shaped beds, and not till all risks of this are past may tarpaulins be used with safety, as these serve to enclose the heat as well as exclude cold winds and rain. Fortunately Mushroom spawn is not so easily destroyed as some may think, and it would be unwise to break up a bed prematurely, as a crop may be forthcoming directly warm weather sets in next spring. They must not be left to take their chance though, and it is most advisable to examine all the beds on the first fine and mild day, clearing them of all saturated mulching material, and covering afresh with not less than a foot in thickness of dry litter. Much may be done towards warding off heavy rains by means of thatched hurdles meeting together well over the beds. There ought also to be a clear course for all the water that runs from the ridges, as if it remains about them far too much moisture will soak up into the beds. Beds in full bearing to be uncovered as little as possible, and by the same man each time.

#### PLANT HOUSES.

**The Stove.**—During the past mild weather the temperature has ranged higher at night than is usual for this structure. Some care is now needed to keep the temperature as low as possible consistent with external conditions. If severe weather should set in the temperature could not be maintained without unduly heating the hot-water pipes, which is injurious, and the reverse of economy. If the plants are gradually hardened to a temperature of 60°, or a few degrees higher on mild occasions, no check will result to the plants if that temperature, or a degree or two lower, is maintained during severe cold weather.

**Watering.**—Let all watering be done in the early part of the day, and some care is needed not to give the plants too much. Plants are easily overwatered at this period of the year, when growth is practically at a standstill. On the other hand, they must not be allowed to suffer by an insufficient supply. Employ the syringe whenever there is a prospect of a fine day, in fact twice daily when the pipes have to be made fairly warm to maintain the desired temperature. Failure in damping and syringing during the winter months often ends in the plants being seriously injured by thrips. A warm dry atmosphere is favourable to the spread of these pests.

**Cleaning.**—Thoroughly clean plants that are infested with insects, as well as the houses in which they are grown. A few days devoted to thorough cleaning at this season of the year will save weeks of sponging at a busy time. It must be remembered that cleaning every corner in the house is equally as important as cleaning the plants. The glass inside and out should be washed, and the walls whitewashed, so that the house will be light and sweet. Every ray of light possible must be admitted at this period of the year.

**Hotbeds.**—Where Allamandas, Clerodendrons, Bougainvilleas, and other plants are needed early, lose no time in making up a hotbed to give them a start. It is surprising how quickly plants start into growth when stood on or plunged in a bed of fermenting material composed of litter and dry leaves. If plenty of Oak or Beech leaves can be obtained they may form three parts of the mixture. The leaves must be dry, and the whole carefully mixed together in some position where it will be safe from rain, and turned two or three times before it is taken into the house and the bed made up. Make the bed firm so that fermentation will not be rapid and violent heat produced. Young *Dracænas* that have been recently placed into larger pots will make rapid progress in a temperature of 60° if the slight bottom heat is given them that a hotbed affords.

**Eucharises.**—Plants that have flowered and need repotting may be attended to as soon as the hotbed is ready. They soon become established when gentle bottom heat is given them, and they start more quickly by the aid of heat and moisture from fermenting material than is the case when plunged in cocoa-nut fibre refuse and bottom heat supplied by hot-water pipes. Plants that have been resting in an intermediate temperature will soon push up their flowers under the conditions advised for those to be repotted.

**Cyperus distans.**—If these are not throwing up fast enough it is a mistake to place them in heat, in fact the plants are quickly ruined by such treatment. They will advance without injury in a temperature of 50°, but in a warmer house they often fail to open properly, and the foliage becomes drawn and weak, and is broken when the plants are

moved about. Few plants are more useful for furnishing purposes either in pots or for cutting.

*Nepenthes*.—In the prospect of severe weather setting in these plants should be arranged at a safe distance from the glass. We have had them injured by being too close during very cold weather. In houses that are well glazed the plants will be perfectly safe if the top leaves are about 18 inches below the glass. Keep these plants liberally watered and freely syringed. Thrips soon attack them in a dry atmosphere, and these pests are difficult to destroy because strong insecticides cannot be used without injury to the plant. The method we have found most effectual is to lift the plants down carefully and plunge the baskets in a tank of tepid water. If the leaves are sponged with water, and the plants thoroughly syringed, they may be cleaned by this simple method.

## THE BEE-KEEPER

### APIARIAN NOTES.

#### WATER POOLS.

WHILE the temperature keeps low bees do not fly much during December, but as soon as the days begin to lengthen they commence breeding, are more active in the hive, and are thereby better able to resist the evils of low temperatures; but are also more liable to fly abroad, which, if there is nothing to contend against, is much to their advantage. Water pools, resulting from melted snow or rain over a frozen surface, are much against bees, as many of them are drowned. These should be drained away wherever practicable, and where not should be so covered as to prevent any risk of bee loss. From now till May is past great care should be exercised not to have bees destroyed needlessly, and the best means to accomplish this is to have them well supplied with the necessities of life, and leave the rest to Nature.

#### A DEPARTURE.

To those who have the good of the cottager at heart will, I am sure, be pleased to learn there is now a movement amongst some bee-keepers to throw off from amongst them the conventional practices of modern times, and act in future more upon their own responsibility and common sense bee-keeping, and to constitute their societies on a basis that will benefit the members. Of course it is too early to say as yet the measures that will be adopted, but we can with some degree of confidence say that the system will be one dealing direct with manufacturers for appliances, and with the public direct with the produce of the bees. To secure this members will use every means to have all honey jarred without coming into contact in any way with the hands, and to be of good quality only. I have been already asked by several Scotch societies to give some advice in the matter and bee-keeping generally, but have not yet consented. I have also proof that a feeling of a similar nature exists in some parts of England, and have read that some Irish bee-keepers are strongly averse to what has been aptly termed autocratic bee societies. I have long pointed out the evils and irregularities that exist in our present-day guilds, but trust that bee-keepers will now join in the cry of self-reliance and self-help, and revolutionise the management of bees.

#### SUPERING.

For a long time many of our unfledged bee-keepers who knew but little of bees or bee-keeping advocated hives that gave much super space as a means of securing the greatest quantity of honey in the most desirable form in supers. This teaching, however, was erroneous and on a par with many more of such teachings, having the opposite effect. There are many hives with supers I see offered for sale having the fault of supers projecting from the line of the cluster of bees in the hive. Broad hives have this fault, because the bees are sometimes compelled to contract themselves much within the line of the outer edge of the supers, while narrow hives have their supers projecting the cluster.

Bee-keepers who are desirous of having well-filled and finished

supers of purity should during the winter, if they are in possession of these faulty hives, put them right. Hives should never be wider than what the bees will during summer always crowd the outer sides of the combs, and the supers a little less in diameter, and to have them protected with wrappings in addition to the super protection, admitting the bees to the supers only from the outer spaces. If the frames are of the standard type close up all the centre openings with thin spale board, obviating the colouring of supers and the use of excluder zinc.

#### CONSUMPTION OF STORES.

So far as the season has gone bee-keepers are puzzled as to whether the peculiarly wet and changeable weather has caused the bees to consume or economise their stores. Bee-keepers who had their stocks supplied in September with 20 lbs. and upwards of food need not be alarmed for the safety of the bees as yet. I will neither examine nor advise anyone to examine their stocks until they have had a thorough airing, which, as a rule, takes place during January. I have seldom known that month to pass without a good bee-airing day, and sometimes several. After, but not before, these airings is the proper time to make an examination; but it is better, if there is any doubt, not to uncover the bees at all, but rather supply several pounds of syrup from below until the season is further advanced. Remember, that any top feeding with candy or syrup lowers the temperature of the hive greatly, and it should therefore be left undisturbed.

Bees that have a scarcity of stores during winter are frequently upon the wing, when well supplied hives remain at rest within. Except for experimental purposes I will not uncover any of my hives until the time for supering.—A LANARKSHIRE BEE-KEEPER.

#### TRADE CATALOGUES RECEIVED.

- E. P. Dixon & Sons, Hull.—*Catalogue of Garden Seeds*.  
 E. H. Krelage & Son, Haarlem, Holland.—*Catalogue of Pæonies*.  
 H. & F. Sharpe, Wisbech, Cambridgeshire.—*List of Seed Potatoes*.  
 Dicksons, Chester.—*Catalogue of Vegetable and Flower Seeds, 1892*.  
 A. C. Russell, Tranchiennes, Ghent.—*Catalogue of Chrysanthemums, 1892*.  
 James Veitch & Sons, King's Road, Chelsea.—*Catalogue of Seeds, 1892*.  
 B. S. Williams & Son, Upper Holloway.—*Catalogue of Flower and Vegetable Seeds*.  
 Robert Veitch & Son, New North Road, Exeter.—*Catalogue of Alpine and Perennial Plants*.  
 Webb & Sons, Wordsley, Stourbridge.—*Spring Catalogue, 1892 (illustrated with coloured plates)*.

\*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

*Cypripedium (G. Clements)*.—There was no flower enclosed in your letter, nor have we received one in a parcel.

*Floral Committee (G. M.)*.—Write to Mr. A. F. Barron, R.H.S. Gardens, Chiswick, London, W., stating your desire, and he will give you all requisite instructions in the matter.

**Hyacinths (R. J. B.).**—The bulbs that are "raised out of the pots" have not been properly potted. The soil on which they rest has been much too firm, and instead of the mass of roots entering it freely, it has by its resistance caused the displacement complained of. If the roots are not more than an inch or two long, which is probably the case, the bulbs should be at once potted afresh, and if the work is done with great care the Hyacinths will flourish. As much of the soil must be taken from the pots as will enable you to hold each bulb in the left hand in the centre of the pot, the roots hanging so that they do not touch the bottom; then with the right place in the soil carefully, not pressing it about the roots, which are very tender, but giving instead a few smart raps of the pot on a firm bench, still holding the bulb with the hand. When the pots are filled with soil it may be pressed down round the sides, but the bulbs must not be pressed down, nor the roots crushed.

FIG. 99.—LANKESTERIA BARTERI.

Water them immediately through a fine rose, and cover with cocoa-nut fibre refuse for about three weeks, by which time they will be well established. When the bulbs are partially upheaved and not rectified the plants are never satisfactory, as the spikes grow in a slanting direction and are with difficulty staked upright to show them to advantage.

**Potash for Plants (M. B.).**—The correspondent to whom you refer gave the following information on the subject:—"Potash salts may be had under the name of sulphate of potash, muriate of potash, kainit, and nitrate of potash from most seedsmen and all dealers in artificial manures. Kainit, or crude potash salts, is cheapest, but it only contains about 25 per cent. of sulphate of potash (equal to 13 of pure potash); but it also contains large quantities of other salts which have been found hurtful to vegetation when more than 5 or 6 cwt. is applied per acre, and sometimes even that quantity has done mischief. Sulphate of potash contains about 60 per cent. (equal to 34 of potash), and is, though in proportion dearer, altogether preferable. Muriate of potash contains

81 per cent. of chloride of potash (equal to 50 of pure potash), and is so much more valuable. Sulphate of potash is most commonly used. The nitrate (saltpetre) we have found useful on a small scale—i.e., for pot plants when evil smells would not be tolerated. Our source of potash is the cowhouse. Cow urine contains about 40 lbs. per ton, and much other valuable matter; that of the horse contains about 54. Like you, we are inclined to think that the proper use of potash has not yet been fully ascertained; with nitrogen it is wonderful how long a vigorous growth may be sustained with it."

**Disqualifying at Shows (J. D.).**—Your letter arrived too late for our last issue, and to insert it now would be not only "old news," but the incident is only of local importance. The exhibitor it appears was awarded the prizes on the merits of the productions, but disqualified by the infringement of some rules. He will, perhaps, remember this another year.

**Justicia flavicomma (G.).**—Yes, this plant is valuable for conservatory decoration, as the flowers last a long time in beauty. When the first flowers fade return the plants to a heated structure where they will flower a second time from the same truss. In fact, they will flower three times in succession.

**Lankesteria (R. B.).**—Yes, there is a small genus of the family Acanthaceae, and as far as we are aware there is only one species in cultivation—namely, *L. Barteri*, which no doubt is the one you have. The plant is a native of West Tropical Africa, and requires strong heat, with a moist atmosphere. The compost should consist of loam and leaf soil in equal parts, with a little sand. The plant is of bold habit, with large opposite, oblong, lanceolate, dark green leaves, and the rich yellow and orange-scented flowers are produced in large terminal or axillary spikes. The general character is shown in fig. 99.

**Vines Infested with Mealy Bug (Constant Reader).**—If the Vines have any leaves they may be removed and burnt, then syringe the Vines with a petroleum mixture, a third gill or wineglassful of petroleum to four gallons of water, in which 8 ozs. of softsoap and 4 ozs. of washing soda have been dissolved whilst hot, and keep thoroughly mixed whilst being applied. Allow it to dry, and then repeat the application, wetting the Vines thoroughly in every part, and all the woodwork of the house. Let this also dry, and repeat once more. Then the Vines may be pruned, the woodwork washed, the glass cleaned, the walls limewashed, and the Vines, stripped of their loose bark, may be washed with the same mixture as advised for syringing them, reaching well into every angle, crack, hole, or crevice, using a brush, and taking care not to injure the buds. It is best applied whilst warm, 90° to 120°. If there are any plants they must be removed, and the surface soil must be scraped off and fresh supplied in its place.

**Tuberoses (Merchant).**—Thousands of plants are grown to supply flowers for market by placing one medium-sized bulb in a 5-inch pot and three in 6 or 7-inch pots. Very large bulbs are sometimes placed singly in 6-inch pots. The upper part of the bulbs are above the soil, which is similar to that in which Hyacinths are grown. They are usually buried in cocoa-nut fibre refuse under the stage of a warm greenhouse, where no drip falls from the plants. In that way the soil is kept moist without watering, and roots form freely. When top growth is visible light is essential, a shelf in a warm house being suitable. Many plants are grown on shelves and stages from the first, but great care is needed in watering. When flowers are wanted early the plants are grown in stoves or hothouses, and in this case it is advantageous if the pots can be plunged in a hotbed. Not knowing your cultural conveniences we are unable to indicate the best method to pursue in your particular case. Your postcard was overlooked last week, but the bulbs will not have suffered in the least if they are not yet potted.

**Senecio pulcher (S. T. V.).**—This is a vigorous-growing perennial, with large fleshy or almost leathery leaves of a deep green colour and shining; the radical or root leaves are variously dentated and lobed, while those on the stem are ragged and irregularly cut. The flower stems are from 2 to 3 feet high, very stout, freely branching at the top, and supporting numerous flowers with the rays of a brilliant purplish crimson colour, and the disc or centre golden yellow, measuring 3 inches or more in diameter, and lasting a considerable time in beauty. It flowers during the late autumn months, when it is of special interest and very welcome; and when well cultivated it is a most attractive plant. It may readily be cultivated in ordinary borders, but especially does it thrive in rich loamy soil in a damp situation, as it enjoys plenty of moisture during the summer months. As regards the pot culture of this plant, there is no difficulty in securing good flowering plants by that treatment in, say, 5 or 6-inch pots, using as soil good yellow loam, leaf soil, and well-decayed cow manure, with some wood ashes and sand, or in lieu of the ashes fine nodules of charcoal; the latter is of decided advantage in growing the plant. Perfect drainage is also essential, and an abundance of moisture during the growing season; and it would be advisable to plunge the pots in some material such as spent hops or ashes, which would greatly assist to keep the roots cool and moist.

### A NEW YEAR'S GREETING.

"WHY if here isn't that old fogey again," will be the New Year's greeting which I shall probably receive from many readers of the Journal when they open this week's number. "Couldn't the Editor find out some younger and fresher hand?" And I am not quite sure but they are right. However, they have committed to me the honourable task of greeting a wide circle of readers, and I must only do my best; and there is one advantage at any rate which an old 'un possesses, that of experience. Yes, these whipper-snappers of youngsters who would set the world all right have to learn that all the game is not with them, and (that is as it should be) they have something besides scanty locks and grizzly beards, which may tend in some degree to balance the account.

And yet, perhaps, I am not altogether an old fogey. I do not indulge in one of the peculiarities of that class—sing the praises of the past at the expense of the present. I do not recognise myself as one of the two old men pictured in *Punch* sitting over the fire and explaining that the coals do not give out so much heat as they used to do when they were young. I can recognise the immense strides that have been made in horticulture within my memory. I remember Chiswick in its golden days, and I say that the shows of those days were not to be compared with those of the present. There were huge stove and greenhouse plants and Heaths, but there were no Orchids. What would some of the exhibitors of those days have said if such a batch had been exhibited in their days? and not only Orchids, during the sixty years which have elapsed since the days when I first was affected by the mania; the whole world has been ransacked, regions then only vaguely known, some not known at all, have been explored and yielded up their treasures, and every department of horticulture has been enriched by the indefatigable labours of collectors and botanists of every nation. Let anyone go into their garden or greenhouse, I care not at which department he looks, and ask himself how either would look now if deprived of the plants which the last sixty years have produced. Flowers now occupy a prominent place in our gardens and at our exhibitions which were absolutely unknown then, in fact did not exist. The effective classes of Tuberous Begonias were absolutely unknown—and what shall be said of Chrysanthemums, especially the Japanese section? why it is simply a marvel, even to those who have witnessed many marvels in horticulture. Thus I free myself of one of those charges brought against "old fogies," and there is another of which I most sincerely hope I cannot lay to my charge—loquacity. I do not think I am long-winded, although, perhaps these New Year's greetings run into greater lengths than any other of my contributions, but then I have to talk at it for a whole year, and a poor fellow may be allowed a little longer tether on such occasions.

In looking back on the horticulture of a year one instinctively turns to the Royal Horticultural Society and its doings as holding the foremost, but not the only, place in the minds of British gardeners. It has done a good year of successful work, it has acquired more than ever the confidence of horticulturists, it has had its practical and useful conferences, it has held a magnificent and, what is very unusual, a financially successful Exhibition at the Temple, and yet, withal, the great prospect of a Horticultural Hall

hangs fire. Why it should be so it is difficult to say. The times may have been bad, but other projects have been successfully carried out, but this makes little progress, and in the meantime the beautiful exhibits contributed by London nurserymen and a few amateurs have been held as heretofore in that dreary home—the Drill Hall. There is still a feeling amongst some members of the Society, which is, I think, to be deplored—I mean the jealousy of any other effort but that which is made by them; as an example of which one may adduce the cold shoulder which they were inclined to give to the prospect of holding a great international fruit show next year. It is rather a "dog in the manger" notion, for the R.H.S. could not do it, and it is well to recollect that the great Exhibition of 1866 was also a private venture. The Royal Botanic Society has also had some fine exhibitions this year, and is doing good and useful work, although cramped by some absurd regulations, which savour rather much of oligarchism than suits these democratic times, of which the most notable is that you cannot have the honour of attending some of the exhibitions even by payment unless you have your ticket signed by a member. Can anything be more snobbish than this? It may be palatable to the would-be aristocracy of the Regent's Park and its neighbourhood, but cannot be justified on any grounds of common sense or the fitness of things.

The foremost place in the interest of horticulture has been taken during the past year by fruit growing. It falls in with the utilitarian spirit of the age, and the subject has been invested by a glory of its own, and hence conferences, papers, lectures, have been showered down upon us in all parts of the country, while exhibitions such as that held at Manchester have added a fresh stimulus to the subject. All this is calculated to advance the proper consideration of the subject, for wild theories, unsupported by any facts, have been put forward as if fruit growing was to be the salvation of the farmers, and some cases brought forward gave encouragement to them. There is within a few hundred yards of my house a plantation of Black Currants of a little more than an acre which yielded its owner this season £120, while the amount that has come into this county through Strawberry culture is somewhat astounding. Yet there is need of caution. Of bush fruit it does not seem there can be too much, and even when the crop is abundant everywhere, yields a good return; while in seasons when it is bad among one grower here and there, the fortunate owners in such a state of things are enabled to obtain large profits. The case of orchards is different. Pears, Apples, Plums, and Cherries are so much more affected by our capricious climate that it would do not to depend on them, as some enthusiasts advise us to do. But while it may be risky to go in for large plantations, although Lord Sudeley has found it profitable, yet every farm on which there is suitable soil should have an orchard, and be careful as to the sorts which it grows. By far the majority of our orchards are filled with old worn-out trees of inferior sorts, mostly non-keeping varieties. These produce a glut in October, and then after that we are dependant on foreign supplies for our markets. Of course it will take time to alter all this, but I think 1891 has seen a very considerable onward movement in this direction. Old orchards are being renovated in some cases by grafting good sorts on the old trees, but more frequently by replanting them afresh with young trees of good kinds. In such cases where the orchard is used as a subsidiary to the general crop of the farm, and is not made the mainstay of the farm, it cannot but be profitable. The great International Fruit Show, which is to be held in 1892 under the auspices of the Fruiterers' Company, and which has received the patronage of Her Majesty, will doubtless add much to the interest of what we can only hope will be a most successful exhibition.

In flowers Orchids, Roses, and Chrysanthemums still hold the fort, representing, I think, the three classes of horticulturists. The first being the flower of the married man, not so much of the

aristocrat, as of the man who has made or is making his fortune, who delights to have that hobby, and sometimes rides it in an intelligent and appreciative spirit, and sometimes only regards his fine collection as he would do Dresden China or bric-à-brac; while many who have the finest collections in the country take an intelligent interest in them. The Rose is emphatically the amateur's, and especially the lady amateur's, flower; it has been, as I have already indicated in my review of the Rose year, a bad season for it, but the love for it and the consequent interest in it does not flag. The Chrysanthemum is especially the poor man's flower. A tiny bit of garden, a small greenhouse, anywhere in fact where a flower can be grown, the Chrysanthemum rewards the care of the grower; it is easily propagated and will grow anywhere. That Orchids still hold their sway may be gathered, not less from the grandeur of the exhibitions, such as the Temple Show and the Manchester Great Whitsuntide Exhibition, but also from the constant importations of the plants, and the high prices obtained for them. When we hear of a grower for sale giving £250 for a plant to the fortunate amateur who had obtained it, we may be quite sure that the fever is pretty strong. Cattleyas especially seem to have created a sensation the past year; the finding again of the old *C. labiata*, the many varieties in imported bulbs, and especially the discovery of what is said to be the king of all Cattleyas—*C. Rex*, have set Orchid growers all a-gog. *Cypripediums* still claim a large support, and have lost none of the favour with which they have been regarded for some years. Very few new Roses have come to the front this year, the most prominent being *Marchioness of Dufferin*, raised by Messrs. A. Dickson & Sons of Newtownards in the county of Down, Ireland. It becomes increasingly difficult to raise anything that will exceed in beauty those we already possess. Of Chrysanthemums, on the contrary, there seems to be no end, and the difficulty is what to select. The Japanese varieties have almost shut out the incurved varieties, and except by the exhibitors there are, comparatively speaking, but few of these grown. There are two amongst the new sorts which are two amongst the large number, some thirty or forty, to which awards have been given which are likely to be much in favour—*Robert Owen* and *Vivian Morel*. The former is a large flower, but I am not quite sure whether it is not too heavy a flower. Mrs. *Alpheus Hardy* has proved a most difficult plant to manage, as may be evidenced from the fact that at the Great National Exhibition at the Aquarium there were only three blooms of it staged, and I believe that the best way to manage it is to grow on the old plant.

Other plants have also either retained or increased the favour with which they have been held. *Begonias*, both single and double, seem now to have almost reached their zenith, and now the efforts of hybridisers are directed towards getting them to hold their flowers erect. The Dutch growers, *Ant. Roozen & Co.*, announce erect flowering single and semi-double varieties, while in *Cannell's Rosebud* we have the index of an advance in the direction of the double erect flowering varieties. Carnations, and especially the border varieties, have advanced greatly in public estimation, and are now sought for in all directions. The florist varieties are not, as a rule, suitable for garden decoration; their beauty depends so much on delicacy of colour and refinement that all this is lost in the bolder features of garden decorations, while these self coloured ones which the florist rejects are now especial favourites. Messrs. *Harkness's Ketton Rose*, *Veitch's Queen of Carnations*, and others from various sources have shown an advance in size and form of petal which will make them desirable additions. The taste for herbaceous and alpine plants still increases, and although nothing very novel has been brought forward, yet in all directions one sees evidence of the love for plants whose cultivation has so revolutionised English gardening during the last fifteen years, has also exterminated the bedding-out system, and made our gardens so much more enjoyable.

The roll call for 1891 does not show such great and conspicuous

blanks as did that of 1890, but it must ever be in so large a body as that which horticulture claims as its own—there must be blanks as every year rolls round. Roger Cutler was ever in evidence pleading the cause of the Gardeners' Royal Benevolent Institution, and his loss was no ordinary one; ever ready to seize any opportunity for pushing the claims of his "baby," which under his fostering care had grown to be a full-sized power, and his loss will be widely felt. In John Dominy we have lost one of our most successful hybridisers, whom the Orchid grower will remember with gratitude for the good things he has added to their favourite flower. Everyone who has ever attended a Dahlia show in or near the metropolis has known Henry Glasscock of Bishop's Stortford, the leading man amongst the amateur growers and exhibitors of the flower. Fruit growers regret the death of Haycock, who had under his care the most perfect fruit garden in the kingdom, and whose fruit, for size, and especially for colour, were unsurpassed. In Frank Miles, artist and gardener, and in the Rev. A. Rawson we have lost two ardent lovers of herbaceous plants and bulbs; the former, indeed, has been lost to us for some years owing to mental disease. Jean Sisley, a name well known amongst Rose growers, and English in his descent though he lived at Lyons, has passed away at the advanced age of eighty-seven, and was until the last few months vigorous and bright. And so time rolls on, bringing with it its ever-recurring changes, and familiar faces and voices are no longer with us; and the world gets on without them, as it will, my friends, without us when we too pass away.

And now we are looking forward for another year, and I think that we may do so with no pessimistic views. Never was the craft we love in such wide favour as it is now; never so many gardens and hearty gardeners as at the present day; and although we miss some who have been our guides in the past, yet some remain, and younger men are coming forward. To all, then, whether old or young, let me send a brotherly greeting; and may I not, in the name of all the readers of the Journal, salute our venerated chief, express our thankfulness that he is still able to pilot the ship, and our hope that his matured wisdom may be long spared to us? I might have called him our venerable chief, but then I should have to apply that term to myself, for we were born in the same month and the same year. For thirty years I have been permitted to labour with him, and I can cheerfully recognise in him the genial friend and adviser. May his shadow never be less. And now my fellow labourers, especially ye younger ones, remember that there is demand for your energies, and the world will be glad to hear what you are doing. There are now eight weekly journals devoted to gardening, and it requires something to keep up that supply; but give of your best. Don't think that there is nothing to write about, don't hold back because other people have written upon it, for the treatment even of an old subject by a fresh hand is always acceptable. Keep up the credit of our Journal, remembering that you have an intelligent and cultured class of readers.

We have not had a cheering year for gardening, and so we may well hope for a better one. Our gardens have not shown their usual beauty. A long and bitter cold winter, a cheerless summer, and wet autumn, are not promising factors for gardeners, such as we have had in 1891, and, like Mark Tapley, we have tried to be jolly under them. Let us hope that different seasons await us in 1892. "Hope springs eternal in the human breast," and so we hope on. I may not be your chaplain in 1893, but at any rate let me seize the present and wish each and all of you a bright and successful year. Troubles, horticultural troubles, we must have, but in whatever form they come, American blight, phylloxera, woolly aphis, slugs, snails, mildew, orange fungus, green fly, take heart of grace and let me end my homily with the old time-honoured salutation,

PAX VOBISCUM.

—D., Deal.

## RHODODENDRON CHAMPIONÆ.

MESSRS. JAMES VEITCH & SONS, Chelsea, have been the means of bringing many beautiful Rhododendrons into public notice, especially amongst the hybrids of the so-called "greenhouse" section, but others have from time to time been introduced, occasionally novelties, and sometimes old, neglected, or little known species that are equally as welcome as the others. We have an example of a species which has thus been recovered, as it were, in *Rhododendron Championæ*, for which Messrs. Veitch obtained a botanical certificate at the meeting of the Royal Horticultural Society on April 21st, 1891. A drawing was prepared from the specimen shown on that date, and this is now

Captain Champion considered it allied to *R. formosum*, Wall., from Khaysa, and so it is in some respects, but abundantly distinct in the form and vestiture of the leaves, in its large glutinous bracts, in the form of the calyx, in the ovary and fruit, and especially in the copious, long, glandular bristles of the branchlets, petioles, peduncles, calyx, and fruit. It was found by Captain and Mrs. Champion, growing abundantly among rocks in a ravine at Fort Victoria, Hong Kong, April 28th, 1849."

The description then given may be condensed as follows, but at the time no plants were in cultivation in this country.

"A shrub nearly 7 feet high; branches terete; younger ones clothed with long, spreading, glandular bristles. Leaves much confined to the apex of the branches, shortly petioled, lanceolate,

FIG. 100.—RHODODENDRON CHAMPIONÆ.

reproduced in the woodcut (fig. 100). When describing this Rhododendron in 1851 Sir W. J. Hooker wrote as follows:—

"We know from experience that there is no surer way of having a new and beautiful plant introduced to our gardens than by publishing a figure and giving its locality. Hence we are induced, as upon some former occasions in this work, to exhibit a species not yet in cultivation, but for the accuracy of the figure of which we can vouch, by a comparison of the drawing of a Chinese artist with native specimens; both the one and the other being also accompanied by notes drawn up on the spot and sent us by Captain Champion of the 95th Regiment, who made extensive collections of plants in Ceylon, and afterwards in Hong Kong. In compliment to his amiable and accomplished lady, whose partiality for plants equals that of her husband, and who accompanied him on many of his botanising excursions, we have named the species,

shortly acuminate, reticulated, dark green above, rather rusty-coloured beneath, the margin and veins and veinlets clothed beneath and rough with short, harsh, bristly hairs. Umbels four to six-flowered. Peduncles hispid with glandular hairs. Calyx, especially the margins, equally hispid, deeply cleft to the base into four erect, almost linear-subulate, rather long segments or sepals. Corolla 4 inches across, tube rather short, campanulate, white. Limb 4 inches across, deeply cut into five obovate-oblong, obtuse, unequal-veined segments, the upper one the broadest. The ground colour in our figure is white; the lobes, especially the apex and margins, are tinged with delicate rose colour. But there is another state of the flower described by Captain Champion as the more usual colour, 'delicate white, the upper lip pale yellow towards the centre, and copiously dotted with ochre.'

The variety exhibited by Messrs. Veitch was that just mentioned

—namely, the flowers had long white petals, the upper spotted with yellow. It is probably variable, and seedlings might yield several distinct forms.

### BARREN WALL TREES

It is certainly convenient to blame the weather when our wall trees fail to produce good crops of fruit; but if this takes place several years in succession we must look for other causes, and often take extreme measures to restore the trees to a healthy fruitful condition.

Barrenness is usually due in old trees to a crowded condition of their spurs, and even when the trees do not wholly fail to fruit they yield produce that is worthless, being small, hard, and flavourless. Trees are brought into this state through a rough and careless system of pruning, which adds annually to the evil until failure is the result. This occasionally arises from thoughtlessness on the part of those to whom the work is entrusted, and not unfrequently is due to a total ignorance of the requirements necessary to the formation of healthy fruit spurs. Light and air are essential for building up and perfecting the buds that are to produce the following year's crop of fruit. They are robbed of these conditions when the trees are crowded; in fact, the whole mass of weak spurs which the trees possess are hidden from light, being entirely shaded by leaves. This is not the only evil that results from a crowded condition of the spurs. The energy of the tree is devoted to the development of perhaps a hundred more spurs than are needed, while the leaves by shading one another are prevented carrying out their proper functions. If trees then are to be fruitful year after year the spurs must be so disposed that light and air can reach them, and the leaves have room to develop without crowding.

Trees that are crowded may in a season or two be rendered fertile by freely and judiciously thinning their spurs at once. Small spurs near the main branches may be too weak to fruit next year, but they will develop into bold spurs for the following season. One precaution is necessary, and that is preventing young wood that is certain to form freely from the sawed off spurs, from crowding the tree, and then smothering the small fruit spurs that have been left. The shoots that start away from the remains of the old spurs should not be left until they become woody and then be pinched; but directly they are observed to be growths, and not fruiting spurs, they can be thinned, and only sufficient left to furnish the tree for forming new spurs, and sustaining it in health and vigour.

But barrenness is due to other causes which skilful management in pruning during summer and winter will not remedy. Old trees that have occupied positions against walls, and for years have been left to their own resources, have long since deprived the soil of its fertility, and have not only become barren, but gradually declined in health and vigour. Generally, the borders near walls are cropped with vegetables, and any roots the trees might form in them are annually cut away, and thus the roots are driven into the subsoil. If we suppose a border 5 feet wide near the wall is devoted to the trees, and the soil is of a stiff or clayey nature, the trees, if left to themselves, are certain to fail, as can be seen in too many gardens. Trees on a north wall, as a rule, are more likely to suffer than those in any other position; and if we glance at a wall of these trees, and consider the treatment they receive, we need not wonder that they have both failed to fruit and grow. They have probably been summer and winter pruned, and occasionally had an application of manure to the surface of the border. This may be considered ample, and by no means bad fare for fruit trees. It certainly sounds very well, but fails to bear close examination. The treading during the operation of pruning consolidates soil that is adhesive until water will not pass freely through it, and the manure is like adding fuel to the fire. Where water will not pass away freely the air cannot penetrate—a condition that is alone sufficient to account for barrenness and debility. Soils in this condition soon become sour, and are too cold for the well-being of trees. The heat of summer fails to dry and warm borders of this nature. The heat which should penetrate the soil is spent in evaporating the water from the surface, most of which should have passed away in the opposite direction. When covered with manure evaporation is arrested, and the soil thus remains in a similar condition throughout the year.

To restore trees in this deplorable state to health and fruitfulness requires thoughtful consideration before commencing. There is nothing to lose, and the results of renovation in two or three years may be a decided gain. The age and health of the trees must be considered, for in some cases it might be wise to pull out the old trees, clean the wall, and work the soil thoroughly for a season to restore it to a state of sweetness and fertility. When

these measures are taken, if the soil is not properly drained that should be done. This, however, is necessary in any case. The border must be trenched and the subsoil well broken up. The quantity brought to the surface in trenching must depend upon its nature, but several inches may be brought up, and if well worked and left a whole season to the disintegrating influences of the atmosphere, and then thoroughly mixed with what was the surface soil, a considerable quantity of dormant plant-food will be rendered active, ready for the young plants the following season. Fresh loam, if obtainable, manure in small quantities, or other fertilising ingredients, may also be added for the benefit of the trees to give them a good start. When the soil is in the unsatisfactory state that has been described it is unwise to dig holes in which to plant young trees. Trees seldom do well in such holes however good the soil may be, for they prove to be mere pits into which the water from the surrounding ground drains, the new or newly worked soil acting like a sponge.

If the old trees are not too far gone their renovation may prove the most profitable. In the first place the whole of their spurs should be sawn close back and their branches well scrubbed, for frequently trees in a saturated soil are covered with minute forms of vegetation. The surface soil of the border may be picked up as deeply as possible without cutting off the few fibrous roots the trees may possess. Very few will be found near the surface. Leave the soil in a rough state, so that the weather will act upon it and water evaporate freely. It is surprising what an improvement will be effected even in one season by this simple means. Trees that are cut hard back will start a good percentage of strong growths. Disbudding will be necessary and only sufficient left to furnish the tree; these should be secured to the main branches so that they are clothed from the main stem to the end of the branches with young growing shoots. After disbudding or tying any treading on the border must be remedied by forking it again to encourage evaporation throughout the season.

This refers principally, as far as training the young wood is concerned, to Apples and Pears. Plums require slightly different treatment. Young shoots should be laid in where necessary, and others pinched about 4 inches in length. Plums, as a rule, break freely from the old wood, and we have, after cutting back the spurs, furnished trees in a season, with good bearing wood close at home.

Whether Plums, Apples, or Pears are under treatment while the leaves are fresh upon the trees in early autumn, a trench should be cut 3 or 4 feet or more from the stem, according to the size of the trees, and all roots beyond cut off. The cut must be clean, and performed with a sharp knife, about half the remaining soil between the trench and the stem being worked carefully from amongst the roots, preserving every fibre that can be found. The remaining surface soil must be removed down to the roots. The roots that have been bared must be laid into a compost of fertile soil. Refuse from the potting shed and fibry loam in equal proportions will give them a good start. Wood ashes may be added, and a few half-inch bones with the fine portions amongst them. In the case of Plums lime rubbish or a little lime will prove beneficial.

All the pruning that will be necessary after the leaves fall will be the shortening back of shoots and the removal of unripe ends. The following season fruit spurs will be formed almost the entire length of the young wood, tied to the old branches if the shoots made attained anything like strength, and the roots start fairly well in the new compost.

The spaces between the trench cut round the trees should be treated in the way advised if young trees are planted. This will prevent the trees from receiving more than their share of the autumn and winter rains.—WM. BARDNEY.

### TABLE PLANTS.

As a general rule plants for the decoration of tables may be selected from a collection of all kinds, but the most suitable are those which are neat and graceful in growth, light and effective in general appearance, not too large in size, nor growing in too large pots, and which will endure without injury the atmosphere of the rooms in which they are placed for a brief and reasonable time at least. The range of plants which a gardener with plenty of convenience at his command can draw upon for furnishing tables is considerable, and when the duty of decorating tables with plants is confined to making temporary and occasional displays for the brief period of a dinner party, many comparatively tender plants, including numerous flowering plants, may be employed. Such plants need a little preparation before taking them into a warm room, such as ascertaining that they are moderately moist at the roots,

and if growing in a high temperature a few hours' sojourn in a cooler one will tend to strengthen them and their flowers, and they will be less likely to suffer injury from the drying effects of heat and gas. Some plants, however, with the best preparation soon suffer from the lack of moisture in the atmosphere, and it is only when the foliage becomes thoroughly matured that they are able to resist for a time such unfavourable influences. Stove plants, including Ferns, foliage plants, and flowering plants, are the kinds which require some preparatory attention before using them for table decoration, especially at night.

Few plants for table decoration should be grown in larger pots than 6 inches in diameter. Large pots are very objectionable on dinner tables. For side tables or drawing-room tables, one or two plants of larger size and in larger pots are admissible, and often produce good effects; but the pots should, if possible, be hidden from view in some suitable and ornamental receptacle.

Stove and greenhouse plants, hardy British and exotic Ferns, furnish a great variety of suitable plants adapted for table decoration, and in the following notes I will endeavour to point out some of the most popular plants from among them that are most generally used.

#### CROTONS.

Beginning with Crotons, those beautiful stove plants, which take a prominent place for table decoration with those who have the means for growing them. Crotons generally look well under gaslight growing in the smallest possible pots according to the size of the plants, and well furnished with healthy foliage from the base upwards. They should when small be used as single-stemmed plants, for then each plant displays the individual leaves in a natural manner, and the appearance of crushing and crowding, always to be condemned in table decoration, is avoided. There are numerous varieties of Crotons, nearly all good, and brightly and distinctly coloured. A few of the best are Lord Wolseley, aigburthensis, Warreni, Newmanni, angustifolius, and majesticus.

Crotons are real stove plants; they enjoy the humid atmosphere, the strong heat, and revel in plenty of light and sufficient moisture at the roots. These conditions given them they grow freely, and it will be an easy matter to keep up a stock of healthy young plants, which may always be drawn upon for furnishing tables. Good loam, peat, and sand make an excellent compost for these plants. They should be potted firmly; an average temperature of 66° to 70° will grow them well, but they positively enjoy higher temperatures when the atmosphere is correspondingly moist, and the roots never suffer.

#### ARALIAS.

Aralias are elegant and graceful table plants. The stove Aralias have beautifully divided and finely cut leaves, requiring similar treatment to the Crotons. Four and five-inch pots are the most suitable sizes to grow both Aralias and Crotons in for tables. *Aralia Reginae* and *A. Veitchi* are two of the best. *Aralia Sieboldi*, a greenhouse plant, is more common and more hardy than the preceding one, and it is on that account more popular. It is more robust also in appearance, and possesses larger and less finely divided leaves. When small, and the foliage is bright, clean, and uninjured, it makes a very good table plant, being better adapted for occupying positions on tables for a longer period than the majority of plants. The main feature in their management is the supply of water to the roots and keeping the leaves clean. Neglect of these precautions soon causes the leaves to become limp and spoils the appearance of the plants. There is a variegated form of this *Aralia* resembling in every respect except in the colour of the leaves to the ordinary variety. It is, however, much scarcer and dearer than the plain-leaved form, and has to be imported from the Continent.

The ordinary form is easily raised from seed sown in a little heat in spring, and large plants may have their heads rooted in summer by notching the stems below healthy leaves, splitting a 4-inch pot in two and fixing it round the notched stem with copper wire and filling up with turfy material having plenty of sand in it, keeping all moist and daily syringed until the top is rooted and the young roots begin to protrude both top and bottom of the pot, when it is time to gradually sever the stem immediately below the base of the pot. *A. leptophylla* is also invaluable for tables.

#### DRACÆNAS.

Dracænas make excellent table plants. There are both stove and greenhouse varieties, the former have generally deep and richly coloured leaves. Splendid plants may be grown in 5 and 6-inch pots quite large enough for tables, indeed smaller plants in less pots are often wanted. It is a good plan to prick out on the surface of the soil at the last potting, or at any previous shift they may receive, small pieces of *Selaginella Kraussiana*, which will

rapidly grow and cover the surface of the soil, also hang down and cover partly the sides of the pot in time. Table plants are vastly improved by treating them in this manner; the natural living greenery on the surface of the soil almost becomes as attractive as the plant it embellishes. The stove Dracænas require peat, loam, and sand, to grow in plenty of water and heat, as well as a light position to make the colours of the leaves intense. The leaves are easily kept clean by sponging occasionally. Good table varieties are *D. terminalis*, *D. gracilis*, and *D. Guilfoylei*.

The greenhouse varieties though having less ornamental leaves yet make very useful and acceptable table plants in similar sized pots to the stove varieties. They are very useful for other purposes besides table decoration. These Dracænas are all green-leaved, some broad, some long and drooping, some erect and horizontal, some with gracefully narrow leaves. The best of them are *D. rubra*, *D. australis*, and *D. Veitchi*.

They are mostly rapid growers and soon become too large to be effective table plants. Happily this can soon be remedied, as they are the easiest plants to shorten, and root afresh from the stems. When it is desired to shorten a tall plant it may be done in a similar way to that recommended for the *Aralia*. Another equally effective way is to tie moss round the notched stem instead of fixing the stem within a pot. Perhaps it may be of interest and use to describe in detail the process of preparing the stem for the emission of roots, the same method being followed whether the rooting is to take place in soil or moss. The part of the stem most suitable for notching is that part among or immediately below the lower leaves. The stem must be cleared of leaves an inch or two above and below where the notching has to be done. First of all, the stem must be cut clean about half way through, making the cut transversely. About half an inch below that cut the knife must be placed and worked slantingly upwards, so that it meets the bottom of the transverse cut, letting at liberty a wedge-shaped portion of the stem. On the opposite side of the stem, but a little below, a similar nick must be made, taking care not to make either of them too deep or some difficulty will be experienced in preventing the head breaking off. Moss should then be tied round with matting, placing over a fair thickness of the moss, and during the operation securing, if necessary, the stem to a stick to prevent the possibility of its breaking off. The moss must be kept thoroughly moist, and the plant should stand in a warm house until rooted. When sufficient roots have been made the stem below the mossed portion must be severed, and the plant is ready for potting, and is at once a well-furnished specimen. Moderately small heads of Dracænas may also be rooted in bottles of water.

#### CYPERUS.

*Cyperus alternifolius* in a young state growing in pots of from 3 to 5 inches diameter makes a very effective table plant. It is a stove plant, but will do in a greenhouse in summer. It requires plenty of water, and should never be taken into a room when the soil approaches dryness. Being a tropical Sedge plant it thrives wonderfully with the pot immersed in water, but plants intended for indoor use are probably best cultivated like other plants in the stove intended for the same purpose. A large plant, however, plunged in the water tank will furnish abundance of young plantlets, which are freely produced on the old heads of foliage. To facilitate the quick rooting and enlarging of the young plantlets the stem containing them may be cut off and allowed to float on the water, into which the roots will strike and fresh strong leaf stems begin to extend upwards. When large enough they may be taken off and planted in small pots or thickly together in pans, affording them plenty of heat and moisture. Plants quite large enough for tables can be grown in 5-inch pots. Any kind of free and open soil will grow them well.

#### CALADIUMS.

Caladiums of many varieties, with their handsomely veined, coloured, and variegated leaves are very select and choice table plants, though only for temporary purposes. Being stove plants they rely upon the heat and moisture of that structure for their vigour and attractiveness, and should not therefore be expected to remain in good condition for any extended period. They are tuberous-rooted plants, and lose their foliage in the autumn, remaining at rest all the winter, and can only be employed for any purpose during the summer time. They are most effective for tables when grown in pots not larger than 6 inches. Some are very strong growers, and produce large leaves; others are of medium size, but all are beautiful. One little Caladium, growing only a few inches high, with short and slender stems, and small leaves distinctly marked with green and white. This is *C. argyrites*, and it makes quite a model little table plant. Abundance of heat

and moisture is essential for Caladiums during the growing season, they also liking good rich soil composed of peat, loam, and sand, with a moderate amount of sweet leaf soil.—S.

(To be continued.)

### THE APPLE SUPPLY.

THE interesting and practical article on page 509, by Mr. Wright, must set all readers studying this great problem of how to supply the English market with own-grown produce. Having recently visited London I made it my business to visit some of the wholesale markets, as well as to scan the fruit shop windows, as also to "taste and try" some of the most showy American Apples, and I must say I felt somewhat ashamed and humiliated at seeing such poor English produce, as compared with the American specimens. But on comparison with such fruit as was shown at the Smithfield Club Show by Messrs. Cheal & Son (I believe I am correct), I could not help thinking that the climate was not so much to blame as the cultivators. I bought a pound of "American Blenheims," which appeared identical to our own Blenheims, and I found there was more in outside show than in inside substance and flavour. I also examined and tried my Cobhams on my return, and felt convinced there was no comparison in my mind as to our fruit holding its own in quality, if not quite so tempting in appearance.

But my object in making a remark on the subject is respecting the neglected orchards. Some years ago I referred in the Journal to a neighbour who used to grow 500 pots of Blenheim Pippin Apples alone besides other fruits in his orchards annually. I think I am quite correct in stating that during the past three seasons those orchards have not produced ten pots of these Apples collectively. Blight—i.e., caterpillars, and psylla, and neglect have reigned supreme, and no amount of advice gratis and information on undoubted authority and firm basis availed, which have been treated—if not with contempt, with indifference. There is undoubtedly a good field for intelligent fruit culture.—J. HAM, *Astwood Bank, Worcestershire.*

### POTATO DISEASE EXPERIMENTS.

SOME time ago reference was made to Mr. Robert Fenn's fight with the fungus that is the active agent in the Potato disease. His instrument of warfare was the Maalbec bellows, and his ammunition powder—the anti-blight preparation of Messrs. Tait and Buchanan as supplied by Messrs. Barr & Son. This powder having proved so effective in preventing mildew in vineyards in Portugal, it was thought it might be applied with advantage to Potatoes for preventing the disease. Mr. Fenn gave it a thorough trial, and has sent us a record of the results. We have not the slightest doubt of the accuracy of his statement, but as tabulated it would occupy much more space than we have at disposal, and a digest will equally well show that he mastered the enemy which has attacked his crops with more or less energy over a period of forty-six years.

The whole of some of his new varieties, with others of specially high quality and prone to disease, were dressed, and of these, such as Rector of Woodstock, Woodstock Kidney, Eliza Fenn, Sir Charles Douglas, Sutton's Favourite, and Fifty-fold, the plants remained fresh and green to the end of the season, and afforded good crops of sound tubers. In 110½ lbs. of Fifty-fold there was not one diseased tuber. In Rector of Woodstock, 73 lbs. were sound and 3 lbs. tainted; Sir Charles Douglas, 111 lbs. sound, 6¼ lbs. tainted. This variety is not in commerce. For some time the late Sir Charles Douglas lived largely on Potatoes, and after trying many varieties, including Mr. Fenn's seedlings, he preferred this; therefore the raiser, instead of placing the variety in commerce, preferred, as he said, "to keep Sir Charles alive as long as possible," and that is the reason of its name.

Of some varieties portions of rows only were dressed, the other portions left to their fate. The lengths of the rows experimented with, and the results are indicated with precision in the following digest:—

RINGLEADER: 39 feet of row dressed, 27 feet undressed. *Results:* Weight of tubers in the former, 59½ lbs.; in the latter, 23 lbs. No diseased tubers in the dressed row, 5 lbs. in the other.

EARLY BORDER: 45 feet of row dressed, the same length undressed. *Results:* Weight of tubers in the former, 35¾ lbs.; in the latter, 17½ lbs; 3 lbs. of diseased tubers in the dressed row; 10¾ lbs. in the other.

SIR POLYDOR DE KEYSER: 10½ feet of row dressed early and repeatedly, the same length dressed late, when disease appeared on the

leaves. *Results:* 56½ lbs. of sound tubers in the dressed, and 30½ lbs. in the other.

PRIZETAKER: 34½ feet of row dressed, the same length undressed. *Results:* 57½ lbs. of sound tubers in the former; 21¾ lbs. in the latter.

ELIZA FENN.—A selection from Early Regent: 48 feet of row dressed, the same length undressed. *Results:* Weight of crop in former, 75¼ lbs.; 53½ lbs. in the latter; no diseased tubers in the dressed portion; 3 lbs. in the other.

THE DAMSON (new seedling): 26½ feet of row dressed early and repeatedly, the same length of row dressed late. *Results:* 44 lbs. of sound tubers in the former; 23¼ lbs. in the latter.

It will be seen that early dressings gave the best results, and that the powder is more a preventive than a curative agent. This is only what might be expected, for when the fungus takes possession of the cells and tissues of the plants the parts thus injured or destroyed cannot be made sound again by any applications, though the growth of the fungus may be arrested, as has proved to be the case both with Potatoes and mildew on Vines. Mr. Fenn attaches importance to giving the first dusting before earthing, then "following it up," according to the weather and condition of growth. How many times he ran puffing up and down the rows will perhaps never be known; he only knows he mastered the enemy for the first time in his long Potato-growing experience, when its attacks were persistent as during the present season, and rejoices accordingly.

The increase in yield, resulting from the dressings, is not to be attributed to the manurial effect of the powder, but to the prolonged growth of the plants, in consequence of its agency in preventing the germinal tubes of the fungus spores penetrating the leaves and soft stems.

### FLOWERS FOR CUTTING.

#### THE CHRYSANTHEMUM.

THE time is long past when it is necessary to bestow any praise on Chrysanthemums, and perhaps but little that is new can be written as to the methods of employing them as cut flowers. At one time it was thought expedient to cultivate the Pompon section mainly for cutting purposes, and one of the strongest protests made by the opponents of the "large bloom system" was furnished by the plea that the blooms had no decorative value on account of their size. It is many years since I drew attention to the great value of large flowers for decoration when used with judgment, and it is safe to say that mere size at the present day forms no bar to the employment of the largest Chrysanthemum grown; indeed the tendency seems in the direction of size. While that is so, no doubt there is plenty of room for plants which produce a quantity of fair-sized flowers, which, like the Dahlia, when cultivated for flowers in quantity, are eminently useful for home use. The happy medium appears to be the setting aside on the one hand of the whole family of Pommpons, which are pretty, but otherwise of no value, and, on the other, to select from the great number of Japanese, incurved, and reflexed, which of late years has assumed such enormous proportions, and to cultivate these with the double view to utility and beauty.

It is not uncommon that a free-growing floriferous variety is chosen on account of these qualities alone without taking any account of colour. That is a mistake. The primary feature of a good Chrysanthemum is colour. At any period of the year this forms an essential element in a good flower for cutting, but during the winter it is of pre-eminent importance. Therefore, no matter how many other good points a Chrysanthemum may possess, if it lacks clearness and brightness of colouring, it is so far worthless. The best colours in addition to white flowers are yellow, of which there are many intense shades of great beauty; orange; crimson when clear and bright, and pure pink or rose. Lilac, dull reds, and so-called violet shades are all useless.

With regard to the treatment of plants for the production of flowers for cutting there is not much need be said. At the same time there are some points to which attention may be fittingly called. Not uncommonly Chrysanthemums grown solely for decorative purposes receive scant justice in the way of good culture. In the first place good cuttings should be secured, and that as early in the season as possible. I invariably find that the cuttings secured from now until about the middle of January produce the best plants and the best blooms. It is a good plan to pinch out the points of the young plants as early in the year as it can be done. By doing so a good foundation is laid for a large plant, and I like to treat them well from the very beginning. As a rule they are grown naturally, but this year, after allowing the practice to slip for some years, I cut down a certain number in early summer, and

they have done so well and are so much dwarfer than others left to grow unchecked, that more will be cut over another season. Most of our plants are disbudded, leaving one bud to each shoot, and in some cases weakly side growths, which can be seen to be unequal to the production of good flowers, are also removed.

Chrysanthemum flowers lend themselves with the best effect to all kinds of decorative purposes. Large blooms are excellent for "table work." These, also, when cut with long stems and set up a very few in large vases, are most beautiful. If any lack of furnishing is apparent in the portion which springs immediately above the glass, a few smaller blooms on shorter stems may be added with good effect. For the medium sizes of glasses employed in large apartments ordinary well-grown blooms will be suitable, and nothing is necessary in the way of foliage in any case save that on the stems as cut. Overcrowding, or indeed crowding in any form, is to be avoided.

As to the varieties best suited for the purpose under discussion they need not be many. At the same time it would be unwise to be too exclusive, as in addition to the colour we have now so many beautifully constructed flowers that variety in this respect is valuable. There is also the matter of a lengthened season to consider, for without trenching much on the few varieties suitable for cut flowers which bloom in summer and autumn in the open border there ought to be a good supply in pots from October until the end of January, a period of five months, when flowers are not too plentiful. One year I had flowers all the year round, but they are of doubtful utility at any other than the period just mentioned. Like some other flowers, Chrysanthemums in some seasons bloom quite out of their ordinary course; as, for instance, last year we had Lady Selborne in flower at Christmas, and Mdle. Lacroix even later, but as a rule the various sorts can be relied upon with tolerable exactitude.

The earliest plants should include the Madame Desgrange family and the new A. Crepey. Roi des Précoces has for several years held a prominent position. This should not be disbudded, and requires cutting when first open, as, like so many crimson tinted sorts, it rapidly becomes dull when kept. It is a very useful sort. Souvenir de M. Menier, which appears to be a much improved L'Africaine, is worthy of commendation as an early dark flower. M. Hilliot is exceedingly good, bright chestnut red, and a beautifully formed flower. Madame C. Foucher de Careil is an early Source d'Or, deep orange, and good. Lady Selborne is still indispensable, and must not be disbudded. Where few sorts are grown this should find a place, as it keeps so well. Elsie is also very good. We now arrive at the general blooming period, and among these the following will be found among the best to grow:—Fairy Queen, a beautiful variety; W. Holmes, to be cut as soon as open; Amy Furze, one of the best of the pink shade; Maiden's Blush, La Triomphante, Janira, a fine crimsoned tinted purple; Sœur Melanie, fine when well grown; Reverie; Source d'Or, one of the most beautiful; Phœbus, very good; Mrs. Stevens and W. Stevens, both fine, old gold; Gluck, Alice Bird, Gorgeous, Mrs. Dixon, Mr. G. Glenny, and Lord Alcester are indispensable among yellows. Among the best whites are Mrs. Rundle; Elaine, to be cut before full development; Avalanche, Mdle. Lacroix, Felicity, and Mrs. Forsyth. Reaching to a later period we have E. Molyneux, Guernsey Nugget, Condor, Peter the Great, Fair Maid of Guernsey, Lady Margaret, Miss A. Lowe, George Sands, Ethel, Mrs. Jones, L'Ebourriffée, and Val d'Andorre.

The only single variety grown is Miss Mary Anderson, good, which is a great favourite.—B.

### SCARCITY OF VIOLETS.

I WAS surprised to read in the note from "M. H.," p. 517, that Marie Louise Violets in pits were not flowering so freely as usual, because I thought our plants were giving us more blooms and deeper in colour than usual, although plants in our frame are not doing so. These plants were lifted and planted in a spare frame fully two months after the principal plants were placed in their flowering quarters. Not having a spare frame at the time, and thinking we had sufficient, the plants were allowed to remain where they grew during the summer, not needing the land, hence their retention; but I am glad we did utilise them, because it provides a lesson of how necessary it is to lift and plant early the roots intended to flower during the months of December and January. The middle of September is not too early to protect the plants from excessive rains, which is no trouble after the roots are placed in the pits or frames. I attribute our present success to this fact. The foliage, too, is superior to any we have previously had. I have heard complaints in this neighbourhood about the scarcity of bloom this season, but in one instance especially the plants never

grew well enough to form desirable crowns out of doors. The poor-ness of the land in which they were planted was blamed for this defect; and without fully developed crowns it is useless to expect a full crop of bloom, no matter what the season may be. Because I approve of storing the roots early I do not believe in the practice of "coddling" them to give the plants a free growth; my only object is to so have them under control that heavy continuous rains can be warded off. No matter how cold the weather may be—excepting when freezing—the lights are drawn off our Violet frames early in the morning and left off till dark, and when they are on in the case of rain they are tilted to admit of a free circulation of air about the plants, conditions they enjoy, judging by the appearance of the plants and the blooms they bear.—E. MOLYNEUX.

### CYPRIPEDIUM CALYPSO.

HYBRID Cypripediums now constitute a large and important class of Orchids, and yet fresh and distinct variations are continually forthcoming, a large proportion equalling and some exceeding those previously obtained. The hybrid of which a flower is depicted in fig. 101, is one of Messrs. Veitch & Sons' productions,

FIG. 101.—CYPRIPEDIUM CALYPSO.

and resulted from a cross between *C. Spicerianum* and *C. villosum* var. *Boxalli*, exactly the same species, but different varieties having been employed in the production of *C. Lathamianum*, raised in the Birmingham Botanic Gardens. *C. Spicerianum* has been freely employed by hybridisers, and it has constituted one of the parents of several hybrids. *C. villosum* has also been useful in the same way.

*C. Calypso* shows many characters of both parents. The dorsal sepal has a good deal of the *C. Spicerianum* form and marking, the petals and lip being more suggestive of *C. villosum*. White and a yellowish tint with dark lines and dots furnish the chief colouring.

### PRUNING VINES.

I REGRET that the experience of "E. M." differs from my own in regard to the pruning Muscat of Alexandria, because I know him to be a first-rate Grape grower, having had many opportunities of seeing the fine produce he staged a few years ago at some of the leading southern shows, and having also seen the Vines, vineries, and the delightful gardens he has managed so well for the last twelve years. Although the close-spur system has succeeded in the case of "E. M.," I am fully convinced it is not the best method to adopt with Muscats generally, as I have on many occasions seen the benefit derived by Muscats when the close-spur method of

pruning has been relinquished in favour of the system I advocate. Notwithstanding the fact that my critic was this year successful in securing finer bunches than usual, if he will try one Vine on the long spur system, I shall be much surprised if he does not produce still larger examples next season. The fact of his having made an advance in that direction without changing his pruning tactics, seems to suggest he has been giving them extra attention. Possibly his borders may have been renovated a season or two ago, and the Vines are now reaping the benefit of that necessary attention. From the time the Vines were planted up to the present time, I fancy there must have been great fluctuations in the size of the bunches and their quality; times when the Vines showed want of vigour, and by a little assistance in the way of fresh soil at the roots, have been brought to a satisfactory state again. I maintain this is generally the case with Muscats when closely pruned, they never seem to be thoroughly satisfactory for any length of time, unless plenty of young wood is retained and a gradual extension going on; but of course, as I pointed out in my previous article, other details of cultivation must be well attended to, and then, in my opinion, the results are far better than can be regularly insured under the close pruning system of pruning.

I am inclined to think there are other causes which play an important part in the production of better bunches toward the base of the rods than near the top than are brought about by pruning the leader closely in its early stages of growth. Muscats in good condition invariably exhibit this tendency, and I have many times remarked upon the same fact in connection with Vines which were allowed to retain treble the length of leader the first season than your correspondent thinks desirable, and indeed few gardeners care to cut back so severely when they have grand wood to rely upon. There are thousands of Muscat Vines now grown which produce in one season splendid canes, reaching from the bottom to the top of the roof, which are scarcely shortened at all, and yet are satisfactory in every way for years after. As far as my experience goes it is altogether unnecessary to shorten them to more than half their length, seeing that with proper attention the young rods break evenly and strongly from top to bottom, and are well able to carry a bunch or two the following season.

To my mind it is not very clear how a "close method of pruning the leader in its early stages of growth," should have the effect of inducing them to bear the largest bunches near the base twelve years after. Without doubt "people" engaged in Vine growing are anxious to cover the roof as quickly as possible, and in these nineteenth century days the principle to adopt is that by which the quickest and best returns are obtainable. A larger quantity of first-class Grapes could be produced from a given space in twenty or thirty years by replanting after half that time had expired than by cropping one set of Vines throughout. I quite agree with "E. M." that thoroughly ripened wood is an important factor in the production of good Grapes, but it is easy to see that he is a little wide of the mark when he infers that it is only in cases where "two or three" shoots are left to a spur that the long spur system of pruning is necessary. I simply advised (in cases where long shoots were left) that a shoot be retained near the base, and stopped to a couple of leaves, so that the spur might the next season be pruned back to that point. Now this shows that the necessity for a change in the method of pruning was apparent before the second shoot to the spur was produced, but independent of that fact the objection to this basal shoot is more apparent than real. As I have in no instance seen less favourable results follow, as the principal shoot grows quite as strong as is desirable, and the reserve shoot forms two or three nut-brown buds to cut back to another season, but it will not often be necessary to fruit these basal shoots the following season, as a few of the old spurs should be pruned back each season. With regard to training the summer growth of Vines thinly, I have repeatedly penned notes for the Journal in support of that practice, but the majority of Grape growers must have noticed that when Vines have been planted a few years the portion of the trellis most scantily furnished is usually exactly over the main rod. Therefore, instead of having a tendency to overcrowd the main shoots, these basal ones have an invigorating effect upon the general health of the Vine by clothing with healthy leaves the part above indicated, where they can be fully exposed to light and air.

In regard to Lady Downe's, I believe many, indeed the majority of Grape growers, will bear me out in the assertion that this fine late Grape is prone to produce irregular crops if pruned closely year after year. Among other instances I noted a striking one a few days ago, when I had the pleasure of inspecting a fine house of Grapes, the varieties being principally Gros Colman and Alicante, with a few Lady Downe's intermixed. The two first named varieties were in splendid condition, having large berries perfectly coloured (which is not generally the case with Colmans this year), and as a proof of their excellence were selling for 1s. per

pound more than any other Grapes sold in the neighbourhood, and they were purchased by a firm of fruiterers who know what they are about, as they have established shops in nearly all the large towns in the Midlands and the North. Now, in this same house were many fine bunches of Lady Downe's, perfect in shape, large in berry, and quite black. This showed plainly that the Vines were in good condition, yet the crop was irregular and not good enough to satisfy the ambitious cultivator, who intends to take a bold course in the matter of pruning this season.

I must confess I was somewhat jubilant when I read the concluding paragraph of my generous critic's note. Here he admits that with Gros Guillaume, after an eight-years trial of the close spur system, a change in the method of pruning has enabled him to secure finer bunches than at any time previous, and I predict that sooner or later he will find the same principle applies to the Muscat of Alexandria. The former endured restrictive pruning for eight years, the latter after twelve years are still satisfactory, but unless a large amount of young wood is left annually, before many more years have elapsed the gnarled and senile spurs on the Vines under "E. M.'s" charge, will cease to produce Grapes of the high quality I have seen him exhibit in days gone by.—H. DUNKIN.

IN a short note on pruning Muscat of Alexandria, p. 520, I alluded slightly to the pruning of young Vines. As the present is a suitable season for this work I will say a little more on this subject.

I have come to the conclusion that more young Vines are ruined by faulty methods of pruning in their initial stage than by anything else. I have several times inquired of gardeners why such a length of leader was left, not only the first year after planting but for several years. The answer has invariably been, "Oh, I want to cover the trellis." The question, "How many bunches do you reasonably expect that Vine to carry?" pointing, perhaps, to one that was bearing the second season's crop. "Oh, not more than four at the outside." "Why, then, do you want so many side shoots," was my next query. "I always understood that the more foliage a Vine had the greater number of roots is obtained," has been the answer more than once.

I have never yet seen Vines which were allowed to extend 6 feet annually from the first until the allotted space was covered that were satisfactory at the end of ten years, when the same Vines were planted with the idea of their giving full crops of fruit for twenty or thirty years, and this they ought to do if planted properly in well made borders and managed afterwards on correct lines. All the Vines that have come under my notice, treated in the manner described, have shown such defects—an uneven thickness of the rods, a kind of bulging out here and there, with several thin weakly parts, which cannot throw out vigorous side shoots from which good fruit is obtained. Well managed Vines ought to show a gradual decline in the size of the rod from the base to the point, no matter how long or how short it may be, whereas those mismanaged exhibit a great unevenness.

If there is an exception in the matter of cropping and strength of a more uniform character in one kind than another subjected to errors in pruning it is in the variety Alicante. The constitution of this sort appears to be more hardy and better able to contend with such faulty management in pruning. Even this variety, if allowed to cover the trellis quickly, will not last in good condition so long as Vines of the same kind which were more restricted in their youth. It is very well for those persons who have an unlimited number of vineries at command to run the rods up quickly to obtain special bunches for a few years and then replant again for the same object; but as in my case, where there are but three vineries, from which we manage to have Grapes nine and ten months of the year, we have to work on quite different lines. It is the future as well as the present that we ought to consider in the method of pruning young Vines. What is required is a sufficiency of the leading part of the rod to be left annually from the initial stage to provide all the wants of the Vine, such as a sufficiency of foliage to promote root-action, which is essential, and to give side shoots wherefrom the necessary bunches of fruit shall be obtained. Beyond this what greater length of the leader should be left at pruning time that will afford these requirements? I would ask. Is it not a waste of growth to allow more? Far better is it to concentrate the strength of the Vine in a limited space, so that some of its energy is retained until a future day, when the crop of fruit is heavier, and the Vine will have become weaker through other reasons. I have many times seen Vines with serious gaps between the side shoots owing mainly to the fact of too great a length of rod being retained each year at pruning time. Why is this? some will ask, perhaps.

With Vines, as with other trees, the sap flows to the highest point first with greater force, causing the uppermost eyes to start

into growth first; the base buds of each year's pruned leader receive the least force of sap from the flow, and consequently remain, if not quite inactive, in a weak state, never appearing to make up for the loss of energy at the outset, even if growth commences. It is the want of concentration which prevents free growth throughout the Vine in a regular manner.

I have now pointed out the evils of what I term an irrational method of pruning young Vines. The next point is how they ought to be managed so that a superior foundation is laid—not only in favour of present crops, but for the supply of fruit, which ought to be obtained from these Vines during the maximum number of years and for the better appearance of the Vines. It will be wise perhaps to commence with the pruning—quite the beginning. When planting Vines those of one year's growth from the eye are preferred to those which are older; the canes, as they are termed in that stage, will not be less than 6 feet long. My plan is to prune them for the sake of convenience at planting time to within, say, 1 foot of the soil. I prefer that their growth shall commence with about three shoots to each Vine, which better provides a choice of the best when growth commences, although I prefer that which comes from the base; but slugs may be troublesome, or an accident may take place in the shoot depended upon if only one were retained.

It is wise to remember the old adage, "safety in numbers." Even where all the buds start freely into growth, by judicious management that at the base will become the fittest to provide the future rod. At the end of the first season's growth after planting pruning is done, with a view of allowing for a pair of side shoots and a leader above the lower wire.

If it is considered advisable to allow Vines of this age to carry one or even two bunches of fruit, the pair of side shoots will provide them. It is not considered good policy to allow the leader of a young Vine to carry any fruit, nor would it be so to crop a Vine of this age with two bunches, having in view its future; but even were that so, two bunches could be easily obtained. And why, then, is it necessary to allow more shoots? The plan adopted by persons of experience in the cropping of Vines the first year is to allow one bunch each, just to prove the variety as it were. The second year the length of the leader should not extend more than 2 feet for the same reason as previously given.

Three bunches to each Vine will be a sufficient crop for Vines of this age, bearing in mind the future maximum number of years the Vines are to last. The two side shoots formed the previous season are certain to form suitable bunches, and several more growths will spring from the 2 feet of leader left in addition to the leading shoot, which is to continue the progress of the Vine for future years. The third season an extra length of 6 inches may be added to the leader if the prospect warrants such a proceeding—that is, equal strength being maintained in all parts of the Vine.—E. M.

THE WEATHER IN THE METROPOLITAN DISTRICT during the greater part of last week was distinguished by continuous dense fogs and very low temperatures. On the evening of December 25th the fog suddenly dispersed and a rapid thaw commenced, the two following days being clear, sunny, warm, and spring-like. The hoar frost had been so thick upon the trees and shrubs, that in some places when it fell it formed a snow-like covering 2 inches in depth. Very seldom does hoar frost last so long as on this occasion. Slight frosts have been experienced since, with rain at intervals, and some fine clear days.

— THE MARKET GARDENERS, NURSERYMEN, AND FARMERS' ASSOCIATION.—The annual dinner of this Association took place on the 17th inst., at Simpson's Hotel. William Poupart, Esq. (the President of the Association) took the chair, and upwards of seventy gentlemen, representative of the growers' trade in its various branches, partook of an excellent repast, a selection of vocal and instrumental music contributing to the success of the gathering. A full notice of the Association, its constitution and objects, will be found in our advertisement columns.

— DEATH OF A NONAGENARIAN GARDENER. — We hear with regret that Mr. James Williams, father of the late Mr. B. S. Williams of Upper Holloway, and grandfather of Mr. Henry Williams, died on December 24th last, in his ninety-fifth year, he having been born on January 18th, 1797. He went into the service of Mr. Warner, Woodlands, Hoddesden, December 17th, 1817, and remained in the family until he retired, some few years ago.

— HONOUR TO MR. GEORGE DICKSON OF NEWTOWNARDS, COUNTY DOWN, IRELAND.—All lovers of the Rose, whether they are personally acquainted with this renowned rosarian or not, will be glad to learn that the Lord Chancellor of Ireland has admitted him to the dignity of a Justice of the Peace for the County Down. Mr. Dickson has already filled several public offices with distinction, and there can be little doubt that his business qualities and sound sense will find ample scope in the new position he has been called upon to fill.

— NEW YEAR'S REMINDERS.—Messrs. J. Weeks & Co., Chelsea, send us a sample of the pocket book they annually distribute. It is a sound, useful book, as it ought to be, as representing this well known firm, and will be of service to its possessors throughout the year.

— GOLD MEDAL TO MR. SELL OF FLEET STREET.—We are informed that the Jury of the Exposition Internationale de la Publicité, 1891, Palais des Beaux-Arts Paris, have awarded Mr. Henry Sell the highest award—viz., the gold medal, for his "Dictionary of the World's Press," and other publications relating to advertising.

— GARDENING APPOINTMENTS.—Mr. John Tweedie, foreman under Mr. Clark, Wemyss Castle, has been appointed gardener to Sir R. Abercromby, Bart., of Birkenbog and Forglen, Banffshire. Mr. William Leath, a late foreman to Mr. Lambert, Onslow Hall, Shrewsbury, is appointed to succeed Mr. Townsend at Mytton Hall, Shrewsbury (T. R. Greator, Esq.).

— PRIMULAS.—A visitor to Messrs. J. Veitch & Sons' Nursery, Chelsea, was so charmed with the Primulas that he could not be satisfied without bringing samples with him for our opinion of their merits. Only a glance is needed for recognising the substance of the blooms, with the richness of the dark and the delicacy of the light colours. They are good in every respect, and represent excellent varieties admirably grown.

— MESSRS. FOSTER & PEARSON send us their clear and excellent almanack of twelve sheets. It is admirably adapted for offices and gardeners' cottages. A new feature is introduced in the form of excellent portraits of Mr. Jennings of Ascott Gardens; Mr. J. Douglas, Great Gearies Gardens; Mr. W. Bennett, Rangemore Gardens; Mr. Davies, Mote Park Gardens; Mr. Bailey Wadds, Birdsall Gardens; and Mr. Elphinstone, Shipley Hall Gardens.

— THE PRESTON AND FULWOOD FLORAL AND HORTICULTURAL SOCIETY.—The forty-third monthly meeting of the members and subscribers of the above Society will be held in the large room of the Legs of Man Hotel, Fishergate, Preston, on Saturday evening next, January 2nd, 1892, when Mr. John Williams, of the Priory Gardens, Penwortham, will read a paper on "Our Homes, and Climbing Plants to Beautify Them." Chair to be taken at 7.30. Exhibits of plants, flowers, fruit, or vegetables are invited.

— FRUIT CULTURE IN SOUTH AUSTRALIA.—According to official returns, lately reviewed by the *Adelaide Observer*, the area of land devoted in South Australia to gardens and orchards has advanced since 1885 from 10,775 acres to 15,362 acres, representing an increase of 50 per cent., this area apparently including that devoted to viticulture. The statistics show that the Orange, Almond, Walnut, Chestnut, and Olive are largely cultivated. The number of Almond trees is given as 134,038, or 27,768 more than last year; Olive trees, 59,118, or 11,694 more; and Orange trees 56,341, the latter producing 41,762 cases of fruit, or 3040 more. The increase in the manufacture of olive oil is even more marked. The quantity made is returned at 6838 gallons, as against 1486 in the previous year. Almond trees are stated to have produced 3311 cwt. of nuts, being an increase of 1468 cwt. In 1890 Walnut trees numbered 7644, and Chestnut trees 1128. The climate and flora of South Australia are also well adapted to the needs of the bee-keeper. According to the rough estimates of the bee-owners, 25,383 hives in the colony last year produced nearly 500 tons of honey, of which 80,793 lbs. were exported.

— **SHIRLEY HIBBERD MEMORIAL.**—At a meeting of the Committee appointed to carry out this scheme, held at Chiswick on November 17th, 1891, Dr. Masters in the chair, it was announced that the sum received from all sources was £259 9s. 6d., and that after the payment of all expenses, amounting to £38 14s. 4d., there remained a balance in the bank of £220 15s. 2d. A satisfactory portrait of Mr. Hibberd has been hung in the Lindley Library. The balance of the moneys received is, after payment of the expenses of the deed, to be invested for the benefit of the orphan daughter in the names of Mr. W. R. Hargreave, Mr. Leonard Barron, and Mr. John Collingridge. The trust-deed is to contain provisions (1), that in the event of the death of the child, previous to her attaining her twelfth year, the amount then standing to the credit of the Trustees shall be paid to the Gardeners' Orphan Fund; (2), that in the event of the decease of the child at any period between the twelfth and the twenty-first year of her age, then the moneys invested shall become the absolute property of her uncle and guardian, Mr. C. M. Mitchell.

— **THE LEE, BLACKHEATH, AND LEWISHAM HORTICULTURAL SOCIETY.**—The annual meeting of the above Society will be held at the Working Men's Institute, Old Road, Lee, on Monday, January 11th, 1892, for the election of committee and for other business. The chair will be taken at eight o'clock by John Penn, Esq., M.P., the President.

— **WE** understand that it has been arranged between the CROYDON AND THE LEE, BLACKHEATH, AND LEWISHAM HORTICULTURAL SOCIETIES to hold their respective exhibitions on different dates in 1892, and not on the same day as heretofore. The dates fixed are for Croydon, Wednesday, July 6th; Lee, Thursday and Friday, July 7th and 8th.

— **AMERICAN APPLES.**—The shipments of Apples from America to England during the week ending Nov. 28th were:—From Boston to Liverpool, 15,195 barrels; to Glasgow, 9,123 barrels; to London, 3,925 barrels; a total of 28,243 barrels. From New York, 18,298 barrels to Liverpool, 6,518 to Glasgow, 4,133 to London, and 359 to other ports, a total of 29,308 barrels; 9,184 barrels were sent from Halifax to London, and 5,358 barrels from Portland to Liverpool, a grand total of 72,068 barrels for the week. The corresponding week last year there were 1,397 barrels sent from Boston, 7,021 barrels from New York, and 8,177 from Portland, a total of 16,595 barrels.

— **THE WEATHER IN THE CRAVEN DISTRICT OF YORKSHIRE.**—The weather here during the last week has been exceptionally severe and changeable. On Tuesday, December 22nd, we registered 18° frost; on Wednesday, December 23rd, 8°; on Thursday, December 24th, 14°; and on Christmas morning the thermometer went down to 4°, or 28° frost, and at noon on the same day the thermometer stood at 8°, or 24° frost, the trees and shrubs being covered the whole day by a beautiful hoar frost. On Saturday it rained nearly all day, and on Sunday morning frost again appeared to the extent of 13°, and on Monday rain again, also showers of hail and snow during the day.—JAMES PATTERSON, *Gardener to H. Christie, Esq.*

— **MILD WEATHER IN IRELAND.**—I am not sure I should not recommend the aged and delicate to try the south of Ireland as a winter resort instead of the Mediterranean villages. I see by Wednesday's *Times*, when the thermometer registered an average of 28° Fahr. at Biarritz the average for the south of Ireland was 40°. Though inland here I cut Chrysanthemums off my garden walls uninjured and fresh on Christmas Eve, and Christmas Day was as fine, with soft genial sunshine, as a similar soft day in April or May here. In London on those and several days previously you were enveloped in a dense fog, and even policemen walked into the canal from a similar cause in Leeds. The pastures are still quite green.—W. J. MURPHY, *Clonmel.*

— **PRIZES FOR VEGETABLES IN 1892.**—We understand that prizes will be offered by Charles Sharpe & Co., during 1892, at the following floral and horticultural societies' shows—viz., The Royal Horticultural Society, at Chiswick, in July, for Peas, £2 2s., £1 1s., and 10s. 6d. Sleaford Floral and Horticultural Society, in July, for Peas, 15s., 10s., 5s. For Potatoes, 10s., 6s., 3s. For collection of vegetables (cottager and allotment holders only), 10s., 7s. 6d., and 5s. Lee, Blackheath, and Lewisham Horticultural Society, in July, for collection of vegetables, 20s., 10s., 5s. Enfield Horticultural Society, in July, for Peas, 15s., 10s., 5s. For Potatoes, 10s. and 5s. Holbeach Flower, Fruit, and Vegetable Show, in July, for Peas, 15s., 10s., 5s. For Potatoes, 10s., 5s. Heckington Floral and Horticultural Society, in July, for

Peas, 15s., 10s., 5s. For Potatoes, 10s. and 5s. Tibshelf Floral, Horticultural, and Rose Society, in July, for Peas, 7s. 6d., 5s., and 3s. For Potatoes, 7s. 6d., 5s., 3s. For Conqueror Long-pod Beans, 4s., 3s., 2s. The Royal Aquarium Summer and Winter Garden Society, at Westminster, in July, for Peas, £1 15s., 10s., and 5s. — **CALIFORNIAN FRUIT.**—Southern California will produce more Oranges this coming year than last. The crop of 1890 was estimated at 130,000,000 Oranges, which would be 1,200,000 boxes, or 4000 carloads. It is estimated that the crop will be 200,000,000 Oranges this year, enough to fill 1,850,000 boxes, or 6000 cars. Hundreds of orchards commenced to bear this year, and, of course, markets must be sought for those larger crops of Oranges. The Orange groves of California are all yet young, and thousands of acres now planted with trees have not come into bearing. In a short time production must be doubled, and in the course of a few years there will be ten times as many Oranges grown as at present. Such a production would require a market for 60,000 carloads, or four times as great a market as that now predicted. And it must be remembered that the Florida crop is not included in the above estimate. One thing is certain, railroad companies must reduce their price of freight in order to permit of Oranges being sold at lower rates in the East. Growers in California have great faith in the future, as they are setting out new orchards, though many land owners are turning their attention to other products, notably the Lemon. Lemons are cured in darkened well-ventilated buildings, and require skilful and gentle handling. Not many Lemons have been shipped East as yet from California, because the process of curing has not been fully understood, and the railroads do not give the shipments proper care. Olives are being planted largely on lands in Southern California, also Figs where water is not available. The fruit products of California are very large, and in some cases phenomenal, but the profit is not always so large as is represented in some glowing circulars sent East by land speculators. Like any other legitimate business it pays a good profit to those who follow it carefully and intelligently, and some years exceptionally large profits are made, but the business will finally settle itself down to a regular legitimate industry, with a fair average profit. One expert in California expects that State to be a large producer of tea at some future period. The one drawback to making California a great tea-growing State is stated to be the price of labour. It is quite probable that extensive experiments will be made in Southern California in the direction of tea culture.

#### A VISIT TO MADRESFIELD COURT GARDENS.

HAVING business at the well-known firm of Messrs. R. Smith & Co. of Worcester recently, I asked my guide, Mr. J. Lewis (who kindly piloted me amongst the fruit and other trees there) if I could manage to get round Madresfield before dark. The answer was, "Oh yes, I will put you right." Madresfield Court is about five miles from Worcester and a little over two miles from Malvern Link Station. The village of Madresfield is one of the most beautiful and cleanest I ever saw; judging from external appearances the cottages are models, and give an idea of comfort and contentment that is lacking in many villages. Going through a pretty lodge entrance, I soon found myself at the Gardens, and received a cordial welcome from Mr. Crump. As the day was short no time was lost in commencing to "look round," beginning with the houses. The first range is devoted to Strawberry forcing early in the season, and later on for Tomatoes and Melons. Another range was occupied by Bouvardias, Roses, and similar useful flowering plants, all in fine condition. Leaving these after a rapid inspection we came to the vineries in which some of the best Grapes I have seen this season were hanging. Gros Colman were fine in bunch, berry and

PICEA NOBILIS CLAUCA.

FIG. 102.—AVENUE AT MADRESFIELD COURT.

finish; Trebbiano was good, large in bunch, and of a fine amber colour. Alnwick Seedling was in perfect condition; also Museat of Alexandria, which were superior to many that gained chief honours at large shows. Black Hamburg was nearly over; what remained, however, indicated high culture of this good old variety, but it will soon be conspicuous by its absence at Madresfield, as the family prefer Madresfield Court, of which young Vines are commencing to crop up between the Black Hamburgs; probably another year will see the end of them. Many find this Grape very difficult to manage owing to the cracking of the berries, Mr. Crump evidently has no trouble in that respect, for better Grapes could not be desired. In answer to a question Mr. Crump said that just before colouring commenced he left a little front ventilation, as well as top ventilation, and he believes that is the secret of his success. That such treatment is correct is strongly demonstrated by the large bunches of fine well coloured berries, without the least sign of cracking.

Leaving the vineries we passed into the Peach houses, containing magnificent trees, qualified to produce the finest fruit. Pines are not much cared by the family, hence they are being gradually reduced, and the houses filled with fruit trees, such as Figs, Peaches, &c., which are more appreciated. One house formerly occupied with Pines contained some really grand Eucharises in the rudest health, and with foliage of immense size. In other houses a large quantity of Chrysanthemums were on view, all grown on the large bloom system, and splendid they were, the plants very dwarf, and the blooms large and well grown.

Time would not permit of notes being taken of the many choice Conifers, &c., in the extensive grounds; it will be sufficient to state that some of them are the finest of the kind in the kingdom. The avenue of Cedar of Lebanon is beautiful, but not equal to the one of *Picea nobilis glauca*, and which I believe has no equal.

Mr. Crump now led the way to the young fruit trees which he raises by thousands for the tenants on the estate, and better grown trees it would be impossible to find in any nursery. Some 3000 were ready for planting this season, and if the Madresfield Court Estate does not become famous for its fruit the fault will lie with the tenants and not with the owner or his energetic gardener. All the very best varieties of Apples, Pears, and Plums are raised in bulk; new kinds are very carefully tested, and treated according to their merits. In one plantation Mr. Crump has 200 varieties of Apples under trial, besides many others received from America and elsewhere which are receiving close attention in other quarters. It being now dark we looked in the fruit room by lamp light, and a grand lot of fruit was there, speaking volumes in favour of British fruit grown in good soil, favourable situation, and sound management. My pen fails to do justice to the good work going on, and to the beauties of the Madresfield Court Gardens and Estate. I left it with a feeling of gratitude to Mr. and Mrs. Crump for their kindness and hearty welcome, which had helped to render my visit very pleasant and interesting.—S. T. WRIGHT.

[The illustration (fig. 102), representing the avenue of *Picea nobilis* at Madresfield Court, was kindly supplied by Messrs. R. Smith & Co., who, we believe, supplied the trees.]

### KEEPING GRAPES.

WHEN once the leaves have fallen from the Vines the sooner the latter are also lightened of their load of bunches, pruned, and rested the better will it be for them. In addition to benefiting the Vines an early removal of the bunches is also a relief to the grower, as according to my experience Grapes can be kept more surely and with far less trouble during the winter and spring months in bottles of water than they can on the Vines. Grapes cannot long be kept in a plump presentable state in other than somewhat low and equable temperatures, and in spite of very close attention it is scarcely possible to prevent an injurious rise in the temperature of a vinery, whereas the case is very different with fruit and other rooms.

With regard to keeping Grapes in vineries up to bottling time I find I am rather at variance with some of our leading authorities on Grape culture, and have been taken to task for recommending rather higher temperatures than are supposed to be advisable. We are told the temperature of a late vinery in which ripe Grapes are hanging ought to be kept as near 45° as possible, my old friend Mr. W. Taylor holding to this theory, and he certainly kept Grapes remarkably well when at Longleat. According to my ideas, however, 50° ought to be nearer the minimum, a rise of 5°, or rather more, being allowed in the daytime. During November and December there are great fluctuations of outside temperatures, and which cannot well be prevented from affecting the interior of glazed houses. If, therefore, we allow the temperature of a house to fall to 45° in the daytime, a sudden change to cold during the night may lower the inside temperature another 5°, the berries, naturally very cold, becoming still cooler in consequence. Before either these or the house can be warmed bright sunshine and warmer outside air may quickly raise the temperature to 60° or thereabouts, and a moist coat on the berries be the result, than which nothing can well be more prejudicial to long keeping. By the maintenance of higher temperatures, this necessitating keeping the hot-water pipes constantly heated, sudden fluctuations are

far less likely to injuriously affect the Grapes, and the somewhat free use of fire heat is also conducive of a freer circulation of dry air. Whether I am right or wrong in my conclusion, there is no gainsaying the fact that our Grapes keep as plump and good as most, and nothing could well be more satisfactory than their present state. While the Grapes are hanging there is nothing to prevent the borders being freely watered whenever they approach dryness, care being taken to carry out this work in the mornings of fine days, and to ventilate freely.

Towards the end of December is a good time to cut and bottle the bulk of late Grapes, and if these fail to keep satisfactorily it may be either owing to their not being properly ripened—the colouring having been delayed till October—or else to non-attention to a few very important details. There are natural seasons of duration for all varieties, and it is very risky to try to keep them much beyond these times. Of so-called late Grapes the worst keepers are Gros Maroc and Alnwick Seedling. If these can be kept good till the end of November that is as much as need be expected of them, very few growers succeeding in keeping them any later. Black Hamburg in some few cases is kept till mid-winter, but it must be ripened late to do this, and unless I am much mistaken there will not be many bunches to bottle this winter. Gros Colman is really improved by keeping, the quality being decidedly good in March, but with us, and in many other private gardens, it cannot be kept in quantity, for the simple reason that no other black Grape is considered good enough for shooting and other parties while their more showy rival can be had. This variety ought to be quite fit for bottling now, and so also ought Alicante and Gros Guillaume, all keeping better bottled than on the Vines. The last-named should be at its best at midwinter, and it is unwise to attempt keeping it much longer, unless indeed the bunches are much below the average in size. Lady Downe's and Mrs. Pince's Muscat are the two longest keeping varieties in cultivation, and should be taken care of accordingly, all other sorts being used up before many of these are sent to the table or market. Both keep well till May. The Muscat of Alexandria will keep good till March, and Mrs. Pearson and Golden Queen still longer. Trebbiano I do not grow, but have known it keep plump and good till the middle of March.

In each case it will be found that freely thinned medium-sized to small bunches invariably keep the best, the reasons for this scarcely needing iteration, and I will only add that it is advisable to keep these to the last, using the larger and very compact clusters first, the latter being most liable to decay wholesale, owing to a single unsound berry not having been seen and cut out in time. All alike should be perfectly free of any rubbish, or anything that would start a spread of fungus in the footstalks, an open interior being also most desirable. Both before and after bottling a daily look out ought to be kept for decaying berries, the timely removal of one of these frequently saving the best part of a bunch.

The question now arises, What is to be done with the Grapes where there is no regular store-room for them? But this is a difficulty easily overcome in many cases, though perhaps not generally. Modern fruit rooms are not as a rule the best places for keeping Grapes, the majority of them being far too well heated or else too airy to meet the requirements of the case. Heaps of Apples especially are scarcely fit associates for Grapes, though if kept clear of all decaying fruit it is doubtful if Apples greatly interfere with the keeping of the bunches.

It must be understood that I have seen many failures as well as successes in keeping Grapes, and have well tested a great variety of storing places. None that I have tried in the way of makeshifts for regular Grape rooms, or as good substitutes for the same, have answered so well as an unoccupied bedroom facing north. The walls are all thick, the ceiling comparatively low, the window tight-fitting, and the floor free of currents of cold air. There is a fireplace in this room, but this is never used—but, on the contrary, is blocked to prevent draughts as much as possible; the room is further darkened, the window never opened, and the door opened as seldom as possible. Beyond this no attempt is made to prevent fluctuations of temperature, and, as may be imagined, these frequently fell below freezing point last winter. In spite of this our Grapes never kept better, the last of Lady Downe's being used about the middle of May, though they would have kept still longer. Grape rooms ought, therefore, to be constructed or selected on somewhat the same lines indicated, everything being done to guard against rushes of either cold or warm air, the latter being particularly to be guarded as containing most moisture at this time of year, extremes of heat and damp being also guarded against.

When there are a large number of bunches to be bottled, either a series of rails for suspending bottles from, or better still racks for resting them in a sloping direction, ought to be fixed, no great amount of ingenuity being needed in the matter. If the fruit room has to be utilised, then the simplest plan is to cut notches in

the front boards of the shelves to hold the necks of the bottles, a strip of wood, unless the shelves are latticed, being also necessary to prevent slipping back. It is of the greatest importance that the bunches swing quite clear of the bottles, their own weight accomplishing this if rather small bottles are suspended from rails. No particular kind of bottles are needed, though I prefer them to be of clear glass, and use as many soda water bottles as I can get. There is nothing to be urged for or against using soft water or lumps of charcoal in water of any kind. The good charcoal does have never been apparent to me. I use nothing but clear hard water, and take good care that the wood reaches well into this, there being then no necessity for adding more later on. The bunches are cut with a good length of lateral growth attached, that part below the bunch only being trimmed so as to get it into the bottle easily. If need be the wood beyond the bunch can be inserted in the bottle, reversing the positions not affecting the keeping properties of the bunches in the least. Bottles must not be filled with water, or some of it may be driven or trickle out into the bunches; but there must be no mistake in a contrary direction, the wood not reaching the water, or shrivelling quickly ensues.—W. IGGULDEN.

#### NOVELTIES IN CHRYSANTHEMUMS.

HAVING read with much interest Mr. Molyneux's remarks on the above, and hints from other of your correspondents, I think I may venture to name some not mentioned up to date, knowing that many of your readers are on the alert for novelties of merit. The varieties I am about to name are of American origin, except where otherwise mentioned.

*Flora McDonald*.—A charming incurved variety of the Queen form; a good deep solid flower of a creamy white tint, nearly as large as the above mentioned, and very tightly incurved. This is a really good variety of dwarf habit.

*Aeta* is another incurved variety, somewhat like Mrs. Coleman in form but brighter in colour, having more gold about it; very dwarf in habit, and should make a good front row flower.

*John Farwell* is charming, something after the form of Sunflower; colour the brightest crimson. The flowers fill well, and are nearly as large as the above-mentioned, and keeps a long time in perfection, which alone should recommend it. This will make a good exhibition variety.

*Lizzie Cartledge* has been mentioned I know, and received a certificate. All I have to say of this—it is one of the strong growers, about 5 feet high, promises to make a good show bloom.

*Harry E. Widener* is a very promising variety of the bright yellow class, in this respect resembles *Soleil Levant*, though a larger and fuller flower; the outer florets are split at the ends, giving the flower a chaste appearance. Height about 4 feet.

*Elmer D. Smith* promises to be a charming variety of exquisite colour; when opening reminds one of *Triomphe du Nord*, changing to almost the colour of M. N. Davis. The outer florets are long and flat, twisting somewhat like Mrs. J. Wright in the centre. This is a good flower, quite distinct, and is a rather strong grower; height about 5 feet. I think this will become popular when better known.

*Frank Thomson* is late with us, which may be remedied another year. This is a large flower, the petals incurving slightly, full in the middle; colour creamy white centre, the outer florets blush pink; very promising.

*Mistletoe*.—If this keeps its character it will be an acquisition; in colour it is of the silvery pink class. A large spreading flower, about 7 or 8 inches across; the florets are incurved at the tips, while it is very full, the inner florets whirling in an extraordinary manner, very much resembling J. C. Price in this respect; dwarf in habit.

*Mrs. R. J. Baylis*.—I am told this much resembles the new seedling Robert Owen in colour, though I have not seen it; the florets are broad and incurving. Very promising.

*Mrs. Needs*.—The variety here mentioned was sent out from Chilwell this spring. It was much admired during our show. In form and colour it much resembles *Belle Paule*, though much dwarfer in habit; many visitors declared it superior to that esteemed kind. We had handsome blooms upon cut-down plants; in fact, it seems to do better under this treatment than the general way of running up though our plants were not stopped early enough in the season. The middle of June would be about the right time. This is a local seedling.

*E. G. Hill* has turned out a good variety if not too late, though much may be done with management. The colour is of the brightest golden yellow, the florets broad and of rare substance; altogether a noble bloom. An award of merit was granted at the last meeting of the R.H.S. for this novelty. The variety is a very strong grower. Height 6 to 7 feet.

*Edwin Lonsdale*.—I expected to have heard more of this, for it is one of the best of the deep purples. We have had fine solid blooms keeping for weeks, the blooms about 7 inches across by 4 inches deep. This wants a long season, as it is one of the strong growers, producing an enormous amount of large foliage, which perhaps accounts for its scarcity at the exhibitions this season, through lack of sunshine. It should be stopped early, as the buds are a long time swelling. It does well cut down the first week in May.

*Golden Mme. Pages* will prove a very useful Christmas decorative variety; it is of the sweetest yellow, with silvery reverse, somewhat better in form than its parent, which itself is one of the most useful varieties for late work in existence. Hundreds of plants are now at their best in one of the large houses here. They were in strong demand for Christmas and will continue through January. This kind will be distributed from Chilwell in March.—J. PITHERS.

#### INSECTS OF THE FLOWER GARDEN.

(Continued from page 469.)

WE have now reached the ant tribe, in our notice of a division of the four-winged insects, called the order of Hymenoptera. Every gardener knows ants full well; scarcely a garden is without its colony, or its several colonies, of some familiar species. Occasionally we find a foraging party has entered some house, drawn there by the attraction of ripe fruit perhaps, or it may be a predatory excursion in pursuit of other insects, or else they are seeking to regale themselves upon the juices of tender plants. A great variety of opinion exists, as we might anticipate, on the question whether the small amount of benefit possibly derivable from the proceedings of ants entitles them to any mercy at our hands, or whether it is not quite overbalanced by the mischief they do. Amongst our borders and flower beds, however, the ants cannot be said to be conspicuous as troublesome insects; sometimes they raise unsightly hills on lawns or paths, and some people condemn them because they appear to be collectors and nurses of the aphids, which is one of our worst enemies in all departments of the garden. The late Mr. Wood maintained that in the flower beds ants were not injurious. He believed that they devoured many minute insects; also that, like the bees, they might help fertilisation by carrying pollen attached to their bodies from one plant to another. Then in the case of choice flowers, such as the Rose, which ants might happen to frequent, he pointed out that they could easily be kept off by winding round the stem a piece of cotton wool, which is an article through which they cannot pass. Again, as to their intrusions into houses. It has long been known by traders that if a chalk line be drawn round the top of a tub or cask the ants will not cross this to attack the contents. We may, therefore, by rubbing some chalk along the edges of shelves in a greenhouse keep away ants from any pots that they seem likely to infest. If it should be thought necessary to diminish their numbers in a garden ants may be trapped by putting down slices of Apple, on which they will congregate in scores, or by laying along their haunts strips of rope that have been moistened with syrup. Their nests when discovered may be destroyed by the application of quicklime. Diluted petroleum is also used for this purpose, and also gaslime. Some gardeners fire off ants' nests by dropping into them on a dry evening a small quantity of gunpowder, which they explode by a bit of touch-paper tied to the end of a long stick. Of the species occurring about gardens the yellow ant and a small brown species are the commoner, but some damage is also done to oldish fences by a black kind, which, however, cannot touch wood quite sound.

In many districts the sand wasps are not unfrequent visitors to gardens, and they decidedly resemble the true wasps, their form being slender, the body banded or spotted, black, yellow, and red often occurring amongst them, hence they are rather conspicuous. A few of them, like the common *Ammophila sabulosa*, have long, spiny legs. This is about an inch in length, and distinguishes itself by being a busy destroyer of caterpillars. By means of its legs and jaws it excavates on some sandy bank a burrow or chamber into which it carries the caterpillar of some moth. Then an egg is laid, a second caterpillar obtained, and another egg follows, probably a third or a fourth; for each a caterpillar is provided. The burrow being closed, the insect commences another, and so proceeds till all her eggs are laid. This, therefore, is a beneficial insect, but its relative, the hairy sand wasp (*A. viatica*) occupies a different position, because it chiefly attacks spiders; and though we must allow that the webs of spiders are not ornamental in garden walks, yet they certainly dispose of a large number of flies and other insects, troublesome to us in various ways. It is, however, a curious instance of retribution in Nature, that spiders, great killers of insects, should form the special prey of one species of insect. The spider, however, that is their mark is not one of the web-weavers, but one of the hunters, which

darts upon its victims from hiding places, lurking under the leaves of plants or loose fragments of the soil. One who has often watched these sand-wasps in a garden says that he, or, rather, she, pursues the chase with a fury, quickness, and eagerness, hunting about here and there, beating the ground carefully over as a pointer beats a field. The spider, when caught, seems unable to act on the defensive. It is, as soon as seized, pierced by the wasp's sting in the centre of the thorax, and rapidly borne off to a cavity prepared for its reception. Having thrust the body into the hole, the insect lays upon it one or more eggs, afterwards filling the hole up with earth, and levelling the surface so that it may not present any unusual appearance. All the time it is at work the sand-wasp makes a shrill piping noise.

Another of these wasps, which is minus an English name, is called *Mellinus arvensis*. It is about half an inch in length, black, banded with yellow, and is common in gardens, haunting particularly any spot where manure has been recently deposited in search of the flies likely to hover about. This insect makes a chamber in the earth, which it stores with flies for the food of its young. Being a somewhat clumsy flyer itself this wasp has to try stratagem, and when it sees one of its objects at rest it goes towards the spot and passes to and fro in an indifferent manner, gradually coming nearer till it pounces suddenly on the fly and carries it off.

Some of the solitary wasps form burrows in wood that is beginning to decay. They are partial to the sprays of the Bramble, and in gardens they visit the stems of the Rose. An abundant species is *Trypoxylon alternatum*. Its nests are small and very curious. We have reason to suspect the existence of one when we see a little round hole in a Rose branch. If it be the fact that this species stores up aphides for its progeny we must pardon it for attacking the Rose, especially as it does not meddle with wood quite sound. Amongst the family of the Philanthi are several that are familiar to the eye as being lovers of flowers, being often noticed basking upon Umbelliferous plants. Some of these wasps bore into wood, some into banks, and capture a variety of insects, such as caterpillars and flies. One species has been found to destroy quantities of bluebottles. Another species hunts up weevils, and actually hides in its burrows; amongst others, that well known enemy the grooved weevil, *Otiorhynchus sulcatus*. Some surprise has been expressed that the young wasp should be able to feed upon such a hard-cased insect, but it appears that the weevils are buried some time before they have to furnish food, and by this means they become softened, so that the jaws of the grub can penetrate them. The common social wasp is often to be seen flying about flower beds; it is then seeking to make prey of various insects that are attracted to the flowers.—ENTOMOLOGIST.

### PROFITABLE FRUIT GROWING.

[A paper by Mr. S. T. WRIGHT, Glewston Court Gardens, Ross.]

So much has been written and spoken of late years on the subject of fruit growing, that any addition thereto would seem to be useless. Some of our teachers, however, are men who are so evidently without experience that intending fruit growers are liable at the outset to be led into serious errors, which are almost certain to result in failure. I hope therefore you will pardon me if I have founded this paper on my own practical experience in a modern fruit field, containing some 6000 dwarf trees (Apples, Pears, and Plums), which was planted shortly before the present fruit growing craze came to the front. The locality is about two and a half miles from Ross, in Herefordshire, above the fog line of the River Wye. The position is admirable, being about 180 feet above sea level. The soil is a warm-looking loam, on the old red sandstone, and in some places rather shallow; the rainfall moderate.

The first planting was made in the autumn of 1883. The plantation is, I think, unique, there being no standard trees in it. A few trees were planted experimentally at a distance of 6 feet, the main body at 8 feet apart. Guided by our experience, when planting more trees two years ago, every other of the 6 feet trees was removed, and the new ones planted at 9 feet. I do not wish to speak too decidedly, but my impression is that this is not far out. For the first year or two we planted Potatoes between the rows of trees, but after that the network of roots ran across the intermediate spaces, and I think it is a mistake to allow anything to interfere with them. I confess to seeing no advantage in planting standard trees. Dwarf or bush trees require no staking when planted, and they come into bearing at once. I may here say that we have picked 23 lbs. of Apples from trees planted two years ago, which could not happen with standards for some years later. All work (pruning and gathering fruit) is done from the ground, which is a distinct economy. The fruit is not so much exposed to high winds, and there is less risk of its being bruised in falling. Planting standards is planting for posterity, which is in direct opposition to the spirit of the age, which demands quick returns.

To listen to all that is said or written it might be supposed that it is only necessary to plant a fruit tree in order to gather a crop of Bank of England notes. Let me try to dispel the illusion. Probably no calling

or profession has so many difficulties to contend with as that of the fruit grower. Success depends not alone on the competency of the grower, but on a favourable combination of circumstances, any one of which being wanting may imperil the success of the whole. For a full measure of success we require suitable varieties of fruit for the district, a favourable climate and position not too much exposed, good soil, where necessary well drained, intelligent management, and careful and honest packing. Over these matters we may have some control, but there are other elements not under our command. A season too wet or too dry, late frosts, an insufficiency of sun to mature the wood and buds for the next season, gales of wind, insect and bird pests, reasonable railway rates, fair prices, and an honest salesman.

When naming pests, I would wish to express my regret that I am deterred from speaking as decidedly as I could wish to do on some points. In 1887 our plantation was attacked by the caterpillar of the winter moth, and owing to our ignorance of its habits, &c., a year was lost before we could take effectual steps to combat it. We applied grease bands in the autumn of that year, and although I am a great believer in their efficacy, they can only be satisfactorily applied to standard trees, owing to the short stems of dwarf trees. I may also say that very great care is necessary that the grease should not come into contact with the bark—especially of young trees—otherwise the result will be disastrous. The caterpillar attack was so severe, that in the month of June, 1888, there was hardly any sign of vegetation left on the trees. The next season, 1889, the attack being again severe we set to work with Paris green, and as the hatching of the caterpillar goes on for three months we were compelled to syringe all the trees ten times. Some injury was done, but on the whole there was not much to complain of, and the treatment proved so successful that we were only obliged to syringe twice in 1890, and once this season, and the trees are all in splendid condition. But the result was that we lost three crops. Many gardeners who have suffered little or nothing from caterpillar attack are somewhat incredulous as to the value of Paris green, and hesitate to use so deadly a poison. I have, however, no reason to doubt its efficacy, as I have found quantities of dead caterpillars on the leaves, and as to the risk it practically amounts to nothing if carefully handled. There is another enormous benefit resulting from the use of Paris green, and that is the utter destruction of the codlin moth, the grub of which causes such wholesale falling of our Apples. We have not seen anything of it this season. We have now an apparatus, specially made for us by Messrs. Boulton & Paul of Norwich, and fitted with that capital little invention, Stott's sprayer, which enables us to go over 2000 to 3000 trees a day with a minimum consumption of water. In saying anything about our bird pests, I feel that I tread on dangerous ground. It would be foolish to deny that all of them do some good, but there are some birds whose evil doings exceed the good, and which should be destroyed as far as possible. These are the sparrows, blackbird and tits; all others, except perhaps the robin, should be encouraged.

To revert to my more immediate subject. It will readily be understood that there is no more a royal road to fruit growing than to learning; the path is beset by many a thorn. I need hardly insist upon the absolute necessity of careful selection of the site for a fruit plantation. Nor ought there to be more need to urge the nature of soil. As well put an Orchid in clay as expect good results from inferior and unsuitable soil and climate. Not that I would insist that fruit cannot be grown on any but first-class soils. I merely wish to urge upon you that really first-class results can only be attained through first-class surroundings. Drainage is essential with a retentive subsoil. The next point is the choice of trees to plant. By preference I should plant Apples; the crop is not so risky as either Pears or Plums, and there is less liability to damage on the way to market. Plums must be sold on arrival; but Apples, in case of a glut, can be held a day or two. We come now to the general management, and it must be clearly understood that I am laying down no hard and fast laws for other growers, but simply giving my system in my own soil and climate. The trees having been planted, and having come into bearing, I advocate summer pruning, as I think the removal of all useless young growths tends to throw vigour into the wood and buds of the next season, and thus promotes the ripening of the same. I think more pains should be given to intelligent pruning; but no doubt gardeners will (as they always do sooner or later) rise to the necessities of the case.

In my somewhat light soil and porous subsoil, I find it of advantage to turn over the surface to a depth of 2 or 3 inches each spring; the moisture is better retained, and the warmth of the atmosphere acts more rapidly on the roots. I do not find root-pruning at all needful, the crop of fruit should render it unnecessary. Still, doubtless it may be of value in some cases. Under this head manuring fairly comes. Dung of a fair quality is admitted to be a perfect manure, but when it comes to buying, carting some miles, and barrowing and spreading between the trees, it must be acknowledged that it is very costly. Not only so, but dung differs largely in the nature of its constituents, according to the feeding of the dung-producing animals, and therefore the grower is working in the dark. Many people are prejudiced against the use of artificial manures. And I would here warn my brother gardeners against indulging in any prejudices—they are a bar to progress—I am not allowed to indulge in any. There is this to be said, many experiments must be made and much time lost before anything approaching certainty can be arrived at. But so far as my experience goes, as good fruit can be grown with artificial manures as with dung, only at present we must act with caution. I look to the day when

"practice with science" will enable us to be independent of dung. This is the more desirable, because I hold the opinion, that instead of our trees bearing good crops every alternate year, they should by the aid of manure produce as a rule good average yearly crops, and that would be one way of avoiding seasons of alternating glut and famine—extremes of low and high prices. The proper use of manure should be to develop the strength of the tree, so as not only to produce fine fruit one year, but to forward the maturity of the wood (especially in years of low temperature) which has to build up the next season's buds. Every year will, however, add to our knowledge on this point. Meanwhile this is I think what we should aim at.

There is a point as to which my theory has been so far better than my practice. I am of opinion that all small and imperfect fruit should be picked off so soon as proof of their being inferior is clear. By that process the size of the remaining fruit will be increased, and there will be less labour in grading for market, and a higher average of price, but great courage is needed to do this.

I would now pass to the question, What class of person must the fruit grower of the future be? This is a very debateable matter. Whoever he be, he must have plenty of capital and backbone, he will find ample need of both. The farmer is not qualified by his technical education, and of recent years his outgoings have been so much in excess of his incomings, that it is more than doubtful whether capital would be forthcoming. A separate class must come into existence, whether of gardeners who could get sufficient capital to work a few acres, or a combination of the capitalist to furnish the sinews of war, and the gardener to supply the rest. Even then the matter is not very simple, because the gardener must not only be capable as such, but he must be able to conduct all the various steps necessary, from selecting and planting the trees, to packing and marketing the fruit. In fact you require an all-round man, and where is he to be found in quantity? He has to be raised, and no doubt will be in time. As to the sorts to be selected, and many other matters, I would refer you to a little pamphlet just issued by the Royal Horticultural Society, and which embodies the opinions of forty able authorities on all points of fruit growing, and I only demur to two of their recommendations. It recommends planting the Blenheim Pippin. To which I say "Don't." Life is not long enough; and it gives too many sorts. A little time will be well spent in finding out those which suit the soil and climate, and then have the courage to resist the inclination to buy more than half a dozen varieties. What consumers want is a regular supply of so far as can be of the best sorts. As to early or late kinds of Apples, it is an open question.

Our supply should come in before the American and Canadian shipments interfere with them, and after the best of them have gone into consumption, avoiding also competition with the Tasmanian imports, some of which are excellent. There is less expense with the early sorts, as they go directly into consumption from the trees, whereas the late kinds must be housed, and there is some loss by rotting, and also in weight, still the enhanced price of the late kinds may compensate. Whatever the sort, they should be carefully handled and honestly packed. When I was at the Edinburgh Show a fruiterer said to me, "It does not suit us to buy English fruit, as you cannot depend upon it; usually there is a good sample on the top, and a lot of rubbish underneath; now with the American Apples it is different, they are of one quality throughout." What a short-sighted policy this shows on the part of English growers, and how it involves all of us in an undeserved suspicion of rascality; you may depend upon it that honest packing will meet with its reward.

Local trade should receive more attention. There are places where growers sent supplies to Covent Garden, while at the same time local retailers supply themselves from that centre. Wherever your produce goes, let it be carefully selected with regard to quality, size, and appearance; every producer will have his own ideas as to markets and salesmen. We are guided more by the salesman than by the market, and believing our salesman is an honest man—which I am sorry to say cannot be said of all—the bulk of our fruit comes to Manchester. Well, supposing all to be gathered in, the moment has arrived for looking over results and facing facts as to fruit-growing for profit; possibly in the course of the year you have built castles in the air which are never realised. If you can secure a fair price the result would be very satisfactory; but how about a year such as the present, when Plums and Pears have been a perfect glut? Let us look practically into the matter. On the one hand we have to pay rent, tithes, rates, taxes, interest on capital, labour, manuring, railway carriage, tolls, portage, and salesmen's commission. On the other hand are our receipts.

Owing to the frost on the 16th of May our Plum and Pear crop has been small. Our Apple crop has, however, turned what would have been an actual loss into profit. The size of what Plums we had was, according to our salesman, A1, and yet the top price was only 7s. per cwt., or say 4d. per lb. Of that the railway company took about 1d. per lb. or one-third of the gross value. Pears have been very disappointing; a large grower told me that he sold his W. Bon Chrétien at 6s. per cwt., the sample being good, many of the fruit weighing 1 lb. each. After paying railway and other expenses little is left for the grower. The ways of the railway company are incomprehensible. They charge us 38s. 4d. per ton for Plums for preserving purposes, and 26s. 8d. per ton for Apples, a difference of nearly 12s. per ton. Why? Partly encouraged by low preferential railway rates, and partly owing to the low price of labour, which is some countries half the price of ours, foreigners have not only established a large trade with this country, but are straining every nerve to increase their production.

Still, in spite of all, I am sure there is a future for fruit growing. Englishmen, as a rule, are fond of grumbling at their climate—mainly, perhaps, because they are not obliged to live in another. Is there any other climate which grows finer men and women, finer horses, cattle, and sheep, finer crops of grains, finer vegetables and fruit? If that be so, does it not prove that, take it all in all, there is not much ground for grumbling? In 1889 I sent up Apples to Covent Garden, and the salesman reported that no such fruit had been seen there that season. This year I have sent Peasgood's Nonesuch Apples to Manchester, which have sold at 30s. per cwt. Our salesman, Mr. John Mills, said they were the best grown Apples in England or America, and that on the same date the best American Apples (Ribston Pippins) sold in Liverpool at 24s. per barrel of 140 lbs., or 19s. 3d. per cwt. There is, therefore, no ground to despair, but there is abundant reason to be certain that such results can only be attained under the most favourable conditions. There is much to be said against putting all our eggs in one basket. Damsons will do admirably as bush trees, and are excellent to plant for shelter of other crops, and they have paid better than Plums this year. With soft fruits we possess a great advantage over our Continental rivals, as they cannot put such goods on our markets in a presentable condition. Green Gooseberries I do not include amongst soft fruits, and the French send large supplies keeping down our prices. Black Currants and Raspberries are very easy to grow, and if the cultivation is good they are remunerative. For fine fruit cleanly gathered there is always a good demand.

Strawberries have been so extensively planted of late years that they do not fetch such prices as they did, and it is an open question if it will pay to add much more to the enormous quantity already under cultivation, as the demand cannot be unlimited. However, by growing a variety of crops, it must be a wretched season indeed if all fail. I have now been through my subject. It is in no way my wish to discourage fruit growing on sound principles. I have spoken frankly on my own experience, and have shown you both sides of the picture. I have not the smallest doubt that when fruit growers have selected the right spot to plant the right sort of trees, where they have sufficient capital, average intelligence, and untiring perseverance, they will succeed. I am equally certain that numbers of those who have started these undertakings without the above elements of success will hopelessly fail, and, as a matter of fact, some are already falling out of the race. The universal law of Nature is invariable—the law of the survival of the fittest.—(*From the Manchester Conference Report.*)

#### THE ASHFORD VINEYARD.

MESSRS. A. & J. QUERTIER have, under the able management of Mr. Stephen Castle, made the Ashford Vineyards famous throughout these isles for the grand crops of Tomatoes and Grapes that are grown there. All the houses are built on the Jersey principle—light, commodious, and well ventilated, but the heating is open to improvement. The season throughout has been against Grape culture in unheated structures, and those defectively heated have suffered correspondingly. The ground on which these houses have been placed has a gentle slope to the south, and is fairly well sheltered from the north and east, but exposed to the west winds. The work of describing these houses is simplified by every house being numbered. Nos. 1 and 2 are mixed houses, and call for no particular comment other than the Vines were planted in 1890 and 1891 respectively, and are carrying a few bunches for the first time. The varieties are Hamburgs and Gros Maroc. In the No. 2 house Tomatoes are grown in pots, which are set on each side of the path and trained to strings up to the roof, and have done remarkably well as the stalls will show; but when we come to No. 3 one might linger and look on in such a house for a very long time without wearying. This house was planted in March, 1890, with Muscat of Alexandria, not cut-backs, and now with the Vines but a little more than a year planted are carrying from four to ten bunches of Grapes from each, some of the bunches weighing 5 lbs. The success here attained is of no ordinary character, and a few more particulars respecting this house and the borders may prove of interest.

The house itself was originally a Cucumber house, and has bottom heat pipes beneath the border, being the return from the top pipes which heat the atmosphere. If the one is to be heated the other must be also. The border in which these Vines are growing is not more than 9 inches deep, and was during the early stages of their growth confined to a width of 3 feet, but is now allowed a run of 5 feet or a little less. With such a border and heat beneath watering must be attended to with judgment. It will be of considerable interest to myself, probably to others, to watch the behaviour of these Muscats in heated borders, as the idea is not new, for I believe some such arrangements were made many years ago at The Denbies, Dorking, and for a time very fine Muscats were grown, and the heated border had the credit for it, but when others adopted it they were not so successful. On inquiring of Mr. Castle whether he had any faith in bottom heat, and whether he had any fear of the Vines going back after a time, he was very sanguine of its good, and hoped I should see them again another year, and his manner left no doubt as to what his expectations were—viz., that they would be better than they are now.

No. 4 is also a span-roof, and was planted on one side in 1889 with several kinds, there being Vines of Black Hamburg, Madresfield Court, Black Alicante, Gros Colman, and one or two Gros Maroc. These Vines were also remarkable for the weight of Grapes they were carrying. They are allowed to carry a bunch, whether large or small, to

every lateral, and in the space of 6 feet run of rod in several instances fourteen bunches of Grapes could be counted, so close that the bunches touch, and which Mr. Castle puts, and I think without exaggeration, at more than 40 lbs. weight for each rod. This sight drew from me the exclamation that the weight was too great; but my guide again pointed out the strong leaders, as thick as one's middle finger, that the Vines had made and clothed with plump buds, giving promise for better results another year. The remaining portion of this house was planted in 1890, and these young Vines were allowed to carry two or three bunches of Grapes near the surface of the border, and the deep black colour and fine bloom on some of them gave evidence that they had plenty of strength. One bunch on a Gros Colman Vine was so much like Alnwick Seedling in every particular that if cut and staged as such it would deceive the best judge, but strange, the remaining bunch exhibited Gros Colman in its true character, and the young rods they have made left nothing to be desired.

The borders to this, as well as to the several other houses that succeed it, are planted in the natural soil, which is a sandy loam of moderate depth resting on gravel. The ground was previously cropped with Potatoes, and all the preparation made for the reception of the Vines was to trench 18 inches deep, no manure or anything else being added. Length, 78 feet. The description of No. 4 also applies to No. 5, except that the house is rather longer; and No. 6 is 90 feet long, was planted in 1889 with Gros Colman and Muscat of Alexandria, and here the crop was almost as prodigious as that in the two preceding houses. No. 7 is 120 feet by 20 feet, also planted with Gros Colman; and to give some idea of their health and strength a leaf of one of the Vines in No. 7 was measured and found to be 15 inches long by 15 inches broad. The whole of the foliage look healthy, and have not that parched appearance that marks this kind in many places. No. 8 is a large span-roofed house about 100 feet long by 20 wide, and was planted last March with Gros Colman. It was from this house the fine crops of winter Tomatoes were taken. The Vines are planted at the front of the house near the hot-water pipes, and the Tomatoes are on either side of the pathway near the centre, and are up to the roof. No. 9 is a lean-to, and was one of the first to be planted with Vines. This house, which is in three divisions, is 200 feet long. Many of the rods were carrying 40 lbs. of Grapes. Some bunches of Alicante and Gros Colman would turn the scale at 5 lbs., and to show that there has been no diminution in their strength is seen by the leaders, which have this season reached the top of the house, and they are apparently as strong as though the Vines were carrying no Grapes, at least as strong as it would be safe to be consistent to getting them well ripened.

The remaining long range, which is 130 feet long in three divisions, and probably 30 feet wide, the first division entered was planted this spring with Gros Maroc, and the Vines were making excellent progress. Mr. Castle made this house the first to point to convince me of the damage done by frost last March after the Vines have commenced to move into growth, as they were killed to the ground, but this I can readily understand with the imperfect heating arrangement, for which he is not responsible, and which it is his wish to remedy (and no man is better able to do so) at the earliest possible date. Whatever check these young Vines may have had early in the season, they leave under the able management here nothing to be desired, as many of them have grown to the top of the house, a distance of not less than 30 feet. The next division is planted with Muscat of Alexandria, and these also are as promising as the first division. The last division is planted with Alicante, and all are doing well, as there are two sets of Vines in each of these divisions, one set on each side close to the pipes at the outside of the house and another set on either side of the path, which is down the middle, and at the usual distance, 3 feet apart, that being the distance allowed here; each row contains twenty-five Vines, or 100 to each division. As I have previously stated, no manure is put into the border at planting time, and it must be patent to all that something must be given to maintain the strength and vigour of these Vines, and this, Mr. Castle assures me, is silicate, for except a little cow manure that has been had very recently for mulching purposes, and which has not had time to benefit the crop, no other manure has been had on the place. The silicate, which has the appearance of sand highly charged with ammonia and other fertilising matter, and is in the form of a dry powder. This is strewn over the surface of the border, and watered in with the hose. It would be useless to attempt any such an undertaking as is here seen without a good water supply, which is provided on the spot by erecting large galvanised tanks at the highest part of the garden, which are filled by means of pumps worked by a gas engine, and stand pipes are set at convenient places in the houses, so that every part of the borders can be reached.

Grapes are not the only things grown at these Vineyards, as there has already been upwards of four tons of Tomatoes packed off the present season, and that they have been fruitful there can be no question, and the first bunches have formed within a few inches of the ground. There was also a large stock, 1000 plants, of Elaine Chrysanthemums, which were looking remarkably well.

The Grape room is not by any means one of the least interesting features of this fine establishment. This is situated at the back of the range of vineries No. 9, which are lean-to. The range of sheds run the entire length of the houses, which, it will be remembered, are 200 feet long. The first portion is used as a packing shed, store room, and for various purposes; but the far end for about 30 feet has been made into a Grape room, and is a model of its kind, and is another mark of the original and practical mind of the Superintendent. The whole of this

range is heated with a flow and return 4-inch pipe. The division that has been fitted up for the Grape room has hollow double front walls, and boarded roof covered with asphalt, and being on the north side of the vineries it is not affected by solar influence. The entrance to this room is provided with double partitions and doors, so that on entering the first door may be closed before the second is opened, so as to avoid an inrush of dry air. The front and back of this room is boarded up, and by means of angular blocks screwed to the boards, on which another board is fastened, forming pockets or brackets, are formed the entire length, into which small champagne bottles are set at suitable distances, a small block fastened at a certain distance up the boards at the back, and at the right height to prevent the bottles tipping up with the weight of the bunch when that is inserted. The house was empty at the time of my visit, but those who have seen this house with a great number of bunches of Gros Colman hanging say it is a sight not easily forgotten, and it must be good to fully answer the expectations of the designer. While many growers have cause to complain that their Grapes deteriorate in colour when bottled, Mr. Castle declares that his improve considerably for a very long time. His method of testing that is somewhat new to me—viz., to stroke one of the berries with his finger, and he avers that the mark in question will be almost effaced after a time, which is proof that the change in the berries is going on in the right direction. The room is perfectly dark, but means are provided for ventilation by means of ventilating shafts let into the roof at suitable distances. In conclusion I may be permitted to say that however much there may be to admire at this Grape-growing establishment at the present time there is proof everywhere that greater results are to follow, and in the near future too, for Mr. Castle is not one of those men who need three or four seasons to establish Vines in a fruitful state.

—C. WARDEN.

### FEEDING OUR FRUIT AND VEGETABLE CROPS.

COMPLAINTS about the ineffectiveness of applications of bonemeal or other plain phosphates or superphosphates to orchards, vineyards, small fruit patches, and vegetable gardens are nothing at all uncommon. Yet such negative results are just the ones that should have been expected. Why? Because the substances named have little or nothing of value besides phosphoric acid, of which fruit and garden crops require very small quantities.

The following table will show, approximately, what great demands for potash fruit and vegetable crops are making on the soil. This table gives the number of pounds of the principal plant foods removed in a full crop.

FULL CROP, PER ACRE.	NITROGEN, LBS.	POTASH, LBS.	PHOS. ACID, LBS.
Apples, 15 tons .....	30	45	3
Pears, 10 tons .....	12	36	10
Plums, 2 tons .....	16	8	2
Grapes, 4 tons .....	13	40	12
Sugar Beets, 20 tons .....	110	72	12
Carrots, 20 tons .....	70	150	24
Mangolds, 20 tons .....	90	160	18
Turnips, 20 tons .....	75	110	25
Onions .....	32	26	23

In all this we have not yet taken any account of the plant foods that have gone into the foliage and the wood of the trees and bushes. Here again potash is just the substance needed in considerable quantity. The leaves dropping in autumn may remain on the ground under the trees and bushes, and thus return their constituents to the soil; or they may be blown away by the autumn gales into fence corners, road sides and ditches, and thus be lost to the soil. The prunings also may be burned up in the orchard or fruit patch, giving their mineral constituents back to the soil; or they may be carted off and burned in some back field, where the ashes will do no good to the orchard. Usually there is from these sources at least some loss, chiefly in potash, that, together with what the fruit crop has taken off, will have to be made good again by application of manure.

The table here given may not be more than approximately correct, yet it shows that in fruit crops we remove from the soil an amount of potash, ten, fifteen, and often more times as large as that of phosphoric acid. Many farmers imagine that orchards need no manuring. Perhaps a crop of grass, with all its large amount of potash, is taken off besides. With such great and incessant drain on the potash supply, it will not be long before that supply is getting too short to allow healthy growth of tree, vine or bush, and a full crop of fruit.

Phosphoric acid is used in only small quantities. For these reasons bonemeal, phosphates, &c., alone, are not what is wanted for a fruit tree manure. Potash is needed more than any other substances, and unleached wood ashes is one of the best forms, if not the very best, in which this can be applied. Where good ashes can be bought at ten to fifteen cents a bushel, we will not often be able to get a better or cheaper fertiliser.

—Prof. C. C. James, of Ontario, Canada, recommended at a recent fruit

growers' meeting the following formula for compounding a cheap and effective orchard fertiliser:

- 40 bushels of unleached ashes.
- 100 pounds of crushed or ground bone.
- 100 pounds of sulphate of ammonia, or nitrate of soda.

This quantity is to be applied at least once in two or three years. It supplies about 120 lbs. of potash, 23 lbs. of phosphoric acid, and 20 lbs. of nitrogen.

Nitrogen, if such be needed in greater quantities, can be obtained in a much cheaper way by the help of crops that are nitrogen gatherers (such as Clovers and Peas, which should be left on the ground to decay), than by outside applications.

In a majority of cases, perhaps, yard manure is the only form in which plant food is ever given back to the orchard or fruit garden. Twelve tons of it will furnish the 120 lbs. of potash needed, but also two or three times as much phosphoric acid and nitrogen as required for the crops. It will hardly be good economy, therefore, to use yard manure exclusively, especially if we should have to purchase it at anything like full value. The cheaper way would be to apply a smaller quantity of yard manure, say one-half of the named quantity, or six tons, every second or third year, and add to it the missing 60 lbs. of potash in the form of unleached wood ashes, muriate of potash, sulphate of potash, kainit, &c. My ration for the yard manure and potash salts combined would be six tons of the former, and 120 lbs. of muriate or sulphate of potash, or 500 lbs. of kainit; and would prefer to apply this every second year at least.

We should fully understand, however, that simple phosphates alone are no manure for fruit crops. Potash, on the other hand, is the chief substance needed, and we cannot easily apply it in too large doses for fruits. A sufficiency of potash makes bush and tree fruits finer, sweeter, better in flavour, and renders the wood more resistant to severe cold.

Vegetable crops usually make still heavier draughts on the potash stores of the soil than fruit crops. In Carrots, Mangolds or Turnips, for instance, we remove over 100 lbs. of potash per acre, if the crop be simply a fair one, and perhaps over 200 lbs. if it be a heavy one. This loss, of course, is usually made up by heavy dressings of yard manure, every ton of which returns to the soil about 10 lbs. of potash. This calls for applications of at least from fifteen to twenty tons of such manure per acre for every crop, and for larger ones, where very large yields are obtained or aimed at. In every event, yard manure will be found a most excellent fertiliser for these crops, and one of the best means to maintain the balance of soil fertility.

The query now comes up, what to do in case that yard manure is not available? Perhaps the grower, following the advice given by expert gardeners, has used bone flour or other phosphates for some time as a substitute for yard manure. He may have been very liberal in his applications, using a ton or more per acre; yet in all this dressing he has not furnished a single pound of the potash so urgently needed, only a large quantity of phosphoric acid, for which his crop has little use. Consequently the crops must soon suffer for the want of potash, and perhaps of nitrogen.

Having made the correct soil diagnosis again, the proper treatment is easily prescribed. Apply potash, and perhaps some quickly available nitrogen. My rations, in such case, would be almost as follows, per acre—viz.

- (1). 50 to 100 bushels of unleached ashes.
- 200 to 400 lbs. of nitrate of soda.

The phosphoric acid, contained in the ashes, would do no harm, and in some cases may be needed.

- (2). 200 to 300 lbs. of sulphate or muriate of potash.
- 200 to 400 lbs. of nitrate of soda.

—(From *Practical Farm Chemistry*, by T. GREINER, La Salle, N.Y.)

### BRITISH GROWN FRUIT.

ILLUSTRATIVE of what Mr. J. Wright says at page 509 regarding the superiority of home-grown Apples. Upwards of a quarter of a century since I had on hand a large quantity of Apples saleable to fruit merchants at a price that would barely pay the working of them, although they sold similar fruit at from 2d. to 3d. per lb. I had the fruit graded, and sent a hamper of them, mostly Keswick Codlins and "Perstons." These pleased so well that an order in several days arrived for upwards of a dozen similar hampers, and this dozen hampers was the immediate cause of more orders than I could supply, while the smaller and deformed fruits brought a higher price amongst poorer people than I could possibly get from any fruit merchants. While I bear no malice towards fruit merchants, I have a strong antipathy to goods rising in price more than 100 per cent. to the consumer above what the raiser or producer realised, and I am astonished at the latter abandoning the custom of olden times dealing direct with consumers, who, as a rule, laid in stores of fruit annually of the good keeping sorts, and this from the poorest to the more wealthy, the quantity being regulated by their requirements and purse. All had their store of Apples, the rich getting the luxury of Apples cooked with sugar. Its high price in those days compelled the artisan to be content with his Apple in its uncooked state, or, as a luxury, roasted or boiled.

There can be no question that as home-grown fruit becomes more plentiful a different mode of putting it into consumers' hands must be adopted than is practised at present; but if it is to be successful there

must be co-operation, and a system established that fruit will be always plentifully exposed for sale, but never in excess. A few years since two persons belonging to my native town established a system of retailing groceries at as low a price as was paid for the same goods wholesale. This system has proved successful, and is rapidly extending to most places and commodities, and is already being felt by the monopolising fruit merchant, who, notwithstanding the competition, clings tenaciously to his 100 or more per cent. system, and even the most wealthy will not fail to discover that Apples can be had at half the price at their grocers a few yards distant.

Producers must agitate and teach the public to their mutual interest before it is too late. The present generation have not the experience or the knowledge of many really good things in domestic economy which our forefathers had. Then there are too few Fenns to experiment and lecture us. Many luxuries and comforts are denied us because of our obstinacy in following fashion and custom. The producer must use every legitimate means in his power to spread the knowledge of good and bad fruit; and how to secure the latter to the interest of all concerned.—W. T.

### HARDY FRUIT GARDEN.

APPLES AND PEARS—PRUNING ESPALIER TREES.—Proceed with this when the weather is mild enough. All remains of shoots that were cut off at the summer pruning may now be still further reduced to about 1 inch in length, cutting them off just above a bud. All weak wood should be cut off close to the main branches, and the remainder thinned if they are not 3 inches or more apart. Cut all wood clean out that has a soft or greenish appearance, which shows that it is unripe and useless. Any spurs that are more than 2 inches in length must be shortened back to a bud or cut out altogether. The uppermost branches, being the most favourably situated as regards the supply of sap, are very apt to produce these long spurs, and also strong woody pieces, which never make an attempt at fruiting. If not over-abundant the latter should also be taken clean out, but if the tree produces many of them it is a sure sign that the supply of sap is in excess of the requirements of the tree at its present size, and some of the roots must be severed before this state of things can be remedied. Young shoots at the ends of the branches should be preserved if any extension in the size of the tree is desirable, but they must be shortened to about two-thirds of their length in order to make them produce fruit spurs. This form of tree will produce a large quantity of fruit in a small space for a number of years, and is particularly well adapted for small gardens where they may be trained near to the walks without shading the ground overmuch, or taking up room required for other things; but when they get old the lower branches gradually lose their strength and die away, until only the two upper ones are left, when the trees become unsightly. Unfortunately there is no remedy for this state of things, although careful pruning in a young state will extend the period of usefulness for several years, but when they become old the best plan is to cut them down and plant young ones instead.

The above remarks on pruning apply equally to horizontally trained trees on walls.

STAKING AND TYING.—The best plan to support espalier trees is with iron uprights fixed in stone and fitted with fencing wires at one foot apart, on which the main branches are to be tied. Care must be taken that none of the iron uprights is placed against the main stems of the trees, as this would in time cause much inconvenience and damage to the trees. The old system of training them to stakes may be followed if the above is impossible. Ash stakes are very good, selecting them straight and clean and about 2 inches in diameter at the thickest end. Pull the old stakes out whole, if possible, as leaving the broken ends in the ground only encourages fungus among the roots. Stakeing and tying is warmer work than pruning, and may be done in frosty weather if the ground is not too hard.

CORDONS.—All kinds of these require similar treatment to the above as regards pruning. They are more inclined to run into wood than to form fruit spurs, and this is especially the case with low-trained horizontal cordons at the bend of the branches if they are on free-growing stocks. Root-pruning judiciously done is the only remedy.

CLEANSING THE TREES.—All moss and lichen, wherever it is found, must be cleared away periodically from Apple and Pear trees, as it stops the pores of the skin and harbours insects which attack the fruit and foliage. Where only a few trees have to be attended to they may be scraped with a knife in the affected parts, but where large quantities are grown, and in the case of large standard trees this is impracticable, and the next best remedy is to throw lime over the tops of the trees when they are moist enough for it to adhere to them, and to whitewash the main stems and large branches with hot limewash. American blight and canker are generally found together, although we do not suggest that canker is caused by the insects. The worst places should be pared with a knife to get rid of all excrescences. Next wash the wounded

places thoroughly with a solution composed of 4 ozs. softsoap and 1 oz. carbolic acid to a gallon of water, working it well in with a stiff brush, and if it can be applied hot it is best to do so. This will effectually kill any insects that remain, and stop any others from coming for a time. As soon as the wounds are thoroughly dry they should be still further protected from fresh attacks. Where only a few have to be done this may be accomplished by covering them with cold grafting wax, called also *Mastic l'homme Lefort*. If a large quantity require attention it is much cheaper to melt some pitch and cover the wounds with it. The new bark will grow underneath this, and the wounds will eventually heal completely.

**PROTECTION FROM RABBITS.**—During severe weather these vermin often attack young fruit trees in exposed places, and in a few hours will ruin a large quantity by gnawing the bark from the stems. All such trees should therefore be protected by rabbit-proof fencing or wire netting as soon as planted. The latter must be let into the ground to a distance of 6 inches, and should stand 3½ feet above the surface, but not fit too closely to the tree, as the stem should have room to swell for a few years. Another good plan often practised in the Kent plantations, which also secures the trees from the attacks of all kinds of cattle, is to take some stakes (old Hop poles are used in Kent), cut them into 6-foot lengths, bore a hole through each at 1 foot from each end, and thread wires through them when placing them around the trees, leaving plenty of room for the trees to swell. A length of 3 feet is sufficient protection against sheep and ground game. This system also shades the stem of the trees from bright sunshine, preventing excessive evaporation, and is better for this purpose than haybands and similar materials, as it is not so liable to harbour insects.

**THE FRUIT ROOM.**—Look carefully over stored fruit regularly once a week and remove all that show signs of decay, but do not move the sound fruits if it can possibly be avoided, as every movement when the fruits are ripe tends to bruise them and starts decay. Cover well in frosty weather if the room cannot be warmed. Newspapers are a great protection, and can be put on without any fear of damaging the fruit. Hay or straw may be placed over these in very severe frosts. One or two petroleum stoves will keep frost out better than any covering if no other means of heating are available.

#### FRUIT FORCING.

**VINES.**—*Early Forced.*—Exercise great care in ventilating, avoiding chills, such as those resulting from cold currents of air, admitting it chiefly by the top ventilators, and only moderately when the air is cold and sharp. As the foliage is developing root action will be excited, and should be encouraged by supplying tepid water at a temperature not less than the mean of the house, nor exceeding 90°. If fermenting materials have been introduced into the house they should not be allowed to decline in warmth, but be added to from time to time, having a good heap of leaves and stable litter in reserve, from which the supply of sweetened material may be drawn as required. The outside borders must be well protected from frost. Disbud and tie down the shoots before they touch the glass. Do not be in too great a hurry in stopping nor restricting to a certain number of joints, being guided in this respect by the space at command and the vigour of the Vines. If weakly stop them at three or four joints beyond the bunch; if strong they may be pinched at one joint beyond the fruit, and then pinch to one joint as regards the weak shoots, and leave two or three on strong growths after the flush of sap has been centred on the bunch, extending the growth so as to insure a supply of well-developed foliage all over the house, avoiding overcrowding in any part, not allowing any to be made for which there is not room, or that must afterwards be removed. Remove surplus bunches as soon as choice can be made of the best, reserving the most compact, and avoid overcropping. Maintain a night temperature of 65° until the flowers open, then keep the house at 75° by artificial means, with a rather drier condition of the atmosphere.

Vines in pots should, as soon as the fruit is set, be copiously supplied with liquid manure, maintaining a moist atmosphere by damping the paths two or three times a day, and occasionally with liquid manure, keeping the evaporation troughs charged with the same, taking care not to use the liquid too strong, or the ammonia will injure the foliage.

**Houses to Afford Ripe Grapes in June.**—The Vines for this purpose must be started at once, for, though they may be forced so as to afford fruit in May, they are best brought forward gently and a margin allowed for unfavourable weather. The outside border should be well protected from inclement weather. If fermenting materials are used they must be kept uniform in temperature, and if that cannot be effected it is better to dispense with them altogether. A good thickness, say 6 inches of dry leaves, dry fern, or litter, with shutters or glazed lights to throw off rain and snow, answer admirably. Inside borders will need thorough supplies of water at 90°, which will warm the soil and cause the roots to transmit sap freely. Fermenting materials introduced into the house, and formed into a ridge-like heap on the floor, and turned over frequently, adding fresh as necessary, will give out heat, moisture, and ammonia, highly conducive to a good break, and save fuel. The temperature should be maintained at 50° to 55° by artificial means, advancing to 65° from sun heat. Damp the house and Vines two or three times a day, but do not keep them constantly dripping with water, for that only encourages aerial roots, and in dull weather sprinkling once or twice a day is ample. Ventilate freely on all favourable occasions, for a sweet atmosphere is felt by dormant Vines; at least, those brought forward in a properly ventilated structure do better than those kept in a confined atmosphere.

**Houses from which the Grapes Have been Cut.**—Delay in pruning

Vines after the leaves fall is undesirable, because they are not given that complete rest which pruning and keeping them cool assures. Healthy Vines may be cut to one, or at most, two buds, but weakly Vines, and those with long-jointed wood, may be kept a little longer, cutting in all cases to a plump bud. This will cause the spurs to sooner become long than by close pruning, and necessitate a renewal of the rods, which it is easy to effect by training up young canes for the displacement of these, or by having a succession of rods from the main rod, and cutting out those that reach the extremity of the space to a cane nearer the base and well situated for displacing that cut away. Thoroughly cleanse the house, and remove all loose bark, but avoid close peeling and scraping the Vines, as is often done, down to the wood, and wash them with tepid softsoap and water, following with an insecticide if there have been any insect infestations. Remove the surface soil or mulching down to the roots, and supply fresh material, good fibrous loam being the most suitable, with an admixture of bone meal. The house should be kept cool, but vineries are frequently utilised for plants, and the temperature kept warm on their account, which is prejudicial to the Vines. The plants are not always clean, and the insects pass from them to the Vines, hence so many vineries are infested with mealy bug, red spider, and thrips. The temperature ought not to exceed 45° by artificial means, and plants only needing protection from frost should be placed in vineries when the Vines are at rest, and air should be admitted upon all favourable occasions, so as to keep the structures as cool as possible.

**Late Houses.**—In some late houses the leaves are not all fallen, the Vines keeping the foliage a longer time than usual in consequence of the wet season and unusual moisture in outside borders. The leaves must be cleared away as they become ripe, and this should be effected without brushing the Grapes or raising dust by sweeping up the fallen leaves. Maintain a mean temperature of 45°, with a dry atmosphere in houses in which Grapes are hanging. Examine every bunch frequently, and remove all decayed berries. Ventilate the house on fine dry mornings, and keep it closed when the weather is damp, but there must be a gentle warmth in the pipes to prevent a stagnant atmosphere. In the case of late Grapes ripened comparatively early, and those are the best for keeping, the Grapes may be cut, the ends of the stems being inserted in bottles of rain water secured in an inclined position so as to admit of the fruit hanging clear of the bottles. Any dry room will be a suitable place where an equable temperature of 40° to 45° is maintained. This will admit of the Vines being pruned and the house cleaned, the Vines thus having a few weeks' complete rest, and with that they start strongly when set to work, as they should be soon after the middle of February.

#### PLANT HOUSES.

**Lilium Harrisii.**—If these have been grown cool since they were potted the plants will be strong and about 18 inches high. Keep them near the glass in a temperature that does not fall below 45°. A little artificial manure may be applied to the surface. Later bulbs that are only 5 inches high should be placed on a shelf near to the glass in a cool house, where plenty of air can be admitted daily when the weather is mild. Bulbs of *L. eximium* may now be potted, 5-inch pots are large enough for these. Use the soil in an intermediate state of moisture, and do not water the bulbs after potting. Place them in a frame or cool house where frost can be excluded, and cover with cocoa-nut fibre refuse until they grow through.

**French and Fancy Pelargoniums.**—Plants raised from cuttings and placed into 3-inch pots should be ready for 5-inch size. Pot these in loam, sand, and one-seventh of manure. After potting place them on a shelf in a cool house where they are safe from frost. Water these plants carefully; in fact, the whole stock if overwatered at this stage is almost certain to be spotted.

**Cyclamen.**—Pot seedlings singly into thumbs if not already done, and arrange them on a shelf close to the glass where the temperature ranges from 55° to 60°. Fill between the pots with sand, ashes, or cocoa-nut fibre refuse to prevent their drying. Seed sown at the present time will be capital for flowering next winter. Sow the seed in pans filled with leaf mould, loam, and sand. When sown just cover the seeds with fine soil, water them, and cover with a square of glass. In a temperature of 60° to 65° they will soon germinate.

**Greenhouse Climbers.**—These should be well thinned and pruned so as to admit full light to the plants beneath. The houses must be washed and cleaned at the same time, and the plants tied into their places again ready for growth in spring. Top-dressing these plants may also be attended to; if left until the spring the pressure of more important work often prevents this being done until it's too late in the season to benefit the plants much.

**Lapagerias.**—Plants that have been kept close have practically ceased flowering. These may, if infested with insects, be loosed from the trellis. Some care is needed, as the foliage is easily broken. Thrips are the greatest enemy to the Lapagerias, and the best means of destroying them is to dip the plants in a solution of tobacco water. The portion of house they occupy can be washed, and the plants retrained. In doing this portions that have flowered may be removed down to where a growth bud is observable. If not removed these ends only die back. If the plants are confined at their roots a top-dressing of rich material composed of cow manure and loam will assist them greatly.

**Roses.**—These in cool houses may be thinned, and any pruning necessary must be done at once. If red spider has infested the plants, the whole of the old foliage may be removed with little or no injury. If the old leaves are left on the spider is certain to attack the young growths. Such varieties as Gloire de Dijon, Lamarque, Maréchal Niel, and others

require very little pruning, only unripe ends need removal. The dwarf growing Teas may be liberally thinned out unless buds only are needed, and then the more wood left the greater the quantity of buds produced. H.P.'s and Teas established in pots may be pruned for starting. We have found them start well in a cool house on a bed filled with leaves without the aid of heat unless the weather proves cold and severe. Nothing is gained, but puny blooms result if the plants are hurried in their early stages.

## THE BEE-KEEPER.

WE have to state that the article which appeared on page 582 of the *British Bee Journal* of the 24th inst., headed "An Explanation," and signed T. W. COWAN, Editor *British Bee Journal*, was premature. We had consented to allow Mr. Cowan to publish an explanation in our columns, and a proof print was sent to us for approval. This proof print was returned by us on the 21st inst. with certain alterations, some sentences being expunged which we considered libellous, and the actual form in which we finally agreed to publish it was as follows:—

### AN EXPLANATION.

To the Editor of the *Journal of Horticulture*.

I have had the *Journal of Horticulture* sent me, and my notice has been directed to an editorial explanation on page 485.

In your zeal to do justice to your correspondent you certainly appear to embrace the opportunity of being unjust to your contemporaries. When I wrote to you on the 19th September last, "I can find no allusion made in the *Record* about Punic bees, either editorially or by any of its contributors," I did so in perfect good faith, but I frankly admit that I was led into the error by an unintentional oversight on my part. To have admitted that Punic bees had been once alluded to editorially in the *Record* would not have altered the nature of the statement, as there was no question about this paragraph, but about a reference by your correspondent to an article in which there was no mention of Punic bees at all. Any unprejudiced person can see that the editorial allusion you quote has nothing whatever to do with personal experience, as it is couched in general terms, just as the same term "our limited experience" is daily used in a legitimate way in ordinary language in connection with things the writers have had no experience about, but about which they are writing from the reports of others. Such language is in daily use in all our papers, and it would be a stretch of the imagination to attribute personal experience to the writers.

The context will also show that it is more the expression of the limited experience of "A Hallamshire Bee-keeper," who had just been given as the authority, as he was the only one who had said anything about Punic bees, and this in the concurrent number of the *British Bee Journal*. This reply given by Mr. Carr could not have been from personal experience, as he had never seen a Punic stock, and knew nothing about such bees; in fact, although Mr. Carr was anxious to do Mr. Hewitt full justice, so little value did he attach to these bees that there is no reference to them in the index, hence the reason for my overlooking the paragraph referred to. Mr. Carr seemed perfectly oblivious about this paragraph, and I am not surprised at it. The first description of Punic bees was given by Mr. Hewitt in *B. B. J.*, on page 271, 1890. He again refers to them on page 511, and on page 512 Mr. J. Luck asks for results respecting Punic bees from those who have tried them. There was not a single response to this appeal from anyone who had tried them except Mr. Hewitt himself. He had already had full justice done him, and we naturally wanted to hear about the experience of someone else besides Mr. Hewitt. No one will be surprised that after such a complete failure of reports, Mr. Carr should have dismissed the matter from his mind as being of no importance.

Now, sir, I think I have just cause for complaint. When I placed all the papers before you (including the *Record* of June containing the passage now referred to), you promised to have the matter investigated, and in your letter to me of the 23rd of September you stated, in reply to my letter of the 19th of September: "When Mr. Wright returns to the office I will authorise him to see to the matter." Mr. Wright was to have returned about the 2nd of October, and not hearing from you I wrote on the 22nd of October, and from your reply on the 23rd of October I gathered that you had not made the investigation which you had promised to make, although a month had elapsed. Had you made this investigation probably the error, which I am sorry was made, would have been detected and avoided.

You refer to this mention of Punic bees, and take the opportunity of saying: "In the *British Bee Journal* for August 27th, 1891, page 381, the same Editors, in reply to 'Inquirer,' say, 'We know nothing about the so-called Punic bees, and can give no informa-

tion as to their value.'" This reply to "Inquirer" was written by me alone, and I was speaking of my own experience and not of Mr. Carr's. You will see by the *British Bee Journal* that I am responsible for the conduct of this paper, while Mr. Carr conducts the *Record*, so that there was no inconsistency in my reply of not knowing anything about so-called Punic bees, and you must disconnect Mr. Carr, the writer of the reply in the *Record*, from my reply in the *British Bee Journal* altogether. But, after all, one of the main points at issue was the statement in the article by Mr. Hewitt in the *Journal of Horticulture* on the 3rd of September, in which he says: "They do not say that the Punic stock in Mr. Carr's apiary in the spring of 1890 was the 'best and strongest' he had" (see *Record* for June, 1890). On reference to the article from which the quotation is made by Mr. Hewitt, it will be seen that there is no mention whatever about Punic bees or to a Punic stock in Mr. Carr's apiary. The article refers to quite another matter altogether—namely, to virgin queens sent out to test a wintering theory of the writer's. I have simply to emphasise what I have already said, that I know nothing about so-called Punic bees, although I know North African bees very well, more especially those of Algeria, Morocco, and Tunis. Some of these days I shall have plenty to say about the bees of this last place, also about the apiary belonging to a French gentleman (whose name, for obvious reasons, I withhold), and who exports Tunisian bees, and whose apiary I intend visiting during my rambles in Africa, whither I contemplate going for the purpose of finding out why the bees of Tunis are not pure, like those of the same varieties in Algiers, and why they sometimes show yellow bands.

By arrangement with the Editor, the above explanation will be printed in the *Journal of Horticulture*.—T. W. COWAN, Ed. *British Bee Journal*, 7th Dec., 1891.

\*\*\* We ought to add, for the information of many of our readers who may be unacquainted with these two bee journals referred to above, that both of them are announced on their wrappers to be, "Edited by Thomas W. Cowan, F.G.S., F.R.M.S., &c., and W. Broughton Carr."

## APIARIAN NOTES.

### THE WEATHER.

ON December 23rd the thermometer rose during the day from 20° to 40°. Being calm and mild, many of our stocks took an airing, and we were delighted to see the lively Punics on the wing. It seemed there was more than a mere flight in the air, as many bees scoured the garden in search of flowers. Hellebores are in great profusion, and on the eve of flowering; Snowdrops are showing distinctly, also Crocuses; Wallflowers have never deserted us, nor the Primrose, and the Daffodils disdain not to give proof they will not allow a gap to be made, but will in succession and in season enliven our borders and make the bees merry. The Winter Aconite and Anemones will soon also contribute their share of usefulness, the last two excepted; all the others mentioned promise to be early and abundant.

### THE PAST YEAR.

The year 1891 has been an eventful one, and bee-keepers have shared in the calamities, at least the majority have; and as is the case in the failure of other rural pursuits, the million become sufferers. A good bee year is always a good one for horticulture and agriculture, and all are benefited thereby. Nothing of importance which is likely to benefit bee-keepers has been brought before the public if we except the great development of fruit growing in some districts. Extensive orchards are one of the mainstays of bee-keepers, and bees are the insurance agents of fruit growers, so both must go together. Several prizes have been awarded by the B.B.K.A., and several patents have been taken out for inventions that were made, used, and sold many years since, but blunders such as these never occur amongst men of experience.

### THE SELF HIVER.

This new invention has been put to crucial tests in some places, but has not been as yet a success, nor do I think it likely to be. There are easier and profitable methods of managing the apiary. But the funny part is, and prompts the question, why a self hiver, when the advocates have for so long advised non-swarming bees, non-swarming hives, and the prevention by giving timeous super space. If swarming could be prevented there would be no need for self hivers. The *Journal of Horticulture* is

the only journal that practically showed the impossibility of the prevention of swarming by any of the modern methods of management as advocated and practised previous to our letters in this Journal, and appears to have enlightened the bee-keepers of America as they have done some in Britain.

Those who cannot attend their bees during the honey gathering and swarming season, or act in accordance with the instructions laid down in these pages, should not keep bees if they expect to be successful with them. Particulars as to what to do regarding swarming, and how to guard against the loss of absconding swarms, will be given during the coming spring.

Bees never swarm without preparing some days beforehand, but they swarm at all times of the day between 6 A.M. and 6 P.M., and under every known condition, plenty of breeding space with a young prolific queen excepted. When several swarms issue at the same time they create confusion, and damp the hopes and spoil the plans of the keeper; queens are killed, and not unfrequently whole swarms. To avoid these losses is the object of this letter.

The bee-keeper should never have his eye off the apiary during the swarming and honey gathering season, and if this is impossible, someone should be employed to do so. When one swarm issues and the hives are in a convenient place, most people will secure it easily; but when several attempt to swarm at the same time, unless the attendant does something more than stand and gape, even although he hives the huge cluster of bees, they may shortly thereafter unobserved leave the hive, as several queens is one of the causes of unsettled swarms. Swarms about to issue should not be closed in, as that, through the excitement, overheats the hive, which creates incipient foul brood.—A LANARKSHIRE BEE-KEEPER.

(To be continued.)

#### TRADE CATALOGUES RECEIVED.

Charles Sharpe & Co., Sleaford, Lincolnshire.—*Catalogue of Garden and Farm Seeds.*

J. Cheal & Sons, Crawley.—*Seed List, 1892.*

Dobbie & Co., Rothesay.—*Catalogue and Competitors' Guide, 1892.*

Ellwanger & Barry, Rochester, N.Y.—*List of Bulbs and Hardy Plants.*

Chr. Lorenz, Erfurt.—*Illustrated Catalogue for 1892.*

Little & Ballantyne, Carlisle.—*List of Garden Seeds, 1892.*

Wm. Cutbush & Son, Highgate and Barnet.—*Catalogue of Flower, Vegetable, and Farm Seeds, 1892.*

C. Fidler, Reading.—*Catalogue of Vegetable Seeds and Potatoes.*

Dickson & Robinson, 12, Old Millgate, Manchester.—*Seed Catalogue, 1892.*

\*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Unanswered Letters.**—Replies to several letters received during the "holiday season" cannot be published this week.

**Camellia Buds Falling** (R. S.).—There is no doubt whatever that the dry heated air from the hot-water pipes is the chief cause of the evil; it is possible, too, that the plants in pots do not have the support they need, and a gentle stimulant such as soot water might be beneficial. If the stage is of open latticework you would do well to cover it with something that would hold a layer of gravel, and by keeping this moist and syringing the pot occasionally the flowers of the Camellias would probably expand.

**Potatoes for Planting an Acre** (J. J.).—As obviously the weight of sets for a given extent of ground depends not on their size alone, but on the distances at which they are to be planted, in answer to your question we can only suggest a 'case. Suppose the sets are planted a foot apart in rows 30 inches asunder, 17,424 will be required for an acre; and if they average 2 ozs. each their total weight will be 19 cwt. 1 qr. 22 lbs. By weighing a few sets and deciding on the distances for planting you will now have no difficulty in making an approximate estimate of the weight you will require.

**Microcarys Tetragona** (W. M. T.).—The Tasmanian plant concerning which you inquire is one of the most remarkable of the Conifers found at the Antipodes, and indeed in the whole family. The

FIG. 103.—MICROCARYS TETRAGONA.

great peculiarity of the plant is that the female cones are of a semi-transparent texture, fleshy and most brilliantly coloured, being of a rich red hue that in sunlight is very striking. These cones, though small, are borne in considerable numbers on short branchlets, and, the main branches being of a decumbent or drooping habit, the plant has a graceful and really beautiful effect grown in a pot with the main stem secured to a stake. It is found growing on the western mountains of Tasmania, where it forms a low straggling bush, the branches being four-angled, as the specific name indicates, the leaves small and closely pressed to the stem. It was introduced to Kew about 1862 by W. Archer, Esq., of Cheshunt, and several plants in the temperate house there succeed very well and produce their attractive cones very freely. Several Conifers produce coloured fruits, but in most cases it is a disk, aril, or some appendage that is so coloured, and not a true cone, as with the Microcarys. For instance, the fleshy aril of the common Yew is well known, and in the genus Podocarpus several similar examples occur, one of the most noteworthy being *P. neriifolia*, the Oleander-leaved Podocarp. The fruit of this species has a large fleshy globular or ovoid bright red disk about half an inch long, upon the top of which is seated the seed, a true fruit about the size of a large pea, but more egg-shaped and bright green, forming a most peculiar contrast with the richly coloured disk.
