**Latest Plants.**—These are now well up the trellis and showing fruit blossoms, which should be fertilised daily, the atmosphere being kept dry, a little ventilation being given at night so as to insure a circulation of air and prevent the deposition of moisture upon the blossoms. Stop the shoots at the time of impregnation one joint beyond the fruit. As soon as a sufficient number of fruits are set on a plant remove all the staminate and pistillate flowers, reducing the fruit to three or four on a plant, or according to their vigour. Earth up the plants after the fruit is fairly swelling, and be careful in syringing the foliage, only using it on bright afternoons, but maintain a genial condition of the atmosphere by damping in the morning and afternoon. Be careful not to give too much water, but encourage healthy root action by moderate moisture in the soil. The temperature must be maintained at 70° to 75° by day artificially, and 80° to 90° by day from sun heat, with a night temperature of 65° to 70°.

**Plants in Frames and Pits.**—These will not require further damping over the foliage, and should only have sufficient moisture in the soil to prevent the foliage flagging, which should be kept rather thin, and the fruits well elevated above it on flower pots, each fruit being placed on a piece of slate, applying good linings for affording the requisite heat to finish the fruit satisfactorily, maintaining also a dry atmosphere with free ventilation.

**STRAWBERRIES IN POTS.**—Late runners may yet be potted, giving them 5 or 6-inch pots, and if these are filled with roots before winter the plants will produce some good fruit, though not as plentifully and large as those potted earlier; nor are they available for early forcing, but they do well for succession, especially when brought forward very gently. Plants potted some time ago should be examined, and if making side buds these should be removed with a piece of hard wood, so as to throw the vigour into the central crown. If the plants grow vigorously liquid manure will not be necessary, but those that are weakly should be supplied with it twice a week. Remove all runners as they appear, and loosen the surface of the soil, especially round the sides of the pots, so as to secure the more thorough moistening of the ball. As the plants grow set the pots wider apart. If red spider attack the plants hold each inverted with one hand, and with the other dust the under sides of the leaves with soot from a dredger.

## THE BEE-KEEPER.

### SEASONABLE HINTS.

THE weather has been most unpropitious of late, and bees have been unable to collect sufficient honey for their daily wants, and will, in most cases, have had to draw their supplies from the honey already stored in the hives. This is unfortunate, as there is a great quantity of white Clover still in blossom; in fact, I do not recollect such an abundance of it at this season of the year. A few days of hot weather, such as we expect at this time of the year, would have given quite a honey flow from this and other sources, and enabled the bees to collect a fair amount of honey. The continued wet, which appears to be very general, will, I fear, also be the cause of disappointment to those who have taken their bees to the Heather. At present there does not seem any sign of its clearing and having settled weather.

### TAKING THE SURPLUS.

I must repeat my advice that no time should be lost in taking such surplus as can be spared, for if this weather continues any unsealed honey in the supers will either be consumed or carried down into the body of the hives.

Those who continue to keep bees in skeps will do well to take up those selected for that purpose at once, for except in Heather districts it is not likely that any additional weight of honey will be obtained after this time.

It is to be hoped that the plan of sulphuring the bees in skeps is now seldom practised, for in addition to its cruelty it spoils the delicate taste of the honey.

### DRIVING THE BEES FROM THE SKEPS.

Those who have attended the Shows of the Bee-keepers' Association will have seen how easily driving may be done, but there may be some to whom a short explanation of the *modus operandi* will be useful. Driving can be done by any person of moderate intelligence. In this, as in all manipulation with bees, we should proceed quietly and deliberately, taking care not to jar the hive or excite the bees, everything being ready before touching the skep containing the bees.

### CLOSE DRIVING.

An empty skep about the same size as the one to be driven, a pail, and a towel or cloth are required; then blow a little smoke into the mouth of the hive before removing it from its stand. The bees being alarmed will run up to the honey, and if we wait a few minutes they will fill themselves, and in this condition they seldom sting. Raise the skep gently, turning it upside down, and place it in the pail; put the empty hive on it, so that the rims touch, and bind the two together with the cloth. Should the hive have a flat top the pail will not be required. Now commence and continue rapping the sides of the skep containing the bees with the open hand, hard enough to jar the combs without breaking them down. In a few minutes the bees will make a buzzing noise and commence running up into, and cluster in, the empty skep. The rapping must be continued for some time, usually from five to ten minutes, when most, if not all, of the bees will be found in the hive that a few minutes before was empty. To ascertain if such is the case

untie the cloth and gently raise one side of the skep; if all are not up continue the rapping as before until they are. The skep containing the bees should at once be removed and placed on the stand that it originally occupied, when any bees that are on the wing will join those in the skep. Having now got rid of the bees from the honeycombs a cloth should be at once covered over the combs to prevent robber bees from getting into it. Remove the hive to a place of safety, and extract from such combs or portions of comb as contain honey as soon as convenient.

### WHAT TO DO WITH THE BEES.

The bees can now be united to any other colony as follows. Blow a little smoke in at the entrance of the colony to which it is wished to join the driven bees, and give them a few minutes to gorge themselves with honey. Lift up the hive and sprinkle them with some very thin syrup; then put it on the ground on its floor board, raising up the front edge of the hive on a wedge or stone. The driven bees should also have a little smoke to keep them from flying, and a very little of the same thin syrup sprinkled among them, and should then be thrown by a sudden jerk in the front of the raised hive entrance. A cloth or newspaper should be first placed under the floor board to prevent the bees from being lost, and they will run in and join the others. In my next I will further explain what may be done with driven bees.—JOHN M. HOOKER.

### MODERN BEE-KEEPERS BEHIND THE TIMES.

It is a well-known fact that I have for years exposed the shortcomings of modern teachers, and taught very much like what appears on page 166, August 20th. The system there described is an ancient, and not a modern one, as the writer of the notes appears to imply. I should be pleased if he would tell us when their views were altered, giving date, and where the record is to be found, as it is not so very long since extracting from brood combs was strongly recommended by the modern school.

The want of some ready way of getting bees from supers has, no doubt, as the writer says, long been felt amongst modern bee-keepers, of whom he is confessedly one, but not amongst ancient bee-keepers, more practical and more experienced. A short time before I described the carbolic acid with the paper method, modern bee keepers were at their wit's end how to get the bees cleared from them without clearing the honey at the same time. Shortly afterwards my plan was pronounced by novices and experienced bee-keepers alike as the best and speediest of all systems, and the late Mr. William Raitt once duly accredited me with the idea, although Mr. Cheshire in his work leaves the impression that it was Mr. Raitt's; and many others, as I anticipated through the Journal, have also laid claim to it.

It is not many months since I gave a description of super clearers, and as I am fully acquainted with all sorts can speak advisedly on the subject. Cone super clearers have been before the public for many years, and were not invented last year, as stated at page 166; nor is the method of working as described so good as is practised in America, the home of the invention. Some people object to what they term the "nasty acid," but it is cleanly and safe, and far superior to smoke, which contains creosote. I never use smoke, and my first article appeared in the *Cottage Gardener* against its use upon bees at least thirty years ago.

Clearing supers with carbolic acid paper is almost instantaneous; combs are neither broken nor soiled, and the work is finished quicker than the time it takes to replace a super with the cones, and sometimes robbers will get in.

One of my earliest super clearers consisted of a close box, having a sliding mouthpiece, and a pane of glass covered by a sliding shutter. The super or supers were simply placed in this box, the mouthpiece being kept closed until many bees appeared at the glass, when the shutter was closed and the mouthpiece opened; then out rushed the bees to a platform leading them to the entrance of their own hive. The plan was a good one, superior to the cone clearer, but much inferior to the carbolic paper.—A LANARKSHIRE BEE-KEEPER.

### PUNIC BEES AND THOSE WHO KNOW NOTHING ABOUT THEM.

IN the "*B. B. J.*" for August 27th someone signing himself "Inquirer" wants to know who I am, my real name, &c., and he also feigns ignorance as to "*A. L. B. K.*," Messrs. Stokes and Robinson who are mentioned in the *Journal* on August 20th, and "if they are known in the bee world as men of experience," and runs to Messrs. Cowan and Carr to advise him to have nothing to do with Punics.

These kind persons preface their advice by saying, "As a rule we do not like to import into our columns controversies originating in other journals," a very good rule too, but they have not adhered to it. They do not say that the Punic stock in Mr. W. B. Carr's apiary in the spring of 1890 was the "best and strongest" he had, see *Record* for June 1890. They do not say that Punic bees were mentioned in their *Journal* on June 5th, 1890, and where they came from; nor do they say that when Mr. J. W. Woodley wrote on October 30th, 1890, condemning them before he had ever seen a bee, I wrote offering to supply him with two queens, to be tested against any two he choose, and if they failed I would make up the difference. Oh! for consistency. They would on no account break their rule, made for the occasion, to do me a favour, but they break it on the first opportunity to do me something else.

I never had a very high opinion of their accuracy, and certainly it is not improved after reading the following:—"The only other person besides 'A Hallamshire Bee-keeper' (otherwise John Hewitt), who has written in favour of Punic bees is E. T. Pratt." Mr. Henry Alley says in the *Apiculturist* for August, "Our opinion is most favourable of them. If the Punic bees are one-half as good as is claimed every bee-keeper will want them, and all other races will be superseded, and now that we have seen these bees and have become convinced of their superiority we shall commence to rear them." If this is not "in favour of Punic bees" I should like to know what is. I have never seen or exchanged a line with Mr. Alley. Another person I will name who has written in favour of Punic bees is Mr. W. B. Carr, one of the editors of the *B. B. J.*, but this was before he found out how difficult it was to import them; yet these learned editors now say, "We know nothing about the so-called Punic bees, and can give no information as to their value."

"Inquirer" thinks he makes a great point of the bees being here seven years. Is it seven years since 1886? I trust you will find space for this in the *Journal*, and if the Editors of the *B. B. J.* want it let them break their rule again and import it into their columns. It is no use my sending it to them, as it would be destroyed judging from past experience. "Inquirer" should remember that it is in very bad form to ask for a writer's name without giving his own, and I think no editors, save those who conduct the *B. B. J.*, would either have printed the anonymous request or supplied the information. Anyone sending his name and address to John Hewitt & Co., Sheffield, can learn all about—A HALLAMSHIRE BEE-KEEPER.

#### TRADE CATALOGUES RECEIVED.

Mr. H. C. Hartvelt, Lisse, Haarlem, Holland.—*Bulbs*.

Mr. G. Shrewsbury, 36, Gray's Inn Road, London, W.C.—*Heating Appliances*.

Mr. B. Soddy, 243, Walworth Road, London, S.E.—*Bulbs*.

Robert Veitch & Sons, 54, High Street, Exeter.—*Catalogue of Bulbs and Other Flower Roots, Carnations, &c.*

J. C. Wheeler & Son, Gloucester.—*Catalogue of Flower Roots, Strawberries, &c.*

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Begonias** (*F. Geeson*).—We have received the flowers, which are very good indeed, but your note cannot be inserted this week.

**Hardy Annuals** (*F. W. I.*).—French and African Marigolds would not be permissible in a stand of twelve hardy annuals, or at least most judges would disqualify stands containing them.

**Roses on Manetti Stocks** (*W. K. B.*).—It is neither desirable to earth up the stocks as soon as they are budded nor after they have started into growth. The earth is cleared from them for the purpose of budding and not returned.

**Certificates for Plants** (*Subscriber*).—The certificates of the Royal Horticultural Society are only granted by the Fruit and Floral Committees of the Society for fruits, plants, and flowers placed before them at the Society's meetings and shows.

**Roses in Pots** (*New Subscriber*).—You cannot do better than repot your Roses at once, the H.P.'s in a compost of good fibry loam, one-seventh of manure, and sand. If the loam is light add one-seventh of clay which has been dried and reduced to a powder; if heavy, add

more sand, charcoal, or any gritty material. A 6-inch potful of bone-meal and the same quantity of soot may be added to a barrowful of soil. For the Teas add one-third leaf mould. Turn the plants out of their pots and carefully reduce the old balls by one-third, destroy no more fibres than possible. Place these plants in the same size pots, but carefully drain them. The soil should be pressed firmly round the old ball. After potting plunge the pots in ashes and syringe two or three times a day during dry weather to keep the foliage fresh, which will induce the plants to root freely before autumn, and thus be in the best possible condition for flowering another season. When to prune and how to prune depends upon the time you require them to flower. If you grow them in the greenhouse or bring them forward in that structure prune the H.P.'s early in January, thinning out the weak wood and cutting the stronger shoots back to one or two eyes. The Teas may be pruned at the same time, and the method of pruning depends almost entirely whether you are satisfied with buds only or require large flowers. If the latter prune well in, that is cut hard back; if the former, only remove unripe ends and shorten back weak shoots. If the varieties are of the Gloire de Dijon type only remove the unripe ends and tie the shoots in January round stakes. After flowering the growths need to be pruned back—that is to have all the old flowering wood cut away. We are glad to help you, and if there is anything you do not understand write to us again.

**Amaryllis Belladonna, Nerine sarniensis, and Fothergilli** (*J. N.*).—*Amaryllis Belladonna* succeeds fairly well in pots, and making its growth in winter requires to be kept near the glass in a temperature of 45° to 50°, also to be judiciously watered during that time, by not giving any until the soil is becoming dry, and then a thorough supply. When the leaves fall water should be gradually withheld, and the soil kept somewhat dry. We have flowered it very successfully in a greenhouse from which frost was merely excluded, but it is the better with a little heat when making its growth, and must have a light position. The plants do not require frequent repotting, but surface dressings and watering with liquid manure are beneficial while growing. *Nerine sarniensis* does not succeed very well in pots, as the bulbs usually become dry before they are potted, being weakened in consequence, and require a time to recuperate before they become sufficiently strong for flowering again, but they are not free flowering under artificial treatment. *N. curvifolia* (*Fothergilli*) is a better and more vigorous grower, and is variable in its time of flowering, but it is usually in late summer. It is a very beautiful species. When making their growth the plants should be kept well watered and in full light. They are best in a frame on a bed of leaves and manure, which afford gentle bottom heat. Failing this they may be kept on shelves in the greenhouse in all the light practicable, and when the leaves die the plants may be stored in a cool place, keeping the soil quite dry, until signs of growth are again apparent, but the bulbs should not be removed from the soil. They must be well cared for at other times, giving them a surface dressing of new soil in the autumn at the time of starting into fresh growth. They do not require potting oftener than absolutely necessary through the increase of bulbs.

**Rockery Plants** (*E. S.*).—You do not say how many you require. We have the following, among others, thriving well on a sunny rockery:—*Achillea Clavennæ*, silvery foliage and yellow flowers; *Alchemilla pentaphylla*, greenish yellow; *Alyssum saxatile compactum*, yellow; *Antennaria*, silvery foliage; *Aquilegia alpina*, purplish blue, with white centres; *Arabis alpina*, *A. alba*, *A. lucida variegata*, *A. caucasica variegata*, all with white flowers; *Aubrietia deltoidea grandiflora*, lavender blue; *Campanula garganica*, purple; *Cerastium tomentosum*, white; *Cheiranthus alpinus*, yellow; *C. Marshalli*, orange; *Cistus formosus*, yellow; *C. Ledon*, yellow; *C. roseus*, rose; *Convolvulus mauritanicus*, blue; *Cyclamen coum*, red; *C. repandum*, rose colour; *C. europæum*, rosy pink; *C. neapolitanum*, red; *Daphne cneorum*, pink; *Dianthus floribundus*, pink; *Draba aizoides*, *D. boeotica*, both yellow; *Dryas Drummondii*, yellow; *Erinus alpinus*, rosy purple; *Genista procumbens*, *G. triquetra*, both yellow; *Glechoma hederacea foliis variegatis*, reddish pink; *Gnaphalium hyperboreum*, white foliage; *Iberis saxatilis*, *I. sempervirens*, *I. Tenoriana*, all white; *Linaria alpina*, bluish violet; *L. cymbalaria variegata*; *Lotus corniculatus flore pleno*, yellow; *Meconopsis cambrica*, yellow; *Mimulus cupreus*, orange; *Orobis vernus*, purple; *Oxalis tropaeoloides*, yellow; *Phlox Nelsoni*, white; *P. verna*, rose; *Polygala depressa*, blue; *P. vulgaris*, bluish purple; *Rhododendron hirsutum*, pink; *Rubus chamaemorus*, white, ornamental edible fruit; *Saxifraga affinis*, brownish crimson; *S. aizoides*, yellow spotted orange; *S. biflora*, rosy purple; *S. caryophylla*, white; *S. cotyledon*, white; *S. Cymbalaria*, sulphur, spotted orange; *S. hirculus*, yellow; *S. juperiana*, yellow; *S. oppositifolia*, rose; *S. umbrosa crenata*, white; *Sedum acre*, anglicum, cruentum, *Elversii*, and *virescens*, all yellowish; *S. purpureum*, purplish rose; *S. pallidum roseum*, light pink; *S. albicans*, white; *Trifolium alpinum*, rose; *Vinca herbacea*, *V. major*, *V. major elegantissima*, *V. minor*, *V. minor plena*, all blue. Of all of the above you may procure plants, but some of them may be raised from seed. It is best, however, to obtain plants. They all will succeed well in a rather shady situation, but not under trees.

**Barbe de Cupucin** (*S. O.*).—This, the blanched leaves of Chicory, may be produced in many different ways, all that is requisite being to keep the roots in a dark place with a temperature of from 50° to 60°. Seed may be sown from April to July, and the culture may be the same as for Endive. The French, according to Thompson's "Gardener's Assistant," adopt the following modes of treatment.—"The seed is sown thinly in April or May. In November or December, one or several beds of light sandy soil, or well-decomposed dung, about 2 feet

AT the time this issue of the *Journal of Horticulture* reaches the majority of its readers probably the greatest autumn exhibition of fruit, plants, flowers, and vegetables that has ever been seen will be displayed in the Waverley Market, Edinburgh; and as the Show continues over Friday this reminder may still be in time for inducing some of our constituents to pay a visit to the "modern Athens" and be satisfied. Edinburgh is, in truth, a beautiful city, indeed in many respects unique; and apart from its public and scientific gardens is surrounded by fine seats of the Scottish nobility, the names of which are familiar as household words, and the fame of the gardens and gardening proverbial. Any horticultural pilgrims with a little time to spare, and who may desire to see the work of some of the best gardeners in the world, will only have to give expression to their wishes and they will find good guidance and as warm a welcome as they can wish from our friends in the north.

The provision made for this great Show by the Royal Caledonian Horticultural Society is of the most generous description, as is proved by the schedule. This contains no less than 282 classes, and more than thrice that number of prizes, apart from silver medals offered by the Turner Memorial Trustees and by the Society, and three Veitch Memorial medals. The Turner cup is for the best collection of fruit in the Show, the Society's cup being provided for the competitor who wins the greatest amount in stipulated classes. One of the Veitch medals is offered for the most meritorious dish of fruit in the Show, one for the most meritorious Orchid, a stove or greenhouse plant, and one for the most meritorious and interesting hybrid, plant, or fruit in the Show. A correspondent draws attention to the conditions of the competition, and says they will of necessity exclude all new and useful fruits, inasmuch as the word "hybrid" is to mean a cross between two distinct, or reputedly distinct, species, and not between two varieties of one species. It is within the bounds of possibility that some curiosity in fruit may be produced; but new and meritorious Apples, Pears, Plums, Peaches, Nectarines, Grapes, and indeed all fruits usually grown for consumption, are placed beyond the pale of competition. We mention this view of the case, as it is presented by a gentleman who is interested in the improvement of fruit and its culture, but is neither a grower nor exhibitor of either fruit or plants.

To revert to the schedule the Edinburgh prizes are not only numerous but valuable. When these lines appear nearly 900 awards will have been made. The greatest amounts appear to be £20, £15, and £10 in the specimen plant class. In two other plant classes 10 guineas are offered as first prizes, smaller yet substantial amounts following in each case, nearly 150 other prizes being provided in the classes. In the fruit classes £15, £10, and £5 are offered for twelve dishes; in another class, £10 10s., £5, and £3; and in three others, for orchard house and hardy fruit respectively, similar amounts. The greatest prize for Grapes is offered by Messrs. W. Thomson & Sons, £15 for eight bunches in four varieties, the second and third prizes being £8 and £4 respectively. Messrs. Mackenzie and Moncur offer a prize of 10 guineas for six bunches, £5 and £3 following. Besides these upwards of 120 prizes are provided in the Grape classes alone, and a considerably greater number in the classes for hardy fruit.

As might be expected, and as our telegraphic report shows, the display is extraordinary. Our critical correspondent, before alluded to, says he never before observed such generous latitude given to exhibitors of fruit, as Rule 2 says all competitors "except fruit growers" are held to declare that the subjects exhibited have been grown by them, the converse, he remarks, being that fruit can be bought or borrowed for winning the prizes. There must have been some mistake, but however that may be, we have seen sufficient of fruit growing under glass to satisfy us that British cultivators north and south can well afford to rely on their own skill, and we have not a doubt that the prizes won by gardeners will be for produce absolutely of their own growing.\*

Vegetables have the prominence to which they are entitled by their usefulness, amounts of £10 10s., £5, £3, and £2 being offered by Messrs. Methven & Sons for a collection of twelve varieties. For another twelve, from which Tomatoes, Mushrooms, and Cucumbers are excluded, £5 is given by Messrs. W. Dawson & Sons as a first prize; upwards of seventy other prizes being provided in the classes, including 10 guineas, 5 guineas, and 3 guineas for eighteen varieties of Potatoes by Messrs. James Dickson & Sons.

Cut flowers invariably constitute an important feature at the autumn shows in the north, and liberal provision was made for all the principal sections. About 100 prizes were offered, ranging from £4 downwards, for Roses, Gladioli, Chrysanthemums, Pansies, Asters, Dahlias, Hollyhocks, Carnations, and other popular autumn flowers.

Beyond all these special prizes were offered in seventeen classes, and there is also a department of ten classes devoted to bees and honey. Such in brief is an outline of the arrangements made by the Council and Committee to ensure an exhibition creditable to the horticultural fame of our northern friends, and it only remains for us to endeavour to convey an idea of the extraordinary success which has attended such well-directed efforts. A telegram comes to hand which enables us to do this of the Show, which opened yesterday (Wednesday) morning.

#### TELEGRAPHIC REPORT.

Great expectations had been formed concerning the Edinburgh International Show the present year; they are more than realised in the magnificent Exhibition provided in the Waverley Market. Extensive as that spacious building is, its resources are taxed to the uttermost; in fact it would have been impossible to find room for more exhibits of any kind. The market is 380 feet long by 160 feet broad. The majority of the smaller plants, the cut flowers, and the whole of the fruits are arranged upon eight rows of low tables, extending nearly the whole length of the building, while the central portion is devoted to the large specimen plants, and the handsome tables of plants arranged for effect, which constitute one of the principal features in that section of the Exhibition. A raised portion in the centre of the fruit tables is occupied with small ornamental plants, and the tables themselves are neatly draped with red and pink baize. Tall Palms and Tree Ferns are employed with excellent taste in various parts, of the market, and broad convenient gangways are left for the numerous visitors, who are now crowding into this remarkable Show.

As regards fruit, flowers, and vegetables, it is one of the grandest displays of British garden produce and British gardening skill that has ever been held. Plants are not so abundant as is usual at southern shows held during the earlier summer months. But those which are exhibited possess much merit, and some of the specimens have rarely been equalled, notably a superb example of *Ixora Duffi*. Altogether over 4000 entries have been received, or 1500 in advance of any previous Edinburgh Show, and these include exhibitors from many districts in British Isles. Very few have failed to appear in the lists, but some entries were received too late for admission, though a few important non-competing exhibitors arrived on the morning of the Show. In all respects the Exhibition is thoroughly representative, for both northern and

\* We have since found that instead of "Fruit Growers" the word "Fruiters" was intended, and inserted in a re-issue of schedules, and they are justified in exhibiting the best fruit they can purchase, as they compete only with each other.

southern cultivators compete keenly for the prizes, and well have they all maintained the credit of this district. Defeat in any of these classes is certainly not disgrace, as very rarely are exhibitions distinguished by such even and close quality.

Chief interest centred in the classes for collections of fruit, and the awards were awaited on Wednesday morning with much eagerness. In class 1, twelve dishes, including two Pines, two dishes of Grapes, two Melons, and six other kinds of fruit, there are four competitors, the leading honours being secured by Mr. McIndoe, Hutton Hall Gardens, Guisborough, who has an excellent collection, in which the Grapes were very conspicuous. Mr. David Murray, Culzean Castle, Maybole, follows closely, and Mr. J. Hunter, Lambton Castle, Durham, is third, all three being very close in merit. In class 2, twelve dishes, Pines and Bananas excluded, Mr. Hunter wins the first prize, the Grapes also being the most conspicuous part of this exhibit. The second prize goes to Mr. McKelvie, gardener to the Duchess of Roxburgh, and the third to Mr. Fairgrieve, Dunkeld. There are four competitors in this class also. In class 3, twelve dishes, Grapes and Pines excluded, Mr. Hunter is again first with most creditable Peaches, Plums, Apples, and Pears; Mr. McIndoe is a very close second; and Mr. Melville, gardener to the Hon. G. G. Dalrymple, St. Boswells, is third. In class 4, twelve dishes of orchard house fruit, Mr. McIndoe wins the chief award, and is followed by Mr. Hunter and Mr. Melville in the order named. In class 5, eighteen dishes of hardy fruit grown outdoors in Scotland, after a brisk competition Mr. Fairgrieve gains the first honours with admirable examples. Mr. J. Day, Galloway House Gardens, is second; and Mr. G. Goodfellow, gardener to E. C. S. Gray, Esq., Perth, third, all staging well. Five collections. In class 6, eighteen dishes of hardy fruit grown outdoors in England, Mr. Crasp, gardener to Lord Wimborne, Canford Manor, is far ahead of the two other competitors with fresh well grown fruits, in which the Pears, Apples, Plums, Peaches, and Figs are very notable for their fine quality. Mr. Nicholson, gardener to Wm. Miller, Esq., Sewardstone Lodge, Essex, is second; and Mr. Wright, gardener to C. L. Campbell, Esq., Hereford, is third.

The display of Grapes is astonishing both in number and quality, the entries varying from four to fifteen in each class, and including these in the collections nearly 600 bunches are exhibited, a large majority of which are admirable examples of the best varieties. It was generally known that Alderman Chaffin's Grapes had arrived from Bath, and the decisions of the Judges were looked for on the morning of the opening with the keenest interest. In class 7, eight bunches in four varieties, there are eight entries. All the sixty-four bunches thus provided are alone a beautiful exhibit of skill in Grape culture. After careful consideration the first honours were adjudged to Mr. Kirk, gardener to J. T. Paton, Esq., Norwood, Alloa; his bunches of Black Hamburg are grand, wonderfully well finished, and as nearly perfect as possible. Mr. Taylor, gardener to Alderman Chaffin, is second with superb bunches, but apparently they suffered in their journey north. Mr. Murray, Polmont, is a good third. Class 8, six bunches in three varieties, brought eleven competitors with a total of sixty-six bunches, and here again Mr. Kirk is the most successful, leading with Black Hamburgs, even and handsome, followed by Mr. J. W. McHattie, Newbattle, and Mr. G. Mackinnon, Lasswade. In the other Grape classes the exhibits are highly meritorious, and the principal prizes go to Messrs. McHattie, Day, Potter, W. Murray, Morrison, Taylor, and Witherspoon.

Peaches, Nectarines, Plums, and Apricots are extensively shown, Messrs. Lunt of Keir and Blair of Trentham winning the chief prizes. Hardy fruits are very largely shown, especially Apples, which occupy three long tables. Pears, also, are numerous, and one of the most successful exhibitors is Mr. Crasp, who secures prizes in many of the classes for single dishes.

Vegetables afford a wonderful display, as may be judged from the fact that there are seventeen exhibits in the class for a collection of twelve varieties, and the premier prize is well won by Mr. Pope, gardener to the Earl of Carnarvon, Highclere Castle, Hants, a victory of which he may well be proud. Mr. Muir, Margam Park, is second, losing by a few points only, and Mr. Wilkins, gardener to Lady Guest, Dorset, is third. In the class for twelve dishes, Tomatoes, Mushrooms, and Cucumbers excluded, the prizes go to Messrs. Cocker of Stranraer, Low of Stirling, and Potter of North Berwick. Potatoes are represented largely and well in the class for eighteen varieties, no less than thirty-six collections being staged, and the Judges had the most difficult task of anything in the whole Exhibition. Ultimately Mr. Sinclair of Harviston, Dollar, gained the first prize, followed by Mr. Robertson of Hartrigge House, and Mr. Gentleman, West Craigmorrie, Armadale. In all the other classes of this division the competition was keen, and the exhibits of fine quality.

Concerning the plant classes we can say but little this week, but in the class for twelve stove and greenhouse plants Mr. Finch, gardener to J. Marriott, Esq., Coventry, wins first prize of £20, with grand specimens of flowering and foliage plants. In the class for a table of plants 20 feet by 5 feet Mr. J. McIntyre, gardener to Mrs. Pease, Darlington, is the most successful with a beautiful exhibit, and in the nurserymen's class, for a table 30 by 18 feet, Messrs. Ireland & Thomson, Edinburgh, win the first prize with a most tasteful group of plants. Cut flowers, including Roses, Hollyhocks, Carnations, Chrysanthemums, and many others, are a bright feature, and the non-competing exhibits are of considerable importance, but reference to them in detail and other exhibits of interest must be reserved till our next issue. It may, however, be said, in conclusion, that amongst exhibitors from the south Messrs. B. S. Williams & Son, Messrs. J. Laing & Sons, Messrs. Cannell and Sons, Messrs. Cutbush & Co., and the Royal Horticultural Society, are the principal, while of the northern exhibitors Messrs. Thomson & Son, Clovenfords, Messrs. Dobbie & Co., Messrs. Stuart & Mein, Messrs. Dickson & Sons, Messrs. Cocker & Son, Messrs. Laing & Mather, and Messrs. Methven & Sons, are also notable contributors to this splendid exhibition.

In recognition of the services rendered, not in connection with the Royal Caledonian Horticultural Society alone, but to British horticulture, we insert portraits of a few Scottish gardeners, whose features have not hitherto been depicted in these columns, also of the late Secretary of the Society, Mr. C. Stewart, who contributed so greatly to its prosperity, and of Mr. W. Young, the untiring Assistant Secretary and valued official. We have other portraits in hand to appear with a fuller report of the Show, those being first inserted that were first received—namely, Mr. R. W. Fairgrieve, Dunkeld, Perthshire; Mr. W. McKelvie, Broxmouth Park, Dunbar; Mr. W. Murray, Parkhall, Polmont; Mr. James McIndoe, Hutton Hall, Guisborough; Mr. J. Hunter, Lambton Castle; Mr. A. Kirk, Norwood, Alloa; Mr. M. Dunn, Dalkeith Palace; and Mr. A. McLeod, Superintendent of the Parks of Edinburgh. The excellent work of all those able men has been recorded in this Journal, and probably will be again.

## NOTES ON BEDDING PLANTS AND BEDDING ARRANGEMENTS.

FLOWER gardens ought now to be in full beauty. Many gardeners are reluctant to take cuttings from the plants for propagation lest the beds should be marred in appearance. It is, however, of the greatest importance that cuttings of all kinds be inserted as soon as possible, so that they may become well rooted before the dark days of winter. The only exception to this rule is in the case of Calceolarias, and the beginning of October is soon enough to insert cuttings of these, as if the cuttings callus before very severe weather sets in they may be depended upon to grow freely in early spring and make better plants than those which by reason of early propagation make growth during the autumn months.

Before commencing the work of propagation a careful survey should be made of the flower beds, noting those which have been the most satisfactory, determining the arrangements for another season, and propagating in quantity accordingly. In some instances where beds in particular situations have been especially striking it may be good policy to repeat them another season, but as a rule the arrangements each year should be as original and varied as possible, at the same time, of course, trying to make each succeeding display more attractive than the last. Although we may not always succeed in doing this it is a laudable ambition to try. In this district the soil is rather light and dry, so that the present, or I might almost say the past, summer has been favourable in many respects for bedding plants. White Marguerites are much more effective bedders than I have known them to be in any other locality, the plants being extremely floriferous, the tendency with them in many places being to make a great amount of growth without giving a proportionate display of flowers. This shows the necessity of noting the adaptability of plants to district. Dianthus Heddegi edged with a broad band of Cineraria acanthifolia or Golden Feather makes a charming bed, many of the colours being extremely rich and the marking of the flowers exquisite. The flowers are invaluable for cutting for vase decoration. The plants should be grown rather thickly, so that they soon form a mass so close that the flower stems support each other. The only attention required is to tie down to sticks a few of the longest flowering

shoots which spoil the evenness of the bed. I strongly recommend those who have not hitherto grown this fine type of *Dianthus* to give it a trial.

*Tropæolums* have been somewhat disappointing this year, owing no doubt to the want of sunshine and the continual showery weather. The plants have grown so strongly and continually as to completely hide the majority of the flowers, although many of the leaves were frequently removed. Two Maltese cross shaped beds were planted with a broad band of Golden Feather round a circle of *Pelargonium* Mrs. Perry with the flowers picked off. The remainder of the bed was filled in with *Amaranthus melancholicus ruber*. These have been quite a success, and at the present time look particularly attractive. The Ivy-leaved *Pelargoniums* Madame Crousse and Souvenir de Charles Turner are also splendid for bedding, and have quite superseded the old type of Ivy-leaved varieties. A large bed planted with the first-named, edged with a band of *Pyrethrum*, has found a host of admirers; the pleasing shade of salmon the flowers have seems to suit almost everybody, and as a combination of good colour the two varieties mixed in a bed are simply perfection.

Among Zonal *Pelargoniums* *Vesuvius* still holds its own as a dwarf scarlet, but where a very dwarf habit is not of much consequence John Gibbons is the finest of all scarlet bedders. The

FIG. 32.—MR. R. W. FAIRGRIEVE, DUNKELD.

flowers and trusses are very large, bright in colour, and freely produced. F. M. Atkinson nearly approaches it in merit, but where a sufficient stock can be obtained I would depend chiefly on John Gibbons. Mrs. Pollock, Black Douglas, and Marshal McMahon are a trio of showy and distinct golden tricolor and bronze varieties, while among the silver-leaved kinds Mrs. Perry and Bijou are the best I have seen. A very pretty silver tricolor which I have not seen for some years used to be grown under the name of *Italia Unita*. I wonder if any of the Journal readers grow it still.

*Clematis Jackmanni*, trained over sticks bent in the form of an arch, is simply grand when in flower, especially if the bed is edged with a band of *Dactylis glomerata variegata*. The praises of these two plants when associated in a bed have been sung over and over again, but they are still worth repeating.

Pansies have done remarkably well as summer bedders this season. They require a deep rich soil. When seen in good condition they are always admired, especially where the beds are filled with mixed varieties. Seed obtained from a reliable source produce many fine flowers, and the variety is so great that they are a constant source of delight.

PROPAGATING.—*Pelargoniums* should be taken in hand first. After trying various methods I have come to the conclusion that by far the best course to pursue is to strike the cuttings in boxes and pot them off in the spring. In this way a large number can be wintered in a limited space. The cuttings root quickly and make fine plants. Shallow boxes of any reasonable size answer the purpose well, but those which I prefer are 1 foot in width, 3 in length, and 3 inches in depth, half a dozen holes half an inch in diameter being made in them for drainage. This is afforded by a layer of partially decayed leaves, and the boxes are filled to within a quarter of an inch of the rim with sandy soil made moderately firm. If the cuttings are about 2 inches apart the best use will be made of the space without having them so crowded as to cause damping, for the boxes are best placed on boards in an open position. If the weather is bright and apparently settled, apply

water through a rose when the cuttings are inserted, but do not repeat the operation until the soil is quite dry. If showery withhold water.

*Verbenas*, *Ageratums*, *Alternantheras*, *Mesembryanthemums*, and *Petunias* I like to have either in pans or 7-inch pots, as they are handy for wintering on shelves. If pots are used they should be filled one-half of their depth with drainage, and the cuttings kept quite close in a frame till rooted, shading them from sunshine, and damping with a syringe in the middle of bright days. *Coleuses* and *Iresines* succeed well with the same treatment. *Marguerites* are conveniently wintered in boxes to supply a good stock of cuttings in the spring. Spring-struck cuttings grow into plants quite large enough for bedding by the time they are wanted.—H. DUNKIN, *Warwick Castle*.

## KEEPING PEARS AND APPLES.

HAVING been very successful last year in keeping the above named fruit many months longer than usual, I wish to record my mode of treatment. Some might like to prevent their fruit ripening all at once, and to extend the process over a long time. For instance, I had a fine sample of Blenheim Pippin Apples until the middle of June last year. The plan is very simple. I provide a package of German moss, or peat, and break it up rather fine, also hampers, boxes, large garden pots, and anything which will hold the fruit. I then hand-pick the finest fruit on a tree (Apples or Pears) before they become quite ripe and fit for table, leaving the smaller fruit some time longer on the tree that it may gain its full size. I then take a hamper and lay the moss over the bottom about 1 inch thick, then a layer of the fruits evenly, just touching each other, then moss on them an inch thick, thus alternately until it is filled. I fill all the pots and pans and boxes in this way, and put them in a dry cellar where the frost cannot reach them, occasionally examining the different sorts, as of course some ripen earlier than the others. It is of no use to pack away any that have ripened on the trees; they must be of full size, but not quite ripe, and they must be free from bruises and other faults, or they will not keep. Those which the winds cause to fall, if they fell on grass lawns or soft mould, will do very well in this way, but if placed on wooden floors they would shrivel and never ripen. Many small Pears have lately fallen in my garden, and I have stowed them away as I did last year so successfully, and they will keep till after Christmas.

The fruit is green as a rule when packed away in the dry moss, but as it ripens it gains its perfect colour and flavour, in no case shrivels, but remains firm and sound if not left too long. It seems to me to be most desirable to retard the ripening of fruit in this or any other simple way, for a long time to suit consumers or dealers in fruit, rather than have the whole crop on a tree ripen all at once. If you think well to insert these notes it may be specially useful to growers of fruit at this season of the year.—WM. MOODY BELL, 8, *Colonnade, Cheltenham*.

[They are most readily inserted, as they describe clearly a simple method of keeping fruit that has proved successful.]

## AURICULA GROWING MADE EASY.

I SHOULD like to describe my manner of treating these beautiful plants, not only in summer but during spring, summer, autumn, and winter. I consider it so simple that any person may grow them well without a glass house or even a garden frame if he has only a garden border or a yard where a border might be made, open to the sun and fresh air. A few handlights are required to protect them from too much sun heat, by shading, also from the intense cold and cold winds in wintry weather, and from the autumn and spring rains.

Some twelve months ago I described my treatment to Mr. Turner of the Royal Nurseries, Slough, and in reply he said, "He should think I would be very successful." Most persons know him to be a great grower of all the best Auriculas. I have plants of all sizes—named, stage, and commoner ones, all perfectly healthy. The largest one I have, as the leaves lie on the ground border, a self, measuring from tip to tip, is no less than 16 inches, which anyone may see by calling at my garden, Belleville, St. Marks, Cheltenham.

When I bought my edged plants in pots I immediately removed the pots and planted the Auriculas near the edge of my Vine border, which is about 2 feet above the path, so that the drainage is good. I take them up in the beginning of August and add fresh loam, leaf mould, and cow manure (two years old), then replant in groups of four or five according to the size, and cover them with handlights placed on three pots about 4 inches high. To give shade for about

a fortnight while the plants take root again the inside of the hand-lights is covered with whiting and milk.

After this I wash off the whiting and still keep the handlights over them to shelter them from the autumn rains, still raised night and day on the three pots. When the frosts come on and there is less sun by day I use lower pots, say 2 inches high. During the severities of winter at times, night especially, I put the handlights right down on the ground, or one side raised on a small pot.

As the spring advances they again have more air. At that season the ground is watered when necessary round the handlights, and never on the plants, as that would spoil the meal on the leaves and the advancing blooms also. For any approaching horticultural show they may safely be placed in pots for exhibition. I am careful to remove all decaying leaves at all times.

When I replanted them in August all but one was perfectly free from any sign of decay at the roots, to which they are so subject when in pots. The part of a long main stem was touched with decay, the one I speak of because all the fibrous roots were above it. This bare part should have been cut off a year ago. It was done now to the safety of the plant.

I have given this statement of my mode of growing Auriculas as I consider it to be easier, safer, and more natural than to have them in pots; and some persons may like to try the same way. All my plants survived the last very trying winter. By inserting the above in your valuable periodical you will oblige. I should have been very glad to have written occasionally to those growers, of Auriculas who have written in your periodical if they had given their addresses as well as their names. I refer to Mr. J. Douglas, Rev. F. D. Horner, Mr. Henwood, Mr. Dean, and many others. Would you ask them to oblige by so doing in the future?—WILLIAM MOODY BELL, 8, *The Colonnade, Cheltenham*.

[We are obliged by this communication, but cannot ask any of our friends to depart from their usual practice. Some writers on florists' flowers and other subjects are obliged to withhold their addresses to avoid correspondence taxing them too severely.]

#### A VISIT TO COLCHESTER.

THE attractions of a Rose show are generally two in number. First, the Roses; second, the band (occasionally, perhaps, this order may be reversed!). A good band will generally draw an attendance, and really first-class Roses are to be seen every day in few places; but the town of Colchester is unable to support a Rose show, because its fortunate inhabitants are quite *blasé* to both these attractions. I do not know whether the old Roman soldiers when they camped here had much martial music, or whether the British young men and maidens turned out much to hear them; but at all events the effect of a good band can have been no novelty to the good people of Colchester for many years. And as to Roses, they are fast becoming a speciality of the place. With three large nurseries almost entirely devoted to Roses nearly touching one another, and yet, I hope, in no way impeding each other's trade, you might as well expect the people of the place to come to exhibitions of cotton at Manchester or coals at Newcastle as Roses at Colchester. It is otherwise, of course, with those who live elsewhere. It is far better than any exhibition to see the plants themselves growing in such profusion, and if you have been charmed with a single bloom of any particular variety as shown in a stand, how much is your knowledge of it increased by the sight of a hundred plants or more of the same growing altogether, and with flowers in every stage of development.

In company with a distinguished brother rosarian, I paid my annual visit to the City of Roses this year about the middle of August, too late to see any of the Roses at their best. A good time to go, in an ordinary season, is about the third week in June, when the lovely Teas are fast approaching their prime (the first blooms being generally the best), and the busy show season, when one cannot expect any attention, has not commenced. At the close of a week of fine weather there would always be plenty to admire in any of the summer months, and we had been waiting for such a time, but as it did not come we had to go without it, though well aware we could not see many good flowers after such a sunless, rainy time. On arrival at the station we found

MR. PRIOR,

who has been most indefatigable in competing at exhibitions during the last two seasons, superintending the arrangements at his stall on the railway platform. It looked exceedingly bright and fresh, with much better blooms than are usually seen in such places, and there are certainly few stations which provide such a pleasant and attractive sight gratis to passing or waiting travellers.

MR. FRANK CANT

was kindly waiting for us outside the station and drove us direct to his grounds, which are at no great distance. He needs no introduction from

me, as the success of his exhibits during the last three or four years especially have helped to spread and increase the reputation of the name which his uncle first made so famous. We know that the lateness of the blooms this season rendered him unable to show in the champion class at the Crystal Palace, but he made considerable amends for it afterwards; from about July 7th he maintained, I believe, a nearly if not quite an unbeaten certificate, and if Yorkshire has in the past triumphed at the Crystal Palace, the return match was played off this year when the Northern (Jubilee) Trophy was carried away to Colchester.

It is two years, I believe, since Mr. Frank Cant opened his new grounds at Braiswick. The soil seemed to me a trifle lighter than that at Myland, but they are not far apart, on the same slope of hill, and I daresay there is but little real difference. The largest field of Roses which runs right down to a cutting in the main line of the G.E.R. seemed to be particularly well situated in its slope to the sun, with a fair amount of shelter and protection from cold winds on all sides, and one amateur at least (who has attempted staging in wet weather, under trees, in a greenhouse, a coach-house, a bell tent, a storeroom, and a dining room) felt just a little covetous on inspection of the large and commodious staging shed at the bottom of the field.

Many of the H.P.'s showed rust, which is certainly very detrimental to their general appearance, though I believe it does no harm, but if anything helps the ripening of the wood; still, when plants have lost a good many of their leaves they look un-summerlike and depressing to any but experienced eyes. There was not much mildew, and it goes without saying that the plants looked well cared for.

Budding was in full swing, and my friend and I, being both hard-working amateur "Buddists," were much interested in seeing how this operation is carried out on a large scale. What astonished me most—but then, I have a long way to stoop, and am no longer young—was to see a man budding *Manettis* from a standing position. There were four different operations, performed by different individuals. First one man to bend and hook the branches of the stocks back so that the stems could be easily got at; then another to clear away the earth an inch or two deep from the stems all down the row (it comforted me a little to see this man at least with one knee on the ground); then the actual operator—he stood behind the row of plants with his budding knife in one hand, and his prepared bundle of shoots containing buds in the other, and bent over his work (it gave me the backache to see him).

His first stroke astonished my friend, for it was an upward slice at the stem of the stock, taking away an inch or two in length of the outer but not going through the inner bark; the cross and longitudinal cuts followed as quick as possible. Without waiting to reverse the knife the bark was opened on each side in no time by the blade, the bud was taken from the prepared stem from the lower end with a long sliver at the other end, the wood came out in a moment from this long end, in went the bud, and the long part was cut off to fit the cross cut with great precision; and by the time I stooped down to see how well it was done he was half-way through the same operation on the next stock.

It was explained to us that the first upward cut of outside bark was in lieu of any wiping of the stem from adhering earth, which is generally practised. We know that a particle of soil or dirt getting inside the cut between the inserted bud and the stem would be highly detrimental, but it must require great accuracy to avoid injuring the stock by such rough and ready means, and amateurs in general would certainly prefer wiping the stem. A boy followed to do the tying in with raffia, which was well done, in double fashion, and tied tight with a double knot. Mr. F. Cant told me that he had given up the staving or pinching back of the starting buds in spring, which is often done to ensure there being more than a single shoot to the new plant, and so have I, both in H.P.'s and Teas.

There were really few good blooms to see, nor could we expect it, at such an unfortunate time. Of those unknown to me I noted Mrs. George Dickson and Souvenir de Rosieriste Gonod as possibly good, and Augustine Guinoiseau, the white La France, as decidedly worth growing; Sappho (T.) seemed better than I expected; L'Ideale (N.) was flowering most beautifully on quite dwarf maiden plants, at which I was surprised, but was told that this is its character as a maiden, and that the next year it sends up great long shoots. Another Noisette, Cloth of Gold, astonished me even more. There were whole rows of dwarf maidens in the open, and almost all of them in a flowering condition. I was informed that they always would bloom like this as maidens if budded from flowering shoots, but would, perhaps, never flower again.

Our time was expired before we had completed our survey, and our host kindly drove us off to the house of his uncle, Mr. B. R. Cant, of whom and his work more anon.—W. R. RAILLEM.

#### GOOD TOMATOES.

I THINK of all the Tomatoes I have seen this season, nothing has been better both as regards size, appearance, and eating quality than Perfection early in the season, and Trophy for a later crop. Of the latter it may be said that it requires a somewhat special treatment, inasmuch as quantities of fruit that I have had the opportunity of seeing have been much ribbed, of bad colour, and unequal in size. I have plants raised from seed from the same packet which are in some respects quite different in appearance. Those of the worst quality are growing in an extended border of good soil, and comparatively few of these are really good. The others planted as a kind of catch crop on

the surface of a bed of ashes and gravel, on which pot plants stand during winter and spring, have been so fine that it is difficult for visitors who know something about Tomatoes to determine the variety; the flavour, moreover, is quite as good as is Perfection. The plants have been fed with regularity. I noticed something of the same type in a large Kentish establishment, where the fruits grown in strong soil with plenty of manure were coarse, while on plant stages they were of much better quality. I have thought this note might be of service to those who have not much room to grow Tomatoes, and who may put themselves to much trouble to introduce good soil in order to have them finer. But with a really good variety it is astonishing what grand results may be secured in the manner described.—B.

## THE BRITISH FRUIT GROWERS' ASSOCIATION.

THE third conference of the present season was held in the Garden Hall, Crystal Palace, Sydenham, on Friday, Sept. 4th, in conjunction with the fruit show, and attracted a large audience of cultivators and amateurs. The proceedings commenced shortly

FIG. 33.—MR. WM. MCKELVIE, BROXMOUTH.

after 4 P.M. with a short address by the Chairman, Mr. T. F. Rivers, who referred specially to the steady advance in fruit culture for profit, and to the assistance the British Fruit Growers' Association had rendered in that direction.

The first paper was the following, by Mr. G. Hammond, which was fully appreciated by the audience, as Mr. Hammond's addresses invariably are, and Mr. J. Wright discoursed on pruning.

### GATHERING, PACKING, AND MARKETING FRUIT.

WE are all familiar with the usual instruction in cookery books on how to cook a hare—viz., "First catch your hare," which, if not the most important point, is certainly one indispensable; but having accomplished this, it is desirable to know how to cook it properly and well.

So, perhaps, some will say concerning the subject of this paper, "We want you to tell us how to grow a crop of fruit; anybody can gather it when it is grown." Stay, ye critics, I am not so sure of that. Nay, I go further, and say I am quite sure that comparatively few people know how to gather and pack fruit properly. In a few words, therefore, I will endeavour to tell first how it should not be done, and then also how it should be done.

Perhaps the way which gives least trouble (and this is the way lazy folks look out for) is to let the fruit hang until ripe (and then to climb the tree, if a large one) and give the branches a good shaking, when nothing will be needed but to pick up the fruit from the ground. Some may feel inclined to laugh at the mention of such a method, but I knew of a case in which this method was adopted with small dessert Pears, ripe and juicy, and from a high tree, with what results I leave you to guess. This is one way of how not to do it. Another way in which it should not be done is suggested by a common expression of "pulling" the fruit, which always seems to me to suggest much too rough usage both for the fruit to be gathered and for the tree from which it is to be taken. Anyone who has had any experience in this matter knows that if you take hold of any kind of fruit, and pull it off anyhow, that you break some part of the tree with almost every fruit. On examination of a fruit tree it will be observed that clustered round the present fruitstalks are numerous fruit buds, which are next season's fruit in embryo. Now if by carelessness or ignorance these be destroyed it is evident that not only has the present crop of

fruit been pulled, but with it also a large part of next year's crop as well.

Then, again, when the fruit has been gathered from the tree it is often allowed to fall from the hand into the basket, thereby causing it to be bruised and unsightly, and of course, to some extent, unsaleable, or at least it looks like what a friend of mine calls "tumble-down Pippins." This should not, and need not, be. As a general principle I may say, Always turn the fruit upwards, putting the thumb against the base of the stalk, when (if the fruit be ready) it will part readily from the tree without breaking a single spur or fruit bud. This applies especially to Apples and Pears; with Plums it will be generally found that the fruit parts more easily from the stalk than the stalk from the tree, and it is as well in ordinary picking that it should be so, as less damage is done to the tree thereby. Care should be taken in picking Plums not to destroy the beautiful bloom which most kinds have upon them; they should never be touched by hand except to pick them from the tree.

For large trees I think nothing has yet surpassed the ordinary fruit gathering ladder—i.e., wide at the bottom, and the usual kind of basket, somewhat smaller at the bottom than the top, with a cross handle and hook attached. For low trees a pair of steps will be found of very great service. In all cases the ladder should be set as nearly upright as possible, so as to press lightly against the tree, and keep the basket close to the picker, so that the hand may easily reach the bottom of the basket. The fruit should never be dropped into nor rolled about in the basket, or it will speedily show signs of rough usage. When it is intended to send the fruit direct to market, place it at once into the market sieves from the picker's basket.

Notwithstanding many suggested improvements during the last few years I think there is nothing so suitable for general use as the ordinary market baskets known as bushels, half-sieves, flats, half-flats, and pecks. These all allow the escape of heat, which is one of the greatest enemies of fruit after it has been gathered. Place the fruit into these carefully, and in doing so it should be properly sorted into large and small, or best and seconds, and of one quality throughout, not small at the bottom and large at the top, which in the end means loss. All packages should have a sheet of paper (blue tissue is generally used) over the top, and may be covered with fern or straw in any way most convenient, and is then ready to be despatched to the market or elsewhere. In the matter of packing fruit we have much to learn from our neighbours across the channel, who do more in grading the fruit and putting it into small baskets or boxes than we do. As a rule, it may be said that the smaller the packages into which the best fruits are placed the better, especially in a scarce season.

As to the time of picking, everything depends upon what is intended to be done with the fruit when gathered. If it is to be sent direct to market, in the case of Apples they may be gathered as soon as they have attained a saleable size and will part fairly easily from the tree, but if they are to be stored for winter use they must be allowed to hang until fully developed, and if possible until they are well ripened and the pips turned brown. Fruit to be stored should only be picked when quite dry, and must also be handled with great care; but if for immediate use it is not necessary to be quite so particular. Plums for ordinary kitchen may be gathered when only slightly coloured and still hard, but if of the best dessert kinds they must be allowed to ripen first. Most Pears require to be kept for a time after being gathered to become ripe and fit for use. Care must be taken not to gather too early, which causes them to shrivel, nor to let them hang so long as to have most of the crop blown down by a moderate wind.

I need not say much upon the marketing of fruit, but a few hints may be useful. As most of the fruit grown is consigned to salesmen I would say, Try and discover someone who bears the character of honest dealing, and trust him. Do not dodge about from one to another, which often has led to getting "out of the frying pan into the fire." Let the fruit be honestly packed, giving good measure, and customers soon discover this, and inquire for the goods, with the result that full market price is obtained with little difficulty. I find it to be a good plan as a rule to have a continuous supply of the same kind of fruit. In sending, say, 100 bushels of Apples of one kind to market, I would not send them all at once; but commence, say, with 15 to 20 bushels, increasing the quantity as the customers seemed to appreciate them. On the other hand, do not send a small quantity of a large number of sorts, which is very bewildering to the salesmen, who finds such consignments a great nuisance.

Lastly, let all fruit be in marketable condition when sent, or it will probably be left for days or weeks before finding a purchaser, and then only at a low price, alike unsatisfactory to the salesman and the grower. I have this year seen Damsons upon the market while still quite green, and absolutely unsaleable. How can

salesmen be reasonably expected to give satisfaction under such circumstances? One great advantage of the fruit from abroad is this, "That when placed upon the market it is fit for immediate use," which seems to suit the circumstances of most buyers, who say, "We do not want fruit to keep, we want it to sell." We must, therefore, try and supply not only the article they want, but supply it also in the condition in which they require it.

[We have a digest of Mr. Wright's lecture on the "Principles of Pruning," but cannot find room for it this week.]

## MILES OF FRUIT PLANTATIONS AND MILLIONS OF FLOWERS.

JUDGING from the letters I have received the article which appeared under the above heading a fortnight ago seems to have excited rather widespread interest, and more information is wanted by persons in various parts of the country and beyond its shores. One correspondent asks if I can tell him how much capital would be required to start places like Mr. Wood's and Mr. Cannell's, as he would "like to go into that kind of thing." If he is content to start as they did I suspect their greatest capital was in their heads and their hands, but if he wishes to establish a twin business such as theirs, supposing they were linked together, obtain land and stock it as it is stocked now, I dare not venture on an estimate, but it would amount to a very large fortune. Those businesses, it seems necessary to say, are quite distinct, one consisting of between 1000 and 2000 acres of land, a large and constantly increased extent of it devoted to the production of fruit, mainly for preserving; the other, a great emporium of flowers, with an adjunct of 300 acres under what may be termed mixed culture, and to simply enumerate all the different varieties grown would make up a very large

FIG. 34.—MR. W. MURRAY, PARKHALL.

catalogue. Businesses such as those cannot be made in a year or two, no matter how great the investment, but are like fruit trees in full profit, must have time to grow. When I first saw Mr. Cannell's establishment it consisted of one greenhouse, a few frames, and perhaps half an acre of land, possibly less, on what appeared a railway embankment at Woolwich. Mr. Wood was the son of a farm foreman, worked hard, saved a little money, and like his neighbour commenced action in a small way, and both of them by diligence in business, good judgment, and hard work made themselves what they are to-day. It is not many who make great industries at a bound, but men with business capacity and endowed with indomitable perseverance, who have "learned to labour and to wait" for the reward of success usually achieve it. As has been previously stated very little time was spent among the flowers, only an hour or so, but certainly "millions" were really seen, both at the beginning and the end of the drive through the "miles" of fruit plantations in a beautiful and salubrious district.

### FLOWERS AT SWANLEY.

It is only a question of climbing over the fence from Mr. Wood's fruit factory to Mr. Cannell's flower beds. One of the first to pause at was planted with Marguerites, half a dozen varieties in rows, but one so far excelled the rest in its vigour and the size of its yellow flowers that its name was sought for. It is simply known as the Branching Etoile d'Or, which it distinctly supersedes in all points except colour. Etoile d'Or is miffy, liable to lose its foliage and become generally unsightly, but the giant form is robust, always flowering, and "never has anything the matter with it." The flowers are in great demand in Covent Garden for various decorative purposes, and are cut at Swanley every day. There is no better test of merit than the Covent Garden test, and this variety is destined to become the yellow Marguerite for the million.

Carnations were losing their freshness, still the large collection grown in pots made a charming display. There is quite a run on Carnations and Picotees, and well do the sweet and charming flowers deserve their growing popularity. The new yellow or primrose ground varieties, with pink and red stripes, Saccharissa and Duchess of Fife, are highly regarded, and greatly in demand is the distinct white fimbriated Lizzie McGowan. Near them, not in flower of course, yet equally noteworthy, was a fine block of plants of the plumed pink Chrysanthemum Louis Boehmer. This is a counterpart in the character of its blooms of Mrs. Alpheus Hardy, but in habit and character of growth is altogether superior. The plants are sturdy, and appeared to be forming buds as freely as any other variety, and at the right time. They are mostly in 7-inch pots, and gaps in the rows and packing going on was suggestive that many more "Boehmers" will be seen during the ensuing season than "Hardys" were last year. This dainty variety appears to need a sunnier clime than ours, but the new plumed pink seems quite at home. Begonias in thousands made great squares bright, but the prolonged wet and cold weather checked their growth in the strong land; in the lighter, richer soil of flower beds in gardens generally these plants have put Zonal Pelargoniums in the shade this year. The best of these at Swanley for bedding is the scarlet King of the Bedders, and Mr. Cannell says it will have to go everywhere before it stops. It is of the John Gibbons type, but excels that excellent variety for massing, which is a sufficient test of merit.

But to see both Zonal Pelargoniums and Begonias in all their brilliancy, and it may be added purity, they must be seen under glass. House after house is filled with them, forming dazzling banks of beauty along each side of the long central paths. No doubt the very light structures are admirably adapted for the plants, but all the same such an imposing display could not be produced except by the best varieties and the best culture. The Begonias are arranged in blocks of colour, the Pelargoniums in mixture.

"Then people are not tired of these Pelargoniums, Mr. Cannell?" was a sort of fishing observation. "Tired, bless you; no, I should think not. Just look at them. Tired, did you say, of such flowers as these, and even better in winter than now? See the size and the shape and the colour and the trusses. Who do you think can tire of them? Why they will have them. They come to pick out a dozen, and go on picking. They can't leave them, don't you see. Tire! I should think not, indeed. We are always getting new varieties better and better. I have sometimes thought they couldn't be better, but they keep coming—yes, and going." I felt it time to explain that I did not wonder at it, and say if I was a man of wealth I would have a houseful of them, and only thought that possibly Begonias had become the favourites. "Begonias, yes, they are grand. I don't know what we shall come to with them I am sure, but they are summer flowers, while the Zonals go on all the time, all the time." "Well," was the next question, "where do you send them?" "Send them," was the response, "why all over the world." "Sent any to Mashonaland yet?" was the next feeler. "Now, come, come; not quite so fast, my friend; that is a little too previous. But," after a moment's reflection, "they will have to go some day after Lord Randolph comes home. They would do well there." That shows the earnestness of the florist, his spirit of enterprise, his belief that no part of the world is furnished without flowers. He has faith in their humanising influence, and there is not much doubt that he regards those who grow them and love them so well as to keep buying the new sorts as ranking among the best people in the world, and perhaps he is not far wrong. If the best people want to know the names of the best Zonals up to date they will find them here recorded. Double varieties.—Turtle's Surprise, Goldfinder, Nydia, Beauté Poitevine, Gloire de France, Rosea Superba, Tendresse, Mrs. Gordon, White Abbey, Golden Rain, H. M. Stanley, Sombre Horizon, and Salamander. Single varieties.—Lord Salisbury, Hercules, Rose du Barry, Mrs. Robert Cannell, Maud of Wales, Lady Brooke, Lord Rosebery, Cannell's Favourite, John L. Baldwin, Miller's Favourite, Winkfield Gem, Dr. R. G. Tucker, Mrs. Keeler Improved, Madame Patti, Souvenir de Mirande, Granville, Swanley Single White, and Lily. Several of these are quite new, and all well worth growing. The colours will be found in the autumn catalogue, just published, as also will the names and colours of the new Begonias, and how fine these are many persons have seen at exhibitions.

Selected seedlings, doubles and singles, of the last named flowers, arranged as in beds of separate colours under glass, crimson, yellow, rose, white, and a pleasing glowing amber colour, had a remarkable effect as viewed from the end of the long structures, and they lost nothing in merit by a closer inspection. It seems difficult to imagine that a much greater advance can be made on the best Begonias of the day; but that was an opinion often heard expressed three or four years ago. There has been a great march onward since then. They are large enough now to please most people; but who can say that in future varieties will not be forthcoming as sweet as they are beautiful?

Time only permitted a survey of the contents of other houses by a view from the doors. In one long stretches of Balsams laden with massive blooms; in another thousands of Achimenes, charming summer flowers, so distinct from all outside; in a third long banks of graceful Fuchsias, double and single, dark and light; in a fourth a forest of Coleuses in all imaginable colours, from bright yellow to dark maroon; in a fifth grotesque Cactuses, and all sorts of plant curiosities; and so we might go on. But still just one more house demands mention—a long structure filled with Cannas. The latest varieties of these are as far in advance of the old familiar forms as are the Begonias on their progenitors five or six years ago. There was no getting past these handsome

Cannas without learning their names, and here they are:—Antonin Chantin, Edouard André, Felix Crousse, Louis Thibaud, Lutea Splendens, Madame Just, Petit Jeanné, Ulrich Brunner, Victor Hugo, and Simon Délaux. They are valuable alike for conservatory and garden decoration, and continue in beauty for a very long time.

A rush was made through the Dahlias, which are extensively grown, but only a few flowers were open, so late was the season. Varieties of great beauty have expanded since then, and been honoured at meetings and shows as described in reports. Mr. Cannell was the introducer of the Cactus Dahlia Juarezi, and though not a few persons regarded it as

FIG. 35.—MR. JAS. MCINDOE, HUTTON HALL.

a sort of monstrosity and as violating all the rules of florists, it yet "caught on," and became the progenitor of a race that was evidently wanted by the great flower-loving public, or the demand for plants would not be so great, exceeding that for varieties in any other section. Many beautiful Cactus Dahlias are now grown over the length and breadth of the land, and one that is bound to spread far and wide is the new twisted, pointed, starlike, but double and softly rich form, Robert Cannell, a perfect Cactus Dahlia.

#### FRUIT AGAIN.

We now leave them and everything else in the floral home and drive through a land of plenty—at least, plenty of fruit, especially in plantations of young trees, for old Kentish orchards are like hundreds of others in various parts of the country, obsolete and comparatively worthless. They are relics of the past, and cultivated fruit plantations will in future supply produce for our markets.

Our first stop was at a splendid young plantation of standard Plums not on very tall stems, the trees about 5 or 6 yards apart, and Gooseberry bushes between them, about 5 feet asunder. The crop of these was being gathered by a little army of women and girls who were filling small deep narrow baskets quickly, swinging four of these over their shoulders and carrying them, two hanging in front and two behind, to the larger baskets at the end of the rows, and men were conveying the fruit to the factory in vanloads. Though these bushes were only planted three years ago last autumn, so well had they grown in the deeply worked fertile soil, and so sensibly had they been pruned, that they were bearing a remarkable crop of unusually fine fruit. The weight from each bush certainly exceeded 8 lbs., and 10 lbs. would be nearer the mark; but put it at 7 lbs., and even at the low price of three farthings a pound, or say, £7 a ton, the crop would be worth nearly £40 an acre, and, as the whole cost of cultivation, gathering—everything, would not exceed £20, we have a very respectable profit from these thrifty young three-year-planted trees. But that is not all. This was the second gathering, for the crop had been thinned when the berries were large enough for using green, the remainder left to ripen or nearly so, being asked for, the reply was as laconic as a reply could well be—"Lads." This meant Lancashire Lad—a large round dark red profitable market Gooseberry. Then there were the Plums above. The trees had been cut back twice to give sturdiness. They had made wonderful growth, and many of them were clustered with fine fruit. The variety appeared to be the Victoria, at least, in the part of the plantation under notice, though others in the far distance might be different. This was as fine an example of modern fruit culture as anyone could desire to see. The soil was well worked and made fertile to a good depth, the subsoil broken, weeds prevented, and the trees and bushes not overcrowded with shoots. No mere orchard planting on grass, or sticking trees in poor shallow ground and letting weeds make it poorer could approach the results attained. It was the best garden culture on a large scale, and that is the best and most profitable way of growing fruit. Some other plantations passed had Apples as standards, and under crops of Raspberries and Black Currants as well as Gooseberries, but the best Red Currants are grown in fields to themselves, with no large trees to shade them.

With the exception of one field of 500 acres without a fence, belonging

to Mr. Wood, and here and there a smaller field of Wheat, root crops, autumn Cauliflowers, or pasture, the eight or nine miles traversed was through a country of fruit. Speaking of Cauliflowers, one cultivator is said to have contracted to supply 500 tons to one firm for pickling, the heads to be cut up and tubbed on the ground. For miles we pass through avenues of Damsons, the trees growing almost close together in the fences. When they become old they are simply pollarded like Willows, and push up stronger growths again. Many of the trees were fruitless, while others were bearing good crops. Stretching away behind them, up hill and down dale, as far as the eye could see, were fields of Strawberries, Raspberries, and Currants in openings between plantations, not of tall forest but fruit trees. At every homestead were fruit baskets piled up waiting to be filled; but round several of the dwellings the old orchards were like jungles, and suggested that they could not be very profitable. Some old orchard possessors are like farmers who laugh at fruit-growing and everything else but their own jog-trot ways, and will grub along to the end; then the old order of things gives place to new methods—more intelligent routine, higher, cleaner culture, and greater productiveness. The change is coming steadily along, and is, in some districts, well established. There is yet much land in Kent, as in other counties, good in staple, yet in a woefully neglected state; the weed-infested, impoverished fields being blots on the face of Nature, that might be so fair and so satisfactory, if only men did their duty.

Higher and higher we go steadily dragging along till we reach the summit of a lofty range, drink in the pure sweet air, and look around on a landscape as beautiful surely in its way of hill and dale, wood and water—green meads and waving cornfields on the one hand, fruit fields and plantations on the other—as could be found under the sun; and far away in the distance and far down below us we see a shimmer of light, the reflection of the sun on the glass at Eynsford. We reach it at length after many a jerk and slide down the steep hill, glad enough to get to the bottom.

#### AN EYNSFORD MIXTURE.

Mr. Cannell has chosen a very delightful situation in which he can operate in raising flowers and seeds, and rusticate on the old farmstead down in the vale. In sheets of flowers and sleek horses, Potatoes, Peas, and partridges, fowls, fruit trees, and fattening pigs, geese and German Asters, rabbits and Roses, cows and Curly Borecole, and so on, he has a diversity of interests; and even if the combinations seem a little incongruous they suit him extremely well; and it is not in the least unlikely that he is even just a little proud of seeing inscribed on heavy carts "Henry Cannell, farmer." That is what he is; he is, in fact, farmer, florist, and seed grower, and has plenty of scope for his energy at Eynsford.

The "farm" is a long curving valley with a high slope eastward and northward to the upland, and one more gentle to the west and south. His new and commodious residence is on the higher ground and overlooks the park of Lullingstone Castle, the seat of Sir W. Hart Dyke, Bart, M.P. Mr. Robert Cannell and his pretty young wife have plenty of room, and the former has plenty to do as general overlooker of all that is going on, the head of the firm only driving over occasionally from Swanley to pat his horses, look at his pigs, and give a few general instructions.

The soil is excellent, a good free working yet substantial loam on chalk. Seed crops of all sorts of vegetables were filling out well, and the Peas just in the right place on the steep hill side during the dull wet season, but the new English Wonder was lower down, and bearing heavily. It is a decided improvement on its American prototype, producing larger pods, and peas of the highest quality, quite equal to the best of the later sorts. Flowers of all kinds, annuals, biennials, and perennials that will produce seed for raising others for flowering, no one knows where, made a rich and varied display. Seed as it became ready for gathering was secured daily, and spread out to dry in the long glass structures which are occupied with various plants during winter and spring. Mr. Cannell has already done much on this beautifully situated and fertile farm, and what he will make of it in future is not easy to anticipate, but no doubt a great and productive garden. Roses grow splendidly in the soil, and budding was going on briskly; indeed, everything appeared to be in a highly flourishing state.

It is good for a district, this conversion of land from agricultural tillage into fields of fruit and flowers in affording employment to men and women who would otherwise have to wander far from their homes, many of them to possibly starve in towns or struggle for existence in distant lands, to which they are tempted by shipping and other agents, who seek to make capital out of them. There is not the least doubt that since Mr. Cannell took possession of the land at Swanley and Eynsford it affords employment to at least a hundred times more men than it ever did before. England is not worn out by a very long way—its land is not worked out; but, on the contrary, vast tracts are comparatively worthless by want of working and well-applied labour, higher and cleaner culture would render them productive.

Letters still keep coming in. A Yorkshireman writes:—"My journey down to Swanley proved a great treat, in fact an eye opener;" and a Kentish man says:—"Every one of the Journals (of August 27th) on the stalls up and down the line was bought up. There is only one error in the account—the printer put an "0" too many in the east of the London factory. What has been done in the district is wonderful enough, apart from the London building."

I am greatly indebted to Mr. Cannell for guiding me through an interesting district, though so little time was left for inspecting his own establishments.—J. WRIGHT.

**EVENTS OF THE WEEK.**—The Great International Fruit Show held by the Royal Caledonian Horticultural Society at Edinburgh is continued to-day (Thursday, September 10th) and to-morrow. The National Chrysanthemum Society's early autumn Show at the Westminster Aquarium is also continued to-day. The Show of the East Anglian Horticultural Club at Norwich takes place to-day, and Galashiels Horticultural Exhibition on Saturday. Sales of Bulbs and Orchids by auction will take place at Messrs. Protheroe & Morris's rooms during the week, and particulars will be found in the advertisement columns.

— **WEATHER.**—Brilliant days have prevailed this week in the London district, and as the barometer is high and rising, hopes are high that a sunny autumn will follow.

— **MISS ORMEROD.**—We are informed that this talented and industrious lady has resigned her connection (as consulting entomologist) with the Royal Agricultural Society, but does not intend to be less useful to the agricultural and horticultural community. An untenable claim was made on her works, and though this was ultimately withdrawn she prefers to be free.

— **DEATH OF THE LORD MAYOR OF YORK.**—Many of our readers who have been associated with the great gala and horticultural exhibitions at York, will regret to hear of the death, on the 6th inst., of Mr. Alderman Philip Matthews, the Lord Mayor and President of the Society for this year, after several weeks' serious illness, the result of influenza followed by typhoid fever. Mr. Matthews has for a number of years been an active member of the Gala Committee, and his death will be very sincerely regretted by every person who knew him. Raised to the highest position in the city by his fellow citizens, he fully justified their choice, and profound sympathy will be felt for the Lady Mayoress in her great sorrow.

— **THE EAST ANGLIAN HORTICULTURAL CLUB** will hold the first autumn fruit, vegetable, and Dahlia Show, with other flowers (in aid of the Gardeners' Benevolent Fund), in St. Andrew's Hall, Norwich, on Thursday and Friday, September 10th and 11th, 1891. The Show will be opened at 1 P.M., on Thursday, by the Sheriff of Norwich, Geoffrey Buxton, Esq. Various musical attractions will also be provided. The Hon. Sec. is Mr. Albert F. Upstone, 16, Exchange Street, Norwich.

— **THE DALSTON AND DISTRICT AMATEUR CHRYSANTHEMUM SOCIETY** held their first excursion on Saturday afternoon last, when a party of about forty paid a visit to the Royal Gardens, Kew, and spent some time in an inspection of the glass houses and the outdoor collection of plants. Several hours were occupied in this way; the party then assembled at the Lion Gate, and drove through Petersham, Ham, and Richmond Park, concluding a brief but most enjoyable trip with a high tea at the Star and Garter Hotel.

— **NEWCASTLE HORTICULTURAL SOCIETY.**—In response to the appeal of the Mayor of Newcastle for subscriptions to meet the liabilities incurred by the disastrous gale announced in your last issue, the public have subscribed most handsomely, £525 being forthcoming up to Saturday, September 5th. This speaks well for the love of horticulture in the district. We trust the future efforts of the Society may be crowned with success.

— **WEATHER AT LIVERPOOL.**—Exactly one week has elapsed since the storm mentioned in last week's Journal, and now we have again to chronicle one of equal severity, but unaccompanied by the heavy rain which prevailed during the former. The wind blew from the S.W., and did much damage to forest and fruit trees. In many places the foliage of the forest trees is quite brown and cut to pieces, whilst under the fruit trees the ground was literally strewn with fruit. We counted 800 fine Beurré Diels, which were blown from a standard tree some thirty-six years old. Of course it is quite useless, and what remains on the tree is so bruised and blackened that it will never be of much use. We have had a little more sunshine it is true, but during the night and to-day we are having torrents of rain, accompanied by a strong S.W. wind.—R. P. R.

— **GARDENING APPOINTMENT.**—Mr. Charles Ritchings, for the last four years gardener to W. Lindsay, Esq., Brandries, Beddington, has been appointed gardener to Dr. Frankland, F.R.S., F.R.H.S., The Yews, Reigate Hill, Surrey.

— **WE** learn from an advertisement in the present issue that the **LEICESTER AND MIDLAND CHRYSANTHEMUM SOCIETY** will hold their fifth annual Show in the Temperance Hall, Leicester, on November 13th and 14th of the present year. The Hon. Secretary is Mr. W. Bell, Knighton Road.

— **EDUCATION IN GARDENING.**—From six candidates who were invited to attend Worcester last Saturday Mr. J. Udale was chosen as gardening instructor by the Committee of the Worcestershire Union of Workmen's Clubs and Institutes, a grant having been allowed by the County Council for the purpose in question. Mr. Udale is a sound practical gardener and competent man.

— **RAINFALL IN SUSSEX.**—The total rainfall at Cuckfield, Sussex, for August was 5.83 inches, being 3.53 inches above the average. This amount has only been exceeded on two occasions during the last twelve years—viz., October, 1880, when 8.23 inches fell, and October, 1882, when 6.86 was recorded. The heaviest fall was 1.18 inch on the 20th. This amount has been exceeded on eight occasions during the same period. Rain fell on twenty-five days. The highest temperature was 71° on the 14th, lowest 40° on the 30th. Mean maximum, 64.2°; mean minimum, 49.2°. Mean temperature, 56.7°; mean partial shade readings, 3.1° below the average.—R. I.

FIG. 36.—MR. J. HUNTER, LAMBTON CASTLE.

— **RAINFALL IN HAMPSHIRE.**—I have several times observed in your columns accounts of rain in various parts, and also that some exceeded the amount here. We are twelve miles N.W. of Southampton, and I think the rainfall here for August is extraordinary, and more than in some parts, as we have had during August 5.10 inches of rain. To those who observe the rain record it will be interesting to note how the storms vary.—A. J. LONG.

— **THE French Société de l'Encouragement** lately offered a prize of 1000 francs for **CONSERVATION OF POTATOES AND OTHER VEGETABLES**. Four of the five applicants used some isolating substance (woodash, sawdust, rye straw, with sand). M. Schribaux, who gained the prize, put Potatoes for ten hours in a 1½ per cent. solution of commercial sulphuric acid to kill the buds (a 2 per cent. solution for thick skins). The Potatoes are taken out and thoroughly dried, and they will keep without alteration more than a year. The same solution serves for repeated immersions, the concentration remaining constant. The process is not applicable to Onions. Another prize by the same Society (3000 francs) was awarded to M. Candlot for a memoir treating of the action of sea-water on cements. He shows that the sulphate of lime resulting from decomposition of sulphate of magnesia by lime salts of the cement combines with aluminate of lime to give a double crystalline salt containing half its weight of water. The crystallisation of a salt so greatly hydrated involves considerable swelling, and this accounts for the disaggregation of cements in marine work. M. Candlot has observed the curious fact that over-baked lime, which takes several days to extinguish in water, is extinguished in a few minutes in a 3 per cent. solution of chloride of calcium. This is thought to have important practical bearings.

— **TUREROUS BEGONIAS.**—Mr. F. Geeson, Cowdray Gardens writes:—"I enclose a few blooms of seedling Begonias for you to see, though they are not quite at their best. I have raised many hundreds of plants from my own seed and grown them out of doors, lifting the best as they bloom. I have doubles with perfectly upright stems, but not many of the largest; but they improve in that respect every year. They have not done so well outside with me this year, and are much later than usual, although at planting time our plants were larger." [The blooms referred to are the finest which have been sent to us by a private gardener. In form, substance, and colour they are alike excellent, and such examples would have been thought impossible a very few years ago.]

— **A PROFITABLE industry**, little heard of, is carried on among the hills of Connecticut (Sci. Am.). It is the **MANUFACTURE OF BIRCH OIL**, which is used largely for confectionery, and gives a perfect Wintergreen flavour. There are eight mills in the State—the first built only ten years ago. Birch brush without foliage, and not over  $2\frac{1}{2}$  inches in diameter from the Black Mountain or Sugar Birch (not the yellow or white), is chopped up and boiled with water in tanks. The steam, passing through an iron pipe near the top, is condensed in a coil immersed in running water, and drops into a glass jar. The oil is much heavier than water, and in the crude state is of copper hue. The mills work only from October to April. A good deal of adulterated birch oil is used in tanning leather to imitate Russia leather.

— **TOBACCO FERMENTATION.**—A very essential process is brought about by firmly packing ripe tobacco in large quantities. It had been generally supposed that the fermentation is of purely chemical nature, but Herr Suchsland, of the German Botanical Society, finds that a fungus is concerned in it. In all the tobaccos he examined, he found large quantities of fungi, though of only two or three species. Bacteriaceæ were predominant, but Coccaceæ also occurred. When they were taken and increased by pure cultivation, and added to other kinds of tobacco, they produced changes of taste and smell which recalled those of their original nutritive base. In cultivation of tobacco in Germany it has been sought to get a good quality, chiefly by ground cultivation and introduction of the best kinds of tobacco. But it is pointed out that failure of the best success may be due to the fact that the more active fermenting fungi of the original country are not brought with the seeds, and the ferments here cannot give such good results. Experiments made with a view to improvement on the lines suggested have apparently proved successful.—(*Nature*.)

— **WALNUTS.**—The approach of the Walnut season, says a daily contemporary, has prompted Mr. P. L. Simmonds to publish a few notes on this popular fruit. Few Kentish village greens are without their spreading Walnut tree, but we have an impression that Walnut planting has of late years suffered a considerable decline, and this is confirmed by Mr. Simmonds's statement that the greater part of the Walnuts consumed in England nowadays are of foreign growth. They average in quantity about a quarter of a million of bushels, and come chiefly from France and Belgium, Germany, Holland, and Italy contributing also in a less degree. In large market towns, where they are bought at first in the husks by the sack or bushel, they command a ready sale. When the nuts are fully ripe—that is, in September and October—the pickling and ketchup-making period is for the most part at an end, and the "wine and Walnut" time—somewhat injured by the decline of port in public estimation—may be said to have set in. We are bidden to beware of dry Walnuts. It is only when the skin can be easily removed that Walnuts are digestible and wholesome.

— **A LONDON daily paper** is responsible for the following:—"One of those things that Lord Dundreary would declare 'no fellow can understand' is that the four or five millions of people residing in the British metropolis are not capable of consuming the fruit which grows in their immediate vicinity, while they import hundreds of thousands of pounds' worth from distant lands. 'A Fruit Grower' writes:—"I have some 5 or 6 bushels of Morello Cherries absolutely rotting on the trees in consequence of the very low price offered by the middleman. Foreign fruit commands a higher price than English, simply because greater facilities are offered them by the railway companies. For instance, a sack of Potatoes weighing 168 lbs. can be sent from Jersey to London for 1s., but I was charged by the railway company 3s. 5d. for a distance of seven and a half miles only. I have the company's receipt in my possession. The Potatoes were sold for 6s., and after paying expenses 1s. was all I had left. Some Morello Cherries I sent up to Covent Garden, after paying expense of carriage, left me the sum of 1d. a pound, which did not pay me for the growing. As the Lord Mayor and Fruiterers'

Company have interested themselves in the production of fruit perhaps they would kindly show the small producer how to sell his produce. The only way I see is by causing markets to be formed at different centres, where fruit could be sent with the hope of a fair profit.' In this question the people of London have a deep interest. There seems to be a 'missing link' somewhere between the producer and consumer. In there being too much home-grown fruit we do not believe."

FIG. 37.—MR. A. KIRK, NORWOOD.

— **SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, 56 feet above mean sea level, for August.**—Mean temperature of the month,  $58.2^{\circ}$ . Maximum on the 14th,  $72.5^{\circ}$ ; minimum on the 5th,  $40.0^{\circ}$ . Maximum in the sun on the 20th,  $128.7^{\circ}$ ; minimum on the grass on the 5th,  $32.4^{\circ}$ . Mean temperature of the air at 9 A.M.,  $58.5^{\circ}$ . Mean temperature of the soil 1 foot deep,  $58.1^{\circ}$ . Total duration of sunshine in the month, ninety-five hours, or 21 per cent. of possible duration; we had two sunless days. Total rainfall, 3.11 inches; rain fell on twenty days. Average velocity of wind, 9.9 miles per hour. The velocity exceeded 400 miles on three days, and fell short of 100 miles on three days. Approximate averages for August:—Mean temperature,  $60.2^{\circ}$ ; rainfall, 2.52 inches; sunshine, 149 hours. A very dull, rather cold, showery, windy month. The nights were mild, but there were no hot days. Much less sunshine than in any of the previous ten years, except 1885.—J. MALLENDER.

— **ONION SHOW AT BANBURY.**—On September 3rd the valuable prizes offered annually by Mr. H. Deverill, Corn Hill, Banbury, were competed for at his seed stores, the display being open for the inspection of seed growers, the trade, and those interested in horticulture. Hundreds of fine specimens were shown of the types known as Deverill's Pedigree kinds, and weighing 16, 17, 18, 20, and 22 lbs. per dozen bulbs, and this is all the more remarkable considering the adverse season we have experienced. The most successful exhibitor was Mr. T. Wilkins, gardener to Lady Guest, Inwood House, Blandford, Dorset, his 144 bulbs being considered to be the finest lot ever staged by one grower. Other successful competitors in the classes devoted to gardeners were Mr. Bowerman, gardener to C. Hoare, Esq., Hackwood Park, Basingstoke, whose magnificent examples of Ailsa Craig were very noteworthy. Mr. Pope, gardener to the Earl of Carnarvon, Highclere Castle, Newbury; Mr. Wiles, Edgecote Park Gardens, Banbury; Mr. Lye, Sydmonton Court Gardens, Newbury; Mr. Kneller, Malshanger Park Gardens, Basingstoke, and others also exhibited. The competition in the class set apart for artisans, allotment holders, and cottage gardeners produced an interesting display of bulbs.

— **THE WEATHER AT RIPLEY, YORKS, DURING AUGUST, 1891.**—In common with other parts of the county we suffered from an excessively wet August, but we had no such terrific downpour that we learn from press reports visited some districts. Our greatest fall in twenty-four hours occurred on the 17th, when 0.60 inch was registered. The total rainfall for the month was 3.75 inches, which fell upon twenty-four days. Mean reading of barometer  $29.83^{\circ}$ ; mean max. temperature  $64.5^{\circ}$ ; mean min. temperature  $46.0^{\circ}$ ; mean temperature of month  $55.2^{\circ}$ . On the evening of the 25th, continuing to mid-day 26th, we were visited by a heavy gale, which played sad havoc among the plants in herbaceous borders, also thinning the Apple crop to an alarming extent. Not having an opportunity before, on September 3rd and 4th we lifted our early Potatoes for seed purposes and found

fully one-fourth affected by disease. The varieties were Sharpe's Victor, Improved Ashleaf, and Royal Ashleaf; they were all equally affected. The latter varieties keep very clear as yet. Harvest operations commenced here last week (September 2nd); crops are very indifferent owing to the heavy storms of wind and rain, also through the devastation caused by birds; one farmer told me yesterday that he had lost half his crop of Oats through the destruction caused by birds alone. Bright sunshine is sadly needed not only by farmers, but also by gardeners to finish off late Grapes, ripen up the wood of fruit trees, and to harden the Broccoli tribe to enable them to withstand the winter frosts.—J. TUNNINGTON, *Ripley Castle Gardens*.

FIG. 38.—THE LATE MR. C. STEWART.

### ROYAL HORTICULTURAL SOCIETY.

THE Drill Hall was not so full of exhibits on Tuesday last as on the occasion of the previous fortnightly meeting, but considering the season of the year the display was good.

**FRUIT COMMITTEE.**—Present: P. Crowley, Esq., in the chair, with Dr. Hogg, and Messrs. R. D. Blackmore, Harrison Weir, T. F. Rivers, A. H. Pearson, W. Warren, W. Bates, A. Dean, G. Noiman, J. Willard, H. Balderson, and J. Wright.

Mr. A. Gibson, gardener to T. F. Burnaby Atkins, Esq., Halstead Place, Kent, sent a medium sized, well-netted, green-flesh Melon of good quality, and a certificate of merit was awarded. Mr. Harding, gardener to T. Philpot, Esq., Vale Road, Guernsey, sent a large handsome Melon, the result of a cross between Golden Perfection and Orion, but though juicy and sweet was deficient in flavour, and no award was made.

Messrs. Keynes, Williams & Co., Salisbury, sent a dish of a red seedling Plum, which, though good, was not considered sufficiently distinct and meritorious to be granted a certificate. Mr. P. Crowley placed on the table some splendid specimens of Jefferson Plums from a branch on which a wire ligature had been accidentally left. This arrested the downward current of sap, causing a prominent enlargement of the branch above the ligature, the sap being "held," so to say, in the branch for supporting the fruits. The largest weighed 4 ozs. The fruits on the other parts of the tree were not half the size. It was really a case of "ringing," but this does not always have such marked results. A vote of thanks was accorded. Mr. P. Crowley also placed on the table nineteen excellent fruits, the largest weighing 6 ozs., of Louise Bonne of Jersey Pears from a tree grown in a 10-inch pot by his gardener, Mr. W. King. The tree was placed under glass in March and removed to the open air in June, where the crop ripened. A cultural commendation was awarded.

Messrs. G. Jackman & Co. sent from Woking a dish of a new seedling Apple, Victoria, having some resemblance to Duchess of Oldenburg, but sweeter, though not so good as Irish Peach. No award was made. Mr. Lee, Clevedon, Somerset, sent a seedling Apple somewhat resembling the Devonshire Quarrenden, but larger and not so good. It was passed by the Committee. Mr. Roupell sent excellent specimens of Apples Lord Suffield, Duchess of Oldenburg, and Bietigheimer, a large red German Apple, and a cultural commendation was unanimously awarded. Mr. W. Whiteley sent a dish of Hillingdon Favourite Tomato, bright medium fruit, for which a vote of thanks was recorded. Messrs. Jas. Veitch & Sons staged nearly fifty varieties of Plums, for which a silver medal was recommended. In the collection was a dish of Frogmore Orleans, a variety not known by the Committee, and said not to split like many others during wet weather.

The records of a meeting held at Chiswick on Thursday last were read, when after examining a number of Potatoes and cooking them three marks (xxx) each were granted for Mottled Beauty, Ellington's Prolific, and Crawley Prizetaker. Three marks were also recorded for the following Turnips:—Early Milan, Early White Strap-leaf American, Large White Globe Purple Top, and Large Green Globe.

Similar marks were granted for Tomatoes Golden Sunrise, Sutton's Golden Nugget, and Italian Wonder, all having yellow fruits.

Scarlet Runners had been so much injured by the wet that no fair estimate could be formed of their merits, except in the case of Sutton's Tender and True, a most productive variety of moderate growth, having fine tender pods of the same character as those of the dwarf varieties but larger. It is a distinct and excellent variety, and was granted a first-class certificate.

**FLORAL COMMITTEE.**—Present: Messrs. W. Marshall (in the chair), C. T. Druery, H. B. May, R. Dean, G. Phippen, J. T. Bennett Poë, G. Paul, C. Noble, J. Fraser, and W. Watson.

A very large collection of Gladioli came from Messrs. Kelway and Son, Langport, quite in their best vein. It comprised some of the best of their magnificent collection of varieties, such as Pandanus, salmon with purple throat; Mrs. J. Eyton, white suffused and feathered with rose; Lassia, rich scarlet; the Rev. J. Stubbs, brilliant scarlet, carmine throat; W. S. Gilbert, described below; Sheila, also described below; Harrison Weir, orange scarlet; Beauty of England, white, throat flaked purple; and Baroness Burdett Coutts, rosy mauve; but there were many others equally beautiful. They also had a display of hardy flowers, including varieties of Papaver nudicaule, Rudbeckia purpurea, Phloxes, Solidago altissima, Anemone japonica rubra, a deeper form of the well-known Japanese Windflower, and Dracocephalum speciosum. A silver Flora medal was awarded.

Mr. G. Phippen, Reading, had a collection of herbaceous Phloxes, named varieties, amongst the best being Miss Robinson, white; Vesuvius, deep rose; Paragon, purplish violet; and Mons. Luney, crimson. He also had a large group of Liliiums interspersed with Ferns and foliage plants, which was very effective, and a group of Cactus and Decorative Dahlias similar to that exhibited at the Show of the National Dahlia Society, the flowers being in bunches of about twenty-four, and interspersed with Ferns. Such excellent varieties as Robert Maher, Panthea, Zulu, W. Pearce, Professor Baldwin, Empress of India, Mrs. Hawkins, Beauty of Brentwood, Honoria, Henry Patrick, and Juarezi were represented. A silver Flora medal was awarded for this group, and another for the Liliiums. Mr. Phippen also showed a box of Lapagerias.

British Ferns were an interesting feature of the meeting. C. T. Druery, Esq., F.L.S., Fernholme, Forest Gate, Essex, had a collection of select varieties, embracing a beautiful form of Polystichum angulare named divisilobum plumosum densum, Scolopendrium vulgare var. crispum majus, S. v. var. grandiceps, S. v. Keratoides, S. v. ramo-cristatum, Athyrium filix-femina seticerum pinceristatum, Polystichum angulare var. plumosum, P. a. var. revolvens, and many other forms. E. J. Lowe, Esq., F.R.S., Chepstow, had a large exhibit of Ferns in many varieties, amongst them Nephrodium paleaceum var. Willsi, N. p. var. ramosissimum, N. p. depauperatum, Scolopendrium vulgare crispum var. Kitsoniae (L.), S. v. undulatum var. cochleato-cristatum, Asplenium filix-femina flexuosum var. Cymba, A. f.-f. torquera, A. f.-f. grandiceps

FIG. 39.—MR. W. YOUNG

var. Arthuri, Osmunda regalis var. capitata, Aspidium angulare divisilobum var. laxum, A. a. decompositum var. frondosum, Adiantum Capillus-Veneris var. Lowæ, Scolopendrium vulgare marginatum var. corollarium, S. v. crispum robustum, and many other good forms. Mr. Lowe also had two baskets of Ferns. Several were honoured by the Committee as noted below. In the competition for the best collection Mr. Lowe was placed first and Mr. Druery second, the former receiving also a silver Flora medal.

A small but highly interesting group of plants came from the Royal Gardens, Kew, the central figure of which was an extraordinary flower of Aristolochia grandiflora (syn. A. gigas), 18 inches across, and with a "tail" 3 feet long. The flower is creamy white, deeply marked with brownish purple, and the capacious throat is velvety purple. There were also Ixora macrothyrsa, Clematis Stanleyi, Mucuna purpurea, and Solandra grandiflora. Messrs. Paul & Son, The Old Nurseries, Cheshunt, sent a Dahlia named Claxton's Harlequin, described below; a box of Roses, Liatris pycnostachya, Actaea fructo alba, Spiraea japonica compacta, Sarracenia purpurea, Spiraea palmata alba, Lythrum salicaria.

roseum, and *Lilium* Mrs. Anthony Waterer, white dotted with red. Mr. Hole, Commercial Road, Teignmouth, had *Carnation* Devon Beauty. Mr. Whiteley, Hillingdon, Uxbridge, showed a *Chrysanthemum* named Mrs. Whiteley, a large white flower with fluted florets. Mr. C. G. Van Tubergen, jun., Haarlem, had a small collection of hybrid *Gladioli*, for which a bronze Banksian medal was awarded; and Mr. J. Walker, Thame, was commended for an excellent strain of Quilled Asters. Messrs. J. Veitch & Sons, Royal Exotic Nurseries, Chelsea, had *Lilium auratum rubro-vittatum*, *L. a. virginale*, *L. a. platyphyllum*, *Francoa ramosa*, freely flowered; *Hydrangea paniculata*, and *Abies* (*Picea*) *Omorika*, referred to below. A bronze Banksian medal was awarded.

First-class certificates and awards of merit were adjudged to a number of Ferns; but interesting as the many varieties are to specialists,

FIG. 40.—MR. M. DUNN, DALKEITH.

it is practically impossible to indicate their special characteristics in a brief description. They were as follows:—First-class certificates to Mr. Druery for *Athyrium filix-fœmina plumosum Drueryi*, and to Mr. Lowe for *Scolopendrium vulgare crispum decorum*, *S. v. supralineatum Moonæ*, *S. v. rameo inæquale laudabile*, *Asplenium filix-fœmina luvulatum Wellsiæ*, *Aspidium angulare grandiceps tæda*, *A. a. cruciatum Nymphæ*, *A. aculeatum cristatum hybridum*, *Nephrodium paleaceum Wellsiæ*, and *Osmunda regalis capitata*. Awards of merit to *Athyrium f.-f. superbum densum* and *A. f.-f. revolvens* from Mr. Druery. Also to the following from Mr. Lowe:—*Scolopendrium vulgare muricatum superbum*, *S. v. m. crispum*, *Aspidium angulare grandiceps coronale*, *A. a. setosum gracile*, *A. a. plumoso-divisilobum gracile*, *A. aculeatum cristatum adrastia*, and *Asplenium Ceterach* var. *multifolia cristatum*. Botanical certificates were awarded to him for *Scolopendrium vulgare peraperens nepenthesoides* and *Aspidium aculeatum cristatum circumglobatum*.

Awards of merit were made to the following flowers:—Show *Dahlia* Arthur Rawlings, deep crimson, exhibited by W. Keith, Esq. (gardener, Mr. J. T. West), Cornwall, Brentwood; Show *Dahlia* William Powell, rich yellow, well formed, from the same exhibitor; Decorative *Dahlia* Mrs. Keith, a combination of rose and yellow, the former suffusing the florets somewhat deeply, same exhibitor; Decorative *Dahlia* Claxton's Harlequin, yellow, flaked and streaked with crimson, from Messrs. Paul and Son, Cheshunt; *Gladiolus* George Meredith, white heavily flaked with crimson, pale yellow throat (this and the following *Gladioli* came from Messrs. Kelway & Son); *Gladiolus* Lady Brooke, ivory white, with a few short streaks of crimson; *Gladiolus* W. S. Gilbert, salmon with paler throat, excellent form; *Gladiolus* Sir Arthur Sullivan, brilliant scarlet, splendid spike; *Gladiolus* Sheila, white, purplish carmine throat; *Croton* Golden Ring, a graceful variety with slender twisted leaves, yellow marbled green, exhibited by Mr. H. B. May, Edmonton.

Botanical certificates were awarded to Messrs. James Veitch & Sons for *Abies* (*Picea*) *Omorika*, a graceful species from South-east Europe, with dark green foliage; and for *Davallia assamica*.

ORCHID COMMITTEE.—Present: Dr. Masters (in the chair), Messrs. Jas. O'Brien, E. Hill, C. Pilcher, H. Ballantine, A. H. Smee, and T. B. Haywood. A first-class certificate was awarded to Baron Schröder (gardener, Mr. Ballantine) for *Miltonia Bluntii* var. *Lubbersiana*, a large flowered form, the sepals dull greenish grey nearly covered with broad brown blotches, the lip white very faintly suffused with rose, the upper portion, as also the base of the sepals, purplish mauve, lined and blotched with brown. Messrs. Hugh Low & Co., Clapton, received a botanical certificate for *Mormodes buccinator* var. *aurea*, with small deep yellow flowers. A similar award was made to them, and also to W. Wright, Esq., Denmark Hill (gardener, Mr. G. Parrott), for *Cataseum fimbriatum*, an interesting form, with green lip and throat, sepals and petals light green dotted with brown. Messrs. F. Sander & Co., St. Albans, received a similar award for *Cattleya granulosa* var. *dijancaana*, a peculiar form, the solitary flower having sepals of a light brownish green, and a small fringed magenta coloured lip. They also exhibited *Vanda Hookeriana*, *Cattleya crocata rosca*, *Lælia elegans Robinsoniana*, *L. e. marlbroughensis*, *L. e. Turneri*, *Vanda cærulea*, *Peristeria elata*, and *Dendrobium undulatum*. T. Statter, Esq., Stand

Hall, Manchester (gardener, Mr. Johnson), exhibited *Lælia elegans Turneri atro-rubens*, *L. e. Turneri* Stand Hall variety, *L. e. blenheimensis*, *Mesopitidium vulcanicum*, *Odontoglossum Harryanum superbum*, and *Saccolabium Blumei longiracemosum*. A vote of thanks was awarded. D. O. Drewett, Esq., Riding Mill-on-Tyne (gardener, Mr. Keeling), had *Cypripedium Beatrice* and *C. Eyemannianum* Drewett's var. C. J. Lucas, Esq., Warnham Court, Horsham, received a cultural commendation for *Angræcum articulatum*, and Messrs. Charlesworth, Shuttleworth & Co. Heaton, Bradford, a vote of thanks for *Oncidium macranthum* var., a freely flowered deep yellow form.

#### CARNATION SOUVENIR DE LA MALMAISON.

VERY rarely do we see these beautiful flowers grown to such perfection in a private establishment as their merits deserve. Their culture being simple, and fire heat not necessary, amateurs with only an unheated structure should include them in their collections. They are easily increased by cuttings or layers, the latter being the surer and quicker method, besides being more likely to afford strong plants. About the middle of July, when the plants have flowered, they should be taken out of the pots and planted deeply in a warm south border in which a quantity of leaf mould and sand has been incorporated. The shoots can then be pegged down and layered about 6 inches from the tops, for if too low they never make such good plants. In about a month, if the operation has been successful (watering in dry weather being well attended to), they will be well rooted and ready for potting. Three-inch pots are the best, the compost being three parts loam, one part leaf mould, and a dash of coarse sand.

After potting stand them on ashes in a cold frame, the lights being left off as long as there is no danger of severe frosts or too much rain. During winter they are best kept in a house from which frost is excluded, as near the glass as possible. A look out must be kept for green fly, which is apt to attack them in all their stages, fumigation on two or three successive evenings, or where that is inconvenient an occasional dusting with tobacco powder, being efficacious. When they show signs of renewed growth in the spring they may be shifted into their flowering pots, 6 or 7 inches being most suitable. For this potting some horse droppings, prepared as for Mushroom beds and rubbed through a sieve, may be mixed with the soil. The plants should have as light and airy a situation as possible, no advantage being derived from hurrying their growth. Where large blooms are desired some of the buds may be cut away, leaving five or six to the spike. When the buds are swelling a little feeding, either with liquid manure or some good plant invigorator used as a top-dressing, may be applied with advantage. Some of the side shoots will throw up flower stems in the autumn, which can be developed with a little heat. A fresh annual stock should always be maintained, one year plants giving by far the best results.—O. C.

FIG. 41.—MR. A. A. MCLEOD.

#### NATIONAL DAHLIA SOCIETY.

SEPTEMBER 4TH AND 5TH.

GLOOMY skies, with the concomitant absence of sunshine, heavy rains, boisterous winds, and low temperatures have combined to make the *Dahlia* exhibitor's lot the reverse of a happy one this season. That other specialists have suffered in a similar manner is, according to the gospel of Rousseau, some consolation, but otherwise it does not mend matters. Roses were backward, Carnations were backward, Dahlias are backward. There has been an all-round retardation in the flower gardens as well as in the corn fields of wettest England, and following as it does on the cold summer of last year, and the severe winter that succeeded, gardeners will begin to feel uncomfortable misgivings that Flammarion's prophecy of another glacial epoch may not, like others of that accomplished savant's ideas, be so absurd as many have supposed.

Last year a fine autumn enabled Dahlias to do yeoman's service in compensating for summer disappointments, and although the start is not promising, it is not too late to hope that we may be similarly favoured this season. So far the cold and wet have greatly retarded

the opening of the flowers, as many who do not exhibit have found to their sorrow, and it was therefore to be expected that the Dahlia Society's Show would suffer in some measure from the same cause. Such anticipations of this nature as were formed were fully realised. The supply of tabling proved to be far more than adequate for the exhibits, and the ominous gaps between the stands told their own story. The amateurs' section was very weak in point of quantity, but the nurserymen's classes were better filled. Naturally the southern and western exhibitors had matters nearly all their own way; doubtless the flowers of northern growers are still far from ready.

The quality of the flowers was, on the whole, admirable, and probably turned out to be much better than many had expected. Taken altogether, the Show and Fancy varieties seemed to be somewhat lacking in weight, but in other respects they were excellent, and as breadth and substance of petal, form, and correctness of colour are more important than mere size, there was very little cause for complaint. A point worth noting is the unmistakeable manner in which the Pompons and singles were eclipsed by the Cactus and Decorative varieties. The latter have now developed into a most important and beautiful group, and they are of such value for garden decoration and cutting that their growth in numbers and diversity is cause for satisfaction. They have sprung up since the late Mr. Shirley Hibberd prophesied that the Pompons would in course of time acquire the leading position, and have already far outstripped the latter. The following are particulars of the Show.

#### NURSERYMEN.

The principal class for Show and Fancy varieties intermixed was for sixty blooms. There were five stands in competition, and that of Mr. C. Turner, Royal Nurseries, Slough, was ultimately selected as the best. Perhaps in point of size his flowers, like those of the other exhibitors, were a shade below the average, but in form, substance, freshness, and colour they were unexceptionable. The varieties were as follows:—Back row: Wm. Rawlings, Earl of Ravensworth, Comedian, Prince Bismarck, Rev. J. B. M. Camm, Geo. Rawlings, Mrs. Langtry, Colonist, Rev. J. B. M. Camm (self), Harry Keith, Henry Walton, Rebecca, John Bennett, Maud Fellowes, T. W. Girdlestone, John Standish, Clara, Statesman, Miss Cannell, and Old Tom. Middle row: Matthew Campbell, Mr. Harris, Alice Emily, a seedling of the same shade as Mr. Harris; Mrs. Slack, Glow-worm, Zorina, Jas. Cocker, Ethel Britton, J. Hickling, a dark crimson seedling; Mrs. Saunders, Miss Fox, Crimson King, J. T. West, Mrs. Gladstone, Goldfinder, Excellent, R. T. Rawlings, and Bendigo. Front row: Emily Edwards, Mrs. Foster, John Henshaw, Robert Turner, Sunbeam, Agnes, Mrs. Harris, Jas. Green, Florence, J. Ashby, Seraph, Burgundy, Nellie Tranter, Flag of Truce, Mrs. Hodson, Willie Garrett, Chas. Wyatt (mauve self), Georgina, Lustrous, and Primrose Dame. Messrs. Keynes, Williams, and Co. were second with flowers in admirable condition, but hardly so heavy as the first prize lot. John Hickling, Nellie Cramond, T. W. Girdlestone, Mrs. Jefford, Clara, Jas. O'Brien, and Ethel Britton were extremely good. The third prize went to Mr. A. Rawlings, Romford, for somewhat small but well-coloured flowers; and the fourth to Mr. M. V. Seale, Vine Nurseries, Sevenoaks. There was one other stand.

Class 2 called for forty-eight blooms, Show and Fancy intermixed, and brought several very good stands. Messrs. Keynes, Williams & Co. were placed first, flowers somewhat undersized, but broad in petal, and good in form and colour. They had the following varieties. Back row: Thos. Hobbs, Royal Queen, a scarlet sport from Duchess of Albany; Rev. J. B. M. Camm (very good), Wm. Rawlings, Jas. O'Brien, Mr. Glascock, Agnes, Edmund Boston, Henry Walton, Colonist, Mrs. McKenzie, Nellie Cramond, Coronet, Miss Cannell, and Harry Keith. Middle row: R. T. Rawlings, King of Crimson, Shirley Hibberd, Mrs. Saunders, Frank Pearce, Nero, Joseph Ashby, Duchess of Albany, Gaiety, R. Dean, Queen of the Belgians, Goldfinder, Mrs. J. Downie, Mrs. G. Herbert, Jas. Cocker, and John Hickling. Front row: Mr. Spofforth, Mrs. Langtry, J. T. Vaughan, John Henshaw, Hercules, Mrs. Gladstone, Prince of Denmark, Comedian, a very dark crimson sport from Rebecca; R. T. Rawlings, Mrs. Foreman, Prince Bismarck, Eclipse, T. S. Ware, Miss Barber and Dorothy. A fine stand from Mr. A. Rawlings, in which George Gordon (splendid), Maud Fellowes, Geo. Rawlings, R. T. Rawlings and Mr. Glascock were conspicuously good, secured him the second prize, the third going to Mr. Turner, and the fourth to Mr. Seale, both having good stands.

There were five stands of thirty-six blooms, and Mr. G. Humphries, Kington Langley, Chippenham, was placed first for Duchess of Albany, F. Pearce, Agnes, W. Rawlings, all fine blooms; Ethel Britton, Harry Turner, J. W. Lord, Salamander, Hope, Hercules, Mrs. Kendal, G. Barnes (self), Mrs. Saunders, Jas. Stephens, Mrs. Langtry, Jas. Cocker (very good), Colonist, Maud Fellowes (beautiful), Nellie Cramond, Goldfinder, Sunset, Shirley Hibberd, Jos. Ashby, Mrs. D. Saunders, Mrs. Gladstone, Lustrous, Royal Queen, Crimson King, Rebecca, Mr. J. Downie, Rosetta, R. T. Rawlings, Major Clarke, Mrs. Harris, Matthew Campbell, and Willie Garrett; these were an even, fresh lot of flowers. Messrs. Saltmarsh & Son, Chelmsford, were second, and they had Frank Pearce, R. T. Rawlings, Mr. Glascock, Jas. Cocker, Goldfinder, Willie Garrett, Mrs. Foreman, and Miss Cannell in capital condition. The third prize went to Mr. J. Walker, Thame, for a heavy lot of flowers slightly lacking finish, and the fourth to Mr. S. Mortimer, Rowledge, Farnham, one other competing. There were five stands of twenty-four, the best being a beautiful collection from Mr. Humphries, which, though not large, were in splendid condition; they were so even that it was difficult to pick out any that were exceptionally good. The varieties were Duchess

of Albany, Mrs. J. Downie (scarlet self), R. T. Rawlings, Wm. Rawlings, Mrs. Saunders, Harry Turner, Maud Fellowes, Frank Pearce, Prince of Denmark, Mrs. Humphries, Jas. Stephen, Mrs. Gladstone, Nellie Cramond, Agnes, Colonist, Mr. John Downie, Hope, Lustrous, J. T. West, G. Barnes (self), Ethel Britton, Wm. Keith, Edmund Boston, and Rosetta. Mr. J. Walker secured the second award with an excellent stand. Mr. Mortimer was third and Messrs. Saltmarsh & Sons were fourth. The best of the six stands of twelve came from Mr. J. R. Tranter, Henley-on-Thames, consisting of neat fresh examples of Henry Keith, Mrs. Gladstone, Willie Garrett, J. T. West (two seedlings), Jos. Ashby, Geo. Rawlings, Harrison Weir, John Standish, Chorister, and a crimson variety marked "Unknown." Mr. H. Harris, Writtle Road, Chelmsford, was second, his best blooms being Mrs. Gladstone, Frank Pearce, and Mr. Glascock. Messrs. Cheal & Sons, Crawley, were third, and Mr. George Gilbert, Ipswich, fourth.

Cactus and Decorative varieties in bunches of six blooms formed some extremely beautiful stands, the rich and distinct colours of the flowers giving a most pleasing effect. Messrs. Keynes, Williams & Co. had the best twelve, the varieties being St. Catherine, a new and good yellow; Juarez, Mrs. Hawkins, the richly tinted seedling Baron Schröder, which received an award of merit from the R.H.S. recently; Duke of Clarence, Countess of Pembroke, a beautiful seedling, with pale mauve flowers; Mrs. Arthur Newall, deep brownish red, new; a yellow seedling, unnamed; Kynereith, the new scarlet, a splendid variety; Viscountess Folkestone, pale yellow seedling; Lancelot, and Dr. Masters, a seedling, with pale mauve tinted flowers, hardly of the correct Cactus type. Messrs. Cheal & Sons also had a fine stand, in which the new Beauty of Arundel, crimson, shaded carmine; Black Prince, Mrs. G. Reid, Harry Freeman, and Empress of India were very noteworthy. They were placed second. The third prize went to Mr. M. V. Seale for a very bright and fresh stand, and Mr. C. Turner was fourth. Messrs. Cheal & Sons turned the tables on the winners in the above class with nine Cactus varieties only, winning with a very beautiful stand in which Beauty of Brentwood, rich purplish magenta; Juarez, Mrs. Hawkins, Panthea, and Amphion were exceptionally good. Mr. Seale was second with Honoria, Juarez, Panthea, and Henry Cannell as his best; and Messrs. Keynes, Williams & Co. third with a somewhat crowded stand of smaller flowers. For a similar number, in which Decorative varieties were admitted, Messrs. Burrell & Co. won with a very good stand, Robert Maher, Juarez, Mrs. Hawkins, Mrs. G. Reid, Mrs. Douglas, Black Prince, H. Freeman, Amphion, and Professor Baldwin being all admirably shown. Messrs. Paul & Son, the Old Nurseries, Cheshunt, were second with a very fresh, well-coloured collection, and Mr. G. Humphries third.

Pompons were extensively shown, and on the whole were very bright in colour. The principal class was for twenty-four varieties in bunches of ten, and Messrs. Keynes, Williams & Co. were placed first for a delightful stand. The flowers were under rather than over-sized, which is a fault in the right direction, and in very fine condition. The varieties were Darknesh, Phoebe, Rosalie, Lady Blanche, White Aster, Grace, Heeter, Little Darkie, Dora, Golden Gem, Isabel, Airy Fairy Lillian, a charming seedling with medium-sized flowers of a soft rosy mauve; Crimson Beauty, Whisper, Eurydice, E. F. Jungker, Red Indian, Leila, Favourite, Karl Goldenburg, Mdle. Faconet, Janet, Achilles, and Admiration. Messrs. Cheal & Son followed very closely—so closely that there could have been very few points between the two stands. Their flowers were very fresh and good in colour. Achilles, Othello, Admiration, Little Bobby, Isabel, and Favourite were charmingly represented. Mr. C. Turner was third with another capital box; and Mr. Such, Maidenhead, fourth. With twelve varieties Messrs. Paul and Son were first, having an exceptionally good box, the varieties being E. F. Jungker, Grace, Iolanthe, Darknesh, Rosalie, Mignon, Kammerherr Van Hinkel, Red Indian, Admiration, Eurydice, Nymph, and H. Milesky. Mr. Humphries was second with a very neat stand, and Messrs. Burrell & Co. third.

Single varieties exhibited a great falling off in numbers, and the quality was not up to the average. Messrs. Cheal & Son won from three competitors with twenty-four bunches of ten, and if not up to their highest standard it was, considering the season, of great excellence, the flowers being in good condition—clear, bright, and fresh. The varieties were Duchess of Fife, Victoria, Mrs. Coninck, Duchess of Westminster, Mrs. Bowman, T. W. Girdlestone, Jas. Seobie (orange sport), Miss Henshaw, Amos Perry, Hugo, Beauty of Uplands, Miss Jefferies, Gulielma, Northern Star, Marie Linden, Cleopatra (new dark maroon), Alba Perfecta, W. C. Harvey, Miss Glascock (a new variety, honoured by the R.H.S.), Cetewayo, Eclipse, Miss Roberts, and Formosa. Mr. M. V. Seale also had a very rich and diversified stand, which included a new white variety named Mrs. W. Seale, growing only 2½ feet high, and was placed second, Messrs. Paul & Son, Cheshunt, being third, and Mr. Such fourth. There was no entry with twelve varieties.

#### AMATEURS.

The amateurs' classes were somewhat thin, but they comprised some very good stands. Mr. J. T. West, gardener to W. Keith, Esq., Cornwall, Brentwood, had the best stand of twenty-four Shows and Fancies intermixed, and they were unmistakeably a beautiful collection of flowers, being of large size and superbly coloured. The varieties were Arthur Rawlings, R. T. Rawlings, Harry Keith, Maud Fellowes, Mrs. Gladstone, John Henshaw, Matthew Campbell, Shirley Hibberd, Prince of Denmark, Mrs. Langtry, Glow-worm, Frank Pearce, Duke of Fife, Mrs. Saunders, Harry Turner, Clara, J. T. West, Wm. Rawlings, Henrietta, Lord Chelmsford, Willie Garrett, Henry Glascock, Mrs.

D. Saunders, and Wm. Powell. These formed one of the very best stands in the Show. Mr. T. Hobbs, St. Mark's Road, Easton, Bristol, was second with a good stand of somewhat smaller flowers, the best being J. T. West, W. Rawlings, Jos. Ashby, Mr. Harris, and Mrs. Foreman. Mr. H. Glascock, Rye Street, Bishop's Stortford, was third with small, but very fresh and well finished flowers, the remaining prize going to Mr. W. Mist, Ightham, Sevenoaks. There were six stands of twelve Show blooms, and Mr. A. Ocock, gardener to Mrs. McIntosh, Havering Park, Romford, won with fine blooms of W. Rawlings, Clara, Prince of Denmark, R. T. Rawlings, Maud Fellowes, Mrs. D. Saunders, Mr. Glascock, John Standish, Mr. Gladstone, Majestic, Geo. Rawlings, and Mr. G. Harris. Mr. S. Cooper, Chippenham, also had a very even and fresh collection of flowers, and was placed second, his R. T. Rawlings being a very fine bloom. Mr. Thos. Anstiss, High Street, Brill, was placed third, and Mr. G. Boothroyd, Red Hill, Havant, fourth. There were nine stands of six blooms, and Mr. J. Gilbert, Brocklands, Freshwater, Isle of Wight, won with J. T. Saltmarsh, Willie Garrett, Florence, Earl of Ravensworth, Mrs. Gladstone, and Jos. Ashby. Mr. Gibbs, Ightham, Sevenoaks, was second with Imperial, Mrs. Langtry, Miss Cannell, James Vick, Mrs. Gladstone, and Harrison Weir. Mr. J. Couzens, Langley's Burrell, Chippenham, was third, and Mr. Vagg, gardener to J. Theobald, Esq., M.P., Bedford, Havering, fourth.

Mr. West's was the best stand of twelve Fancies, a very even and fresh lot of flowers, the varieties being Professor Fawcett, Mrs. Saunders, Duchess of Albany, Rev. J. B. M. Camm, Buffalo Bill, Henry Eckford, Egyptian Prince, Hugh Austin, Chas. Turner, Comedian, John Britton, and Henry Glascock. Mr. S. Cooper was a very good second, his Duchess of Albany, Edmund Boston, Frank Pearce, and Dorothy being admirable. Mr. Glascock was third with smaller examples. There were eleven stands of six, Mr. Ocock winning with Peacock, Mrs. Saunders, Rev. J. B. M. Camm, Frank Pearce, Mrs. N. Halls, and Hugh Austin, all fine flowers. Mr. Boothroyd was second with Mrs. Saunders, very good; Mr. Mist third with Frank Pearce as one of his best; and Mr. Couzens fourth.

Cactus and Decorative varieties were but thinly shown. What there were, however, were good. Mr. West won with six bunches, showing Glory of Brentwood, Marchioness of Bute, Mrs. Rolfe, Mrs. Keith, Black Prince, and Mrs. Douglas. Mr. Perry, gardener to J. C. Tasker, Esq., Middleton Hall, Brentwood, was second with good flowers, but too flatly arranged to be effective; and Mr. C. Osman, South Metropolitan District Schools, Sutton, was third. These varieties in bunches of three were ineffective. Mr. Glascock won with Black Prince, Marchioness of Bute, Robert Maher, Mrs. Hawkins, Harry Freeman, and Edmund Wakley. Mr. E. Mawley, Berkhamsted, was second with Panthea, Juarez, Mrs. Hawkins, Zulu, Asia, and Honoria, small, but very attractive, Mr. S. Cooper third, and Mr. Hy. Gibbs fourth. There were two other stands.

Pompons were also scantily shown. Mr. West won with six varieties in bunches of ten, showing Fair Helen, Darkness, Fairy Tales, Grace, Leila, and Isabel; Mr. Glascock was second with very neat flowers, and Mr. Perry third. Mr. Cooper won with six varieties, six flowers of each; Mr. C. Stew, Croydon, being second; Mr. Mist third, and Mr. R. C. West, Northlands, Salisbury, fourth. There was not much to pick between any of these.

Singles were few and weak. Mr. T. W. Girdlestone won with Annie Hughes, Demon, Lady Helen, Gwendolen, Yellow Perfection, and Bessie Hatton, for six varieties in bunches of ten; Mr. Glascock second, and Mr. Osman third; none were of a very high order. Mr. Mawley was the only exhibitor with bunches of six in six varieties, and was placed first for W. C. Harvey, Victoria, Amos Perry, Miss Henshaw, Miss Roberts, and Sunningdale White. For twelve varieties, the same number of flowers to a bunch, Mr. Girdlestone again took the premier award, his varieties being Mary Evelyn, Gwendolen, Maize, Mikado, Phyllis, Marion Hood, Irene, Hester Dorothea, Sunningdale White, Edie Clegg, Tessa, and Ruth; Mr. Osman, the only other competitor, was placed second.

#### OPEN CLASSES.

In the one variety class the competition was pretty brisk. There were nine stands of dark varieties, Mr. Turner being first with Wm. Rawlings; Messrs. Keynes, Williams & Co. second with the same variety; Mr. A. Rawlings third with Geo. Rawlings; and Mr. J. T. West fourth with Arthur Rawlings. There were seven stands of light varieties, yellow excluded. Messrs. Saltmarsh & Son were first, Mr. H. Gibbs second, Mr. Seale third, and Mr. A. Rawlings fourth, all with Mrs. Gladstone. The same number competed with a yellow variety, Mr. A. Rawlings being first, and Messrs. Keynes, Williams & Co. second, with R. T. Rawlings; Mr. Mortimer third with Jos. B. Service, and Mr. J. T. West fourth with Wm. Powell. For six of any tipped Dahlia Messrs. Saltmarsh & Son were first with Mrs. Saunders, Mr. A. Rawlings second, Messrs. Keynes, Williams & Co. third, and Mr. Stew fourth, with the same variety. There were seven stands of striped, Messrs. Saltmarsh & Son being first with Frank Pearce, Messrs. Keynes, Williams & Co. second with Mrs. John Downie, Mr. Humphries third with the same variety, and Mr. A. Rawlings fourth with Frank Pearce. In the edged class Mr. J. T. West was first with his namesake, Mr. Seale second with Henry Walton, Messrs. Saltmarsh third with J. T. West, and Mr. A. Rawlings fourth with T. J. Saltmarsh.

The miscellaneous exhibits were extensive and attractive. Messrs. Cheal & Son had a collection of their Tom Thumb Dahlias in pots; a very bright display, which received a good deal of attention. Messrs. Wm. Paul & Son, Waltham Cross, had a large and very fine assortment of flowers and fruit in the auditorium, the former comprising Roses,

Dahlias, and herbaceous flowers, and it was much admired. Mr. T. S. Ware, Tottenham, had a brilliant collection of single and double Begonias, to which popular flowers he is now giving much attention, also a fine display of Dahlias. Messrs. H. Cannell & Sons, Swanley, exhibited a splendid stand of Dahlias and Begonias, the former mainly composed of Cactus and Decorative varieties, comprising the best in cultivation, the latter representing the excellent qualities of the Swanley doubles. Mr. W. Piercy of Forest Hill had a collection of early Chrysanthemums, as had Mr. H. J. Jones, Lewisham, and Messrs. Reid and Bornemann, Sydenham. Messrs. J. Laing & Sons, Forest Hill, had an admirable group of their well-known Begonias, and also a beautiful display of herbaceous flowers. Messrs. Paul & Son, the Old Nurseries, Cheshunt, were represented by an interesting assortment of hardy plants. Mr. G. Phippen, Reading, had a very attractive display of Cactus and Decorative Dahlias, and Mr. Such, Maidenhead, had a large stand of hardy flowers.

First-class certificates were awarded to the following Dahlias—\*St. Catherine, yellow Cactus; \*Kynereith, rich orange red Cactus; \*Baron Schröder, rich magenta Cactus; and Airy Fairy Lilian, Pompon, suffused pearly rose, exquisite flower, from Messrs. Keynes Williams & Co.; Rayon d'Or, small quilled Decorative variety, white, edged brownish yellow; Mars, Pompon, brilliant orange scarlet; and Lorna Doone, Pompon, from Mr. C. Turner; Beauty of Arundel, Cactus, fine bright purple crimson sport from Juarez, from Messrs. Cheal & Sons; Harlequin, Decorative, bright "Fancy" flower, yellow, flaked crimson, from Messrs. Paul & Son, Cheshunt; \*John Rawlings, Show, pale mauve, from Mr. A. Rawlings; \*John Walker, Show, white, faintly suffused lemon, from Mr. J. Walker; Ernest Cannell, orange Cactus, and \*Robert Cannell, rosy carmine Cactus, from Messrs. H. Cannell and Sons; Mrs. Keith, Decorative, distinct yellowish rose; William Powell, Show, yellow, and Arthur Rawlings, Show, crimson, from Mr. J. T. West; Evelyn, single, smooth, silky flower, tender blush, and Annie Hughes, single, very smooth circular flower, lemon centre, margined peach, from T. W. Girdlestone, Esq. Those marked with an asterisk were described somewhat more fully in our issue of August 27th.

#### CRYSTAL PALACE FRUIT SHOW.

SEPT. 4TH AND 5TH.

COMPETITION was not very keen in the majority of the classes at the Sydenham Fruit Show on Friday and Saturday last, and the quality in many cases was not equal to the customary standard. Probably the season was partly the cause of this falling off, and it is possible also that the near approach of the Edinburgh Show deterred some who intend competing in the north from risking their exhibits at the Crystal Palace. About fourteen prizes, however, were not awarded, and these, too, were of fairly good amounts.

Still, with so many classes an extensive display was provided, and considerable table space was required. Besides the fruits cut flowers and vegetables were well represented, and the National Dahlia Society's Show at the opposite end of the building constituted another attraction of much interest.

*Collections.*—The leading class was that for a collection of fruit, not less than twenty dishes; but though the prizes were £12, £8, £4, and £2, only two competitors appeared—namely, Mr. J. H. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derby, and Mr. H. W. Ward, Longford Castle Gardens, Salisbury, who were placed first and second respectively in the order named. Mr. Goodacre's collection comprised the following:—Grapes: Gros Guillaume, large bunches of fair colour; White Tokay, also large and of good colour; Black Hamburgh, of medium size, solid, and well coloured; and Muscat of Alexandria, rather small in the bunch, but fine, clean, well coloured berries. A handsome Smooth Cayenne Pine was notable, also a neat even Queen Pine. The other dishes were Williams' Bon Chrétien Pears, Bellegarde Peaches of high colour, Moor Park Apricots, Violette Hâtive Nectarines, Morello Cherries (excellent), Conqueror of Europe and Victory of Bath Melons (both capital fruits), Noblesse Peaches (admirable in size and colour), Kirke's Plum, Rivers' Orange Nectarine, Brown Turkey Figs, Coe's Golden Drop Plums, Worcester Pearmain Apples, Warrington Gooseberries, White Dutch Currants, and Filberts. The fruit throughout this collection was in good clean condition, suitable for table, and the position accorded was well deserved. Mr. Ward was only a few points behind his rival, and staged praiseworthy examples of the following:—Foster's Seedling and Alicante Grapes, Smooth Cayenne Pines, Amberwood Beauty and Hero of Loeking Melon, Sea Eagle and Prince of Wales Peaches, Elruge and Pineapple Nectarines, Kirke's and Washington Plums, Moor Park Apricots, Brunswick Figs, and Morello Cherries.

The next class was for twelve dishes of fruit, and there again only two collections were staged. Mr. T. Coomber, gardener to J. A. Rolls, Esq., The Hendre, Monmouth, was first with excellent samples of the following fruits:—Gros Maroc and Muscat of Alexandria Grapes were fine alike in bunches, berries, and colour; Bellegarde Peaches were notable for their high colour; a Smooth Cayenne Pine was well developed and ripe; Morello Cherries, Brown Turkey Figs, Blenheim Orange Melon, beautifully netted; Pineapple Nectarines, Jargonelle Pears, Countess Melon, and Kirke's Plums and Apricots completed the collection. Mr. Ward was again second, showing Morello Cherries, Sea Eagle Peaches, Washington Plums, Moor Park Apricots, and Brown Turkey Figs in admirable condition.

Still another class was devoted to collections of fruits, this time for

eight dishes, and here the competition was better, as the whole of the four prizes were awarded. Mr. A. Ocock, gardener to Mrs. McIntosh, Havering Park, Romford, secured first honours with most creditable fruits, every dish good, and in one or two cases scarcely surpassed in the Show. His Black Hamburg Grapes were of fine colour. The Muscat of Alexandria Grapes were remarkable for their clear bright appearance. Havering Park Melon was a large oval beautifully netted fruit. Pitmaston Orange Nectarines and Noblesse Peaches were both fine; Astrachan Apples, Brunswick Figs, and Williams' Bon Chrétien Pears were also shown in good condition. Mr. W. Nash, Badminton Gardens, Chippenham, was second, his most noteworthy dishes being Beauty of Bath Apples very brightly coloured, Barrington Peaches large, and Alicante Grapes of excellent colour. Mr. W. Howe, Park Hill Gardens, Streatham, was third, including fine Madresfield Court Grapes; and Mr. C. Warden, gardener to W. D. Watson, Esq., Clarendon Park, Salisbury, was fourth.

**Grapes.**—The chief class for Grapes, that for ten varieties, two bunches of each, was not satisfactory. Only one collection was staged, and this did not include Grapes of very remarkable merit. Mr. C. Warden was adjudged the first prize for the following varieties—Lady Downe's, Black Hamburg, Muscat of Alexandria, Muscat Hamburg, Gros Maroc, Buckland Sweetwater, Alicante (this and the two preceding varieties were represented by fine bunches), Gros Colman, Foster's Seedling, and Madresfield Court.

With a collection of five varieties Mr. G. Reynolds, gardener to the Messrs. Rothschild, Gunnersbury Park, Acton, took the lead, staging Black Hamburg, medium sized bunches; Chasselas Napoleon, clear even bunches and berries; Alicante, small berries, solid bunches; Muscat of Alexandria, excellent colour; and Gros Maroc, large berries and solid bunches. Mr. T. Osman, The Gardens, Ottershaw Park, Chertsey, was the only other exhibitor, and secured the second prize with Alicante, Muscat of Alexandria, Black Hamburg, Mrs. Pearson, and Lady Downe's.

In the classes restricted to certain varieties of Grapes, the competition was much keener, and some excellent samples were shown. For instance, there were ten entries with three bunches of Black Hamburg, and Mr. J. Gibson, Draycot Gardens, Chippenham, won first honours with even solid bunches well ripened and of capital colour. Mr. G. Reynolds was second with compact bunches of good colour; Mr. W. Nash being third.

Six competitors exhibited Muscat of Alexandria, and Mr. J. Dumble, gardener to Sir C. Phillips, Bart., Picton Castle, Haverfordwest, won first for ripe well-coloured samples, but rather disfigured by spots on some of the berries; Mr. Reynolds won second with large bunches slightly wanting in colour; and Mr. G. Winter, gardener to W. Man, Esq., Barrow-on-Humber was third, large clean bunches of good colour.

Gros Maroc Grapes were shown by five exhibitors, Mr. Reynolds leading with large bunches of excellent colour; Mr. C. J. Waite, gardener to the Hon. W. P. Talbot, Glenhurst Gardens, Esher, was second with good bunches, but the berries somewhat rubbed; Mr. T. Robinson, gardener to W. Lawrence, Esq., Elsfeld House, Hollingbourne, Kent, was third, his bunches being of good size but deficient in colour.

Of Madresfield Court seven exhibits were staged, Mr. J. Gibson winning first honours for much the best examples, the bunches very even, the colour and bloom good. Mr. Griffin, gardener to the Misses Christy, Coombe Park, Kingston, was second, the berries being very large, but the colour not first rate; and Mr. Ward was third for medium specimens.

Seven also entered with Alicante. Mr. W. Marsh, 9, Henrietta Villas, Bath, secured the premier award with even bunches of excellent colour. Mr. Howe followed with large bunches bearing dense bloom, but they appeared to have suffered a little in transit to the Show. Mr. Griffin was third with even bunches, the colour capital. For any other white variety Mr. Warden took the lead amongst half a dozen competitors with Buckland Sweetwater, well proportioned clean ripe bunches. Mr. Bury, The Gardens, Tewkesbury Lodge, Forest Hill, followed with Foster's Seedling, large bunches; and Mr. Reynolds was third for the same variety, both these being somewhat green. In the any other black Grape class Mr. Ward was placed first with three good bunches of Mrs. Pince, but much deficient in colour. Mr. Reynolds was second, showing Alnwick Seedling in excellent condition; and Mr. Bury was third.

Two classes were provided for baskets of Grapes, and some excellent examples were staged, especially in that for a basket of black Grapes. In this Mr. D. McIntosh, gardener to J. Parrott, Esq., East Barnet, was first with Gros Maroc, beautifully coloured and weighing 12½ lbs. Mr. E. Langley, gardener to T. Twigg, Esq., Croxted House, West Dulwich, was second with the same variety, weighing 12 lbs.; and Mr. Iggulden was third, also with Gros Maroc. There were six other unsuccessful exhibitors. In the white Grape class Mr. W. Lane, King's Road, Ascot, was first, showing Muscat of Alexandria, fine in bunch, berry, and colour. Mr. Winter followed with the same variety of a very deep colour; and Mr. Bury was third for Duke of Buccleuch, excellent in bunch and berry.

**Peaches.**—These were fairly represented in numbers, and the majority of the fruits were good in size, colour, and ripeness. Mr. W. Iggulden, gardener to the Earl of Cork, Marston House, Frome, won the leading prize with four dishes of Peaches, good sized fruits of Sea Eagle, Barrington, Walburton Admirable, and Crimson Galande. Mr. W. H. Divers, gardener to J. T. Hopwood, Esq., Ketton House, Stamford,

followed closely, all his fruits being of excellent colour. The varieties were Crawford's Early, Bellegarde, Prince of Wales, and Grosse Mignonne. Mr. J. McIndoe, Hutton Hall Gardens, Guisborough, took the third place, showing Golden Eagle, Princess of Wales, Exquisite, and Sea Eagle.

There were twelve entries in the class for a single dish of Peaches, and the first prize was won by Mr. W. Lawson, The Gardens, Lovell House, Crawley, who had fine fruits of Grosse Mignonne; Mr. Ward followed with Sea Eagle, and Mr. A. Gibson, gardener to T. F. B. Atkins, Esq., Halstead Place, Sevenoaks, was third with Barrington.

**Nectarines.**—With four dishes of Nectarines Mr. Divers gained the chief place, exhibiting handsome fruits of Pincapple, Lord Napier, Victoria, and Rivers' Orange. Mr. McIndoe was second for smaller finely coloured fruits of Darwin, Pincapple, Humboldt, and Spenser. Mr. R. Potter, Kemsay, was third. In the single dish class Mr. Divers was first for excellent specimens of Lord Napier; Mr. Bury followed with the same variety, and Mr. Potter was third with Humboldt.

A class was devoted to a collection of Peaches and Nectarines, six dishes of each, and in this Mr. Divers continued his success, taking premier honours with admirable fruits of the following varieties:—Peaches, Crawford's Early, Grosse Mignonne, Dymond, Violette Hative, Prince of Wales, and Bellegarde. The Nectarines were Lord Napier, Victoria, Violette Hative, Pineapple, and Dryden. Mr. Potter was a good second, some of his best dishes being Exquisite and Mr. Gladstone Peaches, with Rivers' Orange and Goldoni Nectarines.

**Melons.**—To these fruits two classes were devoted, and in each the competition was exceedingly keen, much larger than that in any other class of the whole Show. For one green-flesh Melon there were twenty-three entries, Mr. A. Gibson leading with Halstead Favourite, beautifully netted, the flesh deep, of good flavour; Messrs. Goodacre and W. Palmer following with good fruits but unnamed. In the scarlet flesh variety class the exhibitors were only one less in number. Mr. Palmer was first for a handsome fruit of Sutton's Triumph; Mr. J. Matthews, gardener to W. Stride, Esq., Coulsdon Grange, Caterham, was second with Blenheim Orange, and Mr. Coomber was third with the same variety.

**Plums.**—Of the eleven entries with four dishes of red Plums Mr. H. Markham, gardener to Viscountess Falmouth, Mercworth Castle, Maidstone, won the first place, showing Victoria, Goliath, Sultan, and Prince of Wales, large, and finely ripened. Mr. Iggulden took the second place with Victoria, Pond's Seedling, Angelina Burdett, and Prince of Wales; Mr. J. Neighbour, Bickley, being third for Pond's Seedling, La Delicieuse, Victoria, and Cox's Emperor. The entries in the next class for yellow and green Plums were also eleven, and there Mr. Iggulden was first for good examples of Transparent Gag, Golden Emperor, Jefferson, and Oulins Golden. Mr. Neighbour followed, his best fruits being Pershore Yellow, and Magnum Bonum; while Mr. Ward was third, his collection including a fine dish of Washington. Ten lots of purple Plums, four dishes each, were contributed, and Mr. A. Bolton, gardener to Earl Ashurst, Montreal, Sevenoaks, was accorded the first place with Prince of Wales, Diamond, Prince Englebert, and Kirke's. Mr. Ward was a close second, having Mitchelson's, Belgian Purple, Diamond, and Kirke's; and Mr. Neighbour was third, a good dish of Diamond being conspicuous in his collection. Only one exhibit of three dishes of Figs was shown, for which Mr. J. Wallis, gardener to R. Sneyd, Esq., Keele Hall, Newcastle, Staffs, was awarded the first prize. The varieties were Brown Turkey, Negro Largo, and Brunswick.

**Apples and Pears.**—These were not largely represented, but the collections staged were of excellent quality. For twelve varieties of Apples (orchard house), Messrs. Bunyard & Co., Maidstone, the only exhibitors, were deservedly first, and it would have been difficult to surpass their specimens. The varieties shown were Stone's, Alexander, The Queen, Mother Apple, Lady Sudeley, Red Bietigheimer, Warner's King, Washington, Peasgood's Nonesuch, Bismarck, Ribston Pippin, and Melon Apple.

Mr. McIndoe was first for ten varieties of Pears (orchard house), good samples of Beurré d'Amanlis, Van Mons Leon Leclerc, Brockworth, Pitmaston Duchess, Doyenné du Comice, Souvenir du Congrès, General Todleben, Clapp's Favourite, Beurré Clairgcau, and Louise Bonne of Jersey. Messrs. Potter and Bunyard followed closely. For outdoor Apples and Pears, Messrs. Bunyard, Waterman, and Paul and Son, Cheshunt, were the successful exhibitors. With collection of six varieties of Tomatoes, Messrs. R. Spinks, A. Rawlings, and T. Roberts secured the prizes in the order named.

#### CUT FLOWERS AND PLANTS.

We cannot refer in detail to the exhibits under these heads, but the following were the prizetakers in the principal classes:—

**Open Classes.**—Collection of Gladioli spikes, not less than thirty-six varieties or over 100 spikes.—First, Messrs. J. Burrell & Co., How House Nurseries, Cambridge; second, Mr. W. H. Fowler, Claremont, Taunton. Twenty-four Quilled Asters.—First, Mr. J. Walker, Thame, Oxon; second, Messrs. Saltmarsh & Son, Chelmsford; third, Messrs. Webb and Brand, Saffron Walden. Twenty-four French Asters.—First, Messrs. Saltmarsh & Son; second, Mr. W. F. Catlin, 9, Midsummer Buildings, Bath; third, Messrs. Webb and Brand. Twenty-four Hollyhock blooms, distinct.—First, Messrs. Webb & Brand; second, Mr. Thos. Hobbs, Easton, Bristol; third, Mr. W. Smith, Kingswood, Bristol. Collection of cut stove and greenhouse flowers.—First, Mr. A. Gibson, Sevenoaks; third, Mr. W. Slogrove, Gatton, Reigate. Six Cockscombs, grown in pots not exceeding 8 inches.—First, Mr. T. Crosswell, Eden Park Gardens,

Beckenham; second, Mr. T. Slater, York House, Lower Sydenham. Collection of early flowering Chrysanthemum indicum, grown in pots not exceeding 8 inches.—First, Messrs. Reid & Bornemann, Sydenham; second, Mr. H. J. Jones, Ryecroft Nursery, Lewisham; third, Mr. W. Piercy, 89, Beadwell Road, Forest Hill.

*Amateurs.*—Eighteen Gladioli spikes, distinct.—First, Mr. W. H. Fowler, Claremont, Taunton; second, Mr. E. B. Lindsell, Bearton, Hitchin; third, Mr. A. G. Brown, Wethurn, Sunderland. Twelve Hollyhock flowers, distinct.—Second, Mr. Thomas Hobbs; third, Mr. J. Newman.

#### SPECIAL PRIZES.

The exhibits in competition for the numerous prizes offered was good, and they occupied considerable space. The awards were as follows:—

comprising many of the useful novelties which have originated at Sawbridgeworth. Mr. W. Taylor, Uxbridge, had a collection of Apples; and Messrs. William Paul & Son, Waltham Cross, had with their beautiful group of Roses a collection of 150 dishes of Apples and Pears.

#### THE FINEST VINE IN BRITAIN.

IN our issue of the 6th ult. a note appeared under the above heading briefly describing a wonderful Vine at Roehampton. Its seven rods, straight as lines, extend along a roof 224 feet, the aggregate length of the rods thus exceeding a quarter of a mile, the weight of crop exceeding

FIG. 42.—THE MANRESA VINE.

The prizes offered by Messrs. James Carter & Co. for the best six fruits of Carter's Blenheim Orange Tomato were won by Mr. J. Slater, Lower Sydenham; Mr. Joseph Slater, Shepley House, Carshalton; and Mr. W. Palmer in the order named. Messrs. Sutton & Sons' prizes for the best collection of vegetables, nine sorts, were secured by Mr. C. J. Waite, Mr. W. Palmer, Mr. J. T. Barney, Boxley Road, Maidstone; and Mr. E. Chadwick, Hanger Hill House, Ealing; the same firm's prizes for Perfection Tomatoes, nine specimens, going to Mr. C. J. Waite, Mr. J. Gibson, Mr. Thos. Crosswell, and Mr. J. T. Barney. Messrs. Daniels Bros. offered a prize for the best fruit of Daniels' Westley Hall Melon, which was won by Mr. W. Chessleburgh, Worsted House, Norwich.

The non-competing fruit exhibits were not very numerous, but Messrs. T. F. Rivers & Son, Sawbridgeworth, had a magnificent collection of fine fruits—Plums, Peaches, Nectarines, Grapes, and Pears,

1000 lbs. In a subsequent issue (the 27th ult.) a correspondent said the Speddoek Vine must be finer because it produces an equal weight of fruit in a house only half the size. Another "Seot" now writes, and says if the greatest weight in the least space is to be the test for the "finest Vine" he shall put in a claim for a single rod bearing a prodigious crop. He thinks a fine Vine and fine crop somewhat different, and claims for the Kinnell Vine the honour of being "the finest in Britain." He concludes by asking "for a photograph of the Manresa Vine to appear in the Journal so that we can judge for ourselves." A view of a portion of the Vine has appeared. The whole could not be shown, and appears again for examination by new readers. Will our friend now return the compliment and send a photograph of what he

considers the "finest Vine in Britain?" It would perhaps not be without interest to have the weights of heavy crops of Grapes grown on a single rod, stating the extent of roof space thus occupied.

## HORTICULTURAL SHOWS.

READING.—SEPTEMBER 2ND.

A DISHEARTENING disaster, similar to that which rendered the great Exhibition at Newcastle abortive in the previous week, attended the preparations for the Show of the Reading Horticultural Society on the above date. In the Forbury Gardens, a public pleasure ground in the town of seeds and biscuits, stand the ruins of Reading Abbey, and within the walls, still erect and strong, notwithstanding that they are dark with age, it has been the custom to fix a huge tent covering the whole space, the plants being arranged on grassy mounds at the ends, sides, and in the centre. As may be imagined, a picturesque and beautiful effect was produced, rendering the Show of exceptional interest. This year the canvas erection was fixed as usual, but in the heavy gale that prevailed on the day previous to the Exhibition the wind found its way beneath the tent and tore it to pieces. Fortunately no exhibits were staged, but the Committee found themselves in a very embarrassing position. To erect fresh tents would mean a heavy additional drain upon an exchequer already seriously depleted by weather vagaries at other shows, with the contingency of their being also dashed to pieces. However, the gale abated on the evening of the 1st, and with an energy and courage deserving the highest praise the officials set to work early on Wednesday morning and made a determined effort to retrieve the initial misfortune and keep faith with the public by holding the Show. Fresh tents were procured and erected as rapidly as possible, a new plan of arrangement was quickly sketched out, and the exhibits taken in hand and promptly "located." The result was that when our representative reached the ground soon after 11 A.M. nearly everything was in place, and at 2 P.M. the judging was completed, and everything in readiness for the admission of the public as usual. The utmost credit attaches to everyone connected with the undertaking. The task was an uphill one, but it was successful, and Mr. William Smith, the Secretary, together with every other official who assisted, merits warm commendation. The Society must inevitably suffer severely by the *contretemps*, as it was stated that the large tent was their own property, and to replace it would cost a very large sum; however, it is to be hoped that it will be found to admit of repair, and that they will safely weather the storm, and continue their good work as of old. Let friends rally round as well as the officials did their duty, and the efforts of the latter will not be in vain.

The Show, as usual, was a good and interesting one. Plants and vegetables were splendidly shown, and fruit moderately well. The principal awards are referred to in the following notes.

The best group of plants, covering a space of 12 by 10 feet, was staged by Mr. Aitken, gardener to C. Meeking, Esq., Ritchings Park. White, supplied by Lilliums, *Pancratiums*, *Tuberoses*, and *Campanula pyramidalis alba*, largely predominated. The latter showed up splendidly towards the back, and should be frequently used in such arrangements. *Gloxinias*, small *Crotons*, *Francoa ramosa*, *Vallota purpurea*, and one or two *Begonias* were tastefully interspersed. Mr. Bright, gardener to R. Karslake, Esq., Whiteknights Park, was second with a handsome but less graceful display. Mr. Butcher, gardener to G. Palmer, Esq., Reading won in the smaller group class, Mr. Sumner, gardener to G. Philbrick, Esq., Reading; and Mr. Balchin, gardener to B. Simonds, Esq., Reading, following.

Variegated and handsome foliage plants were well shown by Mr. Aitken, his *Crotons* being very clean and healthy. Mr. Mould, Pewsey, was second. Mr. Aitken also had the best six stove and greenhouse plants, *Bougainvillea glabra*, *Eucharis grandiflora*, *Ixora Williamsi*, and a *Clerodendron* being very finely flowered plants in the best condition, doing him great credit. Mr. Mould, who was second, had a grand *Erica Eweriana superba*, a fine *Lapageria alba*, but not yet in full bloom, and handsome specimens of *Erica McNabiana rosea* and *Phenocoma prolifera Barnesi*. Mr. Aitken had an excellent exhibit in the class for stove and greenhouse Ferns, the plants being large and in perfect health; *Microlepia hirta cristata*, *Gymnogramma peruviana argyrophylla*, *G. Alstoni*, *Davallia fijiensis plumosa*, and *Davallia Mooreana* were all good, the latter superb. Mr. Willis, gardener to H. J. Simonds, Esq., also had a grand plant of the latter in his second prize lot, together with several other good plants. Mr. Dockerill was third. Mr. Mould won with three Palms, Mr. Turton second; and Mr. Dockerill was successful with *Selaginellas*; Mr. Mayne, gardener to Lord Saye and Sele, Reading, following.

The greenhouse and conservatory flowering plants were a very bright feature. Mr. Lockie's *Begonias* were very good, and were placed first; but Mr. Dockerill, gardener to G. W. Palmer, Esq., Reading, was not far behind. His plants were smaller, but they were dwarf and the flowers fine. Mr. Booker, gardener to C. Littledale, Esq., Twyford, had some excellent Lilliums, dwarf and full of bloom, the lancifoliums being particularly good. Mr. Dockerill was third, but his plants were inferior both in diversity and quality. Mr. Lockie had some capital *Cockscombs*. He grows these plants admirably, and beat Mr. Booker very decisively. The latter won with Balsams. Bedding *Pelargoniums* were in excellent condition, Mr. Bright having a splendid half-dozen, large, well clothed, and full of bloom. Mr. Castle, gardener to Mrs. Malet, Twyford, had some very richly coloured *Coleuses*, and won easily from Mr. Turton, gardener

to J. Hargreaves, Esq., Maiden Erleigh. *Fuchsias* from Mr. Bright were splendid examples of culture, being pyramids 7 to 10 feet high, healthy, and full of bloom. These had been grown from cuttings inserted in February, 1890, and richly merited the premier award. *Achimenes* were not of a very high order.

Cut flowers were abundant. Mr. Such, Maidenhead, had some fine clusters of herbaceous *Phloxes*, and was placed first. Mr. Booker won with eighteen bunches of cut flowers, these being cut from stove and greenhouse plants, and Mr. Castle followed. With twelve, Mr. Howard, gardener to Mrs. Myers, Benham Park, was first, and Mr. Bright second. Messrs. Cheal & Sons, Crawley, had one of their well-known delightful displays of single *Dahlias*, beautifully set up, and they won easily, Mr. Such being a good second with flowers more loosely arranged. The latter had a fine white named *Maud Such*, and the new varieties *Gulielma* and *Miss Glasscock* were noticeable in the first prize box. Messrs. Perkins & Sons won with *Roses*, the flowers being surprisingly fresh and good, Mr. Such was second. Mr. Thorne, gardener to Major Joicey, Sunningdale Park, third, and Mr. Turton fourth. The quilled *Asters* from Mr. Walker of Thame formed a charming stand, and his French varieties were little less attractive. He was placed first for each. Mr. Mould had some capital *Gladioli*, and won very easily; while Mr. Walker was victorious with *Zinnias*. *Hollyhocks* were not a success, but double *Dahlias* were very good. Messrs. Mortimer and Walker were first and second with eighteen, but although the former won in this class their positions were reversed in that for twelve. Each box contained excellent blooms.

Fruit was fairly good taking it altogether and considering the season. Mr. Aitken won with eight dishes, his *Black Grapes* (*Alicante*) being good, but the *Museats* not well coloured. *Sea Eagle Peaches* were excellent. Mr. Goodman, gardener to Miss Hammersley, Bourne End, was not far behind; his *Grapes* were somewhat weak, but his *Peaches* (*Bellegarde*) and *Melon* (*La Favourite*) were good. Mr. Perkins, gardener to the Right Hon. W. H. Smith, Henley, was third. Mr. Johnson, gardener to A. Gilliatt, Esq., won with six dishes, a capital collection of fruit. Mr. Paxton, gardener to the Hon. C. S. Irby, Taplow, being second, and Mr. Smith, gardener to R. Ovey, Esq., third. Mr. Turton was first with *Black Hamburg Grapes*, the bunches good but not perfectly coloured; Mr. Ashby, gardener to J. R. King, Esq., Whitechurch, being second, and Mr. Osman, gardener to L. Baker, Esq., Ottershaw Park, third. For any other black the latter won with *Alicante* in admirable condition; Mr. Pound, gardener to A. Sutton, Esq., Reading, being second, and Mr. Waite, gardener to Colonel the Hon. W. P. Talbot, Esher, third; extra prizes going to Mr. Willis and Mr. Turton. Mr. Johnson had some splendid *Museats* and won easily, Mr. Lane, gardener to Miss Dunning Smith, Ascot, being second and Mr. Pound third; extra prizes going to Mr. Pound, gardener to G. May, Esq., and Mr. Osman. These formed a very strong class. Mr. Ashman, gardener to C. Crews, Esq., Billingbear, won with any other white, showing *Buckland Sweetwater*, Mr. Smith second with *Golden Queen*. *Peaches*, *Nectarines*, *Apricots* and *Figs* were all good, the principal winners being Messrs. Pound, gardener to G. May, Esq., with a splendid dish of *Bellegarde Peaches*; Smith, Paxton, Howard, Ashman, Bright, Ashby and Dockerill. *Plums* were abundant and fairly good, Mr. Goodman having the best dishes. The winner's card for eating Apples was lost, but Mr. Webb, Benham, was second and Mr. Dockerill third. The latter had some fine dishes of culinary varieties, which were also admirably staged by Messrs. Turton, Aitken, Goodman and Webb. Messrs. Cheal & Son had an excellent display not for competition. Mr. Goodman won with a basket of miscellaneous fruits; and prizewinners in other classes were Messrs. Read, Allum, Goodman, Paxton, Howard, Turton, Kneller, Lees, and Booker. Messrs. Sutton's prizes for *Melons* were won by Messrs. Goodman, Haslam, Dockerill and House. *Hero of Lockinge* and *Sutton's Triumph* were good, and a green flesh variety without a label, probably *La Favourite*, was splendid.

The vegetables, principally in competition for special prizes, covered tabling 120 yards long in the open air, and were a magnificent display. Messrs. Sutton & Sons offered over fifty prizes, and these brought some good produce. Turnips were excellent, as also were Lettuces, Runner Beans (*Sutton's A1*), and Peas (*Duke of Albany* and *Royal Jubilee*). Tomatoes, too, were very good, especially *Perfection* and *Golden Queen*. Parsnips (*Student*) were well up to the average. Onions were fair, and Leeks moderate, with the exception of Mr. Lye's samples of *Prizetaker*, which were very fine. Of Sutton's *Sulham Prize Celery* there were some splendid sticks. Sutton's *Autumn Mammoth Cauliflower* was good, and their new *Intermediate Carrot* very fine. Messrs. Lye, gardener to W. K. Kingsmill, Esq., Sydmonton; Waite; Pope, gardener to the Earl of Carnarvon, Highclere; Durman, gardener to J. W. Workman, Esq., Reading; Lockie, Palmer, Kneller, Balchin, Scammell, gardener to the Rev. St. John Thackeray; Booker, Knight, Pound, Haslam, gardener to General Swettenham; Ashby, Turton, Goodman, Dockerill, and House were the prizewinners in these classes, Messrs. Lye, Lockie, Waite, Pope, and Kneller showing the most prominently. Messrs. Carter & Co., High Holborn, London, offered prizes for the best collections of vegetables, and these also produced some fine produce. The first prize of three guineas was won by Mr. Pope, who had a splendid exhibit. Carter's *King of the Russets Potato*, *Summer Favourite Carrot*, *Jersey Lily Turnip*, *Standard Bearer Celery*, *Perfection Beet*, and *Telegraph Peas* were all admirable examples. Mr. Waite's second prize collection was very little inferior, his *Telegraph Peas*, *Holborn Model Leeks*, *Standard Bearer Celery*, and *Delight Potato* being very fine. Mr. Palmer, gardener to the Hon. Hume Dick, Thames Ditton, was a highly

creditable third, having good examples of Holborn Masterpiece Runner Bean, and Abundance Potato amongst others. Mr. C. Fidler, Reading, also offered prizes for a collection of vegetables. The first was won by Mr. Kneller, who had splendid Perfection Tomatoes, Rousham Park Onion, and Clayworth Park Celery. Mr. Waite was again second, and Mr. Goodman third. Mr. Fidler also offered prizes for his excellent Potatoes. Messrs. Webb & Son, Wordsley, offered special prizes for collections, which brought out some capital produce. The first prize went to Mr. Kneller, who had excellent examples, Rousham Park Onion, New Intermediate Carrot, Satisfaction Potato, Webb's Prize Pink Celery, and Webb's Perfection Tomato were all excellent. Mr. Lye was placed second, his Satisfaction Potatoes being very fine. Mr. Pope was third, and Mr. Lockie fourth.

There were many excellent exhibits in the amateurs' and cottagers' classes, but want of space forbids their being particularised. Mr. Phippen of Reading had a small tent to himself, in which he had a large bank of plants and flowers very effectively arranged. Mr. Such had several stands not for competition.

#### [BATH AUTUMN SHOW.—SEPTEMBER 2ND AND 3RD.]

OF the five shows annually held at Bath the fourth or "Autumn Floral Fête" is always the most popular, nothing but fine weather being wanted to make it a complete success. On the whole the Committee may be said to have been fortunate in their choice of dates, only a few heavy showers falling on the first or opening day. In some respects the display generally was scarcely equal to what has been seen in former years, the falling off being most perceptible in the Fuchsia classes, and this can easily be accounted for, some specimens having been lost during the last winter and many badly damaged by stormy weather. The best nine specimens were shown by that veteran raiser and grower, Mr. J. Lye, gardener to the Hon. Mrs. Hay, Market Lavington. These were all about 10 feet high, somewhat closely tied in and beautifully flowered, the varieties being Bountiful, Duchess of Fife, Lye's Favourite, Lye's Rival, Abundance, Novelty, Mrs. Bright, Final, and Charming. The second prize went to Mr. G. Snell, gardener to Mrs. Counsell, Bath, who had much larger specimens; but in a very backward state as regards flowering. For six specimen Fuchsias Mr. W. Marehant, gardener to Mrs. Jolly, Bath, was well first, having perfect pyramids of Arabella, Bountiful, Charming, Doel's Favourite, Lye's Favourite, and Elegance. With four varieties Mr. W. Marsh was first, and Mr. J. H. Wilcox, second; while the prizes for single specimens of different colours were principally taken by Messrs. Lye, Snell, and Wilcox.

Stove and greenhouse plants in and out of flower made a good display, most of the classes being well filled. With eighteen specimens Mr. J. Cypher, Cheltenham, was easily first, having *Kentia Canterburyana*, *Caryota sobolifera*, *Crotons mutabilis*, *Newmanni*, and *angustifolius*, *Allamanda nobilis*, and other specimen plants in perfect condition. Mr. J. Currey, gardener to Colonel Pepper, Salisbury, was a creditable second, and was also well first for eight ornamental foliaged plants, Mr. G. Dagger, gardener to Mrs. Simms, being second. The best six flowering plants were shown by Mr. W. McD. Bennett, gardener to C. W. Mackillop, Esq., Bath, who had good specimens of *Stephanotis floribunda*, *Bougainvillea glabra*, *Allamanda Hendersoni*, *Clerodendron Balfourianum*, *Erica Eweriana*, and a *Dipladenia*. Mr. G. Tucker, gardener to Major W. P. Clarke, Trowbridge, was a very close second, his specimens, though smaller, being better flowered than Mr. Bennett's. With single specimens Messrs. Tucker and Cypher were the most successful. Mr. Cypher had a first for six varieties of Heaths, and was also well first for six Orchids, the latter consisting of *Odontoglossum grande*, *Cattleya Gaskelliana*, *Odontoglossum Harryanum*, *Oncidium ineurum*, *Vanda cœrulea*, and *Epidendrum prismatocarpum*. Exotic Ferns were not so numerous as usual. Mr. G. Tucker was first for twelve, showing fine specimens. Messrs. Cole & Son, Bath, were second. For six varieties Mr. T. Truckle, gardener to T. Carr, Esq., was first, and Mr. Currey second.

The best Zonal Pelargoniums were shown by Mr. Tucker; Messrs. Marchant, Oakhill, W. J. Stokes, S. Tottle, Cole & Son, and G. L. Palmer also being successful in different Pelargonium classes. Messrs. Cooling and Sons were most successful with Lilioms, showing these in beautiful condition in two classes, Mr. Truckle also being successful. Coekscombs were good, Messrs. Cooling & Son having the best. Mr. G. L. Palmer was the most successful exhibitor of Tuberous Begonias, Messrs. Blackmore and Clarke also showing well in both classes. Coleus were wretchedly bad, while the British Ferns were both badly grown and wrongly named. The collection of the latter, however, as shown not for competition by Mr. Harris, Clifton Zoological Gardens, formed an admirable group, not often seen. There were only three competitors in the class for a group of miscellaneous plants arranged for effect on a space not less than 100 square feet, but all made highly creditable displays. Mr. J. Cypher was first, his exhibit comprising valuable Orchids, Palms, Crotons, Lilioms, Ferns, and Grasses arranged in a light and artistic manner. Mr. J. Currey was second for a very tastefully arranged group a little weak in the front, while the third prize went to Mr. Bennett.

Cut flowers are always a great feature at these autumn shows, and on this occasion appeared to be more numerous and better than ever. Roses were surprisingly good. With twenty-four varieties Dr. S. P. Budd, Bath, was well first; Messrs. Perkins & Sons, Coventry, were second. Very good also were the first prize twelve varieties shown by Dr. Budd. Messrs. Perkins & Sons were again second. For twelve Teas equal firsts were awarded to A. Hill Gray, Esq., Bath, and Dr. Budd, each having

several excellent blooms. A fine display was made by W. H. Fowler, Esq., Taunton, in the class for thirty-six spikes of Gladioli, this comparatively new exhibitor easily winning first honours; Mr. Vincent Slade being second, and Mr. R. H. Poynter, Taunton, third. With twelve varieties of Gladioli Mr. A. A. Walters, Bath, was first, and Mr. S. Tottle, Taunton, second. Dahlias were not particularly numerous, but the prizewinning stands were all good. Messrs. Heath & Sons, Cheltenham, were placed first for twenty-four varieties, Mr. Humphries, Chippenham, being a very close second, and Mr. J. Nation third. In the class for twelve varieties Mr. T. Hobbs, Bristol, took the lead, Mr. J. Newman being second, and Mr. W. Smith third. For twelve Fancy Dahlias Mr. G. Humphries was first, Mr. J. Nation second, and Messrs. Heath & Sons third. Single Dahlias were beautifully shown by Messrs. T. Truckle, who was first, and A. A. Walters, second. The best collection of bunches of stove and greenhouse flowers was shown by Messrs. Cole & Son, the second prize going to Mr. H. Pocock; Mr. G. Pymm, gardener to Mrs. Gouldsmith, Trowbridge, being third. A grand display was made in the class for herbaceous flowers, no limit being placed on the number of varieties shown. With these Messrs. Cooling and Sons were first, Mr. A. A. Walters second, and Mr. Marchant third. Annuals again were beautifully shown in unlimited collections, one unfortunate exhibitor being disqualified for having a bunch of *Salvia eocinea*. Mr. Marchant was first, Mr. C. Baker second, and Mr. J. Stuckey third. Classes were also provided for Zonal Pelargoniums, Verbenas, and Hollyhocks, Mr. W. Smith, a noted grower, being easily first for the latter. Asters, both French and German, were extensively shown, and fine blooms were to be seen. Messrs. Jones, Budd, Lansley, and Catlin were the principal prizewinners with these. A magnificent hand bouquet gained Messrs. Perkins & Sons the first prize, Mr. C. Winstone, Clifton, being a creditable second. The competition with vases or epergnes was very keen. Mr. J. Cypher was first and Mr. C. Winstone second.

One large tent was wholly devoted to fruit, and this did not provide sufficient room. There were four competitors with collections of twelve varieties, but Mr. W. Nash, gardener to the Duke of Beaufort, Badminton, was easily first, having good Alicante and Muscat of Alexandria Grapes, handsome fruit of Golden Gem and Countess Melons, exceptionally fine Barrington and good Bellegarde Peaches, Downton and Pineapple Nectarines, Moorpark Apricots, Jargonelle Pears, Angelina Burdett Plums, and Black Tartarian Cherries, all in excellent condition. Mr. G. Pymm was a creditable second, and Mr. A. Miller, gardener to W. H. Long, Esq., Rood Ashton, a close third. Another class, that for eight bunches of Grapes in four varieties, was fairly filled on this occasion. Mr. W. Taylor, gardener to J. Chaffin, Esq., was easily first, having grand and perfectly coloured bunches of Muscat of Alexandria, Alicante, Gros Maroe, and Alnwick Seedling. Mr. J. Gibson, gardener to Earl Cowley, Draycot, was a creditable second, Madresfield Court and Black Hamburgh being good in this collection. Mr. J. Bury, gardener to C. Bayer, Esq., London, was third. Mr. Taylor was placed first for two very good bunches of Muscat of Alexandria, the second prize going to Mr. J. Marshall, gardener to J. Dole, Esq., Mr. W. K. Waite being third. In the class for any other white Grape Mr. J. Marshall was easily first for two grand bunches of Buckland Sweetwater, probably the best yet seen at Bath, Mr. J. Atwell being second with the same variety in good condition, and Mr. S. Fletcher third.

The best three bunches of Black Hamburgh were shown by Mr. J. Gibson, these being good in every way. Miss Marriott was second, and Mr. W. Nash a close third. In the any other black class Mr. Taylor led with good Madresfield Court, Mr. W. Nash following with Alicante in perfect condition, and with the same variety Miss Marriott was third. Melons were well shown in two classes in addition to those for which Messrs. Sutton & Sons offered special prizes. The principal prizewinners were Messrs. H. Chislett, gardener to E. T. D. Foxcroft, Esq.; T. Wilkins, gardener to Lady Theodore Guest, Blandford; W. Haskell; J. Gibson; C. Adlam, gardener to J. A. Martin, Esq.; and A. Lemsley. Peaches were somewhat poor, and Nectarines not much better. With the former the principal prizewinners were Messrs. W. Fidler, gardener to Baron C. de Tuyl; F. Fletcher, gardener to Capt. J. G. Bayley; A. Holbrook, gardener to A. G. Hayman, Esq., Frome; T. Wilkins; and F. Rice, gardener to Mrs. Home. Mr. J. Bury was well first in the principal Nectarine class, having a grand dish of Victoria; Messrs. F. Fletcher, T. Wilkins, and W. Coombes, gardener to J. W. Langdown, Esq., being the other prizewinners. A capital display of Plums was provided, such serviceable sorts as Kirke's, Jefferson, Green Gage, Washington, Victoria, and Pond's Seedling, being the best represented. Pears, again, were very numerous and good. Mr. Bannister was first for three varieties, having Doyenné Boussoch, Pitmaston Duchess, and Jargonelle in excellent condition. The other prizewinners were Messrs. Fletcher and E. Hall. A pretty lot of dessert Apples were shown, including several very good dishes of Beauty of Bath, for which the introducers, Messrs. Cooling & Sons, offered special prizes. Culinary Apples, again, were most extensively and well shown, the first prize collection of three varieties staged by Mr. A. Millar, and consisting of Ecklinville, Warner's King, and Lord Suffield, being particularly good.

It is doubtful if such fine vegetables have ever previously been seen at the Bath Shows. For twelve varieties Mr. T. Wilkins was first, showing Autumn Giant Cauliflower, Ailsa Craig Onion, Wright's Grove White Celery, Lyon Leek, Intermediate Carrot, Satisfaction Potato, Duke of Albany Pea, Cheltenham Beet, Student Parsnip, Ne Plus Ultra

Runner Bean, Tender and True Cucumber, and Perfection Tomato, all remarkably good. Mr. J. H. Copp, gardener to W. E. E. Erle Drax, Esq., was a close second; and Mr. G. Garraway, Bath, third. In the class for eight varieties, the prizes being offered by Messrs. Sutton and Sons, Mr. Copp succeeded in beating Mr. Wilkins, his collection consisting of Suttons' King of the Cauliflower, Perfection Tomato, Suttons' Seedling Potato, Duke of Albany Pea, and Wright's Grove White Celery, all being very good. Mr. J. Lye was third. For Messrs. Webb & Sons' vegetable prizes Mr. Wilkins was first, staging Webbs' Mammoth Cauliflower, Ailsa Craig Onion, Webbs' Sensation Tomato, Duke of Edinburgh Pea, and Webbs' Defiance Carrots in fine condition. Mr. G. Garraway was a good second, and several other excellent collections were shown in this as well as in the preceding class. The competition for Messrs. Jarman & Co.'s prizes was also keen, Messrs. Wilkins, Copp, and Garraway taking the prizes in the order named. There were also well-filled classes for Potatoes, Peas, Turnips, Onions, Beans, Tomatoes, and other vegetables in season.

#### WALKLEY, SHEFFIELD.

THE annual Show of the Walkley Amateur Floral and Horticultural Society was held on September 2nd at the Church Schools, South Road, and was favoured with beautiful weather; in fact, the day of the Show was exceptional in this respect, the prevailing weather for the previous few weeks having been of a most boisterous and showery character. Even the day before the Show it was so inclement that many members were debarred from preparing exhibits to send to the Exhibition, which had been fixed three weeks later than the usual time owing to the lateness of the season.

The exhibits upon the whole were very creditable to the members. Several groups of plants were arranged very tastefully, Mr. M. Taylor, the Secretary, taking a leading place with a mixed collection of stove and greenhouse plants, which made an effective display of foliage and flowers. The second prize group, belonging to Mr. H. Willford, was of a wholly different character, being composed almost solely of greenhouse plants, Zonal Pelargoniums and Fuchsias largely predominating, the group being edged with blue Lobelia. The third prize fell to Mr. G. Walker, who had a group of choice stove plants, and fell behind the others in nothing but the size of his group. The fourth group was a mixture of flowering and foliage plants and Maidenhair Ferns belonging to Mr. G. Coulson.

The chief prizewinner in the classes for specimen flowering and foliage plants was Mr. G. Walker, who had a superb specimen of *Pteris scaberula*, and a smaller but good specimen of *Davallia bullata*. He also had good Zonal Pelargoniums, stove flowering Begonia, and well-grown seedling Gloxinias. His specimens of *Coleus* were very good indeed. Mr. J. Marson had the best Fuchsias. Mr. R. H. Laughton had a splendid *Yucca aloifolia*, and Mr. Coulson showed a well-grown *Pteris serrulata*, also a large plant of *Begonia Rex*. Mr. Willford exhibited a splendid *Lilium auratum*. The classes for cut blooms were rather weak. Competition was keen with Stocks and Asters, also Pansies. Dahlias were absent except one or two exhibits of Bouquet varieties, and good examples of Show Dahlias exhibited by Mr. Carlton, who also took the leading place with Pansies, Picotees, and Carnations. Few Gladioli were shown, but the specimens were good.

In the fruit and vegetable classes competition was good with Potatoes, Turnips, Tomatoes, Peas, &c. Special mention should be made of Mr. R. H. Laughton's Grapes, which were well finished, and the bunches were large and shapely. In addition to obtaining first honours they were highly commended by the Judges. Several members and friends lent plants and flowers for decoration only. Mr. Wm. Smith had a beautiful collection of British Ferns, including a few exotics. Mr. Wm. Wood sent an epergne of flowers, and a stand of Pansies was also included among these loans. Stands of cut blooms and bouquets were largely represented. Mr. W. S. Singleton was first with a stand of *Lilium auratum*, and Mr. Willford took the lead with bouquets.

Not the least interesting feature of the Show were the neatly printed cards hung about the room, announcing the prizewinners in the best kept garden and greenhouse competition. These are inspected, and the awards made a few days before the annual Show. The successful competitors in the best kept greenhouse competition were Messrs. Walker, Taylor, Willford, Laughton, Marson, Wilson, and Cuckson. In the best kept garden competition the following:—Messrs. Laughton, Marson, Turner, and Taylor. The Judges in the garden and greenhouse competition were Messrs. A. Malcolm and E. D. Smith. At the Show the produce was judged by Messrs. Malcolm, Hannah, Hardy, Smith, and Shelley.

#### ROYAL AQUARIUM, WESTMINSTER.—SEPT. 9TH AND 10TH.

As a Show of early Chrysanthemums alone the Exhibition held on the above dates would have been of small dimensions, but as it was supplemented by a splendid display of Dahlias an excellent Show was provided. A few notes on the principal features are appended, time and space not permitting of full particulars.

In the Chrysanthemum section Mr. Vince, London Cemetery Co., Highgate, showed well. He had some well-flowered and healthy dwarf bushes in the class for six plants in not larger than 8-inch pots, and won from Mr. W. Wells, Earlswood. Messrs. Reid & Bornemann, Sydenham, were placed first for a group, their plants being well arranged, freely bloomed, and many of the flowers good; W. H. Lincoln, yellow, was very fine. Mr. Vince was second with an excellent group; and Mr. H. J. Jones, Ryecroft Nursery, Lewisham, was third; an extra prize

being awarded to Mr. Norman Davis, Lilford Road Nurseries, Camberwell, London, S.E. These were all highly attractive. For a collection of cut Chrysanthemums, any varieties, in bunches, Mr. Robt. Owen, Castle Hill, Maidenhead, was placed first, and these, with the other exhibits in the same class, formed a very bright display. Some of Mr. Owen's seedlings were very promising, and R. du Meniel de Montchauveau, Marginata, M. Zephyr Lionnet, M. Vauvel, Madame C. Desgrange, Autumn Queen, Souvenir de M. Menier, Golden Madame Desgrange, Mrs. Burrell, and Empress of Germany were very attractive. Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, was second with beautiful bunches of Jacintha, Mrs. Hawkins, Blushing Bride, Strathmeath (a charming pale rose variety), Golden Shah, Mrs. J. R. Pitcher, and others. Mr. Such, Maidenhead, and Mr. Vince also had good collections. Mr. Calvert, gardener to J. A. Houlton, Esq., had a grand lot of Madame Desgrange, and also a splendid stand of G. Wermig, being placed first in each case. Mr. Douglas's stand of Madame Desgrange was also very fine. Mr. W. Beech, gardener to L. Seligman, Esq., won with six in each class. Mr. H. Neary, gardener to the Rev. R. W. Powell, was first with Pompons.

Cactus and Decorative Dahlias were a rich display, Messrs. Cheal and Son winning in the trade section, and Mr. Glasscock in the amateurs' classes. Other charming stands came from Mr. Seale, Messrs. Keynes, Williams & Co., Mr. J. T. West, and J. G. Fowler, Esq. Singles were not so numerous, but Mr. Girdlestone had a very attractive stand. In the nurserymen's classes Messrs. Cheal & Son had a very fine display. Mr. Glasscock and Mr. West both showed Pompons well amongst the amateurs, and Messrs. Keynes, Williams & Co., and Mr. Seale won in the nurserymen's section with splendid stands. The largest Dahlia class, however, was that for sixty blooms of Show and Fancy Dahlias, and Messrs. Keynes, Williams & Co. were the winners of the first prize, their flowers being in grand condition. Mr. Seale also had a very fine stand, and was placed second; Mr. C. Turner, the Palace winner, being third. Mr. Arthur Rawlings won with a fine stand in the class for thirty-six. Mr. West was the most successful amongst the amateurs.

The galleries were bright with Dahlias and miscellaneous displays. Messrs. J. Prior & Sons, Colchester, had a beautiful collection of Roses, for which a silver medal was awarded. It was a wonderful collection for the season. Mr. W. Salmon, West Norwood, received a bronze medal for a highly creditable display of Dahlias, Marigolds, and miscellaneous flowers. Messrs. Cheal & Sons, Crawley, had a beautiful display of Dahlias, Phloxes, and Gladioli, for which a bronze medal was awarded. Mr. P. Spinks, Worley, had some excellent Tomatoes, for which a special award was made. Mr. J. T. West, gardener to Mrs. Keith, received a bronze medal for a collection of Show Dahlias. Messrs. W. Paul & Son, Waltham Cross, had a superb collection of Roses, Dahlias, Asters, hardy flowers, and 160 dishes of Pears and Apples. A silver medal was awarded. A similar honour was accorded to Mr. G. Phippen for a splendid display of Dahlias and Liliums in conjunction with foliage plants. E. B. Lindsell, Esq., and Messrs. Burrell & Co. showed Gladioli admirably. Mr. T. S. Ware, Tottenham, received a silver medal for a magnificent bank of Dahlias.

#### FRUIT FORCING.

**PEACHES AND NECTARINES — Earliest Forced Trees.**—The trees have now shed their leaves, and may be syringed with water at a temperature of 140°. It must not, however, be used carelessly; if too hot it will injure the trees, and if lower in temperature it is useless as regards scale, and red spider, thrips, and aphides. The trees being loosened from the trellis, and tied in small bundles for facilitating cleansing operations, wash the woodwork with brush and soap, reaching every angle and crevice. Limewash the walls, and if required paint the wood and ironwork. Pruning will be a light affair, merely thinning the shoots where too crowded or too weak for carrying fine fruits, no shortening being necessary except for the production of shoots for extension. Wash the trees with soft soap solution, 4 ounces to a gallon of water, and afterwards dress with an insecticide, being careful not to dislocate the buds. Tie the trees to the trellis loosely, leaving sufficient room for the swelling of the branches and shoots. Remove the loose surface soil down to the roots, and supply a couple of inches depth of fresh loam containing a sprinkling of bone meal and wood ashes. Avoid heavy surface mulchings of manure, they only exclude air. If the lights have been removed they need not be replaced until the time arrives for starting the trees, as with proper drainage the borders are not unduly saturated by the autumn rains, but where the drainage is not thorough it may be expedient to replace the lights before the borders are soddened by the cold autumn rains. For very early forcing Alexander and Waterloo Peaches are valuable. Waterloo is the brighter and heavier fruit, but in other respects they are similar.

**Second Early Forced House.**—The trees are commencing to shed their leaves, and the lights having been removed in August the buds

are well plumped, and not over-matured as occurs under fixed roofs, especially with such varieties as Early York and Noblesse. The removal of the roof lights prevents the buds falling if taken in time. When the leaves are all down treat it the same in every respect as the earliest house.

**Succession Houses.**—Any trees that have a tendency to over-luxuriance should, as soon as the wood is sufficiently firm, have a trench taken out one-third the distance from the stem the trees cover in trellis and quite down to the drainage, so as to detach all roots, and this may be left open for a fortnight; then the soil may be removed down to the roots and picked from amongst them with a fork, laying-in the roots in fresh material; good loam rather stiff being best, with about a sixth of old mortar rubbish. If a good watering be given the roots will soon grow freely in the fresh material, and the fruits invariably set well afterwards. In removing the soil care must be taken not to disturb the roots enough to cause the sudden collapse of the foliage. Defer root-pruning and lifting until the leaves give indications of falling. The above plan is more especially necessary with young trees, the taking out of the trench being very effectual in assisting the wood to ripen thoroughly.

**Late Houses.**—Late varieties are remarkable for size and beauty, and if given proper supplies of water and liquid manure are excellent in flavour. When kept too warm and dry they are apt to be deficient of juice. A free circulation of air is necessary, utilising sun heat if the fruit is backward, as with ventilation in the early part of the day the temperature may rise up to 85° or 90°, which is of infinitely more value than fire heat at a later period. The trees must have sufficient water, but a rather drier condition at the roots is advisable when the fruit is ripening. Keep the wood thin, stop any growing shoot to about 15 inches, and all laterals closely to one joint as growth is made.

**VINES.**—*Young Vines.*—These must have every encouragement in keeping the foliage clean, removing all laterals, as growth produced after this period is of no value, and maintain a warm well ventilated atmosphere until the canes are ripe. The ripening of the wood may be accelerated by keeping the house rather close in the day, so as to secure a temperature of 85° to 90° from sun heat, opening the ventilators at night. Any supernumeraries intended to fruit next season should have the laterals cut away to the principal buds, leaving, however, an outlet for any excess of sap by a few laterals at the top of the cane, and be careful not to injure the principal leaves.

**Late Houses.**—Muscats and other late Grapes still require fire heat, as they are late this season, accompanied with a free circulation of air, continuing it until they are thoroughly finished. Muscats should have the foliage rather thin, indeed the leaves may be tied aside, as it is necessary the fruit have abundance of light and air, so essential for thorough ripening and producing the amber colour characteristic of good quality and finish. Keep the night temperature at 65° to 70°, with a fall of 5° through the night, and turn the heat on in good time in the morning so as to allow an increase of ventilation and the temperature to be raised to 70° to 75° so as to insure to the Grapes a long ripening day, the temperature being kept at 80° to 85° from sun, and with a free circulation of air, 90° to 95°. The heat should be kept up by reducing the ventilation with the declining sun, and the temperature allowed to gradually decline at night, only keeping warmth in the pipes to allow the top and bottom ventilation to be left open to a slight extent so as to insure a circulation of air, and prevent the deposition of moisture on the berries during the night. This should be continued until the Grapes are thoroughly ripe and finished, when a gradual reduction of temperature must take place, otherwise the fruit will shrivel; this must be further guarded against by not allowing the border, especially inside, to become dry. If there is any fear of this a good watering should be given on a fine morning when air can be freely given, and the border may be covered with dry material to keep down moisture. A temperature of 50° to 55° is necessary for keeping Muscat Grapes in good condition after they are ripe, and other houses of late thick-skinned varieties will require a similar temperature for the benefit of the Vines.

**Late Houses of Hamburgs.**—The Grapes are well advanced in colour and ripening. A gentle warmth in the pipes is necessary so as to admit a free circulation of air and to maintain the temperature at 60° to 65° at night. A little artificial heat during the day will also be of benefit in allowing free ventilation and making the most of sun heat. Hamburgs colour and finish best beneath a good spread of foliage, but it is well not to encourage lateral growth now, at the same time the tendency to shanking is accelerated by large reductions of foliage, and equally so by sudden fluctuations of temperature. A little air may be admitted at top and bottom until the Grapes are ripe. If there is any deficiency of moisture in the borders it will be better to give a supply of water now than delay it until a later period, covering with dry material so as to prevent damp rising. Outside borders will in most instances be sufficiently moist, if not they must be watered, and unless the weather become wet they need not be covered at present, but light shutters or tarpaulin should be in readiness for placing over them so as to throw off heavy rains.

#### PLANT HOUSES.

**Fuchsias.**—Young plants that are rooted should be placed singly into 3-inch pots, well watered, and arranged on a shelf close to the glass. Keep these plants steadily growing throughout the winter, and then if transferred into 5-inch pots they will flower early and prove useful for decoration. Where plants have not been rooted cuttings may still be

inserted, young wood being selected, and as soon as they are rooted pot them singly, and give them a start in heat. When this practice is followed it is necessary to carefully harden the plants before placing them into cool quarters. A temperature that does not fall below 45° will keep them moving during the winter.

**Solanums.**—Plants that have set good crops of berries and have been kept in pots should be supplied with stimulants. Soot water in a clear state is most beneficial for these plants; it acts quickly, and prevents the foliage turning a sickly yellow. Careful watering and feeding are necessary after the pots are filled with roots, or the foliage is liable to turn yellow and spoil the appearance of the plants. Those that were planted out and have set well may be lifted and placed into suitable pots. Where there is abundance of frame room and the Solanums were planted out the plants have a beautiful crop of berries; but outside plants in many localities are not satisfactory. After the plants are lifted and potted in loam and one-seventh of manure, place them in a northern position and give a good soaking with water. Syringe frequently until they commence root activity, when they may be placed in a sunny position.

**Bouvardias.**—Plants outside are growing too soft owing to the damp, cold, and sunless weather. Lift all those that are making robust growth and place them into 6 and 7-inch pots, according to their size. Establish them on the principle advised for Solanums. When they will bear exposure to the sun arrange them in frames or in a cool greenhouse where they can enjoy full sunshine. Plants lifted at once will, if the present month proves fine, have every chance of ripening their wood and flowering profusely. Bouvardias in pots under glass must not have their shoots pinched again, but allow them to extend and form trusses. If staking is needed supply a central stake, and support the other shoots with matting. The trusses are not heavy, and thin pieces of matting will support them equally as well as using more than one stake. Feed plants in this condition with weak stimulants every time they need water. Yellow thrips are troublesome, but can be kept under by a free use of the syringe. Fumigation may be resorted to if syringing does not at once check their ravages.

**Mignonette.**—Plants grown for standards should have the flower trusses removed as they appear, and the shoots tied to the trellis once a fortnight. Keep the plants perfectly cool, so that strong growth will be made until the trellis has been covered, when they may be allowed to come into flower. Later plants required only for spring flowering should be supplied with their trellis, and given the same treatment. Let the whole of these plants stand on a moisture-holding base, and during bright weather syringe twice daily. Plants for pyramids can be tied to the wires or string as they extend. Care is needed to furnish the base first. Water carefully, do not give too much; on the other hand, do not allow them to become dry. Once they are allowed to approach dryness the plants become woody, and they seldom do well afterwards. Mignonette from seed sown in 6-inch pots and kept in frames until germination should be liberally thinned. Failure frequently results from allowing too many seedlings to grow together in the same pot. About half a dozen are sufficient. Sow more seed thinly for spring flowering. Place the pots in a frame, and shade until the seed has germinated, when the plants enjoy full light and abundance of air.

**Calceolarias.**—The earliest seedlings are large enough for small pots, place them singly into 2-inch, and grow them in cold frames. Those of a smaller size should be pricked out singly into pots or pans, 1 inch apart, so that by the time they fill the space they will be ready for potting singly. Shade from the sun, and keep moist.

#### APIARIAN NOTES.

##### BEES AT THE MOORS.

AN improvement in the weather appears to be taking place, and should it continue for ten days the yield of honey will be great, as the Heather could not be finer. On the same moors from thirty to forty years ago I have known after swarms set down 14 lbs. in weight rise to 1 cwt., when prime swarms would be making much less progress, and swarming. This demonstrates in a clear manner the value of young queens in hives early enough to allow the brood to be well forward at the proper time, and proves the fallacy of the dictum that "young queens do not breed much till they are three months old." Where the honey gathering is of long duration hives judiciously managed with young queens provide the key to profitable bee-keeping.

##### SLAUGHTERING DRONES.

Notwithstanding the very untoward season here for bees few drones were killed till the 17th ult. On that day a general onslaught was made both at the moors here and at home. Queenless hives, and those with unfertilised queens, were no exception;

but why was this? To me it is a mystery. But doubtless the knowledge of coming untoward weather possessed by the bees had something to do with it, and the simultaneous attack at two separate places makes it the more remarkable.

#### STOCKS FOR 1892.

No time should be lost in having stocks made up for the ensuing year, keeping none but tested young queens and rejecting those of a puny appearance. Of course the judicious bee-keeper will have a few surplus ones to make a choice from, and it will be wise to preserve several in case any blanks occur at a time when queens cannot be had. Not unfrequently in olden times we could depend upon hives having extra prolific young queens, although the hive in autumn was not half full of combs, but since we have had a succession of untoward springs such stocks cannot be depended upon.

To expect success, hives should be filled with worker comb in the autumn to as near as is consistent with a due proportion of drone comb, but not more. Hives containing nuclei can be readily filled with the pollen-laden and partially filled combs of condemned hives. Such hives constitute the very best stocks for another year, and will not fail to give the bee-keeper entire satisfaction.

#### PUNIC QUEENS.

I have a good opportunity of isolating queens for pure fertilisation. If spared till another year I shall probably make the experiment, but fear I shall be unable to rear them in sufficient numbers to be a paying concern. Had I been stronger it might have been otherwise, but I must content myself with bees as a recreation, not as a trade.

#### CORRESPONDENCE.

Already I am in arrears with a number of queries and some interesting statements. The former will be answered and the latter made use of when writing facilities are greater than among the Heather.—A LANARKSHIRE BEE-KEEPER.

#### DRIVEN BEES AND HOW TO TREAT THEM.

We will suppose the bees are driven as directed in my last, and that the skep containing them is on the original stand, that a frame hive is at hand properly prepared, and all the colonies at present to be in skeps, and that no frames having combs in them are available.

#### HOW TO FIX FOUNDATION IN THE FRAMES.

Take full sheets of foundations—that is to say, of a size when fixed in the frames that will hang about half an inch from the bottom bar, and be within an eighth of an inch of either side of the frame. If the frame has a saw-cut in the top bar the foundation can be easily fixed in the manner described in my little book as follows:—"Take a piece of  $1\frac{1}{4}$  inch board, 17 inches long, and 3 inches wide; drive two  $1\frac{1}{2}$  inch French nails through it in the centre longitudinally 2 inches apart, so that they project a quarter of an inch on the under side. Turn the board over, and screw or nail it to a bench or table parallel to its edges, and it is ready for use. Put the strips or sheets of foundation on the table beyond the board, the frames on your left hand with the top bars towards you, and the hive into which the frames are to be put on the floor to your right. Take a frame in your left hand and place the saw-cut in it over the nails; take up the foundation with the fingers and thumbs of both hands, rest the edge of foundation in the saw-cut, and pass the thumbs round the sides of the frame, holding the foundation between the fingers and thumbs; then give the frame a slight turn, pressing it against the nails to open the saw-cut wider, and insert the foundation, pushing it well into the saw-cut, when on releasing the frame it will be securely fixed. Lift the frame off the nails, carefully turn it over, and hang it in the hive as it is to remain." The majority of frames are now made with a saw-cut, and the above is the most convenient way of fixing foundation in a satisfactory manner.

#### METAL ENDS FOR KEEPING DISTANCE.

The frames should be furnished with some means of keeping them in the position required, and metal ends are now generally used for that purpose, preferably those known as the W. B. C. ends, because with these we are able, when using full sheets of foundation, to space the frames  $1\frac{1}{2}$  from centre to centre until the combs are built out, when they can without difficulty be altered to the distance the bees build in the natural way in a skep. The object of placing the frames closer is to prevent the newly built-out comb from breaking down.—JOHN M. HOOKER.

#### PRICES OF PUNIC QUEENS.

MAY I ask our friend from Hallamshire how he could afford to sell, or rather to advertise, Punic queens at 2s. 6d. in the *B. B. Journal* of last year (May 15th to July 24th), and also in the *Record*, while he now writes in your Journal that he asks £5 5s. for a queen, and of course, he "considers them cheap at the price?" I also notice that he wishes to prevent people writing to him for a queen on the expectation of getting one for 5s. I did not know until I saw this week's Journal that "A. H. B. K." and the advertiser mentioned above were one and the same; but although he certainly praises the Punics very much, I for one am not sufficiently verdant to part with £5 5s. until I hear more about the Punics from our friend from Lanarkshire and others who are not interested in their sale.—SPREAD EAGLE.

#### TRADE CATALOGUES RECEIVED.

Dobbie & Co., Rothesay.—*Autumn Catalogue*.  
Charles Sharpe & Co., Sleaford.—*Spring Flowering Roots*.  
Barr & Son, King Street, Covent Garden.—*Catalogues of Daffodils and Bulbs*.  
J. Jefferies & Sons, Cirencester.—*Catalogue of Bulbs*.  
Robert Sydenham, Tenby Street, Birmingham.—*Unique Bulb List, and How I Came to Grow Bulbs*.  
H. Cannell & Sons, Swanley, Kent.—*Book of Reference in Horticulture*.  
Charles R. Shilling, Hartley Wintney, Winchfield, Hants.—*Catalogue of Trees and Shrubs*.  
James Veitch & Sons.—*Catalogue of Plants*.

\*\*\* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Phyllocactus** (*L. A. J.*).—The plants flower at different times, but often in the spring or summer, and are of great decorative value. You will not, however, find them of much use for cutting purposes, as the flowers do not last long.

**Cordon Pears** (*W. Morris*).—There are no finer Pears than those grown as cordons against walls where the soil is of the best character and the management of the trees correct. Our remarks apply to Pears grown in the open air, not under glass.

**Tomatoes** (*C. B. G.*).—You should have written sooner. Replies to Wednesday's letters have to be held over for another week, or be very brief. Do not use the mixture on the fruits if you can help it. We have not heard of injury, but should prefer to wash dressed fruits before using them.

**Vitis heterophylla** (*York*).—This variegated Vine requires all the sun it can receive, and not enriched soil. A shaded position and liquid manure would have the effect you describe. This Vine is employed as a groundwork in bedding, and colours well in the open ground. The growths are cut close back in winter, as if cutting down Pelargoniums.

## WOOD RIPENING AND ROOT-PRUNING.

**A**FTER so wet and sunless a season as we have experienced special attention ought to be given to Vines and other fruit trees, so as to assist them in every possible way to ripen, as far as practicable, the strong sappy growth many trees have produced. Peach trees from which the fruit has just been cleared should have all the young shoots not required for next year's fruiting, or for filling up vacancies, removed at once, and the shoots spread evenly over the surface of the trellis, so as to expose them to every ray of sunlight. If the shoots are tied here and there, it will be sufficient to keep them in position till the general clearing and retying takes place in the winter. All lateral growth, if any still remain, should of course be unsparingly removed. If we happen to be favoured with fine bright weather for a few weeks during September and October all may yet be well, as trees generally are unusually clean and free from insects. The great desideratum is sun to ripen the wood.

Where trees have made extra strong wood a trench should be cut round them from 3 to 5 feet from the stem according to the size of the tree, and if roots are not plentiful at that point remove the soil nearer to the stem till strong roots are formed. These should be carefully preserved and the soil worked out from between them a few inches beyond the point at which they were cut with the spade. The surface soil should then be removed from the remainder of the ball right up to the stem. If but few roots are formed near the top take out another layer of soil, and continue to do so until a fair quantity of roots is formed, as it often happens when trees make over-strong growth that their roots are found to have penetrated deeply into the soil, and are strong and almost devoid of those little fibry rootlets which fruit growers know are so necessary for the production of high-class fruits. As soon as the old soil has been removed all the roots left should be cut at the ends with a sharp knife, and a few of the strongest notched at intervals to cause them to send out fresh fibres. The trench should then be gradually filled in with good sound loam, with which lime rubbish at the rate of one part to six has been mixed. As the work of filling the trench proceeds work the compost carefully among the roots, and those which have been completely freed from the soil right up to the main stem must be raised and brought near the surface, trenching the soil moderately firm as the work proceeds.

Should the leaves show any sign of distress after this operation has been performed shade and syringe for a few days, but do not let the shading remain on a day longer than is necessary to keep the foliage fresh. Trees treated in the way described often produce exceptionally fine fruits the following season. When the root-pruning is done thus early it has the effect of greatly checking the flow of sap, and therefore stopping growth. The energies of the trees are employed in plumping the buds and solidifying the growth already made, while roots are being formed ready for the work of another year's active growth. Trees with weak wood generally produce abundance of fruit, but to obtain really fine specimens strong shoots well ripened are required.

Vines with the fruit ripe or ripening should have all lateral growth promptly removed, that is, growth which has been recently made, or which has been allowed to become somewhat crowded. Care should always be taken not to cut away a great amount of growth at one time. If from any cause the laterals have been allowed to unduly extend, remove a few at a time, and arrange the others so that they will not interfere with the main shoots. Extension of lateral growth early in the season is often of great benefit to Vines, but as the season advances it must gradually cease, especially in a dull season like the past, so that by the present date every leaf retained is thoroughly exposed to light and air. Wherever laterals make their appearance they should be rubbed off at once, for they not only have an injurious effect, by keeping out the sunlight from other shoots, but are also very susceptible to mildew at the present season, especially in districts which have a naturally humid atmosphere.

Those who have vineries situated on high ground, provided they have the control of plenty of water, have, in my opinion, a great advantage in Grape growing generally, and more especially where perfectly finished bunches fit for the show table are required.—H. D.

## SULPHATE OF COPPER AND THE POTATO DISEASE.

I READ the leading article on "The Potato Disease and Remedies" in your issue of the Journal, September 3rd, with particular interest, because last year and this also, I, as an amateur Potato raiser and grower, experimented with the solution of sulphate of copper and quicklime as an antidote to the Potato murrain. I have not used these chemicals as a dry preparation, and therefore am unable to pass any opinion thereon; but if they are used as a solution of proper potency I am well satisfied from my own experience that they are effectual in opposing murrain onslaughts.

Several recipes for making the solution have been published; but some of them are not absolutely reliable, because, if the solution is too strong, it corrodes the tissues of the leaves, and does almost as much injury as the fungus would. My proportions have been 7 lbs. of sulphate of copper, with an equal quantity of quicklime, to 20 gallons of water. The sulphate of copper should be bruised to a fine powder before mixing with the water to facilitate solution.

There is some difficulty in the means of application in the case of a field or a large plot of ground, because in using an ordinary garden syringe the lime obstructs the small orifices of the syringe and prevents the free passage of the solution. Doubtless special machines should be available for the purpose. Then, too, the operator must walk between the rows and convey the liquid with him. In continuous wet weather this would be most unpleasant work; the soil, too, in the furrows would be terribly down-trodden and the haulm bruised and broken by the passage of the operator up and down the rows. One application is by no means sufficient. I would therefore recommend that in field culture alleys be left at proper distances for passing along with a small machine.

There is one question of importance which I have heard many ask, "Is the game worth the powder and shot?" My opinion is decidedly yes; for not only is the present crop protected, but the spores and zoospores of the fungus are doubtless robbed of their vitality if they come in contact with the solution. Therefore it is a mode of horticultural sanitation that not only insures immunity from diseased tubers, but must also have a marked effect in reducing the quantity of hibernating germs for the future season.—HENRY FINCHAM.

## AURICULAS.

## CULTURE UNDER HANDLIGHTS.

No doubt since Mr. Bell has done it Auriculas of the higher types can be grown by planting them out under handlights, but I think that "Auricula growing made easy" by this method would only be so in an inverse ratio to the number of plants grown. As a collection increased so must also handlights multiply, and thus the method gradually become cumbrous and laborious compared with the old-fashioned pot culture in frames, still more so as against the well proved advantages of a cool span-roofed Auricula house.

As to pot culture being obnoxious to these plants it is not so. They are by no means greedy of pot room, and indeed never do so well as when the pots are small enough for the plants to fill them with roots. A 3-inch to 4½-inch pot will afford any high-class Auricula sufficient root room. If it be an object to save time and attention in watering the stages may be of flag or slate, with 4 or 5 inches of coarse sand upon them in which to plunge the pots. I write without any experience in handlight culture of the Auricula, but there are several conceivable disadvantages that might, I fear, attend it. Even a moderate collection, say of five plants under each glass tent, would require an encampment of handlights, and what would become of them raised on pots, or tilted in a situation at all open to such winds as have blown during this summer, to say nothing of equinoctial expectations? Perhaps a stake at each corner might help to keep them in position, but in any garden exposed like Mr. Simonite's in Sheffield even this device would fail to keep the flighty and frolicsome handlight on the premises in a high wind.

In many gardens, especially suburban ones, there is certainly the cat and his many friends to be reckoned with, and he may issue his noisy invitations to a garden party, with tilted handlights as one of the attractions of his entertainment. This is no remote contingency where there are cats about. I have grown many seedling Auriculas in the open ground, but have found it difficult under these circumstances to effectually keep down the all but inevitable green fly. This is most troublesome in a spell of dry weather. Syringing with softsoap dissolved in rain water will destroy all the insects visible on upper surfaces of the plants, but the multitudes hidden on the under side of the foliage are difficult to deal with on plants in the open ground. Young offsets under parental foliage are liable to be smothered with green fly, and therefore it is most important that the Auricula should be grown in such a way that each plant shall be under complete supervision and control, and easily handled. They are not large plants, and whether in bloom or not, they always look best, and do best, when not placed far from the eye. It would be very troublesome to attempt fumigation under a series of handlights, and, probably, in such small confined spaces it would not be safe.

Another enemy, to which I think valuable Auriculas under handlights would be subject, is the nocturnal snail. True, that by setting the lights down before dark he might after that time be excluded; but there remain the chances that he may have already walked in on a rainy afternoon, and be only waiting under leafy shelter till feeding time. His touch is ruin to an Auricula flower, and the whole plant, in its fragrance of leaf as well as of blossom, is highly attractive to the snail, though to our tasting its juices are acrid.

In some places small birds will pick the buds of Auriculas and Polyanthus, but particularly the latter. Sparrows are the most mischievous, but here they are too wary to enter the Auricula house, and probably would not venture under a handlight. I would not, however, trust them with valuable Auricula buds in the open.

I should fear that the heavy bumble bee of the spring, who is a great lover of the scented Auricula, and who will get into the Auricula house if he can, would require much care to exclude him from raised handlights. A very slight touch of his wing or legs will blur or scratch Auricula flowers, and of course there is no saving of any trustworthy seed where a bee has had access to a flower. It is doubtless better to grow a few Auriculas than none at all, and to have handlights than no protection whatever; but if there be garden space enough, I should prefer frame culture for a small collection, and a span-roof house for more than a frameful or two of Auriculas.

Mr. Bell will find an Auricula plant of 16 inches diameter in summer not a very uncommon size in the lower orders of Auriculas, and very strong plants in the "self" class will at times be as large, especially if they are new seedlings. Such plants, however, and even smaller, are too big for blooming kindly—i.e., in best character for quality and refinement, and they may subsequently pull themselves to pieces by throwing up two, or even three, flower stems, followed by a weak or divided heart. None of the good edged Auriculas are likely to make such huge plants under sensible treatment.

Mr. Bell includes me in his reference to writers on the Auricula

who do not give their addresses as well as their names. He will, however, find that I have always given both for some twenty years past in the Journal, though in papers few and far between.—  
F. D. HORNER, *Burton-in-Lonsdale, Kirkby Lonsdale.*

## THE PRINCIPLES OF PRUNING.

THE following is a digest of Mr. Wright's lecture at the Crystal Palace on the occasion of the meeting of the British Fruit Growers' Association on the 11th instant:—

Mr. Wright did not prepare a paper, but spoke from short notes, making reference to a number of diagrams, and thus taught through the eye as well as the ear. He said he was aware he had amongst his audience men as capable as himself in growing and pruning fruit trees; some of them could, no doubt, teach him something on the subject, and he should be at least as pleased to learn from them as he was willing to try and teach others who had less education in the school of experience. Hundreds, indeed thousands, of persons were endeavouring to grow their own fruit, and all would wish them success. They needed instruction in pruning fruit trees and bushes, as did many young men who had taken the charge of gardens after gaining most of their experience under glass.

After describing the objects of pruning—namely, producing fruitful trees in required forms adapted to certain positions, also the different kinds of pruning—summer and winter, root and branch—the lecturer said that both symmetrical garden trees, also informal standards and dwarf bushes, could be made essentially fruitful in character. They could not be made to bear full crops of fruit unfailingly, because gardeners could not control the weather and prevent frost destroying the blossom; but if the trees were brought into the best condition of fruitfulness by correct management and methods of pruning, those who had brought them into that state had done their duty. Fruitful examples were shown in diagrams of the different forms of trees—pyramid and bush—from sketches made at Chiswick, and a thrifty, fruitful, open standard as grown at Cardiff Castle, the methods of pruning adopted in producing such trees being shown in each case.

Crowding trees with a thicket of growths in summer to be cut out in winter, a too common habit, was strongly condemned. A sturdy framework was advocated by shortening the branches of young trees for two or three years, then having the main branches so thinly disposed that the sun could shine between them, and directly on the leaves, not near the tips of the shoots only, for that was of small service, but on the leaves near the base for rendering them structurally perfect for performing their important functions in storing nutrient matter in the stems, and so becoming spur and blossom formers and fruit manufacturers. With healthy root action in good soil, a due balance of force between roots and branches, leaves of the best character by the direct action of light and air on their surfaces, blossom buds were bound to form and fruit to follow, weather being favourable to its setting and development.

Particular attention was asked to the following statement.—  
"No matter what kind of trees were in question—restricted and formal, or large and free—all pruning must be based on this fundamental fact—namely, the roots of a tree are part of the stem, the hidden counterparts of the visible branches, and one part cannot be manipulated—weakened or strengthened—without influencing the other." "That," he went on to say, "is the concrete condition on which all action in pruning must be based. The cultivator must not induce by mistaken practice a great preponderating power of roots over branches or branches over roots; he should, in fact, regard roots as what they are—underground stems, and be able to form a clear conception of the parts of a tree within the ground from a critical inspection of the parts above it, shoots and leaves; and until a man can do that he cannot be regarded as a competent, safe, profitable pruner." The lecturer said he had found that a large number of successful fruit growers were distinctly of opinion that as much fruit was prevented by the abuse of the knife as was produced by its use, and he did not call that pruning but butchering. "A butcher," he said, "can cut off limbs and destroy life in doing so; a surgeon amputates and prolongs life by the operation. The butcher's work is physical mainly, the surgeon's intellectual, scientific; and we want intellectual pruning in gardens, not butchering; producers of fruitful trees, not preventers of crops of fruit."

Right and wrong methods of pruning were illustrated; roots were shown as influenced by branch growth, and *vice versa*; both fruitless and fruitful wood were portrayed; the causes that produced certain effects demonstrated, and remedies for obvious evils pointed out. Waste of material was made clear in the form of a dense thicket of summer growths, rampant roots and no fruit on

one side of a tree; spur formation, fruit production with corresponding fibrous roots on the other—the latter the natural outcome of rational pruning. This, it was stated, “consists in disbudding and thinning to prevent overcrowding instead of shortening branches, yet letting the roots extend to create it; encouraging the roots of weakly trees and shortening the branches to promote necessary vigour; but when trees grow too luxuriantly in summer cutting back the shoots in winter is simply followed by more and stronger growths. It is a case of man fighting against Nature, and the combat may go on for a generation, Nature inevitably winning in forcing growth. If man must conquer he must use his brains and change his tactics. The branches of a strong-rooted tree, if kept thin and not shortened, will in time counteract the root power, form blossom buds and bear fruit, weather permitting; but if for special reasons the growth must be arrested and restricted within certain bounds, the roots must be shortened to a greater extent than the branches, especially strong roots that strike deep down in the subsoil; then with otherwise good cultural attention, trees hitherto practically barren will produce valuable crops of fruit.” Mr. Wright spoke for about an hour to a highly attentive audience.

At the close of the lecture Mr. Read of Oatlands Park said that by a change in the system of pruning of the trees in his charge, and especially root-pruning and adding chalk to the limeless soil, much larger crops of finer fruit were had than the trees had ever borne before.

Mr. A. H. Pearson said he could follow what he had heard and seen, because he had been taught fruit culture in continental schools of horticulture, and he was sure that the principles advocated that day were sound. He was glad to have heard them expounded, and should like to have hold of the diagrams.

Mr. Ivatt, a fruit grower in Cambridgeshire, spoke of the great advantage he had found in attending to fruit trees and bushes in summer, keeping them open. The cost was trifling and the practice remunerative, for it gave him finer fruits than he could otherwise obtain, and he had no difficulty in selling it at the best market prices.

Mr. Udale wished to know if root-pruning could not be overdone and trees injured by it. Mr. Roupell wished to know the best time for a root-pruning, and Mr. Rivers said when new roots were produced as they were by the process we should remember the old had exhausted the soil in which the new were formed, and fresh soil should be added for giving them the requisite food for promoting and sustaining healthy growth.

Mr. Wright, in reply to the questions and comments, adduced examples of success through following the methods advised. In reply to Mr. Read, he said fruitfulness could be induced when there was space for extension and thinly disposed growths without root-pruning, but more quickly by its aid. In answer to Mr. Udale, he said undoubtedly trees could be injured by excessive root-pruning; he had seen them killed, but that was butchering, not intelligent pruning. Mr. Roupell was told the best time for root-pruning was early in the autumn when the leaves were changing, and the descending current of sap would cause the smoothly cut ends to callus in a few weeks. He also said Mr. Rivers' remark on giving fresh soil was important, and ought not to be forgotten. Votes of thanks to the lecturers and the Chairman brought the proceedings to a close.

### THE SHOWING OF SPRING ONIONS.

Now that the shows of the year are nearly over we may reasonably talk over the points of interest which have struck us in our various experiences, either as exhibitors, judges, or on-lookers. One matter which, as a judge at more than one show this year, has attracted my attention is the present-day manner of setting up spring Onions. It is not unusual now to find Onions set up as spring Onions as large as any of the autumn-sown ones. To the casual observer this will appear strange, especially when contrasted with the rank and file of the other exhibits in the same class. To the initiated it is not strange, because they know that these very large Onions were raised under glass, some very early in the year, and moved on and on by degrees until they were finally planted out in the open ground, all this being done specially for exhibition purposes. It must be, however, plain to the meanest understanding that all this is not exactly right, or why is there such a wonderful difference between these bulbs and those others, which, of course, were sown in the ordinary manner in the open ground, and at the ordinary time of the year? That is the point I desire to bring out. As a first thought it might be suggested that the Judges ought to disqualify these immense bulbs on the ground that such could not be produced from a spring sowing; but then the Judges are tied down by the schedules, and as these schedules say “Six Spring Onions” or “Twelve Spring Onions,” and the Judges know that these have been, or can be, produced by sowing under glass in the current season, though sown in the late winter or very early spring, they cannot conscientiously disqualify, though they may feel that it is a very elastic reading of the schedule, and that the exhibitor who has read his schedule simply and literally is severely handicapped thereby.

What is the remedy for this? It is for the compilers of schedules to

say. It is clearly a hardship on the man who has read and interpreted his schedule according to the simple and literal meaning of the words, and has acted thereon, to see his honest productions set aside for those which he knows have been produced by sowing under glass as soon as the year came in, or very soon after, and shifted by degrees until they are being planted out, or ready for it, almost at the time his are being sown in the open ground. Will the difficulty be met by the addition to the item in the schedule, “Six or twelve spring Onions, to be sown in the open,” being added thereto?

I should like the opinions of others who may have been interested in this matter, either as on-lookers, exhibitors, or judges. The most conspicuous example of this way of showing was at Shrewsbury, and Mr. Muir of Margam, Mr. Ward of Longford and myself discussed the point, as well as our duties and the time permitted, but not having an opportunity to talk it out and arrive at some conclusion, I thought I would open the subject here, by permission of the Editor, and see if something could not be done to put the honest and literal reader of the schedule on a more equitable footing with his more elastic-minded and forward neighbour. It may be urged that judges would be perfectly justified in disqualifying these very large bulbs, inasmuch as that they are not spring Onions at all, being sown before the calendarial spring (March 21st), but then the feeling is that this would be as arbitrary an interpretation of the schedule as the other is an elastic one. Clearly there is a want of fairness and equity in the present way of showing, but how to remedy the matter is somewhat difficult.—N. H. POWNALL, *Lenton Hall Gardens, Nottingham.*

### APPLE BENONI.

LAST week reference was made to this pleasant September Apple, and we now give an illustration of one of the fruits that was grown on

FIG. 43.—APPLE BENONI.

a pyramid tree at Chiswick. The crop was one of the best, and the tree is one of the healthiest growers in the collection, being upright in habit, and hence well suited to borders in gardens. Mr. Barron regarded it as one of the best varieties for following the summer Apples such as Mr. Gladstone, Red Astrachan, and others, and preceding the regular autumn Apples. The quality of the Chiswick fruit was good, pleasant, and refreshing, but we have tasted fruits richer from Sawbridgeworth, while in Kent we have heard the variety is not regarded as superior. Soils and circumstance have their influence on fruits; but, generally speaking, Benoni may be regarded as a September Apple well worth growing.

### FAVOURITE FLOWER BEDS.

I HEREWITH send a few combinations which have struck me as being novel and effective. Two years ago I saw a particularly effective arrangement, composed of strong flowering plants of *Veronica Andersoniana variegata* intermixed with *Lobelia cardinalis*. The bed was isolated, and there was nothing to interfere with the beautiful soft blue of the *Veronica*, and the deep dark crimson spikes of the *Lobelia*, the creamy white and green foliage of the first-named plants providing a harmonious undergrowth.

Last year one of the prettiest mixtures I noted was a combination of yellow and white *Chrysanthemum coronarium* fl.-pl. in front of a cottage. I pirated the idea, and this season have a long background of these planted alternately. The combination in most, or perhaps all instances, where white and yellow are employed is of great beauty.

An exceedingly soft and harmonious flower bed of the present year is composed of a large central block of a dwarf *Ageratum* planted alternately with the rosy flowered *Crystal Palace Gem* *Pelargonium*. This is a combination, as most flower gardeners will notice, of rose, soft

yellow, and lilacy-blue. This block of colouring is encircled with a band of Crystal Palace Gem Pelargonium, this again with a band of Agcratum; then outside of this a narrow line of Mesembryanthemum cordifolium variegatum, and the edging of Lobelia Lady McDonald, the idea of toning down the yellow and blue with the last two plants being successfully compassed.

A series of beds very simply planted is also very effective. The centres are Königa variegata dotted thinly with Pelargonium Flower of Spring, and surrounded with a band of Lobelia Brighton Blue, and this, again, edged with Lobelia Lady McDonald. The colouring of the series of beds of which the above form a portion is provided mainly by Henry Jacoby Pelargonium, but the combination of light blue, emphasised by the deeper shade of blue, which stands out from the block of soft white and deep rose, to which it lends character, is what I mainly wish to make a note of here.

I am sure that the designers of flower beds fail more often in providing a suitable finish in the shape of edgings than is generally thought. I have had many opportunities of inspecting flower beds in different parts of the country during the present season, and I could not help noting this defect. A soft finish is generally the best, but this is not always necessary, and even bright yellows or deep scarlet may on occasion be employed. The main reason for edgings in summer bedding is to provide a harmonious finish, and either to tone down the principal colouring, to emphasise its effect, or to carry the general character on to other beds or borders. The subject, however, is too wide for discussion in this short note.—B.

THE interesting notes on this subject contributed by "E. M." show that this matter is receiving the attention it deserves in some quarters, and the effective combinations he so well described should stir others up to attempt the grouping of plants in mixed beds on the lines your correspondent indicates, so that we may have abundant variety of form and elegant growth as well as bright colours in our flower garden arrangements. I have long held the opinion that in the majority of plant and flower decorations too much attention has been paid to bright colours without giving sufficient weight to the effect produced by associating with them plants of graceful habit of growth. This not only applies to flower gardening but also to groups of plants and flowers arranged in glasses. By all means let us have bright colours, but as showy flowers so often have a somewhat formal outline let their beauty be enhanced by association with those which possess what they lack—viz., grace and beauty of outline. Zeas, Abutilons, Humea elegans, Fuchsias, the many varieties of ornamental Grasses, Acacias, and Maples are all useful for the purpose, and a further record of favourite beds worked out in various gardens would, I am sure, prove very instructive.—D. W. G.

#### HARDY FLOWERS AT EDGE HALL, MALPAS.

ONE day in the last week of August a solitary pedestrian with umbrella overhead might have been seen wending his way from Malpas Station, Cheshire. Rain was falling heavily, the roads were wet and anything but pleasant, and two uncomfortable thoughts would persist in intruding themselves upon his mind. The first that the Rev. C. Wolley Dod, the well-known owner of Edge Hall, might be from home; and the second, that the heavy rain might prevent his accompanying the writer through the gardens, in which are grown his famous hardy flowers. Had either of these uncomfortable ideas resolved themselves into actual facts great would have been the writer's loss. As it was, however, he need not have entered the domains of Doubting Castle, as fortunately Mr. Wolley Dod was at home, and, as fortunately, the rain ceased when we were about to begin our round of the flowers. I question much if the rain would have put a stop to our inspection, as Mr. Wolley Dod did not mind it, and it would have taken a torrent to have quenched my enthusiasm to such an extent as to have prevented my viewing the flowers. The fine old hall in itself would have been worthy of a visit, but there was so much to be seen among the plants that the time flew all too quickly, and I had eyes for little but flowers, which were magnificently grown, and which far surpassed my anticipations.

With so much to write about I must confess to feeling some difficulty as to where to begin. To the rockeries on the grass, however, we first directed our steps, and there perhaps we had better start. I shall make no attempt to describe these, as I noted more particularly the plants grown upon them than the style of their construction. All, however, were built and planted with exquisite taste and skill. No attempt at formal arrangement is made, but mounds of Saxifrages, sheets of Campanulas, masses of Alpine Pinks, Drabas, Androsaces, Dryas, and countless other plants grow in a manner I have never seen surpassed. "It is too late to see this; it is a May and June rockery," said my courteous guide. Late it was to see the flower, but not too late to see the magnificent growth of the plants. Nor was it too late to realise in one's mind what must be the beauty of the rockwork when these grand rosettes of Saxifraga longifolia uprear their spikes of bloom; when Dryas octopetala unfolds its white blossoms, or when D. Drummondii expands its yellow flowers, and when countless other "stars of earth" shine from the rockwork like in beauty to the stars which bedeck our winter's sky. Nor is it yet too late to see some plants in flower. A number of plants of that beautiful Campanula—isophylla alba—were in full flower, and like everything else was beautifully done. A very beautiful Sedum—S. maximum—was also very fine, and it was all the

more interesting as I had not seen it before. The heads of flower are large and of a fine deep crimson. The habit is more erect than is that of many of the other species, and it is a plant well worthy of growing if it can be procured anywhere. Several other Stonecrops were in flower, but this was the most attractive to me. Very remarkable, too, were the many magnificent plants of Saxifraga longifolia. They had been raised from seed by Mr. Wolley Dod, and varied much in form. Some had the leaves more incurved than others, some were much broader in their leather-like foliage, but noticeable in all was their great size, some two rosettes in particular being of such an immense size that I shall refrain from attempting to put on paper my estimate of their diameter. This Saxifraga abounds at Edge Hall, and adds much to the beauty and interest of the rockeries. I have no time to speak of the many other Saxifragas grown, but must pass on to speak of other things.

Remarkable as are the Saxifrages equally so were the Ramondias. I was quite surprised at the many fine plants of R. pyrenaica growing so luxuriantly. We find it difficult to manage well in this locality unless covered with a frame or handlight to retain the moisture about the plant. At Edge Hall this was not done, but Mr. Wolley Dod keeps his plants as dark as possible, but in what one would call a natural way. They are planted behind a large stone, which gives the necessary shade. The only approach to artificial protection from the sun appeared in one place where a low close fence kept the sun's rays from reaching the rockery on which a large number of plants were growing, and which sloped downward from the fence. Here a considerable number of seedlings of R. p. alba were growing well but had not yet attained a flowering size, so that it had not been ascertained if they would come true from seed. R. serbica and the allied Haberlea rhodopensis were grown in a similar manner. Many of us might, with profit, endeavour to imitate Mr. Wolley Dod's method. I was particularly pleased with the use made of Sempervivum arachnoideum and various Sedums by planting them in fissures and hollows of the stones of the rockery. As in nature many stones are adorned with various mosses and lichens, so in cultivation we might well adopt other mediums for a similar purpose, and thus add to the interest and beauty of our gardens. This little Cobweb Houseleek seems a great favourite at Edge Hall.

We now pass into what may be called the herbaceous garden proper, and here I was quite unprepared for the scene of beauty which presented itself. I was almost transfixed with surprise and admiration at witnessing a splendid clump of Boeckonia cordata. I have seen it well grown many times, but I had never supposed it capable of forming such an ornamental object in the garden. This mass was taller than any I had ever seen, but I do not mean to estimate its height, for truth to tell, one had little inclination to descend to feet and inches with such a splendid plant. The great spikes of Oak-like leaves with the wealth of creamy coloured flowers will remain imprinted upon my memory for many years—should these years remain to me. But here we were passing from one object of interest to another. Asters, say you! Well, Mr. Wolley Dod has a great knowledge of Asters (what hardy flowers does he not know about?) and he tells me, to my great regret, that it is almost impossible to determine the names of many of our perennial Asters. Those of us who are at our wit's end to name our Michaelmas Daisies would be glad to give the Chiswick Conference in October almost a *carte blanche* in the way of the names of these plants. One magnificent Aster in Mr. Wolley Dod's large collection of this family is a comparatively new one, A. Thomsoni, and is so fine as to be worth looking after. The flowers are very large, of a deep purplish blue, and the plant, although attaining a good height, is very neat and compact. Another good flower closely related (although relegated to another genus) is Boltonia asteroides, synonymous, according to Asa Gray, with B. glastifolia. This is not nearly so fine as Aster Thomsoni, but there are many inferior plants of the Asteraceæ in our gardens which might well give a place to this Boltonia.

Very fine, too, in this garden are the yellow-flowered Composites. Many of this family are, it is true, closely alike in appearance, but our gardens would be sadly deficient in colour if they were deprived of their welcome shades of yellow. The Edge Hall collection is a large and select one. Helianthus doronicoides is very good, with tall slender stems surmounted by good yellow flowers with dark centres. Imposing, too, is a very tall variety of Helianthus multiflorus, probably the one grown as H. multiflorus maximus. The Edge Hall variety of Heliopsis lævis is now known to be distinct from another offered by the trade. A large clump of this had a fine effect, and I admired it very much. The exigencies of space must make me leave unnoticed several others of this family, but mention must be made of one not often met with, Chrysogonum virginicum. This is a neat little plant, growing about 1 foot in height, with small bright yellow flowers, and is of a somewhat prostrate habit.

Among the many fine effects in garden arrangements which were to be seen in passing through the gardens, none, I think, surpassed that produced by a line of Anthemis tinctoria pallida planted at the base of a hedge. Some of the plants drooped gracefully forward, touching the ground with their flowers, while others growing through the branches of the hedge were upright, and their flowers projected from its surface. The effect was a charming one; the pale yellow flowers showing beautifully against the dark foliage of the hedge. Mr. Wolley Dod informed me that he had had it photographed, and such a beautiful arrangement was well worthy of permanent preservation. Close to this were large numbers of plants of A. tinctoria, and a white variety, A. t. alba. Noticeable, too, on the same hedge was Lathyrus tuberosus (Sibthorpi?) a good climbing Pea with small but bright purple flowers. I was

informed that this is a troublesome weed in some parts of the south of England, but it is a "weed" some of us in the north would be glad to have in our gardens.

*Veratrum nigrum*, the Black Hellebore, is grown in quantity, and a large mass in full flower was a grand sight. Alongside were plants of one of the other varieties, which generally flower more freely than the black, but they have not flowered at all this season. Although past its best, a plant of *Spiraea kamschatica* (gigantea) had been very fine. A plant such as this, 9 or 10 feet high, with grand flat heads of white flowers must have been an object worthy of all admiration when in good condition. Passing on among hardy flowers in endless array we came to a bed where *Acæna microphylla* or *Novæ Zealandiæ* was apparently revelling in a congenial spot. It was simply splendid to see the mass of yards of crimson spikelets covering the ground like a carpet. Most effective, too, were the best grown plants I have ever seen of *Chrysanthemum latifolium*—seedlings of Mr. Wolley Dod's raising. The flowers were large, broad petalled, and of purest white, some being beautifully notched at the ends of the petals. Deeply interesting were some of Mr. Wolley Dod's seedlings—one a hybrid between a Sweet William and an Alpine Pink; another a tall, large-flowered white *Polemonium*, a seedling from *P. flavum*, and probably crossed with *P. cœruleum*, but finer than either. Another good seedling was a pure white *Aconitum*.

Time and space fail me, however, in my task of endeavouring to tell something of the plants in this wonderfully beautiful garden. I have still notes of many interesting plants I saw. *Eryngiums*, with spikes and heads of blue of various shades, such as those of *E. giganteum*, *amethystinum planum*, and others; *Echinops*, *Iberises*, *Campanulas* of all sorts and sizes; a beautiful clump of *Potentilla nepalensis*, which is an old favourite of mine, and which I shall now know to plant in a mass; *Epilobium Fleischeri*, *Veronica virginica alba*, a mass of grand white spikes; *Lysimachia clethroides*, *Dianthus*, *Androsaces*, *Gentians*, *Cimicifuga racemosa*; *Centaureas*, *ruthenica* being highly praised by Mr. Wolley Dod; *Cytisuses*, *Hypericums*, *Phloxes*, and a host of others make me feel ashamed that I have had the temerity to attempt to write here of what would require the whole of the Journal to treat aright.

I have said little of the courtesy and kindness shown to me by the owner of this beautiful place. I have said nothing of the vast stores of knowledge regarding his favourite flowers which he possesses, and which he does not regard as for his own benefit alone, but which he is ever ready to impart to others in such a manner as to make a walk through the gardens in Mr. Wolley Dod's company so interesting and so edifying that I was loth to tear myself away from a guide so courteous and a scene so fair. The farewell had, however, to be taken, and I left Edge Hall feeling even greater love for my favourite plants, but regretting that my little garden in "Bonnie Scotland" cannot lend itself to yield such beautiful effects. Mrs. Beecher Stowe has written a book with the alluring title of "Sunny Memories of Foreign Lands." I have many "sunny memories of other gardens," but none will linger longer in my mind than that of my visit to Edge Hall, with its incomparable flowers which seem to laugh to scorn my feeble attempts to describe their beauties, but which make one long for the inspiration of some of the poets who can so worthily sing of their loveliness.—S. ARNOTT.

#### LARGE GROWERS IN SMALL CLASSES.

MR. RAILLEM has failed to answer the chief argument, and again evades the main question at issue. He does not appear to be very happy on the ground he has taken up. He must know full well he is wrong, but he does not seem to like to admit it. It was never a difficult problem to solve if the will was there, but as Butler puts it, "Convince a man against his will, he's of the same opinion still."

Reverting to your correspondent's statements. In the first place he states that an exhibitor and his friends took no steps to bring the matter before the N.R.S. in the proper manner. This, I think, he will find erroneous if he will take the trouble to inquire of the Hon. Secretaries. I think he will find a gentleman of the Committee two years ago brought the matter before that body, with a draft of a revised schedule prepared for their consideration and approval. I also forwarded one of a similar character to the last general meeting. Again; has it not been brought before the Committee, and every one of your readers who is interested in Rose growing and Rose showing week after week through these columns? and is it not a fact that the most effective mode of seeking redress for any grievance is through that powerful organ the Press?

Secondly, he states that the N.R.S. have done something in the direction desired by adding one class and two medals. This has no connection whatever with the question of large and small growers. The class referred to is especially for exhibitors who have never before taken a prize at the metropolitan show. When once that prize has been obtained by an exhibitor he cannot enter the same class again.

Thirdly, he states that no such just grievance existed or exists. To

this statement it is sufficient to say, If there were no grievance there would be no cause for complaint. I think I could not do better than refer your correspondent to the observations of the Rev. Mr. Pemberton upon this subject in the *Gardener's Magazine* of August 27th.

In referring to the instance at Hereford Mr. Raillem states that there was no case made out against the schedule or management, but that I admitted justice was done. Justice was done by the Committee in not allowing the exhibitor to re-enter, but had that exhibitor in the first instance entered for twelve instead of twenty-four there is no rule in the schedule that could have prevented his doing so. That is the bone of our contention. That the large growers shall not slide down into the smaller classes.

One word in answer to your correspondent's last paragraph. In backward seasons small growers are just as much handicapped as large ones, if not more, considering their respective requirements, but all that they ask is that they should only have to fight their equals; while what Mr. Raillem requires is, that when he is not up to his usual strength he shall be allowed to slide down and snatch the prize from the man of one-quarter of his equipment! This certainly is not my view of fair play.

As I am tired of continuing a correspondence that seems to lead only to contradiction without argument, Mr. Raillem may retain his own opinion, and I will of a certainty hold mine.—AN EXHIBITOR.

#### A VISIT TO COLCHESTER.

MR. B. R. CANT'S.

WE were glad to see our old friend and his wife and family looking well, and to partake of their never failing hospitality; with "The Trophy" in its old place of honour on the table, and pleasant talk of the present and past seasons we might have been disposed to linger had not the unwonted occurrence of a tolerably fine afternoon urged us to go out to see the Roses.

No one can, I think, deny to Mr. B. R. Cant the foremost place among professional Rose growers, not only from the mere fact of his having most often won championship honours, but also because he may be looked on as quite the veteran pioneer of all Rose growing competitions. That he still so successfully holds his own shows that the famous "Alderney butter" subsoil of his land is by no means exhausted, and that himself, his sons, and experienced foremen are able to keep up the old reputation in spite of the greatly increased competition of young and vigorous firms.

The original *Maréchal Niel* which we used to reverence on the south wall of the house has had to give way to an enlargement of the building, but many fine standard Teas still remain near at hand in full vigour, though of considerable age. From one of these a lovely specimen of *Madame Berard* was cut for us, perfect in form, and most beautiful in its many varied shades of colour. The backwardness and lateness of the season was naturally a theme of general comment. I understood Mr. Cant that by the date on which he cut his first blooms this year he had last season sold £300 worth.

We went first among the dwarf stocks, and in one piece of ground noticed alternate rows of cutting and seedling Briars, which were to be budded with the same sorts in order to test the difference. I was struck with the absence of weeds, which in such a season means not only care and trouble, but also expense. The most troublesome and necessary parts to clean are those where Briar cuttings are being struck for next year's budding—troublesome because the shoots grow horizontally almost if not quite on the ground; and the weeds must be drawn by hand, which is a terrible job, as I know to my cost; and necessary, because all parts of the plant being so close to the ground the weeds are more smothering and harmful.

The standard stocks were a sad sight indeed, a very large proportion having been killed by the severity of the winter. Old and young had suffered alike, and even some of those which had grown out had shrunk and died afterwards. There can be little doubt (and it is a fact that amateurs should bear in mind) that in November, 1892, standard Roses of all sorts will be scarce indeed, and good strong ones rarer still.

Teas were being budded on the standards, and the method pursued did not differ from that generally in use among amateurs, except that Mr. Cant surprised me by saying they did not unfasten the ties of raffia at any time, even on the standards, but left them to decay when they would. I think amateurs, who have more time to potter over individual plants, will find it better to remove the ties from their standards at the end of a month; on dwarfs, contact with the damp earth causes the raffia to rot off just about the time when it ought to be loosed, but on standards I think the shoot will often be indented and the flow of sap checked if the tie remains, and if it be removed I fancy the inserted Tea buds will ripen more, and be in a better condition to withstand the winter frosts. Nevertheless, I feel very strongly that in venturing this opinion I am "teaching my grandmother" with a vengeance. One other item in budding we learnt here—that the bud nearest the bloom, and generally of a more pointed shape than those lower down, is not fit for use; it commonly produces a flower bud at once on a very short stem, and even if it does not then die outright a satisfactory head seldom results. I recognised the description of the result at once, as having several times occurred with me, but did not before know the cause.

Mr. Cant thinks that bad growers, both among H.P.'s and Teas, make stronger growth and better heads as standards than as dwarfs. We were to note as instances *Princess of Wales* (T.) and *Germaine Caillot* (H.P.). We did not compare, I think, the former variety, but we know that Teas do better as standards if they can be kept alive

through the winter. In comparing the standard and dwarf examples of Germaine Caillot, I personally imagined that the difference was more in appearance than in reality; but we did not make any measurements, and no doubt Mr. Cant was right. Still, Germaine Caillot has certainly, I should think, a Tea cross in its constitution. I wish I had asked to compare standard and dwarf specimens of Madame Ducher (H.P.), for instance.

The large numbers of Roses of certain sorts grown to order for America were rather a matter of wonder to us; but I fancy they do not make budding out of doors answer over there, and I suppose the plants were principally meant for pots under glass. Our transatlantic cousins are credited in general with liking "anything big;" but I saw Boule de Neige reserved for them as well as Ulrich Brunner.

There were very few noteworthy blooms to be seen worthy of mention, which may seem odd, but of course it was just the slack season, and we came perhaps with eyes and tastes which had grown rather hypercritical during the show season. Moreover, I should have mentioned previously that all available blooms, here and at Mr. F. Cant's, had been cut the day before for a large display at a Colechester bazaar.

Buttonhole Teas, which gratefully respond to even a couple of decently fine days, were perhaps looking best. Among these I pointed out to my friend an unusually fine strain of Madame Faleot, which seems to me to be decidedly larger and fuller than the well known variety. Whether it will prove to be distinct or nothing more than an improved strain is now being tested; but the smallest sport for the better is worthy of propagation, and a good Rose slightly improved may be really more valuable than an absolutely distinct sport.

In taking leave of our kind friends I registered a mental determination to make my visit earlier next year, and a general hope was expressed that next season would at least be an improvement upon that of 1891.—W. R. RAILLEN.

### A DAY AT THE LAKES.

NOT much to be seen of the Lakes in a day, many of your readers will say, but if one only gets a route arranged, and is in the right frame of mind, he may see not only a great deal of the scenery, but the associations with which this delightful country abounds will linger in his mind for many long days. So one day last week I left Liverpool by the early train and reached Windermere shortly before eleven. As the conveyance took me from the station to the boat beautiful glimpses of scenery opened out here and there. The houses, built of stone, the greater portion showing no signs of mortar in the building, seem to be thoroughly in harmony with the surroundings.

Proceeding up the Lake to Ambleside, few could fail to be impressed by the magnificent view opened out before them. The day was not of the brightest, but what of that? The summits of many of the hills in the distance were clouded in mist, whilst below the effects the clouds produce must be seen to be believed. Many artists give us canvas representations of these cloud effects which in some instances are looked upon as exaggerations, but seeing the deep purples, golds, and greys made me feel that I for one must have been mistaken many times. The journey up the Lake being accomplished, I joined the Grasmere coach at Waterhead, and it is this delightful drive that is perhaps the most enjoyable feature of the day. We pass along the road skirting the Lake, and at every turn new views open out. At one moment we are under avenues of splendid trees, at the next we have views of the distant mountains, many clothed to the summit with Pines, Larches, &c., while small streams of water, like silver streaks, flowing down help to swell the beautiful blue waters at their feet.

We pass Wordsworth's seat, and the house in which Hartley Coleridge lived. There are old-fashioned cottages, quite in keeping with the rusticity of the place, over which are growing the Virginian Creeper and purple Clematis side by side, the former just beginning to put on its crimson tint, and forming a pleasing combination with the deep purple of the Clematis. Here in a profusion to be found in few other places is *Tropæolum speciosum*, growing over the fronts of the houses, but it is not so fine as I have seen it in former years. The gardens, too, how I wished time would have permitted me to make an examination of their contents. Lilies in many varieties were expanded and expanding, and seemingly quite at home; herbaceous Phloxes, with flowers of the most delightful hues; Carnations and old-fashioned Roses adding their fragrance, and many other flowers which could not all be noticed as the coach whirled past, were to be seen in these gardens, planted without any orthodox system, and growing and flowering in the greatest luxuriance. Lovely hardy Ferns, amongst them the Royal Fern and many other kinds, are here to be met with. It is little wonder that Wordsworth has left us so many delightful reminiscences of his beautiful country. There is no need to ask the way, as we enter the old-fashioned church gates at Grasmere to look on the resting place of the poet, for the grass is already trodden by the feet of numberless admirers from all parts of the world. At

one corner lie Wordsworth and his relations, whilst a few yards distant is the grave of Hartley Coleridge.

On the return journey we pass the residences of De Quincey, Harriet Martineau, the late Dr. Arnold, and others. In no way can the scenery be seen to such advantage as from the coach. With railways would in time come works of various kinds, the smoke and gases of which would destroy much of the vegetation. We have in the railway journey glimpses of all this, where for miles may be seen trees dead or leafless. Is it benefit to their fellow creatures that is the one consideration of those who would deface such a charming retreat? I am afraid not. Is it not rather as Wordsworth has so beautifully put it:—

"The world is too much with us; late and soon,  
Getting and spending we lay waste our powers,  
Little we see in Nature that is ours;  
We have given our hearts away—a sordid boon?"

—R. P. R.

### NOTES AT READING.

DISHEARTENED and dispirited flower gardeners may be forgiven if they turn somewhat impatiently from the gloomy pictures, real and descriptive, of the effects of the season, and seek to find relief amongst indoor plants. The beauty of the bedders has been seriously marred in many places, and annuals are greatly lacking in colour, while notwithstanding care in tying, herbaceous plants have suffered from the heavy gales. The absence of warmth and light has of course not been without a certain influence on plants under glass, but they at least have only suffered in a negative sense from wind and rain, and greenhouses and conservatories have had more than their usual share of patronage from the frequency with which the elements have rendered the flower garden untenable. The choicer florists' flowers in their improved forms are of great usefulness, and it is interesting to note, when opportunities arise for observing progress at the respective fountain heads, that the work of improvement still goes on. Messrs. Sutton & Sons of Reading hold an honoured place in the ranks of those who have enriched our store of valuable flowers, and their nurseries in London Road, Reading, which are a few minutes' walk from the great seed warehouses, are invariably full of interest to those for whom flower fertilisation has special fascinations.

The large flowers and rich colouring of the ennobled Gloxinias now ready to any grower's hand show forcibly what immense strides have been made with this particular flower. Even a dozen or score of plants are capable of producing a most bright and cheerful effect in a greenhouse or conservatory, but at Reading there are between 3000 and 4000 of them, a truly wondrous display. There are many hundreds of plants that were raised from seed sown in February this year, dwarf, well clothed in healthy foliage which curls down and hides the pots (5-inch) in which they are growing, and bearing several large flowers. The colours are very beautiful and diversified. This is an excellent strain admirably grown. One variety named Her Majesty is of exceptional beauty. It is a pure white, with large substantial flowers on very short sturdy stalks. It has the true crassifolia habit, and when sent out should speedily become popular. Many persons fail to have Gloxinias in good condition, amateurs frequently erring by saturating the foliage daily. This is a serious mistake. They like a cool shaded spot and plenty of water at the roots and a genial atmosphere during growth and flowering, but from the seedling stage no water should be allowed to fall upon the leaves.

Begonias provide another strikingly beautiful display. Two or three housefuls of plants bear brilliant testimony to the merits of the "Reading Beauty" strain. The great majority of the plants now in bloom were sown in February of the present year, and for some time they have been flowering in rich profusion. They are remarkably dwarf and compact in habit, with the flowers thrown well up above the foliage on substantial stems. The day of the Tuberous Begonias with flowers half hidden amongst straggling foliage is past. The type is hopelessly out of date. The newer forms have not lost in beauty of colouring or size of flower by the change in character of growth. We now have blooms of the largest size standing boldly up clear of the leaves, and the rich effects which Begonias are capable of producing are more fully realised than they could ever have been by the old type of plant. A pure white, a deep crimson, and an orange-scarlet were particularly noticeable, and the rose and pink shades, which are so popular and pleasing, are numerous. The plants are in 5-inch pots. There are, too, some thousands growing out of doors, and it is worthy of note that the rain has by no means washed all their beauty out of them; on the contrary, the flowers have stood it remarkably well.

Cyclamens sown in November last are the picture of robust health and vigour. They are in 6-inch pots, the surface of which is almost hidden by the abundant leafage, and they are unmistakeably handsome even while flowerless, for the marbled foliage is distinctly ornamental. Differing from Gloxinias, these plants love moisture over the leaves, and it is practically certain that the majority of the failures which occur with them are attributable to too dry and arid surroundings. There are between 2000 and 3000 plants, all of the same sturdy healthy type, and all bristling with flower buds. The houses in which they grow are low, and the roof is only sloped sufficiently to allow of rain running freely down; this, combined with the high stages on which the plants rest, bring the latter close to the glass, and no doubt accounts for their

dwarf and sturdy habit. Primulas, Calceolarias, and Cinerarias are flourishing in a young state in pits and frames. There is a splendid batch of the latter in 6-inch pots that were sown in June.

One of the most attractive houses in the nursery at the present time is that filled with Achimenes, which are grown for the tubers. The varieties are not numerous, but they are strikingly select. One of the most beautiful as grown there is *A. splendens*, five plants being flowering in a 5-inch pot. These make charming little examples a foot high and nearly as much through, loaded with their vivid scarlet flowers. More pleasing ornaments for an amateurs' greenhouse it would be impossible to imagine. *A. coccinea* is another beautiful little variety, with brilliant scarlet flowers a trifle smaller than those of *splendens*, and even more freely produced. *Margaretta*, white, with much larger flowers; *Rosy Queen*, a variety with beautiful rose-coloured blooms sent out last year, dwarf, free, and exceptionally fine; *Lady Lyttleton*, rosy carmine, with fringed Primula-like flowers; *Ambrose Verschaffelt*, white, splashed and veined with purple; *Carl Wolfarth*, purplish violet; and *A. longiflora major*, bluish mauve, with lovely, long-tubed flowers, are all eminently worthy of culture.

*Gesnera zebrina discolor*, of which a batch is grown, is a distinct and handsome plant. It has large glossy leaves, green when young, but deepening to purple with age, and tubular flowers of which the exterior is bright scarlet and the interior yellow dotted with brown. Both leaves and flowers are effective. The plant requires substantially the same treatment as *Gloxinias*.

Out of doors, one of the principal features of interest, apart from the *Begonias* already mentioned, which are this year's seedlings, is a large quarter of Stocks and Asters grown for trial. The former are now past their best, but the latter are coming into splendid bloom, and will be worthy of inspection by any visitor. Nearly all of both Asters and Stocks were sown in the open ground where they are flowering. Seedling Carnations have been wonderfully full of bloom. A large bed of *Zinnias*, dwarf and freely flowered, is very attractive, and *Portulacas* have only wanted a little sun to show their wonderful colours in perfection. It is somewhat strange that these brilliant dwarf annuals are not more generally grown. As something a little out of the common may be mentioned a number of Egg Plants fruiting freely in the open border. The varieties are white and purple, the former closely resembling the eggs of poultry. They were put out about the end of May. In another part of the establishment, too, were shown what is not often seen, *Freesia refracta alba* flowering at less than six months old from seed. The latter was sown on the 13th of March this year, the plants grown in the open air until they showed flower, and then placed in a cold pit. This is interesting as showing that bulbs have not to be absolutely depended on when quick flowering is wanted. *Fuchsias* seven months old from seed are also blooming freely.

Perhaps in such a season as the present it may be worth while to mention a really fine crop of Tomatoes in the open air. There is a large breadth of about 1500 plants in rows 3 feet apart, and a foot from each other in the rows. They are exceptionally healthy, not showing a trace of disease, and are bearing abundance of fruit. The ripening, of course, is somewhat backward, but the foliage has been well thinned to admit as much sun as possible, and if a warm month should come there will be nothing whatever to complain of. The pick of the varieties are *Perfection*, *Earliest of All*, *Abundance*, *Golden Perfection*, *Maincrop*, *Golden Nugget*, and *Cluster*, all of which are cropping splendidly. The plants are growing in unmanured land, but have recently been assisted by a good mulching.—NONDESCRIPT.

### FRUIT GROWING IN THE SOUTH OF IRELAND.

At the Cork School of Art a Conference on fruit growing and market gardening, considered as a profitable industry for the South of Ireland, was held last week under the presidency of the Mayor. There were also present Sir George Colthurst, Captain L. Beamish, Dr. Colthurst, Colonel Hall, the Dean of Ross, Sir George Wycherley, Messrs. T. F. Rivers (Chairman British Fruit Growers' Association), Bullock Hall, W. L. Cole (Dublin), James Byrne (Chairman County Cork Agricultural Society), and others.

The Mayor having opened the Conference,

Mr. Bullock Hall said he had made the land question a study in different parts of Europe, having travelled through Belgium, Germany, France, and Italy, and he was greatly struck at the great variety of crops that were grown in the small narrow strips of land in those places, especially on the south side of Paris. The English farmer rushing through these lands in a train generally got hold of the idea that they were worse farmed than the average farms would be in England, because he did not understand the principle on which they were worked. Farmers holding crops of 10 acres or under made a mistake if they farmed on the same principle as they would work a large farm. They should instead of growing cereal crops turn their attention to the cultivation of fruit on small holdings, and with such a market at hand as they had in Cork the change would pay well. With a view to encouraging this industry in England they had approached the Great Eastern Railway Company and obtained from them an agreement to carry 1 cwt. of the produce to London for 9d. and deliver it within an area of four miles. He had no doubt that would excite their railway companies of the south of Ireland. He had received before leaving home the prospectus of a society called the Cork and Waterford Farm and Garden Supply Society. That was the very society which he should like to see started, and he hoped the railways will be induced to give

them the same facilities as the English railways gave the small growers.

Mr. T. F. Rivers then read a valuable paper on the subject of the Conference, in the course of which he said the question of a continuous and abundant supply of fruit to the British markets grown on British soil was a matter of serious consideration, and public attention had rightly been aroused to the fact that a great industry had been in danger of passing away from those who ought to be the first to reap the profit arising from that industry—the fruit growers of Great Britain and Ireland. The capital required for this industry was very small compared with that required for business or manufactures, and the value of the produce increases year by year by the sole action of natural forces. Fruit shows had lately been held in England, at which fruit from Ireland had been shown in excellent condition, which proved that British fruit is second to none in quality.

In Ireland the orchards were too old and too much dependance was placed on the supply of fruit on these old trees. The idea that a fruit tree will last and produce fruit during three or four generations of men was entirely erroneous, the life productive power of an orchard at its best being not more than thirty years. In his opinion, the modern orchard should be planted on a totally different system. Instead of a standard 20 feet apart, giving 108 trees to the acre, it is possible to plant trees of Apples, Pears, and Plums at 12 by 12, and to keep them at the height of 9 to 10 feet high. This system can be most efficiently carried out by planting trees of from two to three years old, with fibrous roots and healthy and vigorous stems, allowing a clear stem of 3 feet before branching, and removing all buds and shoots below this height. This clear stem is necessary for the free circulation of air, and also for the growth of bush fruit between the rows of the taller trees. He had hitherto been very successful in fruit growing, which was due to the way he had studied the soil.

The Apple occupied the highest position as an industrial fruit, and was an article of diet of the greatest importance in Great Britain, owing to the very great importation of this fruit from America and Tasmania. The British grower should endeavour to give sorts that will be available before the foreign supply reaches our shores, as there is less competition in the summer months than in the winter. The culinary Apples now recommended for England are—Lord Grosvenor, Keswick Codlin, Duchess of Oldenburg. Dessert Apples—Irish Peach, Quarrenden. Autumn culinary—Ecklinville, Stirling Castle, Warner's King. Dessert—Worcester Pearmain, Kerry Pippin, &c. Winter—Hawthornden, Lord Derby, &c. Spring—Bramley's Seedling, Lane's Prince Albert, Braddick's Nonpareil, Scarlet Nonpareil, &c.

As an industrial fruit the Plum is next in importance to the Apple, and requires the same conditions of soil and position, although the fruit orchards of Germany and France supply a large proportion of the fruit sent to the British markets. The earliest sort was the Early Rivers, which in soils containing a large percentage of lime is a certain and abundant bearer. He had never known it to fail owing to the time the tree is allowed to recover strength between the gathering of the fruit and the bearing of the succeeding year being nearly eight months. With reference to French Pears, they brought such a good price that they should be grown wherever the climate suited. Grafted on the Quince stock the Pear will bear fruit in three years, and will bear fruit on this stock for fifteen years. They can be grown with great facility in many parts of the south of Ireland, and there was no reason why Pear-growing should not become an important industry (applause).

Mr. Hartland then read a paper, in which he stated that they possessed a rich store of true Irish Apples, quite unequalled in their respective seasons. He named a few in their order of ripening:—the Irish Eve, the Irish Peach, the Kerry Pippin, the Donoughmore, the Blackwater Pearmain, the Molly Gibbons, or Irish Russet, the Ross Nonpareil, the Scarlet Cluster, and the grand Belfast Apple, the Ecklinville, the last two being bakers, and the remainder table fruit. Our soil and climate offered early and special advantages, and the greater portion of first fruits found a ready and profitable sale in Dublin, while in Cork, where twenty years ago a basket of choice fruit had to be hawked through the city, and was often returned unsold, several firms now bought by the ton. As to employment, children were nimble bush fruit gatherers, and anyone who had visited the Continent at summer time must have been delighted to see whole families thus healthily and profitably employed. Some might have seen this in our own country fifty years ago, when the autumn drive along the Blackwater was one not soon forgotten. That valley was thickly covered with fruits.

With regard to the question as to how they proposed starting and carrying on this work, anyone who had observed our market gardeners—who had made Cork vegetables famous—should see that these men were precisely the class most suitable for fruit growers. The day could not be far distant when fruit would form a part of every meal as it did in America. The Government, he was sure, would assist with small loans repayable during six years, and proper security could be given. With good instructors very few lessons would suffice, and that fine industry might be at once established—possibly in a small way at first, but the growth would be rapid and a good slice of those millions sent to America and to the Continent would find plenty of empty pockets at home. Mr. Hartland then quoted from several well-known pomologists as to the possibilities of the soil of the South of Ireland as regards fruit growing.

Sir George Colthurst, in proposing a vote of thanks to Mr. Hall and the gentlemen who had read papers, expressed it as his opinion that the reason for the disappearance of the orchards which used to line the

Blackwater was found in the fact that the trees were too old, and were never removed. Mr. Hartland had said that the Government should help them in that matter, but he (Sir George Colthurst) would like to know what the Government of Australia did to foster the industry in that country. They were too fond of ascribing everything that went wrong to the Government of their country. However, he thought the Government could and should do something in the way of instruction (hear, hear). If they could get school teachers thoroughly "ground" in the culture and growing of vegetables and in the practice of good pruning and good cultivation then they might hope in the near future to do some real good in the matter.

The Dean of Ross seconded the proposition, and hoped they were inaugurating a new era in the fruit growing industry of their country.

The proposition was carried unanimously.

On the motion of Mr. B. Hall, "The County of Cork Fruit Growing Association" was formed in connection with the County Cork Agricultural Society. Mr. Hall promised to give a donation of £10 and an annual subscription of £5.

A vote of thanks having been passed to the Mayor, the Conference terminated.—(*Cork Examiner*.)

**EVENTS OF THE WEEK.**—The Royal Horticultural Society's Fruit, Floral, and Orchid Committees will be held in the Drill Hall, James Street, Victoria Street, at twelve noon, on Tuesday, September 22nd, and at the afternoon meeting papers by Mr. R. Lindsay of Edinburgh and by Mr. Lewis Castle will be read concerning Insect-eating Plants. Upon Friday, September 18th, Messrs. Protheroe & Morris will hold an important sale of Orchids at their Cheapside Rooms. This will comprise an importation of the true old autumn-flowering *Cattleya labiata* from Messrs. F. Sander & Co. It is the species upon which Dr. Lindley founded the genus *Cattleya*, the plant having been found by Mr. Swainson, and introduced in 1818. The present plants are said to have been brought from the same district over which Mr. Swainson travelled.

— **BRILLIANT SUMMER WEATHER** was experienced over England on several days last week. In London the thermometer in the shade rose to 82° on Saturday, or 16° above its average maximum height for September, and 1° higher than at any time during the previous three months, and on Sunday it rose to 83°. Although a cool wet summer is more often than not followed by a fine warm September, it is seldom that the thermometer at this time of year rises much above 80°, but it has done so on four successive days in London, a circumstance that has not occurred for twenty years. There have been eight Septembers in the course of the past twenty years in which the thermometer in London has exceeded 80°, but only four in which it has reached a higher level than it did on September 10th and 12th. During the whole of the twenty years, 1871 to 1890, there was only one instance in which the extreme warmth of the summer months was exceeded by that of September. This was in the year 1880, when the thermometer on the 4th September rose to 87°, or 6° higher than at any time in June, July, or August. Heavy showers fell on Monday and Tuesday this week, and there has been a great fall in temperature, the minimum yesterday (Wednesday) morning being 53°.

— **A NEW TEA ROSE.**—An attractive new Tea, named *Corinna*, was shown by Messrs. W. Paul & Son, Waltham Cross, at the recent Aquarium Show. It is a wonderfully free bloomer and a good grower. The colour is salmon. If good in the bud state it will prove a valuable variety for cutting, as the tint is popular and pleasing.

— **AN INCREASE OF PREMISES** has again been found necessary by Messrs. Carter & Co., and they have secured the huge building lately occupied by Messrs. Day & Martin in High Holborn, which will add largely to the conveniences at their disposal for coping with their large and growing trade.

— **FRUIT IN KENT.**—A good deal of damage was caused to the fruit crop in Kent by the very boisterous and wet weather recently, a large quantity of Apples, Pears, and Plums having been blown from the trees, and in consequence coming on the market in such quantities as to keep prices on a low level. In the fruit-growing centres of the county most remarkable sights are presented by the Damson and Pear

trees, which, generally speaking, are loaded to almost a phenomenal extent, while Plums are also very plentiful. Apples seem fairly plentiful, but they are "patchy," some parts having abundance, and others just the reverse.

— **THE POTATO DISEASE.**—Mr. Robert Fenn writes:—"My Potato haulms (dressed as described on page 193), where they are not ripening off a proper yellow, still maintain a remarkable greenness amidst the blackness of desolation around. Most prominent are the Woodstock Kidney, the Sir Charles Douglas, and the second plantings of Early Border and Ringleader. I do not propose to dig any of my trial rows till every green leaf has ripened, thus giving the tubers a test to appear at their best or worst."

— **GARDENING APPOINTMENTS.**—Mr. A. Abrahams, for the last twelve years gardener to T. H. Wilson, Esq., Hazelholt Park, has been appointed gardener to Lord Clifford at Ugbrook Park, Chudleigh, Devonshire. Mr. Robert Raisbeck, general foreman at Witley Court, has been appointed gardener to Lord Heytesbury, Heytesbury, Wilts. Mr. J. Brand, who has been for thirteen years gardener to the late Mrs. Gardiner, has been engaged to continue his services at Essendene, Caterham, Surrey, by the present occupier, C. Warren, Esq.

— **THE BEDDINGTON, CARSHALTON, AND WALLINGTON HORTICULTURAL SOCIETY** have decided to hold an Exhibition of fruit and Chrysanthemums, also a Conference on Apples and Pears for the district on similar lines as adopted by the Royal Horticultural Society at Chiswick in 1888. A sub-committee has been appointed to draw up the schedule. The date of the Show is not definitely fixed, but it is expected to be towards the end of October, in the Public Hall, Carshalton. Mr. G. W. Cummins, The Grange Gardens, Carshalton, is the Honorary Secretary.

— **FLOWER SHOW FUND AT NEWCASTLE.**—It is very gratifying to learn that the Newcastle-on-Tyne Horticultural Society has been speedily relieved of the financial troubles brought upon it by the storm which compelled the Committee to abandon the autumn Exhibition. At a recent meeting it was announced that, after all the Society's liabilities had been discharged, there would remain a balance of some £200 to go on with. It will not therefore be broken up. We are glad that the appeal made on its behalf has been so successful. The suggestion that a substantial sum should be subscribed, and kept in hand as a sort of insurance fund, is a good one, and deserves to be acted upon.

— **THE GALA AT GATESHEAD.**—A northern daily asks what is to be done for the Gateshead Flower Show Society. They have been quite as unfortunate as the Newcastle Society, for their tents were blown away by the gale; and, although some portion of the exhibits were shown, it is understood that the financial results of the venture were most discouraging. A hope is expressed that the Gateshead Society will receive the generous consideration of the public, and that those who intended to visit the Show, but did not on account of the weather, will forward to the Secretary the sum which they intended to pay at the gates of Saltwell Park.

— **WEATHER AT LIVERPOOL.**—Very agreeable is the change in the weather since I last wrote. Instead of storm we are having a calm, continuous sunshine prevails, and altogether we are having the most delightful weather. Short though the time has been since the welcome change we can see the beneficial results on the fruit trees, and Apples are already beginning to assume a rosy tint, whilst Pears are swelling fast, and Plums ripening. Harvest operations are in full swing, and bad as the outlook seemed such a very short time ago it is brighter now. The thermometer has registered 88°, 90°, and 86° on three of the days in last week.—R. P. R.

— **HARDINESS OF CAMPANULA PYRAMIDALIS.**—There seems to be a doubt prevailing as to the hardiness of this species of Bellflower, but with us it is perfectly hardy. I have repeatedly kept it through the winter in the open borders, and for several years past we have had one or more self-sown plants in flower that have wintered with their roots well established in rough stone walls. If a plant will live through such a winter as that of 1890 and 1891 unprotected, it must be considered perfectly hardy, and although we had none of the *Campanula pyramidalis* in the borders, a strong wall plant came out of the ordeal quite uninjured, and is flowering well at the present time. Although quite hardy, I yet prefer the species for pot culture as it is most effective in conservatories while those in the open are nearly always spoilt in appearance by either strong sunshine, wind, or rain.—SOMERSET.

— CRYSTAL PALACE SHOW.—In your issue of 10th inst. I notice you state that the first prize at the Crystal Palace Show for the best dish of Carter's Blenheim Orange Tomato was won by Mr. J. Slater, Lower Sydenham. This is erroneous, as I was awarded first in that class. Kindly correct in your next edition.—JAMES FRY, *Haydon Hall, Eastcote*.

— A NEW TROPEOLUM.—Messrs. Clibran of Altrincham have evidently secured a decided acquisition, judging from the specimen now before me, and which differs from anything of the kind I have hitherto seen. At first it looks like a bunch of fluffy gamboge yellow Crocuses, but the colour is much more brilliant and peculiarly telling. The height is about 4 inches, and never exceeds 6. One of the sights of the flower garden next year may be a long effective line, or a central bed of a colour never seen in the flower garden before. Then it must be remembered that this will be one of the easiest grown and raised.—W. J. MURPHY, *Clonmel*.

— THE FLOWER ARTIST IN JAPAN is described by Mr. Condor in a volume he has just issued at Tokyo as avoiding a grouping of colours and transplanting his flower in a vessel specially designed to receive it. A solitary spray of flowers in a slender vase, a water plant in a graceful bowl, a creeper climbing the handles of a basket-shaped receptacle, an Orchid growing in a joint of Bamboo, or a cluster of Wistaria depending from some quaint hanging vessel—these are some of the forms in which the Japanese flower artist loves to indulge. The arrangement of flowers, Mr. Condor says, has always been regarded in Japan as an occupation befitting learned men and literati. "Ladies of the aristocracy have practised it, as they have other arts, but it is by no means considered as an effeminate accomplishment. Priests, philosophers, and men of rank who have retired from public life have been its most enthusiastic followers."

— THE HEADING OF CABBAGES.—It has recently been stated, as the result of an experiment in one of the United States stations, that if Cabbages are slightly tilted over with the plough in the fall, it produces a tendency to make them have larger heads. We now learn, as an experiment by Prof. L. H. Bailey of Cornell, that if the Cabbages are planted shallow and earthed up, the per-centage of large and heavy heads is much greater. As a matter of physiological principles these two experiments in different directions both accord. It goes to show that whatever favours the nutritive power is against their disposition to produce hard heads. In Mr. Bailey's experiment the plants got the benefit of abundant moisture and nutrition, when headed up. When not headed, or when not earthed up, or slightly tilted, there is an obstruction to complete nutrition. Although these experiments seem of a somewhat unimportant character, they afford very interesting lessons to the study of plant life, from a practical point of view. We think the experiments ought to be repeated in view of these valuable and suggestive lessons.—(*Meehan's Monthly for September*.)

— BOURNEMOUTH AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—The third annual excursion of the Association took place on Wednesday, September 9th, to Longford Castle, near Salisbury, the seat of the Right Hon. the Earl of Radnor. The party, which included Dr. Hitchcock (President of the Association), and Councillor J. A. Tyler, also Mr. J. J. Swaffield, Mr. G. Watts, jun., Mr. W. Watts, and Mr. J. Phillips, nurserymen, journeyed by rail to Alderbury Junction. A pleasant walk of about a mile brought them to the entrance to the park, where they were heartily welcomed by Mr. Ward, the head gardener, who, with his two sons, and Mr. Warden, gardener at Clarendon Park, conducted the party over the extensive gardens and pleasure grounds. The old castle, portions of which date from the sixteenth century, was much admired, and the fine bedding display on the terrace gardens received well merited praise. After viewing the pleasure grounds, which were in splendid condition, the party were next shown the fruit and kitchen garden and glass departments, and as Mr. Ward was well known to be a successful exhibitor of fruit, &c., each department was critically examined and favourably commented upon. The party next proceeded to the cricket ground in the park. Here, in a tent kindly lent by Lord Radnor, a capital luncheon was served, after which hearty votes of thanks were accorded to Lord Radnor for his kindness in granting permission to the Association to visit his beautiful park and gardens, also to Mr. Ward for the manner in which he had received the members. The afternoon was spent in cricket and quoits, and after partaking of tea, the return journey was commenced about 6.30, Bournemouth being reached after a most enjoyable day about nine o'clock.—J. B. S.

— RAINFALL DURING AUGUST IN HAMPSHIRE.—The month of August will long be remembered for the excessive quantity of rain which fell in this part of the county. I do not remember any month when the quantity, 6.69 inches, was exceeded during the last twelve years; but twelve dry days are recorded for the whole month, the last nine days rain fell on each day, in all a total of 3.21 being recorded. In spite of the wet state of August we are still 3.17 inches below the total amount recorded for the first eight months of last year, which was 22.1 inches, while this year so far but 18.85 inches has been registered. Up to the end of August we have had 156 days upon which no rain fell as compared with 151 during the same period of 1890. During February of the present year not a single drop of rain is registered, and but on three days did rain fall during the same month of 1890, which upsets the old saying of "February fill dyke" very considerably. Swanmore Park being situated on a hill 395 feet above sea level accounts for so many dry days, upon many of which showers fell in some cases heavily in the valleys around.—E. MOLYNEUX.

— FRUIT CONGRESS AT MANCHESTER.—Mr. Bruce Findlay sends us the following letter he received from the Right Honourable W. E. Gladstone:—"I will not withhold the expression of my good wishes for the fortune and effect of the meeting you are to hold in October, but it will, as I hope, have the support of those who are much better entitled to speak with authority. For many years, through the activity of the Press, the humble advice given by me locally to our cottagers and farmers has become an exposition to the country at large which I was hardly entitled to deliver, and for which I have naturally enough been made the subject of witty animadversion. I have, however, a very strong conviction that the work which you have in hand is a great and beneficial work—that there is a great commercial void which ought to be filled by British skill and labour, and that the extension of what we may term the small culture, in all its branches, will produce very considerable moral and social as well as economical benefits." The Congress will be held on October 21st and 22nd. The Earl of Derby is the President, and the following subjects will be introduced for discussion:—"The Fruit Growing Movement: Present Day Features and Prospects," by Mr. Baillie of Chester; "The Condition, Preparation and After-Treatment of the Soil for Fruit Culture," by Mr. Cheal of Crawley, Sussex; "Fruit Growing for Profit," by Mr. S. T. Wright of Hereford; "The Raising, Budding, Grafting, and Pruning of Apple Trees for Orchard and Estate Planting," by Mr. Crump of Madresfield; "Orchard House Culture," by Mr. T. F. Rivers of Sawbridgeworth; "The Importance of Early Planting and Shelter in Fruit Culture," by Mr. Edward Luckhurst of Romford.

— FLORICULTURE IN AMERICA.—The United States Census Bulletin just issued notes that floriculture in the United States has come to be simply the growing of a few things for cut flowers. It has found that there are 4659 greenhouse establishments in the United States, and that the total number of plants raised is about 125,000,000; of these 49,000,000 were Roses alone, and the rest were made up of plants in the following order:—Violets, Chrysanthemums, Lilies, Hyacinths, Smilax, Bouvardia, Heliotropes, Pansies, Tulips. These together make 90 per cent. of the whole of the plants raised. The other 10 per cent. were made up of Orchids, Tuberoses, Mignonette, Primroses, Camellias, Daffodils, and a few others. Three hundred and twelve of these establishments are owned and managed by women. The value of the greenhouses, including heating apparatus, is placed at 38,000,000 dols. For outdoor gardening the demand has been in a great measure confined to Geraniums, Coleus, Roses, Pansies, Verbenas, Heliotropes, and Carnations. Among all the large classes of florists' flowers the Fuchsia is the only one noted as being grown in sufficient numbers to be worth naming. When it comes to a matter of profit the report says the Roses have been the most profitable, the Carnations next. Some few florists, however, speak of the Carnation as being more profitable than Roses.—T. B. M.

— NOTES AT CLEVELEY, ALLERTON.—Those beautiful climbers, Lapagerias, are now in full bloom at Cleveley, and are worth going a long journey to see. So often do we see them under conditions quite the opposite, that I cannot refrain from dwelling for a short time on their merits and the culture they receive to bring them to such perfection, with the hope that some little information may be gleaned by the readers of the Journal, who are not quite so fortunate as Mr. Cromwell in the cultivation of these plants. The roof of a house some 30 feet long is now covered with thousands of flowers, some of the racemes being from 2 to 3 feet in length, the red and white varieties

intermingling with each other and presenting a charming effect. For decorative work they are useful for festooning if shoots of some length are cut, and they are equally so used individually; in fact may be employed in many ways to suit various tastes. There are two varieties of the red. One, *L. rosea superba*, is rightly named. The colour is intense rose, and the petals finely reflexed. The other is a much longer flower, of good substance, heavily spotted with white, but not so much reflexed as the former. It is very showy, and a striking contrast to the brighter form, the chaste alba completing an excellent trio. As to their cultivation, Mr. Cromwell informed me that they were planted about

FIG. 44.—MR. J. W. MACHATTIE, NEWBATTLE.

six years ago. In February last they had quite exhausted the compost, and the roots had penetrated through the joints of the brick enclosure into the surrounding earth. Extension of root-room was found to be necessary, so the roots were carefully traced and laid in a good compost consisting of rough hand-picked loam, peat, broken bricks, charcoal, and a liberal addition of coarse Demerara sand. They are now feeling the benefit of this extension, as may be seen by the substance of the flowers and purity in the white variety. Copious supplies of soot water is what Mr. Cromwell finds the best of all fertilisers for the *Lapageria*.

— THE CORRIDOR in the same garden always contains some noteworthy plants in flower, but at the present time it is exceptionally gay, being filled the whole length of 120 feet with Tuberous Begonias. Almost all shades of colour are represented, some of the flowers being 6 inches across, the strains being Laing's and Sutton's. Baskets of *Achimenes* might be oftener seen. Here they are the whole length of the corridor, baskets 3 feet in diameter, and one mass of bloom, while the back wall is aglow with *Bougainvillea* very bright in colour, Tea Roses in variety, charming plants of *Plumbago capensis* and *P. capensis alba*. Many other pleasing arrangements might be noticed in this well-kept garden, but for the present this must suffice.—R. P. R.

— SCENT-YIELDING PLANTS.—The plants cultivated in Italy and the south of France for the yield of essential oils have suffered so from the severity of the last winter as to considerably impair the market supplies. Oil of Bergamot is exceedingly scarce in Italy, and brings higher prices after every transaction. The principal plants cultivated in France for essential oils, which have been most damaged by last winter's frosts are Thyme, Rosemary, Lavender, and Pennyroyal, and the output of Geranium oil in Spain will this year be very small. The Peppermint crop in England has been winter-damaged, especially on the heavy damp soils and on the more exposed positions, so that some of the plants were taken up. Lavender, also, has suffered severely, especially the old plants, of which the frosts have apparently made short work, nearly all being killed. During the closing week of April the price of the oil advanced from about 35s. to 40s. per lb. The Camomile plants have also suffered. It is worth noting that the first consignment of Cassia pomade shipped from British India was recently received in London. It was only a sample shipment, but, if successful, it may be the precursor of large quantities, as the flowers (*Acacia Farnesiana*) are found growing wild in abundance. It is claimed for the Indian pomade that it is very considerably stronger than the strongest French.

## THE EDINBURGH INTERNATIONAL SHOW.

SEPTEMBER 9TH, 10TH, AND 11TH.

A GENERAL outline of this great Exhibition of garden produce was given last week with the names of the more successful competitors in the leading classes, but it is necessary now to refer to some of these in detail, and to indicate some features of the Show which had to be passed in a hurried telegraphic message. It is pleasant to be able to record the International Show of 1891 as an unqualified success. Upon the first day (Wednesday) about 10,000 visitors were admitted, on Thursday the takings were said to exceed £600, and on the last day the admissions were correspondingly numerous. Altogether, therefore, the Council of the Royal Caledonian Society, and all the officials concerned in the organisation of so gigantic a Show, have every reason to be pleased with the result of their efforts. Certainly the management, as regards all the preliminary matters, was eminently satisfactory; the exhibits were all in their places on Tuesday night, and at a comparatively early hour the market was cleared and everything was in readiness for the Judges to commence their duties the next morning. These important functionaries assembled at 6.30 A.M., and, with a few exceptions, the work was so well divided that the awards were completed in good time and the prize cards were on the exhibits very promptly. Scarcely a hitch occurred to interrupt the progress, and unstinted praise was accorded to all concerned. Unfortunately as much cannot be said for the success of the removal arrangements at the close of the Show, for an extraordinary scene of confusion occurred on Friday evening, and complaints respecting the loss of fruit were numerous. This matter will be referred to again more fully on another occasion, and for the present it is only necessary to add that the Committee was somewhat hampered by the fact that a market was held in the building on Thursday morning, and the whole space had to be cleared on Friday night in readiness for the large market on Saturday morning. The removal and replacement of some of the tables on Thursday, and the dust produced, damaged the fruit and flowers considerably. Apart from this the market is an excellent building for a show of this character, and full advantage was taken of it in every respect.

Mr. McIndoe may fairly claim the honour of being the champion exhibitor in the fruit classes, for in addition to the numerous prizes in the several classes, he was awarded the Turner Memorial silver cup, value £10, presented by the Trustees for the best collection of fruit in the Show, and we also understand that he has secured the ten-guinea silver cup presented by the Scottish Horticultural Society to the competitor in Classes 1, 2, 3, 4, 5, 6, 7, and 10 who was awarded the largest aggregate amount in prizes.

### COLLECTIONS OF FRUIT.

The principal class in this section was that for twelve dishes, to include two Pines, two dishes of Grapes, and two Melons, the prizes being £15, £10, and £5. Of the four competitors, Mr. J. McIndoe, gardener to Sir Joseph Pease, Bart., M.P., Hutton Hall, Guisborough,

FIG. 45.—MR. JAMES DAY, GALLOWAY HOUSE.

was the most successful, taking first place with the following grandly coloured Gros Maroc Grapes, Golden Champion Grapes, large in bunch and berry, very clean and bright; a Queen and a Smooth Cayenne Pine, well developed and ripened; excellent fruits of *Musa Cavendishi*, large ripe Brown Turkey Figs, fine Ribston Pippin Apples, Stanwick Eluige Nectarines of good colour, and Golden Eagle Peaches of remarkable size and colour, Exquisite and Hero of Lockinge Melons, and Souvenir du Congrès Pears, making up an even, well arranged, highly creditable collection. Mr. David Murray, gardener to the Marquis of Ailsa, Culzean Castle, Maybole, took the second place with handsome Alnwick Seedling and Muscat of Alexandria Grapes, the latter with rather small berries, but large clean bunches; a large bunch of Bananas, Pitmaston Orange Nectarines, Duchess of Oldenburg Apples, Williams' Bon

Chrétien Pears, Favourite Melon, Peaches, and Figs. Mr. J. Hunter, gardener to the Earl of Durham, Lambton Castle, Durham, was third, his best dishes being Calabrian Raisin and Gros Colman Grapes of good size, Magnum Bonum Plums, and Souvenir du Congrès Pears, but it was evident that Mr. Hunter had reserved his strength for the succeeding classes.

The second class also was for twelve dishes, to include three dishes of Grapes, two of Peaches, and one Melon, Pines and Bananas being excluded, the object of which was to admit other competitors. The same number of collections were staged—viz., four—and Mr. J. Hunter was a good first with superb Alicante, Gros Colman, and Barbarossa Grapes, large Lord Napier Nectarines, and Royal George Peaches, well

FIG. 46.—MR. T. LUNT, ARDGOWAN.

ripened Moorpark Apricots, and a fine Premier Melon. Mr. McKelvie, gardener to the Dowager Duchess of Roxburgh, Dunbar, secured the second place with admirable examples of Barbarossa, Muscat of Alexandria and Alicante Grapes, Bellegarde Peaches, and Humboldt Nectarines. Mr. P. W. Fairgrieve, gardener to the Dowager Duchess of Athole, Dunkeld, was third, showing Alicante and Madresfield Court Grapes, and Alexander Apples being conspicuous.

The third class was for a collection of twelve dishes, excluding Grapes and Pines, and Mr. Hunter followed up his previous success by taking premier honours again from three other competitors. His exhibit included praiseworthy samples of the undermentioned varieties: Albert Victor and Imperial Green Flesh Melons, Denbigh Plums, Goshawk Peaches, Lord Napier Nectarines, Moorpark Apricots, King of the Pippins Apples, Victoria Nectarines, Grégoire Bordillon and Souvenir du Congrès Pears, Worcester Pearmain Apples, and Alexandra Noblesse Peaches. Mr. McIndoe was a close second with fine fruits of Exquisite and Golden Eagle Peaches, Pitmaston Orange Nectarines, and Doyenné du Comice Pears. Mr. D. Melville, gardener to the Hon. G. G. Dalrymple, St. Boswells, took the third place with a good representative collection of useful fruits.

There were also four competitors with collections of twelve dishes of fruit grown in an orchard house (Grapes excluded), and Mr. McIndoe won the leading position with an excellent collection of Bismarek Apples, Humboldt and Spenceer Nectarines, Kirke's Plums, Princess of Wales and Exquisite Peaches (the last named of great size), Kirke's and Magnum Bonum Plums, Alexander Apples, Brown Turkey Figs, Souvenir du Congrès and Doyenné du Comice Pears, and Passiflora edulis. Mr. Hunter was second, Warner's King Apples, Goshawk Peaches, Moorpark Apricots, and Denbigh Plums being the most notable dishes; and Mr. D. Melville was third.

Classes 5 and 6 were for collections of hardy fruits, the former for eighteen dishes grown in the open air in Scotland, and the prizes included a handsome clock, valued £10 18s. as the first, with £5 and £3 as second and third. These brought five competitors, who staged extremely good specimens of fruit cultural skill in the North. Most unfortunately the Judges considered it necessary to disqualify one of the collections that would undoubtedly have won a prize. It was staged by Mr. Brown, Abereairney Gardens, Crieff, and included two dishes of Apples, one of Worcester Pearmain, and the other of Red Astrachan, which showed some little variation, and it was thought they were mixed and indistinct, and to that effect the card was marked and the collection shut out. The opinion of several who subsequently examined the Apples very carefully was that the varieties were true, and in another class a first prize was awarded for a collection of Apples, comprising a dish of Worcester Pearmain, showing exactly the same difference, but which was unquestioned. However, Mr. Fairgrieve was adjudged first honours, which he well deserved, for fine dishes of White Genoa Figs, Worcester Pearmain Apples, Morello Cherries, Magnum Bonum Plums, Williams' Bon Chrétien Pears, Violette Hâtive Nectarine, Peasgood's Non-such Apple, Governor Wood Cherries, Nectarine Plums, Pitmaston Duchess Pears, Eluge Nectarines, Brown Turkey Figs, Orange

Apricots, Early Silver Peaches, Fay's Prolific Red Currants, Early Alfred Peaches, Warrington Gooseberries and Apricots—a capital all-round collection, most creditable to Scotland. Mr. J. Day, gardener to C. J. Massey, Esq., Galloway House, had good examples of Williams' Bon Chrétien Pears, Hale's Early Peaches, Late Duke and Morello Cherries, and Castle Kennedy Figs. Mr. G. Goodfellow, gardener to E. C. S. Gray, Esq., Perth, was third with several fine dishes, Gooseberries being especially notable.

The last of the classes devoted to collections was that for eighteen dishes of hardy fruits grown in the open air in England, and the substantial first prize of £10 10s., offered by Messrs. Little & Ballantyne, brought three competitors, amongst whom Mr. T. H. Crasp, gardener to Lord Wimborne, Canford Manor, Wimborne, Dorset, easily succeeded in winning first honours, his fruits being well-grown specimens of the following:—Williams' Bon Chrétien and Doyenné Boussoch Pears (the latter richly coloured), excellent Ribston Pippin Apples, well-ripened Brown Turkey Figs, Worcester Pearmain Apples, Jefferson Plums, Morello Cherries, Sea Eagle Peaches (very fine), Lord Napier Nectarines, Green Gages, Red Astrachan Apples, Pond's Seedling Plums, Duchesse d'Angoulême Pears, and Pitmaston Orange Nectarines, all in first-class condition. Mr. J. Nicholson, gardener to Wm. Melles, Esq., Sewardstone Lodge, was second, his Apples being extremely fine, especially Warner's King, Peasgood's Non-such, and Alexander; while Mr. S. T. Wright, gardener to C. L. Campbell, Esq., Hereford, was a close third, showing clean fruits, but somewhat smaller than the others.

#### THE GRAPE CLASSES.

Beyond all question the Grapes constituted the special feature of the Edinburgh Show, and most critically were they examined by the numerous gardeners present. For such an unfavourable season the Grapes shown were of surprising quality, and though exhibits of extraordinary merit were not numerous, yet there was an evenness throughout that caused the Judges much difficulty in several cases. It was stipulated in the schedule that all Grapes should be exhibited on properly inclined stands, neatly covered with white paper, of a uniform breadth from front to back of 14 inches, depth at back 10 inches, and depth at front 2 inches. As this was followed consistently the effect produced by the regular stands was good, and it also to some extent facilitated the judging. The leading class was that for eight bunches of four varieties, two bunches of each, the prizes being £15 (offered by Messrs. W. Thomson & Sons, Clovenfords), £8, and £4, and the eight collections contributed constituted a grand display of fine Grapes. Mr. A. Kirk, gardener to J. T. Paton, Esq., Norwood, Alloa, was adjudged first honours for grand bunches, well coloured, of the following black varieties—Madresfield Court, large berries, excellent colour; Black Hamburg, medium sized berries, but fine solid bunches, bearing a dense bloom; Gros Maroc, admirable bunches of fine colour; and Alnwick Seedling, finished to perfection. Mr. Wm. Taylor, gardener to Alderman Chaffin, Bath, was placed second, but the contest was a close one, and the bunches staged were superb examples of their respective

FIG. 47.—MR. G. MACKINNON, MELVILLE CASTLE.

varieties, which were as follows—Alnwick Seedling, Muscat of Alexandria, excellent colour; Alicante, large bunches and berries, but slightly rubbed; Madresfield Court, also very fine, but, like the last named, it had apparently suffered in transit. Mr. W. Murray, gardener to T. C. Learmouth, Esq., Polmont, was a good third with Alicante, Alnwick Seedling, Muscat of Alexandria, and Black Hamburg.

For six bunches (not less than three varieties), Mr. Kirk was again first with black Grapes, even and excellent bunches of Black Hamburg with rather small berries, Madresfield Court, large bunches of fine colour, and Gros Maroc, with very large berries and excellent colour. Mr. J. W. Machattie, gardener to the Marquis of Lothian, Newbattle, was second with well grown specimens of Muscat of Alexandria, Madresfield Court, and Black Hamburg. Mr. G. Mackinnon, gardener to

Viscount Melville, Lasswade, was third, his Gros Maroc being wonderfully fine in bunch and berry, Madresfield Court slightly deficient in colour, Golden Hamburgh well ripened, and Muscat of Alexandria rather small. There were eleven competitors in this class, the total number of bunches thus exceeding those in the preceding class.

Ten also entered with four bunches, one bunch of each variety, and there Mr. Wm. Taylor easily secured first honours for Alnwick Seedling, Madresfield Court, Muscat of Alexandria, and Alicante, all represented by large bunches in excellent condition. Mr. Kirk followed, again staging all black varieties—viz., Black Hamburgh, Madresfield Court, Alicante, and Gros Maroc; Mr. W. Murray being third for Madresfield Court, rather small berries, Muscat of Alexandria well ripened, Gros Maroc of fine colour, and a large bunch of Alicante.

Following those already noted in the order of the schedule ten classes were devoted to special varieties, two bunches of each, and the same for one bunch, in which the competition was good, and the awards were made to the exhibitors here named.

**Black Hamburgh.**—This variety was not shown in its best condition generally, but with two bunches Mr. Witherspoon, Red Rose Vineries, Chester-le-Street, was well first amongst nine competitors with compact, neat, useful examples; Mr. T. Boyd, gardener to W. Forbes, Esq., Falkirk, being second with rather small bunches and berries, Mr. McHattie following with good bunches of large berries, but not fully coloured. Twelve single bunches of the same variety were shown, and Mr. Morrison was first with large bunches, the berries medium sized and the colour fair. Mr. J. Day was second for a compact bunch, and Mr. Murray third for a medium bunch of large berries.

**Muscat Hamburgh.**—Only one class was devoted to this variety, and there were but four competitors, each staging two bunches. Mr. J. Day easily won the leading place with solid bunches, exceptionally well coloured. Mr. T. Boyd followed, his exhibit also being distinguished by good colour, and Mr. D. Murray was third for large bunches but somewhat red.

**Madresfield Court.**—A fair display was provided of this excellent Grape. With two bunches Mr. Day was first for grand examples both in size and colour. Mr. W. Murray was second, staging large handsome bunches a little wanting in colour; and Mr. Witherspoon was third for medium sized bunches of good colour. Six single bunches were contributed, Mr. Wm. Taylor leading with a fine bunch of medium-sized berries, but capital colour; Mr. McKelvie occupied the second place, staging a fine bunch, only slightly deficient in colour; Mr. Witherspoon being third again with a medium-sized bunch of good colour.

**Alicante.**—This variety was well represented, the eight pairs of bunches in class 13 and the six singles in class 21 comprising some fine specimens. With two bunches Mr. Murray won first honours for heavy compact bunches, the berries rather small, but the colour excellent. Mr. Taylor was second with large handsome bunches; and Mr. S. T. Wright third for good bunches bearing a dense bloom. For a single bunch Mr. Taylor was deservedly first, the bunches large and the colour excellent; Mr. W. Murray followed very closely, and Mr. Witherspoon was third. All these being nearly equal in merit.

**Gros Colman.**—The pair bunch class was the only one allotted to this variety, and five capital exhibits were contributed, Mr. Wm. Taylor securing first honours for grand bunches, the berries remarkably large, and the colour good. Mr. J. Potter, gardener to W. P. Moore, Esq., Whitehall, Carlisle, secured the second place with medium-sized bunches and berries, the colour dense; and Mr. J. Day was third, his bunches being heavy, and with fine bloom.

**Lady Downe's.**—It is evident this variety is a great favourite in the north, for ten pairs of bunches were shown, and the same number of single bunches, making an array of thirty, surpassed only by Muscat of Alexandria in numbers. Mr. Wm. Murray had the best two bunches, solid, and of excellent colour. Mr. J. Morrison was second for long compact bunches with rather small berries; and Mr. W. J. Green, Yester, took the third place for smaller bunches, but equally good in colour. The finest single bunch came from Mr. J. Laing, gardener to General C. Rathay, Blairgowrie, which was nearly perfect in all respects. Mr. Murray, who followed closely also, had an even and well coloured bunch; Mr. Morrison being third with a large bunch.

**Muscat of Alexandria.**—Thirty-nine bunches of Muscats were staged in the two classes, and it can be imagined that these formed an imposing display, but there was perhaps greater variation in the merits of the exhibits than in any other of the Grape classes. The best two bunches (amongst thirteen exhibitors) were contributed by Mr. Machattie, and well did they deserve the honour, for very seldom are such fine clean rich golden coloured specimens of this beautiful Grape seen in gardens or at exhibitions. It was not surprising, therefore, that it was selected for the Veitch Memorial medal and £5 prize offered for the best dish of fruit in the Show, no mean honour in such an extensive display of fruit. Mr. W. Taylor followed with heavy well proportioned bunches, fine berries and beautifully coloured, but wanting the golden tint of the first. Mr. G. Winter was third for large bunches of clean medium sized berries. Thirteen single bunches were also staged, Mr. Machattie leading with medium sized but beautifully coloured bunches; Mr. Green was second, and Mr. Wyton third.

**Buckland Sweetwater.**—Eight pairs of bunches were shown in this class, Mr. J. Potter leading for specimens of an excellent amber colour. Mr. W. Allan, Gunton Park, Norwich, was second for medium-sized bunches, large berries, and beautifully ripened. Mr. J. Heath, gardener to J. Wakefield, Esq., Sedgwick, Kendal, followed with medium-sized examples.

**Alnwick Seedling.**—In Class 23, for one bunch of this variety, there were seven exhibitors, and the premier award was secured by Mr. Green, who had handsome specimens, the berries very large and the bloom dense. Mr. Murray followed with solid even bunches, perhaps not quite so well coloured; and Mr. Taylor was third, his exhibit being distinguished by the size of the berries and the fine colour.

**Gros Maroc.**—An admirable class was formed by the twelve exhibits of this variety, which indicated its characters in the best possible way. Mr. J. Leslie won the premier prize for exceedingly large solid bunches of capital colour. Mr. W. Taylor was a very close second—in fact, it was difficult to detect a point of difference in favour of the first. Mr. J. Day was third, the berries being of medium size, but the colour capital.

**Mrs. Pince.**—Six bunches of Mrs. Pince were placed in competition, but none were very remarkable. Mr. Stewart had good bunches and uncommonly fine berries, but the colour was not quite perfect. Mr. Murray was second, his specimens having small berries but capital bloom. Mr. Day took the third place, both bunch and berries small, but the colour was excellent.

**Duke of Buccleuch.**—Seven bunches were shown, and some were extremely good. Mr. Chalmers had medium bunches, excellent berries, clean, and of good colour. Mr. Copeland had small bunches, but fine bright berries; and Mr. McIndoe's third prize bunch was noticeable for its good finish.

**Golden Champion.**—Only three bunches were exhibited in this class, but the premier one, from Mr. McIndoe, was uncommonly good for the variety, the bunch solid and berries large. Mr. Witherspoon was second with ripe specimens, and Mr. Hannah third for rather greenish samples.

**Miscellaneous Grape Classes.**—Competition was brisk in the classes for two bunches of any other black or white variety, nine entering in each. The best black was Gros Maroc, shown by Messrs. Day, Taylor, and W. Murray in the order named. The best in the any other white classes (two bunches) was Duke of Buccleuch from Mr. Copland, whose specimens were clean and excellent in all points, the berries large, and the colour admirable. Mr. McIndoe had the same variety also represented by large clean berries; and Mr. Potter was third for huge bunches of Trebbiano.

Prizes were offered for the best bunch of a seedling Grape not in commerce, and Mr. McIndoe won leading honours for a variety named Black Duke, the result of a cross between Gros Guillaume and Duke of Buccleuch. It appears to be a promising variety, the bunches large, the berries oval, and of considerable size, black, fleshy, with a pleasant but not very pronounced flavour, and a thick skin. Mr. D. Murray was second with a black seedling, concerning which no particulars were furnished; Mr. Myles was third for Appley Towers, a cross from Gros Colman and Alicante, which has been noticed before.

The finest flavoured black Grape was a rather red bunch of Muscat Hamburgh from Mr. D. Murray. Mr. McKelvie was second for Madresfield Court, and Mr. Houston third for Black Hamburgh. (Thirteen exhibits.)

The best flavoured white Grape was Muscat of Alexandria, with which Messrs. Machattie, G. Winter, and McKelvie won the prizes. For one bunch of a Grape with the finest bloom Mr. Day led with Gros Maroc, followed by Mr. D. Murray for the same variety, and Mr. Chalmers for Gros Colman. In the class for the heaviest bunch of a black Grape Mr. Matheson was first with Gros Colman, weighing 12½ lbs., an enormous specimen with large berries, but nearly green. Mr. Leslie followed with Alicante weighing 11 lbs. 2 ozs., and Mr. Kirk was third for Gros Guillaume of considerable size in bunch and berry, but reddish. In the corresponding white Grape class Mr. Morrison was first for Raisin de Calabre, Mr. Hannah second for the same variety, and Mr. Murray third with Syrian. The weights were not stated, but they were not so heavy as the black. Besides these there were fourteen classes for Grapes open to gardeners and amateurs from which competitors in the preceding sections were excluded. In these most of the varieties already named were included, and the chief prizes were awarded to Messrs. McDonald, Caldwell, Harper, Dobbie, Cocker, McLeod, Cameron, and Scott.

#### OTHER FRUIT CLASSES.

Fruit trees in pots constituted a section of three classes, but the exhibits, with few exceptions, were not remarkable. For a Vine in a pot (black) Mr. A. Duff, gardener to R. Bell, Esq., Clifton Hall, Ratho, was first, showing Gros Maroc with a few indifferent bunches. In the corresponding white Grape class Mr. J. Harvey, gardener to Colonel Trotter, Morton Hall, secured the same award for Muscat of Alexandria. A class was also provided for four fruit trees in pots, Vines excluded, and there Mr. McIndoe was first with well fruited specimens of Pears, Apples and Peaches.

Pine Apples were not shown in large numbers, and though the fruits were generally good they were not so fine as has been seen at some southern shows and meetings. Mr. M. McIntyre, gardener to Sir D. Tennant, Bart., The Glen, was the principal competitor, and staged fine fruits. He was first for two ripe Pine Apples in pots, for two Smooth Cayennes, and for two Queens. For any other variety Mr. A. Kirk was first; and for one seedling not in commerce Mr. Hunter was first with a handsome fruit of Lord Carrington.

Melons were numerous, the chief prizes going to Mr. J. Wilson, gardener to Lord Elphinstone, Carberry Towers, who had the best two fruits, Blenheim Orange and La Favourite, the last-named variety from

the same exhibitor leading in the scarlet-flesh class, and Blenheim Orange from Mr. A. Miller, gardener to W. H. Long, Esq., M.P., Rood Ashton, in the green-flesh class.

Peaches and Nectarines were fairly well shown, Mr. Lunt, gardener to H. Stirling, Esq., Keir, being the principal exhibitor, and won the first prize for twelve Peaches, six ditto, and twelve Nectarines with beautiful fruits; but for six Nectarines Mr. T. H. Crasp won easily with Pitmaston Orange of good size and capital colour. Apricots were also good, the best coming from Messrs. Goodfellow and Fairgrieve.

Plums were largely represented, over seventy dishes of dessert varieties, and nearly as many of culinary varieties, being entered in competition, the classes being devoted to the chief sorts grown in gardens. The majority of the prizes in the single dish classes were won by Mr. Peter Blair, Trentham Gardens, other successful exhibitors being Mr. G. Bowman, Lasswade; Mr. A. Wilson, gardener to R. A. Oswald, Esq.; Mr. J. Day, Mr. J. Harper, Jersey, and Mr. McIndoe.

Apples were an excellent show in themselves, for the exhibits were extremely numerous, and the quality, in the majority of instances, was highly satisfactory. Pears also were largely shown, and in both instances, while a few classes were devoted to collections, the majority were for special varieties, as in the case of the Grapes, Plums, &c. It was a subject of comment that Mr. Harper of St. Helier's, Jersey, who carried off many important prizes, should have been allowed to compete in these classes, especially as provision was made for Channel Island fruits under the heading, "Fruits Grown Abroad." Some of the competitors who were defeated by Mr. Harper entered protests in the matter, but no decision was made public before the close of the Show. Next to Mr. Harper, who exhibited excellent fruits, Mr. T. H. Crasp was the most successful, being first amongst Pears for Jargonelle, Louise Bonne of Jersey, and Haeon's Incomparable, with minor prizes in several other classes. Prizes also went to Messrs. Donald McBean, Renfrewshire; J. Day, R. Sinclair, A. Wilson, McKelvie, and Gilmour. In the Apple classes the chief prizewinners were Messrs. J. McKenzie, Linton Park Gardens, Maidstone; Nicholson, J. Day, S. T. Wright, T. H. Crasp, Goldie, and Gilmour. Strawberries, Currants, and Gooseberries were also fairly well shown, but do not call for special comment.

#### PLANTS.

The section of the Exhibition appropriated to plants was the weakest of all, as the exhibits were neither very abundant, nor were they in most classes up to the high standard distinguishing the other part of the Show. Although prizes of £20, £15, and £10 were offered for ten stove and greenhouse plants, only two competitors had the courage to enter, and one of these journeyed a long distance for his honours—namely, Mr. W. Finch, gardener to J. Marriott, Esq., Queen's Road, Coventry, who was deservedly awarded the first prize for well-grown specimens of *Ixora Williamsi* and *amabilis*, each about 5 feet high, nearly as much in diameter, well clothed with foliage, and bearing fine heads of flowers. Other good specimens of similar size were *Croton Warreni*, *Lapageria rosea* and *alba*, *Croton Johannis*, grandly coloured; and *Erica Eweriana*, with tall stately examples of *Kentia Belmoreana*, *Kentia Fosteriana*, and *Cycas circinalis*. Mr. A. Crichton, Southfield, Camberton, was second with much smaller plants, and his prize was easily won. Six stove and greenhouse plants were not of remarkable merit, but Mr. Thompson's, of Eskbank, first prize collection included several healthy specimens of moderate size. The fine-foliage plants were also of medium size, Mr. McIntyre of Inverleithen, Mr. McIntyre of Darlington, and Mr. Stewart, Brayton Hall, being the prizewinners in that order.

By far the most remarkable plant in these classes was that with which Mr. Finch won the first prize as a single specimen in flower. This was a magnificent example of *Ixora Duffi*, some 5 feet in height, clothed with its long dark leaves down to the pot rim, and bearing upwards of twenty large globular trusses of flowers. This plant was so conspicuously prominent that it easily gained for Mr. Finch the Veitch Memorial medal and £5 prize offered for the best Orchid, stove, or greenhouse plant in the Show.

Ferns were amongst the freshest and best of the plant exhibits, and furnished a very agreeable foil to the bright tints of the cut flowers, which supplied the principal colour in the building. Adiantums and British Ferns were the most abundant, and amongst the latter the *Scelopendriums* were very notable. Some of the more successful exhibitors were Mr. McIndoe (table Ferns), Mr. Napier, Rockville (exotic Ferns), Mr. McIntyre, Darlington (*Gleichenias*), Mr. Henderson, Polmont, (Adiantums), Messrs. Leman, Restalrig House; Napier, T. Pringle, Dalkeith; E. Cameron, Scott, Anderson, Pilrig, and J. Cumming.

Orchids were not in their best, and could not be expected to be at this time of year. The result was the exhibits occupied but small space, and comprised but few plants of an exceptional character. The leading six Orchids came from Mr. Sharp, Freeland; moderately good specimens of *Lælia elegans*, *Odontoglossum Pescatorei*, *O. vexillarium rubrum*, *Cypripedium superbiens*, and *Cattleya Gaskelliana* being the most noteworthy. Mr. Curror of Eskbank was second with smaller plants of little importance except *Oneidium incurvum*, which was one of the finest ever exhibited, being loaded with its small delicately tinted flowers, but it was rather spoiled in appearance by the panicles being trained tightly into a globular form. If they had been taken up straight from the plant the effect would have been much more pleasing—indeed, some thought it would have stood a good chance for the Veitch Memorial prize. The prizewinners with three Orchids were Messrs. Wilson,

Sharp, and McGregor, the last-named being also first for a single specimen. Crotons, Palms, Tuberous Begonias, Fuchsias, table plants, and Vallotas were all represented by numerous exhibits, but the Vallotas were unusually good, and are rarely seen at southern shows in such numbers or such good condition.

The groups of plants with which we are familiar in England assume a different character in Edinburgh, for instead of being arranged upon the ground as with us they are disposed upon tables, which must unavoidably impart considerable formality to the arrangement, though the space can be very accurately apportioned. However tasteful a margin is formed—and much skill was displayed in this matter—it is impossible to give the same freedom to the edge of a group upon a table as it would be on the ground level. Nearly all the classes of this kind provided in the schedule were for nurserymen, but there was one for gardeners and amateurs, in which Messrs. R. B. Laird & Sons, Edinburgh, offered a ten-guinea clock as the first prize for a table of plants 20 feet long by 5 feet wide. This was accorded to Mr. McIntyre of Darlington, who had a tasteful arrangement, in which a due proportion of flowering and foliage plants were employed with good effect, the margin also being skilfully managed. Mr. Wood, Oswald House, Edinburgh, followed closely, Crotons predominating in his arrangement, while Mr. Reynard of Hamilton was third with a group of healthy little plants.

In the nurserymen's division the chief class was that for a group of plants arranged on a table 30 feet long by 8 feet wide, and the exhibits in this class not only occupied much space, but they formed one of the most pleasing parts of the plant display. Messrs. Ireland & Thomson, Edinburgh were adjudged first honours for an exceedingly handsome group, in which brilliantly coloured Crotons were employed with Palms, Ferns, and other graceful foliage plants, together with Orchids, especially *Cattleyas* and *Odontoglossums*, *Liliums*, *Eucharises*, and a fine margin of *Panicum variegatum* and *Caladium argyrites*. Messrs. Thyne, Glasgow, were second, *Odontoglossums* being largely employed, and with an edge of *Caladium argyrites* gave rather too light an appearance to the group. Messrs. Laird & Sons, Edinburgh, were third with a rather different style of arrangement, the plants being disposed in circular groups on the table, margined with *Panicum*, *Selaginellas*, and *Ficus repens*.

The nurserymen's Crotons, though not of great size, were exceedingly bright in colour, particularly those with which Messrs. B. S. Williams and Son, Upper Holloway, London, won the first prize for six plants. These included *Williamsi*, *Rodeckianus*, *formosus*, *Warreni*, *Queen Victoria*, and *Comtesse*. Messrs. Ireland & Thomson were second also for finely coloured plants of *Warreni*, *Evansianum*, *Newmani*, and *angustifolius*.

New and rare plants not in commerce before January 1st, 1889, were not represented by many collections. The best six were shown by Messrs. Ireland & Thomson, and included *Caladium Marie Freeman*, *Dracaena species*, *Coeos Pynaerti*, *Maranta Mooreana*, *Alocasia Thomsoni*, and *Nepenthes Dicksoniana*, a hybrid which was selected for the Veitch Memorial medal, but it was subsequently found that this was contrary to the regulations as being exhibited by a nurseryman, and the award was therefore disallowed. Messrs. B. S. Williams & Son were placed second with some fine novelties, and Messrs. Laird & Son were third. Coniferæ were shown by Mr. Butler, Greenock; Messrs. Laird and Son, and Messrs. Stuart & Mein of Kelso, who won the prizes in that order. Messrs. Ireland & Thomson were first for six Orchids, healthy medium sized plants of *Cypripedium Ashburtoni*, *Odontoglossum grande* and *vexillarium*, and *Vanda Kimballiana*.

#### CUT FLOWERS.

Although this was an autumn Show Roses were shown in capitally fresh condition, and excited even more interest than the Dahlias. For thirty-six Roses Mr. Cocker of Aberdeen was awarded premier honours with bright beautiful blooms, amongst which the following varieties were conspicuous:—*Alfred Colomb*, *Her Majesty*, *Waban*, *Comtesse de Serenye*, *Mrs. John Laing*, *Ulrich Brunner*, *Charles Lefebvre*, and *Marie Van Houtte*. Mr. Dickson of Belmont was second, and Mr. Smith of Stranraer was third. Mr. Cocker was also first for twelve Tea Roses, and Mr. Smith again followed.

The best twenty-four Show Dahlias were exhibited by Messrs. R. B. Laird & Co., Messrs. Clark & Sons of Leeds following closely, this exhibitor being also first for twelve Fancy Dahlias, followed by Mr. Campbell and Messrs. R. B. Laird & Co., the last named being first for six Chrysanthemum blooms. Messrs. A. Kerr & Son, Roxburgh, were first with twelve spikes of Hollyhocks, Messrs. Stuart & Mein, with Mr. G. Wood, Hawick, securing the other prizes, but the first and second collections were much superior to the others in competition. Mr. Campbell had the best thirty *Gladioli* spikes, massive, well proportioned, with large richly coloured flowers.

In the gardeners' and amateurs' classes there was a fairly good display of Roses, Pansies, Stocks, Hollyhocks, and Dahlias, but the competition was not so keen as in other departments of the Exhibition. With twenty-four Roses Mr. A. H. Gray, Bath, was first, followed by Mr. D. Wallace of Rothesay, and Mr. William Parlanc, Golffhill, Ross. Mr. Gray was also first for twelve Tea Roses, Messrs. Mellinder and Bryden following. In the Pansy and Viola classes the chief exhibitors were Messrs. A. Ollar, McCan, Frater, Storrie, Adam, and Paterson. The best Stocks were staged by Mr. Morrison, the best Hollyhocks by Mr. Rae and the Rev. J. Middleton, and the best Dahlias from Mr. Spoor.

## VEGETABLES.

The vegetables were exhibited in exceedingly large numbers and fine quality, and strongly as these important products always are represented, at northern shows very seldom have such displays been seen as that under notice. In the great class for twelve distinct varieties there were seventeen competitors, and they contributed vegetables so nearly equal in merit that the Judges had a serious task in making the awards. Mr. Pope, gardener to the Earl of Carnarvon, Highclere Castle, Hants, won the premier honours—a 10-guinea prize—with admirable examples of Standard Bearer Celery, Autumn Mammoth Cauliflower, Oxonian Leeks, perhaps the weakest dish; Perfection Tomatoes, Sutton's Student Parsnip, handsome Satisfaction Potatoes, Ne Plus Ultra Beans, Long-keeper Onions, Duke of Albany Peas, Green Globe Artichokes, and Pragnell's Exhibition Beet. The second place was taken by Mr. J. Muir, gardener to Miss Talbot, Margam Park, Glamorganshire, whose specimens were very even, clean, and true in character. They included Early Rose Celery, Champion Leeks, Eclipse Cauliflowers, Yellow Perfection Turnips, Cardiff Castle Cucumbers, Webb's Sensation Tomatoes, Duchess Peas, and Satisfaction Potatoes in fine condition. Mr. T. Wilkins, gardener to Lady Theodora Guest, Norwood House, Dorset, was third with a highly creditable collection, and it was remarked by several as a curious fact in so keen a competition that all these prizes should have gone to exhibitors from the south. Mr. W. Harper, gardener to J. R. S. Richardson, Esq., Perth, was fourth, his exhibits comprising some well-grown vegetables.

The next class was also for a collection of twelve varieties, but excluding Tomatoes, Mushrooms, and Cucumbers, and the competition was again very keen, though the entries were not so numerous. After careful consideration Mr. J. Cocker, gardener to Sir William Wallace, Bart., Stranraer, was placed first, his Leeks, Celery, Cabbages, Onions, Turnips, and Peas being notable dishes. Mr. J. Low, gardener to J. Paton, Esq., Stirling, was second, being defeated by only a few points, his specimens being extremely good. Mr. G. Potter, gardener to Mrs. Laidlaw, North Berwick, was third with a good exhibit.

Potatoes were shown in extraordinary numbers, there being thirty-six entries in the class for eighteen dishes, for which prizes of 10 guineas, £5, and £3 were offered. Long consideration the Judges devoted to this class, and without a doubt they had the most difficult task in whole Show. It was not surprising if their professional skill was taxed severely where so many exhibits appeared of first-rate quality, and if about a dozen first prizes could have been awarded it would have relieved them materially. The decision was at last given in favour of Mr. J. Sinclair, Harviston, Dollar, who had clean even tubers of the undermentioned varieties—Best of All, Satisfaction, Vicar of Laleham, Matchless, Lord Tennyson, Lady Francis, Handwood's Perfection, Reading Russet, The Dean, Jeannie Dean, Village Blacksmith, Abundance, Jubilee, Mr. Breeze, Snowdrop, Chancellor, Puritan, and Lady Dundas. Mr. J. Robertson, gardener to Lord Campbell, Hartrigge House, was second, and Mr. J. Gentleman, West Craigmerrrie, Armadale, was third, both exhibiting collections of much merit. Several fine exhibits were of necessity left unrecognised, but one collection, from Mr. Wiles of Edgecote, Banbury, was certainly worthy of an award, and should have had a place amongst the winning exhibits. For six varieties of Potatoes, Mr. Gentleman, Mr. J. McFarlane, Alva, and Mr. Wiles were the prizetakers, but even here the awards did not give entire satisfaction, and the last-named should have had a higher place.

Classes were provided for Cucumbers, Peas, Beans, Brussels Sprouts, Cauliflowers, Cabbages, Celery, Leeks, Parsnips, Carrots, Turnips, and all the principal crops of the vegetable garden, but to enumerate them all with the exhibitors would far exceed the space at our disposal. It must, however, be mentioned in this section that valuable special prizes were offered by seedsmen and nurserymen for vegetables which brought an astonishing competition. Messrs. Sutton & Sons, Reading, had thirteen classes for their special varieties, and when it is stated that the number of entries in these reached no less a total than 278, it can be imagined what an extensive and handsome display was provided. Messrs. Dobbie & Co., Rothesay, also offered prizes in two classes for vegetables, and Mr. J. Wilson, Hereford, had two classes for Onions, and in all these the competition was keen.

## NON-COMPETING EXHIBITS.

Considerable space was required by the non-competing exhibits from nurserymen and others, which imparted much additional interest to the Show. It is somewhat strange, however, that with one exception of unquestioned merit, none of the beautiful collections of plants and flowers, many of which had been brought a great distance, received any recognition from Judges or Council. At least this was the case as far as could be ascertained at the close of the Show, and certainly no awards were affixed to the groups. A magnificent exhibit of plants, cut flowers, and fruits arranged with remarkably good taste won for Messrs. Wm. Thomson & Sons, Clovenfords, the award of a gold medal, an honour that was amply deserved, for without doubt it was one of the best displays of the kind ever exhibited. With it were included some large paintings of Orchids, especially of the new and handsome *Dendrobium Phalaenopsis* var. *Schroederianum* from Messrs. Sander and Co., St. Albans, and some interesting Orchid photographs representing the re-discovery of the true autumn-flowering *Cattleya labiata*.

Prominent amongst the exhibits from England were the following. An excellent group of Orchids with stove and greenhouse flowering and fine-foliage plants from Messrs. B. S. Williams & Son, Upper Hol-

loway, which occupied a long table and comprised a selection of rare and beautiful plants from their extensive collections, and including many fine novelties. Messrs. J. Laing & Sons, Forest Hill, London, had a group of their grand Tuberous Begonias, Caladiums, Crotons and other plants, which attracted many admirers of these showy plants during the three days. Messrs. Cannell & Sons, Swanley, contributed a superb bank of Cactus Dahlias, one of the largest and most effective exhibits yet seen, and with them also were some handsome Tuberous Begonias. Messrs. Cutbush & Son, Highgate, staged one of their interesting collections of stove and greenhouse plants, fine healthy little specimens of all the more useful sorts.

Ferns in choice variety, forming several refreshing groups, came from Messrs. W. & J. Birkenhead, Sale, Manchester, comprising beautiful novelties both amongst hardy and greenhouse Ferns. Messrs. Bunyard and Co., Maidstone, sent a large collection of fine Apples. Messrs. J. Cbeal & Sons, Crawley, also had a large space occupied with Apples, Pears, and Dahlias. Mr. J. Walker, Ham, Surrey, showed a collection of fine Apples and Pears. Mr. Rust, Eridge Castle Garden, Kent, contributed a collection of Apples and Pears. Mr. Devcill of Banbury showed his fine exhibition Onions. Mr. Watkins of Hereford had a number of Apples and Pears; and the Royal Horticultural Society of London sent a large collection of Apples and Tomatoes, good specimens of their respective varieties.

Amongst the northern and other exhibits, besides those already mentioned, were the following—Messrs. J. Dickson & Son, Edinburgh, a group of hardy trees and shrubs; Mr. J. Forbes, Hawick, a collection of cut flowers; Messrs. James Cocker & Co., Aberdeen, a tasteful display of hardy flowers; Messrs. Dobbie & Co., Rothesay, a group of Dahlias and Marigolds; Messrs. Hugh Dickson & Co., Belfast, a beautiful display of Roses; Messrs. Stuart & Mein, Kelso, choice Hollyhocks and hardy flowers; Mr. M. Cuthbertson, Rothesay, a large group of hardy flowers; Mr. Campbell, High Blantyre, a collection of florists' flowers; Messrs. Laing & Mather, Kelso, a group of Carnations; Mr. A. Lister, Rothesay, Pansies and Marigolds; Messrs. Dickson and Co., Edinburgh, a handsome group of miscellaneous plants; Messrs. T. Methven & Sons, Edinburgh, a table of foliage and flowering plants; and Mr. J. Downie, Edinburgh, had a table of Tuberous Begonias.

## THE DINNER.

On Wednesday evening a company of about 120 gentlemen, members of the Royal Caledonian Horticultural Society, Judges, and visitors, representing probably one of the best gatherings of horticulturists ever brought together in Scotland, dined in the Waterloo Hotel, Edinburgh. Sir James Gibson Craig, one of the Vice-Presidents of the Society, occupied the chair; Mr. W. Thomson, sen., Clovenfords, and Mr. C. Stewart, W.S., the Secretary, acted as cronies; the Chairman being supported by Mr. A. F. Barron, Alderman Chaffin, Mr. Bruce Findlay, and members of the Corporation. In proposing the toast of the evening, "The Royal Caledonian Horticultural Society," the Chairman remarked that the Show in connection with which they were assembled was the finest he had ever seen, especially as regarded fruit, flowers, and vegetables, and that not only the Society, but the City of Edinburgh and the kingdom might be proud of it. Having commented on the useful work which the Society had accomplished since its establishment, the Chairman concluded by pointing to the enormous advance observable in the care of public gardens, and gave it as his opinion that the way in which the Princes' Gardens were managed was a credit to any city in the world.

Mr. Wm. Thomson, in replying, remarked that while the plants shown that day might not be so good as he had seen, the fruit, flowers, and vegetables were equal to anything that had been brought together within his knowledge. In conclusion, he referred to the work of the British Fruit Growers' Association and the Conference to be held the following day, and urged the desirability of more attention being given to the cultivation of fruit. In afterwards responding to the toast of "The Corporation of Edinburgh," which had been proposed by Mr. A. Milne, Edinburgh, Bailie M'Donald adverted to the value of the Waverley Market for such exhibitions as that in connection with which they were assembled, and spoke of the loss which the citizens would have sustained had they been deprived of the building through the proposals of a railway company. The other toasts included "The Royal Horticultural Society," proposed by Mr. Dunn, Dalkeith Palace Gardens, responded to by Mr. Barron; "The Judges," responded to by Mr. Findlay and Mr. D. Thomson; "The Competitors and Exhibitors," for whom Mr. H. Williams and Mr. McIndoe replied; "The Officials of the Society," "The Visitors," coupled with the name of Alderman Chaffin, and "The Chairman."

## THE CONFERENCE.

On Thursday, September 10th, at 3.30, the British Fruit Growers' Association held a Conference on fruit culture in conjunction with members of the Royal Caledonian Society in the Waterloo Hotel, when Councillor Colston took the chair, and there was a representative gathering of northern horticulturists. The Chairman, in a few well chosen words, explained the objects and work of the Association, and Mr. G. Gordon followed with some observations on the present condition and prospects of fruit culture for profit. Mr. Dunn of Dalkeith gave an interesting address upon fruit culture for profit in Scotland, which was followed by some discussion, in which Mr. Cannell of Swanley and Mr. Dickson of Belfast joined. Mr. Sinclair of East Linton discoursed on the

culture of Strawberries for market in an excellent and practical manner, Mr. Carmichael and Mr. Machattie taking part in the discussion. Mr. Joseph Cheal then read an admirable paper on gathering, packing, and storing fruits. A vote of thanks to the Association for arranging the Conference, coupled with the name of the Hon. Secretary, Mr. Lewis Castle, was proposed by Mr. Milne, seconded by Mr. Machattie, and supported by several members of the Royal Caledonian Society, and carried unanimously, and the proceedings closed with a vote of thanks to the Chairman. Concerning the subjects discussed we are promised something farther next week.

[In accordance with our promise last week we present our readers with the portraits of four more northern horticulturists, who as members of the Council, the Committees, or as exhibitors have taken a prominent part in the management of the Royal Caledonian Society and the Exhibition last week. The names of those included are Mr. J. W. Machattie, Newbattle Abbey Gardens, Dalkeith; Mr. J. Day, Galloway House Gardens, Wigtonshire; Mr. T. Lunt, Ardgowan, Greenock; and Mr. G. Mackinnon, Melville Castle Gardens. We have other portraits in preparation for another week.]

#### PRESTON AND FULWOOD HORTICULTURAL SOCIETY.

At the monthly meeting of this Society, held on Saturday evening, there was a large attendance of members. Mr. Alderman Walmsley was voted to the chair. On the tables were displayed several noticeable floral contributions, about which an interesting statement was made later on by the Secretary, Mr. J. Atherton, who also read a letter from Mr. R. W. Hanbury, M.P., expressing his willingness to accept the presidency of the Society for the ensuing year.

Mr. A. Waters read a paper on "The Use and Abuse of Water and Syringing." Referring to plants first, he said that they were not likely to take so much harm from overwatering as fruits were. Fruit must be supplied for the table, and as free from defects as possible. If the fruits were not produced in a satisfactory manner they might depend upon it that flowers would lose their attractions. So he accorded the premier place to fruit. He found there was an idea prevailing among young men employed in gardens that Azaleas should not be watered until the pots in which they were set rang as if they were empty. The sooner that idea was dispelled the better. A too scanty supply of water at the roots had been the cause of many unsightly objects among plants. He no more believed in the Heath or Azalea plants being allowed to become dry than that the forest trees should be put away during the winter. His idea was, therefore, syringing with judgment. Soot water was good for Camellias. Dracenas usually came in for a larger supply of water than was good for them. They would retain their foliage and colour better by being cleansed with a sponge than by being syringed. Some might say that they had no time for sponging, but nevertheless they ought to sponge. Crotons they could not well injure by syringing, because the leaves were so constructed as to throw off the water, while with Dracenas it was different; the leaves conducted the water inwards to the roots.

No one was more in favour of having the vineries well watered than he was, but he thought there was nothing more injurious than to carry buckets of water and throw over the paths at night and then shut up the house until the morning. Some would object to saturating the foliage. So would he; but saturating and judiciously damping were different things. This was particularly the case in forcing houses. In regard to the Vine the root action was slow for the first two months, and he thought they should see less shanking if there was more judicious watering and at the proper time. They must not treat the roots as if they were drunkards. Peaches should have a good supply of water when they require it. He was opposed to excessive watering. It could only have one effect, and that was an injurious one. Many conditions had to be taken into earnest consideration before they could get at a safe principle upon which to work. It was astonishing how little water was needed until the stoning period. After that time they could increase the supply. Syringing should almost cease when the fruit was ripening, but after the crop was gathered syringing should begin again. Neglecting the watering from the time the crops were gathered until the time for forcing commenced again accounted for failure on the part of many gardeners in former times. They should never allow the roots to become dry at any period of the year. Melons required good management, especially in seasons like the one we had just passed through. Melons were always in request for as long a period as they could supply them, and he had got them from March to November. "How have your Melons done this season?" was a question commonly asked among gardeners, and from that they gathered that it was an important question. To those who had to keep up a constant supply in seasons like the present it was a perplexing matter. The weather, which ruled so many things, had a great influence on the well-being of Melons. They should prepare the beds in such a way that the roots may find sufficient food to support the plant until it gained strength with as few waterings as possible. He thought enough had been said to show that he was of opinion that some fruits were injured by excessive syringing, and that hardwooded plants suffered from the opposite extreme.

The Secretary then read his statement upon the contributions they saw on the tables. Mr. E. H. Stott had sent in twelve of the finest blooms of Hybrid Perpetual Roses staged this year, also twelve grand Tea Roses (distinct), and a bouquet of Roses. Mr. Sidney A. Herman of St. Anne's-on-the-Sea had forwarded a stand of twenty-four splendid

double and single Tuberous Begonias. From Mr. J. Wilding had been received twenty-four splendid double Show and Fancy Dahlias, a stand of twelve varieties of Pompon Dahlias, and a stand of thirty-six varieties of single Dahlias. He had himself placed before them one bloom of *Hæmanthus puniceus* and a spike of *Eucoris Regi*. Mr. John Eccles' contribution was a magnificent *Dracena*, which had yet to be named. Mr. Stott was awarded a certificate for his exhibits.

#### OROBUS HIRSUTUS.

THIS is a charming member of the Bitter Vetch family with much brighter flowers than is usual amongst its relatives. They are also

FIG. 43.—OROBUS HIRSUTUS.

produced in short racemes on rather long peduncles, and are consequently well suited for cutting. The colour is a pleasing shade of blue, the standard darker and inclined to purple with deeper veins, the wings a light bright shade, and the keel nearly white.

The plant is found in several countries of the Levant, and appears to have been known in Holland a considerable time before it was introduced to this country. In 1835 Don said it was "cultivated in Dutch gardens in the early part of the last century, but is of recent introduction to our own country, and is still rarely seen except in botanical collections." A coloured sketch which accompanies these remarks in "Sweet's British Flower Garden" had been prepared from a plant in the Chelsea Botanic Garden. It is now found in several nurseries where hardy perennials are made a specialty, and the illustration (fig. 48) was prepared from a specimen shown by Messrs. Paul & Son of Cheshunt, with whom the plant succeeds well. Almost any ordinary garden soil suits this *Orobuchus*; it grows and flowers freely, and produces seed abundantly in favourable seasons. It may be added that Don thought *O. hirsutus* was too much like *O. laxiflorus* of Desfontaines to be ranked as distinct, although Decandolle preserves the two names.

#### FRUIT FORCING.

FIGS.—*Early Forced Trees in Pots*.—Examine the roots, and as it is not advisable to increase the pot room, remove a few inches of soil from the base, cutting back the roots, and supply fresh fibrous loam and about a sixth of old mortar rubbish, with a quart of steamed bonemeal added to every bushel of loam, good drainage being provided. Remove the loose surface soil also, and reduce the sides of the ball about an inch, cutting off the straggling roots, and apply the above compost, adding a fourth of well decomposed manure. Ram the soil firmly, afford a good watering, and place the trees where they can have air with shelter from heavy rains and snow, also safety from frost. This is only available for trees that are not in large pots, as those in large pots and that have been stood on brick pedestals to prevent their

sinking with the fermenting materials, require different treatment. In their case all the fermenting materials, whether Oak or Beech leaves, or other substances, should be removed, and all the surface dressing from amongst the roots with a hand fork. Shorten the strongest roots, and attend to the drainage, then place the trees in position on the loose brick pedestals and surface-dress the soil with the compost named firmly rammed into the pots. Supply water to settle the soil, and after this keep the house cool, dry, and well ventilated until the time of starting in November or December. This is a preferable plan to repotting annually, as the trees are less liable to cast their first crop of fruit, and it is not advisable to disturb trees in 18 or 20-inch pots at the roots more than can be helped. In the case of trees that are not in as large pots as desired, or when it is thought desirable to increase the root space, a liberal shift may be given, the sides of the ball loosened with a hand fork, and any straggling roots cut back, also the matted roots in the drainage. Provide good drainage, using the same kind of soil for potting as previously advised, and ram it as hard as the ball, the soil being well moistened before the potting is proceeded with.

*Succession Houses.*—Houses in which the trees have ripened off second crops of fruit must be kept drier as the days become shorter. A little fire heat is necessary, with a free circulation of air to prevent damp. The wood must be full exposed to the full influence of sun and air. Thin all soft and useless wood, and allow the points of the shoots to stand well out to the glass and light. Supplies of water must be discontinued for borders that have been properly mulched and watered up to the middle of this month.

*Lifting Over-luxuriant Fig Trees.*—Gross feeding as Figs are, they are in rich borders apt to become too strong, and in that case prepare for lifting them as soon as the leaves have begun to turn yellow; indeed, it should be attended to as soon as the second crop of fruit is all gathered. Trees in unheated houses that only produce one crop should also be attended to, as well as unfruitful trees, so soon as the wood is sufficiently ripened. Carefully lift the trees and cut back all long roots, reserving the fibres only. Good drainage is necessary. A foot of brickbats with a thin layer of old mortar rubbish over them, and then a couple of feet depth of soil, composed of good turfy loam, a sixth of old mortar rubbish, and a similar proportion of road scrapings, with a bushel of half-inch bones to every cartload of loam, form a suitable compost for Figs. Place it together firmly, so as to insure a sturdy short-jointed growth. Spread out the tree roots evenly, work in the soil amongst them, and make it firm, placing them in layers as they rise, and keep them well up, not covering the topmost more than 2 or 3 inches. The soil may be moist when used, but it ought not to be wet. Give a moderate watering and keep cool and dry. A border 4 to 6 feet wide is very much better than one with a much greater width, and the pit-like borders filled with rich soil, which becomes a sour mass impervious to air, are very unsuitable to Figs. What is wanted is firm sweet calcareous soil that will admit of the free percolation of water and air and retain the manurial elements essential to the production of fine fruit.

*MELONS.—Latest Plants.*—While the fruits are swelling water must be given. Keep the roots active with tepid liquid manure occasionally, and supply ammonia to the atmosphere by damping available surfaces in the evening. Maintain a moderate moisture by syringing in the morning and at closing time, when a light syringing of the foliage may be practised if the weather be bright. Remove all superfluous growths as they appear, and admit air early, or at 75°, keeping the bottom heat steady at about 80°. Provide a night temperature of 65° to 70°, 70° to 75° by day, and 85° to 90° with sun heat, closing sufficiently early to run up to 95° or more. A little fire heat is necessary to insure a circulation of air constantly and prevent the deposition of moisture on the fruit, and no more water should be given at the roots than is necessary to prevent flagging. This will accelerate the ripening, and do much to improve the flavour.

In manure-heated pits and frames no water will be required, but keep the sides well lined and leave a little air on at the back at night. Keep the fruit well raised above the surface of the bed. Any fruit wished to be kept for a time should be cut with a portion of stem and placed in a dry airy room, or, if wanted ripe, in a warm house in the full sun; it ripens better than in cold frames. It must not, however, be cut until full sized and complete in every respect but the ripening.

*CUCUMBERS.—Autumn Fruiters.*—Give every attention to these, affording copious supplies of tepid liquid manure, removing superfluous growth so as to guard against overcrowding, take off male blossoms and tendrils, avoiding overcropping, and do not allow the fruit to hang on the plants after it becomes fit for use. Maintain a genial atmosphere by damping available surfaces other than the plants in the morning, afternoon, and evening, but the plants may be syringed in the afternoon of bright days. Pinch out the points of the shoots one or two joints beyond the show of fruit, looking over the plants twice a week for that purpose, and retain no more foliage than can have full exposure to light. Earth up the roots as the plants advance in growth, only just covering them each time they show at the sides of the hillocks or ridges, the soil being placed in the house some time previously to be warmed before use. All waterings should be of the same temperature as the house.

*Winter Fruiters.*—Pot these off or shift them into large pots, plunging them in a bottom heat of 80° or 90° until the plants are established, then raise them near the glass, maintaining a temperature of 70° at night, 75° by day, with an advance from sun heat of 10° to 15°. The fermenting materials, if such are used for bottom heat, must be in preparation, throwing into a heap, applying water and turning the heap over to induce fermentation and dissipate noxious gases before

making up the beds. For producing fruit in February, a sowing may be made at the beginning of next month if plants have not been raised previously, but this will not be necessary where there are other plants.

In pits and frames the temperature must be maintained by renovating the linings as necessary, and night coverings should be applied to prevent too great diminution of temperature. Give water very carefully, and sprinkle the plants only on bright days. Keep the foliage thin by removing bad leaves and exhausted growths, and close early with as much sun heat as possible.

#### THE KITCHEN GARDEN.

*CAULIFLOWERS.*—In the more southern districts it is not yet too late to sow seed of these with a view to having a number of plants for wintering under glass, but as a rule it will answer better to sow direct on a seed bed where the plants are to remain, protection being afforded either by frames, handlights, or benders and mats. Supposing a two-light frame can be spared raise this on bricks just clear of the ground, and fill in with old heating material, making it quite firm and of sufficient depth to bring the 4 inches of fine soil placed on the top well up to the glass. Sow the seed thinly and broadcast, taking care to keep each variety distinct, and cover with a little sifted soil. The soil being moist no watering will be needed, nor ought the lights to be put on till frosty weather is anticipated. Look well after slugs, keep clear of weeds, and ventilate freely whenever the weather is not severely cold. The sturdy plants raised and wintered in this manner transplant more readily, and do better than any that have been pricked out in frames, or that have been coddled under glass in pots. During ordinary winters a considerable number of Cauliflower plants might be wintered in handlights where some of them are to grow, and also on dry borders and at the foot of sunny walls. The Dwarf Forcing, Early London, Mont Blanc, Walcheren, Dwarf Erfurt, and Magnum Bonum are all suitable for present sowing, and with two or more of these might well be included Veitch's Autumn Giant, especially so if extra fine exhibition Cauliflowers are required early in August.

*ONIONS.*—The spring-raised crops ought now to be well advanced towards maturity, and in many instances are sufficiently ripened to clear off the ground. Those with their tops still green will scarcely ripen properly, though much might have been done towards altering this by a timely twist to the necks. The bulk being ripened, this being when the tops are died down, all should at once be pulled, allowing them to root afresh greatly impairing their keeping properties; but before they are stored a thorough drying, amounting almost to baking, ought to be given. A dry cool empty vinery or empty glazed pit answers well for harvesting Onions, though much may be done by repeatedly turning them on dry paths or boards, and afterwards they should be stored in cool dry sheds. Onions keep best when bunched or roped up, but this work may be done in wet weather. Keep the unripened Onions by themselves, and use these first. If there is the least likelihood of Onions keeping badly, and there be no early Tripolis sown, sow seed at once on a warm border, the quick-growing Queen not being omitted.

*CABBAGE.*—Seed being sown in July or very early in August there ought now to be a number of plants ready to put out, and no time should be lost in doing this. A better site for this crop than a newly cleared Onion bed cannot well be found. This, in addition to being quite rich enough for Cabbage, is also very firm, the plants put out on it growing sturdily and heart in quickly, side leaves being few in number. All the preparation needed is to clear off all rubbish and weeds and then to stir in, not dig, a surfacing of soot or soot and lime, principally for the purpose of destroying slugs and grubs. Carefully lift the plants from the seed beds, and if any are affected by the evil known as amber or clubbing destroy those already showing traces of it in the shape of a knob at the roots, and well coat the roots of the rest with a puddle made of clayey water and soot. Plants that have had their roots puddled usually take the most quickly to their fresh quarters, and the precaution may well, therefore, be taken generally. It is also worthy of note that sturdy starved looking plants obtained from open fields or other not very rich and well exposed quarters make the best progress when moved to rich garden ground, and such are usually had from those who advertise and grow Cabbage plants largely for sale. Any that have been pricked out ought to be lifted with a ball of soil and roots and replanted with a trowel, but those moved direct from the seed beds can be most firmly and expeditiously planted with a blunt dibber. The stronger growers, notably Enfield Market, Battersea, Sutton's Imperial, and such like may be put out 2 feet apart, and the spaces between temporarily filled in with small quick hearting Cabbages or Coleworts, or the former may be planted 18 inches apart each way, 3 inches less answering well for all the smaller or closer growers. Coleworts, of which the London Rosette is still the most generally serviceable, are usually planted in close succession to autumn raised or Tripoli Onions, a distance of 12 inches apart being ample. Failing Onion ground plant Cabbages and Coleworts on any well manured and deep'y dug open plot of ground, taking care to well break this down and to plant firmly. Slugs are most troublesome on lumpy ground, and for this reason it is advisable to thoroughly fine down and to frequently hoe the surface of the beds.

*PARSLEY.*—There are few or no more important crops than Parsley, and no pains should be spared in preparing as much as possible, or abundance for the winter demand. The more "double" or fine curled strains are the least hardy, plants of the inferior or older stocks frequently surviving when the rest have been killed during the winter. The small amount of shelter afforded by fruit trees will frequently save

much Parsley, and a few or many plants might well, therefore, be moved from the open to the spaces between and about somewhat spreading and not very dense Apple and Pear trees. Now is also a good time to fill frames or pits, or any, say, from which Cucumbers or Melons have just been cleared, and more also might be put out in beds where they can be covered with span-roof or other frames. A few dozens of plants, packed in boxes or boxes of rich loamy soil, and eventually placed under glass, will give enough leaves to meet the requirements of a small family during the severest weather, and this precaution ought not to be neglected. In each and every case the strong outside leaves should be gathered from the plants being moved, as they would not keep good till the winter, and their removal admits of the roots being packed somewhat closely together. The leaves formed after transplanting will require but little room, and strongest roots should be replanted not more than 5 inches apart. The bulk of the plants to stand out unprotected should also be thinned out if at all crowded and cleared of all their larger outside leaves, the young or late formed leaves being the hardiest and most serviceable. Cut down any attempting to run to seed.

**WINTER SPINACH.**—Good breadths of early raised plants are very scarce, slugs and grubs having matters much their own way during the prevalence of wet weather. Unless the rows are nearly all destroyed it is not advisable to hoe up what plants are left, the better plan being to either transplant wherever possible or else to sow more seed where the largest gaps occur. Weeds should be kept down by occasional hoeings, stirring in a little soot and lime, also getting rid of numerous insect pests. If a good breadth of ground, the preference being given to a gentle slope to the south, can be got into a finely divided state, more seed may be sown with every prospect of a serviceable crop of Spinach resulting some weeks before the earliest spring sown crops are available. Either the round or prickly seeded forms are suitable for present sowing, one being quite as hardy as the other. If the Spinach Beet is very strong, remove many of the older leaves, as these would not cook well later on, only the succulent younger leaves answering as a substitute for the true Spinach. Masses of New Zealand Spinach temporarily protected from early frosts will continue serviceable for another month or more.

#### PLANT HOUSES.

**Cinerarias.**—Flower spikes now showing may be allowed to expand. It is useless to place the plants into larger pots. Seedlings of the same sowing that are not showing flower may have pots 2 inches larger than those they now occupy. By providing abundance of air and shade from strong sunshine useful plants will be secured. Later plants should be repotted from time to time, as they need more root room. A good number of those still in the seed pan can be pricked out into boxes or singly into small pots, for these will prove useful in spring if cared for well during the winter months. Too much attention cannot be paid to late plants, for they often prove more useful than those grown for flowering earlier in the year. Watch for aphides, and if they appear fumigate promptly.

**Zonal Pelargoniums.**—Insert cuttings at once in 2½ and 3-inch pots to secure plants for flowering early next year. Cuttings will strike freely in any position under glass at this season of the year. Those required for winter flowering should not be pinched again, but remove the flowers as they appear, also decaying foliage. Give them abundance of room so that air and light can reach every part. They are very soft, having grown too luxuriantly to flower well. If the weather prove wet and dull they will be improved by removal under glass, either in a cool house or in cold frames, where heavy rains can be thrown off and the air kept on the dry side. This assists wonderfully in hardening and ripening their wood, without which they will not flower, or continue to do so satisfactorily for any length of time.

**Petunias.**—Cuttings of good varieties may be inserted and rooted at once, then transferring them singly into 2½-inch pots. Pinch the leader out when 2 inches high, and continue to stop the plants until bushy little specimens are formed. Winter these on a shelf close to the glass where the temperature does not fall below 45°. They will move slowly under these conditions, and be ready for 5-inch pots early in January. Plants subjected to this treatment will flower early during the spring, and prove most useful for conservatory decoration.

**Hydrangeas.**—Those that have been rooted with buds should be fully exposed to light and air. If they are well hardened place them in a sunny position outside; if not, and they are not very well ripened, fully expose them to the sun in the greenhouse. Plants of *Hydrangea paniculata grandiflora* that flowered in pots may be stood outside. They will harden and ripen their wood and be in good condition for flowering another season. Whether they flower profusely or the reverse, depends almost entirely upon the ripened condition of the wood.

**Heliotropes.**—Plants in 5-inch pots and growing outside should not be pinched after this date, the flowers only being removed. Standards or pyramids that are grown under glass may be pinched once more, and the shoots trained as they grow. Feed all plants that have their pots full of roots with weak stimulants every time they need supplies of water. It is necessary to remove the flowers as they appear from those grown inside.

**Kalosanthus.**—Remove shoots that have failed to flower, and insert five or six together in 5-inch pots. If an increase of stock is needed the lower portions of the stem may be inserted; they branch freely, and with one good season's growth will flower profusely. They root quickly in a close moist atmosphere. Place them on a shelf close to the glass. If ripened and kept cool they should flower next season. The old plants

if required can be cut close back and allowed to break into growth under the conditions that have been advised for French Pelargoniums. Those for next season's flowering are better outside than under glass until the end of the month, when they must occupy a light airy position. Do not give too much water at their roots, and if the atmosphere is kept dry all the better.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### AT THE MOORS.

ON September 8th the mists, so much longed for as indicating fine weather, crept slowly over the hills, and the next day, although it rained, the wind had lulled, and being warm the bees worked well, although the Heather was much destroyed by the storm of rain, wind, and hail of September 6th. Happily there are many varieties, early and late, which give a chance of a yield of honey from the 1st August up to the middle of September, or sometimes later; so that while writing the day is promising to be fine, and, if we except February, the first fine summer-like days we have had for twelve months. This is exactly to a day as it was in 1890, and it has proved to be almost similar to 1845.

After the storm abated, and up to September 10th, the honey so abundant on the 8th left the flowers, so there were two days of scarcity, and the weather being fair robbing was prevalent. To stop it taxed my efforts not a little. I contracted the entrance of every hive to about 1½ inch. In one case I stopped it by smearing the alighting board of the attacking hive with carbolic acid, and several others with damp earth. All varieties were alike guilty. The Pronics were, however, the most determined robbers I ever witnessed, insinuating themselves into the richest and strongest hives without opposition.

I know this experience differs from that of "A Hallamshire Bee-keeper," but he has probably not had a similar circumstance. They are on trial, and the concealment of facts would be akin to telling an untruth, so we must be truthful and honest, that your readers may understand thoroughly. I do this the more cheerfully as "A Hallamshire Bee-keeper" asked me to give my experience candidly, and I am sure it will be of more value than the evidence so common amongst many who have no experience of what they write.

I should be pleased if "A Hallamshire Bee-keeper" would assist in making an interesting experiment—viz., to weigh one or more of several varieties with filled honey sacs; or one or more bees before and after being filled with honey. My reason for this is, it will be remembered, I made some observation about the smallness of these Pronics, but since then I have been astonished at the great size of their honey sac. Even in this bad year they will deceive me if they do not surpass many others. It will not be long now before the hives on trial are tested by the balance, which will to some extent decide the honey-gathering qualities of the smartest bee in appearance of any yet imported. I consider the robbing propensity is the fault of the season and not of the bees.

The best hives at the moors are old swarmed stocks having young queens, and the stores and contents of the hive ample and in good condition. Although the season has been the opposite of good, and we shall be unable to report extra heavy hives, on lifting the hive by one side I was astonished at the weight some have reached. Some people in town and country have strange ideas of bees. "What do you bring the bees to the Heather for?" inquired one, the reply to which was Honey; and "When you take them away will you take Heather with you to feed them in the winter?"

#### CLEARING SUPERS.

"An Old Bee-keeper" writes as follows:—"Perhaps 'A Lanarkshire Bee-keeper' would explain more particularly his

method of clearing supers with carbolic acid paper. Is it to be applied wet or dry? If applied wet, and it happened to touch the comb, it would, I fear, give a most disagreeable odour. In some kinds of section crates, where separators are used, it would be difficult to insert the pieces of paper in a wet state, and I suppose the separators would have to be removed in either case. I agree with 'A Lanarkshire Bee-keeper' in disliking separators, but as they are generally used this difficulty must be met."

Clearing supers of bees by the aid of carbolic acid is the most cleanly and most expeditious method ever invented. Use brown paper of medium thickness, and preserve it for future use. Take a feather or brush, dip it into the acid, painting a little on both sides of the paper, which absorbs the acid but leaves the odour, and when slipped between the combs does not stain them in the slightest, and causes the bees to retreat downwards instantly before they have time to break the seals, or to soil the combs. To facilitate the process lay a square of carbolised paper on the top of the super. When bees are managed properly there is no necessity for separators, they are a great hindrance to the rapid filling of sections, and one of the things that ought not to have been introduced into the apiary. When the operator is an adept it is unnecessary to have a paper for every seam, but novices would do well to employ the full number.—A LANARKSHIRE BEE KEEPER.

#### POSITION OF THE FRAME HIVE.

It is important that the hive into which the bees are to be put should stand in exactly the same position as the old skep of bees did before they were driven, that the bees returning from their flight may not be lost. To do this the old stand must be removed, and the bees in the skep placed on one side for a few minutes. Great care must be taken that when fixed the hive must be perfectly level across the frames, as unless the frames hang true the combs will not be built in them and allow of their easy removal singly, but would be joined to the nest, and do away with the object for which frames are used.

#### HIVING.

Everything being ready, the hive in its place, the roof taken off, and quilts removed, exposing the frames, put the skep in which the bees are on the frames, then with the open hands slap the skep hard on both sides at the same time, and the bees will fall on the frames. Raise the skep quickly, give it another shake to dislodge any bees that remain in it, and before they have time to recover the shock put a cloth over the top of the hive and bees, and pull it down over the hive gently. In a short time all the bees will have run down and clustered between the frames.—JOHN M. HOOKER.

#### PRICES OF PUNIC QUEENS.

IN the Journal for September 10th (page 234) "Spread Eagle" wants to know how I could afford to advertise Punic Queens at 2s. 6d. The advertisement says, "Virgin Queens," these two words being in the largest black type, and if your correspondent does not know the difference between a virgin and an imported queen he has yet much to learn. In response to the advertisement I sent out nearly 2000 queens, which were safely introduced, and when spring came there was not one weak or dysenteric stock from them. I sent another advertisement last spring to the managers of the "B. B. J." and "Record," stating these facts, also offering virgins again for the past season at 2s. 6d. each, but they refused to insert it or give the reason for not doing so, returning the money enclosed to pay for it. I then turned my attention to America, and have been sending virgins there with such success that next year I shall be able to dispose of all I can rear.—A HALLAMSHIRE BEE-KEEPER.

#### TRADE CATALOGUES RECEIVED.

T. S. Ware, Tottenham, London.—*Catalogue of Carnations, Pæonies and Bulbs.*

Frank Dicks, 66, Deansgate, Manchester.—*Catalogue of Bulbs.*

Ant. Roozen & Son, Overveen, near Haarlem.—*Catalogue of Bulbs.*

Daniels Bros., Norwich.—*Catalogue of Bulbs.*

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Matricaria and Pansies (W. Innes).**—Your flowers only arrived just in time for this brief reference. The Matricaria, Purity, is pure and good, and the Pansies very effective.

**Double Violets (J. L. A.).**—It is impossible to name a Violet from a flower crushed in a letter. Yours is a dark form of the Neapolitan, as are Marie Louise and De Parme, the latter a trifle the darker. Comte de Brazza is white or nearly so.

**Electric Garden Engine (Maker).**—We are obliged by the information that pumps worked by the electric current are obtainable; but as we presume the manufacturers of them will not give the proceeds of sales to charities we can scarcely be expected to advertise them gratuitously.

**The Manresa Vine (Lankhills).**—If you write to Mr. M. Davis, Manresa House, Roehampton, we have no doubt he will readily afford you an opportunity of inspecting the Vine. Putney Station is within two miles of Roehampton, and there are usually a number of cabmen waiting for "fares." We think this year's crop is cut from the Vine and sold.

**Fasciated Lillium (W. Ainslie).**—The photograph you send of a Lillium auratum, with fifty-eight flowers in a cluster, represents a case of fasciation. It is singular that we have had a stem with exactly the same number of flowers from a plant growing in a border. Yours has been grown in a pot, and has evidently received good cultural attention. A similar case has been illustrated in our columns.

**Large and Small Exhibitors of Roses (C. G.).**—There is not the faintest shadow of foundation for the charge of "boycotting" you bring against this Journal relative to communications that have been received on the above subject. Every letter we have received on your side of the question has been inserted, and your allusions to "hushing up" are wholly misplaced. It was intended to publish your contribution, but you have "boycotted" it yourself by your intemperate tone, and it will therefore not now appear.

**Fungus on Pears (A. B.).**—The cracked fruits you have sent are seriously infested with a fungus (*Fusicladium*), and nothing that you can apply to them now will be of benefit. All such fruits as you have sent should be burned. The trees do not have the support they need. The light gravelly soil is too poor and probably too dry for Pears, the fruits instead of swelling freely becoming harsh, and the cuticle splits. Copious supplies of liquid manure in winter would enrich the soil, and thick mulchings of manure in summer retain moisture in the earth for the support of the trees. Root-pruning judiciously and some fresh soil added might be of great benefit, but in the absence of knowledge relative to the age, growth, and size of the trees we cannot give definite advice on procedure.

**Plum Trees Gumming (J. B.).**—There is no remedy short of sound, healthy, matured growth in suitable well drained soil. By all means cut back the affected parts and cleanse the stems, but if the soil is not such as to encourage healthy root action the evil will return. No one can say what your soil needs without knowing its nature. Perhaps it needs draining. If a black rich mass of humus lime would do good, cow manure and soot probably do harm. We have seen both Rivers' Prolific grow clean and fruitful in some gardens and "gum to death" in others. If your Diamond Plums gum it is not likely that the varieties named would be free if grafted on them. Grow the most extensively those varieties which succeed the best in your soil, and if you like to describe its nature so that we can comprehend it we shall be glad to return to the subject.

**Yellow Tomatoes (T. Crosswell).**—Many persons prefer these, on the ground that they are more delicate in flavour than most of the red varieties. The fruits you send of Suttons' Golden Perfection are very handsome—smooth, large, uniform, and clean. We have only one fault to find with them, and this you will perhaps regard as a compliment—namely, they are too large. Very large Tomatoes are like huge Turnips.

and some other products, their bulk consisting mainly of water. The smaller of the fruits you have sent are excellent in quality, the larger being relatively inferior in proportion to their size. We have found the same difference between gigantic and comparatively small fruits of other varieties of Tomatoes we have been testing of late, the very large fruits in every case being inferior to the smaller. We omitted to say that the large fruits are attacked with the fungus, the small are not, nor is this distinction uncommon. It is by forcing growth for large fruit that many fungoid attacks have been invited.

**Streptocarpus Culture (H. K. V.).**—The reply to your question has been accidentally delayed. Your flower is one of the many varieties of *Streptocarpus Rexi*. They are pretty dwarf growing plants, and require warm greenhouse treatment. They are readily raised from seed, and if raised early and grown well they flower at the end of summer. Grown indifferently the seedlings may not flower until the second year. Propagation is also effected by division in spring. The plants require resting in winter, not allowing them to become dust dry at the roots, but keeping on a rather moist base, where they will receive a little moisture without making the soil wet, and the temperature ought not to be less than 50°. When growth recommences water should be given more freely. They grow well in light rich soil, preferably fibrous loam two parts, and one part of leaf soil with a sixth of sand. Seedlings are sometimes kept gently moving through the winter from a summer sowing of seed, and these make a fine display the following season. The plants do not require a large amount of pot room, and take up little space. They are fine for margins to plants of larger growth. We have seen them luxuriating planted close to the edge of the path in the succulent house at Kew, where they formed an attractive border.

**Ammoniacal Carbonate of Soda Solution and Tomatoes (Tomato Grower).**—A gardener of wide knowledge and great experience sends the following in reference to the subject of our reply to "C. B. A." last week, and appears to meet your case:—"To be effective the solution must be used over the whole plant, fruit included, distributing it in a fine spray so as to coat every part with a thin film, and in advance of an attack by fungi so as to destroy the germs. The small quantity of carbonate of copper is not found deleterious to the fruit, that sprayed with it being very extensively used in the United States of America for canning. It is assumed that the plants will be washed more or less by rain, and that those under glass will be syringed. This is in substantial accordance with our reply, which had to be of the briefest character in consequence of the question arriving too late to be satisfactorily dealt with. When the solution is used, as undoubtedly it should, "in advance of fungoid attacks," the fruits are not in an advanced stage; but in September they are ripening, and some of them, it may be presumed, would be used almost immediately after being sprayed with the copper solution. We should prefer not to eat those fruits with the copper "film" on them, American customs notwithstanding; and we have yet to learn that American growers of Tomatoes and Apples spray the ripening fruits. Their rule is to take action sooner, and they are wise. It is too much the custom in England to wait too long, and thus give the enemies of plants an enormous advantage. When the disease has taken possession of Tomatoes or Potatoes, or, in other words, when the mycelium of the fungus becomes established in their tissues, we have not much faith in the efficacy of any applications, and we should not eat Tomatoes that had been sprayed when ripening with the solution in question. We are all the same obliged to our correspondent for his suggestive remarks.

**Planting Crocuses in Grass (F. J. B.).**—A narrow, gouge-like trowel, about 1½ inch between the edges of the blade, which should curve so as to form in cross section a half circle, answers very well for making the holes, the trowel being inserted 3 or 4 inches deep in the turf, and a similar cut made on the opposite side admits of the soil being readily removed by a twist and upward movement of the trowel. This makes a hole about 1½ inch in diameter, sufficing for the largest bulbs, and a little soil being introduced the Crocus may be inserted crown upwards, and the hole filled level with fine soil, or if the natural soil is light or easily broken with the trowel it may be used for filling up the holes, and made moderately firm. Where large quantities have to be planted it pays to have a gouge made at a blacksmith's, 1½ inch wide at the lower end, and 1¼ inch across at the upper end, the gouge being 3½ to 4 inches deep, welded to a socket, and an ash shaft, with a hilt or box handle fitted into the socket, forming a good hold for the hand. A tread should be formed on the "hand" side of the gouge corresponding to that of the person using the implement, and its lower side level with but clear of the opening of the gouge. To use this a person has only to insert it into the ground at the place desired, give it a slight twist after driving it down to the tread with the foot, and withdraw it, proceeding to the next place, and the gouge being forced into the ground perpendicularly the pellet of the previous hole will be expelled, and the implement kept in working order. In soft ground holes are readily made with an iron shod dibber, or a solid iron point may be used formed in the shape of a T, the cross piece or upper part of the T forming the tread, and with a socket and a handle the implement is complete. It can be forced into the ground up to the tread, and the Crocuses inserted in the holes as advised. A little fresh good soil for them to rest on is very desirable, and in some lawns indispensable.

**Names of Fruits.**—*Notice.*—Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. *In consequence of the large number of worthless Apples and Pears sent to this office to*

*be named, it has been decided to name only specimens and varieties of approved merit, and to pass the inferior, which are not worth sending or growing.* The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*J. Taylor*).—Plums.—Young wood should always be sent with Plums for showing whether it is smooth or downy. 1, Prince of Wales; 2, Pond's Seedling; 3, possibly Nectarine. Pears.—1 resembles Beurré Diel; 2, Williams' Bon Chrétien; 3, Beurré Capiaumont; but the specimens are not fair typical samples. (*J. Hartland*).—1, Worthless; 2, Longville's Kernel. (*Pennell & Sons*).—The Apples were mealy, and therefore the quality could not be tested. Possibly the variety may be the Sack and Sugar: you will find it described in Dr. Hogg's "Fruit Manual," which is no doubt in your library. The Pear resembles small samples of Uvedale's St. Germain. (*J. Austen*).—A fine specimen of Red Astrachan. (*N. C.*).—Pear, Beurré Giffard; Apple, Worcester Pearmain.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*N. C.*).—1, Flowers withered, therefore undeterminable; 2, *Retinospora ericoides*; 3, *Eupatorium ageratioides*; 4, *Rudbeckia triloba*. (*G. Meyrick*).—*Hibiscus syriacus*, of which there are varieties with darker flowers. (*Somerset*).—The name of the Grass is *Alopecurus agrestis*. We agree with you that properly named collections are interesting and approve of your endeavour. (*F. J. R.*).—1, *Rivina laevis*; 2, Flowers all withered; 3, *Viburnum Lantana*; 4, *Crataegus pyracantha*.

## FARMS IN HAND.

THIS is the term applied to farms given up by tenants, and which for some reason or other have not been relet, but have fallen upon the landlord's hands, and as this happens at Michaelmas attention may now usefully be given to the treatment of such land, as it not unfrequently falls to the lot of the home farmer to take up farm after farm as they so fall in. When he has this extra work coming upon him every effort should be made to push on autumn work on the home farm, so that the vacant farm may have prompt attention as soon after Michaelmas as possible.

No rules can be framed for such an emergency, but the farm falling in hand must be treated solely upon its merits, and not at all by line and rule. If it should be a dairy farm with the land chiefly in grass, the work of reclamation will be comparatively easy. But it is quite exceptional for such farms to be given up; it is the poor arable farms that are generally as foul as they are poor, which fall in hand, and no light undertaking is it to bring them into thorough cultivation again. Let the home farmer bear this well in mind, and let him insist upon having sufficient means for the undertaking. If he foolishly agrees to try and do this extra work with the home farm staff of men and horses, he will fail, the home farm will be neglected, and in the end he will be blamed. No, it will be quite enough for him to have this extra work upon his hands, and if he is a wise man he will at the outset make it clear to the landlord or the agent that the new farm must have sufficient implements, horses, and workmen for its requirements. The outgoing tenant will most probably have an auction sale, at which something may be purchased for stocking the farm. But this is very doubtful, both live and dead stock generally being of the worst possible description, and it is mere waste of money to purchase a lot of old implements that require repairing at once. We once took over a farm upon an estate which came under our management, and the first year the wheelwright's bill for repairing old implements was nearly £50. The agent who stocked the farm was an auctioneer who was always picking up "bargains" at sales, and he left behind him at several farms such a collection of them as we hope never to meet with again.

The best rule in such a case is to purchase as few implements as possible, and to have them quite sound and good. Such things as a seed drill, extra harrows, rollers, &c., can always be spared from the home farm; but ploughs and carts must be had. Do not purchase old horses; younger animals are expensive, but they must be had. Using from fifty to sixty horses, it has long been our rule to breed enough young stock to fill vacancies and to meet emergencies, and so we have always been able to stock any farms falling in hand. If occasionally it is found that our surplus horse stock exceeds due bounds there is no difficulty about the disposal of such sound home-bred stock. We never send them to auction sales, but invite one or two respectable dealers to inspect our sale draft, telling them our price, and the matter is settled quietly. It is, of course, well to remember that a dealer never can bring himself to give the price asked by the seller, and a sufficient margin must be allowed for the dealer's "beating down."

It will most probably be found that the only clean land upon the farm consists of a bare fallow, for which a heavy charge for tillages has been paid in the valuation. This must be turned to account for winter corn, and Wheat and winter Oats sown at once,

with a dressing per acre of 1 cwt. sulphate of ammonia and  $\frac{1}{2}$  cwt. each of steamed bone flour, mineral superphosphate, and muriate of potash. This is a safe autumn dressing, and we may feel certain it is required, as the land if clean is very certain to be poor, and we must proceed upon the principle of judicious storing of the soil with fertility. In spring the whole of the winter corn should have mixed seeds sown for a temporary pasture of five or six years' duration, and the labour on that portion of the farm will be reduced permanently.

If there are any root crops they should be clamped for folding with sheep on the land for spring corn, also to be laid down to temporary pasture, and then we must set to in real earnest at the remainder of the land to get it clean at once if possible. But this is a matter dependant upon weather, and we can only resolve to do all we can in autumn, and to go on in spring as weather permits. In any case the work will be expensive, and we must resolve to keep as much of the land as we can under fodder crops, and so keep down expense and gradually improve it.

## WORK ON THE HOME FARM.

A glorious spell of fine weather has come at last, and it has required some self-control to go softly and not cart the corn too soon. The grain is not only soft, but very much of the husk is rotten, and as it dries much corn must be shaken out in the carting, however carefully it is handled. It is at best a good harvest spoil, and the only thing left to do is to make the best of it now, and save all we can. A high price for a good sample of Wheat is now a certainty, and we doubt not plenty of good samples will be forthcoming, as the damage generally proves less than was expected. Malting Barley will be in high demand, and good samples must not be parted with lightly, for they should be very profitable, and we do not intend Mr. Middleman to have too great a picking. He thrusts himself in between grower and consumer simply because we allow him to do so. We say, Sell to the malster and not to the middleman; it may mean an addition of 2s. per quarter to your profits, and why should you let that slip through your fingers?

Do all that is possible to turn corn that runs out upon the land to account by driving every sheep and pig you can upon the stubbles. Store lambs might just as well be pushed in now as not, and every old ewe drafted for fattening should be forced upon the fallen corn. They will eat it freely enough, and the only thing to guard against is over-feeding.

We may have a fine autumn after all, and if so with the soil so softened by rain autumn tillage will be easy work, and should be pushed on with immediately after the corn is cleared off, and the fallen corn eaten. It will be as well, therefore, to clear one stubble thoroughly before turning stock into another in order that plough and cultivator may be at work as soon and as briskly as possible. Do not lose the golden opportunity of fine autumnal weather, for it means early sowing next spring, and a dry open condition of the soil, which can only be had by autumn cultivation and full exposure to frost, snow, wind, and rain all winter. Get the soil clean, and then throw it up to the action of the air, if you would have a good and early seed bed.

## METEOROLOGICAL OBSERVATIONS.

## REMARKS.

6th.—Cloudy throughout and rain at night.  
 7th.—Brilliant early; haze and thin cloud after 11.30 A.M.; overcast after 4 P.M.; spots of rain at night.  
 8th.—Bright and warm.  
 9th.—Slightly foggy early, bright and warm after 9.30 A.M.  
 10th.—Bright and warm.  
 11th.—Bright and warm.  
 12th.—Bright and warm.

With the exception of a little rain on Sunday night, a very fine warm week—one of the extraordinarily few weeks (3) in which a temperature of 80° in the shade has been reached.—G. J. SYMONS.

THAT the subject of planting Apple trees to form orchards will occupy more attention in the future than it has done in the past no one will for a moment dispute. The societies formed with the object of encouraging fruit growing, not only as a pleasure but as a means of procuring a profitable investment for capital, are inducing many persons to plant fruit where land is at command from which the agricultural returns do not warrant a continuance of the methods at present pursued. No doubt there are difficulties in the way of the tenant farmer at present which prevent his carrying fruit culture to any considerable extent.

If Apple growing cannot be made to pay under good culture I am certain it cannot when such work as planting the trees is carried out in an indifferent manner. The selection of varieties is most important. Where many persons make a mistake is in having too many. Much better is it to plant duplicates of known and proved sorts than to extend the list of names. Another important point not to be lost sight of is that of selecting those suitable for the soil. Some will succeed in one class of soil, while others will barely exist in the same place. It is far more a question of soil than locality as regards the varieties that will succeed or otherwise. Experience or information from a reliable source as to the adaptability of any kind should guide the planter in making a selection that is likely to give satisfaction. The soil can be divided into two sections—heavy and light—the former being much the more difficult to manage, and one in which fewer varieties will flourish. If the soil is naturally unsuited for certain kinds it is useless to plant these, no matter how well the preparation of the soil and subsequent planting are attended to by adding a choice compost to start the trees into growth. They may grow fairly well for the first few years until the roots travel beyond the prescribed area originally prepared, but then the trees commence to “go back,” the most prevalent sign being the decay of the young shoots during the winter following their growth; the trees become thickly coated with lichen, and failure results. Few varieties refuse to flourish in light soil if rightly managed, therefore those in possession of this class of soil have an advantage over others in the matter of selection.

Another point which needs especial study is the site of the orchard. It has been said, Never plant Apple trees in a valley. The reason is obvious; spring frosts cause so much damage to the crop of blossom, coming, as it does, very often when the trees are in full bloom. A high position is more favourable to success provided the necessary shelter from winds is assured. That from the south-west is considerably the worst for the Apple crop, much of which is spoilt through no other reason than being blown from the trees through inadequate protection. Shelter is necessary on three sides of the orchard—south-west, north, and east, but should be so arranged that the trees providing the shelter do not shade the Apple trees below. It matters little what kind of protection in this respect is afforded, but nothing is better than a belt of tall deciduous trees placed at some distance from the orchard. Shelter derived from trees on the south-western side of the orchard preserves the fruit on the trees, while that on the eastern side protects the tender shoots and blossom in spring when blighting winds prevail sometimes two or three weeks at a time in elevated situations.

It is useless to plant Apple trees on land that is naturally wet

without first draining it, the roots cannot withstand the continual moisture which they, of necessity, must receive in such a site. Some kinds of soil appear wet and retentive, but at the same time are not so in reality. Soils largely composed of clay, through which the surface water cannot penetrate, need drainage, but where water does not remain on the surface beyond a short time owing to the prevalence of stones in the soil, which act as a conductor for surplus water, draining would be a waste of time. All that is needed in this case is thorough trenching of the soil in which the tree is to grow. What I term a profitable way of orchard planted trees is to have a combination of Apples and grass. The latter if made into hay will provide all necessary labour the Apple trees require; during this time the trees will be growing into money. No doubt a better combination could be arranged, such as growing Gooseberries, Strawberries, or Raspberries between the rows of Apple trees, but these crops require a good deal of labour and attention, more than some would care to expend on them. Besides, grass affords a readier means of getting about among the trees than where all the soil is under cultivation, especially if it be of a strong nature. Lose no time in ordering the trees, much is gained by doing this early, better trees are obtained, which is important; there is no advantage in deferring longer when once a selection is decided upon. I append a list of varieties suitable for heavy soils, classifying them in a simple manner, so that if the list is too long it can be reduced by making a selection, commencing at the top, as I have placed the best in rotation according to my opinion.

The preparation of the stations in which the trees are to be planted requires some thought. All these should be ready at least six weeks before planting, to allow time for the soil to settle down sufficiently. Some persons do not think about having the holes ready for the trees when they arrive, the consequence is the trees have to be laid in by the heels perhaps for two or three weeks; in some instances the trees are not taken from the bundles. The result of such carelessness is the roots in the centre turn mouldy, the fibrous parts are mildewed and useless. Each should be laid separately in a trench, covering the roots with fine soil to maintain the roots in a fresh condition until they can be planted, which, if the weather is suitable and all is ready for their reception, ought not to be delayed a single day longer than is absolutely necessary.

Where the soil is of a light description the work is simplified, but where the soil is heavy, retentive, and cold much labour and thought must be employed to command success. As I have to deal with a soil most unsuited for planting any kind of fruit trees in its natural state I will describe the method here pursued in planting Apple trees for orchard growth. We planted 1100 trees, standard and bushes, last November, and did not lose a single tree. For a permanent orchard on grass I advise that standards be planted 30 feet apart, with bush trees alternately, and a full row of bushes between each two rows of standards in addition, which will allow 15 feet of space between, requiring forty-eight standards to the acre, and 150 bushes. In planting some fields the number of trees required will vary; where the boundary is not a straight one it will be found that more, or it may be less, will be needed; the rows not finishing off in the same order, spaces will be left, in which extra trees can be planted as a saving of space. The above numbers give a good idea of what will be needed.

The bushes will not be interfered with by the standard trees for at least fifteen years, and perhaps not then entirely. Some varieties, which are not so strong in growth, would succeed at half the distance for several years; for instance, bushes of Lord Grosvenor, Stirling Castle, Irish Peach, and Worcester Pearmain might be planted  $7\frac{1}{2}$  feet apart if the most is to be made of the land—however, this is a matter for personal convenience.

The prices of trees vary according to quality and the variety. Splendid bushes, which will fruit the first year if required, can be

Bought for £10 per 100, and perhaps less, although nothing is gained by buying the lowest priced trees; standards about £12 10s. per 100. These prices are for the best trees of course. Special terms may be made when large numbers are required. In planting an orchard, whether large or small, some method should be pursued so that the trees will be straight in the rows in all directions—not merely from one side to the other, but the cross lines too ought to stand in order, not merely for appearance but for convenience in removing the hay or cleaning the ground with the horse hoe should it be decided to banish the grass crop after a few years as giving less trouble. The best plan is to mark out the outside rows first, using two sorts of stakes—long ones for the standards and shorter for the bushes. If the extreme outer rows are measured correctly, and the width from row to row between be accurately noted, the rows diagonally are easily adjusted by taking a sight from one outside row to the other, fixing the stakes accordingly. It is much the best plan to mark all the stations before commencing to dig out the holes. This latter can be done by arrangement with local labourers, according to the kind of soil to deal with; where that is heavy, stony, and bad “moving” from 3d. to 4d. per hole is a fair price, and less according to the nature of the soil. If holes 4 feet square on the surface are marked out, taking off the turf about 4 inches thick, laying that on one side, the next spit and the loose soil in another place; the rougher and worthless taken out to a depth of 2 feet, depositing this by itself on the side of the hole. The bottom is then broken up 3 inches deep, which admits of a free percolation for surplus water from heavy or continuous rains. Breaking up the lower strata thoroughly dispenses with the necessity of laying drains. I prefer to have the sides of the holes perpendicular; this needs some attention in contract work, there being a tendency to have the holes more narrow at the bottom than the top. My idea is that in a few years’ time, when the roots have reached the sides of the holes, if a further width of, say, 1 foot more on all sides of the station is broken up to the same depth the trees will derive much benefit from the fresh food supplied and additional rooting space. By doing the work in this manner the cost is spread over a greater period, and with advantage to the trees.

When the holes are completed they should be filled in to allow the soil time to settle down somewhat firmly before planting. If the digging is deferred until a short time before planting there is a danger of the trees sinking below the surface too far for their well-being in the future. This is most important in a district where the soil is inclined to be heavy and a sure producer of muck and lichen-covered branches. It seems useless to say, Put the bad soil at the bottom of the hole, but there it must go. Chopping the turf into pieces about 4 inches square, laying this in a heap by the side of the hole, as that will be required for planting the tree. I prefer to allow the soil to settle down gradually into its place instead of treading it firmly, as percolation is rendered easier than when the soil is kneaded together in a wet state. Soil of a light character gives but half the trouble in preparing the stations as does that which is of the opposite texture; still for Apple growing the heavy soil, if properly managed, will give quite satisfactory results.

The next point is to prepare for planting the trees in the shortest space after they arrive. Stakes for the standards should be prepared, and ought to be not less than 5 feet 6 inches long or 2 inches in diameter. This will allow for 3 feet above ground, which is quite sufficient. The dwarf trees will not require stakes. What are better than the usually employed tar cord and pieces of cloth or bags to secure the trees to the stakes? Are withies made from young hazel about the thickness of the small finger and from 3 to 4 feet long? These twisted make capital supports for the trees. A loop is formed at one end, which encircles the tree, a handful of hay folded neatly is placed on each side of the tree to protect the bark. This is kept tight with the withy, a turn is taken around the stake, again round the tree, twisting the end itself

around between the stake and the tree, thus making both secure. The tree stands about 6 inches clear of the stake, preventing one rubbing against the other, as is often the case where string or tar cord is employed. These withies if well made of suitable material will last fully a year, often more, and is by far the best way I know of staking any kind of tree. Everyone with the smallest experience fully understands what damage is done to growing trees through faulty staking by the bark chafing against the top of the stake in windy weather, which causes wounds that cripple the after growth considerably.

When the trees arrive they ought to be unpacked at once, and laid in rows singly to prevent their roots becoming dry, arranging all the trees of one sort together, which facilitates planting. I plant the standards first, preserving a straight line. The roots of every tree are examined, any wounded parts are cut away, fibrous roots spring from these neatly pruned fibreless roots. While the trees are out of the ground the roots are covered with a mat. I attach much importance to this, never allowing the small fibres to become dry. On the surface of the soil in filled up holes we place a layer of the chopped turf, the tree is arranged in position, spreading the roots evenly, not allowing any to cross each other, cover with a compost of decayed vegetable refuse, wood ashes, and old potting soil, thoroughly mixed together. A gentle shake is given to the tree, which settles the soil about the roots, another layer of chopped turf is added, treading the whole gently to make the soil firm. We are guided in this by the state of the soil, if this is wet we defer the treading until it has dried somewhat. Two men follow closely in staking the trees; if this is neglected for even one night it often happens that many are displaced in the morning, and the work needs to be done again. The trees stand on a small mound at first, being on the surface of the soil, which in a few months settles down low enough. A mulching of half-decayed stable manure 3 inches thick is then laid all over the surface, covering the whole space of 4 feet, and the roots are thus guarded from the effects of frost. Frost does not injure the roots of trees which have not been disturbed, but with others it is different. Any extra pains taken in this respect well repays the outlay in attention.

The following are useful kitchen varieties in their order of ripening:—Lord Grosvenor, Potts’ Seedling, Stirling Castle, Ecklinville Seedling, Warner’s King, Cox’s Pomona, Mère de Ménage, Lane’s Prince Albert, Lady Henniker, Bramley’s Seedling, and York-hire Greening. Dessert varieties:—Irish Peach, Lady Sudeley, Worcester Pearmain, King of the Pippins, Cox’s Orange Pippin, Gascoigne’s Scarlet, and Braumann’s Red Reinette.—E. MOLYNEUX.

## SALVIAS.

THOSE who during the summer months have grown a good number of these useful plants will, if cultural details are well attended to, be amply rewarded by a good supply of bright elegant flowers during the autumn and winter which are useful for a variety of purposes. When grown for use as pot plants they are extremely effective arranged in masses. Mr. Bethel of Ashton Court, near Bristol, usually has a fine display grouped in masses of distinct colour, and very imposing they are. They are also admirably adapted for interspersing among the other occupants of conservatories and greenhouses, their long tapering and brightly coloured flower spikes, when arranged with taste and judgment among plants of more bushy growth, give that artistic lightness and finish which is so desirable. In addition to these good qualities Salvias are also of the greatest value for use as cut flowers. A few feathery plumes of Salvias when they rise from a thinly disposed base of other flowers are certain to find many admirers.

Many gardeners would find it to their advantage to pay more attention to the culture of Salvias. They may often be seen in good condition during the early stages of growth, but by the time they are in flower the brown foliage and loss of leaves show that the treatment they have received has been faulty. In my opinion, the chief causes of this state of affairs are want of feeding and too dry an atmosphere after the plants are housed. When the soil is well permeated with roots, liquid manure or artificial fertilisers should be given regularly in a weak state, with occasional waterings

with clarified soot water. The latter has the great merit of imparting vigour and colour to the leaves, and enables them to resist the attacks of insects. While in the open air the plants should be syringed daily during bright weather. Frequently the time when the plants suffer the most is just after they are housed; frosty nights are followed by bright days, the ventilators being placed wide open creates a strong current of air and quickly produces atmospheric aridity. The plants must therefore be thoroughly well syringed during the middle of such days, and the floors and stages damped if they are constructed of absorbent materials.

Plants of *Salvia gesneræflora*, which have the pots filled with roots at this season, require another shift, as it is one of the latest to flower, and is difficult to keep in good condition till the flowering time arrives if the roots are much cramped. The finest plants I ever saw were placed into 14-inch pots at the end of September, the soil used being two parts good loam, one of thoroughly decayed hotbed manure, with a little soot and sand added.

The planting out system answers well with *Salvias*, but when they are so treated the plants should be prepared for potting by cutting round the roots with a spade ten days before that operation is performed. The best varieties that I am acquainted with are the following, all of which are good:—

*Salvia splendens Bruanti*.—This is a great improvement on the old variety of *splendens*, being of dwarfer habit and the flowers more freely produced; colour bright scarlet.

*S. Pitcheri*.—An herbaceous variety, producing flowers in great profusion throughout the autumn months, and being of a bright blue colour is very desirable.

*S. rutilans*.—This is charming and extremely useful plant, and ought to become widely known and cultivated. The habit of growth is neat and bushy, and the leaves emit a delicious Apple-like perfume, and its pretty magenta coloured flowers are produced at all times of the year, as after the central flower spike has faded flowering side shoots are produced in great profusion, especially in the case of old plants. For this reason a few old plants should always be kept for supplying cut flowers throughout the year, and other cuttings rooted at intervals from March to August, so as to produce plants suitable for decorative work during the autumn months, when after flowering the majority of them can be thrown away.

*S. Betheli*.—Rose, shaded white. This produces flowers of a lovely colour during September and October.

*S. dulcis*.—An extremely fine scarlet variety, producing flowers in December and January.

*S. gesneræflora* is one of the best known *Salvias*, producing its showy scarlet flowers in great abundance during March and April. The leaves of this variety are apt to turn rusty if subjected to dry atmospheric conditions.

The best time to insert the principal cuttings of all varieties of *Salvias* is during April and May.—H. DUNKIN.

## GATHERING, PACKING, AND STORING FRUIT.

THE gathering of the past, with its picturesque and time-honoured surroundings, will soon disappear with the advance of scientific practice, and the scaling ladder, the shaking process, and the pole to settle with survivors will soon be things of the past. In place of the ladder against the tree, a ladder with a wide base and a wide spreading back to make it self-supporting will save the bruising of the boughs. The hand-picking of all the fruit will save the trees and fruit buds from destruction, and the hand basket instead of the sack will save the fruit itself from irreparable damage. The modern plantation, with its low standards and bush trees, indeed brings the fruit much more within the reach of the operator, which is a great advantage in gathering, as well as in all other operations connected with the cultivation and treatment.

Apples of the early varieties are gathered from the trees and sent direct to market, and it is important to gather them as early as possible. Many indeed may be gathered even before they are ripe, as allowance has to be made for the time that must elapse between the gathering and the consumption of the fruit, and many of the early varieties, such as Mr. Gladstone and Early Joanet, ripen very quickly after gathering, and last but a few days in a fit condition for use. Even some of the later and midseason varieties may be gathered before they are ripe in cases where the crop is short and prices are high early in the season. It will then pay the cultivator to gather some varieties even before they have attained their full size. Warner's King and Professor are two varieties that will often pay for gathering in this way. In gathering the bulk of the fruit, however, for home consumption or storing it is needful to allow them to remain on the trees until fully matured. A general fault perhaps is to gather them too early. The result of this is that the fruit shrinks, the rind shrivels, and the fruit has a

soft leathery and unattractive appearance, besides which the quality is greatly deteriorated through not having been properly supplied with the juices and saccharine matter, which during the later stages of development produce the full flavour of the perfect fruit.

Apples are mostly sent to market in sieves and half sieves, and should be at once graded into the various sizes before being placed in the sieves. To sort the fruit provide a tray made for the purpose, lined with thick felt to prevent bruising. The fruit is emptied from the gathering baskets upon the trays, and the sorter with the fruit in front draws it forward, and passes the various sizes to right and left into the different baskets, taking out all diseased and inferior fruits. Make it an imperative rule never to place two varieties in the same basket. The ordinary style of gathering and sending to market Apples from farm orchards reminds one of the lines in the "Chronicles of a Clay Farm" respecting the stirring of the clods:—

"Mingle, mingle, mingle,  
All ye who mingle may,  
Black spirits and white,  
Blue spirits and grey."

This is the best possible practice for the clods, but the worst for the Apples. The popularity of the foreign fruit sent to our markets has largely resulted from the care bestowed in this respect. A barrel of American Apples will be found of uniform size, and of one variety only. This is of the greatest importance to the housewife for cooking purposes. Some of the choicest specimens of dessert Apples will well pay for a little extra labour in packing, in order to present them to the customer in the most attractive form. Thus small boxes of neatly packed fruits of high quality will fetch a much higher price than if placed roughly in the ordinary basket, and we may also learn much from our French neighbours in this respect.

The storing of Apples for midseason and late use is a subject that should claim more attention than has hitherto been bestowed upon it; much fruit being placed upon the market for immediate consumption which is altogether unfit, and which would pay the grower well for storing until a later period. Many simple means may be found within reach of growers for this purpose. The first condition is that such building should be inaccessible to frost. Secondly, the temperature should be maintained as equable as possible, and not exposed to any sudden rise or fall. Thirdly, they should not be too dry, and some means of ventilation should be provided. A cave in a chalk bank, or a sandhill, makes an admirable Apple store, where all requirements are present with the exception of fitting up the needful shelves. Where this is impracticable it is sometimes the case that a barn or other farm building may be easily converted into a suitable store by the construction of an inside lining of match-boarding, the intermediate space being filled up with sawdust, straw or hay. Where, however, none of these means exist a simple store may be made by excavating the soil, and throwing up a bank on either side, roofing it over with rafters, and covering with a thick coating of thatch. A large quantity of fruit may be safely stored in a simple structure of this kind.

But where numbers of varieties have to be stored for private use, consisting of a collection of dessert and culinary fruit, a more commodious building should be arranged, with plenty of room for examining and drawing from the fruit as required, as well as provision for plenty of light. Arrangements, however, should be made to exclude the light completely when not required, as Apples keep better and retain their freshness more perfectly in the dark than in the light. But it will be necessary to provide double doors, double walls, and double windows, and the position chosen should be as sheltered as possible. Do not on any account introduce hot-water pipes into the Apple room, nor any means of artificial heat, but if properly constructed rely upon the double walls with the intervening air space to maintain the required temperature, and no anxiety need be felt if the temperature should fall several degrees below freezing point during a continued frost, but in such cases when the thaw sets in keep the room close for some time afterwards, and allow the temperature to gradually rise. Any sudden change of temperature will affect the fruit more than anything else. The shelves in such a house may be tolerably close together—say 1 foot from each other—as the fruit should be placed thinly upon them, not more than two layers one above the other. Where many shelves are placed one above the other at a considerable height it is a convenient plan to make the upper ones to slide out in sections, like drawers, for the convenience of placing or removing the fruit as required.

As to gathering, allow the late varieties to remain on the trees as long as possible, and they will not be damaged even by a few degrees of frost. Many people, alarmed by the falling of some of the fruit, gather their Apples much too early. If these fallen

fruits be carefully examined the bulk of them will be found to be maggoty and diseased, and even if some sound fruits are blown down it is better to spoil a few of these early in the season when fruit is plentiful than to spoil the bulk later in the season when fruit is scarce and valuable. Allow plenty of ventilation at the top of the room for a week or two after storing, for the escape of the perspiration, which takes place immediately after gathering. When this has ceased close the room, and subsequently only give air very occasionally.

The same remarks as to the time and mode of gathering Apples apply also to Pears. In the case of a few of the early varieties, such as Jargonelle, Beurré Goubault, &c., it is necessary to use them immediately after gathering, but a few of the second early may be gathered a few days previously; but they attain their best and fullest flavour by remaining on the trees until fully ripe. Where, however, they are particularly required a few days in advance of the time at which they will become naturally ripe, they may be accelerated by gathering and placing in a close box or drawer amongst some sweet, dry hay or Fern leaves, and keeping close for a few days. Colour and appearance may thus be produced quite equal to natural ripening, but the same fulness of flavour must not be expected.

Here, again, the choice dessert varieties are worthy of much more care in packing than they receive at present. For this small shallow boxes may be used, the fruit being packed closely in single layers, placing a small quantity of soft material at the bottom of the boxes, with a little also between each fruit, wedging each layer closely together; then fill up with some soft material on the top, so that the lid presses firmly on the fruit. This is important, in order to prevent the fruit from moving and rubbing each other. Boxes of proper dimensions can easily be obtained of packing-case makers at a moderate price. The best and cheapest packing material to use is wood wool, specially made for the purpose. It is light, elastic, clean, and made of wood which is free from smell.

Pears require when stored a warm, dry room in which to keep them, and they are very different to Apples in this respect. The cool and somewhat moist atmosphere required by Apples takes all the flavour out of Pears, whereas in a warm dry room the aroma, and also the rich saccharine flavour, are fully retained. A Pear store should be built where hot-water pipes can be introduced, or if that convenience is not attainable they may be stored in drawers or boxes in the dwelling house. In gathering for storing let the fruit hang as long as it is safe from frost, and be careful to gather when dry and without bruising. The same varieties should always be placed together in the store, and it will be found a great convenience to place them in the order of their ripening, with a distinct label to each, upon which should be noted the time when they will be in use. They require careful watching as they approach maturity, as in some cases the period in which they are in use is so short that it is needful to commence them the moment they are fit.

Plums may be often gathered before they are fully ripe. For instance, when the trees are heavily laden some fruit may be gathered when still green. This will relieve the trees and allow the remainder to swell and mature themselves, and the fruit makes a fair preserve. In packing Plums for market I would urge growers to take much more pains than at present is the case with the choice dessert fruit, in the way of packing them in small light boxes or baskets, putting them up in an attractive and tasty manner, so that they may be handed to the consumer without being rubbed and mauled about by the various hands through which they may pass. For dessert purposes the fruit must remain on the trees until fully ripe, and some varieties will hang on the tree for some time after they are ripe. But little can be done towards keeping Plums in store for dessert purposes after gathering; therefore, where succession of fruit is required it is essential that care be taken to prolong the season of use by planting varieties which will follow each other in ripening.

Soft fruits must be dealt with as they ripen, and here again it will pay to gather the best quality and pack in small punnets ready for retail purchasers, or in small square card boxes or square chip baskets. These are made to fit into larger packing cases, in which they are forwarded to the agent or salesman. A neighbour of mine has this season adopted an ingenious method of packing Strawberries and soft fruits in square paper pockets to hold 1 lb. each. The pockets are formed by folding the paper upon a square tin mould without a bottom. Twelve of these moulds fit exactly into a flat square box. After being placed in the box the fruit is tipped out of the gathering baskets into the open papers, and when they are filled the tin frames are drawn out. The upper edges of the paper are left about 1 inch above the top of the tin, and when the lid is placed on the paper is gently pressed down over

the fruit. When the box arrives at its destination each pocket with 1 lb. of fruit can be lifted out separately as required. When fruit is packed in some similar method to this, and is good and even in quality throughout, buyers soon find it out, and purchase accordingly. One great advantage in thus packing the fruit is that small purchasers get the fruit without its being repacked, and no handling is needed from the time it leaves the garden till its arrival at the consumers. Ever bear in mind that dessert fruit should be made to look as clean and attractive as possible. A little taste displayed in packing into boxes margined with ornamental paper often insures a ready sale for foreign fruit of even second-rate quality. The dressing and packing of choice fruit can easily be done at the homestead by women and children, who, with a little practice, soon do it quickly and well.—JOSEPH CHEAL, *Crawley*.

[Read at the Conference of the British Fruit Growers' Association, Edinburgh, September 10th, 1891.]

## HARDY FLOWER NOTES.

A SHORT absence from home has left so many arrears of work in both garden and greenhouse that but little leisure is left for writing. We are now, however, in the middle of September, and too soon winter's icy winds will be upon us. Yet no one could imagine this from the garden to-day. Nature has not yet assumed her russet robe, and although the Virginian Creeper is resplendent with its coat of many colours most things still wear a garb of vivid green. A few warm—almost tropically warm—days succeeded the heavy rains, and flowers have grown apace and glow with colour. Weeds, too, have flourished with a luxuriance which bids fair to conquer our utmost efforts to keep them in check. To-day was to have been devoted to a weeding campaign, but "the best laid schemes" have again been shattered by a return of rain. Meanwhile there is much to view in the garden. Annual Asters, albeit not hardy flowers, are none the less worthy of recognition of their beauty. Emerson says,

"Chide me not, laborious band,  
For the idle flowers I brought;  
Every Aster in my hand  
Goes home loaded with a thought."

Thus to the admirer of flowers not only every Aster but every flower seems "loaded with a thought," which will elevate the mind by its wonderful grace and design.

Gladioli, too, raise their gallant flowers with colours of the brightest hue. They have been doing well here this season, although during the dry weather they required frequent soakings of water. One is unwilling, however, even to appear to trench upon the ground of "D., Deal," who can discourse so well upon this and his other favourite flowers.

The Colchicums have again appeared as if some magical art inspired their movements. Yesterday there was a patch of dark earth, which looked as if no flower would pierce its surface until the spring came to call it from its "mother root." To-day the same spot is bright with blossom buds which in a few days will open fully to the advances of their favourite wooer—the sun. I grow about eighteen species and varieties of these Meadow Saffrons, and year after year as autumn comes round I watch eagerly for their appearance. This season they are somewhat late in peeping through the ground. Only a few varieties have as yet appeared, and among them one of the best of all, *C. speciosum rubrum*. This has fine large brightly coloured crimson purple flowers, which are of fine form, and in favourable soils and seasons would almost pass for a Tulip. *C. speciosum rubrum* failed to flower last year, and this season it is about a fortnight later than in 1889. This has been the case with nearly all my varieties, but they are only a week later than last year. The double forms are generally later of flowering than the single. I purpose this autumn and next spring (when the leaves appear) taking more copious notes of the various species and varieties, and to treat of them more fully than I have hitherto done in the Journal. None of the Croci are yet in flower, but they will follow shortly.

Stately as are the Gladioli, still more so are the Tritomas or Kniphofias. The tall species are noble ornaments of the garden, while the dwarfer *T. MacOwani* is one of the most interesting of our garden flowers. For long it looked as if none of these would flower this season, but they have made rapid progress of late. Strictly speaking, they are not usually herbaceous with me, generally retaining their foliage. I have given none any protection during the last winter, and the only one which suffered was *T. nobilis*, which was considerably damaged, but sprung afresh from the root. This will not flower with me this season. *T. MacOwani*, already mentioned, is very beautiful, being about 15 inches in height, with bright apricot coloured flowers. It

would be well if we could come to an agreement as to the name of this fine flower. *Kniphofia* seems to have, perhaps, the weight of authority in its favour; while *Tritoma* is decidedly more easily pronounced, by no means a slight advantage where we desire the scientific name to become familiar to the general public. *Kniphofia* was named after J. H. Kniphof, a Professor at Erfurt in the eighteenth century, and *Tritoma* was derived from *treis*, three, and *temno*, to cut, in allusion to the three sharp edges of the ends of the leaves. The popular names are surely numerous enough to satisfy the most ardent advocate of the use of these vague terms. Red Hot Poker, Flame Flower, Torch Lily have all been applied to the *Tritoma*, while, as if to add insult to injury, it has also been called the "Devil's Poker." My preference is for the name Torch Lily, the plant being one of the Lilyworts, and the form of the flower being more that of a "torch" than of a "poker" or a "flame."

What a fine effect would be made in the garden by a large clump of the white *Hyacinthus candicans* with a background of *Tritomas*. It is singular how slowly this *Hyacinth* makes its way. It attracts admiration from all by its stately yet graceful habit, and the purity of colour of its pendent bells. It might well be termed the "Autumn Snowdrop," were it not that it is not a Snowdrop, and that some day or other *Galanthus octobrensis* will be in clumps in our gardens, and we shall then have a true autumn Snowdrop. *H. candicans* or *Galtonia candicans* (which shall it be?) is so easily grown, so hardy, and so beautiful that it should have an honoured place in every garden in the land. It is readily raised from seed, which is freely produced. Equally fine in their way are the varieties of *Anemone japonica*, which are almost indispensable at this season of the year. They do not do so well on my light soil as I should like, and I purpose removing my plants to a specially prepared position, where with stronger soil and more moisture they may be finer and nearer their natural character.

What a shy flowering troublesome plant *Zauschneria californica* seems to be. I had expected that this hot dry summer would have caused it to flower with me; it will not do so, however, although Mr. James Davidson of Summerville, Dumfries, has it at present in flower. I have had it in the same position for some years now, but must give it a change and try once more. This is one of the plants which has not achieved the high position predicted on its introduction. It was to be a grand autumn bedder, and so forth. Even when it does flower it is by no means brilliant enough for bedding purposes. There is no fear of losing it when once planted, as it spreads so quickly that it soon encroaches on other plants. It should flower with me, and must if at all possible. The *Zauschneria* or Californian Fuchsia is a native of California, whence it was introduced from seeds sent by Hartweg in 1847. These seeds were collected near Santa Cruz. The generic name was given by Presl, in honour of M. Zauschner, a German. There is a superior form named *Z. c. splendens*.

The rock garden presents but little in flower at present. That ever-blooming plant, *Hutchinsia alpina*, is still in flower, producing its little heads of white flower here and there over a good sized plant. Another plant which is in flower for a long time at a stretch is *Arenaria cæspitosa*, the Turfy Sandwort. Although by no means so dwarf as *A. balearica*, it is yet dwarf enough and compact enough to please the most fastidious. It is of free growth, and will soon form a large mass of carpet-like light green foliage not more than half an inch in height, which early in the season is densely studded with tiny white flowers larger than those of the Balearic species, but almost as close to the plant as those of *Silene acaulis exscapa*. It commenced to flower in June, and even yet produces a considerable number of flowers. *A. cæspitosa* is a native of Switzerland, and was introduced in 1826. It is a far superior plant to such species as *A. graminifolia*, and as regards freedom and length of flowering is superior to *A. balearica*, although, so far as I have seen, it has not the power of creeping over stones, which renders the latter so useful and so interesting.

Close to the *Arenaria* is a good sized plant of *Margyricarpus setosus*, the Pearl-berry, one of the family of the *Sanguisorbaceæ*, receiving its rather unwieldy name from *margaron*, a pearl, and *karpos* a seed vessel, referring to the beautiful pearl-like berries produced on the plant. These are now in perfection, and for these and the deep green prickly looking foliage this trailing evergreen shrub-like plant is grown. The flowers are produced in the axils of the leaves, and are almost unobservable, while the berries are about the size of a small pea, and are of a beautiful waxy white colour. This *Margyricarpus* is said to like peat, but is doing exceedingly well in very sandy loam near the base of the rockery, where it is fully exposed to the sun in summer. It was introduced from Peru in 1829, and was for years grown as a stove plant—a mode of treatment quite in accordance with its probable requirements, but which was quite unnecessary, as has also been experienced

with several other plants from that part of the South American continent. The *Margyricarpus* has proved perfectly hardy in many parts of this country, and is possessed of so much distinctness of character that it should find a place in almost every rock garden. It grows only an inch or two in height, but will extend its branches a foot or more. As usual, space fails me, and with the garden gay with Sunflowers, *Oenotheras*, perennial Asters, *Phloxes*, a few Sedums, and dwarf Campanulas, and with Tiger Lilies with their spotted fiery blooms, we need not say that September cannot draw from her storehouse of flowers subjects worthy of our highest praise.—S. ARNOTT.

## INSECTS OF THE FLOWER GARDEN.

(Continued from page 114)

It is about this time of the year that I have had brought to me from gardens an insect akin to the sawflies last noticed—one which awakens surprise or curiosity, sometimes alarm. Occasionally it has been taken buzzing sonorously in a conservatory, or else it may have been caught reposing upon a wall during the day. This is the horn-tailed sawfly, of which there are two species. The larger of these, from its appearance, is generally supposed to be a kind of hornet; but insects of this genus are neither able to sting nor to bite. The explanation of their presence in gardens is, that they are now and then lodged while chrysalids within the wood used for sheds or summer houses, and subsequently emerge; also they may come from some shrubbery near where Firs are growing. As flies they possibly sip honey from flowers, since they have tongues. We are justified in killing them, their wood-boring propensities during the larval state ranking them amongst destructive insects. But the late Mr. Waterton maintained that these flies only deposited eggs upon timber that had begun to decay. These are laid by an ovipositor, which is formidable looking, and which has suggested that the female is a stinging insect. It has not the saw-like blade of the *Tenthredos*, but is armed with a fringe of teeth at the tip, and has ridges along the sides. This ovipositor has the strength and elasticity of steel, its movements being regulated by powerful muscles. Like most feeders upon wood, the larvæ of these wood borers grow slowly. They have a scaly head, with powerful jaws and tiny feet. We see *Sirex juvencus* the most frequently, blue and black chiefly, but with red legs and abdomen. The larger species is *S. gigas*, having a black head and thorax, the abdomen being yellow and black, the wings yellowish. Some think these flies are not true natives of Britain.

We come now to a remarkable group of flies which are known better by their performances than by their own personality, and which are popularly called gall flies. Destructive insects we could not call them; rarely do they imperil the life of a plant, and seldom do they render it unhealthy, but their proceedings make many plants less beautiful than they would otherwise be, as the larvæ or grubs disfigure and contort flowers, leaves and shoots; sometimes, also, they occur in numbers upon the roots of shrubs or trees. The flower garden is not exempt from the visits of gall flies any more than the orchards, woods or fields, and though they appear to be mere idlers amongst the blossoms, they combine business with pleasure. So numerous are the flies of the garden that even the entomologist cannot but overlook the gall flies sometimes amongst the multitude; still, if the gardener could always pick them out there would be little advantage in killing them. All the galls we notice, however, are not attributable to these four-winged flies of the hymenopterous order. Many galls are the work of the small two-winged flies known as the "gall gnats." Other galls are the abodes of some species of the aphid tribe, and galls there are, a few, attributable to caterpillars or to beetle grubs. Galls are very familiar objects. Conspicuous are the round galls of the Oak, the Currant-like galls that are strangely fastened together in strings, and most persons have seen the mossy gall that occurs upon the wild Rose and the Sweetbriar, a curious object, formerly credited with notable medicinal virtues.

In the flower garden the little rounded galls now and then to be seen on Rose leaves, and which may be found on several herbaceous plants, offer an illustration of the work of these insects. Common also are some galls that take the form of small ridges or protuberances noticeable on Composite plants or upon species of the Cruciferous tribe. A peculiarity of these gall insects is that they often take some natural feature of a plant and somewhat exaggerate it. Thus, for instance, in a hairy species galls are produced which resemble the hairs, but are larger, or the fly attacks shoots that are swelled naturally, and makes them bigger. Our present knowledge of these gall flies is not satisfactory, though from the gardener's point of view this does not matter much, for they are not enemies against which remedial or preventive measures can be taken. Galled leaves or twigs might, if removed, be burnt

or buried to prevent the emergence of the flies, but this measure may not be of any advantage, for it is a singular fact, true of galls both in gardens and on wild plants, that when kept quantities of them produce not the gall-maker (or the presumed one), but a parasite which has preyed upon the original tenant, whose skin, perhaps, remains as a relic. So common is it to discover intruders in galls that a name "inquiline" has been brought into use, meaning the occupier or parasite of a gall.

Nor does the matter stop here. The first inquiline is found sometimes to be followed by a second—that is to say, the grub which has killed the true grub of the gall falls itself a victim to the grub of another species of fly. However, in spite of all this destruction of one species by another many of the gall flies must emerge in due course, or the galls would cease to appear upon our plants. Some of the parasites produce four-winged flies and some two-winged.

A few descriptive particulars concerning the gall flies of our gardens generally should be appended. The majority of them are of minute size, and of dull colours; they are mostly summer insects, passing the winter in the larval or pupal state. Probably the most notable peculiarity in their appearance, distinguishing them from other flies, is the thick egg-shaped abdomen joined to the thorax by a short stalk. The thorax is oval, the head small, furnished with slender antennæ (which are much vibrated by the females when seeking places for their eggs), the wings narrow, occasionally very long. In many species the male flies are rarely seen; this has given rise to the supposition that the female may be able, as in the aphid tribe, to continue the succession of broods without the assistance of the opposite sex. The ovipositor is generally short, but the remarkably irritating effect produced upon vegetation by the punctures introducing the eggs, leads us to think that some poisonous fluid is thrown into the wound with the egg. If the gardener feels inclined to be vexed when he sees his plants or shrubs disfigured with, or contorted by galls, I would ask him to remember what he and his fellow men owe to one well-known species of gall we obtain from the East.

An exceedingly curious family of small insects links the gall flies with the ichneumons. They are parasitic in their nature, and are believed to attack occasionally the field cockroach. If they also make our domestic cockroach their victim, they are useful flies; for, as I have pointed out, this household pest visits the flower garden during the summer, often escaping notice from its nocturnal habits. These flies of the *Evania* genus have a very bulky thorax and a tiny abdomen, quite contrary to the usual proportion, but long legs. Their appearance seems to indicate that they follow their victims by running, and some think they were brought over with exotic plants.—ENTOMOLOGIST.

CATTELEYA LABIATA VERA.

QUITE an important gathering of horticulturists took place on Friday, September 18th, in Messrs. Protheroe & Morris's Sale Rooms, Cheapside, and very seldom do so many eager buyers assemble to compete for the possession of imported plants. For several hours the rooms were crowded, it was evident that the Orchid interest was as lively as ever, and a brisk contest resulted in substantial prices. The cause of the excitement was a consignment of fine healthy plants of the true old autumn flowering *Cattleya labiata*, re-introduced by Messrs. F. Sander & Co. of St. Albans, and

it was not surprising that a plant which had been so rare in cultivation should have been in such great demand. Few Orchids have so interesting a history connected with it as the original *Cattleya labiata*, but it is extremely probable that we shall never hear the whole of the facts connected with this beautiful Orchid, for many of the links in the chain of evidence have been lost, and others can only be supplied by those who are not likely to do so at present.

FIG. 49.—CYPRIPEDIUM ANTIGONÆ.

It is certain, however, that for many years every effort made to discover the native habitat of this *Cattleya* failed completely; collectors were repeatedly dispatched by the leading firms, and thousands of miles have been explored without the slightest success. It would be impossible to calculate how much has been expended upon these fruitless searches, and it had gradually become a fixed idea that the original *Cattleya labiata* was really extinct. Continued perseverance has, however, been rewarded, and cultivators have at last an opportunity of possessing one of the most historically interesting, and at the same time one of the most beautiful Orchids.

It is remarkable that while the other forms of the *C. labiata* group are widely spread in the Brazils, and have been introduced in quantities, the old form, which is especially valued for its autumn flowering characters, and the diversity it presents in colouring, should be restricted to so comparatively small an area. Fortunately the supply seems to be fairly large now it is found, and all danger of the plant becoming extinct in cultivation will soon be removed.

In reference to the history of this *Cattleya*, Mr. F. Sander has obliged me with the following note:—

"It was discovered in 1817 by Mr. William Swainson in the Brazils. He sent plants to London, and one flowered in 1818 with Mr. Cattley of Barnet, after whom Lindley named the genus. The elder Hooker also had a piece from Mr. Cattley, and with him it flowered in 1821. There were I should think some two or three dozen plants sent at first. Mrs. Horsfall, Liverpool, received some from the captains of vessels trading with the Brazils about 1830, and about 1845 a small lot arrived in France. There the matter rested until about 1882, when a small consignment came to the London Zoological Gardens, and passed into the hands of Mr. B. S. Williams of Holloway. Again, two years ago, a small consignment arrived in France. For Lord Hume's plant I offered 200 guineas, and was refused; it is a large specimen, and Mr. Turnbull grew it for fifty years. I should think the highest price paid for a plant is 110 guineas, but such figures as 50 guineas and 75 guineas have often been paid. Of course the plants sold were always small, i.e., with few pseudo-bulbs, as its

rarity induced people to cut it up. I should think twenty plants the outside of cultivated plants previous to the recent importation."

With regard to the plants introduced through the Zoological Gardens Mr. H. Williams gives these particulars. "*Cattleya labiata* vera was re-introduced by us from Brazil through Mr. Bartlett of the Zoological Gardens in 1882, and we purchased from him in 1883 five plants, one of which was in flower, the remaining plants subsequently flowering with us. He received them from some friends of his who were engaged upon railway work in Brazil, and by the time the first plant had flowered had left the part where the plants came from; you must understand these people know nothing about Orchids, and they were sent home by chance, not even Mr. Bartlett suspecting what they were. We made all the inquiries possible to find the whereabouts of these plants in Brazil but without avail."

Such are the principal facts respecting the introduction of *Cattleya labiata* vera into this country, and though of course it cannot be expected that the recent importers will tell us where they find the plants, yet at some time we may hear a still more entertaining history.

#### TWO BEAUTIFUL HYBRID CYPRIPEDIUMS.

At the meeting of the Royal Horticultural Society on Tuesday last, Baron Schröder was awarded a first-class certificate for *Cypripedium* Antigone, a hybrid raised by Messrs. J. Veitch & Sons, Chelsea, to whom an award of merit was granted for the plant some months ago. The flower shown on this occasion (fig. 49) displayed so great an improvement in all its characters that the higher award was accorded. The whole flower has a soft pleasing appearance quite distinct from all others; the petals and dorsal sepal very broad, white suffused with a soft rosy tint; the lip being rounded, and of a delicate blush white, deeper in the upper portion.

The other hybrid, which was well exhibited on the same occasion by the raisers, Messrs. F. Sander & Co., St. Albans, was *C. hybridum* Pollettianum (fig. 50). It is a hybrid from *C. calophyllum* crossed with *C. ænanthum* superbum, and therefore possessing a most interesting parentage, both the forms named being themselves hybrids, *C. calophyllum* from *C. barbatum* and *C. venustum*, and *C. ænanthum* superbum from *C. insigne* Maulei and *C. Harrisianum*. *C. ænanthum* superbum is generally regarded as one of the finest hybrids ever produced; but some may probably consider the new comer as, in some respects, an improvement upon that in richness of colouring and general appearance. The dorsal sepal is broad, rounded, margined with white, rich dark crimson, with chocolate spots. The petals are very dark, with three dark dots on the upper margin, the lower half at the base being of a peculiar transparent green with a few dots; the lip is very dark, and the whole surface of the flower has a polished shining appearance that in a bright light is very effective. It is undoubtedly a grand acquisition, and was awarded a first-class certificate last year.—L. CASTLE.

#### SEASONABLE HINTS ON FLORISTS' FLOWERS.

**AURICULAS.**—I have not had (indeed, never have), the opportunity of seeing much of other growers' Auriculas, the only collection, in fact, being that of Miss Woodhead's, of which I have already written in the Journal; indeed, as far as I know, mine is the only one in the county, and therefore my observations refer to that alone; but from what I hear of others, and from my own past experience, I imagine that it is a fair sample of the general condition of the flowers, for during a cold and wet season such as this, the Auricula is, I think, one of the few flowers that are benefited. They do not get so dry, and do not require such constant watering, and the absence of hot sunlight seems rather to suit them. They require at this season of the year but little attention, keeping them free from aphid and picking off the dead leaves being the chief things necessary. Of aphid I have had very little anywhere in my garden this year, and have had consequently but little trouble with them. There is also a green caterpillar which sometimes gets into the heart, and before you are aware of its presence does much

mischievous. This had better be looked for and destroyed. The pots should be carefully looked over and handled to see if they have got under any drip and so become soddened, for this is fatal to them. When the potting of the plants took place in May there were some offsets which had not rooted, and consequently were left on the plants, as I have found it very difficult to get them to grow unless they have a small portion of roots. On examining the plants now it will be found probably that they have emitted some roots, and that they can be taken off the parent plants. The best plan is to remove the earth and then break the offset off with the finger and thumb, tearing the main stem as little as possible. When taken off they should be labelled and potted. When more than one of a kind has to be potted it is well to put them round the edge of a 60-pot which has been half filled with drainage and then with the ordinary Auricula compost. Where the offset is a good size it may be potted singly in a small thumb. In the latter case they will make perhaps more rapid progress, as they can be shifted without disturbing the roots. After being potted they should be kept close for a few days. This is a good time to add fresh varieties to collections; such selfs as Heroine, Mrs. Potts, and Black Bess, and such edged flowers as F. D. Horner, George Rudd, Mabel, and Mrs. Dodwell will be found useful additions.

**CARNATIONS AND PICOTÉES.**—This is the most disastrous season I recollect for many years. There will be with many great difficulties in keeping up their collections, and where, as in my case, severe losses have been experienced it will be a good time now to look out for plants to supply their place. All layers should be carefully taken off when rooted, which will be, I think, late this year, for the weather has been cold and ungenial. With me the grass is stunted, and I have determined to cease growing the plants in pots, and to return to what was the universal custom in my boyish days—growing them in beds. I have no doubt many will consider this a proof of second childhood, but be it so. Such a shock as this

FIG. 50.—CYPRIPEDIUM HYBRIDUM POLLETTIANUM.

present season has given is not easily got over and I have not the hopefulness of youth now.

**GLADIOLI.**—Here again I have had a bitter disappointment. For the first time for upwards of twenty years I have been unable to put in an appearance at the Crystal Palace, owing to the extreme lateness of the season with me. I have fine spikes coming on, but

even some of the earliest bloomers—Atlas, Baroness Burdett Coutts, Ondine, &c., are hardly showing colour. There is but little to be done with them saving putting sticks to them so as to prevent their being loosened in the ground. We have had such a quantity of rain during July and August that I stand in some doubt how the corms will fare. If I find that towards the end of the month the weather becomes cold and adverse to the opening of the flowers I shall cut off the spikes, so as to give the plants a better chance to mature.

**PANSIES.**—These should be now potted, whether cuttings have been made or the roots planted out. This latter is my method as being easier, and I manage to get very good blooms and nice plants. In taking them up I divide the plants, cut off the long shoots, and then place two in a pot to be potted singly in the spring. Of course this is contrary to all propriety, but where many things have to be done at once some are apt to be scamped, and I suppose I must lie under the imputation of scamping my Pansies. I find it is of very little use to grow them in beds, for they do not thrive here as they do in the north of England and in Scotland. In potting them I use loam and leaf mould with very little manure, giving them richer material in the spring.

**ROSES.**—I have never known a season when the growth has been better or the plants freer from mildew and aphids. The former is, I am convinced, more abundant in hot and dry summers than in a moist and cold one like the present. The presence or absence of the latter is unaccountable. The rosery should now be kept, as always, clear of weeds, and I think it is now a good plan to cut clean out the old flowering wood of this year, and allow full light and air into the plants, thus securing ripeness of wood to the vigorous young shoots of the present year, which are to be the *spes gregis* for next season. I do not shorten these now, but if they are very long stake them, and shorten them later on in the autumn, for many of them will have good flowers which it is a pity to lose, as they in no wise injure the shoots. There are, I fear, some very considerable gaps in Rose beds this season, and amateurs will be considering how they may be filled up. The really good varieties are few, but for them and the older sorts also I should imagine higher prices will have to be paid. Should the weather hold fine for the present month we may expect to have a good show of late blooms.

**RANUNCULUS.**—Although nothing can be done at present in the cultivation of these beautiful flowers, I mention them because at this time of the year bulb catalogues from the Dutch growers are pouring in, and it is a good time to commence making a collection. As in the case of Tulips, they are not nearly so particular as to the quality of their flowers as we are. The best plan will be, I think, to get a collection of named sorts, and then eliminate from them when they flower such as are second-rate and increase the stock of the good ones. This I was obliged to do with Tulips as well as these; and, indeed, in the case of the former it will be far better to begin at once with English rectified ones than to encumber oneself with the Dutch kinds, which are mostly foul at the base, and many of them parti-coloured.—D., Deal.

#### SHOWING SPRING SOWN ONIONS.

MR. POWNALL having opened the above subject, which I understand was first discussed at Shrewsbury, I venture to give my opinion, which is in favour of a continuance of the present system. If the clause "to be sown in the open" were added to the schedule as suggested by your correspondent, unless the competition was localised in this and northern counties, gardeners would be placed at a disadvantage, as it is only by sowing the seed early and forwarding the plants under glass that they can cope successfully with exhibitors from the more favourable southern counties. Mr. Pownall's desire is laudable, but the remedy I would suggest is that those who see their productions set aside should follow the example of their more successful and elastic-minded brothers. Exhibitors of vegetables have generally a command of glass, and do not usually confine themselves to Onions alone, and if they treat Cauliflower, Celery, Leeks, and many other vegetables similarly they ought not to begrudge the time and space which Onions require.

I am not an exhibitor, but early next year we intend sowing a few boxes of Onions, and the bulbs will remain in them until planted out. Though they may not make exhibition specimens we think they will repay the trouble, but they will go first to the kitchen. We shall not neglect to sow in the open for later use, but shall not bind ourselves to wait for the calendarial spring.—S. BACKHOUSE, Shrewsbury.

REGARDING the question of how spring Onions should be shown as referred to by Mr. Pownall (page 239), I would ask why cannot those who have hitherto been content with sowing the seed out of doors in the ordinary way advance a step and, like others, sow the seed under glass? Surely more credit is due to the man who cultivates the present year's bulbs, each weighing say 1½ lb., or perhaps 2 lbs., than there is to the man who is content with those which will not bring down the scales at more than half the weight, and generally not that much in the

ordinary method of growing them. Visitors go to shows to see produce a little out of the ordinary quality. One dish of Rousham Park Onions of the weight of those quoted would be more attractive than a bushel of the ordinary. Where would be the interest in seeing an array of bulbs grown under the conditions suggested by Mr. Pownall?—E. MOLYNEUX.

**ROYAL HORTICULTURAL SOCIETY.**—An exhibition of Asters, Sunflowers, and Conifers will be held in the Chiswick Gardens on October 6th, 7th, and 8th, 1891. Fellows of the Society are particularly invited to assist in making the Exhibition a great success, either by contributing specimens of Asters, *i.e.*, Michaelmas Daisies, Sunflowers, or Conifers themselves, or by inducing others to do so. On October 6th a Conference will be held at 2 P.M. on Asters (Michaelmas Daisies) and Perennial Sunflowers, and the following papers will be read:—Opening address, by Mr. J. G. Baker, F.R.S., &c., Chairman; "The Genus Aster," by Professor G. L. Goodale, Director of the Botanic Gardens, Harvard University, U.S.A.; "Michaelmas Daisies," by the Rev. C. Wolley-Dod, M.A.; "Perennial Sunflowers," by Mr. D. Dewar; "Culture of Sunflowers," by Mr. E. H. Jenkins. On October 7th a Conference will be held at 2 P.M., on Cone-bearing Trees and Shrubs, and the papers to be read are as follows:—Opening address on the Special Features of Interest in the Order of Conifers, by Dr. Maxwell T. Masters, F.R.S., &c., Chairman; "Japanese, Chinese, and Californian Conifers," by Mr. H. J. Veitch, F.L.S., &c.; "Conifers as Specimen Trees and for Landscape Gardening," by Mr. George Nicholson, A.L.S.; "Conifers for Timber and in Plantations," by Mr. A. D. Webster; "The Decorative Character of Conifers," by Mr. Edmund J. Baillie, F.L.S.; "Conifers at Bickton, Devon," by the Hon. Mark Rolle; "Conifers at Dropmore," by Mr. Charles Herrin. On October 8th the Conifer Conference will be resumed at 2 P.M., the papers to be read being Opening Address, by Professor Bayley Balfour, M.A., F.R.S., &c., Chairman; "The Value in the British Islands of Introduced Conifers," by Mr. Malcolm Dunn, F.R.H.S.; "The Quality of Coniferous Timber as affected by Sylvicultural Treatment," by Dr. William Somerville; "The Timber of Exotic Conifers Grown in Scotland: its Uses and Comparative Value," by Mr. D. F. Mackenzie; "Fungoid and other Diseases of Conifers," by Professor Marshall Ward, M.A., F.L.S.; "Insects Injurious to Conifers," by Mr. W. F. H. Blandford, M.A. In addition to the prizes offered in the schedule, awards will also be made to coniferous plants plunged in banks or beds of cocoa-nut fibre.

— **ROYAL PRESENTATION TO MR. T. JONES.**—We learn that the Queen has presented a silver tea set to Mr. T. Jones, the recent head gardener at Frogmore, on his retirement from Her Majesty's service.

— **WITH much regret we have to announce the death of M. JEAN B. J. VAN VOLXEM OF BRUSSELS**, which took place on September 14th, in his sixty-second year. M. Van Volxem had travelled widely in Asia and America, and collected many plants, of which *Tacsonia Van Volxemi* is perhaps the best known. He also formed an arboretum near Vilvorde, which contained an interesting collection of trees and shrubs. M. Van Volxem had a large circle of friends, and was highly respected amongst Belgian horticulturists.

— **FRUIT CULTURE.**—Towards the Mansion House Fund which the Lord Mayor, in conjunction with the Fruiterers' Company, recently opened for the promotion and encouragement of fruit culture in this country, the following among other sums have been received:—Messrs. Crosse & Blackwell (second donation), £52 10s.; Mr. John Corbett, M.P.; £21; Sir Humphrey de Trafford, £10; Mr. Hope Edwardes, £5; the Duke of Newcastle, £10; Mr. Chaplin, M.P. (Minister for Agriculture), £10; the Misses Fleming, £10; and the Marquis of Bristol, £10. According to ancient custom the Fruiterers' Company will, on October 7th, present to the Lord Mayor specimens of English-grown fruit. The origin of this practice is that the Lord Mayor's meter was formerly entitled to receive a portion or sample from every load of fruit coming into the City, which practice became the occasion of much controversy between the collector and the persons bringing in the fruit. The dispute

was eventually arranged by the Company's annual presentation of samples of fruit to the Lord Mayor for the time being. In return the Lord Mayor invites the Court of the Company to a banquet at the Mansion House, which this year will take place on the same day as the presentation ceremony.

— GARDENING APPOINTMENTS.—Mr. James Rogers, recently foreman at Nash Court, Faversham, has been appointed head gardener to P. C. Hardwick, Esq., The Grange, Bradford-on-Avon, Wilts. Mr. F. Buckland, late of Sefton Park, Slough, Bucks, has been appointed head gardener to Sir George Elliott, Bart., M.P., The Friars, Newport, Monmouthshire.

— WEATHER AT LIVERPOOL.—We are experiencing another unwelcome change in the weather. During last week we had quite a variety. Saturday was a beautiful day, Sunday rainy and gloomy, whilst at night the rain came down in torrents, with a strong wind from the N.W. To-day (Monday) is the same, and much fruit is blown from the trees. The temperature is much lower.—R. P. R.

— BOCCONIA CORDATA, commonly called the Plume Poppy, is a plant not nearly so much grown as its merits deserve. Not only is it very showy when growing at the back of an herbaceous border, where it is so useful for supplying cut flowers in abundance, but for growing on the grass in isolated places, by the side of water, amongst dwarf Rhododendrons, Hicaths, or Azaleas. It tends to brighten up and make attractive such positions at times when they would otherwise be dull. We have it growing in masses 6 feet across. A capital effect is produced in this way, especially as the background is one of evergreens. As to propagation that is a simple matter, every bit of root will throw up a growth, which in a year's time will form a strong clump.—E.

— VALUABLE as are all the ANNUAL CHRYSANTHEMUMS for bedding and cutting purposes, there is none more so than the *Chrysanthemum inodorum plenissimum*. The seed may be sown in pans or boxes at the end of March or the beginning of April, and when large enough pricked out 3 or 4 inches apart in good soil, finally to be transferred to the beds or borders. The flowers are pure white and equal to any Pompon Chrysanthemum. For bouquets and other decorative work, where white flowers are in demand, this plant is most suitable. Outside at the present time the plants are covered with bloom, and a pleasing sight they make. I write in its praise, after seeing a delightful bed of it at Roby Mount, where Mr. Eaton, the gardener, intends to grow it in greater abundance another season, so useful does he find it. Mr. Osborne, the gardener at Aymestry Court, Woolton, uses it most extensively.—R. P. R.

— THE VINTAGE PROSPECTS.—The fine weather that has prevailed during the present month has greatly modified the gloomy forebodings that were entertained in regard to the coming vintage. In France and Germany the temperature throughout the spring and summer months was so adverse that the Vines fell into an unusually backward condition, and fears were expressed that the vintage would be a complete failure. Fortunately, however, September has brought the necessary warmth, and the ripening of the Grapes is now rapidly proceeding. Even as it is, says the *Wine Trade Review*, the gathering will be delayed considerably beyond the customary period, but, in France at all events, there is hope that the crop will prove to be fairly satisfactory. The champagne country appears to have suffered in a peculiar degree from the inclemency of the weather. At the close of August and at the beginning of the present month there were heavy storms of rain and hail, which did great damage in certain districts, and, though there has been an improvement since, it is probable that the crop will be lacking both in quality and quantity. The Charentes have recovered better, and a Cognac correspondent says that if the favourable conditions continue, there is likely to be a good yield of wine. With regard to the claret vintage, a Bordeaux correspondent states that irregularities are observed in the ripening of the Grapes, so that when some are cut others will have to be left to further mature; but there is reason for believing that a fairly heavy crop will be obtained. In Burgundy, on the other hand, a diminished yield is expected. The outlook in Germany is discouraging in every sense, for there are indications that there will be a lack of quality as well as quantity. From Portugal it is stated that the vineyards show considerable inequalities, owing to more or less harm having been done in various districts by drought and mildew; but it is probable that the yield as a whole will be heavier than last year's. In Spain, also, there is a hopeful feeling prevalent.

— WE understand that the annual dinner of the UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY will take place on October 18th next at the Cannon Street Hotel, Mr. George Dickson of Chester presiding.

— JAPANESE POPPIES.—Those who have not yet given these delightful flowers a trial should make a point of growing a good number next year, as I feel sure they only require to be known to enable them to be extensively cultivated. I have always entertained a great liking for Shirley Poppies, but in my opinion that type will be rapidly superseded by the Japanese kinds, the petals of which are deeply lacinated, and have the appearance of tissue paper, with the edges clipped into narrow shreds. The flowers are white in the centre, each petal gradually shading to pink and rose from the centre to the outer edge. The Mikado is a double form, with the same shades of colour. The plants grow quickly and moderately strong, and are decided acquisitions for supplying beautiful cut flowers.

— THAT beautiful Privet, *LIGUSTRUM LUCIDUM*, is a capital plant for mixed shrubberies, as it flowers at a time of the year when flowering trees and shrubs are not plentiful; and being only a moderately strong grower, it is well adapted for planting in the fore ground. Its white paniculated flowers (which are now fast opening) look exceedingly well as they rear their heads above the green shining foliage with which the bushes are plentifully clothed. The flowers are also useful for cutting.—H. D.

— DAFFODIL PRIZES FOR 1892.—Messrs. Barr & Son, 12 and 13, King Street, Covent Garden, London, have presented the following prizes to the Royal Horticultural Society for cut Daffodil flowers, to be competed for at the Society's fortnightly meetings, to be held in the Drill Hall, James Street, Victoria Street, Westminster, London, during 1892. The number of classes and the dates of the meetings will be published in the Society's prize schedule for 1892. February.—Collection of forced Daffodils, *Polyanthus Narcissi* excluded, open to all classes of exhibitors; large silver medal. Best seedling Daffodil, not yet in commerce, raised in England, Scotland, or Ireland, and shown during the season, accompanied by the history of its origin, not a *Polyanthus Narcissus*, open; large silver-gilt medal. This prize may be competed for at any of the Daffodil meetings, and the award will be given to the best specimen which has been exhibited during the season. March.—Collection of forced Daffodils, *Polyanthus Narcissi* excluded, open; large silver medal. Collection of Daffodils, *Polyanthus Narcissi* excluded, open; first prize, large silver medal; second prize, small silver medal; third prize, large bronze medal; fourth prize, small bronze medal. The same prizes will be offered in April and May.

— STRAWBERRIES IN HAMPSHIRE.—As showing to what extent the culture of Strawberries has developed in this neighbourhood and what a source of profit the fruit is to the railway companies alone, I may mention that from Swanwick Station, which is a very small one on the new Fareham and Netley line, no less a weight than 645 tons 19 cwt. was sent in three weeks, the charge for carriage being £1472 19s. 3d. The bulk of the Strawberries went to Covent Garden. The increase in value was £409 9s. 8d. over that of last year, and the weight showed an increase of 86 tons 12 cwt., or in the number of packages 16,309, the total number of those for the year being 61,222. The large number of packages is owing to the increase in sending so many Strawberries away in separate baskets, each containing one gallon. This shows what an increase in labour Strawberries make at one station only, but it does not by any means represent what the neighbourhood of in, say, an eight-miles area produces in Strawberries. In addition to the above, it is not an uncommon thing to send away 50 tons from Botley alone in one day, this being a station on the Portsmouth and Southampton line.—M.

— NORWICH DAHLIA SHOW.—At the Norwich Dahlia Show held on the 10th inst. the awards in the classes for thirty-six, eighteen and twelve Show and Fancy, distinct, were in each case—first, Messrs. Rawlings of Romford; second, Rev. Charles Fellowes, Shottesham Rectory; and third, Messrs. Daniels Bros.; whereas in the six classes for Cactus, Pompons and singles, Messrs. Daniels took five firsts and one second; this firm also carried off all the first prizes for Pelargoniums. Asters and Marigolds would have been a disgrace to a village show of the third class. The Rev. Page Roberts had some good Roses; for twelve bunches, distinct (six in each), he showed nothing but Teas, and was easily first again for twelve distinct singles. His stand of six hardy cut flowers was beautifully set up, and in the opinion of many should

have been placed first instead of second. Vegetables were good all through, Potatoes especially. Messrs. Daniels had a splendid collection backed by a magnificent row of *Lilium auratum*s. Fruit was well shown. Mr. Green, nurseryman, East Dereham, exhibited a quantity of Pompon and Decorative Dahlias, and his large stand was tastefully and most effectively laid out, adding much to the generally interesting features of the Show. The weather was lovely. All the arrangements were admirably carried out by the energetic Secretary, Mr. A. Upstone, supported as he was by an enthusiastic and working committee.—J. A. W.

FIG. 51.—MR. R. LINDSAY.

— ELECTROCULTURE. — Experiments have been carried out in France, in Lot-et-Garonne, by M. Barat, upon the application of electricity to the culture of Potatoes, Tomatoes and Hemp. A row of Hemp subjected to the influence of the electric current produced a row of stalks 18 inches higher than those not electrified in the same time. A kilogramme (2.2 lbs.) of Potatoes planted in a path of the current produced 21 kilogrammes of very large and healthy tubers, while the unelectrified patches only gave 12½ kilogrammes of medium size. The electrified Tomatoes also became ripe some eight days before the others. A curious fact has been remarked by M. Barat in his experiments. If a quantity of manure is near the positive pole, the constituent parts of this manure are transported towards the negative pole, and their effects make themselves felt around a distance of some yards. This would seem to be a fresh proof of the opinion long advanced upon the part played by electricity in the growth of plants, an opinion also adopted by M. Speenew, who has given some attention to these phenomena; this is, that the action of the electric current upon plants seems to consist in the more active dissolution of the organic principles existing in the soil, which are thus brought within the reach of the roots.—(*Electrical Engineer.*)

— THE LATE MR. WILLIAM HOLMES.—Soon after the death of Mr. Holmes a committee was formed in Hackney to raise a fund for providing a local memorial of his worth and the esteem in which he was so generally held. With the concurrence of his widow this took the form of a handsome headstone in white marble continued round the grave to a suitable height so as to admit of the surface being planted with flowers. The upper portion of the headstone is finely sculptured, showing clasped hands with the sentence below, "We shall meet again," having representations of Chrysanthemums above and at the sides in bas-relief, and at the top of each of the two dark granite columns which support the upper sculptured portion, a bunch of Primroses, commemorative of his association with the local Primrose League. The inscription between the two columns sets forth the date of Mr. Holmes' death, September 18th, 1890, and goes on to state that "This memorial was erected by a number of friends of the late William Holmes as a token of their affectionate regard for his manly Christian character, and to mark their sense of his valuable services to the people of Hackney as one of their most trusted and zealous representatives upon the local boards; also in grateful remembrance of his unceasing labours in the world of horticulture, especially in connection with the culture of the Chrysanthemum." In spite of the very wet weather a considerable number of friends were present at Abney Park Cemetery on Saturday, September 19th, and after a short service the erection was formally handed over to the widow, Mrs. Elizabeth Holmes.

— IN "Seribner's Magazine" for September there is a picture of the SACRED BO-TREE OF CEYLON, from a photograph by Mr. James Ricalton, who states that it has stood for 2130 years, according to authentic records, and is probably the oldest historical tree in the world. The Bo-tree (*Ficus religiosa*), in all countries where Buddhism prevails, has become a consecrated object, and may be seen on the road-side, about houses and temples and in towns, protected by masonry, over which shrines are placed for homage-offerings. This particular tree in Anuradhapura crowns the uppermost of three successive terraces; it has a multiple trunk, and its several divisions are feeble and gnarled, while its leaves lack verdancy and vigour and show the pallor of decrepitude. The soil about its roots is almost saturated with the oil of its anointment, and yet it spreads its protecting arms over its devotees while they deposit their offerings about it. All of them are eager for a single leaf, but no one would dare pluck it from the tree, for it must fall in full maturity to yield its highest merit. When one of these withered leaves loosens from its branch and comes sailing down there is a pious scramble among the multitude, a collision of zealous heads and hands, and then the solitary leaf is borne away in the happy bosom of the successful competitor.

— MR. EDWARD WHITTAL writes to *The Mayflower* from Smyrna very pleasantly of his excursions to the mountains, where he has been collecting CHIONODOXAS. Besides the original *C. Luciliæ*, discovered by Mr. Maw, he found the first variety of this plant on the Mahmut Dag, and named it *Sardensis*, from the beautiful plains of Sardis, which lay before him. This plant is of a darker tint than *C. Luciliæ*, and the intenseness of its colour where many plants were grouped together, with a background of rocks, made a picture not to be forgotten. This variety of the *Chionodoxa* has white and pink sports, and it is an acquisition for the rockery or wild garden. Mr. Whittal found the third *Chionodoxa* on the Tmolus range of mountains. It is a smaller, but brighter coloured, plant than *C. Luciliæ*, and he named it *C. Tmolusi*. It has been considered by some botanists as identical to the one discovered by Mr. Maw, but in its wild state the difference between the flowers is very marked. No white or pink sports of this plant have been found. It was near this third *Chionodoxa* that Mr. Whittal found the variety which he named *Gigantea*, from its more massive flowers. The colouring of this plant is not so brilliant as in the type, but this deficiency is made up by its size and by the erectness of its flower-scape. It varies in colour more than the other Glories of the Snow, and when well established it will be sure to attract attention.—(*American Garden and Forest.*)

FIG. 52.—MR. R. P. BROTHERSTON, TYNNINGHAME.

## THE EDINBURGH SHOW.

### FRUIT STEALING.

THERE was much worthy of praise in the general arrangements of the recent Show at Edinburgh, but there were also several serious defects, and it would be well if they were carefully considered with a view to their rectification in future. One of the greatest of these to which I especially wish to draw attention now occurred in the removal of the exhibits; and with many years' experience in horticultural shows in the United Kingdom I must say I never witnessed such a scene as that which prevailed outside and inside the Waverley Market on the Friday night. It was

little short of a riot round the doors, such fighting and shouting has surely never been known at a show before. Then, too, when admission was obtained some exhibitors discovered that their best fruits had been stolen. This is a very serious matter for gardeners, who are often expected to return their prize fruits to their employers' tables, and even where the fruit had been sold it would lead to many difficulties. If some of those who suffered in this way would record their grievances in the Journal it might result in a considerable improvement on another occasion, for no doubt the Council of the Society are in a measure responsible for

FIG. 53.—MR. THOMAS BOYD, CALLENDAR HOUSE.

the safe custody of the exhibits, and for their own credit they should take active measures to stop such disgraceful procedure.—  
A VISITOR.

#### STANDS FOR GRAPES AT EDINBURGH.

IN your excellent report of the Edinburgh Show you give the dimensions of the stands for Grapes as they should be according to the schedule—viz., "a breadth of 14 inches from front to back, depth at back 10 inches, and depth at front 2 inches." Now as this was probably the largest and best exhibition of Grapes that has ever been held there is a danger of these proportions being copied by other societies, and this is my chief reason for sending you a line on the subject.

As a matter of fact, I believe I was the only exhibitor who used such stands, and they were made specially for this show. The result was that large bunches lying on so flat a surface opened their shoulders considerably, and of course showed where the berries had touched each other, hence the remarks which your reporter was justified in using concerning my exhibits—"suffered in transit," "slightly rubbed," &c. The fact is the Grapes travelled very well, and the damage occurred in the Waverley Market, when the stands which had hinged supports were opened out to the specified angle.

I find the stands I generally use—and they do not differ materially, I think, from the majority of those used at Edinburgh—are about a foot in breadth and 15 inches high at back. This gives a very good angle both for exhibiting and for travelling. It would be desirable to have something like uniformity in our Grape stands, not to be too rigidly enforced, and now is the time for suggestions.—WM. TAYLOR, *Bath*.

#### OUR PORTRAITS.

IN accordance with our promise last week we give four other portraits of northern horticulturists in the present issue, pages 266 and 267. Mr. R. Lindsay is the well-known and respected Curator of the Royal Botanic Gardens, Edinburgh; Mr. R. P. Brotherston has charge of the gardens at Tynninghame, and has contributed to these pages for many years; Mr. Thomas Boyd is the able gardener at Callendar House; and Mr. J. Brown holds a similar position at Abercairney near Crieff, where he grows both fruit and vegetables very successfully.

#### FRUIT CULTURE AND VARIETIES.

AN excellent idea is brought forward in the Journal last week, where we find it stated in the columns allotted to correspondents regarding the naming of fruits (page 255), "In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to pass the inferior which are not worth sending or growing."

In these days, when the fruit industry is being so steadfastly advanced and which must, on account of the great assistance it is receiving from the county councils, societies, and private individuals, be destined to occupy a large share of attention in the future, I think every suggestion of a practical nature likely to benefit those who will be largely dependent upon it ought to be given in the columns of your valuable paper. Quite a revolution in this matter has come upon us. Many people who have not had any serious thoughts on the subject are beginning to find out that, with a proper system of growing and the right varieties, much that was thought impossible may be made possible, and a greater amount may be produced from the land, which will certainly augment their incomes. But it is quite impossible to bring about all this without a great deal of help being given by those qualified to give it. We see fruit, handsome in shape and brilliant in colour, exhibited at many of our leading shows, and which naturally finds many admirers. How often do we hear the remark made by some on-looker that they must have a tree or trees of such a variety? never for a moment asking themselves the question if it will do in their particular locality. The trees are forthwith purchased, and they go on growing, but produce very little fruit, and certainly nothing like what was exhibited. Much time is often spent in trying to bring them to perfection, but all to no avail. Now had some of those persons who do this been instructed that the variety was never meant for their locality, how much time and patience might have been saved, and instead the space could have been occupied by a suitable variety, and one which would give full crops of fruit each year. This, to my mind, is one of the essential points to be considered far and wide, more especially by those who have to make a living by it.

In conclusion, may I ask if it would not be possible to find out of each county at least one who would undertake to gather what information they could as to the most approved varieties for their county, with style of training suitable, and any other information that would prove useful? I think by this means we should have much valuable information imparted which would prove of lasting value. I am well aware that a great deal has been already done in this direction by conferences, reports, &c., the benefits of which cannot be over-estimated, but much more may still be done. Of course this is merely a suggestion. If any of your correspondents who could offer anything better, I should be very willing to give way to them, and do what I could to further the objects in view.—R. P. R.

#### MISS ORMEROD AND HER WORK.

IN answer to a correspondent who desires to know in what manner and on what terms this lady will continue her work in future, we have pleasure in publishing the following statement from Miss Ormerod. It is evident that she is much more generously disposed to the public than the Council of the Royal Agricultural Society has been to her. It appears from what we learn that they not only wanted her services, but

FIG. 54.—MR. JAMES BROWN, ABERCAIRNEY.

that of her helpers, and to turn all over to the Board of Agriculture in a peculiarly high-handed manner. Though the claims made were withdrawn Miss Ormerod prefers to be free to act for the public good, untrammelled by any Society. Writing from Torrington House, St. Albans, she says:—

"I feel I shall work with more comfort and, I hope, usefulness, if free from possibility of claims being urged on me for work other than that of attending to the inquiries of my many and much-respected correspondents.

"I hope to make no change whatever in the nature of the work which I have now been carrying on for fourteen years, i.e., to reply with the greatest care and attention in my power to every inquiry with which I may be honoured (for I esteem it a great honour, as well as pleasure, to be of service in the matter), regarding measures useful in lessening loss

through ravages of injurious crop insects. Through the sound information which has been brought forward during the many years I have worked on the subject, and placed in my hands for publication by my correspondents and co-operators (the agriculturists, fruit-growers, and foresters of this country), enormous advance has been made. We can point to the information they have given on turnip fly, wireworm, hop aphid, warble, and other great scourges, and which they have permitted me to embody in my yearly reports.

"With their help I hope I may be permitted to continue this work. It was begun years before I was connected with the 'Royal,' and has in great part been continued without any official reference to it, and I hope to be permitted the pleasure still of being consulted, and of replying to all inquiries just as before, whether to the 'Royal' members or to the general agricultural public, from which the mass of the inquiries are sent; only that the information that I look forward to being permitted to supply, would be sent wholly gratuitously, instead of as at present being (nominally) in case of members of R.A.S.E. on payment of a small fee.

"As before, I purpose to embody the information received in an annual illustrated report. This (as before), to be presented to each contributor of serviceable information, and (also as before) I hope to be allowed the aid of the agricultural Press, which has so long, and so ably and courteously been accorded, and still to benefit by their help in bringing points of interest regarding crop attacks before the public, and to reply to inquiries of any special interest which their Editors (as for many years past), may desire my opinion on.

"It is, with very deep regret, that I have deemed it desirable to sever my connection with the Royal Agricultural Society, amongst which I have many kind friends, and cease to be able to claim the highly honourable title of its 'Consulting Entomologist,' but my great desire is to be of service practically, and this I believe I can be much more fully when freed from the anxieties and possible ties which public office necessarily brings with it."

### A VISIT TO NORWICH.

"WHAT is Norwich famous for?" was a question once asked me; and although I had never visited East Anglia I ventured to answer the question thus, "What is the ancient City not famous for?" and now that I have visited Norwich three times in four weeks I am bold to think that my question was a good answer to my friend's question. Old Thomas Fuller, in his work styled "Worthies of England," writes: "Norwich is either a city in an orchard or an orchard in a city." It has also been called "the city of gardens," and verily and indeed it may be so called to-day. I have visited nearly every city in Great Britain and Ireland, but never have I had such a general floral treat as in my perambulations around the chief town in East Anglia. Moreover, how very interesting to the antiquary and the archaeologist must be a city held successively by the Romans, Saxons, and Danes! The old part of the city is most picturesque, and its cathedral, as the world knows or ought to know, is one of the most beautiful and interesting in the three kingdoms. But apart from that which appeals to our higher nature, Norwich is, though situated in a purely agricultural district, noted as a manufacturing town. Its crapes and bombazines are world famed, and, believing in the truth of the saying that "there is nothing like leather," we find the staple trade of the city to be that of boots and shoes. Agricultural and horticultural machinery is very largely manufactured, and Messrs. Boulton & Paul's advertisements of conservatories and all horticultural and garden appliances may be seen and read in the *Journal of Horticulture* every week. There are five or six widely known carriage makers; and who has not heard of, if not tasted, Colman's mustard? Perhaps some of your readers may not have heard the story said to have been told by Mr. Gladstone's late host, Mr. J. Colman, M.P., how that the famous mustard firm made their huge profits, not so much by the amount of the condiment consumed, as by the amount left on the plates of the consumers.

On the last two of my visits to this historic city, my "objective," as our only General (not Booth) would put it, was Messrs. Daniels' nurseries, about which I had heard glowing accounts, and I was not disappointed; so I think a short account of my visits may possibly be of interest to your readers.

Met at the Victoria Station by Mr. Forder, one of Messrs. Daniels' trusty lieutenants, we at once made our way to the offices and seed warehouses situated in the heart of the city, and there Mr. George Daniels personally conducted me over these "big" premises. In the flower seed department there are many "cases" of pigeon-holes, each case containing from 700 down to about 350 holes. There is one pigeon-hole corresponding to every number in the firm's catalogue, and as the number of different seeds described as for sale in the catalogue is about 1300, and that the pigeon-holes are reduplicated in order that four sets of workers can be executing flower seed orders at the same time, your readers will easily calculate the number of pigeon-holes required. In the vegetable department exactly the same principle is carried out, the number on each "hole" corresponding with the number in the catalogue.

It was most interesting to note the manner in which the seed Potatoes were stored ready for immediate packing. Trays made of strips from old packing cases, all exactly of the same size, are used. Placed one on the top of another, forty on the floor at eight trays high, you get a solid block of 320 trays, each tray containing five stone, and the whole block exactly ten tons of Potatoes. How many of these

blocks there were I should be afraid to say, but Mr. Daniels told me that when the vaults were filled they reckoned on having in them 150 tons.

But we must off to the nurseries; so after fortifying the inner man a pleasant drive of about two miles, through beautiful suburbs with lovely gardens containing magnificent shrubs and trees, we are landed at Mr. George Daniels' private residence, where my guide and host makes trials of Tomatoes a special study and practice. Out of a great number I noticed as particularly good Solid Scarlet, President Garfield, Horsfield's Prelude, new to me; Chemin, a new French sort; Round Yellow, Laxton's Open Air, and last, but not least, Cluster Plum and Daniels' "Very-Own." This last is excellent. I say this, not because it is of Mr. Daniels' raising; I should say the same if it were called, like one of our crack cavalry regiments, the "Devil's-Own."

Crossing theavenued road we at once enter the extensive nurseries, and make for the Potato and Pea trial grounds. Messrs. Daniels have been long known as very large growers of the staple vegetable, and have sent out varieties fixed as well as distinct in character, and which are now very largely grown, White Elephant in particular, especially in East Anglia. I saw several very promising seedlings shallow-eyed, and with a skin that looked like resisting disease. A curious seedling with black flesh, but said to be a fine cooker, named Norfolk Blackbird, attracted attention. Another fine new one was named after our Poet Laureate. Upwards of 350 varieties are being grown and tried. My attention was now drawn to the Peas, 200 kinds of which are on trial, and 100 acres of land is found necessary for the work. I was glad to find Sharpe's Queen so largely grown, ten acres being set apart for this one variety. I have grown it since it was first sent out and consider it at the top of the tree. Half an acre here of a new Pea, named Matchless, was grandly cropped, and elsewhere eight acres are being grown. I noticed this excellent new Marrowfat in a private garden in July, and the head gardener told me that he should next year grow this variety alone for his main or general crop. One more new one to be noticed and deservedly so, The Daniels, a cross between Alpha and Best of All.

Of Dwarf Beans forty-eight varieties are on trial, and of these Ne Plus Ultra and Early Black Wonder are preferred to Canadian Wonder. This last is too rank a grower, I find, in a wet season; and this year every plant that I did not carefully stake was broken off at the base of the stem.

One more vegetable I must mention, a Lettuce named Continuity. It appears to resist drought well, and certainly not one on the plot I saw showed the slightest sign of bolting. The fact, too, that this useful Cabbage Lettuce is now being grown in 5000 gardens proves that its merits have been discovered.

Next was pointed out to me a hedge 250 yards long—a hedge of the Myrobella Plum. Not only does this hedge afford a grand shelter and a handsome boundary fence, but it is put to practical use, as at intervals of 6 to 12 feet a strong single stem is allowed to grow, and each is budded with either the Victoria or the Czar Plum. Now, when we come to realise that the Myrobella is infinitely superior to the ordinary White Thorn, for a capital fence can be made with it in three or at the most four years, I am not surprised to find that the supply is barely equal to the demand, and yet in these nurseries I saw one breadth of seedlings from 3 to 5 feet high in number upwards of 200,000, the seed having been sown only in April last. Those from cuttings are not so satisfactory. Landlords and farmers ought to take advantage of every opportunity to buy this Plum—(1) for repairing old fences; and (2) for making new ones; and they should adopt the plan of having a profitable Plum tree at 9 or 12 feet intervals. At five plants to the yard (and this is sufficient), the cost is 15s. a 100 yards. Nine years ago the present writer when living in Worcestershire filled up great gaps in fences with this Myrobella, and in four years they were impenetrable to cattle. This Plum is also used as a stock for Prunus Pissardi, a Japanese Plum with very dark purple foliage, which, owing to its rapid growth, is likely to rival the Purple or Copper Beech in gardens and plantations.

Apples and Pears in all forms are largely propagated, the culinary kinds most popular in the Norwich district (so the fruit-tree foreman told me), being Warner's King, Keswick Codlin, Lord Suffield, Cellini, Stirling Castle, Ecklinville Seedling, Norfolk and Striped Beefing, Mère de Ménage, Peasgood's Nonsuch, Normanton Wonder or the Wellington of the London Markets, Norfolk Bearer and Beefing, Jolly Beggar, The Queen, and Lane's Prince Albert; while among the table fruits Cox's Orange, Ribston, Court Pendu Plat, Fearn's Pippin, Adam's Pearmain, Kerry Pippin, King of the Pippins, Sturmer Pippin, and Mr. Gladstone are mostly in demand. A new Apple "Vicar of Beighton" looked promising. What especially struck me was the marvellous growth made by the maiden Plums and Cherries, budded mostly, but a few grafted.

I must get to the flowers, and in passing I stayed a few minutes to watch the rapidity with which quite young lads were helping to bud the 175,000 Manettis. Flowers indeed! Over a mile of single Dahlias, and two miles of Dahlias altogether. Among the Show varieties especially good were Crown Prince (buff), Mrs. Gladstone, Primrose Dame, Mrs. Langtry, Colonist (grand), and two new ones, J. C. Vaughan and Coronet, appeared promising. Among the Fancies a new one named Comedian took my fancy. The new Cactus, Harry Freeman and Crimson Beauty, were to be seen in excellent form, while among the new singles, Eclipse, Northern Star, and Miss Glasscock appear likely to be useful. Raisers of Decorative and single Dahlias must, however, be very careful to, in the first case, keep as close as possible to the true Juarezi type, and in the second case strive towards the smaller rounded

flowers, after Duchess of Westminster and the newer seedlings raised by Mr. T. W. Girdlestone.

Godetias have for years been a specialty in these nurseries, and very shortly, unless I am a false prophet, we shall have a pure yellow one; already it is far yellower than Lacharme's yellow H.P. Rose Gloire Lyonnaise. Immense breadths of Godetias are grown, Duke and Duchess of Fife, Bridesmaid, and General Gordon among the newer kinds being very noticeable. A rapid look through the houses to see some grand Coleuses, Tuberous Begonias, Zonals, Lilies (magnificent), especially speciosum Krætzneri and auratum rubro-vittatum, Balsams, a grand strain (of which Mr. Bishop, the Superintendent of this department, has reason to be very proud), Crotons, &c. At last I was obliged to tear myself away from the flowers and my courteous and friendly guides. To Mr. George Daniels and Messrs. Forder, Upstone, and Bishop my best thanks are due for many pleasant hours spent in the city of gardens.

After seeing what I did I was not surprised to find that Messrs. Daniels Bros. found it necessary to have a distinct business department for their home counties of Norfolk, Suffolk, Essex, and Cambridgeshire.—CASUAL VISITOR.

LARGE AND SMALL GROWERS.

I REGRET that "An Exhibitor" in his last letter has shown a want of courtesy in his statements concerning myself. It is certainly a good way to get the last word, as I cannot follow him into personalities; but on the contrary, if I have made any wrong statement I am ready to apologise. I was certainly under the impression that the matter in question did not come before the last general meeting. I heard nothing of it, either as a committeeman or as a private member. If I think that no just grievance exists, and he and others think differently, it does not therefore necessarily follow that either I or they are right. I am quite willing that the matter should be thoroughly ventilated and tested; that it should be properly brought before a representative meeting, advocates heard on both sides, and a vote taken, and I, for one, will loyally submit to the result.—W. R. RAILLEM.

P.S.—Please allow me to correct a statement in the account of our visit to Mr. B. R. Cant. He does unfasten the ties of his budded standard stocks. He fancies he may be a little deaf, I don't think he is, but am sure that I am; hence perhaps the misconception.

## THE JOURNAL OF THE ROYAL HORTICULTURAL SOCIETY.

PART 2 of vol. xiii. of this Journal is just to hand, and contains several papers of considerable interest, together with reports of the Society's proceedings from February 10th to May 12th, 1891; also including a report of the Temple Show. The papers comprise the following:—"Persian Cyclamen," by Mr. W. Warren; "Hardy Cyclamen," by the Rev. W. Wilks, a very interesting review of the species, their character, and culture; "The Germination of Cyclamen" is well treated by Dr. M. T. Masters, and illustrated. To "Snowdrops" three excellent papers are devoted by Mr. James Allen, Mr. D. Melville, and Mr. F. W. Burbidge, the illustrations being numerous. These are followed by the "Cultivation of Hardy Bulbs and Plants," by Herr Max Leichtlin; "Lachenalias," by Mr. F. W. Moore, an exhaustive essay on these useful plants; "Cape Bulbs," by Mr. James O'Brien; and an important illustrated chapter on "Hybrid Rhododendrons," by the Rev. Prof. Henslow.

The remarks by Mr. Warren on the culture of Persian Cyclamen are brief, and give the outlines of such successful practice that we are tempted to reproduce them.

I have been honoured by receiving an invitation to read a paper on the cultivation of the Persian Cyclamen, and I will at once proceed to describe the method of cultivation as pursued at Worton Gardens, Isleworth, without for a moment assuming that it is necessarily the best or the only desirable method. First, let me say that the old corms left from the previous season are not considered worth the trouble of further cultivation, but are sold for the purpose of extracting the cyclamine they contain. With regard to the plants reserved for seed, of course the best are selected—viz., those that combine the qualities of large, good-shaped, five-petalled flowers, bold foliage, and dwarf growth. The flowers of the selected plants are daily hybridised (when there is any pollen) with the finger, and the plants, potted in 48's, are not allowed to bear more than six seed-pods, or the seed and its offspring would be weak. We cannot always be sure of obtaining six pods, as occasionally some of them decay unexpectedly. The seed ripens about the middle of May, when it is collected and placed in the sun, so that it may be well matured, otherwise it germinates slowly.

The first week in June the seed is sown in pans 1 foot square (as these are found to afford more available space), with plenty of crocks for drainage. The most suitable soil is a mixture of two-thirds Hamp-

shire yellow fibrous loam, one-sixth decayed leaves (not leaf mould) rubbed through a half-inch sieve, and one-sixth coarse Thames sand; the decayed leaves, or the coarse siftings of the loam, being placed over the crocks. The seeds are carefully sown, so that two are not close together, otherwise the seedlings weaken each other as they develop. The pans are then placed in a one-pipe pit, which is covered with mats to keep it dark, and kept at a temperature of about 75° Fahr. The pans are daily looked over to see that the soil does not become dry, as is often the case at the sides of the pans. In about six weeks the young plants appear; the pans are then taken to a greenhouse and placed at near the glass as possible, damped morning and evening, and shaded from the sun. One hundred pans are generally sown, so as to give an abundant supply, and enable us to reject the weakest plants, although it is found that the most precocious plants produce the worst blooms.

About the end of September the seedlings are pricked out in the same sized pans, three dozen in each, with the same soil and treatment as before. Towards the end of November they are transplanted into thumb-pots, no change being made either in soil or treatment. The plants in these two stages are kept at a temperature of 60° Fahr., and the thermometer may without injury be allowed to register as much as 70°. When the external conditions are favourable, air may be freely admitted to them. At the beginning of March they are repotted into 60's, or 4-inch pots, using the same soil as before, and still continuing the same treatment, with the exception of potting them a little firmer. By the end of April last year as many as 750 dozen plants had been potted off in this manner. About the end of May they are transferred to 48's, in which pots they are to bloom, but some few dozen are placed in 32's, or they bloom before they are required for market purposes.

It is necessary to keep the plants well up in the pots, but the corm should nevertheless be covered with the soil. At the last potting the soil is changed, being composed of five-sixths loam, one-twelfth Thames sand, and one-twelfth decayed leaves. The plants are then potted as firmly as possible without pressing the corms, whilst in all the former stages (except when they are placed in 4-inch pots) they are transplanted and potted as lightly as possible. It is surprising what a quantity of water Cyclamen will take with advantage during the summer months; hence it is necessary that the drainage for both pots and pans should be as perfect as possible. The plants are not left too long in the pans and various sized pots before they are repotted, otherwise they are found to be slow at starting again after transplanting. As the sun's power decreases, it is essential that great care be taken with the watering. Overhead damping is discontinued for fear of fog, and only those plants are watered which are seen to be dry. Some of the plants at the beginning of October have a good show of bloom; they are then staked with Currant prunings, on account of their neutral colours, and are tied round with dark carpet-thread, after which they are despatched to Covent Garden Market.

It is of the utmost importance that the plants be kept in every stage of their growth free from aphids or green fly, caterpillars (which latter vary in size, colour, and number according to the heat of the weather), and thrips. Incessant care is required to keep these pests in subjection, as without it the plants may soon be spoiled, in which case all previous effort and expense are lost. Mice, too, as the autumn approaches, are very mischievous; but they may be trapped before they have time to make any noticeable depredations.

Most of the greenhouses at Worton Gardens contain about 3000 cubic feet. Upon an average the Cyclamen plants are placed about 18 inches from the glass upon beds of damp ashes, as it is found that they thrive so much better in such a position during the summer than when placed on dry shelves. In September, however, as the plants become larger and the weather cooler, they are placed on shelves; the floor of the greenhouses is kept wet, and effort is made, by shading, to prevent the plants becoming limp. The plants are kept in a temperature of about 50° Fahr., and plenty of air given to them, even at night, if the external temperature will then admit of ventilation. To keep the plants perfectly free from insect pests in the first three stages of growth, Cliban and Sons' fumigating rolls are used, for the plants are so lightly potted that if dipped in any solution the soil would fall away. In the last two stages George's tobacco juice is used, and the solution is made in the proportion of four parts of soft water to one of tobacco juice.

## USEFUL HARDY PLANTS.

WE now have such an abundance of effective plants suitable for culture in borders and to yield supplies of flowers for cutting purposes that it is difficult to make a selection of the best. The following will, however, be found of special value for the particular situations and purposes named.

### SENECIO ELEGANS.

The old-fashioned Senecio elegans, now called Jacobæa, but which is really a species of Groundsel or Ragweed, is a delightful addition to the borders, especially the newer varieties. Those with double flowers are perhaps the greater favourites generally. The colours vary from crimson to pure white, and any tint can be had separately. They grow from 9 inches to 1 foot high, the deep green of the leaves providing a good base for the flowers. Although they succeed well in most cases sown where they are to flower I generally manage them best when sown in a cold frame early in April, afterwards planting them out. In a younger

stage slugs are troublesome if the weather is showery at the time when they emerge above the soil.

#### THE PERENNIAL GERANIUMS.

As border or rockery plants, where space in the latter position can be found for them, the perennial Geraniums, of which there are fully one hundred varieties, are interesting and worthy of attention. Flowers are produced early in spring, and continue until the end of summer. *G. Endressii* is one of the best. The colour of the flower is a light rose, having darker veins; height from 1 foot to 2 feet; habit, compact and free in flowering.

#### ACHILLEA MILLEFOLIUM.

There are two distinct forms of *Achillea millefolium roseum*, one of a rich rose colour, and the other a dull shade of the same tint, but as compared with the former might be more correctly called lilac. Those who happen to be in possession of the latter should lose no time in making a change. The deeper coloured variety provides a charming show in the herbaceous border, where it continues to flower during a considerable period, commencing early in June. No plant is more easy of propagation; in fact, my difficulty is to keep it within bounds, so freely do the creeping rhizome-like growths extend.

#### PERENNIAL ASTERS.

Perennial Asters are commencing to unfold their blossoms, which is a warning that autumn is at hand. They are charming hardy plants, requiring but a minimum of labour to keep them in order, but they give a maximum of flower in return. One of the best, if not absolutely so, is *A. amellus bessarabicus*; the flower heads are large, of a rich deep purple blue, lasting an extremely long time in a cut state in water. The habit of growth is compact, erect, and stiff, requiring but little assistance in the way of stakes. *A. ericoides* has minute flower heads, but that is balanced by the large numbers borne on stems 2 to 3 feet long; the colour is a dull white with a yellow eye. *A. ptarmicoides* is another of the small-flowered varieties which expands its blossoms early in September.

#### RUDBECKIA LACINIATA.

Where variety in the shrubbery or herbaceous border is desired, *Rudbeckia laciniata* will supply some during September. The pale yellow flower heads are showy and very freely produced upon stout stems, which branch their whole length. The foliage is bold, deeply cut also, and in conformity with the flower heads in that respect.

#### RUDBECKIA NEWMANNI.

Amongst hardy perennials for making a display during September there is hardly one which can be called superior to *Rudbeckia Newmanni*. The deep orange yellow of its florets contrasts so well with the maroon centre that this "Cone Flower" is admired by all. For cutting purposes it is a gem; a mass of it along with some light Grasses and greenery is fit for any form of vase decoration. It is somewhat strange how quickly this plant suffers from drought during the summer; it is the first to lose its leaves under a hot sun. The showery weather experienced during August encouraged a free growth, resulting in a full crop of strong flower stems and ample foliage. One advantage gained by growing this plant in the border is that it is self-supporting, and therefore does not require staking.

#### LYCHNIS CHALCEDONICA.

An exceedingly showy plant for the back of the herbaceous border where bright coloured flowers are required during June and July. Associated with double white annual Poppies the effect is capital, both growing about the same height, 4 to 5 feet. Considering the ease with which this plant can be grown the wonder is more of it is not seen in private gardens, and especially those of large size. The double variety is perhaps more valuable still, flowering during August and lasting a greater time in good condition than the single form.

#### FUNKIAS.

Funkias are more interesting plants than many persons seem to think—not perhaps on account of the beauty of their flowers, but for the great variety of colour obtainable from their foliage, which is both bold and handsome. Take, for instance, *F. Sieboldiana*; what a charming shade of glaucous tint is shown by the bold leaves when growing partly in the shade. All the Funkias are particularly well adapted for growing in the shade of trees, where so many plants refuse to grow. We have strong roots of the kind named by the water side, at the foot of rockery clumps and *Rhododendron* beds—in fact, anywhere that provides a suitable contrast in colour to the foliage. The flowers have a peculiar shade of colouring, which is rather pleasing—pale lilac or ashy grey, rather a strange combination. *Fortunei variegata* has glossy green leaves edged with white, is very striking in appearance; and so is *F. undulata variegata*. The green-leaved variety, *F. subcordata grandiflora*, with white flowers, deserves a place in most gardens. Funkias make grand marginal lines to subtropical beds provided they are not in too hot and dry a situation, they being partial to moisture at the root to give luxuriance of foliage, which is their main claim to flavour.

#### EPILOBIUM ANGUSTIFOLIUM.

The Willow Herb, *Epilobium angustifolium*, has been very gay in the wild garden, also growing among Fir trees. On the margin of a pond it is very effective; but nowhere does it show to such advantage as on a piece of moorland by the roadside, where a quarter of

an acre is densely covered with this perennial. The colour of the flowers appears to be exceedingly rich glistening in the sunlight. Owing to the rapid rate at which it spreads it ought not to be planted in the herbaceous border proper, as there is such a difficulty to banish it from the spot if desired. It is so showy that no garden is really perfect without a small patch. In good soil it grows 6 feet high, and lasts in flower a long time.

#### LYTHRUM SALICARIA.

For planting in a marshy position or by the edge of a pond the common purple Loosestrife, *Lythrum Salicaria roseum*, is one of the best hardy perennials. Its height is about 3 feet, each shoot surmounted with a flower spike. To obtain the finest effect it should be planted in bold masses, the colour of the flower being very effective at a distance.

#### CAMPANULA PERSICIFOLIA ALBA.

The white-flowered form of this *Campanula* is decidedly worthy a place in the most select collection of hardy plants. It may not be quite so valuable in some respects as the double form, but the duration of its flowers and their continuity of production stamps it as one of the best summer flowering plants obtainable. Like all members of this genus, dividing the roots is the most ready method of increasing it.—E.

### ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 22ND.

DAHLIAS were excellently represented at the meeting in the Drill Hall on Tuesday last, by far the greater proportion of table space provided being occupied with these flowers, in all the sections and in wonderful diversity of form and colours. Besides these the Pitcher Plants and Orchids furnished several attractive features, and the display of fruit was also good, though not extensive.

FRUIT COMMITTEE.—Present: Phillip Crowley, Esq., in the chair; and Messrs. Harrison Weir, R. D. Blackmore, T. F. Rivers, G. Wythes, J. Hudson, F. Q. Lane, H. Balderson, G. Reynolds, J. Willard, J. Cheal, G. W. Cummins, W. Warren, T. J. Saltmarsh, A. H. Pearson, A. Dean, W. Bates, G. Cliffe, Rev. W. Wilks, and Dr. Robert Hogg.

Messrs. J. Veitch & Sons, Chelsea, showed specimens of the Crab Apple John Downie, very attractive orange-red oval fruits of considerable decorative value; also heavily laden branches of Farleigh Prolific Damson (votes of thanks). New varieties of Melons came from Mr. G. Wythes, Syon Gardens, Brentford; Mr. Gilmour, Ingestrie Gardens, Stafford; and Mr. Tubbs, Teddington; but the Committee passed them all. Mr. Bloxham, The Gardens, Great Brickhill Manor, Bletchley, sent fine even specimens of Veitch's Main Crop Onions. The Rev. W. Wilks, Shirley, exhibited a large handsome fruit of a Pear named Marguerite Marillat, for which a vote of thanks was accorded. Messrs. T. Rivers & Son, Sawbridgeworth, had four varieties of seedling Plums, which had been dried at Chiswick by the evaporating process, and proved fairly satisfactory; but one sample was over-ripe at the time they were dried, and several fruits burst. From Mr. J. Roberts, Tan-y-Bwlch, North Wales, came excellent fruits of *Passiflora edulis*, well ripened and of good flavour (vote of thanks).

Messrs. Laxton Bros., Bedford, sent several seedling fruits, including a yellow Plum named Golden Nugget and a dark purple variety named The Shah. Seedling Apples named The Duchess of Bedford and the Harpur came from the same firm, but the last named was considered to be identical with Yorkshire Beauty. Messrs. R. Veitch & Son, Exeter, showed a dark red medium sized Peach named Lady Walrond, said to be the result of a cross between Belle de Vitry and Early Walburton. Mr. J. Gilbert, gardener to the Rev. L. R. Flood, The Rectory, Merrow Guildford, contributed two dishes of Salway Peaches, extremely handsome fruits, eleven of which together weighed 7 lbs. 13½ ozs. (vote of thanks). An admirable collection of Apples and Pears from Messrs. W. Paul & Son, Waltham Cross, comprising a fine selection of the best varieties, worthily won a silver medal for the exhibitors.

FLORAL COMMITTEE.—Present: W. Marshall, Esq., in the chair; and Messrs. C. T. Druery, R. Dean, B. Wynne, G. Phippen, G. Nicholson, C. Jeffries, R. B. Lowe, W. T. Bennett Poë, H. Cannell, C. Noble, G. Bryceson, J. Walker, J. Fraser, W. Goldring, and the Rev. H. H. D'Ombra.

As already stated Dahlias were the most prominent exhibits, amongst the flowers and plants, several large groups and collections being staged. The most effective and novel was that from Messrs. G. Phippen of Reading, in which Palms, Ferns, and Lilies were arranged upon the floor of the Hall, and amongst these rose elliptical sloping stands of Cactus Dahlias, which showed the flowers to great advantage (silver-gilt Flora medal). To Messrs. J. Cheal & Son, Crawley, a silver Flora medal was adjudged for a grand collection of Dahlias in all the sections. A silver Banksian medal was accorded to Mr. T. G. Ware, Tottenham, for a bright and beautiful group of Dahlias and the floriferous white treecarnation La Neige. A similar honour was secured by Mr. Arthur Rawlings for a handsome collection of Dahlia blooms, in which Show varieties predominated, and a bronze Banksian medal was adjudged to Mr. J. T. West, gardener to W. Keith, Esq., Cornwall, Brentwood, for a beautiful exhibit of the Dahlias which he grows so well. Messrs. H. Cannell & Sons, Swanley, had a choice selection of new Cactus Dahlias, and Mr. C. Turner, Slough, also had several stands of novelties of the Cactus, Show, Fancy, and Pompon types. Mr. G. Humphries of Chippenham sent seven boxes of Show, Fancy, and Pompon Dahlias,

fine clean well developed blooms. W. Marshall, Esq., Bickley, was awarded a cultural commendation for a fine specimen of *Nerine flexuosa* with about twenty scapes of flowers.

Two important groups were submitted by Messrs. J. Veitch & Sons to the Floral Committee, one of these comprising a series of varieties of *Elæagnus*, of a highly ornamental character, the other consisting of Pitcher Plants, Droseras, and allied plants to illustrate the lectures on insectivorous plants. Mr. J. Walker, Thame, Oxon, had a large collection of Improved German Quilled Asters, the blooms very neat in form and varied in colours (bronze Banksian medal). Messrs. W. Paul & Son contributed a beautiful collection of Roses for such a late period in the season (bronze Banksian medal), and Messrs. H. Low & Co., Clapton, sent a new *Lilium* named *claptonense*, with one medium-sized yellowish flower at the apex of the stem. From Mr. R. Owen, Maidenhead, came a large collection of early Chrysanthemums, including many novelties of much promise; and Mr. T. Godfrey, Hillingdon Nurseries, showed a plant of *Chrysanthemum* Miss Whiteley with long narrow white florets.

ORCHID COMMITTEE.—Present: Dr. M. T. Masters (in the chair); and Messrs. H. Ballantine, H. Low, J. Douglas, E. Hill, S. Courtauld, T. B. Haywood, H. M. Pollett, J. O'Brien, F. Sander, and Lewis Castle.

The principal group of Orchids was that from Messrs. F. Sander and Co., St. Albans, for which a silver Banksian medal was awarded. This comprised several seedling variations of the fine hybrid *Cypripedium* Pollettianum and Maynardi, differing in the size of the flowers and the richness of colouring. *Lælia grandis tenebrosa* is a peculiarly dark and handsome variety, *Vanda Hookeriana* and *Odontoglossum vexillarium* were also included. T. Statter, Esq., Stand Hall, Manchester (gardener, Mr. Johnson), showed plants and flowers of *Cattleya Loddigesi splendens*, a pretty variety with rounded brightly coloured sepals and petals, *Vanda Kimballiana*, *Miltonia Moreliana atrovirens*, and *Cattleya intermedia alba* (first-class certificate). Baron Schröder, The Dell, Egham, sent flowers of the charming hybrid *Cypripedium Antigone* (certificated) with fine varieties of *Cattleyas* Dowiana and Hardyana. Captain Hincks, Thirsk, showed *Masdevallia Stella*, a hybrid from *M. coccinea*, Harryana, and *M. Estradae*, the flower pale purplish lilac, with long sepaline tails. C. J. Lucas, Esq., Warnham Court (gardener, Mr. Duncan), exhibited flowers of *Aerides Rohanianum*, *Vanda Sanderiana*, *Cattleya Schofieldiana*, *Cattleya bicolor*, and *Odontoglossum Pescatorei*. Messrs. W. L. Lewis & Co., Chaseside, Southgate, showed a fine dark *Cypripedium* Harrisianum and *Masdevallia Gaskelliana*. Messrs. Seeger and Tropp, Dulwich, exhibited a plant of *Grammatophyllum Seegerianum* from the Molucca Isles, which was thought to resemble *G. multiflorum*; and Messrs. Pitcher & Manda, Hextable, had a small group of Orchids comprising *Lælia Eyermanniana*, *Cattleya maxima*, *Burlingtonia fragrans*, and *Cypripedium Harrisianum Rougieri*.

#### PLANTS CERTIFICATED.

*Cypripedium Antigone* (Baron Schröder).—See note and figure on pages 262 and 263.

*Cattleya intermedia alba* (T. Statter, Esq.).—Chiefly notable for the pure white of the flowers, which are of good size and form (first-class certificate).

*Rhododendron Ceres* (J. Veitch & Sons).—A fine variety with large flowers, having broad round lobes of a rich clear yellow tint. A grand acquisition.

*Cuphea Llave* (Pitcher & Manda).—A peculiar little plant, 9 to 10 inches high, with elliptical acute leaves, the flowers with long green and reddish tubular calyxes, covered with dark hairs, small brilliant scarlet petals, each having a black spot at the base, and the stamens covered with purple hairs (botanical certificate).

*Dahlia Mrs. Ocock* (Mr. A. Rawlings).—A distinct Fancy variety of good form, the florets yellow tipped with purple.

*Dahlia Draughtsman* (Mr. G. C. P. Harris).—A Show variety of neat form, and of a peculiar deep reddish tint.

*Dahlia Mrs. Walter Besant* (Mr. T. S. Ware).—A Pompon variety, white tipped with deep purple.

*Dahlia Nellie Mackray* (Mr. T. S. Ware).—Another of the same type as the preceding, but of a rich orange shade.

*Dahlia Toxstone* (Mr. C. Turner).—A fine Fancy Dahlia with bronze yellow florets tinged and streaked with red.

*Dahlia Ada Rehan* (Mr. C. Turner).—One of the Show type, of excellent shape, the colour a soft lilac pink.

*Dahlia Lorna Doone* (Mr. C. Turner).—A neat Pompon, bright crimson purple; *Mars*, a brilliant scarlet variety of the same type; and *Cecil*, also a Pompon, bright red tipped with white.

*Dahlia Sultana* (Mr. C. Turner).—A Cactus variety of medium size, and peculiar terra cotta shade tipped with white.

*Rayon d'Or* is another of the same group; white edged with bright red.

*Dahlia Little Sarah* (Mr. Humphries).—A pretty Pompon variety; yellow tipped with purple.

*Elæagnus pungens maculatus* (J. Veitch & Sons).—An ornamental shrub, having the leaves creamy white and yellow in the centre, edged with green (first-class certificate).

*Dahlia Ernest Cannell* (Messrs. H. Cannell & Sons).—A fine bright red Cactus variety. *Mrs. Thornton*, from the same, is one of that type with broad florets of a soft rosy purple tint. Both are valuable varieties, as also is *Sir Roger*, very bright and effective.

#### "SWEET BLOOMING LAVENDER."

Most people like Lavender, "sweet blooming Lavender," and we know that old Isaac Walton loved it; for does he not take his friend Venator to an honest ale-house, where was "a cleanly room and Lavender in the windows?" and do we not read why that friend was willing to stay the night there with them, "for the linen looks white and smells of Lavender, and I long to lie in a pair of sheets that smell so?" and why Coridon, too, was pleased with the place, "for here are fresh sheets that smell of Lavender?" Well do we, also, enjoy the smell of it when in cottage gardens we come upon its untrained bushes amongst a wilderness of homely flowers, all tangled up together—such as Larkspurs, Lupins, and Clove Carnations, Pansies, Gillies, and Cabbage Roses, Candytuft, and Pinks; and even though these gardens might be hedged in with Sweetbriar and Honeysuckle. How our thoughts go back then to the long ago! to the Musk, red Rose leaves, and aromatic herbs that the old dames used to treasure—to that still-room, too, where they made such fragrant compounds, and to those presses where they placed, amongst their clothes, their tiny bags of sweet Lavender; a time of flower-chintz dresses, starched linen, and quaint mob-caps.

Truly has Lavender had many advocates, and it still is valued for its charming scent. Few plants, indeed, have a more welcome scent, and hence we in July always look for "the Lavender girls," who, with their musical cry, come selling; but this time they have missed their season, for, though there was some Lavender last month in Covent Garden—from Hitchin in Hertfordshire, and from Henley-on-Thames, where it blossoms very early—it is only recently that it has freely been sold in the streets, the growth being late in Kent and Surrey, and in parts almost a failure. Time was when townsfolk in London went to Mitcham Fair—the three days' pleasure fair upon the green—to wander by the church into "the fields" to see "the cutting," that fair being held in August; but now, about ten acres only of that sweet smelling crop are grown in once-famed Mitcham. Formerly, "the Lavender country" extended from Croydon to Battersea—hill, road, and "sweep" at Clapham Junction has there the term of "Lavender;" but Beddington, Banstead, Carshalton, and Wallington grow less and less of it now each year, in part owing to the increased value of the land there for building purposes, and partly because very much of it has been so long cropped with it that it will not now grow it any longer. Grown on a small scale at Henley-on-Thames and in Kent, as also on a larger area at Hitchin—where, though cultivated as far back as 1568, not much trade was done in it until 1823—it used also to be met with at Market Deeping, in Lincolnshire, but it is there no longer planted.

Mitcham oil of Lavender, "Mitcham" being the generic term for the whole of that district, has always commanded, with other oils made there, the very best price in the market, the Lavender from Germany being so far inferior. The present price for "best Mitcham," that is last year's oil, is 54s. per lb., but in previous years it has been as high as 126s. and as low as 29s., as it of course varies greatly according to bulk and quality, as was shown in the scarce year of 1879, when the price went from 34s. to 100s. The greatest growth of Lavender, in recent years, was in 1874 and 1887, the Jubilee year; and the smallest, in those years when there was a hard winter or a cold summer; and the present year from the latter cause, has made the crop a late and slight one. The best fields used to grow it for some years, without fresh planting, for four or five years have some good grounds grown it, but now, as Lavender, like Clover grounds, at times, gets "sick," and will no longer crop, a fresh planting each year is almost the rule. In planting Lavender, the ground selected should be dry, light soil, full to the sun, and open, as it will not grow in shade, and the higher it lies the better; but it must not be too good nor too rich, or it will grow leaf instead of blossom. Cuttings are best, not roots, and they take six weeks to strike; and they are grown in rows that are struck with a plough, and that are from 1½ to 3 feet apart, the ground being afterwards worked with hoe and spade, and the soil thrown up against them. Then, when ready for "bunching," they are reaped with a sickle, in just the same way as Wheat, only the stems are held straight, and are cut close to the root. Two men are engaged in the work, as one ties while the other sickles; three handfuls forming one "bunch," and six bunches one "bundle," which must be of the weight of quite 24 lbs., and practice will hit it exactly. The price for these bunches has rapidly risen from 2s. 6d. to 8s. per dozen, and in some years it has been higher still, 10s. to 12s. for that quantity being asked and given. This cutting for bunching lasts a month, and the work in the field then stops till the second week in August, when that breadth of the plant which has been reserved for the still is cut and laid loose in mats, which, when filled and skewered up and carted, are taken to the distillery. There, the Lavender is placed in the copper, trodden, as a man treads Hops, and damped, 120 gallons of water being used to a still that will hold 1200, so that the whole of it shall be kept from burning; and with a good still, practised hands, and proper fires, it will begin to run in an hour. Then, when the water has been expressed from the bloom, the oil on the top is skimmed off, filtered, and bottled, the refuse water being poured into cans or jars, and sold on the spot at a very low rate, at even 8d. or 10d. per gallon. The finest samples of the oil, however, are made from blossoms only, and it takes 60 lbs., weight of them to yield 1 lb. of oil. There are usually three distillings, the top price being for the first one.

Most persons suppose that the perfume called "Lavender" which is sold in the shops, is the "water" that runs from the still; but it is not so, as will have been inferred, as in that state it is but on a par with that which is made from the Rose and the Elder; in fact, the name Lavender "water" is quite a misnomer, as no water is in it,

only spirit. The sweet fragrant scent sold as "Lavender water" is really a compound composed of these things: oil of Lavender, mixed with the rectified spirit of wine, and then these essences added to it—rosemary, jessamine, bergamot, otto of roses, orange flowers, and musk. But as most chemists make a speciality of it each one has his own pet formula, in the preparation of which he has always to bring to bear very much chemical knowledge. The scent has a great sale everywhere, it being a general favourite, but the largest sale effected in it is for that made by Sainsbury in the Strand and by Lunn in Worcester. In this part of the country a Lavender water is "made" by the cottagers, who each season send their cuttings, mixed with Rosemary, red Rose leaves, Musk, and Thyme, to be distilled in their market town, where it is duly made and bottled; the old dames, by the sale of it, helping out their "posies" to make up their rent. This year, though, has been a bad one for them, as also for the "Lavender girls." Let us hope, however, that this first time will be the last time that we shall have to wait till September before our ears are greeted daily with the cry of "Lavender, fresh Lavender, sweet blooming Lavender."

Lavender is a native of those mountainous districts which border the western half of the Mediterranean, and extend from the eastern coast of Spain to Calabria and Northern Africa; where, so hardy is the plant, that in some places it grows at a height of 4500 feet above sea level; and it is cultivated as far north as Norway and Livonia. Its leaves and flowers were used by the ancients to perfume their baths, and hence, as supposed, its name from *lavare*, to wash. The earliest mention of it was in the twelfth century, by the Abbess Hildegard, who lived near Bingen on the Rhine; and in the thirteenth century it was used as a medicine by the herbalists in Wales, under the name of "Llafantly." Cultivated in England chiefly for its oil, there is also a large export trade for its flowers, which are sent to America, the Barbary States, and Turkey. Lavender is so influenced by the weather that the quantity of oil to be obtained from it varies from 12 to 30 lbs. to the acre, as when, as in this year, the weather in June and July is cold and wet the yield is but half as much as when it has been bright and sunny. As oil made from the flowers only is so high priced, the bulk of it is from both stalks and flowers. Mellowed by keeping it corked tightly for two or three years it then, to prevent deterioration, is mixed with alcohol. The best French oil fetches but one-sixth the price of the English, as it is chiefly made from the wild plant, which is collected in Piedmont and the south of France, especially in the villages about Mont Ventoux, near Avignon, where it grows profusely, and in those some leagues west of Montpellier. In olden times a spirit of Lavender was used under the name of "palsy drops," as it was credited with being of service in affections of the nervous system; and at the present day we also use Lavender in the shape of spirit, nine parts of spirit to one of oil; but more often in the form of a compound tincture, composed of Lavender, Rosemary, Nutmeg, and Cinnamon macerated in spirits of wine, and coloured red with red Sandal Wood, or Red Sanders, as it is called, when it is given in conjunction with ammonia and cardamons as a stimulant in nervous affections. In New York Lavender will not flourish freely, but in Philadelphia large tracts of it are grown, the dried flowers being used mainly for scent bags, as is the case with Sweet Basil in America. In Provence Lavender is called *l'espie*, and hence the oil made there, from stalk and blossom, is in England called "oil of spike," which at one time was used in porcelain painting, as also in veterinary medicine. There are many varieties of Lavender—about twenty species if we do not err, some of which extend as far east as India. A very fragrant one is a native of Spain, and another the *Stoechas*, its growth extending from the Canaries to Asia Minor, is still used by the Arabs for coughs and spasms; and the *Stoechades*, near Toulon, now called the Isles of Hyères, owed their name to the abundance of the plant which grew there. "The Sea Lavender," which grows in salt marshes and has fine spikes of bloom, is, strange to say, wholly scentless, and the "Lavender Cotton," an evergreen undershrub, has yellow instead of blue flowers. Some of the varieties, as those with divided leaves, are with us grown in greenhouses.

Lavender, with our poet's love of flowers, has, needless to say, not been overlooked by them, and many of them touch upon it; though, as space presses, we can here but allude to a few of them. Thus Spenser mentions "the wholesome Sage and Lavender still gray," and Shenstone, "Lavender, whose spikes of azure blue shall be, ere while, in arid bundles bound." Drayton, too, deals with it largely, though mainly in reference to herb-strewing. "Some Lavender, with Rosemary and Bays, amongst these strewing kinds," and he elsewhere has this verse on it concerning strewing:—

"With Basil then will I begin, whose scent is wondrous pleasing.  
This Eglantine I'll next put in, the sense with sweetness seizing.  
Then in my Lavender I'll lay, Muscado put among it,  
And here and there a leaf of Bay which still shall run along it."

—SHELSLEY BEAUCHAMP (in the *Worcester Herald*).

## CHELTHENHAM SHOW.

SEPTEMBER 16TH AND 17TH.

THIS Society held their usual Exhibition on the above dates, and in spite of the unfavourable season the display of plants, cut flowers, fruit, and vegetables was first-class. Probably plants were never shown better at Cheltenham, Mr. J. Cypher, Messrs. Heath & Son, and Mr. J. F. Mould of Pewsey exhibiting well. The prizes in none of the classes are large, but the competition is usually very keen, and reflects

great credit on the Committee and their energetic Secretary, Mr. T. H. Packer, in working up and organising such a good Show.

For six stove and greenhouse plants Mr. J. Cypher was first for *Erica Marnockiana*, very fine; *E. Eweriana*, *Allamanda nobilis*, &c., all good; Mr. J. F. Mould occupying second place, *Erica Eweriana superba* being especially well grown and flowered. For a collection of thirty plants, in or out of bloom, Mr. J. Cypher was first for splendid specimens, some of the most conspicuous being *Croton Sunset*, *C. angustifolius*, *Kentia Belmoreana*, a magnificent plant; *Caryota sobolifera*, *Latania borbonica*, *Erica Turnbulli*, *E. Marnockiana* and *E. Eweriana*, Messrs. Heath and Son being a good second with much smaller but well grown plants; and Mr. J. F. Mould a moderate third. With eight Zonal Pelargoniums H. Chapman, Esq. (gardener, Mr. H. Sparkes), was first; Mrs. Lingwood (gardener, Mr. T. Lewis) second; and Mrs. Gillilan (gardener, Mr. A. Mansfield) third. All the plants were well flowered, but too formally trained. Eight Fuchsias.—First, Messrs. Heath & Son; second, H. Chapman, Esq.; third, Mrs. Gillilan; the plants in each case being profusely bloomed. *Achimenes* brought only one exhibitor, Mrs. Lingwood, who was awarded the first prize, an honour well deserved. *Begonias* were not of any particular merit, having the appearance of having suffered in transit.

Dahlias were very good, and the competition very close. For thirty-six varieties, distinct, Mr. T. Hobbs, Bristol, was first; Messrs. Heath and Son second; Mr. G. Humphries, Chippenham, third. Dahlias, twelve varieties.—Mr. F. Harris first; Mr. T. Hobbs second. German Asters, twenty-four blooms in twelve varieties.—Mr. S. Cooper, Chippenham, first. Mr. S. P. Budd, Bath, was a very close second. Mr. T. Evry, Bathiston, third. French Asters, twenty-four varieties.—In this class Mr. S. P. Budd was first, Mr. T. Evry second, and Mr. J. Townsend, Lower Broadheath, third. Roses, twelve varieties, cut in loose bunches.—Mr. J. Mattock, Oxford, first with beautiful blooms, and Mr. P. Rudd second; Messrs. Heath & Son third.

For black Grapes, two dishes, distinct, C. Lee Campbell, Esq. (gardener, Mr. S. T. Wright), Glewston Court, Ross, was first with fine bunches of *Alicante* and *Lady Downe's*; Canon Coventry (gardener, Mr. C. Froud) second with fine *Gros Colman* and *Black Hamburgh*; and Rev. G. Coventry (gardener, Mr. A. James) third. White Grapes, two dishes distinct, Canon Coventry first with well-finished *Muscats* and *Buckland Sweetwater*; Mrs. Southwood (gardener, Mr. F. Rea) second; Rev. G. Coventry third. In the other Grape classes Messrs. Hall, Butt, Campbell, Coventry, Cook, and Lawry were the principal prizetakers.

Collection of fruit, eight dishes.—H. C. Moffatt, Esq. (gardener, Mr. T. Spencer), Goodrich Court, was first with *Muscat of Alexandria*, *Madresfield Court* well finished, *Queen Pine*, *Williams' Bon Chrétien* Pears, *Moorpark Apricots*, *Princess of Wales Peaches*, *Hero of Lockinge Melon*, and *Jefferson Plums*; the Earl of Coventry (gardener, Mr. W. Child) second with a very good collection; W. A. H. Martin, Esq. (gardener, Mr. J. Bailey) third. Collection of four dishes.—Mrs. Lingwood first, Col. Rogers second, Mr. Greaves third. Plums, Apples, Pears, and Cherries were well shown, Earl of Coventry, Messrs. Moorman, Cypher, Campbell, Cook, Turk, Martin, Daubeney, &c., winning the chief honours. Melons were only fair, also Nectarines. Peaches, however, were well represented, Col. Rogers being the most successful in the two latter classes, and Canon Coventry with Melons.

Vegetables are always a great feature at Cheltenham, and they were up to the usual standard of excellence again this year. For nine varieties Mr. A. Cook was first with all-round good specimens, Mr. W. Evry coming second. For six varieties Rev. G. Coventry was first; Colonel Rogers second. Messrs. Sutton's prize for six dishes, Lord Sudeley first; Colonel Rogers second; Earl of Coventry third. The other vegetable classes were all well filled, and the competition close; Messrs. Webb's prizes for six dishes going to the Rev. G. Coventry, and Mr. J. G. Kitching, Burton-on-Trent. The weather was fairly favourable, the attendance appeared large, and it is to be hoped the Show was as great a success financially as it was in other respects.

## HARDY FRUIT GARDEN.

GATHERING FRUIT.—This is one of the most important operations connected with hardy fruit culture, especially with Apples and Pears that have to be kept a considerable time in the store room. If these get damaged before storing many of them will decay afterwards. It is also important that they should not be gathered before they are perfectly ripe. In order to ascertain when this is the case one or two fruits from each tree should be cut open to see if the pips are brown, and if so the fruit may be gathered at once without any danger of shrivelling afterwards, provided other precautions are properly observed in the fruit room. With Apples and Pears of the latest kinds, such for instance as *Alfriston*, *Wellington*, and *French Crab* among the former, and *Easter Beurré*, *Bergamot d'Esperen*, and *Nec plus Meuris* among the latter, it is not always possible to leave the fruit on the trees long

enough for the pips to colour much, through fear of damage by severe frost, and in late districts this year many kinds will probably have to be gathered before the usual state of maturity is reached. In all cases of this kind the fruit should remain on the trees as long as possible; a few slight frosts will not hurt it provided it is not handled until the day following, and when it is gathered a little extra care must be taken not to bruise it. Fruit should never be gathered into sacks or bags of any kind; always use moderate sized baskets and have them as smooth inside as possible. The kind called "Trucks" or "Bodges" in Sussex is one of the very best. They are made of broad strips of wood curved into a circular shape at the bottom and are easily moved about and emptied. No matter whether the fruit is to be stored or marketed at once, each one should be put carefully into the basket and as carefully taken out, for bruises are very easily made. In gathering from tall trees all the lower branches should be cleared first so that the fruit on them is not much damaged by the ladders, and in placing these against the trees they must be put as upright as possible so as not to break the branches. The fruit of both Apples and Pears should be separated from the tree by lifting it gently upwards, not breaking any portion of the tree away with it. If care is not taken in this matter the next season's crop may be seriously interfered with, as many of the flower buds will be destroyed. The season of all kinds of autumn Pears may be much prolonged by gathering a portion of each kind at intervals of a week or so, taking those off first which are most exposed to the sun. Where a continuous supply has to be maintained this system is of great service. Pears and Plums for market must not be over-ripe when gathered or they will not travel well, but must be gathered and packed early enough to keep in good condition while passing from the grower to the consumer. On the other hand they must not be sent off too green or the salesman will have them left for some time on his hands, and they will suffer considerably in appearance before a purchaser can be found. Never gather fruit of any kind on wet days or when it is moist from fogs or dews, no matter whether it is for market or for storing, and always grade and pack all kinds evenly. The smaller sizes are of no use either for market or for storing.

**STORING FRUIT.**—If Apples or Pears are to be kept until after Christmas in good condition, a building where frost can be excluded is absolutely necessary to store them in. If this is fitted with shelves so that the fruit can be spread out in single layers it will be much more convenient for inspection, and a smaller proportion will decay than would be the case if laid three or four deep. Much depends on careful ventilation, especially during the first three weeks after gathering. Many Apples will "sweat" considerably when first gathered, and if kept shut up closely will commence decaying, but after the sweating is over and the weather becomes cooler the ventilation must be diminished, merely giving a little air occasionally in very fine weather to change that of the room. A steady temperature of about 40° and a rather dry atmosphere are the chief points to aim at. In very severe weather the temperature may go as low as 36° without damage, but the room should always be a few degrees warmer than the outside atmosphere, or the warm air on entering will condense on the fruit, and probably do serious mischief. A room partly or wholly underground, if it can be kept dry, is the best position for a fruit store. Never use deal or strong smelling boards to lay the fruit on, and do not place hay, straw, or newspapers underneath it. In severe weather newspapers placed over the fruit will often prevent injury from frost, and dry clean hay or straw may be used in addition if it is impossible to heat the building in any way. Many people would be surprised to see how well the Kent fruit growers keep Apples in their hop kilns and store rooms adjoining, merely laying them in heaps a foot or 18 inches deep, and covering with straw in severe weather to keep frost away. They are never moved until required for market, as a rule very few decay, and they keep plump and good with but little attention.

Late varieties of Apples and Pears keep best if put away in drawers or boxes after they have lain for some time on the fruit room shelves. This will prevent the skin shrivelling and becoming tough, but they must be examined occasionally, and not shut up air-tight. Fruit that is to be kept should not remain in the baskets after gathering for more than twelve hours, and must then be put on to the shelves or wherever it is to remain until required for use or for market.

#### FRUIT FORCING.

**PINES.—Growing Stock.**—To maintain a healthy sturdy condition in young plants free ventilation on all favourable occasions is essential, affording it early in the day and without lowering the temperature. Keep the bottom heat about the roots at 80°, maintaining a temperature of 60° to 65° by night with 5° to 10° rise by day from fire heat. Newly potted plants should have a bottom heat of 90° to 95°, with a view to the roots speedily penetrating the fresh soil. Water the plants whenever they require it, employing weak and tepid liquid manure, and avoid the use of the syringe too frequently, merely sprinkling the paths and other available surfaces. Morning and evening will suffice in all but very bright weather.

**Suckers.**—Recently started suckers should as soon as roots are plentifully made be raised near the glass, it being essential that those intended to be wintered in small pots be brought on very gradually, but they must not be withdrawn from the bottom heat, or only for a short time, so as not to give the plants a check. When the suckers started this autumn are well rooted pot them, draining the pots well. Employ the fibrous part only of turfy loam, and do not tear it up too fine, but use it

in lumps proportionate to the size of the pots. The strongest plants may be transferred to the largest pots at once, the size of the pots being proportioned to the robustness of the plants or varieties. Jamaicas do well in 9 or 10-inch pots, Queens in 10 to 11-inch pots, Smooth-leaved Cayennes and similar varieties in 11 to 12 inches, and Providence in 13-inch pots, which will give fruit of the largest size. Where smaller plants and fruit are desired pots an inch or two less in diameter will answer. The plants not large enough for transferring to the fruiting size should be shifted into 8-inch pots, in which they must be kept until spring. Plunge the pots in a bottom heat of 90° to 95°, in which they must be continued until the roots have taken freely to the fresh compost, when they may be raised, a temperature of about 80° being afterwards sufficient. Fruiting plants should have a night temperature of 70°, 80° to 90° during the day, closing at 85°.

**PEACHES AND NECTARINES.—Trees Ripening the Fruit in July.**—The trees will now be approaching the resting period and the foliage becoming serc. Supply them with water so as to keep the soil moistened through to the drainage, but if the roof lights have been removed, the trees being in a condition to allow of its being done in August, they can remain off until the end of the year or later; but if the wood is not ripe it is not wise to expose the trees to heavy rains and snow. Assuming the wood is firm and the buds plumped it is advisable to remove the roof lights with a view to insure complete rest and the thorough moistening of the border. If the trees are very strong it is not desirable to remove the lights, and if the growth is complete and the wood not ripening kindly form a trench about one-third the height of the trees from the stem, and detach all roots down to the drainage, leaving the trench open for ten days or a fortnight, when it may be filled firmly. Young trees only require this, but older trees that have the wood very strong may be root-pruned and the roots wholly or partially lifted before the leaves have fallen. In the case of weakly trees remove the old soil from over and amongst the roots, supplying fresh rather strong loam with an addition of calcareous matter where the loam is not of that nature, making it firm and following with a good soaking of liquid manure.

**Trees Ripening the Fruit in August and Early September.**—Cut out the wood that has borne fruit, leaving no more than can be freely exposed to light and air. Cleanse the foliage of dust and red spider by water directed with force from a garden engine or syringe, and repeat occasionally. If there is scale promptly apply an insecticide, also against red spider and brown aphides, which sometimes attack the younger parts of the wood in autumn, and can be destroyed with diluted tobacco juice. There must not be any lack of moisture at the roots, therefore apply water to the inside borders as necessary to prevent their becoming too dry. Afford abundant ventilation, and if the wood is not ripening well keep the house rather warm by day and throw the ventilators open at night, but a warm, close, moist atmosphere must be avoided, as that would be more injurious than otherwise.

**Late Trees.**—When the fruit is gathered the trees will need to have the shoots thinned where too crowded, and those which have borne fruit and not required for extension can be cut out to a successional shoot at the base. This, with free ventilation and gentle fire heat in dull weather, in cold localities, and the wood strong, will assist in ripening the growth, which is of primary importance as regards next year's crop. Avoid a too dry condition of the border. The trees must not lack moisture, and yet a rather drier condition of the roots is advisable whilst the fruit is ripening. Some soft netting will be useful to save any fallen fruit, but it must be looped up in small pockets to prevent the fruit bruising each other. With an examination of the fruit every morning by an experienced person, the ripe fruit being removed, there is no necessity for the netting. The fruit is better gathered before it is dead ripe, and kept in a light airy fruit room until required. Prince of Wales is a magnificent fruit when grown under glass and in warm soils, but it is by no means satisfactory against walls and in heavy wet soils. Princess of Wales is, perhaps, the grandest of all late summer Peaches, attaining to a large size and assuming fine colour under favouring circumstances; and, though Sea Eagle is a pale fruit, its size and good qualities render it very desirable.

**CUCUMBERS.**—The plants for winter fruiting should be placed out as soon as they are ready, a good bottom heat being essential to success, whether it be obtained by the aid of fermenting materials or hot-water pipes; but a somewhat higher temperature is needed to commence with if fermenting materials are used, as the heat will decline, and there should be hot-water pipes in the bed to keep up the bottom heat when that of the fermenting material declines. The soil may consist of light turfy loam, with a third of fibrous peat, a sixth of old mortar rubbish, and a tenth of charcoal, the whole well incorporated. For imparting vigour later rely on liquid manure and surface dressings in preference to employing manure in the compost.

**Autumn Fruiters.**—Maintain a healthy and vigorous growth by a genial condition of the atmosphere. Avoid a close moist atmosphere by judicious ventilation, and do not admit cold drying currents. Keep the growths fairly thin, going over the plants twice a week for stopping and removing superfluous growths, being careful not to overcrop the plants. Be sparing in the use of water, especially over the foliage, but damp available surfaces in the morning and afternoon, gradually, however, reducing the moisture as the days shorten and the sun heat declines. Add a little fresh soil about once a fortnight to the hillocks or ridges previously wormed, applying weak tepid liquid manure once or twice a week as may be necessary. Fumigate on two or three consecutive evenings if aphides appear, and be careful not to give too much.

**STRAWBERRIES IN POTS.**—Watering the plants must not be neglected, but though plants in the open ground do not suffer from continued rains, yet those in pots are seriously injured by continued needless waterings; therefore only supply water as required, not allowing the plants to "flag," but permit the soil to become moderately dry before giving any, and then afford a thorough supply. This more particularly applies to the varieties intended for early forcing, which should soon be given the protection of frames, only using the lights in frosty weather, and to throw off heavy rains and snow, ventilating freely when the weather is mild. Any plants that have the soil very wet, and remain so for some time without watering, should have the drainage seen to, as worms, or the material on which they are placed, choke the drainage or outlet, rendering the soil sodden, in which no plant will thrive. Expel worms from the pots with limewater, and rectify the drainage where defective. The crowns are often numerous in some varieties, especially *Vicomtesse Hericart de Thury*, a number of small crowns clustering round the central one. Remove the small crowns sideways with a wedge-like piece of wood without injuring the leaves or central crown. This will concentrate all the vigour of the plant on the chief crown, and though there will be fewer trusses of bloom, there is no need to fear a deficiency of crop. There is nothing like a loose surface for Strawberries in pots, which prevents the soil leaving the sides of the pots, and admits of the water passing evenly through the ball, moistening the soil thoroughly. A little dried horse droppings or cow manure rubbed through a quarter-inch sieve applied to the surface of the pots will keep all right there. Remove all runners as they appear, also weeds, and do not allow the plants to suffer through want of room, giving them plenty of space for the full exposure of the foliage to light and air, which is essential to a sturdy growth and plump well developed crowns.

**Autumn Fruiters.**—Where early forced plants have been grown on through the summer, with a view to affording fruit in late summer and autumn, the plants will have the fruit well advanced in swelling, and will need encouragement with liquid manure up to time of the fruit showing colour for ripening, and when that takes place the plants should be placed in frames, especially in case of heavy rains, affording abundant ventilation, which will improve the quality of the fruit. Late forced plants of *La Grosse Sucrée* and *Sir Harry* are showing and swelling admirably, both being greatly in advance of *Vicomtesse Hericart de Thury*, which, though a free bearer, is small, yet very handsome for jellies, and when well thinned the fruit is improved in size whilst the quality is superior. Any of the autumn fruiters not required for some time yet may be retarded by placing them on a north border. Good fruit may be had by taking up some of the most promising of the planted out forced Strawberries, lifting them carefully and placing them in rich compost in pots. Arrange them in a frame kept close until they have pushed fresh roots, then ventilate freely, and afterwards place them on shelves near the glass in a house with a minimum temperature of 50°, and afford a free circulation of air.

#### THE FLOWER GARDEN.

**Flower Beds in Wet Weather.**—Once more the Tuberous Begonias have demonstrated their superiority and reliableness, in wet seasons especially. Heavy and continuous rains appear to benefit them rather than otherwise, whereas the Zonal Pelargoniums present a very sorry spectacle. Begonias ought always to have good room, and if any less ornamental plants are encroaching on their space trim them back at once. Marguerites are growing far too strongly, and in many cases might with advantage have a spade or long trowel run round them 6 inches clear, or rather less, of the stems so as to cut through many of the wide spreading roots, this checking top growth considerably, and they will also lift more readily later on. If the tops of these, as well as the stronger growing *Heliotropes* and rank Zonal Pelargoniums overgrow less vigorous plants near them it is advisable to trim them back somewhat, as we may yet have a brief period of dry, summer-like weather before frosts intervene. Bedding Asters, notably those of stiff, erect growth with broad flat flowers, have failed badly and are now not fit to occupy prominent beds or borders. In some cases they ought to be cleared off and the beds temporarily filled with mixed pot plants.

**Propagating Zonal Pelargoniums.**—Cuttings are only too plentiful, but they are very sappy, and more than ordinary pains must be taken or they will strike badly. A start ought to be made at once. Abundance of cuttings may be taken off without greatly disfiguring the beds, a dry day being chosen for the operation. After the cuttings have been denuded of most of the older leaves and trimmed to a joint lay them in a dry sunny place till they flag considerably, the wounds also drying. Thus getting rid of much superfluous moisture is a step in the right direction, but this is not enough. The watering after they are inserted in either pots or boxes must be deferred for several days, only enough being given to keep the cuttings from shrivelling. The commoner varieties, or those of a somewhat vigorous habit, will winter fairly well in pans and boxes; but the more delicate sorts, including the variegated and bronze Zonals, will not. Three-inch or slightly larger pots will each hold six or seven strong cuttings, and but few of these damp off during the winter. Added to this they can be arranged very thickly on suspended and back shelves in vineries, Peach houses, and other structures from which frosts are excluded, and cuttings well established in small pots also keep the best in frames and pits. It is not good policy to place the cuttings in the open this season, saturation of the soil being fatal to sappy cuttings, and the least that can be done is to set them in dry pits or frames till they are well rooted. The more

delicate tricolors and bronze Zonals struck late do not often winter satisfactorily, and with these the wiser practice is to leave the plants intact, taking care to lift and store them somewhat thickly in 7-inch or rather larger pots before they are frosted. Kept in a warm dry greenhouse few or no plants will be lost, and a good lot of cuttings be available next spring.

**Propagating other Bedding Plants.**—If no *Iresines*, *Alternantheras*, *Coleuses*, or *Heliotropes* have been kept in pots no time ought to be lost in propagating the requisite number of stock plants. There are plenty of soft young tops, and if some of these are duly made into cuttings and inserted thinly in 5-inch pots, the latter being well drained and filled with light sandy soil, they will strike quickly in a fairly brisk but not too moist heat. Cuttings from the open air plants are apt to damp off if kept too close or moist, as they are very different to the less succulent cuttings obtained from pot plants. Should the cuttings fail to strike then must the required number of old plants be potted up before frosts have crippled them. Shrubby *Caleolarias*, *Gazanias*, and *Violas* need not be propagated before October, late struck plants wintering the most surely in cold frames or pits.

#### PLANT HOUSES.

**Crotons.**—Plants that have fine heads and have become bare at the base may be partially cut through and mossed. Where they can be kept close and moist they will quickly throw out roots, and be well established in small pots before winter. Good heads mossed and rooted now make capital plants for growing on early in the year, when large finely developed plants are needed. Large pieces can with certainty, and without losing a single leaf, be taken off by this method, and are soon ready again for table and other forms of decoration. All side shoots that are rooted, and are needed for table decoration or single vases, have the heads removed after they commence forming large bold foliage. It is only by constant re-rooting that good supplies of well-furnished plants can be kept in the best possible condition in a small state.

**Acalyphas.**—Plants that have grown too tall may be mossed in the same way as advised for Crotons. Although good heads of these plants root with certainty in a suitable place, large plants can be obtained more quickly by the mossing system. There is no difficulty in taking off heads fully 18 inches in length with large bold leaves from the base to the top. If well rooted in the moss they only need a shady position for a week or ten days in a close warm atmosphere. The same remark applies to Crotons, when both may be again gradually exposed to the sun. Small well coloured pieces of these plants as well as Crotons may be rooted in small pots, for they will be found useful during the winter in association with small Ferns and Mosses.

**Panicum variegatum.**—Quantities of this plant should be rooted in small pots, the cuttings being inserted thickly and placed into the propagating frame until they are well rooted. Although these plants do not last long in good condition in rooms during the dark days of winter they are nevertheless useful for edging groups and near the margin of baskets that have to be filled with plants. Variegated forms of *Tradescantias* may also be rooted in quantity in boxes as well as in small pots. When in the latter insert the cuttings thickly, and repot them after they attain a length of 5 inches. They root quickly in any close warm position.

**Coleuses.**—Bright coloured varieties are also useful in 2-inch pots; for this purpose good heads only need be rooted and not pinched afterwards. When they grow too tall they may be re-rooted. They strike freely on a shelf close to the glass in a warm house if well watered and shaded from the sun. *Coleuses* do not last long, but they are easily raised, and are invaluable where many small plants are needed.

**Caladiums.**—Some of the earliest plants are beginning to naturally lose their foliage; these should be allowed to rest. Gradually decrease the supply of water, but do not prematurely send them to rest or place them in a cold position, as under such conditions the tubers are liable to decay. In a temperature of 60° they will be safe. Late vineries where heat is still maintained are capital places for them. Plants of *Caladium argyrites* that have had a long season of rest may be started into growth. Remove the old tubers from amongst the old soil and pot them into fresh. The most suitable sizes are 3 and 5-inch pots. After potting plunge them in the propagating frame and cover the surface with cocoa-nut fibre refuse until the plants start into growth. These plants are not only useful in pots, but the foliage is invaluable for cutting during the winter and spring months when flowers are not too plentiful.

**Selaginella Kraussiana (S. denticulata).**—A good number of 3, 4 and 5-inch pots can be made up now. The best method is to fill the pots with light soil slightly raised above the rim and dibble small pieces thickly over the surface. They grow quickly if kept moist and shaded, often succeeding as well on the floor of moist houses as when given more favourable positions.

**Gloxinias.**—Gradually withhold water from all that are showing signs of going to rest. Do not ripen them too quickly. Repot seedlings into 4 and 5-inch pots. Those that are still small should be grown on a shelf where they can enjoy a little warmth. With care these plants may be had in flower throughout the whole year. Tubers that have enjoyed a fair season of rest may be started again into growth. If a few are started at intervals of a month a long succession of flowers will be obtained.

*Gardenias.*—Thoroughly clean all plants that need it, and expose them to full light and sunshine. Do not pinch the shoots again. Insert cuttings of young growing shoots for another season's stock of plants. Where cuttings have already been rooted transfer them singly into small pots.

## THE BEE-KEEPER.

### NOTES ON BEES.

#### FEEDING BEES.

As we have taken all the honey the bees had stored for their winter use no time must be lost in feeding them up, but not too fast, or the combs may break down; a pint of syrup of an evening will be sufficient. What is called a fast feeder should be used, as the bees get the syrup down from this with less trouble; these can be obtained from any appliance dealers, but be careful to see that they have a tin tray, or there will be trouble with their leaking. At a future time I will give illustrations and a fuller description of feeders.

#### CONTRACTING THE ENTRANCE.

Before leaving the hive, after having put on the feeder and made all warm and secure at the top, the entrance should be contracted to about an inch in width, which the bees can more readily protect than if wider, for it is likely that robbers may be attracted by the excitement caused by the feeding.

#### THE NUMBER OF FRAMES TO BE USED.

The following afternoon, before filling the feeder, examine the frames, and ascertain how many frames the bees can cover on both sides; crowd them on these, that both sides of the foundation may be drawn out at the same time by putting a dummy on either side of the required number. If these instructions are attended to and the bees regularly fed every evening they will be built up into a strong colony before winter, and come out strong in the spring.

#### FRAME HIVES.

If there are already several frame hives in the apiary an additional colony is easily established by taking a comb or two from each, furnishing the new colony with six or seven frames full of combs instead of frames of foundation.

#### SAVING THE BEES LABOUR.

The less work the bees have to do at this season of the year the better will they go through the winter, and the least spring dwindling will there be. If the frames of comb are supplied to them they will not be called upon to secrete any large amount of wax at this time of year. Should we have any spare combs we need not rob other hives. The bees may be saved considerable labour by having the combs filled ready for them. The following is a simple way of doing this, which I suggested at one of the conversaciones of the British Bee-keepers' Association.

#### FILLING FRAMES WITH SYRUP.

Take a box the depth of a hive that will hold two or more frames side by side, and hang in the frames as they will be in the hive; put it on a table as nearly level as possible, then pour the syrup very gently into the box at one end; as it rises in the box the cells will be filled, the air being driven out as the syrup rises. The bees, when put in the hive as before directed, will soon clean up any syrup on the sides of the frames, and will in due time seal up the syrup.

#### PURCHASING DRIVEN BEES.

At this season of the year any quantity of driven bees can be obtained from 1s. to 1s. 3d. per lb., with their queen. Four to five pounds will be sufficient to establish a good colony if treated according to the above instructions.

#### FOUL BROOD.

As there are many districts in which foul brood exists, great care is required, and a written guarantee should be had with any bees purchased that those in the apiary are healthy and that the neighbourhood is free from foul brood.—JOHN M. HOOKER.

### ARE PUNICS ROBBERS?

On page 253 "A Lanarkshire Bee-keeper" seems satisfied that Punic bees are determined robbers, although I have several times stated the contrary. It certainly seems strange that I have not noticed this "robbing" propensity with thirty stocks headed with imported queens, besides hybrids; and if "A. L. B. K." had not given the clue by saying, "I contracted the entrance of every hive," I should have been at a loss to account for the difference of opinion between us. Now, strange as it may seem, I have several times proved conclusively that nothing incites what is called "robbing" sooner than a "contracted entrance" in any variety; enlarge the entrance, and robbing will quickly cease, the reason, of which I will explain under another heading.

Amongst the qualities of Punics I say "they search out sweets and carry them off anywhere," and so strong is this instinct developed in them they will just swarm on exposed honeycomb when honey is plentiful, at which time it is well known native bees will not touch it. Another thing, if a piece of honeycomb or other sweets is exposed, or even given to any other race of bees, Punics will quickly take sole possession; they do not seem to fight for possession, but work themselves in until they are packed so close round it other bees cannot get in. Bottles of syrup inverted on hives will quickly have a thick rope of bees round the neck, while a bottle of syrup covered with a piece of glass stood right way up will soon be found full of bees, having got in by forcing the glass up and creeping in. I think it is this propensity which our friend has noticed, and has mistaken for "robbing," or which I should call stealing. What I mean is—bees that prefer to gather their stores from other hives instead of in the proper way, as I have often noticed Italians and Cyprians do, particularly Italian hybrids, fetching out the honey as fast as the industrious bees collected it. I do not call it "robbing" to clear out exposed combs or an unprotected hive, but while the combs are protected with bees—even a very few—and bees excited over feeding bottles on a few hives, I have not known of one case in which a weak but protected lot of bees have been cleared out or even attacked, providing there was no excitement inside.

#### SMALL ENTRANCES INDUCE ROBBING.

Some years ago I explained the cause of this—viz., that when the entrance was too small the bees had to do extra fanning to ventilate the hive, and bees had to spread themselves out more on the combs. This fanning attracts strange bees either by the noise or smell of the exhalations. I am about sure it is the noise, and they seem to regard the stock as one in which they can enter and carry off what they like. Expand the entrance or set up a current of air through the hive, so that it can be ventilated without so much fanning, and the bees soon put themselves in order to protect their property.

The orthodox entrance is one,  $\frac{3}{8}$ -inch high by 6 inches long, with slides to contract it, so that only one bee can pass at a time. The proper kind of entrance should be  $\frac{3}{4}$  inch or 1 inch high, then cold air can enter at the bottom and warm air pass out at the upper edge without any fanning by the bees. It is not the length of entrance that is wanted so much as the depth. When people ask me what kind of an entrance is best I tell them "One that a rat can get through, and the worst one that will keep a mouse out." Years ago I used to be much troubled with so-called robbing, but as soon as I was satisfied that entrances  $\frac{3}{8}$ -inch deep was the cause I have not been troubled since at any time or by any kind of bees, though I have been much troubled by some kinds fetching honey out of hives when bees have been busy gathering it, at which time they do not seem to protect themselves.

A very large or wide entrance has never in my experience provoked an attack or failed to stop one, but when too wide or too large it reduces the internal temperature too much; hence I do not expand more than is necessary, and if "A. L. B. K." will act on this hint, I think he will fail to prove Punics to be "robbers."

#### SIZE OF PUNICS' HONEY SAC.

"A. L. B. K." wishes my help in investigating the size of this, which is certainly very much larger in proportion to their size than

any other bees. I think Mr. Bonner-Chambers would be more fitted to do this work than I should, and I suggest that he prepare a table, giving the weights of 1000 bees of each variety, with full and empty honey sacs. I don't think Punics will be found to have sacs larger than others, but I am satisfied that their sacs are as large as those of any other race, and they can carry this heavy load with the greatest ease. Nuclei I left at home for queen-rearing have filled their combs with Heather honey, the nearest point to which was fully five miles, and what is more they did not "drop" in a tired condition when they reached home. The honey was Heather honey, so there was no doubt in the matter.

#### THE HEATHER HONEY HARVEST—PUNICS V. NATIVES.

Owing to the bad season all Punic queens, whether old or young, had ceased laying, and all brood was hatched when work was begun on the Heather for the first time this year on September 7th—a month later than it should have been. I left home for a few days, paying them another visit on the 12th to find all empty combs full of honey, averaging 5 lbs. weight each. A friend has an apiary of natives close to my Punics, so I was able to compare one with the other. I did not notice that Punics had more honey than natives compared to their numbers, as I could not expect them to do during a Heather glut, when it is like getting honey from lakes, not casks; but I did find a vast difference between the two kinds. Natives had worked from the centre, filling up the brood nest, completely crowding out the queen, which means a few old bees for winter and no empty comb to cluster in. Punics had worked from the outside of brood nest, well filling supers and outside combs. The queens were again in full laying with large brood nests, and even lots of drone eggs had been laid; this, of course, means lots of young bees and empty combs for winter, without honey all round them. Abbott once had an idea that bees put their honey the farthest from the entrance, but no one has ever verified it till now. Punics do this, going into and working in supers at once, in preference to storing honey below, reserving this for the queen until they are crowded out for honey space. All who have tried Punics agree that they take to supers the quickest and work in them the best; Carniolians and Cyprians are worse than natives in this respect. Of course I am not yet ready to compare the two kinds for the season. The weather suddenly changed on the 15th, since which it has been unsettled, which will give Punics the advantage.

#### THE VALUE OF THE HEATHER TO BEE-KEEPERS.

There is an idea that one has to live near the Heather to reap any benefit from it, while as a matter of fact there is not a place in the British Isles that it would not pay well to send bees to the Heather, even if they had to be all sent to Scotland, providing they were in hives that could be made safe for the journey. Where do we find any hives exhibited at shows that can be sent even short distances with profit to the moors? Five or six hives are as many as can be taken at once, and this number requires more trouble to pack than the profit would come to. Most of my hives are on the "long idea" type, double walled, holding twenty frames in bottom, yet I can load up sixty on a dray, with supers on, roofs, and stands. When I see people explaining the wonders of some of the hives at shows it is a fine joke to just ask how they are packed up for a journey to the Heather.

The Heather honey harvest is more certain and more plentiful than any other; it practically failed in 1888, was bad in 1885 and 1881, but I know of no other failures the past fifteen years, while some years, such as 1883 and 1884, the flow lasted four weeks; 1886, 1887, 1889, and 1890, each lasted seven days only; but seven days flow is quite sufficient to fill all combs covered with bees.

How are bee-keepers to reap the advantage of the Heather if they can't get hives? It is as easy and cheap to make hives adapted for migratory bee-keeping as any other if makers knew how to make them.—A HALLAMSHIRE BEE-KEEPER.

#### BEEES AT THE MOORS.

THE fine weather which we experienced from the 8th up to 13th September gave way to showery weather on the 14th, and has continued since, giving seven fair days only for upwards of two months. As I am preparing for returning home with my bees my time is limited, and the stock of paper exhausted, necessitating brevity, and I must delay my latest experience with regard to robbing bees and test trials with Punics and other varieties till another issue.—A LANARKSHIRE BEE-KEEPER.

\* \* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Mildew on Vines (F. J.).**—The name of the mixture—Anti-Blight—was mentioned in the article, also the London agent, Mr. Peter Barr, and particulars for using are supplied with the material. We are informed by a gardener that it has destroyed the mildew on his Vines. Mr. Barr's address is 12, King Street, Covent Garden, London.

**Abnormal Peach (J. Selden).**—The specimen you have sent is curious, but not unusual. It is caused by the union of two ovaries, one of which has undergone but a partial development, while the other has assumed the normal size and form. We are glad to know that you have been so successful by following the instructions we gave you on the management of your Vines.

**Muscat of Alexandria Grapes Shrivelling (B. C.).**—The cause of the berries shrivelling is a deficiency of moisture until they were sufficiently advanced in ripening, with probably a deficiency of heat and of light to insure their thorough maturity. The check consequent on the breakdown of the heating apparatus a month ago is sufficient to account for the shrivelled condition of the berries, as they were imperfectly swelled and ripened. Nothing will now restore them to freshness, but we presume the shrivelling is confined to the small berries, the larger ones being plump. Make sure that there is no deficiency of moisture in the border. If fairly moist it is sufficient; if dry afford a supply, covering with dry material so as to prevent evaporation.

**Rods of Vines (I. M.).**—You ought to cut away the rods of the old Vines as soon as the leaves have fallen, and the young canes may be trained in their place. It is not wise to treat the Vines on the annual rod system. We should cut the present canes back to a third the length of the rafter, and depress the upper part before the eyes start, so as to cause the lower buds to break, and when they have done so the cane may be secured in position. Train up a shoot from the upper part in continuation of the rod to the top of the house, and this may be treated similarly to that of the previous year. In this way you will have a new rod in three years, the fruit will be borne on spurs after the first year, and they can hardly fail to fruit satisfactorily for some time, only do not keep them too closely pinched, and do not prune closely. The long rod system is not suitable for general practice, but a modification of the rod-and-spur system is most advisable as securing the best results.

**Beetles (Subscriber).**—The beetles you enclosed for our inspection are examples of a species called *Mezium striatum*; it is considered a native, though some entomologists regard it and another kindred species as being originally importations from abroad. It is singular that you should suppose the specimens are foreigners, because if you are right visitors of the species do arrive here from afar, and it may not be indigenous. The species is curious because of its globular body, almost hiding the head, and wing cases thickly covered with a glossy velvety pile, which is of two kinds, and soon rubs off; also it has much the appearance of a spider. Usually it is found about cupboards or closets in old houses, and like its not very distant relative the death-watch (*Anobium*) has been presumed to be a feeder on wood. Presumably you have found it injuring woodwork, but it is quite likely this beetle might be caught in the act of attacking seeds or dry fruits.

**Black Hamburg Grapes Shank and Shrivelling (F. B.).**—There not being any artificial heat in the house for a fortnight previous to the 21st of August, and the weather being dull and showery during that time, would not cause the shanking and shrivelling nor the Grapes to damp had there been a little ventilation so as to permit a circulation of air. The hot sunny weather following the previous low temperature would aggravate the shanking and shrivelling by inducing increased evaporation from the surfaces of the Vines; but that is not the cause of the Grapes finishing badly. The attack of red spider in the month of July amply accounts for Black Hamburg Grapes shrivelling and shanking in the same house and under the same conditions where Lady Downe's Grapes do neither. The latter has very much more substance in its leaves, its whole constitution differs from that of Black Hamburg, and it seldom suffers from red spider like the thin-textured foliage of many other Grapes.

THE value of good leaf mould for naturally heavy soil to mix with other ingredients as a compost for pot plants, and to utilise as a root-producing medium in a great variety of ways, can scarcely be over-estimated. I say good leaf mould, because much of the material used under that name is an unwholesome decaying mass of humus, abounding in injurious fungoid growths and minute insects, which render it totally unfit for plant food. To use such material when preparing the soil for plants in pots is to court failure, and even when mixed with the soil for outdoor crops it in time causes the bulk to become so sour that roots make very slow and unsatisfactory progress in it. To make matters worse the few roots which are formed speedily become a prey to the insects, which rapidly increase while the roots diminish, and before such soils can be again brought to a fertile state they must either be burnt, or receive heavy dressings of lime and soot to kill the insects and sweeten the soil. It may be thought that this is a rather sweeping assertion, but having seen the mischief wrought by using unsuitable leaf mould, I am convinced that so erroneous a practice cannot be too strongly condemned. In all cases where leaf soil is used it should be thoroughly examined to see that it is free from insects, and not in too advanced a state of decay. When in the best condition for use it is somewhat tough, and yet sufficiently decayed to allow of its being easily rubbed through a sieve, and still retain something of a "springy" nature. Roots will speedily take hold of such material as this, and form a perfect network around the small particles, from which they soon extract the fertilising properties, and ramble in search of another supply.

There can be no doubt that the best of all leaf mould is obtained under trees where the leaves decay in a natural way, each succeeding year's growth falling upon and covering the last, being thus disposed in thin layers, so that the air and rain can reach them; they are in all stages of decay in the sweetest possible condition. Anyone who can obtain this kind of leaf soil from the woods should use it in preference to that obtained from any other source, and the way in which healthy rootlets permeate this wholesome material, which remains in a sweet condition for a long time, should speedily convince them of its great superiority over leaf soil formed in a heap in which fermentation takes place, and from which, to a great extent, the sweetening influence of the oxygen of the atmosphere is shut out.

Few, however, are so favourably situated as to be able to command an unlimited amount of leaf soil of the best description, but they can do much towards securing a good substitute for it by collecting leaves into a heap and giving them the right treatment while they are in a state of decomposition. At the present time of the year, when leaves are beginning to fall in abundance, provision should be made for placing a good quantity in a heap where they can be turned several times during the course of the ensuing year, and kept regularly moist to induce continuous decay. Where no sheltered position in which they can be placed without fear of being scattered by winds already exists, a few hurdles, or, better still, a strong wooden fence can be formed into a square, and the leaves placed therein as they are collected, scattering them over the whole surface as they are placed there, keeping them as free as possible from sticks, which create fungoid growths. Occasionally

they should be trodden firmly so as to avoid rapid fermentation. They will require no further attention till the spring months, when decay is visibly taking place. Turn and thoroughly mix them, water being applied as the work proceeds. If they are in the least dry let them remain loosely together without treading, as there will be no danger of excessive heating by fermentation.

The heap can remain in this state till the end of the following September, when it may again be turned, and by this time the leaves should be in a half-decayed state, and may, if the room is required for other leaves, be removed to an open position, as the greater density of their bulk will prevent their being displaced by wind. At this stage a few insects will probably be noticed, and the addition of a little soot will destroy many of these, and also add to the richness of the soil. If it is desirable to hasten decay as much as possible to have a portion of it ready for use a little lime may be added to each layer. This will sweeten it, and have the effect of causing rapid decomposition; but this will be accomplished slightly at the expense of the richness of the leaf soil, though considering the sweet and wholesome condition of it the apparent wastefulness of the practice is not worthy of serious consideration.

Leaves which have been used for supplying bottom heat in the Pine pit till they are thoroughly decayed, are sometimes mixed with soil for plants in pots without further preparation. This practice cannot be too strongly condemned, especially in cases where the whole of the leaves are not renewed annually, but where a portion of the old ones are mixed with the new, this part is generally full of minute insects, which speedily increase and spread throughout the whole heap. Where there is no alternative but to use this material I have found the only safe course to pursue is to place it in thin layers on the top of a boiler or flue, where it gets thoroughly dried and every insect destroyed; a little water is then applied, and the whole well mixed together before using. And I may here slightly diverge from my subject to say, that when there is the slightest suspicion that any soil required for potting purposes is infested with insects of any kind, burn in the way described before using. This simple preventive would be the means of avoiding many failures which are at times recorded.

The uses of leaf soil are manifold, and there are many ways of using it with advantage, which are not thought of by cultivators generally. When in a half-decayed state it forms an excellent mulching for Vine borders and all kinds of fruit trees, especially in cases where roots are not abundant, and it is absolutely essential to attract them to the surface. I know of nothing in which the roots of Vines and fruit trees will root so readily as in leaf soil. At various times, when requiring small quantities for special purposes, I have carefully removed some from Vine borders which had a few months previously been covered with half-decayed leaves, and invariably found them closely matted with roots just under the surface, and I am confident that in many cases a top-dressing of similar material would be of more benefit to fruit trees than the crude manure often given, as roots will not penetrate it until it is in a more advanced state of decay.

For forking into flower beds and herbaceous borders, or for use upon seed or nursery beds in the kitchen garden, leaf soil is also invaluable. For mixing with other soils for pot plants it is in constant demand, and wherever any quantity of plants are grown in pots a heap should always be kept in a suitable condition for constant use. Although almost any plant in cultivation will thrive exceedingly well in a compost in which it is freely intermixed, yet great discrimination is needed to use it in proper quantities on different classes of plants, as it produces quick healthy growth, but is not lasting in its effects. It should, therefore, be sparingly used for plants which are to remain undisturbed for several years, or it

is apt to get into a sour state. Heaths and other hardwooded plants, except the strongest growing kinds, do not require it when good peat can be obtained. The enormous quantities of Palms and *Dracænas* imported into England from the Continent are generally grown almost entirely in leaf soil, and the splendid growth which they make shows that it suits them in the earlier stages of their growth; but if this treatment were followed by using similar material at each successive potting it would be found that by the time the Palms had been placed into the largest sized pots the compost was not a sufficiently lasting nature, and much of that used at the earliest pottings would be sour and exhausted, and the Palms would soon get into an unhealthy state in consequence. Trade growers are well acquainted with this fact, and when they receive their consignments from abroad those that they intend to grow are transferred into larger pots, using a compost of two parts turfy loam to one of peat or leaf soil. In this mixture they produce grand specimens. For softwooded plants which are shaken out annually and repotted a liberal admixture of leaf soil is of the greatest benefit. *Fuchsias*, *Primulas*, *Pelargoniums*, *Cinerarias*, *Calceolarias*, and a host of other plants of similar type, as well as *Abutilons*, *Acalyphas*, *Cannas*, *Selaginellas*, and *Panicums*, all thrive well in a compost in which leaf soil is used at the rate of one-third to one-half of the whole. During the earlier stages of the growth of these and other plants and for all seedlings, it may, with advantage, be used in a still greater proportion, as among the many substances which I am acquainted with there is nothing to equal sweet properly prepared leaf soil as a medium for producing abundance of healthy roots and quick vigorous growth in young plants.—H. D.

### MARKETING PEARS.

THERE is such a glut of common early Pears, notably *Williams' Bon Chrétien*, *Windsor*, *Hessle*, and *Autumn Bergamot*, that they scarcely pay for gathering and sending to the nearest markets. Naturally this is disheartening, especially to those who have had no previous experience in the matter of marketing fruit; but if the common fruit is not a profitable crop this season it does not follow that the later varieties, or those that will pay for being stored for a time, will not fetch remunerative prices. Personally I am of opinion that even the "*Williams*" might be disposed of at something like a profitable rate if only the growers had a little more enterprise. Hereabouts, instead of sending to Bath, Bristol, Taunton, Frome, Yeovil, and Trowbridge, where they fetch very little indeed, the attempt ought to have been made to find better markets in South Wales, the inhabitants of Cardiff, Merthyr Tydfil, Swansea, Aberdare, Dowlais, Newport, and other populous towns and suburbs not being well supplied with fruit generally. If the south-western counties cannot find a suitable outlet for their abundance of fruit in South Wales then no good markets will be found anywhere. When, however, we come to deal with the better samples of fruit than ordinary orchard trees will produce, then different tactics ought to be pursued. These should not be indiscriminately muddled into sieves or baskets and marketed in an equally haphazard fashion, the better plan being to sort them into at least two grades, the best being sold to the high-class fruiterers; the others, fetching much the lowest prices however well it may be handled, being sent to the larger markets, or those say from which the wage-earning classes derive their fruit supplies.

What sells readily in most large towns and Covent Garden market are superior samples of large showy varieties, these not necessarily being of superior quality. For instance, well-grown fruits of the coarse and gritty *Duchesse d'Angoulême* will, if properly consigned, bring as much as 6s. per dozen, this being three times what would be given by the same fruiterer for good average fruit of *Marie Louise*. *Doyenné du Comice* fortunately is both showy and superior in quality, and for the best samples 6d. each can usually be obtained, though to a connoisseur they are worth far more than the best *Duchess* ever grown. The showy *Beurré Clairgeau* also sells readily, and the best samples of *Beurré Diel*, *Maréchal de Cour*, *General Todleben*, *Doyenné Boussoch*, and *Pitmaston Duchess* can always be sold to advantage. Extra fine fruits of the last named being somewhat of a sensational character will, if properly placed, fetch quite fancy prices, or say from 12s. to 18s. per dozen. Even the somewhat despised *Vicar of Winkfield* if grown to its full size on wall trees sells readily at good

prices, and those among us who are able to grow *Glou Morceau*, *Chaumontel*, and *Easter Beurré* to near the same size these varieties attain in the Channel Islands may always reckon on a good sale.

Much, as may be gathered from the foregoing, depends upon the way the fruit is placed upon the market. There must be no trickery, no attempt to palm off a heavy consignment of fruit with a few of the very best displayed on the top as being all of the same quality, and more than ordinary pains should be taken in gathering, storing, and packing. It is too late to enlarge upon the folly of overcropping, and I will, therefore, merely add that this phase of "gardeners' greed" invariably brings its own punishment in the shape of a heavy weight of inferior fruit, which sells badly and takes far more out of the trees than does about one-third of the number of fruit of full size and of six times its value. In each case sound judgment must be exercised in the matter of gathering, storing, and marketing the fruit. If dragged from the trees too soon shrivelling invariably results, while if left a few days too long many may drop and be spoilt in one night, and in any case they rarely keep so well when left on the trees till the dropping stage is reached. Large fruits not being plentiful, few care to test them by cutting one or more open occasionally in order to see if the pips are nearly or quite brown, a good test of fitness, and the only other alternative is to gently lift them out of the perpendicular position. If the footstalks part from the tree readily the period for gathering has arrived, otherwise the fruit must be allowed to hang a few days longer. *Beurré d'Amanlis*, *Beurré Superfin*, *Doyenné Boussoch*, *Souvenir du Congrès*, and *Pitmaston Duchess* are among the first of the best marketing Pears to be fit to gather, these maturing much in the order they are given. Then comes *Louise Bonne of Jersey*, *Doyenné du Comice*, *Marie Louise*, *Maréchal de Cour*, *Duchesse d'Angoulême*, *Beurré Clairgeau*, *Beurré Diel*, *Vicar of Winkfield*, *Chaumontel*, and last of all *Glou Morceau*. As will be gathered from this I do not believe in any wholesale clearance of the trees, but prefer rather to treat each variety separately.

Every fruit ought to be handled carefully, as some of them are very tender skinned, and a bruise detracts greatly from their value, all being stored thinly on clean newly papered shelves in a dry but not very airy room, the finest fruit in a single layer stalk end uppermost. Not till the fruits are commencing to change colour should they be consigned to fruiterers or salesmen. If this period is anticipated lower prices will be returned, for the simple reason that but few fruiterers can afford to store much fruit till it is fit for use; while on the other hand if the Pears are kept till fully ripe they may travel badly, and in any case do not often sell well owing to the extra risks run by the buyers, who always prefer something that will keep long enough for all to be sold at best prices. All the selected fruit ought to be wrapped separately in squares of kitchen paper, and then be packed in one, or at the most two, layers in a box, plenty of paper shavings, soft wood shavings, dry soft moss or the softest chaff being interspersed among them so as to prevent rubbing or bruising, the lid shutting down tightly on a top layer of the packing material used. The small square boxes used by the Channel Island growers, these holding, say, one dozen of the finest fruit, show the latter off to the best advantage, and Pears thus packed fetch the highest prices in the market. Such boxes can be bought very cheaply now-a-days, being made to order in Bristol and elsewhere, and in the long run are much preferable to any that may be bought of grocers. This method of marketing fruit will have eventually to be adopted by all who would succeed in marketing choice fruit, and the sooner it is adopted generally the more quickly will the foreigner be shut out or rather beaten out of our markets. By the term foreigner I do not mean to include our fellow countrymen in the Channel Islands and elsewhere, but I would like to see the rest fairly beaten out of the field, and hold it is only by improving our methods of marketing fruit that this can be done.

The question next arises, What shall be done with the smaller fruits after the best specimens have been separated from it? It is this difficulty, if such it may be termed, that has prevented so many fruit growers from adopting the plan of making different grades, the impression being that it pays best to keep all together. No greater mistake could well be made. At the outset I pointed out what could be done hereabouts with the second-rate fruits, and those who live in other parts of the country may well adopt somewhat similar methods, sending the finest fruit to fruiterers and salesmen in the larger towns, and getting rid of the rest nearer home. As far as private gardeners are concerned, most of these will find that very large Pears are not desired for home consumption, those of a medium size answering well. Then, again, there are a number of comparatively small varieties, which, though they will not sell well, are yet of very superior quality. Among these I would include *Comte de Lamy*, *Passe Colmar*, *Winter Nelis*, and *Josephine de*

Malines, and with good dishes of either of these on the table few employers will be disposed to grumble at the largest fruit of other varieties being sold.—W. IGGULDEN.

### HYACINTHS.

THE most useful of all Hyacinths is the Early White Roman, for with care and a little forethought a succession of its pure white fragrant flowers may be had over a period of nearly six months. They are seldom needed before the middle of October, and there is no difficulty in having them at that date. It may be thought that after the Dutch Hyacinths commence to flower they take the place of the Early Roman, and that is no longer required. The larger spikes, bolder bells, and attractive colour of the Dutch varieties are certainly superior for many forms of decoration; but for cutting they are not useful, as they are too heavy, and only in a limited number of arrangements can they be employed with effect, while the Roman is admirably adapted for such purposes. The small spikes that appear by the side of the larger ones in the case of the Dutch varieties, which the exhibitor is careful to remove as soon as they can be discerned, are far more useful to those who have flowers of various colours to supply in a cut state than such spikes as adorn our exhibition tables.

The Early Roman Hyacinth cannot well be dispensed with for cutting until it yields flowers outside under almost natural conditions. The culture is so simple that I need not go into details. It will suffice to say that successional pottings should be made at intervals of three weeks or a month from August until the end of October. The cultivator, however, must be guided by the condition of the bulbs; sometimes potting cannot be delayed so long as at others. Directly the bulbs show signs of gumming they should not be kept out of the soil, but potted or planted at once. At the time of the last potting plant a good number of bulbs close together in a sunny place outside, and others in a northern position. Those in the former should be planted so that handlights can be placed over them at different times to secure a succession to those grown in pots. The bulbs placed on a north border should only have protection from the time they commence showing the colour of their flowers. If allowed to expand without the protection of glass they might all be spoiled by rough stormy weather. If severe weather sets in after they appear well above ground it is advisable to afford them light protection by covering them with a little dry fern or mats, because I have known frost destroy the flowers, except one or two that had not advanced so quickly. If this plan is carried out flowers of the White Roman may be had until the end of March.

Market growers usually place them thickly together in boxes, and force them in large quantities, but the Roman Hyacinth is not forced in such numbers for the markets as was the case at one time. What home grower can purchase roots and compete with those sent from France, and sold early in our markets at 1s. a dozen bunches? Growing Roman Hyacinths for the market is little better than turning over capital, and to be certain that there is not a balance on the wrong side the bulbs must be bought cheaply and all forced by Christmas or the new year.

The single blue Roman Hyacinth was strongly recommended a few years ago as an early flowering variety, but many were disappointed, and this variety was condemned. It is said to be shy and not very effective. In colour it is pale blue, which is as good as that of many other Hyacinths that are placed in a foremost position. It is not effective as a pot plant from a decorative point of view, because it is too much like *Scilla nutans* in its habit of growth, and its straggling foliage hangs in a confused manner over the sides of the pots. If it is to be arranged with other well-grown plants of Tulips, Narcissus, and Dutch Hyacinths, its foliage needs trimming with the knife or shears before it is staged. The flower stems are rather too long, they need supporting after they have been out a few days or they fall about like the foliage. It certainly has many faults, but that of shy flowering cannot be added to them, for flowers are produced freely; two, three, and often more spikes appear from each bulb, and where blue flowers are appreciated in a cut state this variety will be found well worth growing, as the spikes are of a suitable size for cutting. Like the Bluebell or Wood Hyacinth, its foliage is produced before the flowers are scarcely visible. I have had it in flower directly after Christmas; but this does not give the plant a fair chance. It will not bear forcing, but should be allowed to come forward gently. Even under these conditions there is no difficulty in having it in flower by the end of January.

French Rose is another variety that was also said to be early. It may be described as having semi-double white flowers shaded faintly with rose, possessing, though in a less degree, the faults of the blue Roman Hyacinth. The plants should not be hard forced,

and may be had in creditable condition for the conservatory when the White Roman no longer adorns that structure. It is also useful for cutting, in fact for the latter purpose I principally recommend it.

The extreme beauty and usefulness of the Dutch varieties for exhibition, home decoration, including flower beds and borders in spring, scarcely call for comment. I shall, however, just glance at two varieties that I have singled out for special remark—one is *Homerus*, single red, and the other *La Tour d'Auvergne*, double white. They are not selected because they possess any striking features, either in colour, size of spike or bell that are not possessed by others; in fact the first fades from the bright taking colour that it opens with to one of a dirty hue quicker than any other Hyacinth that I know. *Homerus* is the earliest of red varieties to flower, and where coloured Hyacinths have to be in flower as early as possible in the season it cannot be ignored until a better flower and one as early or earlier can be found. *La Tour d'Auvergne* is the earliest of all Dutch Hyacinths. Its flowers when wired are invaluable in a cut state, and it precedes *Homerus* by a few days. When early forcing is practised the flower spike invariably commences to open at the top, and the result is miserable flowers. This is the cultivator's fault entirely. The mischief is due to exciting the plant too rapidly in its early stages, and the effect is only visible at the stage to which I have referred. In most instances the bulbs are placed in too high a temperature when they are first introduced into the forcing house. Nothing is gained by such a course, but, on the contrary, the spikes are ruined. After the growth of the bulbs has become green in a cold frame, place them in a vinery or Peach house just started, and although they appear to move slowly, they are starting gently, as they should do, and when once they are fairly moving, and growth is visible, they will bear the warmest structure that can be found for them if they are wanted quickly, but the structure must not be a dry one. Instead of losing time by starting them gently time is gained, and the bulbs flower sooner than if placed direct into strong heat.—W. BARDNEY.

### HEDGES OF ANNUALS.

I HAVE been a garden wanderer for many years, and as I love the art of gardening I generally keep my eyes open for any beautiful and natural patch that may chance to come in my vision. Many a time in my day dreams has an ideal garden floated before my eyes—a garden where climbing Roses, Clematis, Virginian Creeper, *Canariense*, Columbine, *Convolvulus*, and Ivies of different shape and hue vie with each other in rank luxuriance, and where beds of the good, old-fashioned Hollyhock, *Spiræa*, *Anemone*, *Delphinium*, and other herbaceous plants spread about in their wild beauty.

In the course of my wanderings this year I visited Grimston Park, Tadcaster, the gardens of which are somewhat famed for their excellence and neatness. There it was I saw the hedge about which I wish to draw the attention of your readers—amateur more especially than professional. A large flat of vegetable land was the view from the cottage windows early in the spring, and this not quite agreeing with the tastes of the inmates of the house a packet of Sweet Peas was sown across the end and down one of the sides, the total length being about 30 yards. Soon after a few seeds of *Tropæolum peregrinum* and tall mixed were scattered along the row; and later still here and there were planted a tuber of some choice single *Dahlia*, together with a few Sunflowers; Pea rods were added, and the foundation was completed of what this autumn has proved to be one of the loveliest pictures it is possible to behold. There is the white, the blue, the pink, the brown, and the purple of the Sweet Pea; the golden yellow of the "*Canariense*;" the deep red, the rich brown, the bright cerise, and the marked red and white of the Dahlias contrasting strangely and richly together, and helping each other to show off its own peculiar charms, with the different hued green foliage of the three as a background. Dead indeed is the soul of the person who can pass by this mass of brilliant beauty without pausing to drink in some of its loveliness. Why, even the Sunflowers gracefully bend their heads and look down upon this sight with seeming wonder and admiration.

The reader perhaps says, "That the hedge is beautiful I must admit, but is it useful?" To this I answer, "Yes, it is." What a quantity of Sweet Pea blossom you can cut for your vases! and what Dahlias for your glass! And that "*Canariense*!" If it were only a guinea an ounce instead of a penny how it would be prized! Then again, what amateur is there who has not some spot in his garden—either adjacent to his neglectful neighbours or near some rubbish or manure heap—where an offensive view could not be changed into a beautiful and natural one by the expenditure of a shilling or two on the seed of the Sweet Peas and the *Tropæolum*.

And you professionals, you cannot find place for this hedge on your terraces, where your carpet beds must be nipped and shaved to keep them like a carpet, and where your Henri Jacoby, Flower of Spring Pelargoniums, Calceolarias, Begonias, and Lobelias must be kept symmetrical and within due limit; but there will be a place somewhere in your area where it may be tried profitably and pleasurably, therefore my advice to you, if I may presume to give it, is—"Try it."—IGNORAMUS.

## NOTES ON PLANTS.

### GYPSOPHILA PANICULATA.

WHERE cut flowers are required in abundance from plants which are strictly confined to the hardy garden those who do not possess the above miss a capital one for the purpose. The flowers are borne in profusion, last long in a fresh state when cut, and can be elegantly associated with other flowers, even Roses being improved by their association. It is surprising what a large bush will grow from only two or three shoots from the root; our plant is fully 4 feet in diameter, and the somewhat quaint small flowers seem to catch the eye at once. Owing to the scarcity of growth from the base it is not so easily increased as some perennials. The slugs, too, have a great liking for the tender shoots when they start in the spring. Abundance of soot worked into the soil round the base of the plant before growth commences is the best preventive of a loss of shoots. No doubt in a light sandy soil it is not troubled to nearly the same extent in this respect as it is in a heavy one, where slugs are more numerous in the spring.

### CHELONE BARBATA.

This is also called *Pentstemon barbatus*, and is a gem for the herbaceous border, summer flower beds, or in a nook on the rockery. The colour of the flowers varies from pinkish red to carmine, a shade which is not too plentiful even amongst hardy plants. What makes this all the more valuable is its natural habit of growth, which is upright, requiring but little space; one small stake in the centre of each root gives enough support if the shoots are loosely tied to it singly, which is a much superior method to encircling the plant with one ligature in a broom-like manner. Two years is long enough to allow the plants to grow without removal, as the centre of the root becomes weak, consequently the flower spikes are not so strong as they should be. The best way to maintain a stock of plants which will provide flowers abundantly is to break up the oldest roots every year the first week in October; every bit with a root attached will grow if dibbled into sandy soil in a cold frame, and left there till the following May. Then plant them out where they are to flower. That year they will throw up two or three stout spikes, but the following summer they will be at their best, producing stout spikes from 2 to 3 feet long.

### CAMPANULAS.

The three varieties of *Campanula carpathica*—*turbinata*, *pallida*, and *alba*—are all worthy a prominent place either on the rockery or at the front of the herbaceous border. The growth is easily kept within bounds. Flowers are freely produced which require no support, an advantage where labour is scarce. To give the best effect broad masses of each should be grown together, as in that way they are the most effective. Plants with two or three stems do not convey any idea of their beauty as compared with masses of flowers half a yard across. By dividing the roots in the spring just when growth is on the move no difficulty need be experienced in increasing the stock.

### ECHINOPS RITRO.

This is not the least interesting plant in the herbaceous border at the present time. The deep blue of the globe Thistle-like blooms are very conspicuous. It is a perennial, easily increased by dividing the roots either in autumn or spring. One strong clump will throw up half a dozen stout flower stems, which branch off into many more smaller ones, and altogether make a brave show at the back of the border, as it grows from 4 to 5 feet high.

### CONVOLVULUS SEPIUM.

This pure white large-flowered Bindweed is a useful plant to grow for covering the stems or branches of deciduous trees where a suitable position can be found for it. We have it planted at the base of a large-flowered variety of Laburnum, up the stem of which it climbs and entwines itself among the branches to a height of 10 feet. This Laburnum is growing by the side of a waterfall among rocks, over which the *Convolvulus* has rambed until it touches the water. Many of its stems have entwined

themselves around the smaller shrubs near, and very pretty it looks just now, the pure white bell-shaped flowers, 3 and 4 inches across, resting on a deep green base. For such a position nothing could have a better effect, and its growth, which is but short-lived, does not interfere with other plants about it.—S.

## CARNATIONS IN POTS.

CARNATIONS have long been favourite flowers, and ranked in popular estimation next to the Rose. The admiration for them, however, is annually increasing, and they are in demand over a longer period of the year in gardens of any pretensions. The cultivation of the Rose under glass has advanced considerably, and like provision is being made for the Carnation. We have but little doubt that ere long the Carnation house will form one of the features of most gardens. Those who have only seen the Carnation as it can be grown outside under good cultivation have but a poor conception of its beauty when grown and flowered under glass. We shall not attempt a comparison of the two. Those grown outside are certainly amongst the choicest of our outdoor flowers and indispensable for cutting, but they are puny by the side of well grown examples under glass. Only recently, when speaking to a friend about the extreme beauty of these flowers in the latter position, it was stated "They do not yield sufficient material for cutting." All of that opinion should either see them well grown or grow them, and their verdict would soon be changed. Well developed blooms of *Souvenir de la Malmaison* remind one of large French *Pæonies*, especially the pink form, *Lady Middleton*. Then, again, those who know *Mary Morris* or *The Governor* outside would fail to recognise the same flowers indoors; the same might be said of many others. If we take the old crimson *Clove*, with its dingy and dirty petals outside, always one of its faults, it is a fine flower under glass, and when well grown is free from these faults. I am not writing from a florist's point of view, or the old *Clove*, which is such a general favourite, might be relegated to the shrubbery or herbaceous border to look after itself, even if tolerated in the garden.

It is to be regretted that many of the finest varieties yield flowers that are practically scentless. This is of but little moment with the florist proper, but very frequently must be duly considered by those who grow for private gardening establishments. Some, however, of these scentless varieties are so charming in colour and such general favourites, as, for example, *Mrs. Reynolds Hole*, that they cannot be excluded from any collection of plants.

To grow Carnations well in pots under glass they should be layered as early as possible after flowering. This is unquestionably the most certain method. Varieties of *Souvenir de la Malmaison* should be well rooted now and ready for potting, either singly or in pairs, in 4 or 5-inch pots, according to the quantity of roots and the size of the plants. The pots should be clean and carefully drained, and the soil pressed moderately firm into them. After the plants are potted they may be stood outside on beds of ashes, and afterwards at the approach of frost removed to cold frames. If frame room is plentiful they will root better in frames; when outside they are liable to become too wet from heavy rains. Carnations need careful watering, but should never be allowed to become dry at their roots during any stage of growth. Other varieties should be potted as they become ready, and with the majority it is best to pot them in pairs; in fact, weak growers may be placed three in each pot, and may have a slightly smaller size.

For some time the plants give but little trouble, as they only need careful watering until they are well rooted. Some attention, however, is needed in not allowing them to become root-bound before they are transferred into 7 to 9-inch pots. The last is large enough for a pair of the strongest growers, while the smaller size will suit those of weaker growth. The plants should be well rooted before they are potted, for over-potting is as great an evil as allowing them to remain too long in their first size. The drainage from the base must be carefully removed without injuring the roots. For the final shift the pots can be more liberally drained, and the surface of the ball must not be covered more than a quarter of an inch deep with the fresh compost. The plants can be returned to frames that are light and airy. From the time they are first potted liberal ventilation is required to prevent weak growth. A shady position or a close confined atmosphere will soon ruin the Carnation. The plants to commence with should be dwarf and sturdy, and kept in that condition afterwards until they are layered for the following year. Cold frames are necessary when the house in which they are to be flowered is occupied with earlier varieties of the *Miss Jolliffe* type, which is one of the best, but these need rooting in

spring and growing on throughout the summer months outside. Span-roofed frames are best for these plants where air can play freely amongst them, although good examples can be produced in ordinary lean-to frames.

Those starting to grow Carnations may place their plants direct into the house in which they are to flower after their final potting. Let the pots stand on ashes or other suitable material, for they prefer a cool, moist base. Open trellis staging is too dry for them and necessitates the application of water more frequently than is good for the roots. When the plants commence to throw up their flower spikes they should be supplied with a neat stake to which the flower stems can be tied as they advance in growth. When particularly fine flowers are needed in preference to quantity disbudding will be needed. Attention is also required in tying the flower buds to prevent their bursting. After the flowers commence to open light shade should be applied to protect them from the strong rays of the sun. Until they reach this stage no shade is needed, or the flower stems and growth from the base will draw up weakly.

Red spider and aphides are the two worst insect pests that trouble the Carnation. If the plants are grown in a cool place, stood on a moisture-holding base, and carefully watered, the former will give very little trouble. Should it appear stir a 3-inch potful of sulphur into 3 gallons of rain water, and syringe the plants thoroughly. It should be left on three or four fine days, after which the foliage can be cleaned by syringing with clear water. Aphides are best destroyed by fumigating the house with tobacco or one of the patent fumigators provided for the purpose. It is important that aphides be stamped out directly they are observed, as if allowed to remain until they almost smother the plants injury and ruin result.

The soil for Carnations may consist of good fibry loam, three parts, of a rather strong nature, the remaining part being composed of sand and leaf mould. To this may be added one-seventh of decayed manure. Cow manure that has been stored some months and passed through a sieve is best. The loam must be hand-picked if wireworms infest it, for they are deadly enemies of the Carnation. Any neglect in this matter will end in a considerable loss of plants.

Carnations resent strong stimulants; in fact, they are positively injurious. If potted as directed little feeding of any kind will be needed. A small portion of suitable artificial manure applied to the surface of the soil after the flowers have commenced to form will do no harm. One or two applications will be ample, and only a little should be given at one time. Two or three applications of soot water in a clear state is beneficial rather than the reverse.

I shall not attempt to give a list of varieties, for a good selection of the very best was given by "A City Man" in the Journal only a short time ago. Until a stock of the best named kinds can be obtained and raised in sufficient numbers, border varieties, or even good seedlings, may be potted and flowered under glass.

—B. O.

CATTLEYA LABIATA VERA.

THE most prominent place in current horticultural topics is still occupied by this remarkable *Cattleya*; indeed, the interest seems to increase, and the announcement that 2000 plants from Messrs. Sander & Co.'s large consignments are to be sold in Messrs. Protheroe & Morris's Rooms, Cheapside, on Friday next, October 2nd, has again concentrated attention on the long-lost Orchid. An outline of its history was given last week, but I have received so many letters on the subject that further and fuller reference has been rendered necessary.

With regard to the general characteristics of *Cattleya labiata vera*, it is difficult to give a technical description which will clearly distinguish it from the numerous other forms of the labiata group, yet it is easily recognised when once known, just as readily as Mendel, Mossiae, Trianae, or gigas can be separated from each other. Some of the earlier illustrations scarcely do justice to the plant, notably that in the "Botanical Register." In Paxton's "Magazine of Botany" for 1838, however, a coloured plate is given portraying the floral characters admirably, and indicating at a glance what a superb Orchid it is, and it is strange that though the plants

in English collections have frequently flowered, a really good representation has not appeared since. The flowers are bold and handsome, well poised, with broad substantial petals, and a finely developed beautifully proportioned lip. There is also a great range of colours from pure white to deep crimson, with many delicate intermediate shades; and though the light forms, such as pallida and candida, have been rare in cultivation, it is said that pure white varieties are included amongst those recently found; in fact, the collector stated there were "plenty of whites" amongst the others.

Then, too, the time of flowering—namely, October and November, is much in the favour of *Cattleya labiata*, for at that period there is a great scarcity of Orchid and other flowers. That the plant should have commanded such high prices in the past, when beautiful varieties of the other labiata types could be purchased for modest sums, is a sufficient indication of its sterling worth, for in such a rich and varied genus rarity alone would not increase the value so greatly. Now that this *Cattleya* is placed within the reach of all Orchid lovers, it is not surprising the sales have been almost sensational, and Friday will probably bring as large a gathering as a fortnight ago, and that has scarcely ever been equalled in the annals of the horticultural auction rooms.

One correspondent asks, "How is it that such a fine Orchid should have been left undisturbed for something like seventy years, as the few plants received hitherto could not have been brought direct from its native habitat." This is a difficult question to answer, and one upon which the successful collector could throw more light than any other person. The plant may be restricted to a comparatively small area and the position difficult of access. Then, too, it may be out of the ordinary routes of botanical and horticultural travellers. At any rate it is quite clear there must be some great difficulties in the way, for strenuous efforts have been made for many years to find the plant. Experienced collectors have been repeatedly dispatched with that object mainly in view, and nothing but failure had been hitherto the result. It is not surprising, therefore, an opinion had become confirmed respecting the extinction of the *Cattleya*. Happily this does not seem to be the case, but I have the most earnest assurance that no collector from Europe has been recently known to visit the particular spot where the plants sent to St. Albans were found.

This brings us to another point raised by an Orchid amateur, who writes to this effect, "It is said that *Cattleya Warocqueana* and *C. labiata vera* are identical. What is your opinion in the matter?" In replying to this it will be necessary to review a few of the facts in connection with the appearance of *Cattleya Warocqueana* in England. The first time I saw the plant was at the meeting of the Royal Horticultural Society on May 13th, 1890, when specimens in flower were submitted to the Orchid Committee. As newly imported plants which had come into flower on the way, it was found they were not in condition to obtain an award, and none was made; but I remember distinctly that several expressed the opinion that it was like *C. labiata Warneri*. The next appearance was at the same place on October 14th, when plants were shown in much better form; the flowers bright and varied in colour, and two varieties were selected for first-class certificates. It was regarded as a distinct and beautiful form of *C. labiata*, but no one ventured to suggest that it was *Cattleya labiata vera*. The plant was welcomed as an acquisition of considerable value, and it was freely praised as such. It was in this light I regarded it, and judging only by what has come before my notice I cannot alter the opinion then formed. Further evidence may be forthcoming that cannot be ignored, but up to the present time I have not seen a *Cattleya Warocqueana* which I could consider identical with the old *C. labiata vera*, with which I have long been familiar in English collections.

I am aware that Mr. Rolfe has pleaded guilty to a mistake in describing and naming it as a distinct variety, but I cannot imagine how so skilful a botanist and careful an observer could be led astray; and though his readiness to admit an error is highly commendable, yet I am reluctant to accept his recantation, and, perhaps, after all he may find his first opinion was the correct one.

A third inquirer wishes to know what evidence we have that "the plants now being offered at the Sale Rooms as *Cattleya labiata vera* are the true thing?" With regard to that we have first the credit of a great firm at stake, which has pledged itself to the matter by guaranteeing all the plants sold, and this will suffice for

most people. Secondly, dried flowers and drawings have been exhibited which confirm as far as such evidence can the statements published concerning it. This will answer the question as far as it is in my power at present, but I am promised interesting information from several different sources both at home and on the Continent, and the subject will no doubt have to be referred to again.

It may be added that while several quotations have been given from Gardner's travels bearing upon the fact that he found *Cattleya labiata vera* in two places in Brazil, as to one of these Messrs. Veitch state "it is now known to have long since disappeared from that locality," and with regard to the other the same authorities have the following note in their excellent monograph of the genus *Cattleya*. "Gardner also states that he detected *C. labiata* at Sapucaya on the River Parahybo which separates the provinces of Minas Geraes and Rio Janeiro, but the form he met with here is, with a very high degree of probability, believed to be the variety *Warneri*." In view of the opinion expressed at the meeting of the Orchid Committee when *C. Warocqueana* was first shown, this is a peculiar coincidence, and has apparently been overlooked by recent writers. It may be remembered that *C. labiata Warneri* is one of the nearest relatives to *C. labiata vera* that is known. It has also been collected in the same district, but flowers much earlier.

Just as I had concluded these notes a poetical effusion came to hand entitled "Who found the old *labiata*?" It bears a distinguished orchidic name, but as "all rights are reserved," and I have no permission to utilise this remarkable production, it must be passed with the observation that the readers of the *Journal* who are partial to verses have lost a composition of absorbing interest, perfectly unique in metre and rhyme. The first four lines, however, convey a geographical reference, and I cannot resist quoting them:—"The woods of Rio Pinto are now a gaudy show, The time is early winter, where old *labiata*s blow, And Sander of St. Albans, the mighty Orchid King, Is filling all his boxes for shipping in the spring." Presumably this is retrospective, and "the boxes" referred to have apparently arrived, but whether "the woods of Rio Pinto" is really the home of the plants or merely a poetical fiction I must leave to others to determine.—LEWIS CASTLE.

### VIOLETS FOR FRAMES.

THE wet and sunless weather we have had has not been favourable to the growth of large plants. It is true they have kept free from red spider, which during some seasons give a good deal of trouble to eradicate, but for a long time plants raised from early runners produced by last season's plants in frames did not make much progress after they were rooted and planted outside. During the past month or six weeks they have grown luxuriantly, in fact too much so to be in the best condition for lifting and flowering profusely afterwards. We have found that plants of sturdy growth flower more freely than overgrown ones. The weather for some time past has favoured the development of large but soft foliage.

For some years past we have been in the habit of changing the ground annually for these plants, but always selected for them a north but moderately light border in which old hotbed refuse has been freely incorporated. At the same time we have been careful not to use too much of this material, so that the plants will be sturdy instead of large and soft. Too much manure and leaf mould will result, especially in seasons like the present, in producing plants that are scarcely capable of supporting their own foliage.

It will prove beneficial to the plants if they are checked by lifting without further delay. Early lifting will not only arrest the soft growth they are now making and induce them to form flower buds, but the plants have every chance of being thoroughly established before winter. The last is important if early flowers are needed. The Neapolitan varieties are the earliest to bloom, and two courses are open to those who grow Violets. Where they are needed as frequently as they can be produced a slight hotbed should be made at once in an open sunny position, and a frame placed over it. On the surface not less than 6 inches of soil should be placed. Select plants that are already showing plenty of flowers. Marie Louise is, perhaps, one of the best for autumn blooming. Lift them with moderately good balls of roots, and plant them fairly close together in the frame or frames provided for them, but avoid crowding, and the heat of the bed should be on the decline. A good soaking of tepid water should be given to start them, and by the aid of a gentle bottom heat they are soon established, and will not be long before they commence pushing up their

flowers. The plants may be kept close and lightly shaded from the sun for a few days, when plenty of air may be given afterwards to prevent their drawing up weakly.

Where frame room cannot be devoted to as many as may be required good success can be attained by placing plants in boxes 5 to 6 inches deep, leaving them outside until established, and afterwards placing them in light positions in vineries and Peach houses. It must be remembered, however, that Violets bear gentle forcing only, and that should always be conducted with free ventilation. In a close confined atmosphere they flower only poorly, and soon become a crowded mass of soft weak foliage.

When needed in spring only, and two frames can be devoted to them, they should be placed in different positions, one where it will catch every ray of sunshine, and the other in a more northerly aspect; these then form a capital succession. The frames for these must be prepared and the plants placed into them at once. For these we place a few inches of old hotbed refuse at the base and then fill up to the depth of 9 inches or 1 foot with old potting soil, being careful that too much manure and leaf mould has not been mixed with it. If the heap at disposal is considered too light we invariably mix with it soil in which Melons or Tomatoes have grown. After a good watering and the plants have been established the lights are thrown off daily when favourable, and ventilation is also provided at night until the approach of frost. Frost appears to do Violets very little harm during the winter. The soil about ours was hard for weeks last winter, and we never remember plants having flowered better.

The old Czar is still a valuable variety for frames and outside flowering in spring, and is much more fragrant than the double forms. After the frames have been filled the remaining plants may be lifted and planted in sunny positions for early flowering outside, while a good batch should be allowed to remain on a north border. It is always wise to plant the latter so that they can be left undisturbed. Last year two or three hundred plants in this position flowered well for us when all others were over.

It is a mistake to leave Violets on the same ground year after year; they soon exhaust it, and then make puny growth and small flowers that have scarcely any stem. They pay for replanting annually in good soil, where they will make fairly vigorous growth and yield afterwards large blooms with several inches of stem.—B.

### JOHN LOVE AND HIS GARDEN.

WHILE driving in September from Bridge of Weir to Kilbarchan (Renfrewshire) we had begun to descend the hill above the latter town, when turning our eyes to the left we saw a wonderful crop of Apples, and found that the place was called Mount Pleasant. The present owner most obligingly escorted us around this fruitful orchard, and we soon found that what was to be seen from the highway was but a sample of the whole stock. In making inquiry we found that about sixty years since the substantial house had been built by one John Tarbet, an old soldier who had in his time been a bombardier at the taking of Martinique. He had an eye for a fine site anyhow, and we can fancy him, while the days were declining, looking over the beautiful country around him and thinking how he could command with his artillery any radical rising which his keen political townsmen might be tempted to undertake. He planted fruit trees instead of batteries of cannon, and after his decease the place came to a relative, Mr. Climie, who continued the garden in cultivation, and his daughter married Mr. Love, the subject of our sketch.

About the year 1840 the young couple came to reside there. With a large garden to keep in order the evening hours were spent at home. In spring time useless trees were regrafted with good bearing sorts, if possible several different kinds being put on each tree. The old Keswick Codlin, the more modern Stirling Castle, with the best of the purely local varieties as the Lochwinnoch Pippin and the Golden Leighton (a variety whose name was suggested by Dr. Hogg) were carefully inserted, and now this year are just loaded with fruit. A curious feature in grafting we observed, and which Mr. Love rejoices over yet, is his successful experiment of placing a Pear on a Hawthorn stock. The thorn is one of many stems, gnarled and twisted most curiously, while the Pear scion is inserted about 6 feet from the ground. To graft Plums on Thorn trees is not uncommon, but in another garden in Kilbarchan there is a Rowan Tree (Mountain Ash) with a Pear graft on it yielding even better results than this experiment at Mount Pleasant. Here we see the old Caledonian Plum in fruit on its own roots. Some years it is so overloaded as to resemble the trees we see in the Vale of Evesham, but this is not a productive year apparently with it. In this old garden of an acre, or thereby, the trees are thickly placed together, many now interwarped in their branches, while beneath them are Gooseberries and Currants galore.

The soil is a rich, red, vegetable mould, sloping to the south, but fully exposed to all the winds that blow. The Rose succeeds to perfection, and old-fashioned border flowers were beautiful, from the Snowdrops of January and February, till the blue autumn Crocus of September were buried beneath a whirling cover of bright October's leaves. All through the summer the busy bees of "friend John" were gathering

honey from every flower and blossom, fertilising the fruit trees, and largely adding to their production, as we all know who have fruit gardens and bees. The hives used were the time-honoured "straw skeps" of John's father and grandfather, and many a lovely "top" of pure honey our worthy friend has taken off here.

"The Renfrewshire Bee-keeper" befriended Mr. Love, and many a hard question on their favourite subject has been discussed between them. Alas! for so many of us that he, who so well exemplified in his own life "the grand old name of gentleman" is now gone for ever and ever, while of all who now mourn his loss John Love's sorrow for his kind friend is not the least. Not a doubt of it, for to a man of over eighty-five years new friends do not succeed quickly, and are never like the old ones. In a sunny space the plot is still defined where Mr. Love grew and raised his celebrated race of laeal Pinks. Year after year in

As we go homewards up through the narrow streets the people are in crowds, while the flower show is attracting all the florists of the district. Thus the bees gather honey, but not for themselves, so John Love's work was not all for himself. He sowed, and to-day we wear his seedlings in our buttonhole. Younger men take up the taste for flowers, but let them look with respect and gratitude on their floricultural ancestors into whose labours they have entered.—A. SWEET.

[We have also received the subjoined notes respecting Mr. Love's career.]

Every man, apart from the profession or employment by which he gains a livelihood, ought to have what is usually called a hobby. It matters little what that hobby is, provided it is innocent, and interests

FIG. 55.—MR. JOHN LOVE.

this spot they were grown to such perfection as to carry off the honours at all the shows round, from Glasgow to Kilbarchan. At every digging new soil was turned up, and thus the situation continued to suit his favourite flower. What grand specimens of the dark "Pirate" and "John Love," were cut here.

Every year seedlings were watched for, and the advent of a pod of promise was an event for local florists to come and see. Altogether the garden is one, for soil, situation, and association, much to be desired still. Now, however, the old veteran still keeps to the Pinks, fruits, and the bees, in a less vigorous fashion than of old in a new garden farther "doon the toon." Hale and wiry, with eye bright and keen, active step, and toil-worn hand, we trust that he may long enjoy his garden joys. And though "down in the valley" the long shadows of life's sunset are falling around him, and the last bees are settling home with their store, he has but to look upward and see that Mount Pleasant is glowing in the light, to have the glory of far distant summers borne in upon him.

his mind and draws his attention away from the anxiety and worry which belong to the daily business of life. Idleness, whether of body or mind, besides being morally dangerous, is not rest. It is better to have a hobby which, by giving an agreeable change of employment, will refresh and improve both body and mind without adding anything perceptibly to their exhaustion. As to the kind of hobby to be chosen everyone must consult his own taste and circumstances. It may be music, or some department of science, or literature, or floriculture, or bee-keeping. This depends very much on the taste of the individual, the nature of his daily employment, and the circumstances in which he is placed.

Floriculture and bee-keeping, two things very much akin, formed the special hobby of the person of whom notice is here to be taken. John Love, the eldest son of a father bearing the same name, was born at Kilbarchan, Renfrewshire, on April 10th, 1806. So healthy has he been that during more than fourscore years he has only on one occasion

required medical advice. Much of this, doubtless, is to be attributed to the simplicity of his life, and to his regular and temperate habits. There he is: of medium height and agile frame; a fine head, once covered with fair hair, but now bald with the exception of a few thin white locks; mild and meditative in expression; the bloom still on his cheek, although eighty-five years of age by next birthday; for many years a happy "Benedict," but now a widower and the father of a numerous family; a good Christian man, and for a considerable time an esteemed elder in a Presbyterian church.

Like his father, and like the inhabitants of Kilbarchan generally, John Love became in youth a handloom weaver, and diligently plied the shuttle till beyond the age of threescore and ten. But while busy at his trade during the time he resided under his father's roof, he had parts of meal hours, and frequently half or whole days, occasioned by the change of one web for another, when he could gratify his taste for flowers by cultivating them, and acquire also a knowledge of the habits and requirements of bees by watching and attending to those kept by his father—who was an enthusiastic bee-keeper, as was also his grandfather before him.

In his love for flowers John Love was by no means singular amongst his fellow tradesmen, the handloom weavers of Kilbarchan having, in most cases, a garden attached to their dwelling house. There is found amongst them a common love for flowers, and no little skill and competition in their cultivation. This refined taste seems to be natural, and is possibly to be traced to the many exquisite patterns and fabrics on which they spend their daily labours, whereby they insensibly acquire a knowledge of the harmony of colours and a taste for the beautiful. Certain it is many of them are keen and successful cultivators of plants, and even very good judges of the merits of flowers which they themselves have never grown and perhaps have seldom seen.

John Love is a man of this stamp. Having by-and-by persuaded one of the other sex to cast in her lot with him as his wife, and got a house of his own, he could, now that he was his own master, follow out more freely the innocent and interesting hobby towards which his heart was drawn. He soon became acquainted with many plants, and not a few of them has he to some extent grown, such as Tulips, Pansies, Roses, Carnations, Auriculas, &c.; but his favourite flower, his *pièce de résistance*, has ever been the Pink. His bed of Pinks, when in its glory, has been generally a noteworthy sight. Looking at it over his garden wall at Mount Pleasant the bed at first glance may seem somewhat strange, and almost comical—short stakes at almost every plant, holding broken bowls and plates, and glass, and other ungainly contrivances; shading and sheltering some plants from a scorching sun or possible rain, holding back others from a too early maturity, and stimulating some to a more forward growth. But turn in and inquire for the master, and ask him to show you his Pinks; and he will cordially welcome you, and gladly, probably with head uncovered, lead you out, and with affectionate pride uncover, for your delighted inspection, his choice darlings. Probably he will tell you, "These there are this year's seedlings. This one here I think will do; it is distinct from all others in the bed, and has qualities equal at least to any one of them. Here are also two or three which are very good, but before deciding what to do with them I must grow them another year. As for these other seedlings, they are below the mark and without promise, and must be cast out. These tallied ones are the named Pinks. This one—'Black-eyed Susan'—is not a very large flower, but it is distinct, well laced, and pretty, and tells well in a stand, &c." Before leaving him it is not unlikely he will say to you, "If you grow Pinks I'll give you, if I can spare it, a little grass of any one of them for pipings;" for John Love is a generous man, and likes to encourage others in the cultivation of his favourite flower.

John Love's Pink stands at a competitive exhibition are worthy of remark. Each flower is so neatly fixed in the centre of a circular piece of white paper a little larger than itself, and the petals so deftly spread as to show to the best advantage the build, and markings, and lacings of the flower; and they are all so arranged on the stand, according to size and colour, as to present collectively to the eye a lovely and effective picture. Besides, after the judges have done their work you will commonly find attached to the stand a ticket, bearing in conspicuous print "first prize," and underneath this, in legible penmanship, "John Love, Kilbarchan." This has been repeated so frequently as to earn for him the soubriquet of "Scottish Pink Champion." John Love's favour for the Pink has been a life-long one. It was cherished by him till his age extended beyond the threescore years and ten. It continued to be cherished by him even practically during his subsequent residence in Paisley for six years, and in Rothesay for five years more; and when, at the end of these eleven years, he returned to his native town happily there was attached to the premises in which he took up his abode an excellent garden, where he has given, and is still giving, abundant evidence that his love for his favourite flower has neither been extinguished or lessened by age nor superseded by a newer favourite, but is as enthusiastic as ever. His life now extends beyond the half of its ninth decade, but he still appears so strong, so active, so healthy, so cheerful, so much in the possession of every faculty with the exception of hearing (whose gates are not now wide open) that he bids fair to see, if not the completion, at least the beginning of his tenth decade.

It may be added that during all his long and active life John Love has been conversant, theoretically and practically, with bee-keeping; but as the present writer is not very well acquainted with the plans and processes he followed in this kindred hobby he leaves it to some other, who is abundantly competent to write on the subject with intelligence and authority.

EVENTS OF THE WEEK.—To-day (Thursday, October 1st) the British Fruit Growers' Association will hold a meeting in the Horticultural Club Room, Hotel Windsor, Victoria Street, at 5 P.M., when Mr. Goaring, Weald Hall Gardens, Brentwood, will read a paper on "Apples for Gardens." On Friday, October 2nd, a great sale of the old *Cattleya labiata* takes place at Protheroe & Morris's Rooms, Cheapside. The Royal Horticultural Society's Fruit, Floral, and Orchid Committees will meet at Chiswick on Tuesday, October 6th, and upon that and the two following days the Exhibition and Conferences relating to Sun-flowers, Asters, and Coniferae will be held, the full programmes of which were published last week. There appears to be every prospect of the Conifer meeting being very successful, for many important exhibits are promised.

— THE WEATHER IN THE METROPOLITAN DISTRICT during the past few days has been extremely fine, the atmosphere clear, and the temperature high. On several mornings the thermometer in the shade has registered 60° at 8 A.M.

— THE *Kew Bulletin* for September gives notes on the "Orange Scale in Cyprus," the "Rediscovery of the Gutta Percha Tree in Singapore," a chapter on the fodder plant *Tagasaste* (*Cytisus proliferus*), the Kangra Buckwheat, and some miscellaneous news from which we extract the undermentioned.

— INDIAN AND COLONIAL APPOINTMENTS.—The Secretary of State for the Colonies has appointed, upon the nomination of Kew, Mr. C. A. Barber, B.A., late scholar of Christ's College, Cambridge, and University Demonstrator in Botany, to be Superintendent of the Botanical and Agricultural Department in the Leeward Islands. The Secretary of State for India in Council has appointed, on the nomination of Kew, Mr. A. B. Westland, late Assistant to the Superintendent of the Botanical and Afforestation Department, Hong Kong, to be Superintendent of the Taj Gardens at Agra, N.W. Provinces, India. The Secretary of State for the Colonies has appointed, on the nomination of Kew, Mr. W. J. Tutchet, Sub-foreman in the Royal Gardens, to succeed Mr. Westland as Assistant to the Superintendent of the Botanical and Afforestation Department, Hong Kong.

— ROYAL BOTANICAL AND HORTICULTURAL SOCIETY OF MANCHESTER.—An Exhibition of hardy and other fruits will be held in the Town Hall, Manchester, on the 20th, 21st, 22nd, and 23rd October, 1891, and a Conference will take place, October 21st and 22nd, in the Town Hall at twelve o'clock each day. On the first day of the Conference the Right Hon. the Earl of Derby will preside, and on the second day Alderman Sir James Whitehead, Bart., Master of the Fruiterers' Company, will take the chair. The following subjects will be introduced by the gentlemen whose names are appended:—Mr. Baillie of Chester: "The Fruit Growing Movement: Present Day Features and Prospects." Mr. Cheal of Crawley, Sussex: "The Condition, Preparation, and After-Treatment of the Soil for Fruit Culture." Mr. S. T. Wright of Hereford: "Fruit Growing for Profit." Mr. Crump of Madresfield: "The Raising, Budding, Grafting, and Pruning of Apple Trees for Orchard and Estate Planting." Mr. T. F. Rivers of Sawbridgeworth: "Orchard House Culture." Mr. Edward Luckhurst of Romford: "The Importance of Early Planting and Shelter in Fruit Culture."

— PRIZES are also provided in FRUIT CLASSES as follows:—Open classes: For the best exhibition of Apples (kitchen and dessert), six fruits of each variety, dissimilar, eighty dishes (fruit grown under glass excluded). First, the Society's large gold medal; second, medium gold medal; third, silver medal; the same prizes being also offered for the best exhibition of Pears, six fruits of each variety, fifty dishes (fruit grown under glass excluded); for the best collection of Apples and Pears, six fruits of each variety, eighty dishes (for fruits grown under glass); and in the amateurs' classes for a collection of Apples (kitchen and dessert), thirty-six dishes, dissimilar, six fruits of each variety (fruit grown under glass excluded); for thirty-six dishes of Apples and Pears, six fruits of each variety, dissimilar (for fruits grown under glass); and for a collection of Grapes, to consist of ten bunches, in not less than

three varieties. Money prizes of £3 to 10s. are also offered for Apples, Pears, Grapes, and Tomatoes.

— MR. THISELTON-DYER.—We learn that the Leopoldinisch-Karolinisch German Academy of Natural History has conferred the honorary degree of Doctor of Philosophy upon Mr. Thiselton-Dyer, Director of the Royal Gardens, Kew, in recognition of the services rendered by him to botany.

— GARDENING APPOINTMENT.—Mr. L. Williams has been appointed gardener to R. O. Leicester, Esq., Toft Hall, Knutsford, Cheshire.

— THE PRESTON AND FULWOOD FLORAL AND HORTICULTURAL SOCIETY.—The fortieth monthly meeting of the members and subscribers of the above Society will be held in the large room of the Legs of Man Hotel, Fishergate, Preston, on Saturday evening next, October 3rd, 1891, when Mr. J. Hathaway, gardener to the Earl of Lathom, will read a paper on "The Chrysanthemum." Chair to be taken at 7.30.

— BOUGAINVILLEA GLABRA is generally classed as a stove plant, but it will also do well in the conservatory, and the flowers last much longer when cut out of a house with a low temperature. A good specimen is very effective, but is rather unsightly when it has shed its leaves, though when grown in pots the plants can be removed to other quarters. We have a splendid specimen growing on the wall in the potting shed, which is at present in a mass of bloom. The shed is a glass-roofed lean-to with a northern aspect, and can be kept during the winter above freezing point.—S. S.

— CHISWICK GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—The annual general meeting for the election of officers and Committee for the ensuing year, and to receive report and statement of accounts for session 1890-91, will be held in the Council Chamber of the Royal Horticultural Society's Gardens on Friday evening next, October 2nd, at eight o'clock punctually. The Committee have decided to hold another concert in October in aid of that deserving charity, The Gardeners' Orphan Fund, further particulars regarding which will be announced at the annual meeting. The opening address of the session, October 9th, will be contributed by Mr. H. Dunkin, gardener to the Earl of Warwick. Subject: "Flowering Trees and Shrubs."

— CUPRESSUS MACROCARPA.—Writing a few notes in the Journal last May respecting the hardiness of this Conifer, I then stated that I had never seen a tree of it killed outright with the frost, and from the then appearance of the forty or so trees here it looked as if the recent winter had only injured them. Since that time, however, I find that four out of them have died. In July they showed unmistakeable signs of being killed, having turned a rusty brown all over. One of the number, I regret to say, was the tallest specimen growing here, being a little over 60 feet in height, and of the upright or fastigate habit. The severe winters of 1879, 1880, and 1881 did not kill any Cupressus macrocarpa here, but the last prolonged winter proved too much for some of them; 28° of frost was the most recorded here.—H., *North Hants.*

— TUBEROUS BEGONIAS are to be seen in all directions at Street, Somerset, cottagers as well as amateurs and private gardeners growing them remarkably well both in pots and the open borders. As might be expected, the best displays are to be seen in the leading gardens in the neighbourhood, and they are remarkably good as grown by Mr. F. Edwards, gardener to James Clarke, Esq. Several beds were wonderfully gay during the wet weather in August, Zonal Pelargoniums cutting but a sorry figure alongside the Begonias. Most of the varieties were unnamed seedlings, the preference for planting being given to bulbs of the previous season's raising. There were, however, several beds planted with Phosphorescence, a remarkably free, though small semi-double flowering variety of dense growth, raised, I believe, by Messrs. Laing & Sons. Begonias are also very effectively employed in the gardens of F. Clarke, Esq., several rustic vases being very gay with them.—I.

— I HAVE sent you a sample of the EVESHAM EARLY TOMATO for inspection. It is a variety that is grown very much in this neighbourhood for open air culture, and I do not remember seeing any account of it in the Journal. I have it growing along with Laxton's Open Air, Abundance, Stamfordian, and Large Red, and I find it a week earlier than Laxton's, which is next earliest, all being from seed sown about middle of January last. It does not grow so large as some of the others, but I find it more solid and even in size than the more corrugated varieties. It is a very good cropper. The samples are not the

largest bunches I have had this season. Up to the present time I do not find it go bad as much as the other varieties which are growing beside it. Last year was considered a bad season, but I had a good crop. It is very dwarf, and I find it the best to select and save the seed myself.—F. NORMAN, *Evesham*. [The fruits sent were of a medium but useful size, and the bunches of ten and twelve each show how prolific the variety is.]

— EAST ANGLIAN HORTICULTURAL CLUB.—The members of this progressive club betook themselves to Dereham on Friday last, having been invited by Mr. John Green of the Norfolk Nurseries. They left Thorpe Station by the 3.20 train (special arrangements having previously been made by the Hon. Secretary, Mr. Albert F. Upstone, with the railway company), and were cordially received at Dereham by Mr. Green, who accompanied them to his grounds close at hand. The party, which numbered about eighty, divided into sections and scoured the pretty environs of the town, eventually meeting in a large tent specially erected in the grounds. After tea the usual toasts were given, interspersed with various songs, and a vote of thanks to Mr. Green, the members dispersed, and left by the 9.15 p.m. train for Norwich. Mr. F. Morris of Witton (President) and Mr. George Daniels (Hon. Treasurer) headed the expedition, and added much to the success of the affair. Many new members were enrolled, chiefly amateurs, and it is yet felt that hundreds in East Anglia might avail themselves of this society, particulars of which will be given by the Hon. Secretary, at Messrs. Daniels Bros., Exchange Street.

— AUSTRALIAN FRUIT IMPORTATIONS.—We have received the following from the Chief Commissioner of The Australian Irrigation Colonies, 35, Queen Victoria Street, London, E.C. The probability of large shipments of fruits to this country being made from our Australian colonies in the early future, the practicability of which has been so recently demonstrated by the great quantities of excellent Tasmanian Apples with which our markets have this year been supplied, is now further exemplified by the arrival this week of a small consignment of raisins from the Australian Irrigation Colonies on the river Murray, being the first fruits received from these settlements, the establishment of which, some three or four years ago, has been attended with such remarkable success that their progress has been described by a colonial bishop who recently visited them (Dr. Thornton of Ballarat) as simply "amazing." A quantity of raisins are now on view at the London offices of the Australian Irrigation Colonies, 35, Queen Victoria Street, E.C. They are entirely sun-dried—the clear dry atmosphere of that part of Australia where the settlements are situated enabling the drying of all descriptions of fruit to be carried out in the most perfect manner and without risk of injury. They have been pronounced of excellent quality both in flavour and appearance, and are very attractively put up in 2 lb., 6 lb., and 12 lb. boxes. The above consignment will, in due course, be followed by others of a no less interesting character, embracing the following valuable fruits of commerce:—Oranges, Lemons, Raisins, Currants, Apricots, Peaches, Figs, &c., together with wine, olive oil, and other products, for which a large demand is anticipated in this country in future years. The total area of land constituting the Australian Irrigation Colonies, and of which some 25,000 acres at each of the two settlements (Mildura and Renmark) are now being dealt with, will fall but little short of half a million acres; and although the colonial demand will probably absorb the entire production for some years.

#### GLADIOLI.

I AM indeed sorry for "D., Deal." On page 263 he tells us that he has not suffered such a disappointment for twenty years as to be prevented putting in an appearance at the Crystal Palace Show this year. I was not there; but I hope "D., Deal," himself put in an appearance, as one of the oldest and most successful of Gladioli cultivators, although owing to the lateness of the season his "spikes" were not sufficiently forward for exhibition purposes.

"D., Deal," mentions Atlas, Baroness Burdett-Coutts, and Ondine as amongst the earliest bloomers with him. Ondine is to-day, September 28th, just showing colour, and Atlas just out with me in East Suffolk, while my two comers of Baroness Burdett-Coutts have gone wrong altogether. My earliest here is Shakespeare, followed by Mons. A. Brongniart (a splendid flower and spike), Horace Vernet, Matador, Crépule (very fine). These are quite over. I have now some very fine spikes of Cameleon, Hesperide (lovely), Conquerant, Amitié, Titania, and Carnation. Among those not quite showing colour on the eve of the festival of St. Michael of All Angels, though the spikes are fine, may be mentioned Mount Etna, Ovide, Phœbus, Pollux, Cervantes, Formosa, Africaine, and Enchantresse. In addition to Baroness Burdett-Coutts I have to number Grand Rouge, Cervantes, Phœbus, Mount Etna, and Rayon d'Or among the actual deaths.

My soil is light to a depth of 15 inches, with a thinnish stratum of clay below. Would "D., Deal," advise me to cut off the spikes of those not showing colour?—J. A. W.

## THE EDINBURGH SHOW.

### NEW PLANTS.

I SHOULD like to know if any experienced plantsmen observed the class for new plants at Edinburgh closely and carefully; if they did their opinions as to the relative merit of the exhibits would be worth having. I have spent a life amongst plants, and most of the novelties of the last quarter of a century have passed through my hands, and in my judgment the collection of new plants from Messrs. B. S. Williams & Son, Upper Holloway, were well worthy of the first prize, though the second was awarded them. Healthy young specimens were shown of *Cattleya Massaiana*, *Dracæna Malletti*, *Dicksonia Lathamii*, *Anthurium eburneum*, *Alocasia Chantrieri*, and *Pteris tremula elegans*, all good and distinct kinds.—A SURREY GARDENER.

### STEALING FRUIT.

THIS subject has very properly been brought to the front, and though I was not a sufferer myself I was present at the fight for the fruit, and know several who are very serious losers by the affair, for which they could obtain no remedy; in fact, their complaints were treated in a very off-handed manner by some of the officials. Whole bunches of Grapes, boards and all, were lost; nor was this confined to the fruit classes, for several lost their boards, tubes, and all the appliances. If this was the first time anything of the kind had taken place it would be excusable, but grave complaints of a similar character have been made in the past, and seemingly with no result. Several exhibitors in the North of England could relate some rather startling experiences in this matter if they were only inclined to do so. Mr. J. McIndoe, for instance, could tell a little history.—R. M.

It was with great pleasure I read the note in the Journal of September 24th on the above subject, accompanied with considerable regret that there should be cause at such a Show for so grievous a complaint. That there is great cause for complaint I can testify, being myself a victim of the light-fingered fraternity who visited the Show. In the course of competitions I have known single specimens taken from the plates on the benches, but it was not until I exhibited at Edinburgh that I experienced the mortification of having whole plates of Peaches, Figs, Nectarines, and collections of Pears and Apples taken. Having received a hint before on this matter I made a struggle to get to my exhibits as soon as possible, but notwithstanding I was there early I found others had been before me, and my fruit was stolen. I am fully aware these facts must be considered as a somewhat grave charge against the management of the Show, but the Council must in their turn consider this must be shown up by gardeners in self protection, and with a view to altering the arrangements, which at any rate should be such as to prevent pilfering on such a scale. To many gardeners, myself included, it is most serious, as I have to return my fruits to my employer's table, and unless we can do so no doubt we shall be either debarred from showing or have to find fresh employers. Besides this, I would like to give what might be considered by some a rather presumptuous piece of advice—namely, that civility on the part of officials tends to increase the popularity of an exhibition. When I saw the "riot and rabble," and noticed the manner people were helping themselves inside, I could not help contrasting the way the Exhibition was managed with that at Exeter. If the Council do not see how to prevent the present state of affairs, they would be spending their money well by sending a deputation to Exeter, where no doubt the officials will receive them with courtesy and freely give them any information they require. Trusting I have not occupied too much of your valuable space.—T. H. CRASP, *Canford Gardens, Wimborne*.

"A VISITOR" at the above Show deserves the thanks of all interested for calling attention to the extremely rough treatment experienced by exhibitors, and I thoroughly endorse all his remarks. Evidently "A Visitor" was not an exhibitor, or he would in all probability have had something to say on the inconvenience caused by gardeners not being able to get their exhibits into the Waverley Market till after mid-day previous to the Show. More than one gardener was told he might take his fruit to the — when he asked where he must put it, and this in some cases after exhibitors had come several hundreds of miles. Surely all courteous men are entitled to courteous treatment, but this was far from being the case at Edinburgh. While making all allowance for the usual market held on Tuesday, I can see no reason why some better arrangements could not be made, not only before the opening, but

also at the closing of the Show. As to loss of fruit I might say a good deal, as my loss was considerable, but there seems to be no remedy.—AN EXHIBITOR.

### AWARDS TO NON-COMPETING EXHIBITS.

It was stated recently that no awards had been made to the non-competing exhibits at the recent International Show in Edinburgh with the exception of the magnificent exhibit of plants, flowers, and fruit from Messrs. Thomson & Son of Clovenfords. We have received an intimation to the effect that the Council of the Royal Caledonian Society held a meeting on September 23rd "to arrange as to special awards," and a list was promised as soon as ready. Just as we are going to press the subjoined has been received, but one correspondent has written to this effect:—"If any awards were to be accorded to my exhibits and those of other firms, it would have been much better to have announced them at the time of the Show, or at least immediately afterwards. Now it will be of little or no value to me from a business point of view."

Royal Caledonian Horticultural Society's International Show, 9th, 10th, and 11th September, 1891. Special awards recommended for exhibits not in competition.

GOLD MEDAL (awarded by the Judges).—Messrs. Thomson and Sons, Tweed Vineyard, Clovenfords, for large table of choice exotic plants, fruit, flowers, and vegetables.

SILVER-GILT MEDALS.—The Royal Horticultural Society, London, for table of Apples, Plums, Damsons, and Tomatoes; Messrs. Geo. Bunyard & Co., Maidstone, Kent, for collection of Apples, Pears, Plums, Kentish Cob Nuts; Mr. Walker, Ham, Surrey, for collection of Apples and Pears; Messrs. Birkenhead, Sale, Manchester, for collection of Ferns; Messrs. Cannell and Sons, Swanley, Kent, for collection of Cactus Dahlias, double Begonias, &c.; Messrs. Dickson & Sons, nurserymen, Edinburgh, for collection of Conifers; Messrs. Williams & Son, Holloway, London, for collection of stove and greenhouse plants.

SILVER MEDALS.—Messrs. Cheal & Sons, Crawley, Sussex, for collection of Apples and Pears, set off with stands of Dahlias, &c.; Mr. John Watkins, Pomona Farm, Hereford, for collection of Apples, Pears, Plums, Damsons, Cider Apples, Perry Pears, Cider Champagne, and Perry Champagne; Messrs. Cocker & Sons, Aberdeen, for collection of Roses and other cut flowers; Messrs. Cross and Sons, Glasgow, for collections of fruits, flowers, plants, and vegetables; Mr. H. Deverill, Banbury, Oxfordshire, for a table of Onions, Carrots, Leeks, &c.; Messrs. Dobbie & Co., Rothesay, for table of choice varieties of cut flowers, &c.; Messrs. Laing and Sons, Forest Hill, London, for table of Begonias and useful decorative plants, &c.; Messrs. Dicksons & Co., Edinburgh, for table of miscellaneous decorative plants; Messrs. Methven & Sons, Edinburgh, for table of decorative plants, &c.; The Saratoga Packing Company, California, for exhibit of sun-dried Californian Prunes; Mr. James Taylor, Bangholm, Edinburgh, for collection of vegetables put up as sent to market; Mr. Currar, Eskbank, for *Oncidium incurvum*, awarded for good culture; Mr. A. McGregor, for *Saccolabium Blumei majus*, awarded for good culture.

BRONZE MEDALS.—Mr. Rust, Eridge Castle Gardens, Sussex, for collection of Apples and Pears grown at an altitude of 400 feet above sea level; Mr. Campbell, Blantyre, Lanarkshire, for table of cut flowers, &c.; Mr. Cuthbertson, Rothesay, Bute, for table of cut flowers, &c.; Messrs. Laing & Mather, Kelso, for collection of Carnations and other cut flowers; Messrs. Stuart & Mein, Kelso, for table of choice flowers, &c.; Messrs. Cutbush & Son, Highgate, London, for table of miscellaneous decorative plants; Mr. Hugh Dickson, Belmont Nursery, Belfast, for exhibit of forty-eight blooms of Mrs. John Laing Rose.

### EREMURUS HIMALAICUS.

A HANDSOME example of this stately plant was sent to the Temple Show last May by Mr. John J. Smyth, Rathcoursey, Ballinacurra, Ireland, when the Floral Committee awarded a first-class certificate for it, an honour that was well merited, for it is one of the most distinct and effective members of a comparatively little known genus. The tall scapes bear numerous small white fragrant flowers, and as the plant is perennial and quite hardy in most southern districts it will become a favourite.

There are few species of *Eremurus* in cultivation, but about eighteen are known to botanists, and in Mr. G. Nicholson's Dictionary the following are noted:—*E. himalaicus*, flowers white, star-shaped; scape 1½ feet to 2 feet in height, bearing a densely packed raceme; leaves strap-shaped, acute, glabrous, entire, about 1 foot in length. *Himalaya*, 1881. *E. Korolkowi* is a rare and handsome species, from Central Asia, growing from 3 feet to 4 feet high, and bearing immense spikes of bright rose flowers. *E. Olgæ*.—Flowers white, star-shaped, with

projecting stamens; disposed in a long dense raceme; summer; leaves tufted, linear, scabrous, recurved. Turkestan, 1881. *E. robustus*.—Flower peach-coloured, disposed in an elongated raceme on a naked

spreading, sulphur-coloured sepals, slightly tinged with orange; anthers oblong, deep orange; June; leaves radical, linear-ligulate, glaucous-green, slightly channelled, and obscurely keeled, sheathing at

FIG. 56.—EREMURUS HIMALAICUS.

scape, from 8 feet to 9 feet in height; leaves rosette-formed, 4 inches wide, and from  $2\frac{1}{2}$  feet to 3 feet long. Turkestan, 1874. *E. spectabilis*.—Flowers sulphur-coloured; raceme elongated, sub-cylindrical, many flowered; perianth divided to the very base, with six ovate-elliptical,

base; height 2 feet. Siberia, 1800. *E. turkestanicus* (Turkestan).—Flowers reddish-brown; perianth segments margined with white; stamens much exserted; raceme very long and dense, borne on a tall scape; leaves broad-linear, acuminate; height, 4 feet.

## A QUAIN GARDEN.

I KNOW of no better adjective to use in describing the garden of my friend, Mr. J. S. Cousens, at Grove Road, Wanstead. It is not what we call an old-fashioned garden, for that implies Yew hedges, Box edgings, grassy walks, and such like, which do not exist here, but a quaint garden it is; and I do not wonder now that when subjects for discussion arise at our Horticultural Club meetings Mr. Cousens has something to say or show. There are no Orchids, few stove or greenhouse plants, but with those exceptions there is something of everything—trees and shrubs, fruit trees, herbaceous plants, and above all Ferns are to be met with in all directions. There is no order or regularity any more than there is in my own garden—fruits, flowers, vegetables, shrubs jostle one another, and you are continually meeting with surprises where you least expect them. The garden or gardens, for there are two or three of them, are of some extent for a suburban garden, being about an acre and a half in extent, the outer one being, however, mainly occupied with grass and a border running round it. In one of these is one of those old-fashioned greenhouses which were in vogue in former days, with a curious constructed roof in the centre and two wings, the one containing a Vine, and the other used for all sorts of plants. The centre is paved with flagstones, as they used to do in those days, and could only be utilised for standing plants on to flower, or plants in large pots or tubs. It was an expensive one I have no doubt, and is equally so to keep up, requiring a good deal of heating, glazing, and painting; in fact, I should imagine it must be to my friend rather a sort of white elephant. As to the gardens themselves it would be vain to attempt their description; in fact they would resent it. Take my own. When people say to me, "You must have a beautiful garden," my reply always is, "No; but I have a garden with beautiful things in it," and so I must just try and jot down a few things which struck me in my wandering round Mr. Cousens' garden.

Mr. Cousens is a great admirer of British Ferns, and being a neighbour and intimate friend of one of our foremost pteridologists (save the mark), Mr. C. T. Druery, it is no wonder that the Fern fever is strong upon him, and consequently in going about the gardens you meet with Ferns in all directions—in frames, on rockeries, in houses, and in glass cases; Ferns of all sorts, tasselled, crested, frilled, and I know not what, precious in the eyes of experts, but to many an outsider only monstrosities. It may be very interesting, and I do not deny it, to see the beautiful Lady Fern turned into that curious form A. F. f. Frizelliae, but I cannot for a moment admit that it is to be compared in beauty to the normal form. Then there are dwarf forms which suggest a stoppage of growth somewhere or at some time, and of course these giant ones are in favour here. Many are the varieties of the crispum varieties of Scolopendrium, amongst them one found by Mr. Cousens, and named after him Cousensi. Here, again, are pans of seedling Ferns raised from spores, many, strange to say, coming true. Here, again, is a case of Filmy Ferns in which the Killarney Fern is flourishing, as is also the Tunbridge Wells Fern and several others of the Filmies; and here, as if to exemplify my title, is a pot containing no less than four varieties of Fern gathered in one clump from the top of Lyons Cathedral. Then here is the crested variety of the Royal Fern (*Osmunda regalis*), doing well and flowering freely, and so one might linger over these treasures which would be so dear to a real Fern lover. But even here there is a Mordecai at the gate, in the shape of the Fern beetle, one of those pests for which there seems neither prevention or cure. In one of the rockeries it was abundant, the leaves were riddled with it, and Mr. Cousens said the roots were thoroughly infested. There seemed to be no remedy but taking up the plants, washing the roots, and replanting, when, perhaps, they would return again in a couple of years.

But this is not the only pest to which the garden has been subjected, the caterpillar of the goat moth (*Cossus ligniperda*) seems in some seasons to be abundant in this neighbourhood, and it attacked some small bush Apples which were obtained from Mr. Bunyard of Maidstone. There were two short rows of them on either side of a walk. Down one side the moth seems to have made her journey, and deposited an egg on each tree. The places of entrance and exit were clearly seen, but, strange to say, the trees had shot out from lower down than the point of entrance, and had a very abundant crop of good and large fruit on them. I do not think that it is usual for this caterpillar to attack such small trees as these, preferring larger fruit trees, and some of our forest trees, especially the Elm. It remains for two years in the larva state, and I should have been inclined to think that these ravages were due to one of the clearwings, but I fear the *Cossus* must be credited with it. The Black Currant bushes were attacked here in a very curious manner, and I shall be anxious to find out what is the cause. The pith in all the branches, great and small, had turned completely black and dried up; the leaves of the bushes were shrivelled, and all of them looked doomed. I have never met with anything of the kind before.

But these are not the only destructive pests Mr. Cousens has to cope with. A discharged gardener is worse than a Fern beetle or a *Cossus* if he be a vindictive man. One such he had, and after he left he found that various pieces of spite and malice had been committed, amongst which was the barking just under the ground of a small tree of *Salisburia adiantifolia*, which was much prized. In order to kill it, the bark had been taken off right round the stem. In order to preserve it Mr. Cousens tried an unusual remedy: he cut off one of the branches, peeled off the bark, and applied it to the place where the damage had been done, much in the way in which surgeons nowadays repair a man's nose, plastered it, and bound it up. The adhesion took place, and the

tree survives—a memory not so much of vindictiveness as of the ingenuity of the owner.

In walking round we come to a clump of *Aucuba* raised from a packet of seed from Lee of Hammersmith, near whose nursery Mr. Cousens in his early days lived. The plants exhibit that wonderful variety which we find in Nature everywhere, no two being alike, and several of them being beautiful; and this is one interesting thing in this garden that its owner is able to tell some little history connected with so many of its inmates. On an arched trellis over one of the side walks is trailing shrub, which, although common enough, and introduced here about two centuries ago, I had never before seen—*Lycium barbarum*. It is a rapid grower, bearing small violet flowers, which are surrounded by a bright red soft fruit, of which birds are very fond. It makes an ornamental creeper for such a position. As the plant gets older and stronger the stems with which it is furnished become fewer. Close by this is some of that queer Japan vegetable about which so much noise was made some time ago—the *Crosnes de Japon* or *Stachys*. I notice it because it seemed to be coming into flower, and it would therefore be interesting, as I understand that was the difficulty in determining its true position. Another curious thing is a large Cape bulb, round in shape and having enormously fleshy roots. The leaves are very long, and when broken across there are long filaments, very fine, which can be drawn out to a considerable length, and under the microscope give the appearance of twisted cables. Although Mr. Cousens had had this for seven or eight years, and although it has increased much, and he has tried it in various ways, in pots large and small, and on the open ground, but he has never yet been able to get it to flower. I have suggested his sending it to Kew, where he would no doubt learn all about it. There was a very pretty white trailing *Campanula*. Whether it was *turbinata* or not I am not quite sure, but it was appearing in all sorts of places, evidently at home, and making a home for itself. Here, again, were a number of seedling plants of *Eucalyptus*, the seed of which had come from Mr. Wilks. Here was a plant of variegated or golden Box, which Mr. Wildsmith had given him on one of our Horticultural Club excursions. In the greenhouse there were some plants of a very pretty and useful double white *Petunia*, useful for those who use double flowers for decorations. Here, again, was a quarter containing the best varieties of Cactus and other Dahlias, and against a wall were two trees of Peaches and Nectarines literally laden with fruits. In other places were clumps of *Salpiglossis*; here a fine plant of *Diplacus* full of blossom, and so all through the garden. You ask Mr. Cousens about a plant. "Oh, yes; here it is." And so in this quaint garden you may find a great deal to interest, but I need hardly say that to enter fully into it you must be a Fern lover.

I hope that these brief notes will show that a good deal of pleasure may be had out of a limited space, and that when Mr. Cousens asked me to visit him and said, "I think that you can show you something that may interest you," he was as good as his word. As we might suppose, he has other curios of a different character, but my concern has been simply to show that there are things in this quaint garden worth looking at.—D., Deal.

## THE PRINCIPLES OF PRUNING.

THE brief digest of Mr. Wright's lecture at the Conference of the British Fruit Growers' Association at the Crystal Palace recently contains many interesting points in connection with the proper management of fruit trees under the head of pruning. I have long since found the advantage of maintaining a thin centre in various kinds of fruit trees, any trouble spent in this way during the summer is laying the foundation for future heavy crops of fruit.

Nothing could be more strongly in favour of this practice as a row of Red Currant trees growing here. Each tree is restricted to six to ten branches, the trees standing on a clear stem; every one of them reach 5 to 6 feet high, each branch is thickly clustered with fine fruits every year, not a few here and a gap there, but a continuous string from top to bottom. This I attribute to attention to removal of the bulk of the shoots during the month of June, so that the spurs and the buds about them may under the influence of the sun and air mature thoroughly, which is the all-important secret in the production of next year's crop of fruit. Some persons may say, "Oh! but Red Currants will grow and fruit well without the trouble of summer pruning." They may do, but in our case the end justifies the aim, and what holds good in this case does so in others. No more striking instance of the advisability of maintaining a thin centre by attention during the summer could be found than in the case of some Apple trees, especially three of Warner's King and the same number of Cox's Orange Pippin, standards as well as bushes. A system of extension training has been practised. Shoots from 2 to 3 feet long have simply had the points removed, but the branches have been kept thin; and although the trees have grown vigorously they have never needed root-pruning, and have not once failed to give us a full crop of good fruit for the last ten years. With such strong growing sorts as Warner's King, which succeeds so well in a retentive soil like ours, it is a good plan to tie the branches downwards to the soil, not below a horizontal position of course. This plan not only gives shape to the trees, but admits light and air to the leaves and buds in the centre of the trees, which in return will scarcely ever fail to give a full crop of fruit. Trees so managed are much better able to withstand adverse weather. Even frost will not injure the blossoms of trees that mature every portion of their growth annually under a rational system of pruning and training. The latter, no doubt, is of great assistance to the former. It often happens that branches are far too close together

to admit of their remaining so simply by pruning, but by judicious training the necessity for reducing the size of the tree is avoided, and a fuller crop of fruit assured.

Some trees of the same variety planted last autumn have made shoots this year nearly a yard long. Beyond removing the extreme point of growth—many have been already treated so—they will not be pruned any more, but the branches will be spread out to give space to the inner parts of the tree for the purpose of maturing leaves and trees alike. No matter how strong these trees may grow I do not apprehend that they will require root-pruning, a judicious manipulation of the branches will cause fruitfulness. I am a firm believer in the encouragement of a corresponding number and kind of roots to the branches. Trees which lack healthy roots cannot have a profusion of branches; the two must go together. Many trees have too much winter pruning, as Mr. Wright rightly says, and are followed by strong growth. Where space will admit the extension system of training is to be recommended, which will generally dispense with the necessity of root-pruning. Where so many persons err in pruning is with newly planted trees, and especially in the case of standards, they do not cut them far enough back the first year. Close pruning gives increased vigour, afterwards to be followed by extension training.

Mère de Ménage is generally considered to be a shy-bearing sort, but if growers would allow it more freedom in growth, at the same time not crowd its branches, I think there would be less cause for complaint. This is looked upon as a certain cropper here. One tree planted as a pyramid twelve years ago now reaches 20 feet high, the thinly disposed branches being at the present time heavily laden with extra fine fruit, the colour of which under such conditions may easily be guessed. Cherries are another instance of the wisdom of this plan. A close summer pruning, keeping the main branches thin, results every year in a full, generally extra full, crop of fruit; in fact I have never known them to fail. Gooseberries are the same, Peaches ditto; in fact, nearly all kinds of hardy fruit will come under the head of "sure croppers" provided a rational system of pruning is carried out and the natural weather elements are anything like propitious during the time the trees are in full bloom.—E. MOLYNEUX.

#### PROSPECTS OF THE SEASON.

WE shall expect to find the columns of the Journal again become full of useful and interesting Chrysanthemum news in the course of the next week or two, for as soon as October arrives attention is earnestly turned to these ever popular plants, and we amateurs are on the look out for every item that can be turned to account. The fine weather of the past few days is improving matters considerably, but up to then the prospect was not by any means all that could be desired. The sunless summer caused much rank growth which had not been well matured, and buds were not likely to develop freely into the kind of flowers we require now to enter even a very modest competition at local shows. If it be not too late a few weeks' fine weather will greatly help matters, and though gloomy forebodings have been expressed by experienced growers the events may prove better than expected.

It is especially interesting to learn something about the collections at the various noted exhibiting gardens and nurseries, and we shall look eagerly for a continuation of the notes which the Journal has favoured us with for some years.—AMATEUR.

#### DOWNSIDE.

IT is surprising what changes are brought about in different establishments by a change of owners. Downside when owned by Mr. Lee gained a reputation that was probably unsurpassed for the fine collection of Orchids. The glass houses, which are numerous, were all designed especially for their culture and well-being. Seldom we find houses so well provided with tanks of water that run the whole length of the house beneath the stages. We must pass from what Downside was, and turn to what it is now and bids fair to become in the future under the ownership of A. Tate, Esq. Those who knew Mr. Tate and his tastes when in the neighbourhood of Liverpool will not be surprised to learn that he is cultivating on a large scale his favourite flower, the Rose, with that enthusiasm that only true rosarians possess. A large amount of success in exhibiting has already been attained, and we have no doubt that before long Downside will be as popular for its Roses as it was formerly for Orchids.

For the benefit of those who have never visited Downside, it may be said that it is situated at Leatherhead, on the side of a hill, and commands extensive views of the Surrey hills and the surrounding country—a beautiful landscape splendidly wooded. The character of Downside has been almost entirely changed since Mr. Tate took possession; some extensive alterations have been made, and others are in progress or contemplation. It is not what may be called a "large" place, but it is extending—adjoining land has been purchased and added to it. Borders

of trees and shrubs have been planted with clumps here and there, which in a few years will give it quite a park-like appearance, and add much to the beauty of its surroundings. Extensive herbaceous borders have been made round one side of the pleasure grounds, which will not only be effective but useful when they are well filled with a choice selection of plants. Portions of ground once occupied by vegetables and crowded with trees and shrubs have been cleared and sown with grass. Large chalk banks on the left of the drive have had a thicket of underwood, beneath some fine Elms, removed from them, and the chalk lowered fully 3 or 4 feet or more in places that had been formerly piled round the stems of the large forest trees that fringe the hill side. The removal of so much chalk has been a work of magnitude, so as to give the bank an easy slope. A winding walk under the shade of these trees has been formed with little bits of rockwork at intervals and patches of plants. When the newly sown grass is established this part of the grounds will look well.

We must just glance at the Rose garden, which covers a large space of ground, and is to be extended again this autumn. A thousand Hybrid Perpetuals were planted last autumn, besides Teas and other Roses. The whole of the Rose garden can be seen from the residence, which stands on higher ground. The garden in question more nearly approaches my ideal of a Rose garden than any I have seen before. It is laid out in squares that hold about four rows of plants with broad grass walks between each. The larger or central beds are divided by a hedge of the old Gloire de Dijon. The hedges are to be extended, and will be broken up at distances by suitable pillar varieties that will be allowed to stand up well above the rest. In the centre of this garden is what is commonly known as a rosery formed of wire which is planted with various climbing varieties. To correspond with this are wire arches in various positions spanning the grass walks that have been alluded to. One object has been to render the garden effective from the residence as well as from any point from which it may be viewed. The broad walks of grass will prevent the garden ever having the crowded appearance of too many Rose gardens. It must not be thought that Mr. Tate is growing Roses only that are suitable for exhibiting; this is by no means the case. One portion of this garden, and the most attractive at the time of my visit, is almost exclusively devoted to China and Polyantha Roses, which were covered with thousands of their small but fragrant flowers. Apart from their beauty in the Rose garden, the beds of these miniature Roses were, without exception, the most effective we have seen this year. These Roses deserve to be planted on a much larger scale in gardens generally for ornamental purposes. Beds of the following were noticed—Mignonette, very fine; Perle d'Or, very striking in colour, even prettier than the famous William Allan Richardson; The Pet or Parquerette, Gloire de Polyantha, and several others. The absence of a note-book and limited time prevented my taking any notes; suffice it to say that this Rose garden contains examples already of nearly every section of the Rose. One or more of the glass houses has been altered and planted with Tea varieties, while a large number had been forced in pots and were standing outside. A scroll pattern of beds which border the Rose garden were filled with such sweet-scented flowers as Carnations and Mignonette, favourites that are not out of place in any position.

Chrysanthemums were everywhere on the walks close to the houses, and wonderfully well they looked. Some hundreds of plants are grown, and later on will make a grand display in the large Cattleya house which I understood was being reserved for the purpose, the sides of which were covered with Tomatoes bearing some large fine-shaped fruit. The houses at present call for no special note, they are being filled with various stove and greenhouse flowering and foliage plants, with a few Orchids. The fruit and kitchen gardens are not being neglected, the latter is being extended, while the old trees in the former are to be grubbed up and young planted, while others are to have their roots lifted out of the chalk and brought near the surface.

My best thanks are due to Mr. Tate for his kindness and courtesy in showing me his garden, and also to his gardener, Mr. Wm. Mease, who seems quite at home and happy in his new sphere of labour, and whose abilities need no comment from me.—A COUNTRYMAN.

#### GARDENING AS A CALLING.

[A paper by Mr. CHARLES GIBSON, Morden Park Gardens, Mitcham, read at a recent meeting of the Croydon Gardeners' and Amateurs' Mutual Improvement Society.]

GARDENING is one of the oldest callings, and provides some of the purest pleasures and most elevating employment. It is admitted by statesmen in charge of the weighty matters of the nation, and by merchants in hard pursuit of trade and commerce, that they derive great delight and solace from their gardens in their intervals of leisure. But the pleasures of the garden are not confined to statesmen and the wealthy, but extend to all classes down to the cottager, who enjoys his favourite Fuchsia or Geranium as much as the gentleman does his Orchid. The cottager comes out well at exhibitions with produce of excellent quality, especially vegetables, and near large towns where exhibitions are held for special flowers—Roses, Carnations, Pansies, or Chrysanthemums; but whatever the subject is, the enthusiasm is extraordinary, and consequently their products good, for seldom are extra fine specimens shown without that enthusiasm. The prosperity the country has enjoyed through the Victorian era has added large numbers to the wealthy classes who all admire and enjoy their gardens in various degrees, and employ gardeners to conduct them. In no other country is horticulture carried on with the same all-round excellence. One of

the agencies which has contributed so much to the wealth of the country—steam power—has also been the cause of our gardens being enriched with choice plants from all parts of the world. The speed with which plants are dispatched home renders loss comparatively small to what it was formerly. The trade of the horticultural builder has developed into a science for building handsome structures to accommodate the choice treasures from abroad, and made a grand addition to the pleasures of the garden. At no time of the year are they more appreciated than in winter.

Gardens possess so much beauty and interest it is not surprising so many men should aspire to make them an occupation for a livelihood, as it is not difficult to find an opening for a start in a garden, although more difficult to obtain a situation as head when qualified for the post. When the garden is seen in its best condition, and all things look so charming, the difficulties to be met, enemies to be conquered, and wintry days to be passed, are not always considered. One wishing to become a gardener should not be afraid of work; he must take a pleasure in his work, and in time he will feel a certain amount of pleasure in being able to master his difficulties. The young gardener has advantages now he did not possess formerly, but more is expected of him. Before the present system of heating became general the gardener had to be up the greater part of the night in bad weather. Now houses have to be filled all the year round to supply the requirements of the establishments, instead of having fruit houses empty half the year as formerly. Fruit and flowers are grown in the same houses, and constant vigilance is required to detect the first symptoms of disease or insects, and apply remedies before serious mischief is done. It requires great experience to detect at a glance the first symptoms of insects and diseases, but the gardener is assisted by the horticultural sundriesman with every aid for banishing them when detected.

There is such a variety of work in the garden, and the cultivation of so many subjects to be well acquainted with, that a boy wishing to adopt gardening as a calling should begin at the age of fourteen. A fair education can be gained by a boy of average ability by that age with the improved methods of teaching now in use at schools. This should be supplemented by attendance at evening classes where possible. In most towns classes are held on winter evenings, where much instruction can be gained that will be useful to the future gardener, and makes a pleasant recreation at the same time. Efforts should be made to get a good knowledge of geometry, as this is very useful to gardeners in many ways. In country districts much may be done by young gardeners meeting together and helping each other, and often a good teacher can be procured to give occasional lessons. Winter evenings are golden opportunities for young men to improve themselves and acquire knowledge, opportunities which diminish as responsibilities increase. One interesting recreation may be found in keeping a book with the English and botanical names of every plant entered, and the natural orders they belong to. It is a capital plan of getting them well fixed in the memory. A second book might be kept for little sprays of shrubs, &c., dried between blotting-paper. They should be neatly fastened in the book with name, and will be useful for reference.

It should be the aim of everyone wishing to become a gardener to make himself conversant with every branch of the business. It used to be considered the thing to get under glass, and once established there the other part of the garden was looked upon as comparatively unimportant, and it was only discovered too late that a mistake had been made in neglecting the kitchen garden department. Fashion changes in gardens, and it behoves a gardener to be abreast of the times. The demand now is for more fruit and vegetables. Hardy fruits must have good attention, and it is no slight matter to be able to keep up a continuous supply of the best vegetables. It requires a good knowledge of the best varieties, nature of the soil, as the soil often varies in the same garden, and times of sowing, as well as cultural treatment. The fine collections of vegetables shown at the leading exhibitions require the best skill of the gardener. In the flower garden herbaceous plants are becoming more popular year by year. They not only impart variety in the garden, but are also useful to meet the growing demand for cut flowers.

To acquire a thorough training I consider a youth should have four or five years in a good garden, and then to change into other gardens to gain further experience. A year or two spent in a good nursery will be a benefit, to gain an insight into methods of doing many things not acquired in a private garden. These changes, besides giving practical experience, are useful in many other ways to gardeners if they hope to hold long service in private situations, where they not only have to study the wishes of their employers, but their equals and those under them.

Other means of acquiring knowledge of their calling are mutual improvement societies and horticultural exhibitions, visiting brother gardeners occasionally, and when opportunities occur visiting leading nurseries and noted gardens. Nothing gives a gardener more pleasure than going to see a show or visiting gardens, and it is a convincing proof, if one were needed, of the love they have for their calling. Although there are many other aids I will but mention one more—the horticultural Press. The various papers contain sound information on every subject connected with the garden, reports of the leading societies and exhibitions, notices of new flowers, fruits, and vegetables, and all news of interest to the gardener brought to his notice week by week. The gardening papers are a credit to the enterprise of their conductors and to their contributors; one at least, more if possible, should be read constantly by everyone connected with the garden.

One pleasant experience in a gardener's career is where he is allowed by his employer to exhibit and becomes successful. Exhibiting rouses some men to active exertion, which so far from being injurious is beneficial to health. To some it brings disappointment, but this often arises from attempting too much. It is more satisfactory to win in a small class than lose in a large one. Employers as a rule are willing for their gardeners to exhibit, and justly proud of their success when it does not curtail the pleasures of the garden in other ways. Gardeners as a rule repay the privilege accorded them with extra exertion to meet home wants and wishes. Where the privilege is abused it brings dissatisfaction and leads to its discontinuance, but the great increase of shows and exhibitors indicates the general approval. The pay of a gardener is a weak point, for while wages have gone up in most callings, in this they have either remained stationary or somewhat declined. But medium sized gardens have greatly increased in numbers, giving scope for a good class of gardening and providing comfortable situations at wages equal to the best artisans in good trades. The wages of the gardener are regular, and supplemented generally by privileges, while artisans are liable to stoppages and to be called away from their homes to work at a distance. One disadvantage is that a gardener, having so much to learn before he feels confident to undertake a situation as head, frequently finds himself nearly thirty years of age before he is able to obtain one, with some of the best years of his life passed at low wages. Many men get impatient at the delay and turn to other employment. It has been the custom in large gardens for the gardeners to take apprentices and improvers in such numbers that many have been unable to get situations when qualified for it. If more skilled labourers were employed and fewer apprentices it should reduce the number somewhat, taking only the most promising ones with a genuine and eager desire to become gardeners. It used to be a passport to a situation if a candidate had been employed in a lord's or duke's garden. It remains to be seen whether the changes taking place in large gardens will not give the persevering man more chance.

To grow good produce in quantity is the aim now rather than to obtain a favourite dish by some particular date out of season. This is a branch of gardening that all should be familiar with, as in private places goods have to be packed for long or short distances, and if not properly packed the finest fruit and flowers are liable to injury. The decorative branch is another which should have special attention paid to it. Where one feels deficient in the decorative part it should be overcome as far as possible by noting the best examples of others, so as to avoid defects. Colours are important to a good effect, and the best decorators have light and graceful combinations, beginners' productions being as a rule too heavy. Horticultural exhibitions give scope for taste in arrangement in the groups, table decorations, sprays and buttonholes, basket and vases of flowers, and bouquets.

Many gardeners who were in private situations now have good businesses as florists or growers for market. They were persevering and enterprising, and when the opportunity presented itself seized it. With the present demand for flowers and fruit there are still openings for persevering and business men with a little capital, but many gardeners hold good situations in private places which have in a great measure been made by the men themselves. Confidence has to be won, and then retained by continued proof of worthiness. Although there is no formal union amongst gardeners, there is an unwritten bond of union amongst them, for no men are more sociable or more ready to help one another. There are also several important charitable institutions now that are well supported.

In conclusion, my opinion is that gardening offers as good an opening now for a persevering man as at any previous period. It is a healthy occupation, full of interest, capable of finding its own pleasures and amusements without going outside for excitements, and if one is only able to live respectably, and do justice to those dear to him without making a fortune, he has lived and done good useful service, filled an honourable position, and has no cause to regret the choice of gardening as a calling.

[Considerable interesting discussion followed, in which Messrs. Shoemith, Roffey, Bishop, Ritchings, Carr, and Cummins took part, and many important points were raised.]

### THE SUNNINGHILL VINERY, BY DERBY.

A VISIT to this vinery is a treat one would little expect from the quiet manner Mr. Innes has been carrying on his successful work during the last few years. Two lean-to houses have been erected against store-rooms, stables, and engine-house, and an original method of raising and heating water for the Vine borders forms a great feature in his success. The two houses in question, each 70 feet long by 16 feet wide, are heated with six rows of 4 inch pipes, and were planted with Muscats on the 10th August in Jubilee year, from eyes raised the same spring. They are 5 feet apart with two rods each. The borders were made very solid, and have two yearly dressings of fertilisers. We counted in the first house 250 bunches of Muscat of Alexandria, splendidly grown and finished, so compact and even in berry, averaging quite 2½ lbs. to the bunch. The top part of the house had still the supernumeraries with a grand crop of Gros Colman, and carrying just 250 bunches.

Two lofty span houses, 100 feet by 24 feet, were planted with Gros Colman in April, 1885, and the Vines are now carrying respectively 1500 and 1600 bunches, equally distributed from bottom to top of the houses, solid compact bunches with all the shoulders taken off, these are a fine

sight. There is also a house of Alicante of the same dimensions that Mr. Innes speaks of filling with Gros Colman. A new house erected last year, 100 feet by 21 feet, is planted with 1000 Tomatoes in seven rows 2 feet apart trained to wires, producing an enormous crop of splendid smooth fruits, with Gros Colman planted for permanent Vines. When Mr. Innes has covered the land with glass adjoining his charming residence, as he intends to do, he will have a place worthy of his efforts.—G. B.

### HYPERICUM MOSERIANUM.

WE have had occasion from time to time to note some fine additions to the lists of Hypericums, but these have been either newly introduced species, or improved varieties of older forms. In *Hypericum Moserianum* we have one of a very different character, and which is especially interesting from the fact that it is of hybrid origin. It was described about two years ago in the "Revue Horticole," and is stated the plant was raised by M. Moser of Versailles from a cross between *H. patulum* and the well known *H. calycinum*, the former being the seed parent.

FIG. 57.—HYPERICUM MOSERIANUM.

We also learn that the reverse cross was made with the same result, the product in both cases presenting a notable combination of the characters distinguishing the parents.

The hybrid has large golden yellow flowers, depicted of their natural size in the engraving (fig. 57), and the plant being of dwarf, compact, yet robust habit, it is capitally adapted for beds. In this way it has been employed at Kew with excellent results, and the flowers are produced over a period of several weeks during late summer—a great recommendation. A first-class certificate was awarded for a plant shown at the Royal Horticultural Society's meeting on August 25th this year.

### FRUIT FORCING.

**VINES.—Early Forced Houses.**—Vines that are to be forced to furnish ripe Grapes in March or early April should be started by the middle of November. It is not advisable to start permanently planted Vines so early where there is convenience for growing some in pots, as very early forcing is a great strain on the energies of the Vines through their having to make their growth at the dullest period of the year and to rest at the hottest, while there is danger that the foliage may collapse from attacks of red spider or ripen too early through lack of sufficient root moisture and aliment. This may cause the buds that are intended to furnish the succeeding year's crop of Grapes to start into growth at the time the Vines should be resting. It can only be prevented by retaining some lateral growths as an outlet for any sap which the roots absorb, and will do no harm provided they are not allowed to interfere with the free access of light and air to the principal leaves. These laterals should be removed gradually and continually from late August until early September, so as to admit of the Vines being pruned by or soon after the middle of September, and they will not bleed, nor will the buds be started into growth, the house being kept cool and dry. If not already pruned, the Vines intended for starting at the time named must be attended to at once, also those to be started in December should be pruned as soon as the foliage commences to fall, so as to give the Vines a few weeks rest. Outside borders, which are a great mistake where early forcing is practised, should be protected from autumn rains by covering them before the ground is chilled with continued wet and cold. A good covering of dry leaves with a little litter to prevent the leaves blowing about is an effective protection, and if tarpaulin is employed over all to throw off heavy rains and snow, nothing further need be done to outside borders, and they need not be covered until they have been well moistened by the autumn rains, yet before they become soddened and much reduced in temperature. Where, however, fermenting materials are available they are a great aid in forcing operations, and especially so for placing inside the house to generate and maintain a genial condition of the atmosphere without recourse to so much fire heat or sprinklings from the syringe. This we advise, and the abandonment of outside borders in early forcing, for covering outside borders is not economical, and the borders are too much deprived of atmospheric influences to assimilate plant food in proper quantity and essential form. The materials need not be used until the house is closed, but they will need to be thrown into a heap a week or ten days previously, turned and moistened if necessary. Three parts of Oak or Beech leaves to one part of stable litter will give a more suitable warmth, and the ammonia generated and volatilised will not be so great as from all dung. If there are plants in the house the fermenting materials must be well sweetened, or the foliage may be seriously injured by the vapour given out. Therefore mix them well together when thrown into the heap, damping them if dry, turning when getting warm, again damping if necessary, and when well warmed through they are fit for placing in the house.

**Early Forced Vines in Pots.**—This is the most eligible method of securing a supply of thin-skinned fresh ripe Grapes early in spring, which are a necessity in some establishments. We have tried many varieties and have not found any to surpass White Frontignan, Foster's Seedling, Black Hamburgh, and Madresfield Court. The great evil in forcing pot Vines is overcropping, the berries not attaining the size and perfection of colour and finish so essential to their high appreciation. Where bottom heat can be given to start them they will mark their appreciation by breaking freely. It is well to stand the pots on pedestals formed of loose bricks so that the rims are slightly higher than the pit edge, and so that the pots will be in the centre of the bed, which should be 3 to 4 feet wide and 3 feet deep. Leaves being placed in to fill the pit a gentle warmth will be afforded the Vines, and the roots will pass from the pots into the leaves, deriving support beneficial to the growth of the Vines, swelling and perfecting the Grapes. The temperature at the roots ought not to exceed 75°, and it is better to commence with it at 65°, and increase the warmth as the growth advances. In the atmosphere a temperature of 50° to 55° is ample until the buds begin to swell, then gradually increase it to 60° or 65° when they are breaking, allowing an advance from sun heat of 10° to 15°. The canes should be depressed to a horizontal position to secure their breaking regularly. Damp the canes morning and afternoon. To have ripe Grapes in March the Vines should not be started later than the early part of November.

**Midseason Houses.**—Black Hamburgh and other descriptions of thin-skinned black Grapes have the colour taken out of them by hanging, and can only be lessened by keeping a good spread of foliage or drawing a double thickness of herring nets over the roof lights. The latter is the preferable plan, as lateral growths interfere with light to the principal leaves and the free access of air so desirable for maturing the wood. Those from which the Grapes have been cut may have the growths cut back to a few joints above the buds, first curtailing the laterals, and then cutting back the main growths. This insures the buds

becoming plumper, whilst the freer access of light and air affects the wood favourably. A free circulation of air is necessary to expel damp where Grapes are hanging, with a little constantly to prevent the deposition of moisture on the berries, a gentle warmth in the hot-water pipes being necessary when the external air is cold and damp, but the wood being ripe and the growth matured it will suffice to maintain a temperature of 50°, and the cooler by day the house is kept the longer the Grapes will keep plump. Vines that have not the wood ripe should not have a less temperature than 60°, and this with a free circulation of air must be continued until there is no doubt on that point. Keep the laterals well in check, not allowing them to interfere with the chief growths.

*Young Vines.*—Those that have a disposition to continue growing to a late period may be checked by stopping the shoots moderately, and facilitate the ripening of the wood by a high and dry temperature by day, shutting off the heat and keeping the ventilators open by night.

*Late Grapes.*—Where these were started in March and aided in spring by fire heat, as well as during the summer, the Grapes will be thoroughly ripe, which is much better than having to maintain a forcing temperature after October comes in to secure the ripening of the fruit. In the latter case the temperature must not be less than 70° to 75° by day and 65° at night, falling 5° through the night, allowing an advance to 80° or 85° from sun heat, continuing this until the Grapes are ripe, at least until the wood is brown and hard. The fruit being thoroughly ripe, in which state only can the Grapes be expected to keep satisfactorily, and the wood thoroughly matured, all sprays or laterals may be removed down to the main buds, ventilating freely on all favourable occasions. Fire heat will then only be necessary to prevent the temperature falling below 50°. To prevent dust falling or settling on the berries raking or sweeping must not be practised. Mats or clean dry straw laid over the inside borders will to some extent prevent evaporation, assist in keeping the atmosphere dry, and prevent the soil cracking. The outside borders must be covered if the fruit is to keep well. Glass lights are best, wooden shutters good, and tarpaulin over dry bracken or straw answers well. A thick thatch of bracken or straw is very serviceable.

*CHERRIES.*—A house of Cherries is not common, but there is no fruit that is more interesting or more profitably grown under glass. The house for Cherries should be light, well ventilated both at the top and bottom, and if to be forced efficiently heated. Side lights may be dispensed with, but wooden ventilators should be provided to open the whole length of the house and on both sides of a span. The trees may be trained to a trellis fixed 12 inches from the glass, or the trees may be trained on bushes or dwarf standards and planted out. In the case of permanent or planted out trees it is desirable to have the roof lights moveable, so that the trees can be fully exposed after the crops are gathered and the growth perfected. A lean-to may be 10 to 12 feet and a span 15 to 18 feet wide with trees on each side, and in the lean-to the front trellis should only extend two-thirds up the roof and the upper part be kept 4 feet from the glass, so as to admit light to the trees on the back wall. Two rows of 4-inch piping will be sufficient for the lean-to and two rows on each side for the span, 3-inch for the 15 feet house, and 4-inch for the 18 to 24 feet wide house. The borders should be entirely inside and not made all at once. A 4 to 6 feet width of border, according to the size of the trees, is sufficient to commence with. It should be drained 9 to 12 inches deep, having proper drains to carry off superfluous water. Nothing answers better for drainage than brickbats with a 3-inch layer of old mortar rubbish over them. From 20 to 24 inches depth of soil is ample, but it must be deeper at first to allow for settling. Good turfy loam, preferably inclined to be heavy rather than light, four parts, lime rubbish from an old building one-fifth, and road scrapings one-sixth, the loam chopped up moderately small, the whole well incorporated, forms a suitable compost for Cherries. The trees may be planted as soon as the leaves begin to fall. Those that have been trained to walls four to six years are most suitable, as they will be in a fruitful state and calculated to give a crop of fruit the first season, and having been lifted annually they can be moved safely. The borders ought to be put together compactly, the trees firmly planted, and a good watering given, mulching the roots with a couple of inches thickness of short but not soapy manure. The most suitable variety is Black Tartarian, but Early Rivers precedes it, and should be given place where early fruit is required. Governor Wood is the best companion Cherry to Black Tartarian.

Cherries are readily forced in pots. This is a very desirable mode of cultivating this valuable fruit where variety and a long succession of fruit is in request. A cool house of Cherries in pots is a most useful adjunct to any establishment, and their culture is very simple, but the house must be well ventilated and the trees placed out of doors after their crops are removed, or the roof lights may be withdrawn for a time, especially when the trees are forced. Trees should be secured at once. If in pots they must be given a large size if they require it, disentangling the roots with a fork at the sides of the ball, and cutting back any straggling and thick ones. Provide good drainage and ram the soil firmly. Trees that are in as large pots as desired need only have the drainage rectified and the surface dressed, or the old drainage may be cleared away, a few inches from the base removed, the roots shortened back, and fresh soil given, as advised for borders, with a fifth of well-decayed manure, removing also the loose surface soil, and supplying rich material. If the trees are not already in pots, pyramids or bushes should be lifted, have their roots trimmed, and be potted firmly, allowing them to become established in the pots before subjecting them to forcing. The trees should be stood on a hard bottom impervious to worms, and surrounded with ashes to the rim, covering the pots with litter on the approach of frost. The trees should have a good watering

after potting or having the roots interfered with. For forcing in pots Early Rivers, Empress Eugénie, Black Tartarian, Governor Wood, Black Eagle, and Mammoth are good. For a cool house the following are first-rate, and afford a succession of fruit from an early to a late period:—Compact growers: Belle d'Orleans, Early Rivers, Early Red Bigarreau, Empress Eugénie, Bigarreau de Schrecken, Governor Wood, May Duke, Black Eagle, Archduke, Nouvelle Royal, Florence, and Late Duke. Large growers: Early Jaboulay, Black Tartarian, Bohemian Black Bigarreau, Elton, Reine Hortense, Bigarreau, Bigarreau de Mezel, Mammoth, Duchesse de Palluau, Bigarreau Napoleon, Belle Magnifique, and Tradescant's Heart.

#### THE KITCHEN GARDEN.

*TOMATOES.*—Disease has spoiled the greater portion of the outside crops; those that have escaped the most being located either against dry sheltered walls, under copings, and quite in the open. The first moderately severe frost would quite spoil the latter, and would also injure those against walls but otherwise unprotected. Seeing also that ripening nearly or quite fully grown fruit in heat greatly improves its quality, it is advisable on these grounds to clear the plants at once, hanging the fruit in bunches where they will ripen quickly. A dry forcing house, or failing this a kitchen in full use, answers well, single fruit being laid on the shelves. Thus treated much of the fruit will ripen sufficiently to eat in an uncooked state, and that which is not good enough for that would be improved by cooking. Should there be abundance of ripe fruit just now, convert much of this into sauce and ketchup, the latter being preferred by many connoisseurs; while quite the smallest fruit, and which would never ripen, could be made into excellent pickle or cooked in pies. Green fruit is also sometimes made into preserve, but with plenty of Plum jam there is less need of the Tomato substitute.

*TOMATOES UNDER GLASS.*—These, whether old or young, in pots or planted out in narrow ridges of poor loamy soil, ought now to be growing strongly, yet sturdily, the principal portion of the crops being either set, or in the course of being set, during September and October. Rank or soft growth is fatal to productiveness, and the most liable to take disease. The latter again spreads most rapidly during warm weather, and before much heat is kept in the hot-water pipes. In a dry, well heated atmosphere, such as can be maintained with the aid of heat constantly turned on, and air in small or larger quantities both night and day, according to the outer weather, disease makes but little headway, and under these conditions is less troublesome during the winter than at any other period of the year. The same treatment favours a sturdy fruitful growth, the flowers being strong and pollen abundant, nothing but a smart tap with a hazel twig towards midday being necessary to distribute the latter and to effect a good set. Lay in young growths thinly all over old plants, and stop the side shoots on young plants fruited cordon fashion at the first joint instead of cutting them cleanly out, fresh additions of young foliage being especially necessary where disease is troublesome. There is no necessity for or wisdom in starving Tomatoes, always provided the other extreme is avoided; therefore top-dress with loamy compost occasionally, heavy crops being further supported by surfacings of special manure, or with liquid manure. Sulphur on the hot-water pipes is fairly effective against disease during the winter months, and proves fatal to the troublesome white fly (*Aleyrodes vaporariorum*). Now is also a good time for trying other remedies for disease, including anti-fungus powder and the Bordeaux mixture.

*OPEN-AIR MUSHROOM BEDS.*—The early part of September is the best time to make or spawn open-air ridge-shaped beds, for the simple reason if all goes on well the crops will be produced towards the end of October and more or less throughout the winter. There is no reason, however, why other similar beds should not be made and spawned throughout October, as these, if properly managed, will yield exceptionally heavy crops early next spring, severe frosts not in the least impairing their productiveness, though too much moisture might. In any case it is of the greatest importance that the material be extra well prepared. Put together in a rank semi-raw state it is certain to heat very violently and perhaps fail to produce Mushrooms, while if the manure is too much exhausted of its heating properties failure may occur that way. Gentle fermentation, and turning it every alternate day is the better plan, this getting rid of much of the rankness in the course of a fortnight or rather more, without undue loss of vitality. If there is not sufficient moisture in it to insure gradual decay, then supply it with a watering-pot and rose, but saturating rains should be warded off with shutters or other contrivances. The manure being of a dark brown colour, sweet, and only just sufficiently moist to bind together when squeezed in the hand, is most probably in a fit state for making into beds. At least one part in three of the material should consist of short stained straw, the longer portions of the latter being stored and kept from heating in the dry, as this will be wanted for covering the beds. A ridge may be of any length, about 3 feet wide at the base, and nearly as much in height, the top being 6 inches or rather more across. It ought to be put together very firmly and neatly, and in a spot where the rainfall draws away rapidly, and if some shelter from cold winds is afforded so much the better. The preference, where possible, may well be given to a spot where neither moles nor mice can get at the beds, both being very fond of burrowing in them, while mice are also very partial to Mushrooms.

*SPAWNING THE BEDS.*—Two or more trial stakes ought to be thrust deeply into the beds when first made, and very heavy rains be warded off, without, however, unduly confining the heat. In mild weather

newly formed ridge-shaped beds are apt to heat very violently, and earlier in the season it is sometimes necessary to pull them to pieces and remake. There is less likelihood of this happening now, but at the same time they must be watched closely both before and after spawning. The heat probably will soon run up to 90° or rather more, but not till it declines to 80°, or till the trial stakes can be comfortably borne in the hand, should the spawning take place. Give the preference to fresh spawn, avoiding old or cheap substitutes, and break cakes or bricks into six, or not more than eight pieces, large lumps being the least liable to be injured by too much heat or steam. Insert these flatly, and just below the surface, in hand-made holes 8 inches apart all over the sides and ends of the beds, none being required for the tops, finishing off with a good beating with the back of a spade. Cover lightly with litter, and if there are no signs of an increase of heat ease over with soil four or five days after spawning. For this purpose use the best fresh loam procurable, breaking this up fine, and failing loam substitute well pulverised garden soil. Cover the beds evenly with about 2 inches of soil, making this firm with the back of a spade, but avoid watering and then plastering it, as injurious shrinkage and cracking would inevitably result. The casing of soil naturally prevents the loss of much heat, and over-heating may be the consequence. Therefore keep a close look out, and on the least sign of the heat increasing to an injurious extent at once form several deep holes down through the centre of the beds, this being best done with pointed iron rods. With such outlets for steam provided, the bed will be safeguarded. Neglect the precaution and failure will most probably be the result. Cover at first very lightly with strawy litter, but when the heat declines somewhat give a heavy covering of it, or, say, to a depth of 12 inches, finishing off with a neat thatch. This covering serves to keep the beds warm, and to ward off heavy rains.

**MUSHROOM BEDS IN SHEDS.**—It is not yet too late to form either flat or ridge-shaped beds in sheds, stables, or other sheltered positions. If they fail to commence cropping this winter they will, if not interfered with, yield abundance of good Mushrooms next spring. Such beds should be well screened from currents of cold air, and be also heavily covered with strawy litter.

## THE BEE-KEEPER.

### RETURNING FROM THE MOORS.

I RETURNED home from the moors after a six-weeks sojourn amidst a fine bloom of Heather and terrific storms of wind and rain, experiencing four calm days only all the time. The Heather at my time of leaving was still in fine order, but the weather was unpropitious. I observed in the Journal that August in London had been the coldest for many years, but at the Leadhills it was a higher temperature than the three preceding years.

Bees had no chance of gathering honey amidst such storms. Exposed hives were tumbled and blown about as if they had been sheaves of corn. They were taken to and from the moors without loss or mishap. Only a few were dead when released, a very different state of matters from others situated near where my own were, whose bees have been completely destroyed on the return journey, the chief causes being defective ventilation and closing the bees in when in a state of excitement. The best means of preventing such a calamity would have been in closing the entrances the evening or early morning previous to their departure, and a day or so sooner had the ventilators opened. I have often called the attention of readers to the fact how ill adapted the modern hives are for profitable bee-keeping, and can therefore corroborate the remarks of "A Hallamshire Bee-keeper" on this subject at page 276. There is no question but that in modern times bee husbandry has been chiefly taught by inexperienced men. The hives recommended by the modern school are by far too bulky and weighty, and are easily damaged by the prominent projections, in most cases quite unnecessary. Cheapness in the transport of hives is of the first consideration, for if that is wanting bee-keeping in its best aspect cannot be profitable.

Then again we all know how much the straw hive has been condemned by the modern school, and yet it has this year surpassed every form of wooden hives; they are the only ones at the moors that have given finished supers. Although I do not place straw hives as superior to wooden ones, still I hold that they are not so much inferior to wooden hives, from a profitable point of view, as has been represented. I shall have something more to say upon this subject on a future occasion.

So far as surplus honey is concerned I am inclined to think it will be almost a failure. It is true some hives have risen in

weight between 30 and 40 lbs., but the greater number of them will be between 10 and 20 lbs., just as much as with little feeding will make good stocks. The greatest surplus will be from surplus or condemned hives, and as these are mostly prime swarms the honey being from new combs will be of good quality, being the only combs that Scotch bee-keepers care to extract honey from, as doubtless old combs taint honey and often unpalatable.

### PUNIC BEES.

These have had a bad chance at the Heather. I introduced two pure queens as they were imported from Africa, one on the 13th and the other on the 20th June last. The first was put into a hive rather more than half full of combs, the whole of the honey being removed, and the half pound of bees fed 1 lb. of sugar. The other was joined to about three-quarters of a pound of bees having three half-sized combs, the others being partly filled with comb foundation, and had no feeding. The bees they were put against had their hives full minus three half combs (being three combs of one shallow division) the bees were crossed Carniolians, and had about 10 lbs. of honey, and were double the number of the Punic queens, the latter being in this respect much handicapped as a beginning. The Carniolian queens were young, and started laying some days before the Punics were introduced.

By the 1st of August the Punics were a long way ahead the Carniolians in numbers, and had there been honey to gather then or after they were taken to the Heather I have not the slightest doubt but they would have made a high record in honey gathering. But before the few fine days came the Carniolians were gaining strength, with the result of these bees being 2 lbs. ahead the Punics—that is from the time they were set down at the Heather till they were lifted; but if we take them from the 13th and 20th June the Punics are far ahead. I am not yet satisfied with the trial. The season has been bad, and the test, although seemingly fairly made, was in every respect against the Punic bee. The crossed Punics are again far ahead of other varieties, and have proved themselves the best honey gathering bees extant.

I am sorry the weather was so inauspicious as to prevent a thorough trial of to appearance the smartest bee yet imported. It was a treat to see them working when they had a chance. But further experience is necessary before I can confidently recommend them as superior honey gatherers.

### ARE THEY ROBBERS?

They are, perhaps, not more so than other varieties; but they have the knack of passing the sentinels of other hives without molestation, carrying off the honey in a style quite in keeping with the nigger race, and I am sure with an alacrity unseen and unknown in other varieties. This is one point in which I fail to support "Hallamshire Bee-keeper's" observations, for when the bees were let loose after they were home from the Heather they at once attacked several hives, and had I not contracted the entrances of the attacked hives, the Punics would very soon have made short work of them. At the Heather they attacked the strongest hives having wide entrances, and the robbing went on until I contracted the entrances of their hives. One extra working hive I observed loitering, gripping at stranger bees and covering the alighting board. I contracted its entrance, and the moment that was done the bees set to work vigorously. I, therefore, must dissent from the statement that narrow entrances favour robbing.

### A CAUSE OF ROBBING.

It often arises from the bees being gorged with honey. When bees are in transit they sometimes fill themselves to repletion; they then when let loose become an easy prey to robber bees, and do not or cannot defend themselves and their stores until they have disgorged themselves and rallied; they then defend their hive from intruders, and the robber bees of whatever variety are compelled to be honest.

When there is scattered honey in the hive, and the bees have comb to make, they are easily robbed, and can only be stopped by contracting the entrance. There is still another incitement to rob which I have often warned your readers against—viz., too

rapid feeding. Rapid or fast feeders as they are called are risky to use, as is the custom of opening weak hives and filling combs with syrup, the bees in both cases will become gorged and be unable to resist robbers.

The above are some of the conditions that affect bees when their hives are robbed and are in the same state we wish them to be when manipulating to prevent stings, or when joining two or more swarms together to prevent slaughter, and bee-keepers should study the different phases. Great care is necessary when feeding that it be not in excess of bees and combs, as well as to be careful all chinks and ventilators of hives be closed during a dearth of honey, or robbing and slaughter will be the order of the day. Other points of interest must be held over till a future occasion.

#### COLOUR IN BEES.

Some time since I drew the attention of your readers to the various colours in drones of the same variety. It is a well known fact that queens and the worker bees of different hives but of the same breed assume different colours; but there has never, so far as I have observed, been any explanation of that fact. During August of the present year, after the drones were either removed to the moors or were well killed off (although many are still living), a Carniolian queen was on the wing, and when she returned to her hive inside a small bee house having an arched entrance, and separated from the hive 4 inches, a light coloured drone came into contact with the queen, both disappearing between the hive and bee-house for a few seconds, when the queen entered the hive in a changed state, her progeny being of a very light colour, and similar to their father. We can now understand the cause of light and dark coloured bees; but who will explain the great variation in the colour of pure-bred drones?

#### PURE CARNIOLIANS.

I am glad to see an exporter of these bees stating in a Continental journal that Carniolians having yellow bands or stripes are not pure. This news would have come with more grace had he thrown more light on the subject, stating why they were ever crossed, or why it was that out of fifty queens I had from him several years ago only three produced workers free from yellow bands.

I have still the Carniolian in its pure state as imported some sixteen years ago, and think them worth keeping pure, so rare to be had from their native haunts in Austria. I am sure many beside myself would like to have these bees pure, and can see no reason why some enterprising person or firm should not start the breeding of these bees for sale in this country. There are numerous isolated places in Scotland where a limited number might be raised annually, and so preserve the most mild tempered bees in the world from extinction.—A LANARKSHIRE BEE-KEEPER.

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Books** (*H. T., Macclesfield, and F., Slough*).—Mr. Lewis Castle's manual on Orchids can be had post free from this office for 1s. 2½d. (*J. B.*).—We do not know any work of the kind you mention.

**Mustard and Cress for Market** (*H. O., Leytonstone*).—The number containing the article to which you refer has long been out of print, but you will find the same in No. 300 of *Garden-Work*, which can be had from this office, post free, 1½d.

**Caterpillars on Trees** (*Inquirer*).—The insect appears to be the caterpillar of one of the small moths called the Pearl moths. The species, we think, is that named *Spilonotes cinctalis*. It is not usual to find it feeding quite so late in the year, but this is a singular season. The food is various trees and shrubs, such as Hazel and Elm, also Maple and some fruit trees. From its habits it is difficult to deal with such a species if troublesome to the gardener. It runs with much celerity either backwards or forwards. If alarmed it usually falls from the food plant, and might be dislodged from leaves by vigorous shaking. We never heard of its being common enough to do any noticeable injury.

**Prairie Roses** (*A Subscriber*).—These are climbing Roses of vigorous habit and rapid growth, well adapted for covering walls, banks, wire trellises, and trunks of trees, but they are not much grown in this country, and little propagated by nurserymen, because in small demand. In your locality it would be necessary to give the plants a warm situation, preferably a wall or bank with southern exposure. On the latter they should be planted about 6 feet apart, and the growths may be pegged on the ground after the shoots are full grown and becoming ripened. They are beautiful as standards trained as "weepers," but the plants in this form are difficult to obtain. The only varieties we know to be cultivated in this country are Baltimore Belle, pale blush; and Caradori, flake white. The best time to cut Box and Privet hedges is in August, from the early part to September, as the season influences the growth. When Box requires much cutting in it should be done in spring, just before or when new growth is being made, choosing mild moist weather toward the latter part of April, or later if frosty.

**Vine Leaves** (*G. S.*).—The leaves have had their surfaces injured by some deleterious substance, or been acted upon by heat so as to cause the destruction of the tissues to the extent of the blotches, which extend over much, and in some cases, the whole of the leaf. There is no trace of animal or vegetable parasites—insects or fungi—but there is a whitish deposit on some of the leaves, which may be a result of using water containing lime. The petioles of the leaves are perfectly healthy; no trace whatever of shanking, nor does it affect the leaves. The blotches are simply caused by scorching. It may be by the use of a corrosive solution; by keeping the house close and moist during cold and prolonged sunless weather, and then the sun in a bright subsequent period acts on their watery tissues, heating them, and thus causing them to scorch, because air has not been admitted early and insured evaporation from their surfaces, and consequently heating slowly and correspondingly with the surrounding air. They may also scorch through inferior glass, or its clearness would cause the leaves to scorch by admitting more light and heat, especially after a dull period, than they are able to endure. This often occurs with Vines under large panes of clear glass, and their tissues being soft, both through the cultivator's effort to induce as much growth as possible and the inherent tendency of young Vines to have tender tissues. Hence we find these scorched by sun whilst older Vines under more rational treatment have their foliage intact. Fumigation would also produce the scorching when excessive, especially if the foliage were moist. That something of the kind indicated is the cause of the leaves being scorched we have no doubt. The leaves certainly are very small, very thin in texture, but they are perfectly healthy, and their footstalks and veins have the rich reddish purple tint or the yellow hue so characteristic of a due supply of nutriment of the chlorophyll-forming character, and we should say that all the Vines want, as regards soil constituents, is a supply of phosphatic manure, as steamed bone meal or superphosphate, and may be potash, but that would be supplied in the leaf soil. Provided the natural soil is a good loam, containing over 50 per cent. of sand, not more than 20 to 25 per cent. of clay, and 5 to 10 per cent. of lime, there is no reason why it should not grow good Grapes with the essential humus—5 to 10 per cent., which seems to have been added—namely, a lot of rotten leaves and old hotbed manure. That soil, naturally or artificially well drained, ought to grow good Grapes under judicious management. The soil, however, may not be suitable, yet it is a mistake to assume that the turfy loam of an old pasture only will grow Grapes, for we have found that the soil of many gardens is far better suited for Grape growing than loam had at great expense off soils not suitable for Vine growth.

**Cucumber and Melon Leaves** (*T. B.*).—The Cucumber leaves are large, thin in texture, and have the appearance of those produced by plants that are infested with eelworm (*Tylenchus* or *Vibrio devastatrix*), in the stems and roots. Though large, the leaves appear ill nourished, and they flag and scorch under powerful sun, some becoming blackened at the edges, and over a considerable portion of the leaves; whilst other parts turn yellow, and are blotched as if scorched by sun. The fruit exudes a gum-like fluid, and extravasation of sap also takes place from the stems. For this disease there is practically no remedy for infested plants, but it certainly is not caused or accelerated by "too much soot and burnt refuse in the soil," unless it produces over-luxuriance and weakens the tissues. This, however, will not cause the infestation by eelworms, though it may facilitate their attacks; for these pests are present in the soil, and usually attack plants that lack a proper supply of potassic elements, as Clover, and plants which, through a deficiency of that substance and phosphoric acid, are unable to assimilate nitrogen. Burnt refuse ought to supply the necessary potash, and soot the needful nitrogen, but there may be a deficiency of other ash elements which are essential to give solidity to the growths, and better enable them to

resist attacks of eelworms and similar micro-parasitic pests. An excess of nitrogenous manures certainly tends to favour eelworms, but they attack plants under any and all circumstances, and there is practically no remedy for this disease. The only means that we have found of any value was to use sweet soil only, and keep it in heaps well exposed to the air and dry until it became well nitrogenised by the minute organisms that exist in the soil for that purpose, and which they often fail to effect through the absence of, or insufficiency of lime in the soil. When fresh turf is used we have found it an excellent plan to heat it in an oven or over a wood fire to the extent of killing the herbage and the micro-parasites that subsist upon it, particularly that of leguminous plants. In using turf it is a capital plan to mix a bushel of quicklime with every ten of turf some little time in advance of using it for compost. This causes the decay of the vegetable matter; but there is no loss, for the nitrogenous elements are converted into nitrates by the minute organisms already referred to. Instead of using nitrogenous manures for Cucumbers and Melons we have found it most advantageous to use phosphates or superphosphates, and if other elements are needed apply them in sulphate form, or as sulphate of ammonia when vigour is needed; but it certainly is not required by your plants, their chief need appears to be solidification and less stimulation. The Melon leaves have far more substance, and evidently only required more air and less atmospheric moisture to have succeeded. But you say nothing about the mealy bug on one of the Melon leaves sent to us. That and the sulphur splashes on the leaves prove that the culture is not of the cleanliest, and without that it is useless expecting good results.

**Grapes Ripening** (*Lady Gardener*).—Gros Colman Grapes are rather late in commencing to colour as compared with the early and midseason varieties, they, and all the thick-skinned late varieties, requiring a long season of growth and a longer time to colour and ripen properly. The temperature you are keeping is quite sufficient, but these Grapes do not finish satisfactorily in artificial heat unless they have plenty of sunshine and air. This is the reason that we advocate starting late Vines not later than March, and giving them encouragement in spring, so that they may be well advanced in growth when the weather becomes warm and the days are long. This secures to the Vines the best part of the year to swell and finish their crops, and all thick-skinned late Grapes should have an opportunity of colouring and perfecting during the months of August and September, during which the solar light and warmth are not greatly diminished. This is not only better for the Vines than artificial heat, but it is more economical, for the most that is then needed is a gentle warmth in the hot-water pipes to insure a circulation of air, and keep the Vines in steady progress during any cold or dull periods that may prevail. It will very much depend upon the state of the weather and the advanced condition of the Grapes as to whether you will be able to ripen them or not. If the Grapes are only commencing to colour they will not ripen perfectly, and though they may colour, which is doubtful, the Grapes will not have the quality and keeping value of those that were ripened under more advantageous conditions. Water will not help them to colour and ripen, but rather retard both. Unless the border is becoming deficient in moisture watering should be avoided; at the same time it is necessary that the soil be kept healthfully moist, and if you give a supply let it be tepid and apply early on a fine day, giving enough to moisten the soil through to the drainage. Watering would not do Gros Colman and Black Alicante any harm whatever, but it would have a prejudicial effect on Madresfield Court, probably causing the berries to crack, especially if the atmosphere of the house were kept close. The half swollen berries on Madresfield Court Grape may be due to shanking, and that such is the case appears probable from such berries shrivelling, but as they have not moved since the stoning process their smallness may be a consequence of imperfect fertilisation. Their only being half coloured indicates shanking. A high temperature causes Grapes to shrivel even when not ripe at this time of year. We should continue the temperature at 60° to 65° at night, and keep it at 70° to 75° by day, and utilise sun heat as much as possible by keeping the ventilators not more open than is sufficient to insure a circulation of air, allowing the moisture resulting from evaporation to pass off freely, and the temperature may rise to 85° or 90° without prejudice to the Grapes. On dull days it is better to keep the house at the maximum night temperature—namely, 65°, than have recourse to sharp firing, and cause the Vines to excessively evaporate, when assimilation cannot possibly take place, and the loss thus occasioned is made manifest in the shrivelling of the Grapes. This is a common occurrence, and is often attributed to lack of moisture at the roots. Dryness at the roots certainly will cause the Grapes to shrivel, and of this matter—namely, the need of water, you only can form a right conclusion. If the soil be moist water will do no good, but absolute harm; but if the soil is dry, or inclined to be dry, a thorough watering, as before advised, will be necessary to enable the Grapes to finish and prevent their shrinking.

**Names of Fruits.**—*Notice.*—Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot

be preserved. (*J. A. R.*).—The Pear is not known. (*Mr. Clay*).—The Plum is Washington. (*Rev. C. P.*).—Beurré Langelier. (*G. H.*).—Both fruits sent are of one variety—i.e., Royal George. (*D. C. Cousins*).—1, Marie Louise; 2, Beurré Amande; 3 and 6, unknown; 4, Manx Codlin; 5, Tom Putt. (*T. W. Wellington*).—1, Cox's Pomona. 2, Striped Beefing; 3, Lane's Prince Albert; 4 and 5, not known; 6, Devonshire Quarrenden. (*F. G.*).—Peach Royal George. 1, Gravenstein; 2, Cox's Orange Pippin; 3, Winter Hawthornden; 4 and 5, not in condition for naming; 6, Longville's Kernel. (*W. M. E.*).—2, Winter Greening; 1, not known. (*J. W.*).—1, Unknown; 2, Beurré Capiaumont; 3, Knight's Monarch; 4, Doyenné du Comice; 5, Autumn Compôte; 6, Lawson's Golden Gage. The plant is *Choisya ternata*. (*A. J.*).—1, Not known; 2, Foster's White Seedling; 3, Madresfield Court; 4, Trebbiano; 5, Mrs. Pearson; 6, Golden Hamburgh. (*A. H. P.*).—The Pear is *Sucrée Vert*.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*G. J. B.*).—The pieces of shrubs sent would not be determined in that condition. The variegated *Asplenium Adiantum-nigrum* is well worth preservation. (*J. W.*).—The plant is probably *Cyphomandra betacea*, which is sometimes termed the Tree Tomato. (*D. D.*).—*Thalictrum adiantifolium*. (*R. S. B.*).—*Malus floribunda*, which is figured in vol. xv. of the *Flore de Serres*. (*H. S. B.*).—*Lophospermum scandens*. (*S. K.*).—We do not undertake to name trees from leaves, and you furnish no particulars as to habit. (*W. H.*).—The above remarks also apply to your specimens. The flower is *Nerine Fothergilli*.

### TRADE CATALOGUES RECEIVED.

L. Späth, Rextorf, Berlin.—*General Catalogue*.

J. W. Woodward, 63, Grenville Road, Hornsey Rise.—*Catalogue of Bulbs*.

Dobie & Mason, 22, Oak Street, Manchester.—*Catalogue of Bulbs*.

Charles Turner, The Royal Nurseries, Slough.—*Catalogue of Roses, Fruit Trees, and Nursery Stock*.

### COVENT GARDEN MARKET.—SEPTEMBER 30TH.

MARKET lighter this week, Plums being nearly finished and pickers employed on Hops. Prices firmer.

## FARMS IN HAND.

THE example given last week of a run-out farm, and the account of its reclamation from a state of comparative barrenness to one of fertility, is but one of many which might be cited to show something of the many aspects in which land management presents itself to us. On that farm every stroke was the result of deliberate forethought, of a settled purpose and plan, and as we have shown by the wise and timely assistance of the landlord it was carried through to a successful end. Not, be it remembered, that we ever are at the end of such work. When a man undertakes to reclaim farmed-out land he must bear in mind that, however carefully restored, land of all kinds falls out of condition again quickly if again neglected. To turn a farm of 400 acres into what was practically a sheep run means one of two things—either that it is to be steadily maintained in a high state of fertility by an energetic and comprehensive system of cultivation, into which sheep folding enters largely, or it is to sink to the level of ordinary pasture, and the sheep left to roam at will. Cultivation here means drainage, weeding, the application of manure, the timely mowing of hay crops, all simple enough, yet so seldom done in the right way, if done at all.

We say, therefore, get the farm into condition as carefully and quickly as may be, and keep it so. All our best farmers use enormous quantities of manure, they literally cram the soil with it, and it answers, just because it gives them crops altogether beyond the ordinary bulk, and of the highest quality. We have seen striking examples of this near large towns, and away in the country. As a general rule sheep farming on a large scale is a safe thing, but the farmer must know his way, and place no reliance on shepherds, and not too much on bailiffs. No, his must be the eye and hand to guide and control, and he will do better than others, because he is always looking forward. To purchase a breeding flock is expensive, and it must be done gradually and with due caution, but never purchase old or inferior animals, for that points to losses and vexation.

It will of course be conceded that a dairy farm has its own peculiar claims. Can we turn our farm to account for such a purpose? Quite possible, only here we have to consider locality before deciding upon the class of dairy farm that will answer our purpose best. Avoid a small cheese or butter dairy; it will not answer, and there will be much disappointment and loss in the future. Either send the milk to a butter factory, or consign it to a salesman. Get it away from the farm morning and night, and the process will be simple enough, and there can be no question but it is profitable. There must be a clean warm cow house, and elevated cistern and refrigerator, and a station or factory cart.

The cows are the rock on which so many home farmers split. Why buy pedigree stock? Why buy any cows or bulls at fancy prices? We know a home farm where the accounts at the last audit were upwards of a thousand pounds to the bad. But then if good people will do such foolish things as to squander their employer's money upon costly stock we say they court failure and ruin, for that was the practical outcome of this extravagance. We know another farm to which additions are made annually, upon which there is an annual loss of several hundreds. Here pedigree stock of all kinds is purchased and bred, but the result is perennial complaints and heart-burning.

Now, why not obtain cows at prices well within the means of an ordinary tenant farmer? Not mongrels, but of such fine breeds

as Red Polls, the Guernseys, or polled Aberdeens? We are confident that excellent animals of such breeds can be had at an average price of £15 per head, and that is decidedly what we term a safe price, because any inferior milker can always be fattened profitably. For the milk market Dutch and Shorthorns often have preference, because they yield such large quantities of poor milk, which meets as ready a sale as the other. Very curious is the deep milking property of a cow. We know a certain village in the midlands where the parson's cow yields 6 gallons of milk night and morning, or 48 quarts daily. His man always takes two buckets to the milking, so abundant is the yield, and what is more to the purpose the milk is of excellent quality. Every farm in the parish is a dairy farm, yet not one of the farmers can approach the parson in this matter. Conceive of a herd of such cows! Why not, why can we not have it? Simply because of the little extra care and trouble involved; yet that is how we approach perfection even in this matter by selection and careful breeding for half a lifetime.

## WORK ON THE HOME FARM.

The corn has been cleared, and the threshing machine has sent its unsuccessful droning far and wide over the land, for as we are told so frequently at this season of the year, "farmers must have straw." Of course they never want money! But that is what the brisk corn threshing really means, for there is harvest to pay for, and it has become so much a matter of hand to mouth with them that very few farmers have the money for harvest payments beforehand. Half a crown is given to each man when the agreement for price is made, and then the men should have £1 weekly on account, but do they? The whole state of things is rotten to the core. There can be no doubt that very many corn farmers are still sadly straitened in means, and that their best efforts are consequently crippled, and they are unable to bide their time for a market. They must have money at any cost, so the corn is threshed prematurely and sold for what it will fetch. Well, we can only say to all and sundry, Don't thresh your corn yet, for the Wheat will probably be soft, and the Barley on sweat in the stacks. Get at the land, and keep the ploughs and harrows going briskly. Every fine day is a golden opportunity for the future; turn it to full account now, and it will make a week's difference next spring. Get the land clean, and then ridge it at once, taking care that water furrows are carried through into the nearest ditch. There will be the land high and dry, cleansed by every passing shower, sweetened by every storm that blows, ready to your hand next spring like a bed of ashes.

Pasture growth is so abundant that it is certain there will be much old fog to clear off at the back end of the current year. Just consider if you have the class of stock to do this. We think the home farmer's dairy cows ought never to be put to this sort of grazing. In Leicestershire, where the cheese making ends with October, and then most of the cows are "dried," it appears to answer; but we are bound to say the cows fell off sadly in condition last winter under this regimen, and a little inferior hay scattered once daily about the pasture. Of course their exposure to all weathers must tell upon condition, and it is questionable if they would have come out much better in spring had they had plenty of really good food. All these things are comparative, but let the home farmer see that his cows have the best food and the best shelter.

## METEOROLOGICAL OBSERVATIONS.

CAMDEN SQUARE, LONDON.

Lat. 51° 32' 40" N.; Long. 0° 8' 0" W.; Altitude, 111 feet.

## REMARKS.

20th.—Bright till 11 A.M., then generally cloudy, with occasional spots of rain.  
 21st.—Overcast and showery till 9 A.M., then generally bright till mid-day, and frequent showers after.  
 22nd.—Bright till 11 A.M., heavy rain at 11.20 and noon, then bright again, thunder from 4.43 to 5 P.M., lightning at 4.43 P.M.  
 23rd.—Cloudy till 4 P.M., then bright.  
 24th.—Fog early, bright sunshine from 9 A.M. to noon, generally cloudy, with spots of rain in afternoon.  
 25th.—Wet early, and generally bright after 10 A.M.  
 26th.—Squally mornings, but fair; shower about 11.30 A.M., then fine.  
 An unsettled week with frequent showers, but a good deal of bright sunshine. Temperature slightly above the average.—G. J. SYMONS.

## THE CONIFERS.

THE family of the Coniferae is one of the most distinctly defined, interesting, and important in the vegetable world, and the Royal Horticultural Society has done well in providing an Exhibition and Conference which should attract prominent attention to such a group of ornamental and useful plants. The Conifers which adorn our gardens and parks, or furnish us from distant regions with an apparently inexhaustible supply of timber, also possess numerous other interesting aspects. Though opinions differ as to their landscape value, and some prefer the varied seasonable changes displayed by deciduous trees, yet we find within the family a great diversity of habit—from the boldest Pines to the most graceful Firs, Cypresses, or Retinosporas. The shades of green that distinguish the foliage are also innumerable, ranging from the darkest and most sombre tints to the lightest and brightest silvery or bluish glaucousness. The Conifers are interesting, too, as representing the flora of widely extended regions, both north and south, and their value is increased by the fact that a large proportion of the species are hardy in Britain. To the student they also present a great subject, linking long past geological ages with the present, and furnishing in the wonderful coal supplies a very practical reminder of the essential utility of the family in all its stages of development.

At one time, within the memory of many readers, much attention was paid to the Conifers for ornamental purposes, and the formation of a pinetum was considered almost indispensable in the design for establishments of any pretensions. Where the situations were well chosen and the circumstances favourable these have now become grand examples of their respective kinds, but on the other hand, the injudicious selection of species which had not been sufficiently tested as regards their hardiness, and planting in unsuitable soils, led to failures that had a most deterrent effect upon the extended popularity of the plants. These failures, in fact, have checked the planting of Conifers on a large scale, which have been neglected in a surprising manner, when it is remembered how many examples of conspicuous success have been observed and chronicled.

In extensive pleasure grounds and parks many strong-growing Conifers can be advantageously planted in numbers. On the other hand, in gardens near the house, or wherever space is restricted, quite a different selection must be made, and ultimate success will depend greatly upon the judgment exercised in this matter. The position, soil, and climate of a garden also require consideration, as many fine Conifers will thrive in the south and west of England that prove quite unsatisfactory in the north, or in any cold exposed localities. In regard to this, however, protection in the early stages is a matter of much importance, as numbers of reputedly tender Conifers only need some adequate screens from cold winds for a few years until they are well established and growing freely. In most northern gardens abundant examples of this are afforded, and where suitable protection, by stronger-growing trees or shrubs, has been afforded, at the critical time, comparatively little difficulty is experienced in forming good collections of Conifers from Yorkshire or Northumberland in England, to Perthshire and beyond in Scotland.

For lawns and pleasure grounds in proximity to the dwelling house single specimens of the dwarf, bushy, or fastigate Conifers, are preferable, but in their employment and the system of planting adopted there is room for the exercise of much taste. An undue proportion of the Biotas, Thuias, or plants of similar habit produce a most displeasing formality, and attempts to place such Conifers in clumps is usually unsatisfactory to a remarkable degree. Well-developed specimens of the green or golden Arbor-Vitæ, Yews, &c., have a fine appearance when not too closely placed, but it is necessary to have a fair proportion of the more graceful Retinosporas or Cryptomerias, with some deciduous trees and shrubs to avoid a monotony of tint. An admirable example of this mode of planting is seen in Baron Schröder's garden, The Dell, Egham, where the numerous specimen Conifers on the lawn and near the house are backed up with massive beds of Rhododendrons, the fragrant and profuse deciduous Azaleas, Kalmias, and other American shrubs. Beyond these are belts of common Laurels, with miscellaneous strong-growing deciduous trees, shrubs, or Conifers, which, while yielding adequate protection, serve as a kind of frame to a tasteful garden picture. In large gardens the pinetum, when well planted and properly attended, is one of the most important departments, but there are thousands of gardens where such extensive experiments cannot be undertaken, and it is still possible to have within moderate compass a fairly representative collection of the principal coniferous types.

Shallow poor or dry soils are the worst for Conifers generally, and though some can be found to thrive on chalky soils they are not very numerous, especially amongst those of dwarf habit. For moist situations several can be named, but all object to stagnant water in the soil. A well-drained deep rich soil is the best for Conifers of all kinds, and when planting near a house it is advisable to form suitable stations wherever these conditions are not naturally provided. Remove the soil to a moderate depth and of a width proportionate to the extent of the roots, refilling with good turfy loam and leaves from which all the woody portions have been taken. This should be trodden rather firmly after the tree is in position and a liberal supply of water afforded. For some Conifers leaf soil is used very freely, and we have seen serious evils result from this, especially where it contained a quantity of woody substances, as fungoid growth is produced that speedily renders the soil sour and the trees unhealthy.

A brief review of the family in its principal divisions will serve to illustrate the range of form and the methods of classification adopted without going into details respecting the structural peculiarities. First in order, and also by far the most important of the sub-divisions, is the Abietineæ, which comprises all the Firs and Pines that constitute such a prominent feature in many northern landscapes. These two take high rank amongst park and garden trees that attain considerable proportions, and above all are of the greatest economic value. Only six genera are included in this division—namely, *Abies*, *Larix*, *Cedrus*, *Pinus*, *Araucaria*, and *Dammara*, which in their geographical distribution cover the whole of the northern temperate zone extending through the members of the *Pinus* group into tropical regions, while the *Araucarias* and *Dammaras* are the representatives in the southern hemisphere. The principal genera in British gardens are *Abies* and *Pinus*, to which so many species belong that still further sub-division is adopted in each; thus in *Abies* there are three groups, *Piceæ*, comprising the Spruce Firs, of which *Abies excelsa* is the best known example; *Sapinæ*, the Silver Firs, including many of the most ornamental Conifers known, such as *A. cephalonica*, *A. Nordmanniana*, and *A. grandis*; and *Tsugæ*, the Hemlock Firs, such as *A. Albertiana* and *A. Douglasii*.

The Pines are sub-divided in a very simple way, and one which can be easily followed and is fairly constant—i.e., according to the number of leaves in a sheath. The first group, termed *Binä*, is devoted to species having two leaves in each sheath; the

second, Ternæ, to those having three leaves in a sheath; and the third, Quinæ, Pines with five leaves in a sheath. As examples of each the following may be mentioned:—1, *P. austriaca*, *P. Laricio*, and *P. sylvestris*; 2, *P. insignis*, *P. macrocarpa*, and *P. ponderosa*; 3, *P. Cembra*, *P. Lambertiana*, and *P. Strobilus*.

The next large group or tribe is the Taxodiæ which, besides the Taxodiums from which its name is derived, includes the Wellingtonia and Cryptomerias, besides some genera of little importance in British gardens. Sciadopitys, Glyptostrobus, Cunninghamia, and Athrotaxis.

The Cypress tribe, the Cupressinæ, include eight genera, mostly composed of smaller growing species well adapted for lawns. They are as follows:—Cupressus, Retinospora, Biota, Thuia, Thuiopsis, Libocedrus, Fitzroya, and Juniperus, the only ones requiring subdivision being the members of the last-named genus, which are classed as Common Junipers (*Oxycedri*), the Savin Junipers (*Sabinæ*), and the Cypress-like Junipers.

The Yews (*Taxinæ*) comprise *Taxus*, *Cephalotaxis*, *Torreya*, *Ginkgo*, *Saxegothæa*, *Prumnopitys*, and *Podocarpus*, all of some interest, but with the exception of the first-named comparatively rare in cultivation.

As examples of the principal types mentioned, and to show the range of cone variation, we give illustrations of the following species:—*Abies Alcoquiana* (fig. 58, page 301), a beautiful Japanese Spruce Fir, which often exceeds 100 feet in height in its native land. *Abies Veitchi* (fig. 59, page 303), a Silver Fir from Japan, introduced in 1879, an extremely beautiful species, also attaining 100 feet in height, but only represented by moderate sized specimens in this country yet. *Abies firma* (fig. 60, page 305), one of the same group as the last, also from Japan, and like the two preceding introduced to Britain by Messrs. J. Veitch & Sons. It is a common tree in Japan, and forms a handsome specimen.

*Pinus ponderosa* (fig. 61, page 307).—This massive Western American Pine is one of the introductions by Douglas, quite hardy in England, and rather effective in some places. *Sciadopitys verticillata* (page 62, page 308), the Umbrella Pine of Japan, makes but little progress in this country, and though it is said to reach the height of 100 feet, we have seen specimens which in the past ten years do not seem to have grown 6 inches. It is, however, very interesting, and the illustration was prepared from imported cones.

*Cupressus funebris* (fig. 64, page 311), a Chinese species, introduced by Fortune, though known for many years. It is very distinct, but not hardy except in extreme south situations. *Juniperus sphaerica* is also one of Fortune's introductions from China, somewhat intermediate in habit between *J. chinensis* and *J. phænicea*. *Thuiopsis dolabrata* (fig. 65, page 313) is a handsome member of the Cypress tribe, which is now well known in British gardens, and many fine specimens can be seen.

As an illustration of the fine proportions some Conifers assume in England, we are enabled by the courtesy of Messrs. J. Veitch and Sons to give a woodcut from their useful "Manual of the Coniferae," depicting a magnificent specimen of *Thuia gigantea* (*T. Lobbi*) in the gardens at Linton Park, near Maidstone, the residence of F. G. W. Cornwallis, Esq. When measured in 1881 this beautifully proportioned tree was 50 feet high, it is now 65 feet high, 6 feet in girth at 5 feet from the ground, and 19 feet 6 inches in the spread of its branches. Very rarely is such a specimen seen, yet there are many other grand Conifers in Linton Gardens, to which fuller reference will be made another week.

It may be added that the Conference at Chiswick yesterday (Wednesday) comprised the following addresses:—Opening Address on the Special Features of Interest in the Order of Conifers, by Dr. Maxwell T. Masters, F.R.S., Chairman; "Japanese, Chinese, and Californian Conifers," by Mr. H. J. Veitch, F.L.S.; "Conifers as Specimen Trees and for Landscape Gardening," by Mr. Geo. Nicholson, A.L.S.; "Conifers for Timber and in Plantations," by Mr. A. D. Webster; "The Decorative

Character of Conifers," by Mr. Edmund J. Baillie, F.L.S.; "Conifers at Bickton, Devon," by the Hon. Mark Rolle; "Conifers at Dropmore," by Mr. Chas. Herin. To-day (Thursday) it will be resumed at 2 P.M., when the undermentioned papers will be read:—Opening Address, by Prof. Bayley Balfour, F.R.S., Chairman; "The Value in the British Islands of Introduced Conifers," by Mr. Malcolm Dunn, F.R.H.S.; "The Quality of Coniferous Timber as Affected by Sylvicultural Treatment," by Dr. Wm. Somerville; "The Timber of Exotic Conifers Grown in Scotland: Its Uses and Comparative Value," by Mr. D. F. Mackenzie; "Fungoid and other Diseases of Conifers," by Prof. Marshall Ward, M.A., F.L.S.; "Insects Injurious to Conifers," by Mr. W. F. H. Blandford, M.A.

## CINERARIAS DURING AUTUMN AND WINTER.

THE whole stock of these plants should now receive a thorough overhauling, ready to be placed in their winter quarters, and except in severe winters like the last, they may be successfully cultivated in cold pits up to the time when the flowers begin to open. Only once during the last eight years have we lost more than 1 or 2 per cent. through frost and damp among plants wintered in cold pits, and even during the protracted winter of 1890-91 very few of our plants were killed, although the foliage was disfigured. I mention this to show that numbers of cold pits which during the autumn months are in many gardens empty may be turned to good account, and that, moreover, such a position is much better for the plants than those they often occupy in vineries and other structures where they are a long way from the glass and crowded. It is generally an easy matter to find room for large numbers of Cinerarias during the summer months when they are in a small state; but when the dewy nights of autumn come, as well as many dull moist days, these plants grow with wonderful rapidity under such conditions before very severe frosts set in, and unless cold pits are utilised during the next three months, not nearly so large a quantity can be grown as would prove acceptable during the spring months.

Any strong plants that are now in the right condition at the roots—that is, with a good number of them showing round the outside of the ball without being matted together, should be shifted into their largest pots, the size of which must, of course, be regulated by the dimensions of those they now occupy, but pots two sizes large will, in the majority of cases, suffice. Where any plants are extra strong they will be all the better for being placed in pots one size larger than those the less vigorous ones receive. A compost of turfy loam two parts, leaf soil one part, and spent Mushroom dung one part, with sharp sand, wood ashes, and a 5-inch potful of scot to a barrowful of the other ingredients added, is one in which the plants will make satisfactory progress. As the potting proceeds keep a sharp look out for traces of mildew, which can easily be stamped out now by applying a little sulphur to the under side of the leaves. Those plants that are repotted should be placed in a pit by themselves, so that they may be kept without bottom air for a time, but at this time of year I find the repotted plants do better with a little top ventilation left on constantly, except frosty nights, than when they are quite closed in the afternoon, as in the summer time.

A good hard base formed of coal ashes is the best material I know of to stand the pots upon. A very important point is to give the plants plenty of room when arranged. The leaves of adjoining plants should in no case be nearer to each other at the points than 3 or 4 inches; this will allow plenty of light and air to play around them, and so induce a sturdy growth with leaves thick and leathery. Such plants can withstand the effects of a low temperature much better than those that have been drawn up with thin leaves and attenuated stems, by reason of their having been placed too close together, and, moreover, they are far less liable to injury from damp when plenty of room is given; indeed overcrowding the plants is one of the principal causes, the condensed moisture being so long in escaping.

Having potted and arranged the strongest plants those remaining should also be re-arranged after raking the ashes, and if they are in the least green adding a coating of fresh ones to have all sweet and clean, and as a preventive against the attacks of slugs dust the surface of the ashes with soot. Also take special care that the plants have plenty of room. If gardeners would only keep this point firmly fixed in their minds and act up to it, dwarf sturdy Cinerarias with thick leathery leaves would be more plentiful, and drawn weakly ones proportionately less. If it is found that more

plants have been grown than can be accommodated in this way it is far better to give all the best plants abundance of room, and then place those remaining closer together for supplying cut flowers, than for want of space to grow the whole only moderately well; and where they are not valued in a cut state, rather than overcrowd it is sound economy to give some of the plants to a neighbour who may be less fortunately placed, or even to consign them to the rubbish heap. The tops of the plants should be about 6 inches from the glass, and as soon as they have grown to within a couple of inches of it they should be lowered by removing a few of the ashes.

Green fly is not as a rule troublesome after this date when Cinerarias are kept in cold pits, but if only a few of those insects are found it is a good plan to fumigate them. But little trouble will be given by insects of any kind till the plants are housed. All plants whose roots have freely permeated the soil in the pots should receive weak liquid manure at each watering, occasionally using soot water instead. The state of dryness at the root they are allowed to reach before water is given must be determined in a great measure by the weather. When dull foggy weather prevails during the short days of winter the plants will sometimes not require watering or even looking over more than once a week, but whenever such weather is followed by a little sunshine always make a point of thoroughly examining the plants and watering those that require it. Many plants are in some hands allowed to suffer greatly during changes of weather, because the method and time of watering are not changed.

Before concluding I must say a word about the important matter of covering to afford protection from frost. Do not be in a hurry to begin this. If the pits are well glazed and in good repair a few degrees of frost in the open air will not injure plants in closed pits, and the more light the plants receive the better; but rather than run the risk of allowing them to be injured it is better to cover to be on the safe side when any doubt exists as to the state of the weather. After one sharp frost in the depth of winter additional covering material should be used the following night, as if frosty weather continues it generally gets sharper each succeeding night. To keep Cinerarias safe from frost during very severe weather, a double thickness of mats, with wooden shutters placed on the top, and the sides of the pit encased in bracken, straw, or hay 2 feet in thickness, and a thickness of 1 foot placed on the shutters, is necessary. And on two or three occasions we have wintered hundreds of Cinerarias, and brought them safely through, with this treatment, after having from 20° to 29° of frost at various times. The really dangerous time is when (as at times last winter) we get the days almost as sharp as the nights, so that it is not safe to uncover, then the plants suffer greatly from want of light and through damp. Happily, however, such winters do not often occur.—D. W. C.

## SIXTY YEARS OF HORTICULTURAL PROGRESS.

(1760—1820).

(Continued from page 153.)

WE cannot expect that many of those persons who, in this unreflective age, hurry along Loddiges Road, Hackney, are likely to recall the fact, even if they ever heard it, that this name survives as a memorial of one of our most celebrated English nurseries, the fame of which travelled over Europe. It must, indeed, be regarded as an establishment which notably helped to advance horticulture at a time of some prostration. Singular have been the changes that have passed over this once suburban village, which we first read about as a favourite place of residence for nobles and wealthy citizens, when Cambridge Heath was a veritable heath, and near it, a broad mere or lake, of which we have a reminder in the modern Mare Street. During Georgian times old Hackney was famous for its boarding schools, its nurseries, and market gardens; but the nursery of Messrs. Loddiges, though limited in space, was really a botanic garden. Evidently, even then, the village was not ill adapted for gardening pursuits, for several amateurs made their abode here, and had flower plots, in which they made a great display of Roses, Tulips, Carnations, &c.

Early in the eighteenth century John Busch, a nurseryman from Holland, took possession of the estate oddly called Barbuir Berns at Hackney, and he was so far successful that eventually a report about him travelled to Russia, and the Empress Catherine II., who was seeking a good gardener, sent him an invitation, which he accepted, and made over the Hackney Nursery to the Messrs. Loddiges in 1771. Some years after the firm bought additional land, but the whole extent was only about 15 acres, though the arrangement followed gave the idea of a larger space. Visitors from all parts came to Loddiges' garden as one of the sights of

London. These gentlemen were at one time the leading consignees of Cape and South American plants, and they sold Cacti, Orchids, Heaths, and Ferns. At one end of the ground the houses were arranged on a systematic plan which this firm seems to have been the first to devise. The visitor entered by the stoves, then went on to the Palm house, next to the Orchid and Camellia houses, and a range of conservatories. Within the space enclosed by these buildings were pits and frames. Beyond was the arboretum formed as a winding walk, one side having named trees and varieties of different sizes, on the other side were planted Roses and herbaceous plants. From this the visitor passed to the American ground, a circular plot, containing a complete collection of all species obtainable. One of the things for which Messrs. Loddiges were celebrated was their skill in packing plants to travel long distances by sea, which was then a novelty. They put these in sphagnum trodden or pressed down, and the plants retained their vitality till they reached the Antipodes. "Loddiges' Botanical Cabinet" was a publication that was issued by this firm in its later history, and which extended to thirty-four volumes. Loddiges'

FIG. 58.—ABIES ALCOQUIANA.

Nursery disappeared about forty years ago, having served its purpose; it might be said to have a successor in the well-known Victoria and Paradise Nurseries of Holloway, where, however, culture is chiefly carried on under glass.

It was in or about the year 1780 that Dr. W. Pitcairn started a botanic garden near Cross Street, Islington, in which, though its extent was limited (somewhere about four acres), he had a great number of exotics and some curious varieties. At all times he was willing to show his specimens, or give information to gardeners and others. The doctor was a native of Dysart, in Scotland, for ten years President of the College of Physicians, and founder of the Radcliffe Library. Much service was also rendered to gardeners by his friend and senior Dr. Lettsom, a Cheshire man, a man of wealth, and one of the few men in his day who were inclined to aid botanical science by money from their own purses. By correspondence he obtained varied information about the natural habits of trees and plants brought over to England as varieties. On Grove Hill, Camberwell, he built a villa, to which he attached an arboretum and an extensive flower garden. So charming was the spot then that two poets, Scott and Maurice, wrote verses descriptive of the doctor's grounds, and the scenery to be viewed from the hill. Dr. Lettsom arranged the plants in his garden according to the countries from which they came, and they were labelled with the Linnaean names. He also had a museum, which contained, amongst other objects, a collection of dried plants, barks, and seeds. He was the author of many books and pamphlets, one of the latter was a rather amusing dissertation on Tea. When his friend Fothergill died he published a list of the stove and greenhouse plants that

were growing in his Upton grounds. This Fothergill was another M.D. partial to flowers, and who sent to the Alpine regions at his own expense a collector, who brought back many new species, duly recorded in the *Hortus Kewensis*. His account of the "Culture and Use of Mangold Wurzel, or Root of Scarcity," appeared in 1787. This was largely circulated, as were his hints on forming bee societies, dated 1796.

The illustrious Miller, botanist and gardener, died in 1771, after many years' service at the Apothecaries' Garden, Chelsea. It is supposed that in the course of his life he witnessed the introduction to Britain of upwards of 4000 new plants, a large number of which passed under his hands in the Chelsea establishment. His successor in office was Forsyth, who had been his pupil; he, too, was a Scotchman, and left the head gardenership at Sion House to preside at the Chelsea garden; subsequently he resigned his post there to enter the Royal establishment at Kensington. He wrote treatises on the management of fruit trees, recommending a new mode of pruning, and on the preservation of Apples and Pears. For about twenty years he paid particular attention to any instances coming under his notice of forest or fruit trees that were diseased or injured, specially the latter; and he professed to have discovered an unfailing remedy, in the form of a plaster or application. In 1791 Forsyth published an account of his presumed discovery, and had there been anything both valuable and original in it he might have deserved the thanks of fruit growers, and merited also the reward of £1500, conferred upon him by Government. His compound was a mixture of lime rubbish or powdered chalk, wood ashes, and sand, all sifted fine, then worked together with a certain proportion of fresh cowdung. This application, according to Forsyth, not only healed external injuries or disease (I presume he would have recommended it for canker); but if inserted within hollows in trees it produced a growth of new wood which combined with the old, and the trees became as vigorous as ever. Such extraordinary statements somehow obtained endorsement from several botanists or naturalists of that time who ought to have known better, and probably a still larger grant would have been made him had not Knight, the first President of the Society, which afterwards became the Royal Horticultural Society, taken up the matter. Of course the controversy became a rather bitter one, but Knight made it very plain that others before Forsyth had advised a similar application, and that it would not effect what he pretended. A son of this gardener—who was not, in the main, an ignorant man—became a prominent London seedsman.

Great attention was given in the reign of George III. to the culture of the Pine Apple, English-grown Pines being much in request. A proof of this is in the various treatises upon this fruit, and also upon the Melon, such as that by Giles, foreman in Russell's nursery at Lewisham, published in 1767; and that by Taylor, of Devizes, in 1769. Of more general value was a work by Speechly, gardener to the Duke of Portland, entitled "A Treatise on the Culture of the Pine Apple and the Management of the Hothouse." This book contained an important addendum—one of the earliest attempts to describe the insects of hothouses, and suggestions for checking their increase.—ENTOMOLOGIST.

### GARDENING IN CALIFORNIA.

THE following notes from an old master of mine, a first-class English gardener, who has been in Napa, Co. California, for the past three years, may possibly interest some of your readers if you can afford space for it at this season. "The Phylloxera is playing great havoc in the vineyards; we shall lose about an acre this year. Altogether in this county about 6000 acres have been destroyed up to date. The resistant stock appears to be the only remedy, grafted a foot above ground. By this means it will take seven years to get a vineyard re-established. I may say the small vineyardists (below 50 acres) are in a poor way just now. Wine is very cheap, from 5d. per gallon. I believe in the Raisin counties things are better, but the price of labour kills all produce here. Peaches, Apricots, Apples, Plums, &c., are very plentiful and cheap; they do not average 1d. per pound in bulk. We have over an acre of mixed trees. The thinning of the fruit cost £2, and I daresay if I tried I could make very little more of the entire crop, although close to the town.

The greater part of our Plums and Prunes were cooked on the trees the 20th of June and following days. The temperature was 115° in the shade, the hottest on record; for over a week it was over 100° daily. We generally have it about 90°, which is comfortable. My opinion of fruit growing here is unless a man has unlimited capital, so that he can "can" his fruit and export it, he is better off growing Turnips in the old country. I had a grand show of Roses this season; our Rose season is in April. I cut some fine Maréchal Niels outdoors in March. From June to October the Roses are

little good here; they develop too fast, and disappear faster with the hot sun. Pelargoniums make fine bedding plants here on a north border. We have to pot them for winter; they will not stand the wet in winter, as when it does rain here it comes down mightily. We are well advanced in the dry season now; all herbage is dried up unless irrigated. We expect rain in October or November. It is a treat to have a foggy morning. In the hot weather I thought the end of the world had come; one could not touch iron without gloves on. I forgot to say Grapes always colour well here owing to having plenty of hot air by day and cool at nights, generally between 50° and 60°. I think Muscat of Alexandria is better for being a little higher at nights, as they do not finish so well as the Hamburgs with us."

From the foregoing notes it would appear that any gardener with a small amount of capital intending to embark in fruit culture would do better to invest it at home than in America. There if he has to employ labour he will have to pay 8s. 4d. per day with board, &c., while unless he can export his fruit he will not make sufficient of it to pay the rent, much less provide himself with the necessaries of life. Good land at a fair rent in any of the British Isles should, I think, prove a far more profitable investment, particularly if a man is possessed with plenty of perseverance and a firm determination to succeed, qualifications which most British gardeners are well stocked with.—HANDY ANDY.

[Is it not a wonder that the "Old Master," who fares so ill, does not turn into a "man" and earn 50s. a week with board, &c. ?]

### PEACHES ON OPEN WALLS.

THIS season has again proved the usefulness of Peaches on the open wall, but the trees have had the most severe test of hardiness through the frost that has been experienced for eleven years. Several trees have died and dying main branches, and a large number of the ends of the shoots died back last spring. It was not through immaturity of wood, for we have had full crops set, and the trees bloomed very freely, but I should think the sap was frozen after it had begun flowing freely, and expanding caused a rupture in the organs—at any rate, many of the branches have died in the old wood.

Then, again, the stocks of several trees do not grow freely, consequently the trees do not make wood large enough to produce useful fruit, and they have a stunted looking appearance.

Inexperienced persons purchasing fruit trees should be very particular in selecting clean grown stocks free from knots. Knotty stocks do not continue growth many years to produce fruitful wood of any use. Nurserymen should not send them out. It is most discouraging after years of work and everything done that can be to be obliged to throw out trees from prominent places. It is a waste of time to plant stocks covered thickly with knots.

I would here direct special attention to Royal George Peach. It is, perhaps, the very best Peach to grow in Northumberland against an unheated wall. We have several trees, some of them in splendid condition, which have produced a crop of fruit during many years without a failure, fine coloured richly flavoured useful size fruit. I have gathered the last fruit to-day (October 3rd) from the open wall of that variety, and the flavour is still good. Dr. Hogg and Dymond are also good about the same time. Noblesse has done well the last two years, the largest fruit has been 9 ozs. Sea Eagle and Prince of Wales are both grand and very free fruiters, come in late, and are useful for tarts. Bellegarde and Stirling Castle are not good here.—GEORGE HARRIS, *The Castle Gardens, Alnwick*.

### AURICULAS IN SCOTLAND.

AURICULA growers in Scotland this year finished repotting a month earlier than usual. My own collection was finished before the end of June, although I retain my old opinion that July and August are the best months in which to repot. This year I have discarded the glazed pots, as I have found the plants do not like so much continuous moisture as they hold about them. Glazed pots may save some trouble in watering, but I would rather give the additional work for the sake of the plants. I find 4-inch pots the best size for plants generally, but the young plants grow well in 3-inch size. No advantage is gained by much pot room. The plants are at present looking remarkably well, the foliage being clean, fresh, and strong. The white foliage is particularly beautiful, and the glossy green of some varieties is pleasant to look at.

One of my Auricula-growing friends writes that he has been a good deal troubled of late with green fly, another is afflicted with

woolly aphis, which, I am glad to say, is not much known in Scotland. This year I have had scarcely any green fly; but when I do have a plant infested with insects I hold it below a gentle run from a water-tap, turning up the backs of the leaves, and holding the pot so that the soil is not disturbed. This plan I consider better than dipping the plant in Fir-tree oil or other substances. I have never cleaned a plant thickly covered with green fly in any other way, and always find it effective. If there are only a few on the leaves the finger and thumb are the best cleansers.

Offsets of all sizes are numerous this season, and, as I mentioned before in your pages, I have increased my stock considerably by beheading, wherever it suited, some of the finest and newest varieties. From last year's stumps I potted eight of Heroine, five of John Simonite, four of Black Bess, five of George Rudd, and several others similarly. In beheading for increase, care must be taken that there is an eye breaking below the cut, and that there are fibres above the cut for the growth of the old plant. Dress the top of the plant and the stump with charcoal. There has been a considerable demand by Scottish growers for some of the new English varieties which could not be met. Mabel and Marmion were two inquired for, but could not be supplied. I have just removed the plants from the frames to the Auricula house, and I am well satisfied with their fine appearance.—JOHN MORRIS, Dundee.

### VEGETABLES AT HIGHCLERE.

READERS of the Journal will be aware that vegetables from the Highclere Castle Gardens, near Newbury, the Earl of Carnarvon's Hampshire seat, were placed first among no less than seventeen competitors at the recent International Exhibition, held in the Waverley Market Hall, Edinburgh, a fact which speaks more than anything else in favour of their excellence. The class in this instance was for twelve varieties, each unlimited in numbers. After this honour achieved by Mr. Pope, a few notes on how the vegetables look at home and the manner in which they are grown will not only be interesting but useful to many Journal readers. At Highclere exhibition only is not by any means the aim in cultivating vegetables up to so high a standard, the home consumption is the first consideration—as it should be with all gardeners—and as the right methods are practised the crops obtained admit not only of a plentiful supply both for exhibition collections and home requirements. Many persons may say where show vegetables are cultivated the crop generally is sacrificed for the few required for the exhibition table; but there never was a greater mistake, because a high state of cultivation must be adopted to obtain success, consequently a greater produce is the result for all purposes. The best varieties must be employed in all cases; improvements on ordinary types are necessary nowadays to keep pace with the times.

The kitchen garden is about 6 acres in extent, having a gentle slope to the west, consequently well sheltered from the east. The walls, which are not high, were built in the year 1770, as shown by a tablet over one of the entrances, therefore the soil has had good opportunities to have been brought into a good state of cultivation. The average depth is 18 inches of what may best be termed stiff loam; the subsoil is clay. On the whole it is a garden which can be depended upon in a dry season, as it does not, to use a Hampshire phrase, "give out" readily. Decomposed leaves and light stable manure are the best materials for enriching soil of this character, heavy cowdung would be of no use. Trenching of the bastard order is much practised, the subsoil being broken up but not brought near to the surface.

Mr. Pope considers that Potatoes constitute the leading dish in a collection of vegetables, although many collections are staged without them. Satisfaction is regarded as the best variety in existence for exhibition, though Sutton's Seedling for the early shows, Windsor Castle, Midseason, Chancellor, and Abundance for the autumn meetings are good. These have a taking appearance, being white and clear in the skin, have shallow eyes, but they are also of capital quality, not being prized for outward appearance alone. The best tubers for planting are those which are whole and of medium size; they are but little sprouted at planting time, which is early in March, allowing 2 feet 6 inches between the rows and the plants. Where the tubers are not sprouted enough at planting to determine which will produce the best growth, they are thinned when a few inches out of the ground. Crowding the haulm is a practice not encouraged. The soil between the rows is frequently stirred and well earthed when the growth is high enough. Preparing the tubers for exhibition needs some care, but is a simple matter. Directly they are dug they are placed in water. It is not a good plan to allow them to become dry before being washed; the skin is liable to be discoloured by exposure. Clear water and a sponge is all that is necessary to cleanse the tubers,

which are at once wrapped in separate pieces of soft paper, thus preserving a clean skin, which is most important.

Onions form a valuable dish in a collection, no matter how small. Apart from their usefulness, they have, when of good quality, a "taking" appearance. For early use Anglo-Spanish is superior. Rousham Park and Lord Keeper for autumn shows are preferred. By the end of January the seed is sown in boxes, which are placed in gentle heat, the plants pricked off the moment they are fit to handle, say an inch high, and again when large enough to keep them "going," and are finally planted out at about 9 inches high after being thoroughly hardened off by growing as near to the glass as possible, with abundance of air admitted when the weather is suitable. The ground on which the Onions are to be grown needs some preparation to give the best results. Early in autumn it is bastard trenched, giving a good dressing of manure, placing

FIG. 59.—ABIES VEITCHII.

this on the broken-up trench at the bottom. Any time in October a thin sprinkling of Thomson's Vine manure is forked in, which is found to yield good results.

Peas are indispensable at all seasons except the late autumn shows. Good Peas carry much weight with practical adjudicators, not only because they are regarded as the most choice vegetable, but owing to the difficulty experienced at some seasons of the year in obtaining them. The Duchess is regarded by Mr. Pope as the best variety in commerce. Duke of Albany is good, but it must give way to the Duchess. The soil should be well worked and manured in the autumn; the very much practised plan of digging out a trench as for Celery, laying a thick coat of manure at the bottom, covering with soil, then sowing the Peas, is not advocated nor practised at Highclere. Mr. Pope thinks the roots go quickly to the bottom of the trench, and do not spread beyond that line, the consequence is dry roots, and, of course, mildew follows. By drawing wide drills at sowing time the firm ground below forces the roots outwards in search of food. A special point is made in

sowing thinly and allowing abundance of space between the rows, 10 feet at least, which ought to always stand north and south. No pinching of the haulm or thinning the pods to obtain extra size is practised. The soil is kept well stirred, especially during dry weather. For the earliest shows the seed is sown in small pots in March in a cool house, afterwards planting out when the seedlings are well hardened. The first sowing out of doors is made in February according to the state of the soil, if wet it is deferred awhile.

Scarlet Runners are a strong dish, and appear to have taken the place of Dwarf Kidney Beans for all but July shows, and when we consider the excellent Beans obtained the first week in August there is no wonder that they are preferred to the other. The soil is treated as for Peas, the rows not less than 12 feet apart. The first sowing is made in pots the first week in April at the same time as the outdoor sowing is made. The plants are grown 3 feet high in 32-sized pots before they are planted. Double rows are grown, as they are less liable to be blown down by strong sou'-westers. Ne Plus Ultra and Sutton's A1 are the most favoured varieties, and richly do they deserve their preference. The rows were 12 feet high, and clothed with Beans from bottom to top—truly a grand sight.

Turnips are a favourite dish, and rightly so, particularly during a spell of dry weather when this vegetable is scarce. Snowball is the only sort required, as it possesses all the qualities of a good Turnip for any season. To have the roots in proper condition towards the end of July the first sowing should be made at the end of May, and every three weeks afterwards in small patches in rows between the Scarlet Runners or behind a north wall, where they will derive much benefit from the shade accorded. Common salt sown over the ground when the seed is put in the drills is good for Turnips; in fact, for all root crops as a preventive of grub or wireworm.

Carrots form one of the leading vegetables in the root section, Early Gem and Model for the early shows, and New Intermediate for midseason and late ones. Veitch's form is regarded as the best, being so good in colour. The soil must be rich to grow good Carrots, but fresh manure ought not to be employed. The first sowing is made in pits in sandy soil the middle of January, the same time in February for the main crops outside. The drills are 18 inches apart, which allows free development for the leaves. The plants are thinned early, which is an important point to observe. A mixture of salt, soot, and soil is sown after the seed in the drills.

Cauliflowers carry much weight when presented in good condition. Magnum Bonum for early, Veitch's Autumn Giant and Sutton's Autumn Mammoth for later use, are preferred. The last named is a better colour than the ordinary autumn Cauliflower which has stood the test so long. Sow the first-named in heat at the end of January and the others early in March outside. These will keep up a succession for autumn use. The two last named should be sown out of doors from the 12th to the 20th of August to provide heads early in the following August. These must be wintered in pits. Cauliflowers cannot have too rich soil; if they do not make leaves freely they cannot produce perfect heads. Good soakings of liquid manure early are of great advantage to a free growth.

Tomatoes are now considered indispensable as a dish in even a small collection. Perfection is the favourite variety. The seed is sown early in January. One great mistake made in the growth of Tomatoes is the employment of loose soil in the pots, which induces a too free growth. Loam is the principal ingredient in a simple compost; it is rammed very firmly into the pots. The plants are liberally treated after the fruit is set. Syringing is not much practised.

Cucumbers during September are appreciated more than they are in the month preceding. Tender and True, Model, and Sutton's A1 are good; the latter is good in colour, which is a point to observe.

Celery in September and onwards is a strong dish. Wright's Giant White is preferred for early shows, not only because it is more seasonable, but by reason of its blanching quicker than the red or pink strain. Standard Bearer and Wright's Grove Pink are the best coloured kinds. Sow at middle and end of February in heat, prick out into boxes directly the plants can be handled, and re-box thinly so as to grow sturdily until 9 inches high, when they are planted in the trenches with a good ball of soil attached. The growth should be made without any check whatever to avoid its running to seed or hollowness of the leaves. The trenches are deeply dug out, the subsoil broken up, on which is placed a layer of manure, covering this with some soil from the surface, in which the plants are put out 1 foot apart. During dry weather water ought to be freely given, once a week is not too often. Stimulants should be varied to be of service in creating sticks thoroughly blanched 2 feet long. Earthing is not done in the ordinary way

with soil; brown paper is employed wrapped firmly round the plants, which renders the produce clean and free from slug depredations. Commence to blanch about a month before the Celery is required.

Parsnips in October and November are a strong dish in a large collection. Student and Hollow Crown are varieties to be depended upon. The best Parsnips are grown in prepared holes, made fully 2 feet deep with an iron bar, filling up with sandy soil, sowing two or three seeds in each at the end of January or early in February if the soil is dry.

Brussels Sprouts should be ready in October for use, taking then the place of green vegetables, obtainable only during the early season. Exhibition is a reliable sort, so is the Wroxton and Aigburth. Extra large sprouts are not encouraged; those firm and compact are favoured. Rich soil will produce them loose and soft to the feel. Firm ground is preferred to that which is loose. The first sowing is made early in March in heat, the next outside directly afterwards; those in heat are pricked off into boxes, hardened, and planted 2 feet 6 inches apart.

Globe Artichokes should be chosen for their close compact heads; they ought to slightly incurve. Good soil is needed. A fresh plantation from offsets is best for late produce.

Leeks are much more sought after now for exhibition than formerly was the case, when the blanched part was but a few inches long; but now it is nothing out of the common to see Leeks with 1 foot of stem thoroughly blanched. Lyon is the best. The end of January is chosen for sowing the seed in heat, pricking off the plants directly they are large enough. Plant out like Celery, and feed well: earth-up with soil about twice. Beet is a telling dish in a large collection. Pragnell's Exhibition and Cheltenham Green-top are thought the most highly of. The poorest soil is chosen to sow the seed in, about the middle of May.

Dwarf Kidney Beans for the July shows are considered choice. Canadian Wonder is the only variety grown at Highclere. Sow at the end of March in pits, and grow as near to the glass as possible. They are not kept too hot or dry at any time.

Vegetable Marrows are but a weak dish in September, but for July shows they are worth a place. The early part of April is considered a good time to sow the seed, Long White being the best sort. Handlights are used to protect the plants at first, when they are allowed to ramble at will.—A RAMBLER.

## THE EDINBURGH SHOW, 1891.

### STEALING FRUIT.

As an exhibitor at the late Edinburgh Show, and as a member of the Royal Caledonian Horticultural Society, I beg to thank you for opening the columns of your Journal to discussion of the above subject.

During the last quarter of a century I have been a frequent exhibitor at international and other shows held at Newcastle-on-Tyne, Leeds, Manchester, York, London, Dundee, Glasgow, and Edinburgh, and in all my experience I have never beheld such disgraceful proceedings as can be witnessed at the close of each Edinburgh Show. For years pilfering has been going on, and gradually getting from bad to worse. In the past the Council of the Society have made light of complaints and have merely winked at the depredation of the light-fingered gentry until this system of plundering has become quite a joke to them. At a former Edinburgh exhibition I had a stand of Grapes and a Pine Apple stolen during the second afternoon. The case was placed in the hands of the police, and the result was that four days after the exhibition I received a note from the Assistant Secretary saying that the stolen fruit had been returned to his office; but the note was accompanied with no word of apology or expression of regret at the incident.

In regard to the closing scene of the late Show, accurately described by "A Visitor" and other correspondents, I wish to say that though supported by four assistants who was each in his place the instant we were allowed to lift, I lost severely in the single dish classes. Unless the Council guarantee that the exhibits in the future shall be better taken care of some exhibitors (myself included) will consider it their duty not to expose their employer's goods at an Edinburgh Show.—J. MCINDOE.

I CAN testify that this is no new complaint at Edinburgh, having 1st a fine lot of fruit there of various kinds some years since. This was the more provoking as I had to send the greater part of it as presents to persons in the neighbourhood who were friends of my employers. When I reached the Show, however, to clear it away none of it was to be found. This was by no means satisfactory, either to the owners or myself, and I have not been to any show there since. I was slightly consoled on my journey home by a fellow passenger, who assured me it was well known

that "they keep the Sabbath, and everything else they can lay their hands on."

Seriously, this state of affairs is highly discreditable to a "Royal" society, and does not say much for the good management of the various officials. I can go to any of our large shows in this country and seldom lose a single fruit; the same thing ought to be as easily accomplished in Scotland. It is merely a question of administration, and the managing Committee should make a decided reform in the matter at the next show.—W. H. DIVERS, *Ketton Hall Gardens, Stamford.*

### THE USE AND ABUSE OF WATER.

IN the Journal for September 17th you publish an extract from a paper that was read at the monthly meeting of the Preston and Fulwood Horticultural Society on the above named subject. I think Mr. Waters has a very poor opinion of the young gardeners of the present day. No gardener will allow Azaleas, Heaths, or any other plants (when in an active state) to get so dry that the pots will ring like bells. One experience of the above would be sufficient for most plants. I think they will often be dry if we have to water them with the syringe, using our own judgment. The idea of syringing Heaths is new. They require plenty of air and a rather dry atmosphere, keeping the roots moist in summer and somewhat dry in winter, but no syringing; mildew will spread fast enough without young gardeners helping it in that way.

I think plants are in more danger from the abuse of water than fruits. Plants must be examined every day. Some plants will need it once a day, some twice, others not for a week, then we have to use our judgment. If a fruit house has four or five good waterings in the year it will not suffer. I think Peaches require more water before the stoning period than Mr. Waters advocates. Ours have more, but no syringing when the fruit is ripening. Does the rain improve outdoor fruit when it is ripening? From a Grosse Mignonne tree in our early Peach house we gathered several fruits which weighed 9 and 10 ozs. each. This tells if the treatment was right or wrong. I think one bucket of water is quite sufficient for damping the path of a house at night, and it does good, as it causes a moist atmosphere, which checks red spider and thrips. When the fruit begins to ripen discontinue damping. As for Melons, anyone can grow them if he has plenty of good manure, but sun heat is needed to ripen them. On the whole, I do not think that the young gardeners of the present day will profit much if they try to work on the lines laid down by Mr. A. Waters.—**YORKSHIRE BITE.**

[Mr. Waters has been excellently trained, and is an excellent gardener.]

### NEW VIOLAS.

I RECENTLY received from Mr. George Steel of Heatherslaw, a correspondent of the Journal, blooms of quite a new type of Viola, which I think will become popular, a variety named "Violetta," raised by Dr. Stuart of Chirnside. It has small blooms of pretty form, and of good substance, and the plant (of which one was sent to me) of dwarf elcse habit. It is of a clear white colour, with a yellow blotch in the centre, and is very fragrant. The blooms are small compared with almost all our Violas, and it is a variety with which I am much pleased.

Mr. Steel has been raising seedlings from Violetta, and sent also blooms of four seedlings partaking of the Violetta character, viz., Maggie Steel, a primrose, shaded white, with yellow centre; Flossie Brutton, pure white; Mrs. George Finlay, pale yellow, shaded with white, and distinct; and Miss Allandale, soft shaded lilac, with bright yellow eye, and of pretty form also. These seedlings will have to be further proved, and are all of the Violetta type; but Violetta will be on sale this autumn, and in it we are preserving the pure Viola character, and it is a charming variety.

So many new Violas come under my notice, and I regret to find that many of the newer varieties have so little of the true Viola character, of which Ardwell Gem, Bullion, Mrs. Gray, The Mearns, and True Blue are types, and that very much of the Pansy breed is being infused, which leads to inferior bedding qualities in being later to bloom in the spring, not so floriferous, or so lasting in the summer and autumn. Many inquiries are made as to what constitutes a Viola and a Pansy. Botanically, both are Violas; but when cornuta and Blue Bell were introduced, many years since, the former by Mr. John Wills when at Burnley in Lancashire, and the latter by my brother Richard, the term Viola was decided upon as distinguishing a type distinct from the ordinary Pansy. Then came other kinds, amongst them Mrs. Gray, an excellent white, sent out from Holloway some eight years or so since. I am anxious to see the Viola type preserved as far as possible, but we are drifting too much into kinds which have a great preponderance of the Pansy character both in size and form of flower and growth.

Mr. Cuthbertson, of the firm of Messrs. Dobbie & Co. of Rothesay, recently expressed a most favourable opinion of my seedling new variety "Bridesmaid." Here, in the immediate neighbourhood of Birmingham, we do not always get blooms so clear and large as can be obtained further away in the country. A box of blooms of this variety was sent

to me a few days ago by a friend near Warwick, who has grown it, and I was surprised to find it to be a much finer variety than I had anticipated; a beautiful pale cream colour, entirely free from any ray or blotch, and of good habit, and such an excellent bedder and distinct.

Messrs. Dobbie & Co. also sent me a few days since blooms of a very beautiful new Viola, "Countess of Elgin," the upper and side petals light grey, clouded with light purple, the lower petals rich maroon purple, with a light blotch at the base, perfect form and of good substance, and distinct; also "Ravenswood," a rich crimson-tinted purple self, of fine form and substance. Blooms of two other new varieties were also sent—"Mary Gray," a distinctly striped variety, white striped, and clouded with light blue purple, with a large rayed centre of a deeper shade of colour, a quite distinct large-flowered variety; and "Sweet Auburn," white, the top petals with a band of

FIG. 60.—ABIES FIRMA.

rich purple, and the lower petals having a narrow margin of the same colour, and with a rayed centre. It is a large flower and distinct.

Of varieties which should be generally known and grown, Countess of Wharncliffe is a very fine pure snow white variety of excellent habit; William Neil, soft pink, and beautiful; and "Delicata," shaded silvery grey and lilac, a charming variety of good form.

Messrs. Dobbie & Co. also sent me blooms of a very fine new Fanev Pansy, "Mrs. Train," the top petals rich shaded violet, with a wire margin of bronze; the lower petals having an immense solid dense blotch, bordered with orange and lemon. Also a fine dark self show variety, "John Dodds," a rich velvety violet purple self, with clear gold eye, of first-class form and substance, and a really fine flower.—W. DEAN, *Sparkhill, Birmingham.*

### STANDS FOR GRAPES.

MR. TAYLOR opens up a very interesting subject on page 266 respecting exhibition stands for Grapes, a topic that will no doubt prompt some among the large number of Journal readers and contributors to give their opinions and experience thereon. It is desirable, as Mr. Taylor suggests, that something like uniformity should be observed in our Grape stands, similar, for instance, to that which prevails in the

stands for Dahlias and Chrysanthemums at the summer and autumn shows. At summer shows the Grape boards are most irregular in their dimensions; in fact, it often happens that no two among a large number of competitors have boards alike.

Exhibitors seldom have any guide in the matter of Grape stands, and thus are at a disadvantage compared to the Dahlia or Chrysanthemum competitors who have their national societies to regulate the sizes permissible for stipulated numbers of cut blooms of either flower. Provincial societies, following the rule set forth by the National, command uniformity throughout their display, which adds very materially to the general appearance, and at the same time places every one on equal terms. If some such rule as this were adopted in the stands for Grapes there would be, as a natural consequence, greater evenness and smartness than is often presented as the matter now stands.

Of course such a rule ought not to be rigidly enforced, because it is not everyone who, like Mr. Taylor, can make a new set of stands for any one particular exhibition for various reasons; but if rules were made most exhibitors will endeavour, to meet the demands of societies in that matter, the same as is now observed in connection with the flowers just named.

The Edinburgh standard of measurement certainly would not appear satisfactory, the boards not being deep enough for any but medium-sized bunches, and the angle allowed much too flat. Although deep stands necessarily require large boxes there is some advantage in having them, because the bunches are displayed much better than when crowded on shallow boards; but this argument will be met, no doubt, by the additional cost incurred in the material and labour required.

Regardless of cost, I am of opinion that the more simple the stands are made the better their appearance on the table, providing they are neatly padded with cotton wool, and covered with clean tissue paper of a white or pink colour, according to the variety of Grape to be exhibited. Moveable rather than fixed supports are preferable, because then an angle most suited to their position on the table can be determined on the spot, whereas when the stand is a fixture this cannot be done. Light wooden supports, fixed in the same manner as that common to Chrysanthemum boards, are most convenient, or they may be fastened at the back with light hinges. The first named would perhaps be best, because with a tight screw the supports would remain at any angle to which they may be placed without danger of slipping.—W. S.

EVENTS OF THE WEEK. — To-day (Thursday) the Royal Horticultural Society's Exhibition of Conifers at Chiswick is continued, and the Conference will also be resumed at 2 P.M., and the programme will be found on page 300. The Exhibition of hardy fruit opens to-day at the Crystal Palace, Sydenham, and will be continued until Saturday. On Monday, October 12th, the United Horticultural Benefit and Provident Society's Committee will meet in the Caledonian Hotel at 8 P.M. The usual monthly dinner and conversazione of the Horticultural Club will take place on Tuesday, October 13th, at 6 P.M. The subject for discussion will be "Choice Dessert Plums," to be opened by Mr. George Bunyard. The National Chrysanthemum Society's Floral Committee will meet at the Royal Aquarium, Westminster, at 1 P.M., on Wednesday, October 14th; and on Thursday, October 15th, the United Horticultural Benefit and Provident Society's annual dinner takes place at the Cannon Street Hotel. The sales comprise a further consignment of Messrs. Sanders' Cattleyas at Stevens's Rooms to-day (Thursday); a large sale of Orchids at Messrs. Protheroes' on Friday, October 9th, again on October 13th, and on October 16th the Elephant Moth Orchid, advertised in another column, will be sold.

— AS marking their recognition of DR. ROBERT HOGG's long and useful services to horticulture and botany, the Council of Administration of the Dutch Horticultural and Botanical Society have nominated him an Honorary Member of the Society.

— NATIONAL AURICULA AND PRIMULA SOCIETY (SOUTHERN SECTION) AND NATIONAL CARNATION AND PICOTEE SOCIETY (SOUTHERN SECTION).—Mr. J. Douglas advises us that the annual general meeting of the above Societies will be held in the Horticultural Club rooms at the Hotel Windsor, Victoria Street, at 4.30 P.M. on Tuesday, October 27th. The business of the meeting will be the election of office-bearers and Committee for the ensuing year, receiving the reports of Treasurer and Secretary, to arrange for the Exhibition of 1892, and any other business that may be deemed necessary.

— THE PROPOSED AGRICULTURAL COLLEGE FOR KENT, SURREY, AND SUSSEX.—At the Sessions House, Newington, a meeting convened by the Technical Education Committee of the Surrey County Council was held recently for a Conference of representatives of the County Councils of Kent, Surrey, and Sussex as to the advisability of the three counties uniting to establish a central college of agriculture for the said counties. Amongst those present were Sir John Bassett Lennard (Chairman of the Kent County Council), Captain the Hon. T. Brand, and E. Eager (East Sussex), W. Arnold (Kent), Messrs. J. Coope, H. Yool, W. Rennie, A. E. Ellis, and B. Bray (Surrey), Mr. R. H. Kew (Secretary to the Central Chamber of Agriculture), Mr. J. Halsey, Chairman of Technical Instruction Committee (Surrey), and Mr. H. Macan, M.A., F.C.S., Secretary of the Technical Instruction Committee of the Surrey County Council. Mr. Halsey presided, and after considerable discussion it was decided on the motion of Sir J. Lennard, seconded by the Hon. Captain Brand, "That it is the opinion of this meeting that the three counties of Surrey, Kent, and Sussex can with benefit to themselves unite in a scheme for joint technical instruction in agriculture and horticulture by means of a joint college." Upon the motion of the Chairman the meeting adjourned until Monday, October 26th.

— GRAFTING GRAPES.—I shall be pleased if you will inform me, through the medium of your paper, as to whether any of your numerous correspondents have had experience with grafting or inarching late varieties of Grapes on Muscat of Alexandria, and if so with what result? —GEORGE CRAIG, *Richmond, Yorks.*

— THE TOTAL RAINFALL AT CUCKFIELD, SUSSEX, for September was 1.53 inch, being 1.60 inch below the average. The total for the nine months is 19.66, 0.61 inch below the average. The heaviest fall was 0.36 inch on the 21st; rain fell on fifteen days. Maximum temperature 76° on 11th and 13th; minimum temperature 39° on 28th. Mean maximum 64.2°; mean minimum 48.2°; mean temperature 56.2°. Partial shade readings 2° above the average.—R. I.

— THE WEATHER LAST MONTH. — September was remarkable for the warm period of nine days, from 6th to 15th, which was the finest and hottest weather we have had during the year. The wind was in a westerly direction twenty-two days. Barometer, highest 30.32, at 9 A.M., on 16th; lowest 29.38, at 9 A.M., on 1st. Total rainfall was 1.25 inch, which fell on ten days, the greatest fall being 0.49, on 21st. Highest shade temperature 85°, on the 10th; lowest 37°, on 24th; lowest on grass 31°, on 3rd. The garden spring ran 12 gallons per minute on the 30th.—W. H. DIVERS, *Ketton Hall Gardens, Stamford.*

— THE WEATHER DURING SEPTEMBER, 1891.—The weather here during September was a great deal better than during the month previous, not nearly so much rain having fallen, and we have had much more sunshine; eleven days during the past month were grand summer days. Rain fell upon twelve days; maximum in any twenty-four hours being 0.34 on the 14th; minimum in any twenty-four hours being 0.01 on the 2nd. Total for the month, 1.40 against 0.39 of 1890.—E. WALLIS, *The Gardens, Hamels Park, Buntingford, Herts.*

— CLEMATIS LADY CAROLINE NEVILLE.—Those who are partial to Clematises should try this one, it is a gem for autumn as well as for giving flowers early in the summer. This is the advantage in growing the Lanuginosa type, the flowering season extends over a long period. We grow this variety on a south-west wall, allowing the shoots to intermingle with Jasminum officinale. The green foliage of the latter gives a capital base for the Clematis blooms, which vary from bluish white to deep mauve in their various stages of development. Three colours of flowers can be had at the same time on one plant. Abundance of water Clematis enjoy during growth. All the care in pruning this plant receives is that of having all current year's growth cut in close at the time the Jasmine is clipped with the shears. We usually cut this to within an eye or so for appearance sake.

— MINIATURE SUNFLOWERS are well worthy a place in the flower garden. Under good culture the plants grow on an average 4 feet high, and give abundance of flowers, which are very useful for cutting, and much more appreciated than many outdoor flowers at this time of the year. We plant a good number in vacant places in the herbaceous borders, and right well do they repay us for the small amount of labour expended on them at any time. The rich orange yellow of the outer florets contrasts well with the almost black disc. Stout plants are almost self-supporting, but for safety we place one stake to each, giving the

main stem one or two ties, and allow the side branches to hang loose, which is so much more effective than bunching them together, as sometimes seen. Sow the seed early in April, afterwards planting out is the best method of growing this annual.—E. M.

— WE are requested to state that the Canterbury Chrysanthemum Show will be held on the 10th and 11th of November.

— CHOICE ORCHIDS.—Among other Orchids in flower at Mr. William Bull's establishment, King's Road, Chelsea, three very remarkable and handsome ones are now in blossom—viz., *Laelia præstans alba*, of which only two plants are known to exist; *Cypripedium Saundersianum*, a very distinct hybrid, and one of the most rare of *Cypripedes* (not to be confounded with *C. Sanderianum*); and *Cattleya chelseiensis*, a natural hybrid, and one of the most beautiful *Cattleyas* known. Anyone interested in Orchids should not fail to avail themselves of the opportunity of seeing these remarkable plants in flower.

— ONE of the most pleasing combinations which I have seen made by two hardy plants was with *CLEMATIS JACKMANI* and *C. FLAMMULA* growing over the gardener's house at Benham Park a short time since. The aspect was east; both were flourishing as well as could be wished, for the deep purple of the larger variety contrasted capitally with the other.

— DYMOND PEACH is certainly one of the best varieties we have for outdoor culture, ripening this year from the middle to the end of September with us on a west wall. Small trees fruit quite freely, which is a strong point in its favour for owners of small gardens who have not the space for large-growing kinds. The fruit is round, somewhat flattened at the crown; the colour is deep on the sunny side; the flesh white, rich, and highly flavoured. Even this season it is the best outdoor Peach we have for flavour.

— PINUS PYRENAICA has not proved itself sufficiently hardy to withstand the weather experienced during the late winter, as during the last month a specimen 12 feet high died, which has had a browned suspicious appearance since the spring, when it refused to make growth freely. I should say it was the long continued frost that caused death, as this tree was sheltered from north and east winds by Portugal Laurel and Spruce hedges. The soil is heavy and retentive of moisture, but not what would be called a water-logged soil owing to the presence of so many flint stones, which provides ready means of percolation for the water.—E. M.

— HIBISCUS SYRIACUS.—This deciduous flowering shrub, which is known equally well as *Althæa frutex*, is one of the finest autumn flowering plants we have. Both double and single varieties are showy. The range of colouring is extensive—in fact, this feature is important as providing such variety. The pale lilac changes to purple, some to nearly blue; the pink with crimson centre, the different shades of blue and rose colours are all showy and interesting. Where the soil contains lime or chalk it is useless to plant these shrubs without a preparation of peat, leaves, and sandy loam.

— HARDINESS OF *CAMPANULA PYRAMIDALIS*.—With me there never has been a doubt about this plant being perfectly hardy. The seed is generally sown in boxes in a cold frame, afterwards pricking out the plants in rows in the kitchen garden, where they remain until the following spring, when they are lifted with a ball of soil attached and planted where they are to flower. Of course the blooms last longer fresh when grown in pots under glass, but given a spell of dry weather when the flowers are ready for bursting, they make a fine show out of doors.—HANTS.

— PEAR KNIGHT'S MONARCH.—There are few varieties to excel the old Monarch as far as quality is concerned, but it has such a wretched failing of casting its fruit prematurely that this must inevitably drive it out of cultivation. For several years past we have not had a dozen good fruit from a large wall tree, nothing that I could do preventing the bulk of the crop dropping off before being sufficiently matured for storing. This season a fairly large young tree, trained as a palmette verrier, came into bearing for the first time, and promised to give us a really good crop. The tree was heavily mulched, and was never dry at the roots (a presumable cause of premature dropping), yet fully half of the fruits are fallen, whereas they ought to have remained on the tree at least another fortnight. The finest fruit I have ever seen of Knight's Monarch were once shown at one of the Birmingham Chrysanthemum shows by Mr. Parker of Impney, and the grower

informed me that he saved the crop by watering freely during the summer. Have any other readers of the *Journal of Horticulture* been similarly successful, or are failures the general rule?—W. IGGULDEN.

— PEAR DUCHESSE D'ANGOULÊME.—From this variety we usually secure fine crops of large handsome fruits, but the Whit-Tuesday frost deprived us this year of the usual bounty. Are the blooms of this fine sort more susceptible to injury than other Pears generally? Why I make the inquiry is because other trees and varieties growing in close contiguity are bearing excellent crops. From three good sized pyramid specimens, which should yield a couple of bushels, we shall

FIG. 61.—PINUS PONDEROSA.

not be able to gather a dozen fruits, although those flowered with the same freedom as the others. In the spring they were pictures with their finely developed bloom clusters, but the frost blackened them to such an extent as to leave us no hope of a crop, and that we now unfortunately realise.—W. S.

— A NOBLE EVERGREEN OAK.—The other day I had the pleasure of seeing the extensive and beautiful pleasure grounds of the Earl of Pembroke, Wilton House, Salisbury, and was particularly impressed by a grand specimen of the Holly-leaved Evergreen Oak (*Quercus Ilex*). The stem of the tree about 4 feet from the ground has a circumference of 24 feet. The circumference of the ground covered by its branches is 99 yards, and besides being so large it is most handsome. Mr. Challis, the head gardener, a few years back foresaw what destruction heavy snow would cause to this fine tree, very wisely had a dozen or two of large props put under the main branches, and thus it

has passed the stormy winter uninjured. There are also several very handsome Celars standing in the grounds of 70 acres in extent, with many others which I consider worth a journey of many miles to see. The avenue of White Poplars, *Populus alba* (Abele), consisting of seventy trees, planted about 24 feet apart on each side of a wide road, has a fine effect, and is worth imitating.—NOTABILIS.

### ROYAL HORTICULTURAL SOCIETY.

OCTOBER 6TH, 7TH AND 8TH.

THE October Exhibition and Conferences in the Society's Garden at Chiswick had been looked forward to with the keenest interest, and it was much regretted by all that the weather on the opening day proved so exceedingly unfavourable. The display of Asters, autumn flowers,

FIG. 62.—*SCIADOPITYS VERTICILLATA*.

and Coniferae exceeded the expectations of all concerned in the arrangements, the specimens in the last named section furnishing a unique attraction. Thousands of handsome cones were shown from the principal gardens where large collections of Coniferae are grown, the tent space not being sufficient and additional table room had to be provided outside. Beyond these, too, were the plants plunged in borders of cocoa-nut fibre refuse, all arranged so tastefully that a most pleasing surprise greeted the few visitors, who, undeterred by the drenching, continuous rain, found their way into the gardens.

**FRUIT COMMITTEE.**—Present: T. Francis Rivers, Esq., in the chair, and Rev. W. Wilks, with Messrs. Peter Veitch, H. Balderson, G. Wythes, G. Reynolds, M. Dunn, W. Bates, W. Denning, J. Cheal, A. Dean, T. J. Saltmarsh, and J. Wright.

Mr. James Shooter, 66, The Grove, Hammersmith, sent a dish of Louise Bonne of Jersey Pear, good fruits, and a cultural commendation was awarded. Mr. Hunter, Lambton Castle, Durham, sent two seedling

Pine Apples, the result of a cross between The Queen and Smooth Cayenne. One much resembled The Queen, and does not ripen in winter. The fruit was stained in the centre, and though very juicy, was not considered to be a distinct advance on its parentage. The other fruit was a fine bold Pine, more resembling the Cayenne, but with spiny leaves. It ripens in the winter, and has been grown 9 lbs. in weight. The fruit cut was extremely juicy, dull orange in colour, sprightly and refreshing, and an award of merit was unanimously awarded. Messrs. Robert Veitch & Son, Exeter, sent a dish of Peaches Late Devonian, the result of a cross between Belle de Vitry and Galande, medium size, dark in colour, but not of high-class quality. This, however, might be the result, to a great extent, of the dull season, and possibly the variety may be heard of again. Mr. Miller, gardener to Lord Foley, Ruxley Lodge, Esher, sent a very fine dish of Barrington Peach, grown on an eastern aspect in the open air, and a cultural commendation was awarded. Mr. Miller also sent a scarlet-flesh Melon named Ruxley Favourite, a promising variety, but the fruit was not ripe, and the Committee desired to see the variety again.

Mr. James Hudson sent from Gunnersbury very fine fruits of Coe's Golden Drop Plum, for which a cultural commendation was awarded. A vote of thanks was also accorded to Mr. Hudson for samples of Success Pear, a dark green productive variety which proved valuable for late use. It was, we think, placed in commerce by Messrs. Jas. Veitch & Sons. Mr. Bowerman, The Gardens, Hackwood Park, sent fine and excellently flavoured fruits of Brahy's Green Gage Plum, a valuable late variety, for which a cultural commendation was accorded.

Messrs. T. Rivers & Son, Sawbridgeworth, exhibited a dozen new Plums in the form of fruit-bearing branches cut from seedling trees. The fruits were of all sizes and colours seen in Plums, and some of the varieties will no doubt be perpetuated. Very fine dishes of the large and productive Monarch, the large and late Grand Duke, and the luscious Late Transparent Gage were also exhibited, as well as a young pyramid tree laden with handsome fruits of the Conference Pear. The variety was certificated four years ago, and is likely to prove of sterling merit. A vote of thanks was unanimously accorded for the collection.

Mr. G. Reynolds, The Gardens, Gunnersbury Park, sent such a collection of Hero of Lockinge Melon as had not been hitherto seen at the Society's meetings. There were three dozen fruits, every one being worthy of a place in a prize competition. A silver medal was unanimously recommended for this meritorious contribution. Mr. G. Wythes was accorded a vote of thanks for an excellent specimen of *Monstera deliciosa*.

Mr. Barron placed on the table several bunches of Hungarian Grapes grown in the Gardens. One of these, Dodrelabi, he considered identical with Gros Colman, and possibly indicated the origin of the market favourite. Another, named the Muscat of Hungary, may be described as a miniature Muscat of Alexandria, but richer, and possibly the finest flavoured Grape extant. The berries are not much larger than fine Marrowfat Peas, but oval in shape, and amber in colour. The Muscat of Hungary is a luscious novelty, and an award of merit was granted accordingly.

Samples of cooked Apples, from "chips and rings," dried in the Gardens by the Mayfarth apparatus, were placed on the table in a cooked state. They were quite equal to American Apples, but not quite so brisk as home-grown fruit cooked from the trees.

Some Plums, also dried artificially, were cooked in syrup the same as Prunes, and were really delicious. The varieties were, Rivers' Prolific, Poupert's Plum, and Fellemberg. The fruit-drying experiments conducted by the Society are not unlikely to prove of great, and it may be, national importance. More will be heard of them as the season advances. Colonel Hayward, Crosswood, Welshpool, also exhibited a good sample of dried and prepared Plums.

**FLORAL COMMITTEE.**—Present: Messrs. W. Marshall (in the chair), Herbst, G. Nicholson, W. Bain, C. Jeffries, R. Dean, J. T. Bennett Poë, H. Turner, E. Mawley, T. Baines, G. Gordon, W. C. Leach, G. Phippen, C. E. Pearson, W. Furze, J. Walker, H. Cannell, J. Laing, G. Paul, and B. Wynne.

An interesting collection of Asters in many species from the Chiswick Gardens included novæ-Belgii vars. Parkeri, Juno, Harpur Crewe, formosissimus, densus, roseus, Andromeda, Vesta, floribundus, Purity, pulchellus, and others; also Aëris, lævis, Amellus bessarabicus, and many others. The Rev. C. Wolley Dod, Edge Hall, Malpas, received a bronze Banksian medal for a collection of Asters, which comprised several of the forms previously mentioned, together with a number of seedlings. Messrs. Paul & Son, The Old Nurseries, Cheshunt, were awarded a silver Banksian medal for some splendid bunches of Asters and Sunflowers, including Aster novæ-angliæ, A. Robert Parker, A. dumosus, A. Tradescanti, A. lævis, A. Amellus bessarabicus, A. cordifolius, A. longifolius, Helianthus giganteus, H. latiflorus semi-duplex, and others. A collection of Asters and Sunflowers also came from the Royal Gardens, Kew. Messrs. H. Cannell & Sons, Swanley, had some beautiful bunches of Cannas, a few Begonias, Chrysanthemums, and Dahlias.

Messrs. Collins Bros. & Gabriel, 39, Waterloo Road, London, received a silver Flora medal for a beautiful collection of hardy perennials, and silver Banksian medals were awarded to Messrs. J. Laing & Sons, Forest Hill, and Mr. Salmon, Norwood, for miscellaneous displays, a bronze Banksian going to Messrs. Cutbush & Son, Highbgate.

Mr. J. Hudson, gardener to Messrs. de Rothschild, exhibited Marguerite Carnations from seed sown on March 20th full of buds, and

received a vote of thanks. A similar award was made to Messrs. J. Veitch & Sons for Java hybrid *Rhododendrons*, a beautiful group, not sufficiently grown.

The classes for hardy perennials brought out some very attractive exhibits. In the first eighteen bunches were asked for, to include perennial *Asters* and *Sunflowers*, and Mr. E. Chadwick, gardener to

perennial "in the garden sense." It is exactly in a "garden sense" that it is a hardy perennial. Mr. Marshall was quite in accordance with the clear wording of the schedule, and should have been awarded the medal. Mr. A. Harding, gardener to the Dowager Marchioness of Huntly, Orton Hall, Peterborough, was placed second with some neat bunches. In that for eight bunches Mr. R. Debenham, St. Peter's

FIG. 63.—*THUIA GIGANTEA* AT LINTON PARK (HEIGHT 65 FEET).

E. M. Nelson, Esq., Hanger Hill House, Ealing, was placed first for some fine bunches, including *Helianthus multiflorus major*, *H. latiflorus simplex*, *H. multiflorus*, *H. m. flore-pleno*, *Aster floribundus*, *A. Amellus*, *A. novæ-angliæ ruber*, *A. Chapmanni*, *Anemone japonica*, *A. j. alba*, and *Phlox amœna*. The second prize went to Mr. G. H. Sage, gardener to the Earl of Dysart, Ham House, Richmond, who had *Aster formosissimus*, *A. Shorti*, *A. Amellus bassarabicus*, *A. sibericus*, *Pyrethrum uliginosum*, *Rudbeckia Newmanni*, and others. The first prize was not awarded in the class for twelve, Mr. W. Marshall's stand being disqualified for containing *Colchicum variegatum*, as not being a hardy

St. Alban's, won, his *Rudbeckia Newmanni* and *Phlox paniculata* being excellent.

ORCHID COMMITTEE.—Present: Messrs. H. J. Veitch (in the chair), J. Douglas, C. Pilcher, and H. M. Pollett. There was very little business for the Committee to transact.

G. O. Sloper, Esq., Highworth, received an award of merit for *Cattleya sp. aurea marginata*, remarkable for the combination of rich crimson and yellow, the lip being deeply coloured with crimson, and the throat broadly margined with yellow on both sides, crimson streaks radiating into it. A cultural commendation was awarded to F. A.

Bevan, Esq., New Barnet, for *Cypripedium Sanderianum*, which has been previously certificated.

#### CERTIFICATED PLANTS.

*Chrysanthemum Miss Watson* (Messrs. Cannell & Sons).—A Japanese in the way of Elaine, but clear soft yellow in hue, large, well-formed, and beautiful; and

*Dahlia Princess Christian* (Messrs. Cannell & Sons) a Decorative variety with broad, pointed petals, colour brilliant rose suffused with carmine. (Received awards of merit.) Messrs. Pitcher & Manda received a similar award for Carnation Lizzie McGowan, a free-flowering variety with pure white fringed flowers good in every respect but fragrance. Mr. R. Owen received a similar award for *Chrysanthemum Madame Edouard Lefort*, a Pompon with distinct bronzy yellow flowers. This was part of an attractive display of these flowers.

First-class certificates were awarded to

*Ixora Duffii* (Mr. Bain, gardener to Sir Trevor Lawrence).—A grand head of a fine species, being quite 9 inches in diameter, colour bright red.

*Asparagus retrofractus arboreus* (Mr. Bain).—A most graceful and pleasing species, the colour a soft light green.

*Lælia Perrini alba* (Baron Schröder).—A lovely variety with very large flowers, sepals and petals pure white, throat faintly tinted with lemon.

#### CONIFERS.

The display of Conifers far exceeded that of cut flowers in extent and interest. A large portion of the conservatory was occupied by them, one whole tent, a portion of another, and in addition there was what might be termed a "Conifer garden," several large groups being plunged in cocoa-nut fibre refuse out of doors, ranging from 1 foot to 10 feet in height, and the various forms and hues contrasted and blended.

There was one class for Conifers, in which the Veitch Memorial medal and £5 were offered as first prize, silver Knightian medal and £2 10s. as second, and £1 10s. as third. There were only two collections in competition, but both were fine ones, and that from Mr. A. Harding, Peterborough, was really remarkable. He had some grand specimens, and many of exceptional interest. The following constituted his splendid collection:—*Abies grandis*, *Pinus macrocarpa*, a very fine example; *Torreya myristica*, *Biota aurea*, *Cephalotaxus Fortunei*, *Taxus baccata fastigiata*, *T. b. aurea*, *Thuopsis borealis*, *Taxodium sempervirens*, *Taxus baccata*, *Pinus Jeffreyi*, also very fine; *Abies Nordmanniana*, *Juniperus chinensis*, *Cedrus atlantica*, *Pinus sylvestris*, *Abies Douglasi*, *Cupressus Lawsoniana*, *C. macrocarpa fastigiata*, *Biota pendula filifera*, *Pinus monticola*, *Larix europæa*, *Pinus Laricio*, *Wellingtonia gigantea*, *Pinus austriaca*, *Cedrus Libani*, *Pinus excelsa*, *Juniperus excelsa*, *Cedrus deodara*, *\*Retinospora plumosa*, a *Pinus* species, *Thuia gigantea*, *Libocedrus decurrens*, *Taxus adpressa*, *\*Thuopsis dolabrata variegata*, *Pinus muricata*, *Araucaria imbricata*, *Abies* species, very handsome, at first thought to be *Webbiana*, but afterwards distinguished from that; *Abies Morinda*, *Pinus ponderosa*, *\*Salisburia adiantifolia*, *Cupressus sempervirens*, *Abies cephalonica*, *A. bracteata*, *A. lasiocarpa*, *A. amabilis*, *Cupressus Lawsoniana variegata*, *Juniperus hibernica*, *Cupressus Lawsoniana erecta*, and *Retinospora plumosa*. All but the last seven, and those marked with an asterisk, had cones.

Mr. Crasp, gardener to Lord Wimborne, Canford Manor, Dorset, also had a fine collection, and was placed second. *Abies Pinsapo*, *Cedrus atlantica*, *Cryptomeria japonica*, *Abies nobilis*, splendidly coned, and *Cunninghamia sinensis* were exceptionally fine.

Mr. C. Herrin, gardener to Lady Fortescue, Dropmore, Maidenhead, had a good collection, not for competition, including some splendid cones of *Araucaria imbricata* and ripened seeds, *Pinus insignis*, *Abies nobilis*, *Cedrus Libani*, *Cupressus Goveniana*, *Thuopsis borealis*, *Cedrus Libani argentea*, *Abies Douglasi*, *A. Brunoniana*, and others. There was an enormous cone of *Pinus Lambertiana* in Dr. Masters' collection of dried cones.

From the Royal Gardens, Kew, came a very extensive collection of sprays of Conifers, showing the colour of the branchlets and the character of the growth, and was highly instructive. *Taxodium distichum pendulum*, *Sequoia sempervirens gracilis*, *S. gigantea pendula nova*, many forms of *Taxus baccata*, including *pendula*, *fastigiata variegata*, *argentea*, *Dovastoni*, *Sieboldi*, *horizontalis elegantissima*, *Washingtoni*, *Cephalotaxus pedunculata*, *C. Fortunei*, *Pinus pungens*, *P. Pinaster*, *Pinus sylvestris*, and several varieties of it, *Cedrus atlantica glauca*, *Larix europæa* in many varieties, *Pinus alba*, *Picea excelsa* in many varieties, a fine collection of Junipers and also of Cypressess, including *Cupressus torulosa*, *C. Benthami*, *C. arizonica*, and *C. Lindleya* were included. An interesting collection of Conifers came from Stuart Fotheringham, Esq., including *Cedrus deodara*, *C. Libani*, *Taxus baccata aurea*, *Cupressus Lawsoniana erecta viridis*, *Juniperus recurva*, *Thuja gigantea*, *Abies pectinata*, *A. Douglasi*, and others. Messrs. R. Veitch and Son of Exeter, Colonel Parker, Cambridge, and Lord Kinnaid, Rossie Priory, Perthshire, showed various specimens, some coned. Sir Patrick Murray, Ochertyre, Perthshire, had a large collection without cones; and Messrs. Dicksons, Limited, Chester, also had a grand display. H.M. the Queen, Balmoral, had a large collection, in which *Abies nobilis glauca*, *Abies nigra*, *A. Douglasi*, and *A. balsamea* were very good.

Amongst other interesting collections were those of the Duke of Sutherland, from Dunrobin, Sutherlandshire; Mrs. Malcolm Patton, The Cairnes, Perthshire; W. H. Maxwell, Munches, Kirkcudbrightshire; Earl of Hopetoun, Linlithgowshire; Earl of Mansfield, Scone, Perthshire. Colonel Tremayne, Carelew, Cornwall; Duke of Buccleuch.

Drumlanrig, Dumfriesshire; W. Nicholson, Esq., Alton, Hants; Mrs. Ford, Pencarrow, Bodmin; R. G. Lakes, Esq., Trevarrick, St. Austell; W. Gunn, Esq., Nutwood, Strathpeffer; C. J. Lucas, Esq., Horsham; Sir T. Dyke Acland; and T. S. W. Cornwallis, Esq., Maidstone.

Unfortunately heavy and continued rain seriously militated against a full inspection of the outdoor groups, as these were of special interest, and would have well repaid a close study. Disposed in groups so that the habit of the plants, the graceful character of the foliage, and the different hues were well brought out, they could not fail to be most instructive. Some more detailed reference will be made to them than can be given now.

Large groups came from Messrs. W. Barron & Sons, Elvaston Nurseries, Borrowash, Derby; Messrs. Dicksons, Limited, Chester; Mr. Anthony Waterer, Woking; Messrs. Paul & Sons, Cheshunt; Messrs. Jefferies & Son, Cirencester; Messrs. J. Veitch & Sons, Chelsea; and Messrs. C. Lee & Sons, Isleworth. Messrs. Paul also had a display of small compact Conifers recommended for rockwork.

On the first day a conference on Perennial Asters and Michaelmas Daisies was held, when the following papers were read, after an opening address by the Chairman, Mr. J. G. Baker:—"The Genus Aster," by Professor Goodale, Director of the Botanic Gardens, Harvard University, U.S.A.; "Michaelmas Daisies," by the Rev. C. Wolley Dod; "Perennial Sunflowers," by Mr. D. Dewar; and "The Culture of Sunflowers," by Mr. E. H. Jenkins. The Conifer Conference opened on Wednesday (see page 300), and is continued to-day (Thursday).

#### CULTURAL NOTES.

I SHALL not easily forget the impression made on me by the first view I ever enjoyed of a Chrysanthemum exhibition. It was about four years ago that I visited the Exhibition at Bath that I was inoculated with the mania attached to the flower, and that the inoculation immediately took effect. I came out of the Assembly Room declaring that I had seen flowers styled Chrysanthemums from my youth up (many years departed!) but had never seen a Chrysanthemum before. Some of those blooms cling to my memory now—notably a bloom of Fair Maid of Guernsey in the first prize Japanese from Marston. I invested in Molyneux's book, and studied all in your columns on a flower that I had for years laughed at as a florists' flower; and of course I expected, with the enthusiasm of youth, to rival the blooms at that Exhibition at once. Well, there is much pleasure and interest in growing Chrysanthemums—there is an interest in watching the growth of the cuttings, mingled with emotion of a painful character, as the best—always the best and most expensive—decline and fail to root; then there are the horrors of such a winter as last year, when the cold frame, with its hundreds of cuttings, covered with wattled hurdle and a foot of snow on the top and with manure on the outside round its walls, nevertheless was invaded by the ruthless cold, and numbers of cuttings, unrooted and rooted, reduced to a mass of blackish pulp. Yes, this is interest in another form. Then there is the interest of growth in the cuttings, the various pottings, the look out for enemies (and they are legion), the stoppings, the selection of buds before the crowning triumph of prize blooms is achieved. Then there is the immense variety of form and colour, of growth and foliage, and the kindness of Nature's God in giving to us at an unseasonable time of year flowers of such great beauty that, unlike the beautiful queen of flowers, are so lasting in their perfections. Certain Roses, Teas especially, will grow and improve for two or three days after cutting; but many Chrysanthemums will improve for as many weeks, and then continue in glory for many days.

Two years later I thought I had learnt how to grow them. They filled me with delight. Friends exclaimed they had never seen such flowers in their lives, &c.; and with great expectations I ventured to compete in several classes at a neighbouring show. I found that if two years had made a difference in Chrysanthemums to me, it had made a far greater difference to the general growers since that Bath Exhibition, and instead of being "easily first," I was easily outside the triple list of prizetakers. I took my man Friday with me to this Show, and his depression was considerably greater than mine.

We struggle on, trying to learn something about a class of plants which has its own particular difficulties. My Rose-growing friend, who, though only a Budd, manages at the Show to be in glorious full bloom, once said to a mutual medical friend, "I know something about Roses; but I confess, though I have grown Chrysanthemums some time, I know nothing about them." Certainly, about some varieties, you never seem to get to the bottom of their whims and vagaries. I confess that the first year I grew Chrysanthemums I succeeded in growing Meg Merrilies better than I have ever done since; the same may be said of Fimbriatum. On the other hand, fired with the memory of that glorious Fair Maid of Guernsey at Bath, I had some plants, and was rewarded by large plants and blooms that would not have disgraced a "single" Chrysanthemum, but had no claim to be even distantly related to the bloom at Bath. The next year I succeeded in getting some florets out of the dark centres

of what were still only "single;" but last year I really obtained white flowers, which I should have called very beautiful but for the memory of the Bathonian, to which my flowers still appeared only cousins very distantly removed. Still, at our local exhibition, I put up as six of one variety six of these blooms, with which many people were very charmed, and they were grown from buds which when "taken" looked no larger than a pin's head. (Query.—Are the buds of this, of Belle Paule, and one or two others generally very small crown buds?)

I fully realise that no amount of book advice can make a person cognisant of the mysteries of "taking the bud." This seems to me a matter so dependent on the look of the bud, the variety with its special peculiarities, and the season, that prolonged experience and note-taking seem the only guide to knowledge. This year, for myself, I have adopted this plan. On the label I put, for instance, "Fair Maid of Guernsey, N. 17." N. 17 means, cutting put in November 17th, and of course D. would be December, and so on. Well, then, I have put "C., A. 28," which stands for "Crown bud, August 28th," and then "T., S. 10," stands for "Terminal, September 10th," then I think of adding, "H., O. 5," which will mean "Housed, October 5th," and then "B., L., P., F., G., V. G., N. 15," will do for blooms, "Bad, indifferent, poor, fair, good, or very good, November 15th," as the case may be; then I can, later on, take my labels and note results in a book. I confess that I am now, like my friend some years ago, I know nothing about them, but I shall try to learn.

"Hope tells a flattering tale," and sometimes I fancy I have already learned something. Some plants as they grow put on a "sickly glare," instead of robust green they have a jaundiced eye greatly developed. Edwin Molyneux has always served me so. A gardener coming into my place in July exclaimed, "Hallo, sir, you've been putting it on too hot." It so happened at that time none of the plants had been extra fed at all. These plants were set aside by themselves, refused all drink, except when actually fainting, and then indulged with a little very weak soot water, and judging from the verdure of the present foliage, the remedy has been most successful.

Now, I should like to learn why a grand looking bud should begin to unfold its glories, and the three or four rows of outer florets expand, whilst the remainder just show colour and remain half an inch long, stunted, curled in, and refusing to grow any more. Why is this? What is the difference between a crown and a terminal bud? Yes, I know what is said in Molyneux's book, the one is the second and the other the third break, but given the branch into your hand is it always easy to tell which the bud is? At first I was disposed to say that in the crown bud branch the shoots in the axils of the leaves are small branches of leaves with eight or ten leaves before the bud appears. On the other hand, the terminal shoots are buds with at most two very small leaves, but almost all the crown buds of Lord Alcester, Bronze Queen, Empress of India, in fact the Queen family, have at any rate this year a crown bud exactly similar to the terminal. Is this the general run of that family? Once again, does not the first break often give a bud of good promise, and one that may with hope be selected when, if not taken, the other buds would be far too late for the shows? Yes, I know that a fool may ask questions that wise men cannot answer. I am, I confess, an ignoramus, but perhaps some kindly wise man will enlighten me. I should be very grateful.—Y. B. A. Z.

### BUYING FRUIT TREES.

THE planting season is now rapidly approaching, and intending planters are, or should be, making their preparations. A few words, therefore, upon the subject of choosing trees may not be out of place. My first advice to purchasers is, Be early in the field, and secure what you require while the stock is still ample. Your nurseryman will be glad to see you now and to go through his stock with you, marking selected trees and discussing the relative merits of varieties, &c. In a month's time or so, when he is overhead and ears in work despatching goods you will have to take a large order with you to be very welcome. Another advantage of an early inspection is that all the free-bearing Apples and Pears are now full of fruits. This is the case with even two-year-old trees of such precocious sorts as Lord Suffield, Cellini, Stirling Castle, Ecklinville, Lord Grosvenor, New Northern Greening, Pott's Seedling, and Domino, amongst Apples; and Fertility, Beurré de Capiaumont, and others amongst Pears, so that much useful information may be picked up on this head during a walk round a good nursery.

Again, it is much easier for a novice to judge of the quality, health, and age of trees whilst the foliage is still green than after it has all fallen and he has only the wood to look at. If he keeps his eyes open he may also see if any stock is kept of aphides, American blight, &c. (this will not probably be pointed out to him), and the utility of such knowledge does not need to be indicated. I would strongly advise buying young trees; even if standards be required, buy two-year-old feathered, as they are called, and then trim them to your liking afterwards. The reason is that a young tree has all its roots near home, and they may all be sent with it; whilst the older tree often leaves some of the best part of its roots—viz., the feeding fibres—in the ground, they having wandered too far to be secured in lifting.

Avoid carefully old hide-bound, badly grown stock, as it is dear at a gift, and will probably be still struggling for existence when healthy young trees are bearing marketable crops. On the other hand, it is possible for trees to be grown too strongly, and so form gross thick shoots, which will not ripen, and consequently suffer from severe frost,

whilst the roots are thongy and destitute of fibre. Trees of this description rarely move well. One other point to be noted is the colour of the bark. Trees grown in suitable soil and situation are bright and clean on the bark, whilst those in wet, bad soil are often dull and discoloured, the stems having the appearance of being covered with a minute lichen or mould. It goes without saying that an undergrowth of Couch Grass does not benefit young fruit trees, and I have seen a consignment of trees whose stems, prettily decorated with spiral markings, showed that bindweed was not unknown where they came from.

FIG. 64.—1, CUPRESSUS FUNEBRIS; 2, JUNIPERUS SPHÆRICA.

I have endeavoured to avoid any questions open to diversity of opinion, under which one might class varieties suitable to various soils and localities, and the important question of the stock employed for various fruits; but there can be no doubt whatever as to the capital importance of procuring trees which are true to name. There are so many men who have taken the trouble to plant fruit and study the very numerous varieties which are now in commerce, and to propagate from what they have proved to be true, that the purchaser should have no difficulty on this score.—A. H. PEARSON.

## WOOLTON GARDENERS' MUTUAL IMPROVEMENT SOCIETY.

### HORTICULTURAL EXHIBITION AND CONVERSAZIONE.

It has been a pleasure to us from time to time to report the progress made by the above excellent Society, but on no previous occasion has the Society claimed such notice as was accorded it last Thursday, where at the beautiful Parochial Hall, Woolton, was opened an horticultural exhibition and conversazione, which was continued the following day. The objects of the Exhibition were to arrange an interesting display of specimens in connection with horticulture, and to provide funds for the extension of the Society's library. Numbering seventy or eighty members, the Society has been in existence for about two years, but never before has any effort in the direction under notice been taken in hand. The experiment cannot fail to prove successful, as everyone who visited the Exhibition must have been struck by the unique display. The platform of the hall presented a very gay appearance. On each side were large Palms, whilst the front portion was decorated with Panium, Maidenhair Ferns, and Zonal Pelargoniums. In the background was a finely flowered plant of *Anthurium Andreanum* from Mr. J. Jellicoe, gardener to F. H. Gossage, Esq., Camp Hill, Woolton. A stage ran round the room, and stages across contained the exhibits, which consisted of fruit and flowers, modern and ancient garden pictures, plates, photographs and literature, fossils, dried flowers, Ferns and Grasses, novelties, varieties and monstrosities of plant life, horticultural appliances, microscopes with botanical sections, insects, and apian exhibits. Much taste was displayed in their arrangement, and the hall presented a most pleasing effect.

The President, Holbrook Gaskell, Esq., Woolton Wood, opened the Exhibition, and stated that the idea, and the successful carrying out of it, was due to the gardeners themselves. He went on to speak in the highest of terms of the work done by the Society, and concluded by pointing out the beauty of gardening for those having a taste for it. Turning to the exhibits the first to be noticed were those belonging to the President, who had contributed to the greater portion of the sections. In literature were Loudon's "Encyclopædia of Gardening," Pontey's "Forest Pruner and Planter," Seboth's "Alpine Plants," Veitch's "Manual of Orchidaceous Plants," "Lindenia," "Fairfield Orchids," "Botanical Magazine, 1782," Warner's "Select Orchidaceous Plants," Williams' "Orchid Album," and a magnificent work printed by order of the Emperor Napoleon by Alphand, entitled, "Les Promenades de Paris." It was undoubtedly the finest work exhibited, and found many admirers. The collection of Orchids which the same gentleman exhibited were arranged in one corner of the room, and a splendid effect was produced by Mr. Todd, Mr. Gaskell's able gardener. Conspicuous were *Lælia elegans* Turneri, which secured a certificate of merit; two fine plants of *Cattleya Dowiana*, *Cattleyas Gaskelliana*, Loddiges', and *Sanderiana*, *Miltonia Morrelliana*, *Masdevallia Chimæra Backhouseiana*, *Cypripedium callosum*, and many others equally beautiful; also fine selection of *Nepenthes*, *Dionæa muscipula* (Venus' Flytrap) *Cephalotus follicularis*, Madagascar Lattice Plant (*Ouvirandra fenestralis*), inflorescence of *Cycas circinalis* (rare), and fruit of *Pyrus Maulei*. Messrs. Charlesworth & Shuttleworth, Heaton, Bradford, had about thirty varieties of Orchids, many of them very valuable; the following were well flowered—*Miltonia Clowesi*, *Odontoglossums Harryanum* and *nebulosum album*, *Oncidium Forbesi* and *macranthum*, *Cattleya Schofieldiana*, *Lælia Perrini*, *Zygopetalum crinitum*. Messrs. R. P. Ker & Sons, Aigburth Nursery, had a fine collection of new and rare plants, amongst others their new *Crotons* Aigburth Gem and Golden Ring.

Mr. J. J. Craven, gardener to J. E. Grant Morris, Esq., Allerton Priory, exhibited six fine bunches of Black Hamburgh Grapes, a plant of the Red Currant Tomato in a pot, and a good specimen of the Silver Fern *Gymnogramma peruviana argyrophylla*. Mr. T. Carling, gardener to Mrs. Cope, Dove Park, Woolton, contributed excellent specimens of Tomatoes Dedham Favourite, Webb's Sensation, and Golden Queen, Dickson's Excelsior Cucumbers, and inflorescence of *Cycas revoluta*, very curious, and which attracted much attention. Mr. Jellicoe showed Loekey's Perfection Cucumber and a collection of plants. Mr. Vaughan, gardener to T. Brocklebank, jun., had remarkably good Cockseombs. Mr. C. Osborne, gardener to Lieut.-Col. H. J. Robinson, Aymestry Court, had four Orchids in bloom, amongst which was the autumn-flowering variety of *Odontoglossum vexillarium*, variety *rubellum*. Mr. G. Eaton, gardener to W. H. Shirley, Esq., Allerton, had a grand stand of hardy herbaceous cut flowers. The lovely *Lychnis vespertina*, *Aster sagittifolium*, and *Helianthus multiflorus* Soleil d'Or standing out prominently, with choice Phlox and Lilliums in perfection. Mr. J. Storey, gardener to Sir T. Earle, had superb samples of Ailsa Craig Onion. Mr. Winkworth, gardener to R. Brocklebank, Esq., contributed a small but excellent collection of Cacti and Succulents, and fruit of hardy Arum and Mulberries, a very interesting exhibit. Mr. Norman Davis had a fine stand of early-flowering Chrysanthemums, amongst them being Mrs. Cullingford, M. Pyneert Van Geert, Blushing Bride, Bouquet Estival, Flora, Scarlet Gem, A. Butcher, Bouquet de Dames, and the new incurved M. Bahaunt. As shown it was rather loose in form, but may come better later in the season. The petals are good, but I think it will have to be seen in better condition before it can be proved any acquisition to the present incurved varieties. Seeing it so early is no criterion of what it may prove. Messrs. Clibran, Altrincham, had a magnificent collection of herbaceous cut flowers, Dahlias, and their new *Tropæolums* Mrs. Clibran and Clibran's Gem. This collection well deserved the certificate of merit awarded to it.

The Liverpool Botanic Gardens contributed a collection of most curious works and horticultural works, and Mr. P. Harbordt, Covent Garden Seed Stores, garden appliances, &c. Grapes were shown by Mr. Thos. Hayes and Mr. H. Cunningham. Mr. E. Molyneux, gardener to W. H. Myers, Esq., Swanmore Park, Hants, exhibited dishes of Quinces, Medlars, Plums, Pitmaston Duchess Pears, &c, the two latter being superb. Photographs embracing many subjects were also shown, the principal contributors being Lieut.-Col. J. B. Gaskell and F. H. Gossage, Esq. From Mr. M. Dunn, Dalkeith Palace, came a collection of 100 varieties of Apples and Pears; Mr. S. T. Wright, gardener to C. Lee Campbell, Esq., Glewston Court, Ross, had a well-coloured collection as well. There were no prizes given, but three certificates—viz., cultural, certificate of merit, and highly commended. The following are the awards:—

*Modern and Ancient Garden Pictures, &c.*—Certificate of merit, Lieut.-Col. J. B. Gaskell, photographic albums; F. H. Gossage, views of Gwysaney; he, Mr. R. Todd, for *Odonto. Alexandræ*, water colour; Holbrook Gaskell, Esq., ancient Chinese landscapes; Messrs. Charlesworth & Shuttleworth, photographs by their collectors; Messrs. Sander and Co., for "*Reichenbachia*;" and to H. Gaskell, Esq., Mr. R. Fleming, and Liverpool Botanic Gardens for ancient garden literature.

*Fossils, Dried Flowers, Ferns, Grasses, &c.*—Certificate of merit, Mr. M. Smout, Seaweed table decorations; Mrs. Hodgkins, Manchester, skeleton leaves; Mr. J. Edwards, Allerton Beeches, dried Orchid flowers; vhc, Miss Jump and Mr. J. Griffiths, fossils and dried flowers; he, Miss Griffiths and Mr. R. S. Waterman for dried Ferns.

*Novelties, Rarities, and Monstrosities.*—Certificates of merit.—Holbrook Gaskell, Esq., and Charlesworth & Shuttleworth for Orchids; W. H. Myers, Esq., *Physalis Alkekengi*; Mr. Jellicoe, Fern-covered water bottle; Messrs. Ker & Sons, new and rare plants; and Liverpool Botanic Gardens for curious plants. Highly commended.—F. H. Gossage, Esq., and H. J. Robinson, Esq., for Orchids; Mrs. Cope for inflorescence of *Cycas revoluta*; Mr. R. Brocklebank for Cacti, &c. Cultural certificate.—Thos. Brocklebank, jun., Cockseombs; Holbrook Gaskell, Esq., for Orchids and other plants.

*Collection of Fruits, Plants, &c.*—Certificates of merit.—Mr. Norman Davis (London), early Chrysanthemums; Mr. J. Leather for butterflies and moths; W. Lees McClure, Esq., fifty varieties of honey-yielding plants; Messrs. H. Thompson & Sons, St. John's Market, for splendid exhibit of foreign fruits. Highly commended.—Mr. T. Hayes, J. G. Grant Morris, Esq., and H. Cunningham, Esq., for Grapes; W. H. Myers, Esq., for collection of fruit; C. Lee Campbell, Esq., and Mr. M. Dunn for Apples and Pears; Mrs. Cope, Cucumbers and Tomatoes; Mr. J. Leadbetter, spring-sown Onions; Mr. T. Leadbetter, case of flies. Cultural certificates.—Mr. Jellicoe, *Adiantum cuneatum* (window plant); J. Grant Morris, Esq., for Silver Fern and well-flowered plant of *Aristolochia elegans*; F. H. Gossage, Esq., Palms; W. H. Shirley, hardy flowers; and Mr. J. Stoney, Ailsa Craig Onion.

There was also a stall set apart for the benefit of the Gardeners' Orphan Fund, to which the following contributed articles for sale:—Liverpool Horticultural Co., R. P. Ker & Sons, Gateacre Nursery Co., Messrs. W. H. Myers, T. White, H. J. Robinson, C. L. Campbell, W. L. McClure, N. Davis, F. H. Gossage, H. Gaskell, M. Dunn, and Mrs. Cope.

The following works were presented to the Society:—"Reichenbachia," by F. Sander & Co., St. Albans; horticultural works, by B. S. Williams, London; "Vines" and "Chrysanthemums," by E. Molyneux; "Training and Culture of Fruit Trees," by Mr. T. White. The judging gave every satisfaction. The Hon. Sec., Mr. J. Rothwell, Hon. Treasurer, Mr. R. S. Waterman, and the hardworking Committee may rest assured that they have done a good work, and set an example worthy of emulation, and it is to be hoped they will have gained the object they had in view.—R. P. R.

## RHODODENDRONS.

I SPENT a summer not long ago in the mountains of Western North Carolina, and saw a part of the Rhododendron procession that is such a famous feature of that sylvan region. The time of my going thither was the second week in June, and the *R. Catawbiense* and *R. Vaseyi* were already out of bloom, while the *R. maximum* and *R. punctatum* were just showing the delicious pink of their opening buds. The interval meantime was superbly filled by the flame-coloured Azalea—*A. calendulacea*—which is the most splendid forest blooming shrub that I have ever anywhere seen.

*R. maximum* well deserves its name, notwithstanding Dr. Hooker's discoveries in the Himalayan mountains, for it is not uncommon to find it from 30 to 35 feet high, with a bole at the base from 10 to 14 inches in diameter. It fraternises perfectly with the *Kalmia*, supplementing it in flowering, and I have seen acres of the two a mass of bloom for weeks, forming a floral display well worth a long journey to see. A Rhododendron jungle is an interesting thing to enter, because of the curious and sprawling way the branches reach out and interlace with each other. But they are detestable to the surveyor or woodsman, who readily calls them what the mountaineers do—"hells." They spring up abundantly from seeds, and they seem to thrive in clearings, quite as well as when surrounded by shade. I remember two particularly fine Rhododendron clumps, 10 to 12 feet high and half as great, or more, in diameter, and beautifully spherical in shape, which grew on the north side of my aunt's house in Burlington, New Jersey, to which place they

had been transplanted several years before from the Jersey woods. The trusses of flowers which they bore were very nearly white.

*R. maximum* of the North Carolina mountains is a delicate pink of varying shades. A sketch I made of what I then thought to be the *R. maximum* in 1885 in the State of Washington, where it grows in the Puget Sound region from 10 to 12 feet in height, shows a highly coloured flower of a rich, deep pink—possibly the *punctatum*. The *R. catawbiense* with its purple flowers is probably the progenitor of most of the delightful varieties produced by English gardeners from what they call the "American Flower"—giving us a broad hint to adopt it as our national posy. It is not weed-like, after the manner of the vivacious Daisy, or the rampant Golden Rod, but elegant and patrician from leaf to flower, grows from New England to Alaska—at least I found the *Kalmia*, its twin brother, there—and all in all, is fine enough to please the most fastidious. The *R. Vaseyi*, which is deciduous, and has I believe only been found in the North Carolina mountains, is a shrub of great beauty, and is placed by some flower lovers at the head of all *Rhododendrons* in point of beauty of bloom.

The Puget Sound basin, by the way, with its England-like climate,

FIG. 65.—THUIOPSIS DOLOBRATA.

produces some growths which seem to us dwellers on the Atlantic coast as remarkable; for instance, I saw a single Vine-stock of English Ivy mantling a house in Seattle, which was a foot in diameter at the base! —(*Meehans' Monthly*.)

**CALCEOLARIAS AND VIOLAS.**—Before the beds are finally broken up abundance of cuttings of these two very serviceable kinds of summer bedding plants ought to be put in. Neither require nor should have any artificial heat. Three parts fill shallow garden frames or brick pits with old heating material, making this quite firm. On this place not less than 4 inches of fine light loamy soil, finishing off with a surfacing of sharp sand, making all level and smooth. Select short flowerless shoots, reduce these to a length of about 3 inches, cutting to a joint and trimming off the lower leaves, and dibble them in just clear of each other all over the bed. Water and keep rather close and shaded till the cuttings freshen up, then give more air and do not coddle in any way, as no top growth is desirable before next spring. Failing frames or pits use either handlights or boxes, the latter being placed in cold frames. Both kinds strike very readily thus treated, and plenty of strong plants ought to be available next season.

#### HARDY FRUIT GARDEN.

**Pruning Large Standard Trees.**—Now is the best time to attend to this, as soon as the fruit is gathered and before the leaves fall, because it is easy to see where the weak and worthless branches are, and where the healthy ones are too close together; but after the leaves are off it is much more difficult to ascertain which branches ought to be removed. Too many persons have an aversion to pruning large fruit trees, and think it unnecessary because the trees do not make growths a yard or more in length every season, consequently the bush and espalier trees get the whole of the attention, and very often a great deal too much of the pruning knife, and the large trees are left to take their chance, becoming in time dense heads of weak wood that cannot bear sound useful fruits, and are interspersed freely with dead or cankered branches. The fruit under these circumstances become smaller every season until at last the tree is condemned as worn out, having become old long before its time from want of proper attention. If the main stem and principal branches are sound a little extra care will often bring such trees round to a healthy condition in a short time. The tops should be dealt with at once, leaving the roots to be attended to a few weeks hence. Commence by removing all dead and decaying branches, and also all those that are merely filling up the centre of the tree. The latter often appear to be the most healthy part of the tree, and probably are, but they only rob the other branches, and any fruit in the interior of the tree is sure to be small and flavourless. The main portion of the head has next to be thinned, so that air and light may reach all the leaves in sufficient quantity. The amount of wood to be taken out will vary with the different varieties. Among Apples, for instance, King of the Pippins and Peasgood's Nonesuch form more open trees naturally than do Wellington, Cox's Orange Pippin, and Keswick Codlin. All should be thinned so that the fruiting spurs can have the full benefit of the sunshine. Cutting out the weaker branches will cause a more abundant flow of sap to the parts that are left, and with good attention in other ways the trees so treated will show a marked improvement next season. All branches taken out should be sawn off carefully close to the main branches, and the wounds on the latter must be pared carefully with a sharp knife. Do not make large wounds if it can possibly be avoided; they are apt to decay extensively before the bark grows over them, and often seriously endanger the life of the tree. If it is necessary to remove any branches more than 3 inches in diameter the wounds should at once be coated with pitch to prevent decay. After thinning the branches to a moderate distance apart no more pruning of the top growths will be required at present. Those branches that remain should be left entire, and not shortened in any part unless they are growing into the neighbouring trees, in which case a space of 2 feet at least must be cleared all round each tree, and this space should always remain clear and open, or the trees overlap each other, and then the weakest grower gradually perishes.

**STRAWBERRIES.**—Keep a strict watch on newly planted beds and others, also remove all runners as soon as they appear, and keep down weeds, which are very troublesome this season. If the summer mulching still remain on any of the beds lose no time in removing it. Autumn fruiting beds will need attention to keep the fruit from birds and from damage by slugs. Beds in poor soil will be much benefited now if a good top-dressing of manure is given them. They will derive strength and nourishment from it all through the winter except during severe frosts, and even then will be much assisted by the protection and warmth it will afford them.

**CLEANING PLANTATIONS.**—Have all the fruit quarters thoroughly cleared of weeds before cold weather comes. Any seed weeds should be removed by hand and destroyed, and others hoed and raked off to prevent their starting into growth again, and to make all clean and tidy for the winter. Weeds with perennial roots, such as Dandelions, Couch, Bindweed, &c., are best attended to now while they are easily found, and must be dug out and burned; nothing but unceasing attention in this way will overcome them.

**LABELLING FRUIT TREES.**—The present season is an excellent time to attend to this wherever it is necessary. Seldom does such a good opportunity occur for comparing the various kinds, and fruit trees should always be labelled for convenience of gathering and storing, so that the whole of each kind may be placed together, and also to assure accuracy when propagating. One of the best kinds of labels is made of sheet lead cut into strips, and the name punched into it by means of moveable type. The end of this must be long enough to roll round one of the smaller branches of the trees. These are not liable to damage the trees in any way, and are almost indestructible, but are not so easily found as the ordinary wooden label, and the latter answer well where only small quantities are required if time can be found to renew them when necessary. Labels attached by wire to the trees are almost certain to be neglected and to cause injury. For wire trellises and walls those made of zinc and inscribed with indelible ink are very

useful, as they can be fastened with wire without any fear of injuring the trees.

#### FRUIT FORCING.

**PEACHES AND NECTARINES.—Earliest House.**—The trees are at rest, and very bright and promising they are. The buds are not too large, an indication that they have not been over-developed, but are perfect, and will retain their hold on the trees. Through the roof lights having been removed some time the borders have been thoroughly moistened, and this, with the invigoration consequent on exposure, is the best safeguard against the buds falling. The trees must be pruned, dressed with an insecticide, and the whole of them thoroughly washed—the woodwork with soap and water, the glass with clear water, and the walls with limewash. The trees can also be tied to the trellis, everything forwarded, so that a start can be made without delay at the proper time. Let the lights remain off until the time of closing the house. If the lights are fixed the inside border must not lack moisture, and air must be given to the fullest possible extent, insuring thereby as complete rest as practicable under the circumstances.

**Second Early House.**—The trees have shed the foliage. Trees that have made strong wood, which takes more time to mature than the moderately vigorous, must not be exposed until the growths and foliage are well matured. Our roof lights have been removed. The exposure of the trees has an invigorating tendency; it insures perfect rest, and the rains do much to free them of insects, besides soaking the borders. When the foliage is all down the necessary pruning, dressing the trees with an insecticide and cleaning the house should be proceeded with, removing the surface soil down to the roots, and adding fresh material, but not covering the roots deeper than 2 or 3 inches. In the case of fixed roof lights watering may be necessary; under no circumstances must the trees be allowed to become dry at the roots.

**Midseason Houses.**—If the trees are in an unsatisfactory condition have recourse to lifting, the wood being firm and the foliage beginning to fall. It must be done with despatch, all the material's being in readiness. Provide efficient drainage, shorten strong roots, and bring any that are deep nearer the surface, employing the compost moderately firm. Good loam, rather strong, with an admixture of a sixth of old mortar rubbish will grow Peaches perfectly. If the soil be light add a fourth of clay marl, and if very heavy a similar quantity of road scrapings. If the soil is deficient in calcareous matter add a tenth of chalk. Avoid manure except at the surface. Give a good watering, and the roots will soon get established in the fresh compost. Trees judiciously treated at the roots whilst they have foliage seldom fail to set and stone the fruit satisfactorily.

Borders that have the surface a soapy mass and it is not possible to remove it may have a good dressing of quicklime quite an inch thick, mixing it with the surface soil as deeply as the roots allow without much disturbance.

**Late Houses.**—October Peaches are quite as much valued as those of May. They are fine in appearance, and when properly supplied with moisture and nutriment during the growing season the fruit is juicy and well flavoured. Sea Eagle is one of the best, large, showy, good flavoured, with a juicy melting flesh, free of the stringiness and meanness too prevalent in some late Peaches. As the wood in many late (especially unheated) houses is not too ripe, the house may be almost closed by day so as to secure a good heat, admitting sufficient air to insure a circulation, continuing the ventilation at night. Any trees that have too gross wood should have a trench taken out as deep as the roots, and about one-third the distance from the stem the trees cover of trellis, and left open for a fortnight, then filled in again firmly.

**MELONS.**—The end of the Melon season as regards those grown in frames and pits heated by fermenting materials is approaching, though fairly good fruit may be had up to November, especially of kinds that will keep some time. Some of our cross-bred sorts also keep well, particularly Scarlet Premier, which is one of the very best for late work. Any fruits approaching ripeness should be cut with a good portion of stem, and placed in a house with a gentle warmth, where they will ripen and be welcome additions to the dessert.

From houses a supply of fruit will be kept up some time longer, the latest fruits only swelling now. Sufficient moisture will be secured to this crop by damping in the morning and again early in the afternoon, affording water to the roots moderately; a supply once a week will be sufficient. All superfluous laterals must be cut out, so as to afford the principal foliage the benefit of the autumn sun. Plants with fruit approaching ripeness should be kept dry, and a brisk heat maintained with rather free ventilation, the temperature being kept at 65° at night, 70° to 75° by day, rising to 85° or 90° from sun heat, affording a little air at the upper part of the roof whenever the weather is favourable.

**CUCUMBERS.**—The latest plants which are to afford a supply of fruit about the new year should be placed out on ridges or hillocks, training with a single stem to the trellis, up which they may be allowed to advance about two-thirds, when the lead may be pinched. Those not having the convenience of a Cucumber house may secure fair supplies of winter fruit by growing the plants in pots or boxes, training the growths near the glass over the paths in stoves, fruiting, Pine houses, or other well-heated structures. Plants in bearing should not be overcropped, or the fruit allowed to remain longer than it is fit to cut, removing all deformed fruit in a young state. Maintain a night temperature of 70°, 5° less in the morning, 75° by day, up to 85° or 90° with sun, admitting a little air at the top of the house at every favourable opportunity. The evaporation troughs should still be charged with liquid manure, and

the floors damped with water about 8 A.M. and 4 P.M., dispensing with the syringe over the plants. Reduce the supply of water at the roots, but not so much so as to cause flagging. A little manure sprinkled on the beds occasionally will benefit the plants through the waterings washing their elements in the soil and the ammonia given off, but this must not be excessive or the foliage will be injured. Keep the foliage thin and the glass clean, so as to secure thoroughly solidified growth.

**STRAWBERRIES IN POTS.**—Where autumn and winter fruiting plants are grown they must without further delay be placed under glass, and on shelves, so that they may enjoy a free circulation of air, ventilating so as to dispel damp, as the fertilisation of the flowers is not satisfactorily effected in a moist atmosphere. Those swelling and ripening the fruit in frames should have moderate ventilation; and though the fruit will ripen in cold frames, they swell better and the flavour is improved in a house where there is a moderate degree of heat, 50° to 55° as a minimum, 70° to 75° as a maximum by artificial means, in which they should have air on all favourable occasions.

**Plants for Next Year's Fruiting are Late.**—The crowns are not well matured nor so strong as desirable. Those intended for early forcing should be placed on a base impervious to worms in frames, or cold pits, exposing them fully to every gleam of sun, employing the lights only to ward off heavy rains, and at night when frost prevails. Keep the remainder of the plants in a sunny position, as they will require every ray of light and sun's warmth to enable them to mature the crowns properly.

**PINES.**—*Plants Showing Fruit.*—These will be valuable when fruit is scarce and dear, therefore such plants should be afforded the best positions in the fruiting department. Maintain a temperature of 70° at night, 75° artificially by day, up to 85° to 90° with sun, closing at 85°, sprinkling the paths when their surfaces become dry and occasionally sprinkling the plants on fine afternoons. Keep the bottom heat steady at 85° to 90°. Examine the plants once a week for watering, and if any require it afford a copious supply of clear liquid manure at about the same temperature as the beds. Care must be taken not to over-water the fruiters, as that has a tendency to cause the fruit when cut to be black at the centre.

**Plants to Fruit Early.**—Queens are best for this purpose, but there is not always a certainty of their doing so unless they are given a period of comparative rest after making good growth. Plants intended to show fruit early in the year should be kept in a temperature about 65° in the daytime by artificial means, 60° at night, ventilating at 70°, closing at 70°, allowing the bottom heat to fall to 70°. Water the plants only when necessary, but do not allow them to become so dry as to cause the foliage to be limp.

**Young Plants.**—All young plants should now be arranged so as to obtain the fullest benefit of light and air. As the sun diminishes a corresponding diminution of temperature must take place at night until it reaches the winter standard of 55° to 60° at night, and 65° in the daytime. Ventilate freely whenever conditions are favourable, paying particular attention to watering. Examine the plants about once a week, and whenever one needs water give it copiously at about the same temperature as the bed.

#### PLANT HOUSES.

**Fuchsias.**—Place singly into 3-inch pots cuttings that are well rooted, and keep them close and shaded for a few days until they are established. They can then be gradually hardened and placed on a shelf where the winter temperature will not fall below 45°. All that is needed is to keep them slowly moving, so that they will be in good condition for starting into growth early next season. Plants that have flowered may be stood outside to harden and ripen until the approach of frost, when they should be sheltered from severe weather in a Peach house or vinery. These plants are better kept rather dry at their roots, and in case of heavy rains throw them on their sides.

**French and Fancy Pelargoniums.**—The latest flowering plants may be cut down without delay. Place the plants in a frame and syringe once or twice daily according to the weather until they break into growth. Those that are already established will be better on shelves where abundance of air can be given and where the plants will be close to the glass. In frames the atmosphere is often too moist for them, and they grow weakly and the foliage becomes spotted. The earliest should have their shoots pinched for the last time. Where special houses cannot be devoted to these plants the Strawberry shelves in Peach houses will be found a capital position. Any that needs potting must be attended to at once. The soil should consist of fibry loam, sand, and one-seventh of manure, pressed firmly into the pots. In addition we use a little soot and artificial manure, but very little of the latter at this period of the year. Cuttings inserted in outside borders may be well rooted, even if only callused they can be lifted and placed singly into 3-inch pots. If well rooted place them on a shelf and pinch out the points of the shoots. Let them have a cool position, as injury results from forcing them into growth by the aid of heat or a close atmosphere. Those that are not well rooted will do so quickly in a temperature of 50°, but as soon as roots are observed remove them to cool airy quarters. Water these plants with care, too much will ruin them at this season and throughout the winter months.

**Chrysanthemums.**—Make provision for housing them without delay, they are not safe outside after this date. Do not crowd the plants when placed under glass, and syringe the foliage freely at first. This is the only means by which the plants can be induced to retain their leaves to

the base. The change from the moist atmosphere at night, which they enjoy at this season of the year, is too great for them when placed under glass and subjected at once to the drier conditions of those structures. Select the plants, so that special treatment can be given them according to the time blooms are required. Those for very late flowering should be left outside, but arranged so that some protection can be given them in case of sharp frosts. A temporary structure, where blinds can be drawn over them at night, insures their safety for a long time. An open shed in which they can be placed at night and stood out again in the morning will also do very well.

Continue to feed the plants carefully, avoiding strong stimulants, they do more harm than good, and often burn the roots to such an extent that the flowers fail to develop properly. Keep the roots active until the last.

*Vallotas*.—These make a beautiful display at this season when grown in quantity. We find they succeed best when kept under glass the whole year round. After flowering they are returned to the greenhouse and stood amongst Azaleas. During the winter they are never allowed to become dry. They are equally as useful for decoration as Amaryllises, and well repay for care and good treatment. Keep the foliage clean, especially from thrips.

*Lilium candidum*.—Throw off the lights during favourable weather, but as soon as severe weather arrives place them where the temperature does not fall below 45°, and they will quickly commence to throw up their flower spikes. *Lilium Harrisii* is growing rapidly. These need some care to prevent them from drawing up weakly. Place them for the present in a light position in the greenhouse close to the glass, where they can enjoy air day and night when the temperature outside does not fall to freezing point. Stand them on some moisture-holding material, and do not allow them to become dry.

*Azaleas*.—Prepare the structure in which these are intended to be wintered. Clean the house thoroughly. Tie and regulate climbers that are on the roof; thin liberally where they have become crowded, so that light can reach the plants below. Wash the pots, and push on the tying of these plants where trained specimens are appreciated. It is a mistake to delay the completion of this work too long. If tied at once the shoots quickly assume a natural position again. Wash all plants in a solution of tobacco water if infested with thrips. Stand the plants on a moisture-holding base, and syringe them once or twice daily to keep their foliage clean and fresh. No treatment is more detrimental to Azaleas than a dry atmosphere.

## APIARIAN NOTES.

### PUNIC BEES.

I HAVE to modify my statement on page 295 that Punic bees are robbers. With my experience of them at the Heather, and after they were brought home, I was about wishing I had never been in possession of them, so great was the uproar among the bees. It was a puzzle to know which hive would succumb in the general battle. My attention was particularly turned to one hive, and from it to several others that had been subjected to an attack at the moors by the Punics. No time was lost in making an internal examination, when, to my surprise, every one of the attacked hives had unfertilised, or drone-breeding queens. These were at once removed, when order was promptly restored in the apiary.

It will be observed that this discovery does not differ materially from what "A Hallamshire Bee-keeper" has said about them. I am now convinced that instead of their being a disadvantage they are an advantage in the apiary, pointing out abnormal stocks, giving the apiarist a timely hint as to queenless colonies. The whole of the hives attacked had June-bred queens. The days suited for fertilisation were few, and there is little wonder that so many hives are at the present time useless on that account. Nor is that all, for we fear that 95 per cent. of prime swarms have changed their queens, and 50 per cent. of these are also either unfertilised, or are drone-breeders. Many of them have but few bees left.

Had I not been prepared with extra nuclei having young queens my stock would have been reduced 50 per cent. from what it was in the spring, and the bees reduced in each hive to a third. I never experienced a season so destructive to bees as it has been from March till October, nor have I ever witnessed such splendid

blooms of Clover and Heather, and so little honey gathered from them. Renfrewshire and Aberdeenshire appear to have been an exception in this all-through exceptional year; I know of some heavy yields of honey from both counties.

I have experienced seasons with less honey, but then the flowers were absent. Very few of my stocks require feeding, so we must hope on and try again; another season, it is to be hoped, will be a better one, and the country demands bees whether there be honey or not. Bee-keepers on reading the foregoing will do well for their own interest if they make a thorough examination of every stock, and see that they have a fertile queen of the current year, and the hives well supplied with ample stores. All hives should be made wind and water-tight, and covered so that a zero temperature will neither affect bees nor stores.

### CAN BEES BE IMPROVED?

I have been prompted to put this question, and to answer it in consequence of an article by Mr. G. M. Doolittle in an American paper, in which he says the common "black bee is a fixed race or variety," while "the Italian bee is nothing more than a hybrid." Now, Mr. Doolittle is wrong in saying the "Italian bee is a hybrid." It may be a cross, but that is very different from hybrid. I do not know how he can make out the Italian not to be a pure race, any more than trying to make out the common black bee the original one. It is as likely as not that there were variety in the honey bee from the earliest times. There is one thing certain, that all the varieties imported into this country have different markings and different traits in their characters.

Neither Mr. Doolittle nor any other person will ever be able to prove conclusively which is the pure race or which crosses. He argues as a proof that queens of the black race can be bred to a colour, but not so with Italians. My own experience is there is as much variation amongst the queens of the black race as in any other race or races. How he makes out that a "hybrid" can be improved and not a pure breed is beyond my comprehension. The Americans, with the assistance of dealers in this country and on the Continent, have managed by crossing to produce bright, almost all yellow, coloured bees, which they term "pure five-banded Italians," but they are neither more nor less than crosses between that bee and the Cyprians or Syrian bees. The first crosses of any variety may show improvement, and the Punic crosses are the best, but after the first cross we are never certain. Sometimes the after crosses are as good as the first, while from others there is a decided backward tendency.

### PREPARING FOR NEXT SEASON.

All hives should be overhauled. Where there is an excess of drone comb it should be removed, and frames filled with worker comb, taken from the condemned hives, substituted. All the frames containing drone comb, and those that are emptied of filled comb, should be cleaned, and filled with foundation forthwith, so as to be in place and in readiness for next season.

I observe that on page 234 Mr. Hooker recommends the cutting of the top bar through as "the most convenient way of fixing foundation in a satisfactory manner," and am glad to see that it has found its way into his "little book." The groove plan which I introduced is far superior, and gives the most satisfaction to all who have tried the different methods. Where the groove is used the top bars are stronger, neater, and easier kept clean and free from comb attachments.

To clean the wax from used frames lay them in front of the fire for a few minutes; when the wax softens scrape immediately, and run a bradawl through the groove. I sometimes use a tailor's goose for softening the old wax, it answers the purpose well. There is no danger of splitting the bar when there is a groove as when it is sawn right through. Then, with the groove the sheet drops easily into it, and is never warped, as is the case sometimes with sawn bars. Simply drop the sheet into the groove, previously

made perfectly straight and flat, then pour hot wax on both sides, keeping the frame at the proper angles to send the wax from top to bottom, and into the groove.—A LANARKSHIRE BEE-KEEPER.

### PUNIC BEES.

In the issue for October 1st "A Lanarkshire Bee-keeper" gives these bees in their purity an indifferent report for the season, although on the whole they have surpassed the stocks he compared them with. I think he has not exactly treated them fairly, for in all experiments with these bees it must be remembered that their natural months for rest is our summer, which is their winter. Next year, when they have become acclimatised, he will have a different tale to tell. Then, again, it has been a bad season to try them; no honey from early July, so that when the Heather yielded they began breeding. If "A. L. B. K." will take into consideration the extra young bees they have bred, and the honey used in producing them, the balance will be on the other side, as bad as it has been. Five imported queens refused to lay at all till the Heather opened.—A HALLAMSHIRE BEE-KEEPER.

### TRADE CATALOGUES RECEIVED.

Ketten Frères, Luxembourg.—*Catalogue of Roses.*  
Robert Veitch & Son, Exeter.—*Catalogue of Alpines, Perennial, and Border Plants.*

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Tea-scented Roses for Growing in Pots** (*J. M.*).—The following varieties will probably meet your requirements:—Niphet s, Safrano, Madame de St. Joseph, The Bride, Sunset, and W. F. Bennett. They are free bloomers and good in bud, forcing well.

**Gladioli in Pots** (*G. P.*).—Gradually withhold water, and when the foliage turns yellow turn the plants out of the pots, shake away all the soil, and place the corms in a dry airy place to dry; then place them in drawers, where they will be safe from frost until spring, when they may be repotted and grown as in the previous year.

**Southern Markets** (*B. A.*).—The towns named by you are well supplied with all kinds of flower, fruit, and vegetable produce, and their markets are not so good upon the whole as those of the great towns of the Midlands and the North. Southern growers send much of their produce to the great manufacturing centres, more being grown than can be profitably disposed of near home. This you must bear in mind; also that competition is keen everywhere, and will become keener, success only resting with those having the best practical knowledge, business capacity, and enterprise, so as to produce at the cheapest rate a superior article.

**Nectarines Eaten by Ants** (*G. L.*).—The best means of destroying ants is by poison, and of those the arsenical solution to be presently named is very efficacious; but it must be used with the utmost caution, as it is fatal to animal life. White arsenic half an ounce, place in an old iron pot with a pint of water, and then boil until reduced to half a pint or little more of liquid, then add 4 ozs. of coarse sugar, and stir well. Place portions of this mixture in saucers in the haunts of the ants. They will eat it and die. Another plan is to lay a quantity of partially picked boiled bones in the haunts of the ants. They will soon be covered with ants, when throw the bones into hot water. Before laying the bones down again let all superfluous moisture drain off. This is a safe, cheap, and very effectual remedy.

**Keeping Apples** (*W. R. R.*).—"A perfectly dry wine cellar of very even temperature, but quite unventilated," would answer well

for storing and keeping Apples, provided it is perfectly sweet through limewashing the walls and cleansing the floor. If the cellar is musty the quality of the fruit would be impaired. Ventilation is not essential to the keeping of fruit, as you may easily prove by wrapping some Apples in tissue paper and placing them in a close sweet box, allowing others of the same variety to remain on a shelf in some ventilated room. Those from which air is excluded will keep much the longer if the variety is a late one, and longer also if early, though in this case the difference, for obvious reasons, is less marked. Your other question will have attention.

**Woodlice and Mushrooms** (*J. R. N.*).—A postcard reply was sent to the address you gave, and if this was insufficient the card would not reach you. If you have no use for the old litter burn it, and in that way you will "prevent accumulations." We are not aware that woodlice injure Mushroom spawn either "during fermentation or afterwards," but they enjoy Mushrooms and often do injury to the crops, especially when the beds and litter are dry in houses and sheds; when moist outdoors little harm is done. The most effective way of dealing with woodlice in Mushroom beds that we have seen is entrapping them between dry dirty old boards, placed face to face under the litter, as described on page 116 of the sixth edition of "Mushrooms for the Million." You may see how to prepare arsenic in our reply to "G. L."

**Proliferous Ferns** (*G. E. C.*).—The Fern you describe as producing a number of little plants along the midrib of each frond is probably *Polystichum proliferum*. When the frondlets are half an inch long or so, the portions of the fronds bearing them, if pegged down in a free mixture of leaf soil, peat, a little loam and sand, or even cocoa-nut fibre refuse, and kept moist in a box, such as a biscuit box, and a square of glass laid across to exclude air, will be kept fresh for supporting the "little plants" till they form roots. If not kept close and moist as suggested the fronds are apt to wither in a room window and the frondlets perish. You may try some now, and if they fail try others next summer when the weather is warmer, but they must be shaded from the sun. It is scarcely fair to send an inferior Pear to be named when you have "several larger and better." We can only say the variety is possibly Louise Bonne of Jersey, a free-bearing excellent October Pear, worth planting, though the fruit does not keep very long.

**Mushroom Bricks Spawning** (*W. H. W.*).—The right condition to have the bricks for spawning is barely half dry, effecting this by standing them edgeway similar to ordinary clay bricks preparatory to burning, turning them occasionally, and having them under cover. After spawning, the bricks are placed on a floor in a shed or house with a little straw beneath, and close together on edge, except that a few straws are placed between the bricks. They are covered with sweet hay or soft straw, and, if necessary, enough fermenting material to raise a gentle heat of 75° to 90°; but in summer this is not necessary, though some practise it to insure the speedy and certain running of the spawn. Care must be taken not to have the fermenting materials too hot, and not too moist; all that is wanted is a gentle warmth and enough moisture in the bricks to insure the spread of the spawn. Are you sure the spawn from the haystack bottom is the proper kind and in right condition?

**Flower Garden Designs** (*Flower*).—There are as many plans and designs for bedding in Cole's "Royal Parks and Gardens of London" as in any cheap work we know. It can be had for 2s. 11d. by post from this office. It contains much information on propagating different kinds of plants and other appropriate matter. We have no recollection of the Australian seeds, and all letters received more than a week ago have been answered. We are always glad to receive your notes, and if they are not inserted immediately you must not think they are on that account lightly regarded. Light sketchy notes, as well as what you describe as "weighty" articles, are equally acceptable when suitable for publication. Some of the heavy brigade order arrived by the same post as yours, but cannot be inserted this week, as the printers had more than enough matter in hand for filling the pages. The articles, however, like your notes, lose nothing by the delay, and are worth waiting for.

**Muscat Grapes Spotted** (*Ten-years Subscriber*).—The remarkably fine berries, over 1 inch by nearly 1½ inch in diameter, are affected with spot. This is caused by a fungus known as *Gloeosporium leucolor*, which seems powerless to penetrate the skin of the Grapes by its spores (germinal tubes) until they are rendered tender, if not actually decomposed by moisture resting upon them. Hence we find the berries most affected on the upper part of the bunches, on the upper side of the berries, and at their base. There is no remedy, but it may generally be avoided by pursuing a course of treatment, which gives density to the surface by judicious ventilation and a moderate amount of atmospheric moisture, especially at night, much moisture has a weakening tendency. The disease does not affect the Grapes generally until the transformation of the juices takes place in ripening, and it is very common in Grapes that have hung some time, and are undergoing acetous fermentation. We can only recommend a gentle warmth in the pipes and a little air constantly so as to prevent the deposition of moisture on the berries. Remove the affected berries and burn them.

**Plum Trees "Cankered"** (*J. B.*).—Plum trees never canker in the sense applied to Apple and Pear trees, but they are very liable to a similar disease—namely, gumming. The trees evidently make too

vigorous growth, and do not mature it properly, therefore the wood is injured by frost. Nothing will help the trees in those respects, except a firmer soil and a dressing of clay marl, so as to harden their tissues. Indeed clay and calcareous matter are essential to the health and profitable bearing of some varieties of Plums. A dressing of quicklime could not be other than beneficial, applying 10 tons per acre, or surface dressings of steamed bone meal 5 cwt., and kainit 2 cwt., mixed, per acre, would tend to promote a sturdier growth and firmer tissues, applying the mixture in autumn, or, as your soil is light, in February. We have found Victoria and Diamond Plums anything but hardy in most localities, which also seems to be your experience, and they certainly ought not to be grown where they do not succeed. Prince Engelbert is a valuable Plum for cold localities, but it is not nearly so great a market favourite as Victoria, which requires good treatment and favouring climate. It ought to succeed fairly well in your locality with phosphatic manure, but the question is, Is it hardy enough? Of that you only can form a right conclusion. Rivers' Prolific Plum does not succeed in all soils, and in light soils sometimes succeeds admirably. The Czar, however, is a better grower and crops heavily, the fruits being in request, and it may be said to be the best general early Plum for market. Mitchelson's, a large Damson-like Plum, is very prolific and hardy, and Gisborne's, an oval yellow Plum with red spots, does well in cold localities, and is a fine market kind.

**Animal Matter as Manure (F. S.).**—Certainly carry out your proposal, and if you blend the matter well with plenty of soil you need not add lime, and you will in due time have a rich compost. Relative to the chemical constituents of animal matter and blood, the following citation from Johnson's "Gardeners' Dictionary" will answer your inquiry:—Animal matters, without any exception, are beneficial as manures, for they all yield, during putrefaction, gases and soluble substances, that are imbibed greedily by the roots of plants. That this is the case affords no cause for wonder, because animal matters and vegetable matters are alike compounded of carbon, hydrogen, oxygen, and nitrogen, with a small addition of saline matters. Blood is a very rich manure, and has been applied with especial benefit to Vines and other fruit trees. The blood of the ox contains about 80 per cent. of water, and 20 per cent. solid matter. The latter contains, in 100 parts, when dried—

Carbon	...	...	...	...	...	51.950
Hydrogen	...	...	...	...	...	7.165
Azote	...	...	...	...	...	17.172
Oxygen	...	...	...	...	...	19.295
Ashes	...	...	...	...	...	4.418

The ashes contain various salts, as chloride of sodium (common salt), phosphate of lime, with a little oxide of iron.

**Gardeners' Mutual Improvement Society (W. J. B.).**—The first matter to be considered is the need of such society, and the probability of its success. Of the first there can be no question, but whether there are sufficient gardeners in your locality within reach of a given centre, and who would attend meetings and give aid in reading papers, taking an interest in the society, and giving it hearty support, you only can form an opinion. If satisfied on that point you must secure approval and patronage of your employer, and solicit his aid in respect of other proprietors of gardens. A room will be required, and that must be well lighted and properly warmed. We may suggest a schoolroom or other room not under any restrictions as regards religion and politics. These you must rigidly exclude, so that all can meet with unbiassed minds to discuss purely horticultural matters. Secure therefore the patronage of the gentry, clergy, and all ministers, as well as other influential persons. Let it be known that they are honorary members, subscribers of so much a year for the benefit of farmers and cottagers desirous of adding to their incomes, and improving the economy of their households by fruit culture and horticulture generally. This will enable you to meet incidental expenses, and it would help much in the establishment of the society were circulars sent round indicating the character of the intended work. Then members will be required, competent teachers of horticulture to form a committee, some good at organisation, all paying a small sum annually in advance as a guarantee of expenses incurred. You will need a president, vice-presidents, patrons, and as many members as practicable, with a committee and a secretary. To inspire confidence you will need an auditor (say the schoolmaster) and a treasurer (say the doctor). Then arrange for meetings, send out circulars and invitations to farmers and cottagers to attend and hear papers read, questions asked and answered, with free discussion. A chairman will be required at each meeting, and if you could arrange to bring to your midst occasionally a lecturer in connection with the British Fruit Growers' Association zest would be given the undertaking. We heartily wish you success, for fruit growing might be pursued with great advantage in the rich valleys of North Wales. True, many of them have been overspread with glacial detritus, and in this case the soil has suffered. In many cases, indeed most, especially in the lovely Vale of Clwyd, Denbighshire, the new red sandstone has been commingled with the glacial detritus, and the result is a very fertile soil, and there are numerous tracts in other valleys that consist of reddish soils, in which orchard trees invariably thrive, and there is no reason why Denbigh and other counties of Wales should not rival in Apples and Pears those grown by the trias of Devon and Gloucester, or even the old red of Hereford.

**Names of Fruits.**—*Notice.*—Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. *In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing.* The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. —(J. H.).—1, Glout Morceau; 2, Knight's Monarch; 3, Gansel's Bergamot; 4, Not known; 5, Maréchal de Cour; 6, The shrub is Hibiscus syriacus, commonly called Althæa frutex. (W. S.).—Greenup's Pippin, a Lancashire Apple. (J. G.).—1, Souvenir du Congrès; 2, Marie Louise; 3, Beurré Diel; 4, Chaumontel; 5, Apple not known; 6, Van Mons Léon Le Clerc. We shall inquire about the letter. It must have miscarried. (F. K.).—1, Cox's Pomona; 2, Mère de Ménage. (Stour Valley).—1, Suzette de Bavy; 2, Maréchal de Cour; 3, Comte de Flandre; 4, Beurré Sterckmans; 5, Flemish Beauty; 6, Not known. (George Heskett).—Doyenné Boussoch. (W. M. E.).—The Apple is Lewis's Incomparable, a fine fruit, but rather pale in colour. (Faie).—A, Dredge's Fame; B, not in condition; C, possibly Manks Codlin; D, Winter Calville; E, Cellini. Your trees are infested with scale. (G. M.).—2, Striped Beeching; 4, Lord Derby; 5, Nouveau Poiteau; 6, Beurré Diel. (H. E. M.).—1, Beauty of Kent; 2, Gravenstein; 4, Blenheim Pippin.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. N. H. P.—1, Polygonum Bistorta. 2, Saponaria officinalis.

### LABOUR MIGRATION.

PERHAPS one of the most remarkable results of the agricultural depression is the steady migration of farm labourers from their native villages to the already overcrowded centres of population, in search of employment for the means of bare subsistence denied to them in the country from stress of circumstances and nothing else. Certain of our legislators affect to be puzzled by this state of things, and we have heard of proposed commissions and special inquiries, but surely no sensible man giving heed to what is going on around him can long be at a loss for a cause which is so apparent and so very real?

It is simply a case of supply and demand. One of the first laws of Nature is self-protection, and the farmer who from the low prices of farm produce becomes straitened in means cannot afford to employ so much labour as of yore, and so the young men have to go; aye, and the middle-aged men too in many an instance. In the instance given a week or two ago of the reclamation of a farm of 400 acres, all the labourers, except those required for tending live stock, were discharged. There was a terrible outcry at the next meeting of the local board of guardians about so many able-bodied men coming upon the union for means of subsistence, but we were prepared for that, and most of the men went away eventually. All this may sound very cruel and heartless, but we repeat self-preservation is the first law of Nature, and for a farmer to go on paying for labour with money which he cannot afford is positively dishonest; because in the end it will land him in bankruptcy, and others will have to suffer loss through his sentimental folly. Really! to read some of the advice given to farmers about their duties to the labourer one would suppose the farmer to be a large hearted philanthropist, whose duty it is to sacrifice himself for the good of his workmen.

Take the other side if you will, the workman's side, and see if there is much to tempt him to cling to the land. In the great corn-growing district of East Anglia his ordinary rate of pay is 9s. per week, of which 1s. has to be left as rent of the cottage he and his family occupy. Can one wonder that the underfed man is a poor workman? Can we wonder at the pallid pinched face of his wife, or the rickety appearance of his children? Of course there is haysel and harvest to afford a little extra money. Our remedy in that district has been to place as much piece-work in the men's hands as we could, so as to give them a chance to earn a fair wage. Hodge's weak point, when he finds himself earning more money than hitherto, is beer. There are some good, thrifty men who do not give way, we have some in our employ at the present time, but the majority will have the beer, and with them nothing short of drunkenness is enough. Publicans are forbidden to draw beer for a man who has evidently more than is good for him; but it comes within our recent experience that in the inns of quiet country villages men habitually become roaring drunk without any interference whatever.

If under the scheme of technical education teachers appointed by county councils can induce habits of self-respect, self-denial, and thrift, by showing the working man how to turn his spare time to profitable account a great work will be done. It will have to be done chiefly at the centres of population, for nothing can check the steady flow of the labourer to the towns. But a glance at the suburbs of such towns as Nottingham and Leicester will show how highly such information will be appreciated by the hundreds and thousands of holders of allotments and garden plots.

When the depression fell upon agriculture great was the outcry

about the burdens of tithes, rates, and taxes upon the land; the hardship of the case was so palpable that the question was often asked, Ought not commercial men to share our burden? They met the proposal with scorn, but what has happened? The labourers have gone to the towns, and have not only to be kept going somehow, but the town and suburban poor rates have mounted up till what with most exorbitant poor rates, highways rates, sanitary rates, and free education, a man has to pay precious dear for the privilege of residing in or near a British town. That is all right. There is a hidden law of Nature always working quietly to set right all great wrongs. There may be, there generally is, much suffering before right is done, but the end is inevitable.

What, we would ask, would anyone do with the people if they could get them back upon the land? A system of *petite culture*? No, thank you. The British workman of the future is not to be brought down to the level of a graveling French *paysan*; he would not submit to it. Again we say the matter long ago resolved itself into a question of supply and demand, and depend upon it it will remain so.

### WORK ON THE HOME FARM.

Glorious weather as we write, a brisk wind from the west, bright sunshine, and dust flying plentifully before the traffic on the public roads. Do not waste a day, do not waste an hour of the golden opportunity to clean and prepare the soil for winter corn or winter weather. It is our local market to-day, and sorry indeed we are to see the road alive with traffic. How heartily do we wish the worthy farmers could afford to keep at home, to stick to the land, and bide their time for a sale. No farmer having a small farm of say 100 to 200 acres ought to look on at the ploughing or any work, but he ought to play first fiddle in all of it: mind that. It is the looking-on so much that has brought ruin to so many farmers. One of the kindest-hearted, best-natured men we know, was a yeoman farmer of some 150 acres to whom the depression brought ruin, yet it never appeared to enter his head to hold a plough or do any regular labour which might tend to help him, and so he went under. The masters' eye and hand tell always, but now especially should they be upon the work early and late.

Next spring will come the usual complaint of arrears of work, of wet seed beds and so forth, simply because the fine weather for autumn tillage which we have now was not turned to account. Our readers can have no excuse, for they have had a weekly reminder lately, and we hope they have acted upon it.

Look closely to the live stock. The nights grow cold, October is here, soon we may have heavy rainfall, and all stock exposed to it will suffer more or less from exhaustion. Have the yards and hovels ready, with an ample store of plenty of dry litter, and let the stock have the full benefit of it. Have you got the young stock quite free from hoose? If not, pray do not suffer the poor animals to continue suffering from a disease which is so exhaustive, and for which the remedy is so simple and so sure. If our warning to keep in the calves has not had attention, see that this is done forthwith. Have your live stock thoroughly in hand, and let no disease or loss arise through any inattention on your part. Let prevention be your policy as regards every form of disease. Be very cautious about any new purchases, and keep them quite apart from other stock till they prove to be quite sound. If this were only done generally, we have no doubt at all about infectious diseases being stamped out. Carelessness and filth unfortunately still prevail, so does swine fever.

### METEOROLOGICAL OBSERVATIONS.

### REMARKS.

27th.—Bright till 11 A.M., cloudy at times after.

28th.—Bright and warm.

29th.—Generally bright and warm, but frequently cloudy after 4 P.M.

30th.—Bright fine day; cloudy evening; rain at night.

1st.—Dull and showery early; fine from 8.30 A.M. to 2.30 P.M., then continuous heavy rain till 8 P.M., and fair after.

2nd.—Brilliant and fresh.

3rd.—Clear and cool.

moderately fine week. Temperature slightly above the average.—G. J. SYMONS.

## ROSE ANALYSIS, 1886-90.

YEAR by year the different varieties tabulated in these analyses are gradually settling down into their relative true positions. The present lists are based upon data obtained from the last six leading Exhibitions of the National Rose Society. Another forward season like those of 1889 and 1890, was however this year wanted to keep the balance true between the early and late varieties; instead of which we rosarians had unfortunately to contend against one of the most backward summers of the series, and to make matters worse the date on which the Society's Metropolitan Exhibition was held happened to be rather earlier than usual. A backward season does not so much unduly favour the earlier kinds of Roses as place at a disadvantage those which come into flower somewhat late in the summer. For instance, A. K. Williams and Sénateur Vaisse, taking into consideration the total number of H.P.'s tabulated each year, were this year shown only about an average number of times, while a still earlier variety than either, Lady Mary Fitzwilliam, was not nearly so frequently staged as at the two previous shows when the seasons were so much more forward; whereas some of the later flowering kinds, like Ulrich Brunner, Merveille de Lyon, and Louis Van Houtte, have never since 1886 been so poorly represented.

For the purpose of this analysis the names of over 11,000 Rose blooms have been tabulated in all—the number of Hybrid Perpetuals and of Teas and Noisettes in each year being as follows:—

	1886	1887	1888	1889	1890	1891
Hybrid Perpetuals ...	1038	1130	1247	1176	1396	1184
Teas and Noisettes ...	509	642	854	778	631	662
	1547	1772	2101	1954	2027	1846

The above figures do not indicate, as in the case of the Dahlia and Chrysanthemum analyses, the actual extent of the different shows, but simply the number of names that have been taken down each year from the different prize stands.

The Hybrid Perpetuals which were exceptionally well shown at the Crystal Palace this year were Madame G. Luizet, La France, Charles Lefebvre, Duke of Edinburgh, Comtesse d'Oxford, Prince Arthur, Marquise de Castellane, Dr. Andry, E. Y. Teas, and Ferdinand de Lesseps. Among those scantily represented, considering the positions they occupy on the list, may be mentioned: Marie Baumann, Ulrich Brunner, François Michelin, Merveille de Lyon, Her Majesty, Louis Van Houtte, Marie Rady, Baroness Rothschild, and Camille Bernardin.

If the present analysis be compared with that of 1886 it will be found that the following Roses have already disappeared entirely from the list—viz., Madame Laeharme (at one time considered such a great acquisition as a white H.P.), Annie Laxton, Annie Wood, Edouard Morren, Lord Macaulay, Penelope Mayo, Boildieu, John Stuart Mill, Souvenir de la Malmaison (B), Mrs. Jowitt, and Nardy Frères. In the place of these varieties we find on this year's list such valuable acquisitions as Mrs. John Laing (No. 3), Her Majesty (No. 11), Earl of Dufferin (No. 38), Viscountess Folkestone (No. 40), and Victor Hugo (No. 44); and of the established varieties quite low down on the list Duchesse de Morny, Auguste Rigotard, and Comtesse de Serenye. Of the fifty-seven Hybrid Perpetuals which both lists contain in common there

are only three, and those light coloured varieties, which show any decided signs of declining in favour as exhibition Roses, and these are Marie Cointet, Marguerite de St. Amand, and Comtesse de Serenye.

It almost invariably takes five years after its first introduction before a new Rose can be placed in this analysis on anything like the same footing as the established varieties. In other words, until this period has elapsed it is seldom that a sufficient number of plants of any new kind are grown by exhibitors generally to allow of its being adequately represented at "the National." In the accompanying tables therefore, as in former years, the positions of all the newer sorts depend upon their averages for five, four, three, or two years, as the case may be, still newer sorts being placed according to the number of times they were staged at this year's Exhibition only.

Of the newer H.P.'s mentioned in last year's analysis, Viscountess Folkestone, sent out in 1886, has improved slightly this year on its previous position. Although one of the most charming of all "garden" Roses it will, I fear, never take a high position as an exhibition variety, owing to the looseness of its petals and their frequent roughness at the edges. Mrs. John Laing, although first introduced only four years ago, now occupies the third place on the list. Last year it was only second to the leading flower—Madame G. Luizet. This loss of one place is, however, not due to this variety being less frequently shown in 1891 than in 1890, but rather to the fact of La France, which was more numerous staged than any other Rose in the Exhibition, being in such superlatively good form, and thus supplanting it. Earl of Dufferin, distributed in the same year as Mrs. J. Laing, has fallen from No. 24 to No. 38; but in so backward a season this late-flowering kind had scarcely a fair chance of showing what its capabilities might be under average conditions. Lady Helen Stewart, another 1887 Rose, which appeared at the end of last year's analysis, does not find any place in this one. Sir Rowland Hill is also absent from the present analysis. Although there are now no fewer than sixty-six Roses in the table of Hybrid Perpetuals, there is not among them a single variety of foreign introduction with a later date against it than 1884—Victor Hugo, at No. 44.

Catherine Mermet still heads the list of Teas and Noisettes, and at the present time holds the premier position without any serious rival, although this year staged but an average number of times. Innocente Pirola, on the other hand, only just manages to retain the second place in the analysis with great difficulty, never before having been so seldom shown. Souvenir d'Elise, Madame Cusin, Souvenir de P. Neyron, and Madame Margottin were also less frequently staged than at any of the preceding five Exhibitions. Maréchal Niel and Madame Lambard were also poorly represented; indeed, the only Teas which appeared in unusual strength were the Hon. Edith Gifford, Madame Bravy, Princess of Wales, and Devoniansis.

Referring back to the 1886 analysis as we have previously done with the Hybrid Perpetuals we no longer find on our present list Belle Lyonnaise, Madame Wellehe, Jean Pernet, Perle des Jardins (how much a really good and dependable yellow Tea Rose is still wanted!), and David Pradel. Their places are, however, taken by such choice new comers as The Bride (No. 5), Souvenir de S. A. Prince (No. 21), Madame Hoste (No. 27), Cleopatra (No. 31), and one established variety Madame A. Jacquier (No. 32), the first three of which at all events are far superior to any of the varieties they have superseded. Next year we shall, I hope, be able to add to these Ernest Metz, an extremely promising new Tea. The only varieties on this year's analysis which show any marked signs of decline as exhibition Roses are Madame Willermoz, Souvenir de P. Neyron, Madame H. Jamain, and Madame Margottin.

We have four new Tea Roses on the list. The Bride sent out in 1885, which, although still at No. 5, is destined, I think,

to take even a still higher place as years go on. 1887 is represented by Madame Hoste. This variety has also not improved upon its last year's position. Souvenir de S. A. Prince, distributed in 1889, has, however, risen from No. 25 to No. 21, and will no doubt sooner or later take a more prominent place in the analysis. The fourth, Cleopatra, an 1889 Rose, secures a place at No. 31. At present

there are only four Teas on the whole list which were raised in the British Isles—Souvenir de S. A. Prince, Princess of Wales, Devoniensis, and Cleopatra.

My best thanks are due to those rosarians who by their kind assistance in taking down the names of the Roses at the Show have rendered this analysis possible.

## HYBRID PERPETUALS.

### NITRATE OF SODA FOR CELERY AND CUCUMBERS.

A FEW years ago I called attention in the Journal to the great value of this much-abused substance for applying to plants in pots which from various causes had become unhealthy, also as a medium for inducing quick growth at times when it is desirable to do so, and to enable plants generally to derive the greatest possible amount of benefit from the soil in which they are growing. I have now to chronicle an instance in which nitrate of soda has been used with marked effect and highly satisfactory results upon Celery and Cucumbers. I do this because I am convinced that if this stimulant is used intelligently it is capable of producing a larger yield from a given space than can be obtained by the exclusive use of manures less rich in nitrogenous salts, because nitrogen is the regulating force which enables plant life to bring into active use the amount of potash and phosphoric acid they are capable of taking up. But when, by their abundant crops, they have in a proportionate degree exhausted the fertility of the soil, it would be unreasonable to assume that nitrate of soda exhausts the soil. The right lines to proceed on are to give abundance of potash and phosphates annually to keep up the fertility of the soil, and apply nitrate of soda at intervals to stimulate to the fullest degree of vigorous growth.

On the invitation of Mr. J. Marsh of the Priory Nursery, Warwick, I lately called there to see a house of Cucumbers (from which the fine fruits he staged at the Show held in the Castle grounds in July were cut). Before reaching the Cucumber house I was taken to a large breadth of Celery, upon which nitrate of soda had been used to test its power of producing what is wanted with this crop—viz, quick and vigorous growth—and in order that the test should be a real one several of the rows were dressed only half their length. It was easy to tell to an inch how far the nitrate had been given. Up to that point the plants were strong and vigorous, and of a deep green colour, while in the remaining portion of the row the colour of the leaves was distinctly paler, and the growth made much weaker. Now as this Celery was planted out late it will make all the difference between securing good sized "heads" before sharp frosts appear, or of being content with only moderate sized ones. This is well worth the attention of both gardeners and market growers. The Cucumber house above referred to is an old lean-to structure about 50 feet in length, which has recently been reglazed with large squares, thus securing plenty of light for the plants underneath. On entering this house a wonderful crop of fine fruits were seen. Long straight fruits of Telegraph were hanging from the roof from one end to the other, many of which were of great length and well proportioned—in fact, though Telegraph is not considered a large variety, under the

conditions in which it is grown here it proves too large for market purposes, and Mr. Marsh is on the look out for a variety as prolific, but which produces shorter fruits.

The plants are growing in a border such as we usually find in Cucumber houses, being about 4 feet wide. They are planted on a ridge which slopes sharply the front of the house to the opposite side of the bed. The soil is mulched with short well decayed manure, and at intervals of two or three weeks nitrate of soda is thinly scattered around the outside of the bed, no portion of it being placed nearer than a foot to the stem of the plants. Wherever the nitrate has been given the roots soon find it out, and quickly cover the soil upon which it has been dissolved with a network of white roots; and the heavy crop these plants have been bearing during the last three months show at present no sign of weakness. But little stopping is done, the shoots rambling about at will, so long as they do not become unduly crowded, then the oldest are cut out. Many of the old gardening friends of Mr. J. Marsh, who lived with him at Trentham and Shrubland will doubtless be glad to know that although he is a flourishing hotel-keeper in Warwick, his old love of gardening is as strong as ever, and as life to him seems incomplete without a portion of his time being spent in horticultural pursuits, he has taken the old Priory Nursery, where he intends to make a speciality of growing Cucumbers, Tomatoes, Mushrooms, and Strawberries for market.—H. DUNKIN.

[Our correspondent sent us three remarkably fine Cucumbers, such as could only be produced by well fed plants.]

### HARDY FLOWER NOTES.

If in summer Jupiter Pluvius regarded us with disdain and refused the favours we so urgently desired we cannot now complain of such conduct. Between wind and rain our autumnal flowers are having a sorrowful time. Drenched and battered, and with stakes loosened in the light soil by the furious gales, the taller plants have, in many cases, yielded to the fates, and assumed a humility foreign to their stature and dignity. While Sunflowers and Asters thus bow their heads dwarfer plants fare but little better. Some are bespattered and disfigured with spots of earth or of dampness, and others, such as the Colchicums and autumnal flowering Crocuses, in addition to this find their stems all too tender to withstand the storms and fall over to the ground. Thus with signs of sadness and destruction does the waning year bring warnings of the time when over all shall fall the power of the frost spirit, of which Whittier speaks in his graphic words:—

"He comes—he comes—the frost spirit comes!  
You may trace his footsteps now  
On the naked woods, and the blasted fields,  
And the broad hill's withered brow.  
He has smitten the leaves of the grey old trees,  
Where their pleasant green came forth,  
And the winds which follow where'er he goes,  
Have shaken them down to earth."

Still, while they are with us let us enjoy the beauty of the flowers which linger in our gardens to cheer us and to narrow the gulf between summer and the opening of the flowers of early spring. Here in a cosy little nook *Crocus zonatus* has pushed its blossoms through a carpet of Saxifrage, which helps to support its flowers, and where it looks like some pale fairy beauty which some untoward fate has forced to face the storms and trials of earth, and which is fain to cling to something less fragile than herself. An exquisite little flower it is with its zone of orange and pale purple cup; pale, as if, as is the case, the sun shone but little upon it to give some depth to its colour. In another spot the deeper coloured blooms of the fine *C. speciosus* still linger on, attracting attention and admiration by the exquisite pencilling of their petals. Others are coming on slowly but surely, and one can but wonder that they are so seldom met with. Chastely beautiful, too, is the tiny *Leucojum grandiflorum*, which, with its tiny Snowdrop-like white bells, seems to claim for itself that adjective which to the Scottish mind is so expressive "bonnie;" no other word can so fitly characterise its charms. Unfortunately I cannot as yet speak with confidence as to the hardiness of this Snowflake here. Should I be successful in retaining it, then a few plants will not be the limit of my growth of this little beauty. *L. grandiflorum* grows only a few inches in height, the leaves appearing after the flowers, which are produced on reddish stems, are shaped somewhat like those of *L. vernum*, but much smaller, and shine inside with a beautiful pearl-like lustre which no Snowdrop can approach.

Colchicums, too, in many shades of purple or lilac or white adorn the borders. The splendid *C. speciosum rubrum*, which I mentioned a short time ago, finds no unworthy rivals in *C. veratri-*

*folium*, *C. latifolium* (Sibthorpi of Baker), and *C. autumnale album fl.-pl.* It is a hard task to select one from the quartet and to say this is the best. So we must e'en admire them all, and fortunately we can do so without reproach, nay, even room is left for others with beauty all their own. *C. Sibthorpi* or *latifolium* is now being brought to the front, and it has much to recommend it. The fine form of its petals, its finely chequered flowers, and its tall stature being all in its favour, with the exception, perhaps, of the latter point, which is a doubtful one in a season such as this. We do not often meet with the true *C. veratrifolium*, the *Vera-trum-leaved Meadow Saffron*, for which *C. byzantinum* is sometimes substituted. It is taller, of more substance, and much deeper in colour than *byzantinum*, and the stems are of a fine deep purple. It is quite distinct in foliage, and the specific name is extremely appropriate from the *Veratrum*-like massive leaves. It is a pity, too, that the double white form of *C. autumnale* remains so scarce and high in price. It is of a fine ivory white, of good substance, and lasts much longer in flower than the single variety. Many a time I linger over this flower and admire it in one of the borders of my garden.

I have lately flowered for the first time young plants of the new hybrid *Scabious*, named *Scabiosa hybrida Victorise*. It is said to be a hybrid between *S. atropurpurea* and *S. columbaria*, and to be quite perennial in its nature. I have not yet proved its hardiness or its perennial habit; but should it prove satisfactory in these points, this variety of the "Mourning Bride" should be of great value in the garden. The flowers are considerably smaller than those of *S. caucasica* and vary in shade of colour, some being white, some purplish, some pink, and some deep crimson brown. The foliage is finely cut, and the plants, which are about a foot in height, with me are of neat habit. It is, I believe, of Italian origin, having been introduced to this country by Mr. W. Thompson of Ipswich. The better known *S. caucasica* is doing very well this autumn, and with fine weather would last a long time in flower. The fine lilac coloured flowers are very pleasing, and having long stems are well adapted for cutting. There are two varieties, the one known as *S. caucasica amoena*, being of better colour than the other, which is known as *S. caucasica connata*, from the stem leaves being connate. This *Scabious* is of easy culture in any soil, and blooms for a long stretch at a time.

Specially beautiful just now is that grand plant *Rudbeckia speciosa*, or, as it is frequently called, *R. Newmanni*, although I believe the former is the correct name. The plant is so compact in habit, growing here about 18 inches in height, and so sturdy that it requires little support, and when a good sized plant is closely covered with its bright orange flowers with their black cone-like centres there are few who cannot admire the beauty of the "Showy Cone Flower." I have this year grown plants raised from seed of one named *R. grandiflora*. It is said to be a perennial, but I know nothing of its origin. It is, however, far inferior to *R. speciosa*, and is scarcely worthy of its specific name. The flowers are considerably smaller than those of *R. speciosa*, the petals much narrower and of a duller yellow, and the central cone flatter and more brownish in colour. The leaves are rough, and are oval in shape. I have considerable doubt as to the correctness of the name, but the plant is distinct from any I have seen in gardens or figured or described in various works. The seed was procured from a firm of considerable repute.

The early flowering *Chrysanthemums* are, as usual, of immense value at the present time, and fine as many of these are Madame *C. Desgranges* has as yet no superior for garden effect. Treated as a hardy herbaceous plant it does quite well in my light soil, and the very poverty of the soil while dwarfing the plants and keeping the flowers of smaller size makes this *Chrysanthemum* of greater value in a season such as this. I have clumps which have stood unprotected in the open garden for five years or so, and at the present time the shade of colour afforded by these is very acceptable. Pleasing, too, is the primrose yellow of *G. Wermig*, but after a trial I am forced to agree with the verdict that Mrs. Hawkins is destined to eclipse the earlier introduction and to form a better contrast to Madame *C. Desgranges*. Very pretty and very useful for cutting is the orange coloured *Piercy's Seedling*, and equally useful but not so sturdy in its flower stalks is the bronze *M. W. Piercy*. I have this year grown the dwarf *Nanum Tolosanum* and *Nain Perpetual*. The former seems the brighter in colour, while the latter seems to remain longer in flower. Both varieties are acquisitions for a positions near the front of the flower border, their small pink flowers being very pretty. *Flora* or *Late Flora*, as it is also called, still remains one of the brightest, longest flowering, and most useful of the smaller yellow early flowering varieties.

*Chrysanthemum* or *Pyrethrum uliginosum* has just begun to open its great yellow-eyed white flowers, and should the storms and frost spare it a little longer will soon have the upper part of

its tall stems wreathed in bloom. Stately in growth, hardy as anything in the garden, and beautiful in habit, yet its late flowering nature makes it a source of anxiety at this season. It should undoubtedly have a warm position well sheltered from a north wind. Planted in good soil and thus favoured few of our late flowers will claim more admiration or be more worthy of a little care. Then Asters are now making what is popularly called a "grand show," but methinks those of us who admire the best of these flowers will agree in repudiating the fitness of such an expression when applied to flowers which are among the most harmonious in colour of our tall autumn flowers. Bright as are many of them with shades of purple, of white, of pink, and of lilac, they can never make "a grand show." Theirs is no glaring contrast to the dying leaf, the shortening day, the gloomy weather, but a harmony of colour in which no Sunflower can share, and which seems to appeal to us in our melancholy moods as we think of the changing, shortening days, and to whisper the message of good cheer just as the smile or the glance of the eye of those around us tell without words of their affection. Nor do these flowers pall upon us. From the time when such species as *A. linariifolius* smother themselves with flower till the beautiful *A. grandiflorus* opens a few flowers, only to be destroyed by the sharp frost, there is a constant succession, and if well selected a small collection will cease not for months to interest and delight. Gladioli are still well in flower, and I for one have reason to be satisfied with their contribution to the decoration of the garden this year. From about the 4th of August I have never been without them, and few flowers are more beautiful in the garden, although looking out as I write I see still much in flower, still many things to make us forget that we are now at the 8th of October, and that while the flowers thus bloom we should not forget the flight of time, too surely revealed by the tokens of which William Allingham speaks in his "Autumnal Sonnet."

"Now Autumn's fire burns slowly along the woods,  
And day by day the dead leaves fall and melt,  
And night by night the monitory blast  
Wails in the key-hole, telling how it pass'd  
O'er empty fields, or upland solitudes,  
Or grim wide wave. \* \* \* \* \*

—S. ARNOTT.

### FRUIT CULTURE IN A TOWN GARDEN.

LAST autumn I referred to Mr. F. W. Mole's garden at Edgbaston, Birmingham, as an example of what can be done in the successful cultivation of Pears, especially in the immediate neighbourhood of manufacturing towns. This garden is not a large one, and is walled in on the north, east, and south sides, and the dwelling house is at the west end of the garden, and in a shady and somewhat sheltered corner, but facing the east. A tree of Doyenné du Comice is bearing a good crop of fine, well coloured fruit. Mr. Mole has for many years made a study of the cultivation of outdoor fruits, and adopts the cordon system of training chiefly, with five leads to a tree in most cases. Very frequent syringings are resorted to and summer pruning is the rule, removing young growth as early as June, and continuing to do so. He also thins out the bunches of blossoms, cutting out a large proportion, leaving sufficient to ensure a fair crop of good sized fruits, the fruit also undergoing a thinning process whilst setting. The trees now are in thorough health, frequent syringings having kept them clean from insects, and with fruit of good size (for the season) and quality, and produced from the ground upwards. Moisture is supplied freely at the roots, and if there should be a tendency on the part of a tree to make too much growth judicious root-pruning is resorted to. Several varieties of Pears which have in the south borne high characters have been tried here and some of them discarded after a few years' trial as being unsuited to the district. Sorts which do well here, and are again this year well cropped, are Souvenir du Congrès; Fondante d'Automne, a rather shy cropper; Doyenné du Comice, always fine; Pitmaston Duchess, very fine, one moderate sized horizontally trained tree with fifty fruits upon it; Bon Chrétien Panaché, the striped Bon Chrétien, Durondeau, Williams' Bon Chrétien, Jargonelle, Marie Louise, and Beurré Diel, one tree of which, 8 feet high and 12 feet in length, has 100 fine fruits upon it, having been well thinned to secure large specimens. All the Pear trees are against walls, as the pyramidal trees are little good here.

A few Apples are successfully grown, notably as pyramids, Cellini and Ecklinville. Against a wall there is a fine crop of the Melon Apple, Margil, and Worcester Pearmain, and a few fruits on the American Mother Apple, which is a shy cropper. The Apple trees are also closely summer pruned, are full of fruiting spurs and in excellent health. Mr. Mole's experience of

fruit growing is conclusive that in the suburban gardens of large manufacturing towns Pears and Apples can be successfully grown, provided always that proper sorts are selected and due attention is paid to their culture.—W. D.

### TULIPS.

THE Tulip is one of the most useful bulbous plants that we possess, for it can be had in bloom over a period of six months. For early flowering the scarlet Duc Van Thol must be placed in the foremost position; the white, yellow, and red-and-yellow forms of Duc Van Thol are not worth growing. After the season has slightly advanced Vermillion Brilliant should supplant the scarlet Duc Van Thol. It has a larger flower with considerably more substance; in fact, it is one of the most handsome single Tulips that can be grown. White Pottebakker is the best white Tulip for early forcing; in fact, it is questionable if it is surpassed by any other white, as it is only a few days later than the scarlet Duc Van Thol. The flowers are sweet-scented, and are admirably adapted for wreaths, crosses, and bouquets. For such purposes its pointed flowers, when young, resemble in a very marked degree the buds of that popular Rose, Niphetos. Canary Bird and Chrysolora are the two earliest yellows, and I have never been able to give a definite preference to the one or the other. Some seasons I have had to decide in favour of the former, and at others in favour of the latter.

For early forcing these are best placed thickly together in pans and boxes. One of the secrets of success lies in having the bulbs in boxes as early as possible, and plunged under ashes in the usual way. They should be thoroughly rooted before they are removed from the plunging material; they can then be gradually exposed to light, and by the time the growth is green they can have a temperature of 50° where the atmosphere is moist. They will soon show signs of movement, and when this is visible they may be plunged in brisk bottom heat in the propagating frame, for they will bear without injury more forcing than Dutch Hyacinths. As soon as the colour of the flower is visible they can be lifted out and placed into pots or small pans, according to requirements. Early in the season Tulips flower very irregularly, and it is next to impossible to have even pots or small pans really satisfactory by placing the bulbs in the pots in which they are to flower. If the plants are gradually hardened before removal to rooms or the conservatory they will last, if the soil is kept moist, equally as long as if the plants had been established in their pots instead of being divested of large quantities of roots, as must be the case when planted thickly in boxes and subjected to lifting.

For late flowering La Candeur and Rex Rubrorum are invaluable. Both are double. The first is white and the last bright red, a large showy flower. These, if placed in pots or boxes early in November, and covered with ashes in a north aspect, or potted, will yield flowers at the end of May, when they will be found exceedingly useful for cutting by those who have large quantities of flowers to supply at that season of the year. They travel well, and last a long time after they are cut.—WM. BARDNEY.

### SOME POTATOES.

IN a season when in many gardens disease has played havoc with the Potato crop, I am glad to say we have fared very well. Thanks for that is, I believe, almost solely due to the varieties cultivated. Flavour and good cooking qualities are with us so much a desideratum that I have been very slow to supplant well-flavoured varieties possessed of constitutions unable to resist disease by others less liable to disease, but lacking the very important qualification of good flavour. As I have worked cautiously into a stock of the Potatoes undernoted, having learned by years of experience the exceeding uncertainty of new varieties, I think the results I have obtained may pretty safely be relied upon as being generally applicable.

For a good early—very early—Puritan has steadily made way with me. When well sprung before planting, it may be planted as late as the end of March or the beginning of April—I refer to a northern county—and be ready to lift a good crop of floury-boiling tubers in ten weeks thereafter. It is altogether ahead of Early Rose, Beauty of Hebron, and the others of this class. Duke of Albany I have tried against Puritan, but the former is decidedly inferior in flavour. A Potato of even better flavour, coming in along with Myatt's Kidney, is Sutton's Early Regent. This variety is so early as to be quite out of the way before disease sets in. The flavour is of the Nutty "Regent" stamp, and it is altogether recommendable. I still grow a large quantity of Snowdrop, but two more of the Reading breed—Matchless and Nonesuch—bid fair to occupy the place of the above. Then for an early

autumn sort, Satisfaction has done great service for the past year or two.

At the present time one of the best Potatoes for either field or garden culture is one which has brought much honour to its raiser, Mr. Finlay of Marckinch—namely, The Bruce. It is not generally known that this very fine Potato is of capital flavour in autumn; but so it is. We have been using it for some weeks past, and, as in past years, so in this, it proves exceptionally good. Mr. Finlay was, during the past summer, presented with a testimonial by northern agriculturists and others as a recognition of the value placed upon his services to the county at large, and to farmers in particular, by means of his seedling Potatoes, The Bruce being one of the finest. A few years ago I drew attention in the Journal to this fine late variety, but it does not as yet seem to be much known in the south.

It is perhaps too early as yet to draw attention to the desirability of getting in a stock of seed Potatoes at an early period of the new year, but no measure in Potato culture pays better. The grower who secures a supply of new seed before sprouting takes place, and who takes the little trouble of starting the tubers slowly, will find himself amply repaid in the quantity and quality of the crop. Some cultivators do not find it necessary to introduce new blood; but where it does not pay to do so the exception to a rule is to be found there. I have heard the statement occasionally made that seed for a light soil ought to be secured from heavy land and for heavy land of a light soil, but I do not know that that is a statement to be absolutely relied upon. For my own part, having a light soil to deal with, I have had splendid crops from seed grown on sandy soil.—B.

### GLADIOLI.

I AM much obliged to your correspondent "J. A. W." for his kindly words of sympathy. Well, there is no use in saying that it was not a bitter disappointment, not being able to even put in an appearance at the Crystal Palace, for I was hindered by sickness at home from going up even to see my "pupil's" stand; "but there are worse troubles than that at sea," and I must only hope that another year I may be more fortunate.

The period at which the different varieties of Gladioli come into flower is a very puzzling matter, and I believe it to be entirely independent of the period at which they are planted. That were I, for example, not to plant Shakespeare until early in May I should still have it in bloom by the end of July; but it is still more puzzling that the same varieties should differ in different localities. Messrs. Vilmorin, Andrieux, and Co. gave in their catalogue of Gladioli indications of this by marking them with the letters A, B, C, and D, and while these in general agree with my own observations there are notable exceptions. Thus Horace Vernet, which your correspondent finds, as I do, to be amongst the earliest flowers, is marked with D, signifying that it is amongst the latest. I cannot suppose that they are incorrect, and can only surmise that the difference arises from some climatic cause. Baroness Burdett Coutts, which your correspondent is surprised that I should number amongst the early flowering ones, is marked in their catalogue B, and with me that is its true position, and I have always found it come in for early shows. There are a few others which may be generally relied on for this purpose. Bicolore, a very distinct and striking flower by reason of the deep contrast the large white blotch creates, is always a dependable bloom for early work; the same may be said of Dr. Bailly, a grand bright flower; and also Magnificus Formosus, another of the new varieties, is a very lovely light-coloured bloom with a beautifully close set spike, and is amongst the earliest bloomers. It must also be noted that occasionally some single bulb of these early flowering sorts will, for some reason or other, not flower so soon, and I have cut even Shakespeare at the end of the season; but these are amongst the exceptions which prove the rule. While writing these lines I have received a note from an unknown correspondent in Brechin, who seems to be a very ardent and intelligent cultivator of the flower, and he mentions a fact in his letter which explains a matter which has sometimes puzzled me—how in those northern latitudes they managed to get their flowers in about the same time that we do in the south. He tells me that he pots all his corms, and is enabled to have them in bloom from the beginning of July. That is not, of course, necessary with us, for as a rule the difficulty is to keep them for the later shows. It has not been so this year; but one swallow does not make a summer, so because we have had one late season it is not to be expected that all seasons are to be late, yet in the matter of Rose shows some seem to be already acting on this supposition, and wish to have dates altered to suit what they suppose will be the normal character of our seasons. I believe, however, that we might take a hint from this with regard to our late-blooming kinds. If they were potted up it would probably hurry them on, so as to get them in flower earlier. Such varieties as Fantôme, Phœbus, and Kelway's Duchess of Edinburgh might be profitably treated in this way. My correspondent is another of those who (*pace* Mr. Kelway) halve their corms, while Mr. Lindsell tells me that he has made careful experiments with half and whole corms, and that unquestionably those treated in the former way gave the better results.

Your correspondent asks me whether I should advise his cutting

away the spikes when they are not showing colour. I should say so most decidedly, just as for the same reason I should cut them away from any spawn. The corm has its attention, so to speak, divided between increasing the new corm and furnishing supplies to the flowering stem, and therefore I think that if the stem be cut away, leaving the foliage as much as possible, that the whole energies of the plant being then given to the increase of the corm, must act very materially to its advantage, and when spikes are so late they rarely can give any satisfaction, even for the purposes of decoration. I cut a number yesterday to send on to a nursery sale, and although to the uninitiated they looked handsome enough they did not satisfy me very well. The flowers become somewhat limp at this season, and lose their freshness very soon.

The work of harvesting the corms will soon begin. Where seedlings or spawn are grown they may be lifted first and laid out in a cool greenhouse or other convenient place to dry off, the larger corms being left until later on. We want some dry weather to mature them, the constant moisture having kept them in a growing state for a long time.—D., Deal.

### CALDERSTONES.

WITHIN easy distance from Liverpool is Calderstones, the residence of Mrs. C. MacIver, one of those establishments, of which there are many in the district, where gardening is carried out in the best possible style in every department. It is under the charge of Mr. W. Tunnington, known to outsiders more especially in connection with the Chrysanthemum, for he it was who undoubtedly gave such an impetus to the higher cultivation. There is no formality about the Calderstones. Hollies, Pines, Rhododendrons, &c., grow luxuriantly. Pleasant nooks abound, and the view from the lawn is excellent, there being some fine specimen Yews. Planting has been done liberally and judiciously, and the effect is most pleasing. The houses, if not of the modern type themselves, contain most of the plants up to date. In the Peach houses the fruit had all been of capital quality, the wood was ripening well, and full of good stout buds, disposed over the trellis at about 5 or 6 inches apart, showed the practice which ought to be oftener followed. The vineries were next inspected. One occupied with very old Vines is to be cleared and young ones substituted. Two others, with some good young canes, carried fine bunches of Lady Downe's, Muscat of Alexandria, and Alicante. In these were some excellent plants of Dendrobiums resting, especially fine being *D. Dalhousieanum* and *D. moschatum*. Passing on we come to the plant house, which contains some fine Azaleas, the front stage being occupied by an excellent strain of *Celosia pyramidalis* of a very deep colour, and the roof was covered by two fine well flowered plants of *Lapageria rosea*.

We follow to a range of span-roofed plant houses and stoves. The first was filled with well-grown plants of Pelargoniums, Primulas, Cinerarias, Tuberous Begonias, Cyclamens, and many others. A stove in two divisions was well stocked with dwarf Poinsettias, winter flowering Begonias in many types, and other plants, which will make a grand display later on. A portion of the roof was occupied by a very prolific Cucumber, the space underneath being filled with Maidenhair Ferns in small pots. Another stove had trained on the roof immediately over the pathway a grand plant of *Allamanda Schottii*, running the whole length of the house, and what a useful variety it is. I could not help comparing it with *Hendersoni*, which, however beautiful to look at, is not nearly so useful for cutting, as it does not possess a stiff habit. On the corresponding side is a fine old *Bougainvillea* trained to a single stem and full of bloom. If not the first, it is nearly the first introduced into Lancashire. At one end was a fine plant of *Aristolochia grandiflora* with a great number of flowers. The centre bed is filled with a capital assortment of plants incidental to such structures, whilst the side stages are devoted to healthy Orchids of the most approved varieties. The last house in this range is the Pine stove, but a portion of it is set apart for *Eucharis* and *Calanthes*, the back part of the roof being covered with two good plants of *Stephanotis*. The *Eucharis* must be seen to be appreciated. About 100 large specimens all in rude health are here grown, and the *Eucharis* mite is absent. On this subject Mr. Tunnington says they would never be heard of if the plants received kindly treatment. The *Calanthes* have pseudo-bulbs 15 and 18 inches long and stout in proportion, and all pushing massive spikes. I never remember seeing such a grand example. Large numbers of Pines are grown, and many carrying fine fruit. The conservatory was very gay for the season with a miscellaneous collection of flowering plants, and I must mention a fine plant of *Plumbago capensis* and *Lapagerias* on the roof which were flowering well.

Outside beds are filled with Scabious, Pyrethrums, Carnations, white and rose *Anemone japonica*. Dahlias, beautiful being Mrs. Langtry, Walter Williams, Mrs. Gladstone, Mrs. Kendal, Mr. Milner, Eccentric, and many others, besides a host of other outdoor flowers in profusion, occupy places in the garden for cutting purposes. The fruit trees have a capital crop, more especially Pears, the cordons being remarkably fine. I was beginning to fear it was nearly an impossibility to cultivate Peaches here out of doors; but Mr. Tunnington believes otherwise, and he is right, judging from the well-coloured samples of Barrington still on the trees; in fact, all the trees had borne well, and this in a most unfavourable situation. Doubtless your readers will wonder why I have not touched on the Chrysanthemums. This is reserved for the present. But I cannot omit the following:—Two fine plants of a seedling Chrysanthemum, carrying enormous buds, seemed

to stand out more prominently than the rest. I was informed they were sent down for trial by Mr. Owen. Should they turn out well we shall, ere long, see a variety bearing the name W. Tunnington, a name which ought to have been honoured long ago.—R. P. R.

**DENDROBIUM PHALÆNOPSIS VAR. SCHRÖDERIANUM** — "THE ELEPHANT MOTH ORCHID;" OR, "THE KING OF THE DENDROBIUMS."

MUCH curiosity has been aroused concerning this *Dendrobium*, of which a large sale is announced to take place at Messrs. Protheroe & Morris's rooms in Cheapside to-morrow (Friday). The type has been supposed to be very scarce, and comparatively few plants are in cultivation, and, beautiful as these are, they are certainly surpassed in size, colouring, and variation by that which has been named in compliment to Baron Schröder. Of these, Messrs. Sander & Co., St. Albans, have succeeded, after many difficulties, in importing a quantity of plants which will make their appearance in Cheapside on the day mentioned above. It seems that about eighteen months ago a collector reached a small port in New Guinea with 400 plants; but the ship took fire, and everything was lost except the crew and passengers. Another troublesome journey became necessary, and as the result of this plants have at last been secured in good condition.

The collector's letter relating to his journey is so interesting that it is well worthy of reproduction here.

"With great pleasure I announce to you the fact that I arrived here yesterday with my plants in the finest order, and you will get striking novelties at last from this terrible country, and you will have every reason to be satisfied. It was the best time to collect the *Dendrobe*; they had just finished growing, and some were in full bloom, and oh what a glorious thing it is! I forgot all my troubles when I saw the first on some rocks near the huts where I was staying, where they grew on the bare limestone between a great number of human skulls and bones. The natives do not bury their dead, but put them in a kind of coffin and then place them on these solitary rocks, which stand scattered about the shore or beach, and which can be reached or got at only at ebb tide. Here in these rocks the plants grew most luxuriantly, exposed to the full sun, and when the weather is rough they often get the spray of the sea water. At first the natives did not like the idea of collecting the plants off those rocks; they were afraid the departed, whose bones were bleaching in the sun, would resent it, but when they saw the gorgeous handkerchiefs, beads, looking glasses, and the brass wire I offered them for the plants they did not trouble themselves any more about their ancestors, but boldly went and rooted out every plant to be found. However, you need not be afraid, I shall send you no bones or skulls with them; the majority of the plants come from places where no bones or such like were found. The plants grew chiefly on these solitary much-honeycombed limestone rocks, always exposed to the sun, or getting only very little shade during a part of the day. It also grows on trees in the Ficus groves more inland, although very sparingly. I found the big specimens on the highest trees in the dense jungle, where it is very rare, and I only saw a few on the highest trees. I should think in cultivation it will require plenty of moisture while growing, and culture like *D. nobile*.

"In size and colouring it differs as much from the ordinary *D. Phalænopsis* as *Dendrobium Wardianum* does from *D. crassinode*; the largest flowers measured  $4\frac{1}{2}$  inches across, none measuring less than  $3\frac{1}{2}$  inches. I saw a few plants with branched spikes, but this seems only excess of strength; the spikes are generally from 20 to 35 inches long; on some I counted twenty-five flowers; the colour is very variable, ranging from pure white to dark purple-red, and some are differently coloured and variegated, but bright and clear. The flowers last a long time, individually eight weeks, and during my stay of three months I saw many flowers in April, May, and June; and a Dutch trader, one of our party who has been here twice, says that he has seen it in flower in July, August, and September. It is without doubt the finest *Dendrobe* in existence, and a gorgeous Orchid. I only hope I shall get safely back again, and that the plants will arrive in good condition.

"Your letter from the 8th of February I have received, but I see no possibility of getting the *Dendrobium* this year. It is not far from the place where the steamship was burnt; the Dutch traders are all away now, and I could not return with them before December. Going by

myself there would mean endangering my head very much, so I think it is better to wait till next year, when I can go with a trading expedition. The natives are not bad, only somewhat troublesome; they think no more of killing anybody than your cook does of killing a fowl, but they would not easily attack a Dutch trading party, knowing how well armed they are, especially when one takes a little care not to quarrel with them.

"One of their idols, the god with golden eyes, I had to place in a case to accompany the plants, and take care of them on the journey; the savages wanted this, and I did it to satisfy their superstition. They always carry these gods into their battles. I put all the plants in baskets I had made by the natives here, and when all were packed they gave a war dance in front of them. I wish my camera had not been lost in the shipwreck, and then I could have sent you photographs of the extraordinary *Dendrobium* and the savages." It may be added that the "Golden-eyed Idol" forms the first lot at the sale in question.

**ORCHID NOTES.**

**DENDROBIUMS.**—It is not uncommon for these to fail or begin gradually to decrease in vigour after they have been established for a few years. Newly imported plants that arrive in good condition invariably, under suitable treatment, make strong vigorous pseudo-bulbs. This is due mainly, if not wholly, to their thoroughly ripened condition and the complete season of rest they have enjoyed. Decrease in vigour mainly results from insufficiently ripening their growths and depriving them of that complete rest that is the secret of health and vigour. It is next to impossible to ripen these plants thoroughly or rest them sufficiently in the houses in which they make their growth; that is, when they are grown in mixed collections. The difficulty is greatly increased when shading of a permanent nature is employed instead of blinds that can be drawn up and down at will. Such species as *D. Wardianum*, if kept in a close confined atmosphere, no sooner finish lengthening their pseudo-bulbs than they start again into growth. Once this condition is brought about it is difficult to know exactly how to treat the plants. If the new growths issuing from the base are cared for, those previously made are imperfectly ripened in consequence. This is not all, for the result is a very poor supply of flowers. It is unfortunate, perhaps, that the growths that may start from the base at this season of the year never attain the same strength and size as the previously made ones have done. Growth

FIG. 66.—*DENDROBIUM PHALÆNOPSIS* VAR. *SCHRÖDERIANUM*.

made during the dull days of winter can scarcely be expected to be so strong as those that start in spring. Frequently when plants are allowed to make these second growths they gradually degenerate afterwards.

The treatment to aim at now is to gradually expose all plants to light and more air that have their growths in an advanced condition once they have ceased to lengthen and have commenced to ripen. This is the only means of preparing them properly for enjoying a complete season of rest, which is the secret of health and vigour.

**A WARNING.**—Beginners in the culture of Orchids or those taking charge of plants that may be in an unsatisfactory condition at their roots must be exceedingly careful in overhauling and

repotting them at this season of the year. It is always somewhat risky, even with plants in good health and at the proper season of the year, to shake away the whole of the material and supply fresh. Where Cattleyas, Lælias, and plants of a similar nature are unsatisfactory water with care, and attempt to ripen thoroughly the small but puny growths they may be making. This is the only reliable course, and then thoroughly renew the compost just before they start into growth during the early spring months.

**POTTING ODONTOGLOSSUMS.**—Where these have not been repotted it may safely be done at once. There can be no question that the autumn is the best time for repotting these plants. Annual repotting is also recommended. The plants are healthier and grow with greater vigour with perfectly fresh than when the material about their roots is decomposed. By potting at this season there is less risk of injury to their roots than is the case in spring. The plants are not long when potted at this season before they push out roots in abundance from the base of young growths.

**TEMPERATURE FOR ODONTOGLOSSUMS.**—No greater mistake can be made in the culture of these plants than to have a low night temperature during the winter months. Abundance of moisture should be maintained, and the temperature should not be allowed to fall below 45° in the morning. The average winter temperature should be 50°. If the plants are subjected to a low winter temperature they become stunted, and will take at least two years to recruit them again. It is surprising how quickly the plants go back with a low temperature, and how long they need careful treatment before they grow again with vigour.—ORCHID GROWER.

### MANURING.

ALL experience proves that profitable crops cannot be had from any soil over a series of years without judicious applications of manure. From the soil plants abstract the elements necessary for their health and productiveness; in fact, the soil supplies all the feeding constituents required by plants except carbon and nitrogen. But growing crops are continually abstracting lime, potash, phosphates, sulphates, and nitrogenous substances from the soil, and, as the crops (often the whole plants), are taken off the ground the soil slowly but surely loses its fertility, weakly plants taking the place of healthy and profitable, unless the substances removed in the crops are restored to the soil in the shape of manure.

The constituents of plants are derived from the air and the soil. They are classed as organic and inorganic. The organic constituents of plants comprise carbon, hydrogen, oxygen, nitrogen, sulphur, and phosphorus. Carbon, forming the woody substances of plants, is obtained from the atmosphere in the form of carbon dioxide,  $\text{CO}_2$ —that is, one atom of carbon connected with two atoms of oxygen. Oxygen and nitrogen are partly derived from the air, but these elements are taken mainly, and in the case of most plants wholly, from the soil. Certain plants, however, possess the power of assimilating atmospheric nitrogen, whilst other plants are incapable of extracting this valuable element from atmospheric air. Hydrogen, sulphur, and phosphorus are taken from the soil.

The inorganic constituents of plants consist of iron oxide, lime, magnesia, potash, silica, soda, phosphoric acid, sulphuric acid, and chlorine. All these are obtained from the soil. Plants require adequate supplies of organic and inorganic elements to render them healthy and fruitful. The organic substances essential to plant growth are carbonic, nitric, phosphoric, and sulphuric acids. Plants also require iron, lime, magnesia, potash, silica, and soda. Some plants require large quantities of certain elements and small proportions only of other substances. This does not imply that the minor constituents of plants need not be applied to the soil, or that they are non-essential for the healthy growth of plants and a full yield in their crops. Possibly all the inorganic elements may be present in the soil in excess of the crop's requirements, but they may exist to no useful purpose, because insoluble, and one of the objects of manuring is to apply such substances as will render the insoluble available as plant foods, instead of allowing them to lie uselessly in the soil. Cereals need liberal supplies of nitrogenous manures, but the application of nitrogen will only give a Wheat plant falling a prey to rust, unless silica in available form is present to strengthen its stem and harden its tissues to the extent of maintaining the plant erect and resisting attacks of fungus. In fact, it is a great mistake to rely exclusively on superphosphates (phosphoric acid) for cereals, or limit manuring to potash. True, M. Ville ignores the minor constituents of plants altogether, as, for instance, his special manure for Wheat, which consists of superphosphate, chloride (muriate) of potash, sulphate of ammonia, and gypsum. Indeed, M. Ville states that the only substances needed by any soil as manure are nitrogen, potash, lime, and phosphoric acid. This manifest reliance on the acid secretion of plants for dissolving the insoluble minor constituents of soils and thus rendering them available as plant food is unwarrantable, and proved erroneous by the system of manuring adopted in this country with the greatest success. This consists in supplying the minor constituents of plants to the soil in such form as will secure healthy crops and full yields of produce, or the manures applied are of such nature and contain elements which, acting on the minor constituents, converts them into soluble compounds.

Kainit, for instance, is admittedly applied to land as a manure for

Wheat on the sole principle of benefit through its potash, but kainit is a very different substance from M. Ville's potassium chloride, or other potash salt. Kainit contains about 24.43 per cent. of potassium sulphate, and it also contains salt (sodium chloride), and the chloride and sulphate of magnesia. Potash effects a better nutrition of cereals, and with nitrogenous manure counteracts the "burning" of superphosphates (phosphoric acid), but potash alone is relaxing, yet kainit, through its soda, sets silica free, and the chloride of magnesia acts on the insoluble, so that kainit not only affords better nutrition to the Wheat plant, but safeguards it against disease, and enables it to maintain itself erect under the weight of grain.

Messrs. Lawes and Gilbert apply the minor constituents under no cloak. Their mixture for Wheat not only comprises M. Ville's superphosphate, potash, and ammonia, but soda and magnesia; therefore direct benefit accrues from the application of some of the minor constituents, and others act indirectly on the insoluble minor ingredients, and by rendering them soluble they are taken into the plant during its period of growth, and thus properly nourished the crop produces a full yield.

Soils may contain a sufficient quantity of the minor constituents for any crop's ultimate requirements, yet not existing in the form of soluble compounds during the period of growth, or only in partial and inadequate quantities, the plant is ill nourished, oft diseased, and the crop does not produce a full yield. A soil may contain potash, lime, and phosphoric acid abundantly, yet be more or less barren, because a soil's fertility depends upon the presence within it of all the ash elements of plants available as food. It must be remembered that gaseous and liquid manures are alone absorbed by the rootlets of plants, and that solids are never admitted into the interior of any vegetable. It is absolutely essential that the nutrient elements of plants exist in the soil in soluble form, and that the constituents of soils occur in such a state of combination as give a constant and regular supply of nutrition. Many crops fail because the soil is not in a condition to support them, and this arises in gardens more often through lack of one essential ingredient than from a maximum of others.

A soil may contain a sufficient quantity of potash to yield ten full crops of Grapes, and of other elements needed by the Vine enough to support twenty crops, yet the excess of the latter will be unavailing, for the soil would be exhausted of its potash by the ten crops. By adding to such a soil a supply of potash it would again become capable of producing a full yield of Grapes, and would go on doing so until some other ingredient was used up, when it also would have to be added; and so on one substance after another would be consumed until the soil became completely infertile. Applying potash annually would maintain the soil's fertility as regards that substance, but it would not supply the deficiencies of lime and phosphoric acid, for the fertility of the soil depends chemically (1) upon the presence in it of all the ash-elements of plants and of nitrates in proper quantity; and (2) on their occurrence there in such states of combination as give a constant and regular supply. Therefore it is necessary to add at intervals a quantity of the elements of plant food equal to that which the crop removes. This is patent to all scientific and practical cultivators, and is the foundation of the use of manures. Soil exhaustion can only be prevented by judicious manuring, and an increase of crop secured by giving the soil a larger quantity of the elements of plant-food than is needed to replace what has been removed in the crop. Thus soil by manuring is made to yield a larger crop than it did in its normal condition. A soil to yield profitable crops must contain all the nutritive elements of plants in due proportion and essential form. It cannot remain fertile unless the ingredients removed with every crop are again added by manure, and from the inexhaustible store of the atmosphere.

Rotation of crops, although useful, is not sufficient to keep the soil in a fertile condition. Alternating on the same soil deep-feeding plants and shallow feeders, or following those crops that require phosphates with those needing nitrogenous manures, are not alone capable of maintaining the fertility of any soil. Crops that require a large amount of potash should be followed by those requiring only a small amount. One crop takes the potash out of the soil, and by the other a certain amount of potash comes into the soil. Brassicas, for instance, extract a large amount of potash from the soil; economy prompts following them with a crop that requires a small amount only of potash. Indeed, it is easy to show by agricultural chemistry that some plants enrich the soil—actually manure it for a succeeding crop. A good Clover crop removes from the soil when made into hay twice the ash elements and nitrogen that are contained in a good Wheat crop, yet the Clover crop may be obtained from a soil that will only produce the Wheat crop when aided by manure; indeed, the Clover crop will not only grow on the unaided soil, but enrich it so that it can support a subsequent Wheat crop. The fertilising effects of Clover are due to its assimilating nitrogen much more rapidly and in larger quantity than the Wheat plant. It flourishes on a small supply of nitrogen, and gives a full yield where Wheat would only make half a crop; besides this, the Clover leaves in the soil where it has grown more nitrogen in its roots than an entire Wheat crop contains. On the other hand, Clover adds nothing to the soil in the way of ash elements, but it transmutes the insoluble substances into soluble, and collects largely by the deep penetrating roots, bringing up plant nutrition, and when its roots decay the stores of food remain where a succeeding shallow rooting crop can utilise them, whilst the roots can follow those of the decayed Clover, and are better able to withstand drought. This enriching process has its limit, for land kept in Clover gets Clover-sick, which is considered due to the exhaustion of the

deep-lying plant food, the Clover having exhausted the available sources of supply.

A judicious alternation of crops enables the cultivator to so operate on a soil as to make it produce profitable crops by economising its resources; stirring and weathering it improves through the fertilising effects of a rotation. It is feasible to produce maximum crops of any kind on the same ground year after year, but it proves easier and more economical to alternate crops. This as regards the mineral as well as nitrogenous substances. In a four-course rotation, say, Roots, Barley, Clover, and Wheat, the principal mineral ingredients of the soil absorbed by the crops are potash, silica, and lime. "1, Turnips abstract, as shown by their ashes, 50.12 per cent. of potash. 2, Barley, 55.03 per cent. of silica. 3, Clover, 56.00 per cent. lime. 4, Wheat, 64.9 per cent. of silica." These data are those of Dr. Griffiths, and show that Turnips and other root crops, especially Potatoes, extract a large amount—53.80 per cent.—of potash from the soil, therefore full yields of these crops may only be had by the liberal use of farmyard manure and artificials that afford a supply of phosphoric acid as in superphosphates, and in the case of Potatoes potash. These substances are wholly derived from the soil, and the preceding Wheat crop only removes 11.67 per cent. of the potash from the soil, hence it is most economical to follow one crop requiring one element or more in less quantity than that by which it is followed. Wheat only takes 4.49 per cent. of phosphoric acid from the soil, though its grain ash contains 45.26 per cent., yet Turnips (ash) show 16.41 per cent. of that substance, and Potatoes 15.63 per cent.; consequently after a Wheat crop the soil is comparatively rich in potash, phosphoric, and sulphuric acids to what it is after a Turnip or other root crop, therefore the necessity in economic husbandry of a proper rotation of crops.

This principle of rotation cannot well be followed in gardens, in fact the gardener grows no crop that corresponds to cereals, but cultivates two descriptions of crops only, and in many respects only one—namely, the nitrogen consumers, hence gardeners use very much more stable and farmyard manure than farmers. Our views as to the use of manures have undergone considerable change of principles during the past few years. We have noted the fact that agricultural crops are of two kinds only, and we have studied them under a variety of soil, climate, and cultural conditions with a view to applying the principles of agricultural chemistry to horticultural subjects. We have given a résumé of the late practice of farmers in which there is nothing that is not sound in theory, safe and economical in practice, for it must be distinctly understood that the farmer cannot manure all his land with ordinary farmyard manure, he not having, like the gardener, the run of the manure heap, which costs nothing, but out of the produce of the land he must manufacture enough manure to restore to the soil the substances abstracted by the crops, and it must be effected in such a way as to leave a margin of profit. This the farmer finds it impossible in practice by the ordinary, and until lately prevalent, methods of rotation and culture. The most the farmer can do is to keep his permanent pastures fertile by giving his stock more to eat than they are able to obtain in grass, for profitable farming demands an increase rather than a stationary fertility of the soil, and manufacture enough manure out of products of the arable portion of his lands as will prove sufficient to maintain fertility, and enable him to produce the essential hay and root crops. This he finds impossible, for there is always a loss in the shape of grain, hay, milk, and live stock, though the latter leaves behind it when cake is used in feeding its equivalent in manure, yearly taken off the soil. Whatever a crop takes from the soil without restoring to it an equivalent impoverishes it. This the farmer is well aware of, therefore we find him anxious to sell hay and straw, which have little manurial value, in order that he may buy the more important and far more valuable potassic and phosphoric elements his soil requires to enable him to cultivate his farm creditably and profitably. Experience has proved, as science had long shown, that the most a farmer can do in the way of manufacturing manure on his farm is to produce enough to manure the land he must necessarily keep under root crops. That being so it follows that the manure produced is inadequate to permanently maintain the fertility of the whole farm, for it goes without saying that the soil's fertility cannot remain unchanged unless all the ingredients of the crops are restored to the land.—G. ABBEY.

(To be continued.)

#### VEGETABLES AT HIGHCLERE.

IN my opinion the description of these (page 303) does not, as is implied, denote Mr. Pope's connection with his growing and showing. Turnips are said to be a favourite dish. I consider them one of the most difficult to obtain perfect. Mr. Pope had none in his collection at Edinburgh. It is remarked Cucumbers are appreciated during September more than in the month preceding. How is this? The absence of Cucumbers in Mr. Pope's collection at Edinburgh was greatly commented on, a rule being stated that the second list of prizes for collections of vegetables were not to contain "Cucumbers or Tomatoes," the inference being that the preceding collections should do so. It is said "Parsnips in October and November are a strong dish." Mr. Pope's collection contained a dish of them on the 9th of September, which may find a parallel in anyone sending Lady Downe's Grapes to the table in the month of July. Globe Artichokes are not a weighty dish. Anyone can cut a dish for a collection from the same plants year

after year without further cultivation than placing a liberal quantity of manure round them once a year. Then "Leeks are much more sought after now for exhibition than formerly was the case, when the blanched part was but a few inches long; but now it is nothing uncommon to see Leeks with 1 foot of stem thoroughly blanched." That is so. The great majority of those staged in the collections at Edinburgh were blanched more than 1 foot, and indicated having received the utmost attention; but Mr. Pope's were in curious contrast to these, as they were not blanched more than 6 inches, and the place given them made more than one grower wonder.—OBSERVER.

EVENTS OF THE WEEK.—To-day (Thursday) the annual dinner of the United Horticultural Benefit and Provident Society will take place at the Cannon Street Hotel, E.C. George A. Dickson, Esq., of Chester, will take the chair at 5.30 P.M. On Tuesday, October 20th, the Fruit Show at Manchester will be opened, and a Conference will be held in conjunction with it on October 21st and 22nd, at noon each day. The sales for the current week by Messrs. Protheroe & Morris at Cheapside include *Dendrobium Phalaenopsis* var. *Schroederianum*, and the old *Cattleya labiata* on Friday, October 16th; a collection of Orchids from Old Park, Ventnor, on October 20th; a large consignment of *Kentia* seeds, on October 21st; and nursery stock at Tunbridge Wells on October 22nd and 23rd.

— WE are pleased to learn that DR. M. T. MASTERS of the *Gardeners' Chronicle* has been nominated an honorary member of the Dutch Horticultural and Botanical Society in recognition of his valuable services to botany and horticulture.

— JAMAICA INTERNATIONAL EXHIBITION, 1891.—Messrs. James Carter & Co. desire to state that they have been awarded the highest prize (a gold medal) for their exhibits of English tested seeds, packed for the Tropics. The display also comprised growing examples of some of the most beautiful varieties of English annuals, many of which originated upon Messrs. Carter's Seed Farms in Essex.

— THE ECCLES, PATRICROFT, PENDLETON, AND DISTRICT CHRYSANTHEMUM SHOW, to be held at Eccles on November 13th and 14th, is, owing to a considerable increase in prizes expected by the Committee, to be one of the best in the north of England.

— CHRYSANTHEMUM SHOWS.—As announced in our advertising columns, the seventh annual Show of the Portsmouth Society will be held in the Drill Hall, Landport, on November 4th, 5th, and 6th next, when over £200 will be offered in prizes. The Hon. Sec. is Mr. F. Power, 26, Queen Street, Portsea. The Twickenham Society will also hold their annual Show in the Town Hall on November 17th and 18th, and schedules can be had from Mr. James T. G. Pugh.

— CHRYSANTHEMUMS IN LONDON.—We understand that the Chrysanthemum exhibition at Southwark Park will be opened on Saturday next, 17th inst., and will continue open daily to the public, 10 A.M. till dusk during the season. The annual display at Finsbury Park was opened last Saturday, and will be at its best in a fortnight's time. The Show of Chrysanthemums at Battersea Park will be opened to the public on Friday next, the 16th October, in the Frame Ground.

— MARRIAGE OF MR. L. G. SUTTON.—We learn from the *Reading Mercury* that the marriage of Mr. Leonard Goodhart Sutton, youngest son of Mr. Martin Hope Sutton, and partner in the firm of Sutton & Sons, with Miss Mary Charlotte Annie Seaton, daughter of Colonel Seaton, Madras Staff Corps, of Salween, Beckenham, Kent, was solemnised at Christ Church, Beckenham, on Wednesday, September 30th, in the presence of a large congregation composed almost entirely of the friends of the contracting parties. The church was beautifully decorated with Palms and flowers for the occasion, and the ceremony was performed by the Rev. S. H. Soole, M.A., Vicar of Greyfriars Church, Reading, brother-in-law of the bridegroom, assisted by the Rev. A. Valpy, M.A., rector of Standford Dingley, near Reading, the bridegroom being attended by his brother, the Rev. Claude H. Sutton, M.A. as best man.

— GARDENING APPOINTMENTS.—Mr. W. Cooper, late foreman at Normanton Park (Lord Willoughby de Eresby's), has been appointed head gardener at Somerby Park, near Gainsborough. Mr. Chas. Crooks for several years foreman at Impney, has been engaged as head gardener to the Dowager Lady Hindlip, Hadzor House, Droitwich.

— AT a recent meeting of the PRESTON AND FULWOOD FLORAL AND HORTICULTURAL SOCIETY held in the Legs of Man Assembly Rooms, Councillor J. Brown in the chair, Mr. J. Hathaway, gardener to the Earl of Lathom, Lathom House, near Ormskirk, read an excellent paper on the cultivation of the Chrysanthemum. Numerous cut flowers and plants were exhibited. Before the meeting was closed it was decided to apply to the County Council for a grant in aid of technical instruction in horticulture.

— MELON CARTER'S AMBERWOOD BEAUTY.—This, in some respects, much resembles Hero of Lockinge, but I consider it quite distinct from that variety, and well worthy of being given a trial in most gardens. It is a moderately strong grower, also free setting and heavy cropping, and suitable alike for house and frame culture. The fruits with me were of medium size, none weighing more than 3 lbs., somewhat oval-shaped, beautifully netted, and of a rich yellow colour. It softens more quickly than the Hero of Lockinge, in this respect more resembling its other parent Blenheim Orange, and keeps quite as well after it is ripe. There is a good thickness of light green flesh, and the quality is decidedly first-rate. In this variety Carter's have an excellent companion for their Blenheim Orange.—W. I.

— PEAR KNIGHT'S MONARCH.—Like Mr. Iggulden, I also have to record the Pear Knight's Monarch a failure. We have a fine espalier trained tree, occupying a south aspect. For the past fifteen years it has always been a sure cropper, the fruit has grown to a good size, but when approaching maturity it always falls, and we have never had it once fit for dessert. Mulching has been tried, and watering as well, but all to no purpose, the fruit will still persist in falling. This year the tree is marked as one doomed. It grieves me to have to destroy it occupying as it does a large portion of our fruit tree arch, and the gap will not soon be filled up. If any of your readers could suggest a remedy I should be extremely grateful, would try it, and give the old tree another year's lease.

— PEAR MUSQUÉ D'AUTOMNE.—Whilst speaking of Pears, could any of your readers give me any information regarding the above-named Pear? We have a fine tree of it, which bears excellent crops of fruit each year; in fact, I always look upon it as one of our best early autumn Pears. The fruit is medium size, with rather rough skin, and of a beautiful pale yellow colour. It is a handsome fruit, and is just ripening. Not being able to find a history of it in any catalogue I possess, I have often wondered if it has been wrongly named. Any history of it would be valued.—R. P. R.

— THE WEATHER DURING SEPTEMBER AT RIPLEY, YORKSHIRE.—The weather during the first fortnight was very seasonable, fairly bright, accompanied by moderate wind, which raised our hopes high in regard to the ripening of late Grapes, and the wood of all fruit trees. But with the advent of the third week it settled down in the old groove, and rain fell almost daily to the end of the month. The total rainfall for the month was 1.81 inch, which fell upon seventeen days. Mean reading of barometer for month, 30.05; mean maximum temperature for the month, 64.9°; mean minimum temperature for the month, 44.6°; mean temperature for the month, 54.7°. Highest maximum temperature during the month, 79° on 11th; lowest minimum temperature during the month, 34° on 3rd.—J. TUNNINGTON.

— SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, FOR SEPTEMBER, 56 feet above mean sea level.—Mean temperature of month, 57.2°. Maximum on the 10th, 80.6°; minimum on the 24th, 36.7°. Maximum in the sun on the 9th, 133.1°; minimum on the grass on the 24th, 31.5°. Mean temperature of the air at 9 A.M., 58.5°; mean temperature of soil 1 foot deep, 56.9°. Temperature fell below 32° on grass on two nights. Sunshine—total duration in month 144 hours, or 38 per cent. of possible duration; we had only one sunless day. Total rainfall 1.07 inch; rain fell on fifteen days. Average velocity of wind 10 miles per hour, velocity exceeded 400 miles on six days, fell short of 100 miles on nine days. Approximate averages for September.—Mean temperature, 55.8°; sunshine, 110 hours; rainfall, 2.51 inch. A very dry and warm month, very similar to September of last year, but not so warm.—JOSEPH MALLENDER.

— TWO GOOD CABBAGE LETTUCES FOR SUMMER USE.—These are Continuity and New York, upon which I shall chiefly rely another

season. They are both of good quality, heart and blanch well, and stand longer than any others I have tried before bolting. In fact not one plant of the several batches of Continuity sown have run, and very few of New York; the latter, too, being the most crisp Lettuce I am acquainted with. For a frame supply we rely upon Hicks' Hardy White Cos and Hardy Hammersmith Cabbage. These are sown in August, and planted in the frames in September, from which we are enabled to cut a daily supply (after the outdoor ones are used) all through the winter. To succeed these, we sow in January in heat, transplant to a frame on a slight hotbed in February, and in this way were enabled last spring to cut serviceable Lettuces on April 16th.—J. T., Ripley, Yorks.

— TOMATOES AT NORMANTON PARK.—Although the past season has been far from favourable to the setting of Tomatoes outside, Mr. Gilbert has been very fortunate in securing an excellent crop from plants trained on the kitchen garden walls. Some fine clusters of beautiful even fruits are still hanging on the plants, which will have to be cut and taken inside to ripen. Mr. Gilbert's plan is to grow his plants in pots about 10 inches in diameter, plunged to the rim in the soil, as by so doing the plants seem less inclined to make gross shoots in wet seasons than when planted out, and consequently a better set of fruit is obtained; it is also much easier to assist plants in pots with stimulants when swelling their fruit. An even crop of Lady Downe's Grape is hanging in a late vinery, the colour and finish being splendid; the rods on which they are hanging are said to be nearly fifty years old, thus amply demonstrating the fact that there is nothing like old Vines for finishing black Grapes.—W. H. W.

— EREMURUS HIMALAICUS.—Mr. W. E. Gumbleton writes: "Allow me to congratulate you on the excellence of your woodcut of Eremurus himalaicus in the issue of October 1st. It is far the best representation of this fine plant and its habit of growth that has yet appeared, and as the first to bloom it in Europe in 1881 I welcome it. It has bloomed regularly without fail with me every year since, the only one of its family that can be relied upon to do so, and I think I possess every variety of the family that has been introduced and have bloomed most of them. They usually die after blooming or split up into a number of useless offsets, but E. himalaicus goes on blooming each May from year to year. The writer of your description, however, is hardly correct in saying that it bears a spike of small white flowers, as each individual pip is at least the size of a florin or 2s. piece. My friend and neighbour, Mr. J. J. Smyth, was the introducer of this fine plant to Europe by seed from India, though one of his seedlings which he gave me was first to bloom."

— THE FRUIT SHOW AT THE ROYAL AQUARIUM, WESTMINSTER, which opened on Wednesday and continues to-day and to-morrow, is excellent in all respects, and we regret that a full report cannot be given this week. For a collection of fruits of not less than twelve dishes, Mr. Peter Blair, Trentham Gardens, is first with twenty-eight dishes; closely followed by Mr. G. Reynolds, Gunnersbury Park Gardens, Acton; and Mr. C. Davies, Mote Park Gardens, Maidstone, all exhibiting extremely well. For a collection of Pears, Mr. C. Davies wins the premier honours, he is also first with eighteen dishes of Apples, grand fruits throughout, and is a prominent exhibitor in several other classes. Mr. C. Blick, Hayes Common; Mr. F. Bridger, Pershure Place; Mr. A. Wyatt, Hatton; Mr. G. H. Sage, Ham House Gardens, Richmond, also secure leading prizes in the other Apple classes; Messrs. Reynolds, Griffin, Davies, Iggulden, and Wilson contributing the best Grapes. Vegetables are well shown, especially for Messrs. Sutton and Sons' prizes, and the trade competing and non-competing exhibits from Messrs. J. Laing & Sons, Bunyard & Co., J. Cheal & Son, Wm. Paul and Son, J. Peed & Son, and R. Smith & Co. occupy considerable space. Many new Chrysanthemums were shown and certificated, to which reference will be made in another issue.

#### DAMSON BRADLEY'S KING.

THOUGH Bradley's King Damson was raised several years ago, it is what may be termed a comparatively new variety. The branch figured was cut from a young tree in the collection of a Kentish fruit grower of wide repute—Mr. A. J. Thomas, Bargains Hill, Sittingbourne. A dozen trees were first obtained for trial, and this having proved highly satisfactory, considerably more were planted.

The trees do not become clustered with fruit so soon as do those of the small Crittenden, Cluster, or Farleigh Damson, but still are more precocious than the Prune or Shropshire Damsons, and the fruit in

quality is superior to them all, for all are grown by Mr. Thomas, and have been tested in comparison.

That extensive, able, and successful cultivator of fruit prefers

compact, yet not spreading. Their growth in the stony soil was free without being rampant, and though all the branches were not so heavily laden as the specimen, the beautiful purple fruits could be gathered in

FIG. 67.—DAMSON BRADLEY'S KING.

Bradley's King to the Cluster or Crittenden, for two very substantial reasons. When asked what they were, he replied, "The Clusters cost much more in gathering than the Kings, and the Kings bring much better prices than the Clusters."

In habit the trees are all that can be desired, not very dense and

handfuls from five or six-year-old trees. Mr. Bunyard grows this variety extensively, and values it very highly.

On calling at Southwell recently some bearing trees of this Damson were observed in Mr. Merryweather's nursery, but the crop was light. It was there I found that this Damson was raised in an adjoining

village—Halam—by the late Mr. S. Bradley, the raiser also of Sir Joseph Paxton, Dr. Hogg, and other Strawberries. Mr. Bradley's death was recorded in this Journal a few months ago, and those Strawberries with this Damson are fitting memorials of his skill and care —J. WRIGHT.

### THE ROYAL HORTICULTURAL SOCIETY.

THE CONIFER CONFERENCE. — OCTOBER 7TH AND 8TH.

THE weather was not favourable for the gathering at Chiswick last week, and though the Exhibition was prolonged a couple of days the result was not satisfactory. On Wednesday afternoon the Conifer Conference was opened at 2 P.M. Dr. Maxwell T. Masters, who presided, delivered an address on the special features of interest in the order of Conifers. Noah's flood was a thing of yesterday compared with the antiquity of some Conifers. All available evidence went to show that we must look for the ancestry of the Conifers among some group now extinct, but which must have been very closely allied to existing Lycopods and Selaginellas. This presumption was based upon certain very remarkable peculiarities in the organs of fertilisation, pollen as well as ovula. There was other evidence dependent upon the generally admitted fact that the progressive changes in the development and growth of each living creature were the reflections of similar changes of growth in its ancestry. As to size, Conifers were as veritable sons of Anak. Only some of the Eucalypts of Australia could approach them in this particular. There were Sequoias close upon 400 feet in height, and *Pinus Lambertiana* and *ponderosa* not much inferior. At the other extreme, there were in New Zealand *Dacrydiums* smaller than our Poplar Willow. Daily did we in some way or another avail ourselves of the products of these trees. With the exception of the Scotch Pine, the Yew, and the Juniper, no species of Conifer was wild in this country. Our earliest records of the introducer of plants did not go beyond the sixteenth century. The Pinaster was known here in 1596, the Larch in 1629, and the Lebanon Cedar in 1664. John Evelyn was credited with the introduction of the so-called Cedar (*Juniperus virginiana*). From 1827 to 1833 Douglas startled the botanical and horticultural world by the number and importance of his discoveries in North-west America. The Douglas Fir, the Lambert Pine, *Abies amabilis*, *Abies grandis*, *Abies nobilis*, and the Menzies Spruce were among the introductions of Douglas. To the Royal Horticultural Society it must always be a source of legitimate pride that these magnificent discoveries, like those of Hartweg and Fortune at a later date, were made by officers of the Society. In this connection it was interesting to note that in introducing the *Araucarias* from Chili and Australia, the Sequoias and *Libocedrus* from the North-West Pacific, and the allied Cycads from South Africa and Australia, we were but bringing back plants that flourished at various epochs upon our own soil. Dealing with the prospects, he hoped that one result of the Conference would be the accumulation of evidence concerning the economic value of these introductions, especially of some of the most recent. The value of the Lebanon Cedar as a decorative tree, and of the Weymouth Pine was admitted, but in regard to others there was still doubt. Had not the Deodar disappointed expectations, and was the Douglas Fir likely to be of any great value? Again, considering the distressing failure of the Larch in many situations owing to attacks of a fungus, had we among newcomers any efficient substitutes? He ventured to think that there were several, as Lobb's Cypress (*Thuia gigantea*), the Lawson Cypress, the Red-wood (*Taxodium sempervirens*), the Nootka Cypress (*Thujopsis borealis*), the *Abies brachyphylla*, and some others of Japanese origin. It was to be feared that many of the Conifers were too precocious in this climate, and attained their full span of life much sooner than in their native land.

Mr. H. J. Veitch read a paper on Japanese Conifers, in the course of which he remarked that there were in Japan no fewer than forty-one species of Coniferae, of which a large number were indigenous. Mr. Edmund J. Baillie read a paper on the decorative character of Conifers. To a natural faculty for art he attributed the introduction of Coniferae which were now so much a part of our landscape decoration. Few classes of plants require greater care and judgment in arranging, and few, if any, were more effective. The Pine was the king of the woods, with its stately shaft, its splendidly balanced branches, and its crowned head of dense dark foliage standing back on the hill side. The Cedar, the Cypress, and the Yew had sharply defined characteristics and indescribable richness of colour. If Pines derived little interest and no decorature from inflorescence they had a distinct advantage in their cones, and their full magnificence in isolation might be seen in the pineta at Woburn, Chatsworth, Dropmore, and Bickton. So abundant was the choice for decorative purposes that it was very difficult to select. He would, however, name *Juniperus chinensis*, *Retinospora squarrosa*, *filifera* and *obtusata*, *Cupressus Lawsoniana* stricta and variegated forms, *Thujopsis dolabrata*, the red Cedar, and the Irish, Chinese, and Golden Yews. There was, he thought, ample room for the introduction of coniferous trees and shrubs in the purely ornamental parts of gardens. Papers were also read on "Conifers as Specimen Trees and for Landscape Gardening," by Mr. G. Nicholson; on "Conifers for Timber and in Plantations," by Mr. A. D. Webster; on the "Conifers at Bickton, Devon," by Mr. Mark Rolle; and on the "Conifers at Dropmore," by Mr. Charles Herrin.

On Thursday the Conference on Coniferae was resumed, Mr. W. T. Thiselton Dyer, Director of the Royal Gardens at Kew, presided, and in his address remarked that they had been able to get together an exhibi-

tion of Conifers unparalleled in completeness and extent. No one who had not travelled in Scotland could form any conception of the beauty and the perfection with which a large number of coniferous trees were cultivated in that country. There were in that part of the kingdom conditions of coolness and of atmosphere that were not to be met with in the southern parts of Great Britain. The result was that in Scotland one saw an enormous number of Conifers represented, not by the small specimens found on southern lawns and in southern arboreta, but by magnificent trees 70 to 100 feet high. In the south-east of England we could offer nothing equal to this. With the Pines, however, we were more successful, and even on the sterile and summer-burned soil of Kew they were able to have a tolerable collection of that species. But with regard to Abies, of which the Spruce is a type, they had in Scotland a state of things that we in England could not rival. In the south-west of England the conditions were more favourable. Here were many notable collections, and here, too, flourished the Mexican Pines or representatives of the family.

Mr. Malcolm Dunn spoke of the value of introduced Conifers from an economic and an aesthetic point of view. Exotic Conifers, he remarked, had played, especially during the present century, an important part in landscape decoration. To the explorations conducted by Douglas and Fortune under the authority of the Royal Horticultural Society, and to the researches of Veitch in Japan, we owed many trees, whose healthy progress gave promise of enduring beauty and usefulness. In all cases where Conifers had been planted with care in suitable soil the hardy species had grown up with a vigour that could scarcely be surpassed, even in their native habitat. A large number were useful forest trees, of which the timber might be used for constructive purposes. Among those introduced within the last hundred years he enumerated *Abies Albertiana*, one of the finest of Jeffrey's importations from the North-West of America; *Abies concolor*, a fine Silver Fir, introduced by Jeffrey and Lobb, and widely planted; *Abies Douglasii*, a grand tree in every respect, and of which there was on the Scone estate a specimen 91 feet 9 inches in height, and 12 feet in girth; *Abies grandis*, another Columbia giant in the front rank of Silver Firs; *Abies magnifica*, a promising tree in Scotland; *Abies Menziesii*, of which there was a specimen 96 feet 11 inches high at Castle Menzies; and *Abies nobilis* and *Nordmanniana*. Of Cypresses, he commended especially *Lawsoniana* and *macrocarpa*; and of *Pinus*, *insignis*, *monticola*, and *gigantea*. Dealing with the ornamental species, he pointed out the great width of the field of choice, and the great value derived from variety of colour, as well as freshness of life, when deciduous trees were leafless and resting.

SCIENTIFIC COMMITTEE.—Present: Dr. M. T. Masters, in the chair; Mr. Morris, Mr. McLachlan, Mr. Blandford, Rev. C. W. Dod, and Rev. G. Henslow, Hon. Sec.

*Strawberries Attacked by Beetles*.—With reference to this subject, brought before the Committee at the last meeting, Mr. Blandford observed that the fact had been recorded before, and attributed to identically the same insects, so that it was very probably the same beetle in the present instance. The fact that the carnivorous beetles thus changed their habit to eat Strawberries reminded Mr. Dod of the interesting fact that squirrels would eat not only Mushrooms but even poisonous fungi.

*Primula rosea, mildewed*.—Mr. Dod exhibited plants, and observed that this species alone had been much attacked this year, and especially during the wet season after great thunderstorms in the last week of June. The specimens were sent to Dr. Cooke for further examination. Mr. Dod also added that he had tried many kinds of remedies for mildew this season, but with no very great success, the best being "anti-blight" and watering with sulphate of copper. *Iris reticulata* had been very badly attacked this year.

*Fog Report*.—Mr. Morris read a communication from Mr. Rix stating that Mr. G. H. Bailey, Secretary of the Town Gardening Committee of the Manchester Field Naturalists, had expressed the willingness of the Committee to work in conjunction with the Scientific Committee of the Royal Horticultural Society in the matter of "Air and Fog," and had applied for the grant of £50 placed at the disposal of the joint Committees by the Government Grant Committee.

The members of the Scientific Committee were unanimous in agreeing to the proposal of Mr. Bailey, as there was still a working balance from last year's grant to go on with.

*Polyporus fraxineus*.—Mr. Plowright forwarded a specimen, with the following observations:—"It was taken from an Ash tree near King's Lynn, which is being killed by this fungus. The tree is still alive, and bears a certain number of leaves, but will evidently succumb before many months. The fungus has attacked the base of the trunk near the ground, which is the usual site of its attack. *P. fraxineus* has hitherto not been generally regarded as a parasite by mycologists in Britain, but it clearly is a true parasite, capable of doing great damage to the trees it attacks. It is not one of the most common species with us. When once a tree is fairly attacked it is soon killed by the fungus." The question was raised whether the fungus be not rather a parasite in consequence of the previous unhealthiness of the tree, as is so often the case with other fungi, as Dr. Masters observed. Mr. Henslow added that *Polyporus squamosus* grows on a dying Horse Chestnut tree in his garden, but not on the healthy ones, from which it might be inferred that when that fungus occurs on Ash trees, as is so often the case, the probability was that the trees were unhealthy.

*Merulius lacrymans*.—He also sent fine specimens of this fungus,

the "dry rot," remarkable for the development of well-formed pilei. Such are seldom seen; they are flat, orange colour, and spreading over the cushion-like mass of the fungus.

*Apple Canker*.—Dr. Plowright also forwarded specimens of this condition; but as is usual in the advanced stage it is impossible to assign a cause; probably some ancient irritation having been set up, the organism having long since disappeared, the abnormal growth continued.

#### CHRYSANTHEMUM NOTES.

ONCE again has the season come round for to record the prospects of the Chrysanthemum. That there is no abatement in the interest they create is manifest from the many excellent collections to be seen on every side. What we should do without them throughout the dreary months of winter is a puzzle which would require a great amount of solving. The varied form of the flowers, combined with the gorgeous hues of some of the later introductions, and the lasting properties, stamps it at once to be the proud holder of the title "Queen of Winter." I have heard it said that the trouble taken to bring them to the highest state of perfection is more than they are entitled to, but I fancy the thought must pass away when they are confronted with a houseful of well-grown specimens. As with all other things successful, we forget in a great measure the labour which has been bestowed upon them when we reap the benefit. Here in Liverpool the early varieties are not so much grown, but Japanese and Incurved varieties are represented by all the finest varieties. The strong winds of the past month have robbed many growers of shoots which would have given flowers of the best quality. Japanese varieties are much about as usual, but incurved do not appear to be so good up to the present as they were last year. A great many new varieties are being grown, but it is yet too early to judge of the merits of any of them. I shall endeavour, with the aid of kind friends, to give some notes on the more noted collections here in the course of two or three weeks. Our Liverpool Show ought to be the best we have ever had, if we may take the excellent schedule as our guide. In addition to our ordinary prizes, we have this year two silver cups added, so that we may expect a lively time of it. The Treasurer, Secretary, and Committee are using every endeavour to make it a success, which I truly hope it will be.—R. P. R.

#### CHRYSANTHEMUMS AT LEWISHAM.

MR. H. J. JONES has made Chrysanthemums the leading feature at the Ryecroft Nursery, Hither Green Lane, Lewisham, and this season he will have a display that is certain to attract an even larger number of visitors than last year. Already one lean-to house or shelter, 100 feet long, is filled with early flowering varieties in excellent condition, and such a bright varied floral exhibition in the middle of October is a most agreeable surprise, well proving what useful plants these are for decorative purposes. In the structure named the plants are arranged to form a bank sloping to the path at the back, and with a large general selection of the most effective early Japanese varieties of proved merit, such as W. Holmes, Madame Desgranges, and its forms; some scores of novelties are included, many of which are very promising, the colours distinct, the habit free, and the blooms of good substance. We cannot enumerate these in the present issue, but shall take an early opportunity of referring to the best amongst them, for a large proportion bid fair to take a prominent place in the section.

The plants for the November display are all under cover, and form a fine bank over 100 feet long and about 20 feet wide, nearly filling a spacious lofty light span-roofed house admirably adapted for a show of this character. The plants are in first-rate condition, vigorous, healthy, well clothed with rich green foliage, dwarf and showing substantial buds of an extremely promising appearance. Mr. Jones thinks the season likely to prove very favourable to the incurved varieties, as all his plants of "the Queen family" are very satisfactory, and he rightly considers that excessively hot dry summers are by no means what these varieties require. Chrysanthemum growers and lovers who take the round of the nurseries and gardens during the next few weeks will find ample to interest them in the Ryecroft Nursery, which is easily reached from Ladywell or Lewisham stations on the South-Eastern line from London Bridge or Cannon Street.

#### THE USE AND ABUSE OF WATER.

UNDER the above head, at page 305, in the last issue of the Journal, appears a letter by a correspondent—"Yorkshire Bite"—taking exception to an extract of a paper by me recently read at Preston. I am not sorry "Yorkshire Bite" has made reference to a few points, one or two of which certainly have been incorrectly reported, thus causing a wrong impression.

I think, however, your correspondent has stepped outside the limit of prudence by disputing my practice, and questioning my opinion of young gardeners before ascertaining whether I had any explanation to

offer upon the points raised. Let me assure him that watering Heaths with the syringe is just as "new" to me as to himself, also the syringing of Peaches when ripening; no such lines of procedure have been laid down or in any way advocated by me.

I have advised a light syringing upon softwooded Heaths while breaking and developing new growth each year for a short period, for Epacris also, and to this practice I adhere. If "Yorkshire Bite" has not made the acquaintance of hardwooded plants that have been ruined by mistakes in watering it does not follow that I have not.

In respect to my opinion of young gardeners, I may inform your correspondent that he could not, if he desired, point to any place in the kingdom where young men work more ardently or with a deeper sense of respect than they do with me. Doing our best for each other, and to make as far as possible the duties of life a pleasure, is the order of things here.

In respect to my treatment of Peaches, your correspondent may yet learn that many fruit borders, both of Peaches and Vines, are much too liberally watered. This applies more particularly to forced trees than to later and successional houses. I have satisfied myself long ago on this point, not from theory, but by results, which have been approved by high practical authority.

"Yorkshire Bite" apparently is endeavouring to under-rate my system of Peach culture by informing your readers that an early house has produced several fruits of nine and ten ounces. Good Peaches I grant, but how many or how few did the tree produce? I will quote one result out of many as the result of my treatment. One day I gathered sixty fruits from an early house, the fruits weighing from eight to eleven ounces each, three turned the scale at the higher figure. These fruits formed part of the dessert at a Mayor's banquet in honour of a visit by the Prince of Wales to a provincial town.

With these few observations I leave the subject to the discretion of readers, feeling that your correspondent would probably have made a more successful "Bite" at an eleven-ounce Peach than he has at my reading.—A. WATERS.

#### FRUIT AT THE MANSION HOUSE.

THE Court of the Fruiterers' Company made their annual presentation of fruit to the Lord Mayor on Wednesday the 7th inst. The drawing-room of the Mansion House, where, in accordance with custom, the ceremony was performed, was well filled by an influential company of ladies and gentlemen, including many members of the Fruiterers' Company and their ladies. The presentation fruit adorned the table, and, of course, attracted considerable attention. It was of the choicest description, and was all English grown—a fact which those who saw it must admit dispels the idea entertained in many quarters that really good fruit cannot be grown in this country. A portion of it had been, as Sir James Whitehead afterwards announced, grown within the sound of Bow Bells—and, in fact, in Sir James's own garden.

The presentation was made, on behalf of the Fruiterers' Company, by Sir James Whitehead, who said that as Master of the Company for this year, and in accordance with ancient custom, it was his privilege to present to his Lordship the usual offering of the Company. In past years the ceremony had been more or less of a formal nature, but within recent years it had had attached to it associations of a very practical character. Each Lord Mayor during the last three or four years had more or less given a portion of his time and his influence in the promotion of what the Fruiterers' Company felt to be a great national object, and they were very glad to recognise that the Lord Mayor had this year given them the weight of his personal character and the weight of his office in the furtherance of their scheme.

The Lord Mayor, in reply, said he accepted with great pleasure the magnificent present which the Company had offered to himself and the Lady Mayoress that evening. They looked with wonder and amazement on the beautiful samples of fruit which adorned that drawing-room. He understood that a dish which was immediately before him contained specimens from Sir James Whitehead's own garden, grown within the sound of Bow Bells, and he thus had given practical proof of what it was possible to do in one's own garden, if only attention and skill were bestowed upon the trees. He again tendered the Company the warm thanks of himself and the Lady Mayoress for their magnificent and bountiful present.

The Lord Mayor and Lady Mayoress afterwards entertained the Fruiterers' Company and the General Purposes Committee at dinner in the Egyptian Hall. The company present included:—Lord Brassey and Lady Brassey, the Master of the Fruiterers' Company (Alderman Sir James Whitehead, Bart.) and Lady Whitehead, Mr. Warden Brocklesbury and Mrs. Brocklesbury, Mr. Warden Martin and Miss Martin, the Chairman of the General Purposes Committee, Mr. H. R. Williams, P.M., Mr. J. Eagleton (Clerk of the Fruiterers' Company), and about 250 others, including Sir Trevor Lawrence, Bart., M.P., Rev. W. and Miss Wilks, Mr. P. and Mrs. Crowley, Mr. N. N. Sherwood, Mr. T. Francis and Mrs. Rivers, Mr. Cheal, and Mr. and Mrs. J. Wright, Mr. G. Bunyard being unable to attend through illness. The loving cups having been circulated, and the loyal and patriotic toasts honoured with the customary enthusiasm,

The Lord Mayor then submitted "The Houses of Lords and Commons," and Sir Trevor Lawrence, in replying for the latter House, observed that the Royal Horticultural Society, of which he was President, had taken the greatest interest in the work, which had been so admirably and so praiseworthy prosecuted by the Fruiterers'

Company, under the very able guidance of Sir James Whitehead their Master. Having mentioned that the Royal Horticultural Society had recently issued, at the smallest possible cost, a pamphlet on the subject of hardy fruit culture, he expressed the belief that the great want of the present day was to bring the producer into direct contact with the consumer. If this were accomplished it would, he thought, give a great impetus to fruit growing throughout the country.

The Lord Mayor next proposed the toast of the evening, "The Worshipful Company of Fruiterers." He said that by an ancient and much-valued custom, it had been the practice from time immemorial for the Lord Mayor for the time being to receive from the hands of the Fruiterers' Company some baskets of the choicest fruits of the season, and the Lord Mayor had had the privilege subsequently of entertaining the Fruiterers' Company. That custom had grown up from year to year, but of recent years it had developed considerably owing to the activity and the energy displayed by one who preceded him only two or three years ago in the civic chair, Sir James Whitehead. During his year of office he conceived a great desire to promote fruit-growing in England, and he displayed so much enthusiasm on the subject that he was elected first on the Court, and subsequently—he believed at the same time—Master of the Fruiterers' Company. No doubt many who had preceded him had been interested in the subject. But he believed that the great advance which had been made in fruit-growing during the past and the present year was greatly owing to the energy and the determination of his friend Sir James Whitehead. The object of the Company of which he was the Master was to promote fruit-growing throughout the land. When they looked at the fruit on their tables and in their gardens, speaking, as it did, so beautifully and yet so silently of the love of that Creator who had sent it as a blessing to mankind, surely it reminded them that they had often forgotten their duty in cultivating that which He had given them for their benefit and for their use. He believed that we had in England gardens which were as good as those of any nation in the world. He believed we had as good soil as any other country possessed. It only needed care and attention to bring our fruit trees to perfection, and he believed that if they gave that attention to it their efforts would be crowned with success. He rejoiced to think that the efforts of the Fruiterers' Company were being seconded in various directions by the Royal Horticultural Society, and also by the Gardeners' Company, which had recently aroused itself to a state of activity.

Alderman Sir James Whitehead, in response, said, it was to him a very great pleasure to be associated with the Fruiterers' Company at a period in its existence when it was probably doing more active and useful work than had ever been performed by the Company in its previous career. The efforts of the Fruiterers' Company just ended were mainly of an educational character, and it was satisfactory to them to feel that in the work they were endeavouring to perform they not only had the countenance, and the assistance also, of the Royal Horticultural Society—represented that evening so ably by Sir Trevor Lawrence—but also of the British Fruit Growers' Association, many members of which were also present with them. He ventured to say to Sir Trevor that something more was wanted in the promotion of fruit culture than the issue of pamphlets. So far as his observation went it was necessary in different localities to give not only educational instruction, but object lessons also. And in the promotion of that idea the Fruiterers' Company propose from time to time to hold exhibitions in various parts of the country, and he thought it not at all unlikely that next year, when their position was more consolidated than it was at the present time, it would be found that they would hold an exhibition either at Bath or Chester, or some other great centre, which would not be inferior in any degree to that which brought so much honour to the Fruiterers' Company last year.

It must be gratifying to all present to know that the first step had been taken in this country with a view to giving instruction in horticultural science in the public schools of this country. At Sewardstone, in Essex, Mr. Melles, a member of the Fruiterers' Company, had been the means of inducing the Government to consent to the teaching of horticultural science in the school of that village, and thus the elements of horticultural science were laid in that district, and a step taken which would lead to very great results in our rate and State supported schools throughout the entire country. The advantage, no doubt, would be the development of the resources in each district in which that education was given, and it would be no disadvantage whatever to the schoolmaster who gave such instruction, inasmuch as he would be able to earn the same grant for the teaching of those sciences as he now did for the teaching of art and science, for which he took a grant from the Government. The Fruiterers' Company felt that so far as the experts and those who were engaged in the country were concerned no education whatever was needed. But they did aim at this, their primary object, the education of the farmers and cottagers of the country in the cultivation of this article of food. The Company would endeavour, as far as it could, to teach them to grow fruit, first for use in their own families, and secondly, if they had a surplus, to send to market with a view of making a profit from it. But a great deal had to be done in this country before the farmers and cottagers would realise any profit from the growth of fruit. Foreign countries were far ahead of us in sorting and packing, and in the technical knowledge which was essential to the growth of various kinds of fruit. But the Company felt that if the farmers had regard to the cultivation of fruit, and showed the same skill and perseverance as they did in the cultivation of corn and other agricultural products, they would achieve results which would be satis-

factory to the country at large, and more particularly to those who engaged in the pursuit. They were aware that there were many great difficulties to be overcome before they could place themselves on a footing of equality with foreign countries.

A subject which deeply affected the profits connected with fruit culture was the manner and the cost of distribution. So far as the Company had been able, it had through the Mansion House Association on Railway Rates done all that within them lay in order to ensure the distribution of fruit in the future being cheaper and quicker than it had been in previous years. It might be in the course of a little while that the railway authorities and the new Postmaster-General would see their way clear to make some modification in the charges for conveyance, which would bring the producer and consumer, so far as small quantities were concerned, into immediate contact. To all these subjects the Fruiterers' Company were giving their very serious attention, and he could assure them that all they had seen in the course of their researches during the past two or three years confirmed them in the belief that they were going on a line which would lead to great advantages for the country. They would travel on in the fulfilment of their self-imposed task in the conviction that they were conferring an advantage upon those who engaged in the culture of fruit, that they were doing a great national service, and something to promote the national prosperity and the national welfare.—(*City Press*.)

## THE CRYSTAL PALACE HARDY FRUIT SHOW.

OCTOBER 8TH, 9TH, AND 10TH.

THE annual display of hardy fruits at Sydenham, which opened on Thursday last and was continued until Saturday, proved one of the best that has been held there for many years. In all it was estimated that nearly 3500 dishes of Apples and Pears were staged, this representing about double the number of entries ever received at any previous Show. This was highly satisfactory, but was to some extent expected, as the crops of Apples are generally good in the south.

The exhibits were arranged on long tables, which occupied considerable space. The open classes for large collections were very important, and comprised some exceedingly handsome specimens. Messrs. G. Bunyard & Co., Maidstone, were very successful, and contributed grandly in several classes. For the best exhibition of Apples, kitchen and dessert varieties, six fruits of each variety, not to exceed 100 dishes, orchard house fruit excluded, the firm just named won first honours for large bright handsome specimens of all the leading varieties, the following being very notable:—Ecklinville, Worcester Pearmain, The Queen, Mère de Ménage, Lane's Prince Albert, Alfriston, Stirling Castle, Loddington, Bismarck, Calville Rouge Précoce, Gloria Mundi, Lady Sudeley, Lady Henniker, Warner's King, Peasgood's Nonesuch, Duchess of Oldenburg, Emperor Alexander, Northern Dumpling, Gascoigne's Seedling, Grenadier, Cellini, Pott's Seedling, Cox's Pomona, Fearn's Pippin, and Lord Suffield. Mr. C. G. Slater, Devon Nursery, Heavitree, near Exeter, was a good second, staging many very fine fruits. Mr. J. Watkins, Hereford, was third; and Mr. H. Berwick, Sidmouth, was fourth, both with praiseworthy collections. In Class D, for the best collection of Apples and Pears, orchard house grown, Messrs. G. Bunyard & Co. were the only exhibitors, and were awarded the first prize for extremely fine specimens, representing a selection of the best varieties.

Another open class was provided for the best collection of Pears, six fruits of each variety, and not to exceed fifty dishes, orchard house fruit excluded. Here Mr. G. Goldsmith, gardener to Sir E. Loder, Bart., Leonardslee, Horsham, won a great victory amongst nine competitors, taking premier honours for about fifty dishes, which included beautiful fruits of Beurré d'Amanlis, Beurré Diel, Beurré Hardy, Louise Bonne of Jersey, Nouveau Poiteau, Pitmaston Duchess, Madame Treyve, Souvenir du Congrès, Grosse Calebasse, Glou Morceau, Doyenné du Comice, Fertility, and Josephine de Malines. Mr. Woodward, gardener to R. Leigh, Esq., Barham Court, Maidstone, was a good second; Messrs. Bunyard & Co. third; and Messrs. J. Cheal & Sons, Crawley, fourth.

Turning to the amateur classes, we found similarly good exhibits—in fact, in one case perhaps better than the others. This was in the class for fifty dishes of Apples, distinct varieties, where Mr. Woodward took the leading position for a magnificent collection of large even fruits. The varieties were as follows:—Bedfordshire Foundling, Golden Noble, Kentish Fillbasket, Loddington, Blenheim Pippin, Royal Russet, Ecklinville, New Hawthornden, Wealthy, Lord Derby, Flower of Kent, Annie Elizabeth, Tower of Glamis, Gascoigne's Seedling, Brownlee's Russet, Bismarck, Ribston, Northern Dumpling, Alexander, Minchal Crab, Cornish Aromatic Pippin, Cox's Orange Pippin, Tyler's Kernel, Alfriston, Lincoln Pippin, Brabant Bellefleur, Queen Caroline, Peasgood's Nonesuch, Reinette de Canada, Duchess of Oldenburg, Warner's King, Calville Malingre, Pott's Seedling, Grenadier, Cox's Pomona, Mère de Ménage, Belle Dubois, Yorkshire Beauty, Stirling Castle, Lord Grosvenor, Golden Spire, Cellini, Washington, Waltham Abbey Seedling, Lady Henniker, The Queen, Worcester Pearmain, Lord Suffield, Lane's Prince Albert, and an unnamed variety. Mr. G. Goldsmith followed closely, and Mr. A. Waterman, gardener to H. L. C. Brassey, Esq., Preston Hall, Aylesford, Kent, was third amongst four exhibitors.

With twenty-four dishes of Apples Mr. Waterman was more successful, securing the first prize with large fruits of Alfriston, Yorkshire Greening, Ribston Pippin, Mère de Ménage, Brabant Bellefleur, Cellini, Gloria Mundi, Tyler's Kernel, De Neige, Lord Derby, Stirling Castle, Queen Caroline, Tower of Glamis, Bismarck, King of the Pippins, Worcester Pearmain, Blenheim Pippin, Peasgood's Nonesuch, Warner's

King, Dumelow's Seedling, Gravenstein, Gascoigne's Seedling, Loddington, and an unnamed variety. Mr. G. Reynolds, gardener to the Messrs. Rothschild, Gunnersbury Park, Acton, was a capital second, and Mr. T. W. Startupp, West Farleigh, Maidstone, was third.

There were also four competitors in the class for twenty-four dishes of Pears, Mr. G. Woodward leading with excellent specimens of Glou Morceau, Durondeau, Gansel's Bergamot, Beurré Diel, Conseiller de Cour, Doyenné du Comice, Marguerite Marillat, Nouveau Poiteau, Pitmaston Duchess, Marie Louise, Reine des Tardives, Triomphe de Vienne, General Todtleben, Bellissime d'Hiver, Louise Bonne of Jersey, Duchesse d'Angoulême, Doyenné Boussoch, Beurré Hardy, Beurré Superfin, Princess, Gregoire de Bourdillon, Beurré d'Amanlis, Fondante du Pansel, and an unnamed variety. Mr. Waterman was second, and Mr. T. H. Crasp, Canford Manor Gardens, third.

The best twelve dishes of Pears were shown by Mr. G. Goldsmith, who had the undermentioned varieties in fine condition:—General Todtleben, Louise Bonne of Jersey, Beurré d'Amanlis, Duchesse d'Angoulême, Doyenné Boussoch, Marie Louise d'Ueele, Pitmaston Duchess, Souvenir du Congrès, Marie Louise, Beurré Diel, Rivers' Princess, and Doyenné du Comice. The second place was taken by Mr. R. Smith, gardener to Lady F. Fletcher, Kenwards, Yalding, who had especially fine fruits of Triomphe de Vienne, Souvenir du Congrès, Pitmaston Duchess, Calebasse Grosse, and Doyenné du Comice. Mr. W. Cotterell, Oxon Hoath, Tunbridge, was third. The entries in this class were very numerous, no less than fourteen collections being shown.

In the corresponding class for twelve dishes of Apples there were the same number of entries. Mr. F. Bridger, The Gardens, Penshurst Place, Kent, securing premier honours for admirable fruits of Bismarck, Queen Caroline, Cox's Orange Pippin, Warner's King, The Queen, Emperor Alexander, New Hawthornden, Worcester Pearmain, King of the Pippins, Wealthy, Grenadier, and Glory of England. The second and third prizes were accorded to Mr. S. H. Goodwin, Mereworth, Kent; and to Mr. T. S. P. Thompsett, Grove House, Hadlow, Kent.

Messrs. G. Bunyard & Co. offered prizes in two classes for the best flavoured Pears (three dishes) and the best flavoured dessert Apples (six dishes), and the competition was very good in both cases. The prizes were awarded as follows:—Pears.—Mr. W. A. Cook, Compton Bassett, Calne, Wilts, first; Mr. G. Woodward, gardener to R. Leigh, Esq., Barham Court, Maidstone, second; and Mr. F. A. Hicks, gardener to A. Cushny, Esq., Pain's Hill Park, Cobham, third. Dessert Apples.—Mr. W. Tayler, Osborne Nursery, Hampton, first; Mr. F. Bridger second; and Mr. J. T. Barney, gardener to W. Bryant, Esq., Hurstdown Cottage, Boxley Road, Maidstone, third.

An extensive show of vegetables was provided in several classes, and the quality was so uniformly good that the Judges had considerable difficulty in determining the awards. The principal class for which the Crystal Palace Company offered the prizes was that for best exhibition of vegetables, arranged for effect, and not more than four dishes (distinct) of any sort; and in this Mr. C. J. Waite, gardener to Colonel the Hon. W. P. Talbot, Glenhurst, Esher; Mr. W. Palmer, Thames Ditton House, Kingston-on-Thames; Mr. W. Salmon, Ivy Cottage, Elder Road, West Norwood; and Mr. J. T. Barney, gardener to W. Bryant, Esq., Hurstdown Cottage, Boxley Road, Maidstone, were successful in the order named, Mr. Palmer having arranged his collection very tastefully. In the other class for twelve dishes of vegetables, not more than two dishes of any variety, the prizes were secured by Mr. Thomas Wilkins, gardener to Lady Theodore Guest, Inwood House, Henstridge, near Blandford; Mr. W. Pope, The Gardens, Highclere Castle, Newbury; and Mr. J. Friend, gardener to the Hon. P. C. Glyn, Rooksnest, Godstone.

The Veitch Memorial prize of £5 and a medal was also offered for a collection of twelve kinds of vegetables, and amongst five competitors Mr. C. J. Waite succeeded in winning the coveted honours with Prize-taker Leeks, Ailsa Craig Onions, Ne Plus Ultra Beans, Sulham Prize Celery, Autumn Giant Cauliflowers, Glenhurst Favourite Tomato, Exhibition Sprouts, Intermediate Carrots, Student Parsnips, Satisfaction Potatoes, Pragnell's Exhibition Beet, and fine Turnips.

The special prizes offered by Messrs. James Carter & Co. for the best collection of vegetables, six distinct varieties, were won by Mr. Thomas Wilkins, Henstridge, near Blandford; Mr. C. J. Waite; and Mr. W. Pope.

Messrs. Sutton & Sons also present valuable prizes in the following classes, which were won by the exhibitors named. For six dishes of Potatoes, nine tubers to form a dish, to consist exclusively of varieties bearing Messrs. Sutton's name in their "Amateurs' Guide for 1891":—Mr. E. S. Wiles, Edgecote Gardens, Banbury; Mr. Jas. Simkins, Shillington, near Hitchin; Mr. W. Pope, Newbury. For three dishes of Potatoes, nine tubers to form a dish (same conditions):—Mr. R. Lye, gardener to W. H. Kingsmill, Esq., Sydmonton Court, Newbury; Mr. F. Peckover, Wardington, Banbury; Mr. C. W. Howard, Bridge, Canterbury.

The non-competing exhibits were very numerous and interesting. Messrs. J. Veitch & Sons, Chelsea, had about 180 dishes of Apples and 120 dishes of Pears, besides twenty-four dishes of Plums, all represented by fine fruits. Messrs. T. Rivers & Son, Sawbridgeworth, had an important and beautiful exhibit of fruit trees in pots, together with specimens of their special varieties. Messrs. J. Laing & Sons, Forest Hill, showed a large collection of handsome Apples and Pears. Messrs. J. Peed and Son, Tulse Hill and Streatham, also had a good collection of Apples, comprising about 120 dishes of select varieties. Messrs. Wm. Paul & Son, Waltham Cross, exhibited Apples and Pears extensively, together with Roses, Asters, and hardy flowers, as also did Messrs. J.

Cheal & Son, Crawley (who also had single and Show Dahlias tastefully arranged). Messrs. G. Bunyard & Co. had Apples, Pears, Plums, Grapes, Figs in pots, Tomatoes, and Peaches—a very effective exhibit. Mr. R. O. Smith, gardener to G. Taylor, Esq., Reigate, showed four dishes of fine Peaches. Mr. F. Michener, Avenue Road, Anerley, sent a collection of Apples and Pears grown in the district, and Messrs. R. Smith & Co., Worcester, exhibited Apples, Pears, and Plums, the Purple Prolific being a notable variety among the latter.

### CUPHEA LLAVÆ.

Most of the Cupheas are singularly attractive owing to the peculiar form of their flowers and the distinct colouring. Some also are useful plants for pots and borders, notably *C. platycentra*, which is still a favourite with many. The species, of which a flowering spray is depicted in the engraving (fig. 68), has been brought into notice much more recently, but is well worthy of a place amongst interesting plants of this character. Messrs. Pitcher & Manda of Hextable, near

FIG. 68.—CUPHEA LLAVÆ.

Swanley, exhibited plants at the meeting of the Royal Horticultural Society on September 22nd this year, when a botanical certificate was awarded for it, and it attracted some attention. As shown the plants were 9 or 10 inches high with elliptical acute leaves; the flowers have long green and reddish-ribbed tubular calyxes, covered with dark hairs; the petals relatively small, brilliant scarlet, each with a black spot at the base; and the stamens are covered with long purple hairs. The plant seems well adapted for culture in pots in a cool house.

### STANTON-IN-PEAK.

A DRIVE through these fine old Derbyshire woods and Miss Thornhill's beautifully undulated park was an unexpected treat last week, Mr. Henry Taylor, the courteous estate agent, pointing out some of the Derbyshire wonders, such as Robin Hood's stride, a most remarkable mass of rock, and the historical Router rocks. The house is approached by lodges from the Haddon Road and Winstan Road, driving through woods with two inner lodges as you enter the park. But my main object was to see the gardens, where I found the glass houses in admirable condition, very clean, and everything looking well. A range of vineries, 120 feet long inside the walls,

proved that not only good Grapes could be grown, such as Mrs. Pince, with rods carrying sixteen bunches averaging 3 lbs., and other good varieties. A first-rate lot of plants grown under the Vines speak for themselves, as Mr. Geo. Harvey has taken leading honours at Bakewell with them. *Clerodendrons*, *Allamandas*, well flowered, are samples, choice Ferns, very fine specimens of Double Zonals having immense trusses. The Vines above are not crowded, and they are kept well under. A fine crop of Tomatoes covers the back walls, one section devoted to greenhouse plants, with Peaches on the back wall, had a specimen of Rose Maréchal Niel planted in April, with rods 20 feet long; an Orange, carrying fifty ripe fruits, very fine; also quantities in other stages; *Lilium lancifolium*, with 150 flowers; *Vallotas* in 5-inch pots, with nine spikes, five flowers to the spike; and remarkably dwarf good *Chrysanthemums*, well budded, occupied some of the walks, but unfortunately suffered from recent winds.

Plums and Pears on the walls were good. British Queen Strawberry has a home here, and succeeds remarkably. Mr. Harvey keeps up yearly plantations. The flower garden has a stock of good old plants. Fine seedling Carnations, and a large bed of various Poppies, intermingled with *Chrysanthemum segetum*, 8 yards by 30 yards, had a fine effect. A conservatory in the flower garden was also very gay with *Chrysanthemum Madame Desgranges*, excellently grown. From this you approach the house, a selection of hardy flowers bordering the walk. A good plant house in partitions for growing room plants had a choice collection, very healthy and clean, and there is a number of frames well stocked. One of the most essential accessories just added is a cemented tank, with pump for draining the stables, &c., completing a good garden, and well managed under Mr. Harvey's care.—GEORGE BOLAS.

#### FRUIT FORCING.

**VINES.**—*Renovating Vine Borders.*—Though Vines thrive for an almost indefinite period in a soil suited to their requirements and where they have a good extent of rooting area, as may be seen at Hampton Court; Cumberland Lodge, Windsor; Manresa House, Roehampton, and other places, all natural soils are not suited to the growth of Grapes, and borders have to be made, and these in time renovated or renewed as the soil becomes effete.

There is nothing equal to turfy loam as an encourager of Vine roots except leaf soil, the loam having rich stores of nitrogenous elements, and the leaf soil replete with potassic substances and humus. Turf, however, may and often does settle into a close mass unfavourable, through lack of disintegrated mineral matter, to keep it open as a rooting area. Then turf, which, by containing particles of sand, limestone, and other rocks would keep porous, is often converted into a close soapy mass by a too liberal admixture of manure and vegetable refuse; but the most frequent need of renewing Vine borders is occasioned by heavy mulchings of stable manure and immoderate applications of liquid manures, particularly of that class which leave a considerable deposit. These deposits fill the interstices of the soil, and by so doing exclude the oxidising influences of the atmosphere, and the soil becomes sodden and sour. This is well known to experienced growers, and instead of soaking the borders with liquid manure, as in watering, they bring the soil into a healthfully moist condition with water, and then apply the liquid manure, by which process the thicker particles of matter in the liquid are kept at the surface and the interstices of the soil are not soon choked. When thick liquid is poured on parched and cracked borders the soil slowly but surely becomes choked with the settlements of the liquid manure. Soil must have air—atmosphere essentials for the conversion of its constituents into available plant food. This is the art of applying liquid manures which contain sedimentary matter, and their abuse is one of the most frequent reasons why the surface soil has to be so often removed from the border and fresh loam added. Want of proper drainage and improperly constructed borders are causes of unhealthy Vines and unsatisfactory crops.

These Vines are not sturdy in growth, produce long jointed wood, thin flabby foliage, bunches that twist and curl instead of developing, and Grapes that shank. No time should be lost as soon as the leaves change, and whilst they are still upon the Vines, in removing the soil down to the roots and picking it from amongst them, so that as much fresh soil as possible may be placed around and over them. If the border is very unsatisfactory and the roots deep and few, it will be necessary to remove all the soil and make a new border, commencing with drainage which may be formed of clean rubble 9 to 12 inches thick, brickbats answering well, placing the roughest at the bottom and the smallest at the top, and over this 3 inches thickness of old mortar rubbish or chalk, preferably weathered—i.e., subjected to frost and air for a year. The border must have 4-inch tile drains, so as to keep the drainage free from stagnant water. Two feet in depth of soil is ample, turfy loam off alluvial soil, or calcareous that grows good Clover, is most suitable, and preferably moderately strong, but not heavy, though that overlying clay is preferable to turf overlying sand. Good friable loam answers

well, especially if rather strong and interspersed with flints, such as occur on limestone formations.

The turf should be broken up roughly, and if heavy add a sixth of old mortar rubbish, with a similar proportion of road scrapings; if light add a fourth of clay marl, dried and pounded, incorporating all well together. Lift the roots carefully, keep them as much as possible from the drying influences of the air, shading the house, keeping it close, and the roots in damp mats, but perform the work with as much dispatch as possible. Lay the roots out evenly in the top foot of soil, encouraging those from the collar by laying any that proceed therefrom only just beneath the surface. The whole should be made firm, and the compost be moderately dry. Afford a good watering with tepid water; mulch the surface with a little short material, preferably fresh stable manure with the straw shaken out. Outside borders should be covered with a few inches of leaves and a little litter to prevent the leaves blowing about. Sprinkle the Vines occasionally and admit air moderately for a time, then freely, and they will break well the following season. The lifting must not be done until the main leaves give indications of falling, but a few laterals with immature foliage will assist root formation.

When the surface soil only is removed, and the soil picked out from amongst the roots, operations may commence earlier, for the Vines will have some roots undisturbed, and those lifted and supplied with fresh soil will push rootlets sooner and more abundantly through the foliage being active. If the roots are inside and outside one part may be done one year and the other the next without any danger of loss of crop the following season.

#### THE FLOWER GARDEN.

*Potting Plants.*—Before these lines are in print frosts will in some places have left a black mark on the tender occupants of beds and borders, and in some cases this ought to have been anticipated by taking up any it is desirable should be saved for propagating or other purposes. If not too late, the requisite number of Coleuses, *Alternantheras*, *Iresines*, *Mesembryanthemums*, and similar plants should be lifted at once. Remove much of the soil from the roots, as this is liable to sour badly, and pot singly, using a rather light compost and not very large pots, those which can be packed on shelves being the best. Place all the heat-loving kinds in a warm house at once, and water carefully both now and for some time to come. *Heliotropes* do not lift readily, but the attempt should be made if there are none already well established under glass. *Ageratums* are even more difficult to recover, and with such excellent strains available it is not advisable to pot *Lobelias*, the required number of plants being the most simply raised from seed sown now or early next February. Tuberous *Begonias* lift readily enough, but fail to flower directly dry frosty weather is experienced, and these therefore may well be stored thickly in boxes, only a little soil being moved with the balls. There is no good reason why they should not be left where they are till frosts cut down the tops. Keep them, when lifted, in a cool dry place, giving additional protection in frosty weather. Several of the fibrous-rooted *Begonias*, including *Carrierei* and *semperflorens*, make excellent bedding plants, and these, if potted before frosts blacken them, and placed in a warm light greenhouse, will flower freely throughout the winter. *Marguerites* pot readily, and large plants will be found serviceable for conservatory and house decoration. The same remarks apply to *Abutilons* generally, and the attempt should also be made to lift late flowering *Gladioli* and *Asters*. Some of the *Dahlias* are now at their best, and would be useful in conservatories till *Chrysanthemums* are more plentiful. They lift fairly well out of moderately light soils. *Chrysanthemums* move readily, even if in full flower, but care should be taken not to unduly reduce the size of the balls. At the same time do not try to move large balls of soil with the roots, or great lumps of it may break away, carrying the roots with it. The safest plan is to pot them on the ground where growing. A slightly heated greenhouse is the best position for the plants. Keep them well supplied with water, syringe frequently on clear days, and afford shade from bright sunshine. A portion of the plants might well be moved to the foot of sunny walls where they can be readily protected with mats. Zonal *Pelargoniums* will stand a little frost, but are of little value now in the flower garden; therefore fork all up that are to be saved, taking particular care of the bronze, silver, and tricolor sections. Lightly reduce the length of roots, and pick off all the old leaves prior to packing the plants thickly and firmly in boxes or pots of loamy soil. Keep them on the dry side throughout the winter, and frost being kept out of the houses abundance of good cuttings ought to be available next spring.

*Bulbs for Spring Flowering.*—Fresh stocks of *Hyacinths*, *Tulips*, *Narcissi*, and *Scillas* have always to be bought, the old bulbs or those that spring from them rarely flowering at all well the second year. Nor do *Crocuses* and *Snowdrops* move well, the best effect in the two latter instances being obtained with the aid of undisturbed roots. All, however, can be bought at much cheaper rates than is the case with bulbs to flower in pots. Order and plant early; the *Hyacinths* and *Narcissi* 9 inches apart each way, and 4 inches deep; and *Tulips* 6 inches apart, and also 4 inches deep. Double or triple lines of *Scillas*, *Crocuses*, and *Snowdrops* are needed to make anything like a good show, and the bulbs of these may be from 3 inches to 4 inches apart each way, and 3 inches deep. If preferred the bulbs generally might be interspersed among the dwarf shrubs, Conifers, and flowering plants, but if they have beds to themselves these may well be surfaced over with short branches of *Aucuba*, *Hollies*, *Ivies*, *Box*, and such like, arranged in masses and lines.

Having their ends thrust into the beds these short tops will present a neat and fairly attractive appearance during the duldest part of the year.

## THE BEE-KEEPER.

### APIARIAN NOTES.

SINCE bringing my bees from the moors the weather has continued wet and stormy, considerably delaying preparations for the winter. On overhauling my hives I was surprised at the singular failure of the queens of stock hives to become fertile. There is only one swarmed stock hive that has a fertilised queen, while not a single one of all the nuclei raised has failed. This is all the more remarkable, as in other years nuclei were, as a rule, the last to become fertile. But what adds more to the singularity other hives besides my own are on a similar footing, many hives throughout the country being either queenless or have drone breeders. I have given away all my surplus queens, and have still inquiries for more.

#### SWARMING

took place this year before the hives were nearly crowded, fully disproving the argument that timely room will prevent it. Then the prime swarms superseding their year-old queens with young ones further demonstrates that extra room will not prevent swarming.

This abnormal state of matters at swarming time no doubt arose from the queens seeking a rest from over-exhaustion by continuous laying from January up till 8th June, that most fatal day of any throughout the year to bees. It was allowed by many experienced bee-keepers, that with a few days more of such weather few bees if any could have survived. The safety of bees during winter never gave me any anxiety, spring being the most anxious time; but now it appears that it is the summer months we have most to dread.

#### PUNIC BEES.

I am flooded with inquiries about these interesting bees. Some of the persons appear to have a similar impression as "A. Hallamshire Bee-keeper," that "I have given them an indifferent report." I gave a most faithful report, although I stated that I could not confidently recommend them as honey gatherers. How could I? The bees had no chance. There was not a single day the honey was plentiful since I had them, and although the Punics were 2 lbs. light, if the reader re-reads the article attentively, and considers the comb-making the Punics had to do, and their fewness in number compared to the others, he will be compelled to conclude the Punics had been the most industrious. I am satisfied the Punics are superior in many respects to other varieties, but I cannot say they will gather more honey until I have ocular demonstration in a good season under a fair trial. Since I brought them home they have been and still are working more vigorously than any other variety, while nuclei having Punic queens have far more young bees; and, what is as satisfactory, every queen I presented has excelled in honey gathering while their combs are beautifully white, thus these bees have done enough to earn for themselves the reputation of the best honey gatherers; but another season must come and go before the pure Punics' honey gathering qualities will be known by me.

I trust the foregoing explanation will satisfy all concerned for the nonce, and that after a little time with patience, until summer weather comes, they may rely upon me—if spared—to give an accurate account of their and of others' doings. Meanwhile, do not lose a good chance of punicising your apiaries.

When drawing out the ventilating floor at the moors I discovered what I took to be quite a heap of sealings of drone cells. Thinking the Punics had been working on similar lines as other varieties do, building drone cells after the bees were increasing

from their first cluster, after they were home I examined them, but found no drone comb as expected, all worker. The question now is, Do the young Punics when leaving the cell set themselves free in the same manner as drones do, and are the seals of workers different in any way from the seals of other varieties? Will "A. H. B. K." say if he has observed, although the Punic is a smallish looking bee, its worker cells measure  $9\frac{1}{2}$  to the 2 inches? Those I have measured are of this size.

#### PREPARING FOR WINTERING.

As bees winter better on sugar than Heather honey, but breed better on the latter, I have fed all stocks with several pounds of sugar; this insures safer wintering, while it preserves the honey for breeding during the earlier part of the year, and raising the temperature of the hive enables the bees to gather the scattered honey and store it above the cluster of bees, the proper place for honey at all times.

Although bees are better to be left alone after September, it is not too late in the season to administer a few pounds of sugar to each hive, so as to reduce abdominal distension to the lowest degree, should the winter be severe.

#### FLOOR BOARDS.

Care should be taken that floor boards do not retain moisture, nor project in any way to draw it to the interior of the hive, the ventilating floor and the insensible upward ventilation obviate all this.—A LANARKSHIRE BEE-KEEPER.

#### TRADE CATALOGUES RECEIVED.

William Rumsey, Waltham Cross.—*Catalogue of Roses.*  
J. Cheal & Sons, Crawley.—*Catalogue of Trees and Shrubs.*  
G. Phippen, Oxford Road, Reading.—*Bulb Catalogue.*  
Dammann & Co., Naples.—*General Catalogue of Plants and Seeds.*  
Wm. Paul & Son, Waltham Cross.—*Catalogue of Roses.*  
Pitcher & Manda, New Jersey and Hextable.—*Bulb, Orchid, and Plant Catalogues.*  
E. P. Dixon & Sons, Hull.—*Catalogue of Roses, Fruit Trees, and Ornamental Trees and Shrubs.*  
Jno. Jefferies & Son, Cirencester.—*Catalogue of Roses and Trees.*  
E. H. Krelage & Son, Haarlem.—*Catalogue of Darwin Tulips.*  
Ketten Frères, Luxembourg.—*Catalogue of Roses.*

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Books (L. B. G.).**—The following books will probably meet your requirements, and you can obtain particulars as to prices from the respective publishers. "The Rose Garden," from Messrs. Wm. Paul and Son, Waltham Cross; "Stove and Greenhouse Plants," Messrs. B. S. Williams & Son, Victoria and Paradise Nurseries, Upper Holloway, or "Greenhouse and Stove Plants" by Mr. T. Baines, from J. Murray, Albemarle Street; "British Ferns," by Mr. Druery, from Upcott Gill, Strand; and "The Handbook of Hardy Trees and Shrubs," translated by Mr. Helmsley, from Longmans, Green & Co., 39, Paternoster Row.

**Tomatoes (A. C.).**—We are glad to see the fruits, for that was the only purpose to which they could be put, for all were over-ripe, some crushed and broken. Of the Reds Dickson's Carentan is distinctly the

best you have sent. Ruby was crushed. Yellow King and Sutton's Golden Nugget are extremely attractive, and we know them to be good in quality. We prefer Conference to Challenger, and like Ham Green Favourite better than either. We know you had finer fruits some time ago or they would not have won prizes in strong competition.

**Vine Laterals** (*Subscriber*).—We presume your house is not heated, or the Grapes would not be so late and the laterals so unripe. You may remove all growths from above the bunches except one leaf on the main lateral, also the whole of the growths below the bunches except the main leaves. This will admit all the sun there may be to the foliage retained, and facilitate the maturation of the wood. If the sub-laterals are numerous it will be prudent to half shorten them at once, and two or three days afterwards remove the remainder. Early Gladioli of the ramosus section may be planted now, corms of the gandavensis varieties in spring.

**Peat Moss Litter as Manure** (*J. E.*).—After passing through stables this will be excellent for incorporating with your heavy clay, because of the humus it will impart, as well as the manurial elements it will contain. We should much prefer it to "heavy cow manure" for strong land, but should not apply it in a very wet state. It is one of the best mediums for mulching fruit trees, Vine borders, and anything else. Dried and pulverised it will be serviceable for mixing with heavy loam for potting. When suitably dried it is good for use in Mushroom beds, and has produced excellent crops, as you will find on consulting Wright's "Mushrooms for the Million."

**Name of Caterpillar** (*S. H. H.*).—It is the species known popularly as the peppered moth (*Amphydasis betularia*). The caterpillars feed in gardens or near them on the Birch, Lime, Robinia, and other trees or shrubs, and occasionally the moth deposits an egg on the Rose. Most years they have entered the pupal state by the middle of September, but this is a late season. It is not an abundant insect, but is found in many places. We would have returned it, as you requested, had not the caterpillar in its journey sustained injury which caused its death. The moth emerges from its chrysalis in May usually; there is only a single brood yearly. The paper box was flattened in the post.

**Nectarines Quartering** (*J. C. C.*).—The usual cause of Nectarines quartering is a deficiency of atmospheric moisture in the early stages of swelling up to and including stoning. The skin thus becomes hardened, and when the fruit swells for ripening the skin does not grow correspondingly with the flesh, and splitting ensues, generally at the apex, and as swelling proceeds the crack enlarges, sometimes so deeply as to expose the stone. The only remedy is more moisture both at the roots and in the atmosphere during the early stages of swelling and past the stoning process, and less moisture as the fruits approach maturity. Peaches are less prone to "quartering" because their skins are downy, and on that account not so liable to induration by an arid atmosphere as is the smooth and more sensitive skin of Nectarines.

**Clematis Dying Suddenly** (*T. L.*).—Sometimes Clematis die off suddenly because their union with the rootstock upon which they are grafted is not complete, when the plant collapses altogether. Occasionally the growths die back to firm wood near the base, and is due to some injury to the stem, sometimes caused by slugs, at others by beetles, or by a fungus which destroys the tissues, the same as or allied to that causing the collapse of *Calceolarias*. Some galvanised wire acts corrosively on plants trained to it, which can hardly be the cause of the plants dying off in your case, as some are not affected by it. If caused by the wire, painting with whitelead paint, or other colour of which lead forms the body, is the cure. Clematises do not long remain healthy in soil destitute of lime.

**Mrs. Pince Grapes** (*L. C.*).—This Grape is upon the whole one of the most difficult to set its fruit and finish satisfactorily. The Vine does not show fruit freely when very closely pruned, and it does not set well on growths from indifferently matured wood. Artificial impregnation is often necessary to ensure a good set of berries. The cause of the small berries in your case is defective fertilisation. To grow this Grape well the Vines should be started in February or early March. By drawing a camel's-hair brush or bunch of feathers over the bunches when flowering and using pollen from Black Hamburgs or other free setting Grapes the berries will set, and by not overcropping and allowing somewhat free growth in the laterals the Grapes swell well, forming handsome bunches, and perfecting fruit of superior quality. The white Grape is Trebbiano.

**Moss and Weeds on Lawn** (*J. E.*).—A mixture of two parts wood ashes and one part soot applied at the rate of a peck per rod (30½ square yards), or 40 bushels per acre, has an excellent effect on lawns. The dressing should be applied evenly in February or as soon after as the weather is favourable early in the year. To destroy moss on badly infested lawns apply half a bushel of wood ashes per rod in autumn, and in spring dress with soot during moist weather at the rate of a peck per rod, which will encourage the grass. The above may be had in most places for the trouble of saving. Bonemeal is excellent as a top-dressing for lawns, and should be applied in autumn or early spring at the rate of 10 to 15 cwt. per acre, and is better adapted for light than heavy clay soil. Dissolved bones—i.e., superphosphate, may be applied at the rate of 5 cwt. per acre in autumn or early spring, but this is less durable in its effects than bonemeal. Both are very useful dressings,

encourage grasses, and proving prejudicial to weeds. Sulphate of iron, 1 cwt. per acre, distributed evenly when the ground is moist, destroys moss and benefits grass.

**Tomato Leaves Shrivelling** (*S. S.*).—The cause of Tomato leaves "drying up like tinder" may be sun acting powerfully on them after a period of dull weather resulting in scorching, when they will become whitish yellow at first, turning to brown; or insects, such as red spider and white fly, abstracting their juices, causing the leaves to die yellow or brown, and to slowly collapse; or fungus destroying their tissues, when the young foliage turns black under powerful sun after a dull period; but the older leaves develop brownish patches covered with a greyish powdery substance, with a depressed spot in the centre of a brownish colour, and the dead leaf when squeezed in the hand falls into "tinder." The plants do not bear syringing with weak softsoap water nearly so well as do Roses, for Tomatoes have hairy leaves, and the softsoap adheres to their surfaces and clogs them. If the plants are affected with the fungus *Phytophthora infestans*, they may be sprayed with a 2½ per cent. solution of sulphate of copper and lime—that is, Bordeaux mixture, or dusted with anti-blight powder. To have Tomatoes ripe early in April next year the plants should be raised from seed, or preferably cuttings now, and kept near the glass until January, when they should be transferred to the fruiting pots or beds.

**Skeletonising Leaves** (*J. S.*).—Nearly all leaves may be skeletonised, but some require a longer time than others to become macerated. For instance, the seed vessels of the Winter Cherry, Henbane, and Poppy require a fortnight or three weeks if the weather be hot. Leaves of *Ficus elastica* (Indiarubber Plant) and *Magnolia grandiflora* require several months; leaves of the Tulip Tree, Poplar, and Maple a fortnight; leaves of the Holly and Ivy two or three weeks. Ferns require a long time, and so do the leaves of Beggars' Broom, Butchers' Broom, the Orange, Lemon, and Camellia. Great care must be taken in choosing the leaves, as the smallest speck spoils one. Many more should be placed in the water than are needed, as not more than one in twenty will be perfect. The time required depends on the weather. Beginners examine them too soon. The leaves should be put into soft water in a sunny situation, taking care that they are covered with water. Evergreen leaves may be skeletonised at any time, but deciduous leaves not before the end of June or beginning of July. Seed vessels must be operated upon when nearly ripe. When quite ready for skeletonising put the leaves into boiling water to remove the offensive smell. Remove the scum from the water. Brush off the pulp with a rather hard brush. If the leaves are tender bump them gently, which removes the pulp without disturbing the nerves of the leaves. Pour clean water over them until quite clean; put them on blotting paper to dry—a piece of glass is useful to brush them on. Tender leaves should be floated in water and caught on a card, as are fine Seaweeds. Bleach with chloride of lime, and then wash them thoroughly with clean water, otherwise they become yellow. It is better not to bleach them until required for setting up. Thistles and Teazels look well when bleached, and aid much in arranging a group.

**Names of Fruits.**—*Notice.*—Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. *In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing.* The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*Thomas Bradshaw*).—The Peach is probably Royal George, but we cannot say decidedly without leaves, and knowing whether the flowers are large or small. Damson, Shropshire Prune. Apples.—1, Mère de Ménage; 2, Not known. (*Amateur*).—1, Tower of Glamis; 2, Winter Hawthornden; 3, Bess Pool; 4, Not recognisable; 5, Dumelow's Seedling, a splendid specimen; 6, Mère de Ménage. (*H. H. D.*).—Louise Bonne of Jersey. (*Nemo*).—1, Emperor Alexander; 2, Herefordshire Costard; 5, Emperor Alexander. The labels were off the other specimens. The Clematis is a variety of lanuginosa. (*W. R. R.*).—1, Reinette de Canada; 2, Cox's Pomona; 3 and 4, Blenheim Pippin; 6, American Mother. (*Anthony Oliver*).—2, Cockpit; 3, Beauty of Kent. (*W. D. & Son*).—25, Ribston Pippin; 22, Golden Knap; 16, Comte de Lamy; 13, Duchess of Oldenburg; 18, Easter Beurré; 20, Claygate Pearmain. We only name six fruits—see note above. (*Walter Jinks*).—1, Golden Winter Pearmain; 2, Beurré Clairgeau; 3, Kerry Pippin; 4, Cox's Orange Pippin; 5, Herefordshire Pearmain; 6, Louise Bonne of Jersey. (*W. S.*).—4, Winter Hawthornden; 5, Hall Door. The others are probably local. (*J. W.*).—1, Tyler's Kernel; 2, Dumelow's Seedling. (*S. S.*).—Fondante d'Automne. (*Farnborough*).—1, Knight's Monarch; 2, Worcester Pearmain; 5, Beurré Superfin; 6, Norfolk Bessing. (*A. M. M.*).—1, Doyenné Boussoch; 2, Van Mons Leon Le Clerc. (*R. W.*).—1, Peasegood's Nonesuch; 2, Reinette de Canada; 3, Golden Winter Pearmain; 5, Duchess of Oldenburg; 6, Cellini. Some correspondents have withheld their names and addresses, and one has not even given a signature. Fruits cannot be named when our simple conditions are not complied with. Several fruits cannot be named because the numbers were pinned into the eyes, destroying the segments, one of the guides to identification.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*Cotswold*).—1, *Abies americana*; 2, *Quercus Cerris*; 3, *Pinus Strobus*; 4, *Pinus Cembra*; 5, *Pinus excelsa*; 6, *Cupressus Lawsoniana*. (*R. C., Edinburgh*).—2, *Retinospora plumosa*; 4, *Juniperus chinensis*; 6, *Cupressus Lawsoniana*. The others we are uncertain about. You might compare them at the Edinburgh Botanic Garden. The curator will also readily inform you of their method of drying Conifers. (*L. C.*).—1, Doubtful without flowers; 2, Not yet identified; 3, *Rivina levis*; 4, *Doodia aspera*; 5, Shrivelled; 6, *Bambusa Fortunei*.

### COVENT GARDEN MARKET.—OCTOBER 14TH.

HEAVIER supplies of Cobs. Trade brisk.

### LIMING LAND.

THE wet summer has been most unfavourable to the work of dressing land with lime by the old plan of bare fallow and lime, nor do we favour the plan, no matter what the season may be, whether wet or dry. The only thing to be said in its favour is

that between haysel and harvest the horses may sometimes be spared to cart lime, and that is why it is done then.

Well, now we have especially in mind heavy land, that heavy, dense, clayey soil, whose adhesion we are so anxious to break up and render friable. For we forget not that the quality of soil depends chiefly upon its mechanical state, and we are bound to do our utmost to break up the tenacious, inert mass, into which we must have air and warmth enter and circulate freely if would have crops full and bountiful as we ought to do.

Clay fires have been kept going all the summer long, notwithstanding the rain, and a grand store of ballast have we now being carted on the land, which was limed last year, and which, therefore, has had a start—a good one indeed; for was it not drained in the previous winter, and has not our work of reclamation been as progressive as gradual?

Mechanical division? Yes! that is what we want, and we sometimes wonder if our Scotch friends have enough of it with their mighty dressings of cowdung. There is no doubt that such rough manure as they plough in so deeply does open up the land for awhile. But we aim at something more permanent in character, while avoiding anything like a heavy outlay.

Lime is not expensive if you are within carting distance of a kiln, and sixty or seventy bushels an acre is a tolerably fair dressing, which we do not often exceed except for blue lias clay, and then the temptation to apply an extra quantity is perfectly irresistible, for we know how greatly it is needed, and what great good it will do.

Having cleaned the land, the lime is placed in small heaps containing two or three bushels, to be slaked by atmospheric moisture, which is generally plentiful enough at this season of the year. It is then spread and ploughed in, or worked in with a cultivator, the aim being to mingle it with the soil as thoroughly as possible. Its effect upon the soil is varied and important. It unites with felspar or clay, setting free potash or other alkalies. It acts on vegetable matter, setting free ammonia, water, nitric acid, and carbonic dioxide, tending to destroy excess of humus. It neutralises organic acids, and so "sweetens" soils. It takes up the nitric acid, is a plant food in itself, aids in the formation of silicates, and opens up clay soil from the curdling effect it has upon its particles. It also renders harmless injurious salts of copper, iron, &c.

Not often is it that farm land has a superabundance even of humus in it. When it has lime is highly beneficial, but it should not be applied long before a crop is sown, but rather as the soil is in course of preparation for a crop.

For clay land there can be no better time than the present, only the work must be prompt, as it is all-important to work in the lime immediately after it is slaked, and there can be no certainty about this when autumn becomes far advanced and the weather broken. The carting, spreading, and ploughing are therefore made to follow each other closely, our aim being rather to get the lime into the soil than to wait till it is all slaked, and a turn or two of the cultivator or drag harrow, when a favourable opportunity offers, serves to mix the lime well with the soil.

Opinions differ as to how often lime may be applied with advantage, but we are strongly of opinion that frequent moderate dressings are desirable in all heavy clay land for all the reasons we have given. We have long been accustomed to make compost heaps by mixing road sidings, coal ashes from the nearest town (always load back when you send in corn or other produce), and some rough farmyard manure. This is turned once, bringing up the thick bottom layer of road sidings to the top. It is turned again before it is carted on to the land, and previous to this the top is covered with lime fresh from the kiln. As the heap is turned

due care is taken to work all the lime into the interior of the heap ; it is then carted and ploughed-in at once, and is good for any land.

#### WORK ON THE HOME FARM.

The flock now requires special attention to get the different sections of it well in hand for the coming winter. If our hint given a month ago about the autumn dipping of sheep had attention, the whole of the sheep have now clean wool, quite free from tick or seab, or parasites of any sort. They are thus free from irritation and the incessant itching which besets an undipped flock, and which tells so seriously upon condition. But there is another evil demanding our best attention, and that is foot rot, if we are so unfortunate as to have it among our sheep. We have repeatedly pointed out that there is no complete cure for this infectious disease. It can be subdued so thoroughly that there may not be a lame sheep in a flock, but once there and it may break out at any time. There need be no great number of bad cases in any flock if the feet are examined at least once a week, or more frequently if necessary. Let the patients have most careful and gentle treatment. If possible place all sheep with sore feet together, apart from the remainder of the flock ; then examine them daily, sponge off any discharge or filth from the affected part (usually between the claws), pare off any loose part of the hoofs, and carefully dress with Gell's foot-rot ointment. Bad cases may require the affected foot to be placed in a bag secured to the leg with tapes.

The most difficult cases are those having swollen feet without any exterior wound or discharge of pus. These we invariably treat by inserting the foot in a bag containing a linseed meal poultice, bathing daily till a discharge of pus is induced, when the swelling is soon reduced and the foot healed.

There is much brutality on the part of shepherds hacking away at broken hoofs with a large, clumsy, blunt knife, causing much bleeding, and needless suffering to the sheep. Let masters see to this, for it is rare indeed that bleeding need be caused. To understand this every flock master should take some of the sheep in hand himself, treating and watching cases till they are cured. Many shepherds are difficult to manage, and are not willing to receive orders about the treatment or care of their charge.

Nothing can be more deplorable than the sight of a neglected flock folded on Turnips now. They go limping about in the mud, rubbing their itching bodies against every hurdle they come to, and are never at rest or free from pain. Such a state of things is a shame and disgrace to all concerned in the ownership or care of the sheep, and the pity of it is that it might all be so easily avoided.

#### REPORT OF THE CLOVER AND GRASS SEED HARVEST OF 1891.

In reviewing the situation, kindly note that we simply express our opinions, doing so in good faith, but we cannot be responsible for the outcome, as it is impossible for anyone to predict the future. There are so many contingencies to be taken into consideration, which are beyond human control, that we can simply give what at the moment appears to us to be as nearly correct an estimate as it is possible to supply.

**Red Clover** (*Trifolium pratense perenne*).—The reports from the Continent of Europe are generally disappointing, large areas were ploughed up after the severe winter, and heavy rains have since destroyed or damaged those crops that survived the winter. American advices speak of considerable damage in many districts by grasshoppers and weevil.

There is a fair acreage of English seed being grown, the condition of which must be entirely governed by the state of the weather at the time the seed is harvested. Irrespective of origin many samples of Red Clover that we have seen bear evidence of being weather stained. American samples are again small and wanting in colour. Values at present show considerable advance upon those at the end of last season.

**White Clover** (*Trifolium repens*).—The European crop of this article outside Great Britain is reported to be a fair one in quantity, but the quality will be below the average of previous years, the seed being more or less damaged by the excessive rains. American advices indicate a fair crop, but as this seed is always very much smaller in the grain than European seed it is not so much sought after. Present values about the same as at end of last season's sales.

**Alsike Clover** (*Trifolium hybridum*).—European reports of this crop are generally very unsatisfactory. The quantity produced is supposed to be smaller than it has been for many years, and where the rains have been constant and heavy the samples will be seriously prejudiced.

American advices speak of a fair average crop of good quality but seed from this district will contain a larger quantity than usual of White Clover.

Present prices are firm, but values may become a little easier than at the end of the selling season last year.

**Trefoil** (*Medicago lupulina*).—Trefoil is a considerable crop both in England and on the Continent, but as much of the seed was not harvested until after the rainy season set in, the quality will be below the average of the past few years, and prices may be expected to continue firm for bright samples.

**Lucerne** (*Medicago sativa*) is a fair average crop.

**Timothy** (*Phleum pratense*).—Again the quality of the new deliveries of this seed is very satisfactory. This fact, combined with the extensive area under cultivation, and the considerable surplus held over in the producing districts last year, will probably have the effect of making the market easy during the present season.

**Rape**.—Reports from the producing districts, both in England and on the Continent, state that almost the entire crop was destroyed by winter frosts. Good conditioned seed comes high in price at the present time, and may be expected to reach even a higher range shortly.

**White Mustard**.—Fair average crop so far as present advices indicate.

**Swedes, Yellow and White Turnips**.—Crops of these seeds were got in under fairly favourable circumstances, but in addition to damage by the severe winter, the plants during the flowering period were in many districts attacked by a black flea, which rapidly destroys that portion of the plant, with the result that the outcome in bushels per acre is very seriously reduced.

Scotch yellows are represented by very limited quantities, and at the present time make higher values than they have done for several years.

#### GRASS SEEDS.

**Rye Grasses** (*Lolium perenne* and *italicum*).—Early advances indicated fair average crops, but the rains that were experienced at a later period have had the effect of damaging the seed, and prices have been gradually and firmly advancing ever since. It is also believed there is a smaller average than usual. This fact, combined with the somewhat unusual and important demand for shipment, tends to make holders very firm in their ideas of price, and it is not expected that any important change will be found in these articles during the year, in the shape of lower values.

**Agrostis stolonifera** (Fiorin).—The home crop of this article is again a fair average one, and the market reports speak of satisfactory crops ; it should be borne in mind that American samples of *Agrostis* generally abound in ergot.

**Alopecurus pratensis** (Meadow Foxtail) is again a fair average harvest, both in quantity and quality. Values may be expected to be reasonable.

**Cynosurus cristatus** (Crested Dogtail) is a very short crop, both in Great Britain and on the Continent, and it is probable before the season is over this seed will be practically unobtainable in quantities.

**Festuca duriuscula** (Hard Fescue) is a fairly plentiful crop, and seed has been harvested in average condition.

**Festuca pratensis** (Meadow Fescue).—The report of this crop from the producing districts speak of a good average output, and reasonable prices may be expected.

**Poa pratensis** (Smooth Stalked Meadow Grass).—The crop of this article is again very short, and as no surplus seed could possibly be carried over from last year, prices will rule high.

**Poas nemoralis and trivialis** (Wood Meadow and Rough Stalked Meadow Grasses).—Smaller acreages than usual of these Grasses appear to have been under cultivation, and with only a moderate harvest prices are likely to be very firm.—JAMES CARTER & Co., 237, 238, 246, High Holborn, London, and Mark Lane, E.C.

#### OUR LETTER BOX.

**Guernsey Cows** (*W. R. R.*).—If you go to a dealer you will, of course, have to give £20 and upwards. Watch for announcements of auction sales, and then you may obtain useful animals at the price we mentioned. There are usually plenty of such sales at this season of the year.

#### METEOROLOGICAL OBSERVATIONS.

#### REMARKS.

4th.—Misty early ; bright day.  
5th.—Misty early ; a little sun in morning, but generally dull and cold.  
6th.—Dull drizzly morning ; wet from 1 P.M., and steady heavy rain from 3 P.M. to 11 P.M.  
7th.—Alternate bright sunshine and cloud ; heavy rain at 11.45 A.M., and with thunder and hail at 0.50 P.M. ; bright afternoon, and heavy rain again from 11.9 P.M. to 2.0 A.M. on 8th.  
8th.—Bright almost throughout.  
9th.—Dull and damp early, generally overcast in morning ; bright afternoon.  
10th.—Overcast and misty till 10 A.M., then dull and showery.  
A damp week, of nearly average temperature.—G. J. SYMONS.

CONSIDERABLE attention is now being devoted in rural districts to the extension of education in useful gardening amongst cottagers, allotment holders, and those in the occupation of small plots of land. The matter is being taken up very earnestly by several County Councils, and there is every prospect, under well-devised systems, of much good being performed. In one county Mr. J. Wright has prepared an admirable course of lectures, covering the whole subject in an efficient manner. I have been invited to undertake a similar task for a neighbouring county, and several Fellows of the Royal Horticultural Society, and other organisations, are already engaged in duties of this character. Before the termination of the present County Councils' period of office, horticultural and agricultural instruction will be in full progress under the conditions of the Technical Education Act in numerous districts, and the new Councils will have the opportunity of benefiting by the experience of their predecessors. At present it seems, to a large extent, to be merely experimental. There is no generally recognised authoritative scheme of working, and the result will be that many different methods will be adopted, and anything like a uniform test of the instruction imparted will be impossible. In some cases it is expected that the instructor will cover the whole range of the subjects in an elementary form in four lectures, to be delivered in different districts in succession, each course to be complete in itself. Another plan provides a course of twelve lectures, and others are arranged upon a two or three-years system of six lectures each, gradually advancing in importance, but each affording a complete stage to be tested at the end of the respective seasons. The character of the instruction imparted should, of course, be chiefly regulated by the requirements of the various districts; it will then not only excite more interest, but will be of more real service than otherwise. In one place fruit culture would be the prominent feature, in another vegetables would occupy the leading position. Allotments might, in some instances, be the prominent considerations; in others, cottage gardens or small farms. In all, it would, however, have to be borne in mind that the lectures or lessons are not intended for gardeners, or to add to their ranks, but to enable the bulk of the people in rural districts to improve the culture of such small plots of land as might be within their reach; to add to their home supplies; possibly, in suitable localities for marketing, to aid in extending slender means; and, above all, to give the rural population greater inducements to remain in the country, and to check the continual flocking into towns. The objects are so worthy that they deserve every effort on the part of all concerned in the welfare of the people to accomplish them, or at least to give the matter so thorough a trial that its success or otherwise can be fully demonstrated.

Apart from the County Council system of horticultural education, another of a more elementary kind is likely to be adopted in country schools. At the special request of one of the leading authorities in educational matters the British Fruit Growers' Association was invited to prepare a scheme of progressive education in horticulture adaptable to schools that could be submitted to the Education Department for incorporation in a new code. A sub-committee was appointed to prepare a draft, which was submitted to a special Committee under the

chairmanship of Sir James Whitehead, Bart., and including amongst those present Dr. M. T. Masters, F.R.S.; Dr. J. Stanislaus Makovski, A. H. Smee, Esq., of the Surrey County Council, and several practical horticulturists. The matter was discussed at considerable length, and it was ultimately resolved that the scheme to be recommended should assume the form of a three-years course, the first stage to be devoted to an elucidation of the principles of plant life, not on a botanical basis, but in strict application to cultural requirements. The second stage would deal with the elementary operations of gardening, to include the description and use of the implements required. The third stage would be simply an extension of the second, giving fuller details of the respective operations, and referring briefly to fruit, vegetable, and flower culture, insects and fungi, and other general matters. It is especially intended that the principles and operations dealt with should be practically demonstrated at every step, and in some cases it is thought that for a suitable fee qualified gardeners in the various districts would occasionally undertake this task. Where convenient or desirable the pupils in the third stage could perform the simpler work under the direction of the teacher, who in the two earlier stages had acted merely as a demonstrator.

To give a better idea of the scheme, the synopsis adopted is subjoined, and could be divided into any convenient number of lectures, though forty were suggested as a suitable number for each stage.

#### First stage.

##### PLANT LIFE.

##### SEEDS, NATURE OF, AND GERMINATION.

Requirements of growth, water, heat, air.

##### SOILS.

Nature and composition.

##### ROOTS.

Nature and functions.

Branches, fibrils, and root hairs.

What they do, and how; what helps, what hinders them.

##### STEMS AND BRANCHES.

Their nature.

Work and uses.

Helps and hindrances.

##### LEAVES.

What they are, what they do.

Helps and hindrances.

##### BUDS AND TUBERS.

Leaf buds, flower buds, tubers.

##### GROWTH.

Increase in size and changes of composition.

Formation and storage of food materials.

##### FLOWERS.

Their component parts.

What they do.

##### FRUIT.

Changes and development during ripening.

Forms and varieties, as Apple, Strawberry, Plum, &c.

#### Second Stage.

##### ELEMENTARY OPERATIONS.

*Description and use of implements under each head.*

##### OPERATIONS CONNECTED WITH THE LAND.—With explanations and illustrations of good and bad methods.

Digging and trenching.

Draining.

Hoeing, stirring the soil, and weeding.

Watering.

##### PREPARATION OF SEED BED.

Rolling and raking.

Sowing, transplanting, and thinning.

##### POTTING.

##### PLANTING.

Positions and shelter.

Staking.

Earthing and blanching.

##### PROPAGATION.—Elementary principles.

Cuttings.

Budding.

Grafting.

Layering.

##### INSECT AND FUNGUS PESTS.

*Third Stage.*

## ADVANCED PRACTICE.

- BUDDING.
- GRAFTING, AND STOCKS USED.
- LAYERING.
- DIVISION.
- BRANCH PRUNING.
- ROOT PRUNING.
- Old and young trees and bushes.
- FRUIT CULTURE.
- Open air and under glass.
- Small fruits.
- Apples and Pears.
- Stone fruits.
- Gathering and storing.
- Packing and marketing.
- VEGETABLE CULTURE.
- Tubers and roots.
- Green vegetables.
- Fruits and seeds (Peas, Beans, &c.).
- Rotation of crops.
- FLOWER CULTURE.
- Outside and under glass.
- MANURES AND APPLICATION.
- TREATMENT OF INSECT PESTS.
- TREATMENT OF FUNGUS PESTS.
- GENERAL KNOWLEDGE OF FRUITS.

This has been duly submitted to the Education Department, favourably received, and is under consideration. In the meantime, however, it is thought desirable to make it as widely known as possible through the Press in order that schoolmasters, teachers, or others interested in the matter may communicate their opinions as to its suitability. If also it were deemed desirable to commence the scheme in any school application could be made at once with that purpose in view, and when it is finally accepted a grant could be earned in the same way as for other subjects.

As a special subject not included in the ordinary school curriculum one difficulty will be the instruction of the teachers; but here the County Council's scheme would prove useful, and in some cases classes are being specially formed for teachers with this object in view, and the matter is being taken up with considerable enthusiasm—LEWIS CASTLE, *Hon. Sec. British Fruit Growers' Association, Hotham House, Merton, Surrey.*

## POTATO DISEASE EXPERIMENTS.

In consequence of the great continental reputation of the Bordeaux mixture, Bouillie Bordelaise, as an antidote to mildew on Vines, some experiments were made in Belgium, France, and Ireland for testing its effects on Potatoes for preventing or mitigating the disease. The results appear to have been such as to lead the Board of Agriculture in co-operation with the Royal Agricultural Society to have further experiments conducted in various parts of the country this year. In results these trials appear to differ considerably, in some cases the dressings having proved beneficial, in others somewhat the reverse, while in others again they had no appreciable effect either one way or the other.

Amongst other trials for testing the merits of the "broth" were an extensive series in the Potato trial grounds of Messrs. Sutton & Sons, Reading. These proved to be of such a remarkable character that a number of gentlemen interested in the subject were invited to inspect them last Friday. After passing through the establishment, which astonishes by its magnitude and completeness, the visitors, numbering about fifty, found themselves in the handsome lecture hall, where an excellent luncheon awaited them. After the close of the repast Mr. Martin John Sutton gave his friends a hearty greeting, and asked them to join him in drinking the health of the "Queen and Royal Family," pleasantly recounting his association with them. He then explained the object of the gathering. It was in no sense of a business character. It occurred to them when experiments were invited on prescribed lines for combating the Potato disease, that they had in their collection of 278 varieties of Potatoes in 810 rows or plantations, grown under absolutely identical conditions, one of the best possible opportunities for giving the remedy a full and fair trial. With the object of doing this half the rows or plants of the different varieties were dressed with Bouillie and the other left undressed. The recommendations of the Board of Agriculture were strictly followed with the sole object of deriving information.

The results were so remarkable that they felt they should be seen by gentlemen capable of judging for themselves and made widely known. Other experiments would no doubt differ, but there could not be much difference of opinion he thought of the character of their own.

The speaker was evidently most careful not to even faintly indicate how great or how small was the effect of the dressings, and no doubt some strikingly beneficial results were anticipated by the inspection. The founder of the firm, Mr. Martin Hope Sutton, in his interesting reminiscences, was also careful to avoid precise statements in respect to the trials he had inspected. They were very interesting, he said, especially as the Potato was the most important food crop except Wheat, and therefore deserving of the best efforts towards improvement and preservation. By this time the company were looking forward to half rows of fine spotless tubers and corresponding portions representing blackness and decay. Whether or not Dr. Voelcker was aware of the facts of the case did not transpire, but said he had satisfied himself that the only object of Messrs. Sutton had been a search for truth, and that was why he was there; and after thanking the firm for what they had done, and would permit them to see, the company were requested to drive to the grounds. On passing out of the hall tabulated records were handed to each visitor, and before the trials were reached the broad general facts were by many discovered. A surprise was indeed in store, and this is the issue. After all the care and labour that had been devoted in dressing the crops, sorting, weighing, and tabulating with the utmost exactitude the effects of the mixture, the outcome of the whole, the "reward," for endeavour was a distinct loss in Potatoes. Here is the significant summary, and there cannot be a doubt that it is in an absolutely accurate representation.

Experiments	Results.			
	Tons	cwts.	qrs.	lbs.
810 rows, total undressed .. .. .	5	8	2	5
810 rows, total dressed .. .. .	4	17	1	1
Total increase of sound produce in undressed .. .. .	0	11	1	4

As the terms of recommendation of the Board of Agriculture may not be in the recollection of all the readers of this Journal they may be in substance recapitulated. It was advised that 20 poles of Potatoes be dressed with a mixture of 4 lbs. of sulphate of copper and 2 lbs. of lime in 20 gallons of water, three dressings to be given. Then 30 poles were to be dressed with 6 lbs. of sulphate of copper and 3 lbs. of lime in 30 gallons of water, or a gallon to a pole in each case. This was done at Reading on June 27th, July 7th, and July 18th. Another plot of 17½ poles was to be dressed with 3½ lbs. of sulphate of copper and 1¼ lb. of lime in 17½ gallons of water, or just over a gallon to a pole. This was done on June 30th, July 10th, and July 25th. If all the applications were made on the same days it might have been supposed that weather peculiarities then prevailing might have influenced the action of the fungicide and consequently the results. It is well therefore that the dressings were made on six different days instead of three in what is supposed to be within the term of the fungoid attack, though the Potato veteran, Mr. Robert Fenn, is of opinion that the first dressing should be made much sooner, and he can certainly show results as satisfactory as those at Reading are undoubtedly unsatisfactory. Mr. Fenn, however, applied the antidote in powder form, Tait and Buchanan's preparation, though this, like the liquid, has not had equal results everywhere.

Returning to the Reading trials. The crops of tubers of each experiment were lying on the ground as dug, those from the dressed and undressed rows side by side, the sound Potatoes in each case having been accurately weighed. In most instances a glance sufficed to show the disadvantage of the dressings, while only in very few indeed were their advantages visible, in several no marked difference being apparent.

The number of rows dressed (in part) varied, presumably according to the relative extent of the general culture of the several varieties. As an example, we take the first on the list, Eclipse. Number of rows five, weight of half rows dressed 2 qrs. 7 lbs., weight of half rows undressed 2 qrs. 27 lbs.; number of rows showing loss of weight after dressing, all—total decrease 20 lbs. Sutton's Ashleaf, number of rows 27, weight of half rows dressed 2 cwt. 2 qrs. 7 lbs., of half rows undressed 3 cwt. 0 qrs. 23 lbs., number of rows of equal weight 5, number of rows showing increased weight after dressing none, number of rows showing a decrease, 22; total weight of decrease in sound tubers 2 qrs. 16 lbs. These examples fairly indicate the effects on the whole of the early varieties—a decrease of crop in every one of them, though the plants were in full growth when the first dressing was applied. Messrs. Sutton observe, "This unsatisfactory result would seem to indicate that the Bouillie is not of any avail as a fertiliser." It is most unlikely that its claim to that merit can be sustained, and where it prevents or destroys fungoid growths on the plants and

thus enables the leaves to remain active the longer, the crop is increased almost if not wholly because of prolonged leaf action, and is not due to the obviously minute fertilising properties of the mixture. In the case of the early varieties it appears to have arrested growth, and from this check they had not time to recover, and therefore the crop was lessened in bulk and value.

Turning to the later varieties the tables denote that Reading Giant, Sutton's Satisfaction, Windsor Castle, and, generally speaking, varieties of the Regent type, Victoria, Woodstock Kidney, and others, grown to a limited extent for their high quality, benefited the most by the applications, while the strong growing, free cropping sorts, that yield produce for the million, were affected prejudicially, and decidedly the expense and trouble involved in the dressing were not warranted by the results attained in this case. It is certainly a fact that out of thirty-four rows of Magnum Bonum only two showed any gain, three were unaffected, whilst twenty-nine were injured by the dressing, the result of the thirty-four trials showing a total weight of 5 cwt. 2 qrs. 24 lbs. for the dressed rows, and 7 cwt. 1 qr. 25 lbs. for the undressed rows, a difference in favour of the latter of 1 cwt. 3 qrs. 1 lb. Thirty-five rows of Abundance show a total weight of 8 cwt. 1 qr. 4 lbs. for the dressed rows, and 9 cwt. 1 qr. 22 lbs. for the undressed rows, a difference in favour of the latter of 1 cwt. 0 qrs. 18 lbs.

It is clear that those varieties proved strong enough to take care of themselves in these trials, the leaf tissues having sufficient power to resist the germinal tubes of the fungus spores, which must have been present on the leaves. In rich or less porous soils the leaf tissues would be softer, hence more vulnerable, and in such case we may expect to hear that the Bouillie dressing has been of benefit in assisting the plants to obstruct the inroads of the enemy. Be that as it may, it is quite certain that if varieties possessing inherent vigour had not been raised and extensively grown for feeding the multitude in cities and towns the supply must have fallen far short of the demand, and prices have been prohibitive to the bulk of the people. There is also no doubt that intelligent land preparation, manuring, seed selection, and general care in culture have contributed to more abundant and sounder crops. As an instance of the value of soil preparation, it may be recorded that most of the strong ground intended for Potatoes this year at Chiswick was deeply dug and thrown in ridges before winter. With subsequent working in favourable weather in spring the mass was pulverised, and brought into the best mechanical condition; but a portion of the ground could not be dug till spring, and in this the disease was by far the most virulent; but the best soil preparation alone did not prevent the outbreak, which seriously damaged the crops.

Before noting some general results of Mr. Fenn's "fight with the fungus," a simple record of special field experiments at Reading may be given as further illustrative of the work there. Three varieties were selected for experiment, with the following results:—

Name of Variety.	Extent of Ground.	Total weight dressed			Total weight undressed.			Total decrease after dressing.			Total increase after dressing.		
		Cwts.	qrs.	lbs.	Cwts.	qrs.	lbs.	Cwts.	qrs.	lbs.	Cwts.	qrs.	lbs.
Sutton's Ringleader	5 poles dressed and 5 poles undressed ....	3	2	27	5	3	22	2	1	13	—	—	—
White Beauty of Hebron .....	5 poles dressed and 5 poles undressed ....	4	0	0	6	0	11	2	0	11	—	—	—
Chancellor .....	2½ poles dressed and 2½ poles undressed ....	3	3	4	3	3	3	—	—	—	0	0	1

It will be seen that the earliest variety suffered the most, its successor following closely; the later, Chancellor, a very fine sample, showing a gain of a solitary pound, obtained at the expense of three dressings of Bouillie. If an acre of Ringleader had been dressed the decrease would have been upwards of 3 tons 18 cwt. This suggests it is better to keep the growths of early Potatoes green than staining them blue with this celebrated mixture, which all through the experiments arrested the growth of the tubers.

Now we run on to Sulhamstead. Mr. Fenn was at Reading, and the crops of his trial plots lying on the land at home awaiting inspection. There was only just time to reach them and have a quick glance before dark. Here, as at Reading, half of some rows had been powdered, and in every case to advantage, the other half not. In some instances a moment's examination of the crops sufficed to show how far the dressing had been done. One or two rows of some of Mr. Fenn's precious high quality varieties prone to the disease had been dressed throughout, and the results appeared to be altogether satisfactory. The veteran rejoiced greatly. He had been fighting with the disease for forty-five years, but had always been beaten, and now for the first time he felt the proud

victor. Every moment he was expected to throw up his hat and shout "powder for ever," but he displayed his enthusiasm in a more unusual way, as will be noted presently.

The varieties operated on in his garden were alluded to in this Journal a few weeks ago (September 3rd). In the field a considerable plantation was made of Eliza Fenn. Exactly opposite the entrance two or three rows were systematically powdered. These, when inspected towards the end of August, were green and growing, the undressed rows stretching away on each side blackened. The difference was most striking, and the crops of tubers lying on the land last week were equally striking. The gain in the dressed rows appeared to approach 50 per cent. The produce with that of contiguous undressed rows will be weighed, and then we shall know. That in one case the crop was good and the other poor was plain enough. Ringleader, too, appeared to be improved by the powder, the first dressing having been given before earthing. Two rows of Potatoes planted after the early crop was dug in July were kept free from the fungus, and afforded sound, though naturally small tubers. This result, Mr. Fenn said, would have been impossible this year without the powder. Granting the powder has been effective, what of the man? Much is due to his persistent and persevering action. Whenever he saw mildew on anything, Roses outside and Vines in, he ran for the bellows and "swept it away;" and how many times the young septuagenarian has skipped up and down the Potato rows puffing away will perhaps never be known. He cannot tell, and does not think it matters; he has conquered the enemy at last, and that is enough for him.

His activity is wonderful and his enthusiasm boundless. By the aid of the old Guy Fawkes lantern we had to see his vineyard, the roof a mass of clusters of Royal Muscadine Grapes for wine making. Until this year they have been eaten up with mildew, but now not a speck is to be seen, nor on the Tomatoes in the same house. "The powder was said to be dangerous," he remarked, so thought "the best way to prove it was to eat a couple of dressed bunches, and tell Eliza to send for the doctor if anything happened." He thought they did him good. We had to go round the garden and shake down seedling Plums, while he flitted about like a Will o' the Wisp, holding up the light to his memorial trees that were sent to him by friends, many now departed, and he calls the trees by their names—Wildsmith, Woodbridge, Bell, Howe, and so on. What a delight to him is his garden. Next we have to go into the barn and see the wine and cider-making paraphernalia, and the work in progress, then into the creeper-draped commodious and picturesque cottage to try the jellies and everything else. Mrs. Fenn is an adept in getting the best that is to be had out of fruits, and not a pound of any kind is wasted, even the purple Berberries, Mahonia aquifolia, and Brambles being stored in the form of delicious conserves.

But the talk was mainly about Potatoes and powder. "What bellows do you use?" casually asked Mr. Barron, who was one of the trio of visitors. "Here, Alice, fetch the bellows, quick!" and forthwith came the maalbec. Miss Fenn is a young lady of taste, and likes to make the room attractive. The bunches of Grasses, Honesty, and other persistent sprays suspended round the walls in fitting receptacles made by deft fingers, had a pleasing effect. Well, what did the old Fennian do but started driving the powder into these to show us the way to use it! It was of no use calling "Father, Father, and Bob, Bob. What are you doing?" for the powder had to fly, and fly it did, till all joined in the cry, "Hold, enough; we understand it!" "Oh, you do, do you? Very well, if there's mildew there it will be settled; that's the way to do it on everything, only do it soon enough and often enough and you will be the master even of the Potato disease." Perhaps we should if we were Robert Fenns, but there is only one, and that is enough in a room when he is armed with a maalbec charged with an impalpable powder of sulphate of copper and lime.—EXPERIENTIA DOCET.

#### THE USE AND ABUSE OF WATER.

IN your last issue I am glad to see that Mr. Waters has in some way put himself right, and I can assure him that it was neither his training nor his practice that I impeached; it was his preaching. Mr. Waters also says that I ought to have ascertained whether he had any explanation to offer before questioning his doctrine. Well, I waited for a fortnight, hoping that he or someone else would have corrected what he now acknowledges were reporter's errors. Surely it was his duty to put himself right. I am also glad to hear of the goodwill existing between Mr. Waters and his subordinates, but that point I never raised. As regards the watering of fruit borders, it is a well-known fact that in the majority of cases they are too sparingly watered. As a rule gardeners have far too much work to waste time in over-watering.

As regards the old tree of Grosse Mignonne Peach to which I referred I am credibly informed that for the last twenty-five years it has borne fruits of equal size and weight to those mentioned—a crop numbering from fifteen to twenty dozen year by year. Mr. Waters speaks of

gathering Peaches which weighed over 11 ozs., but he does not name the variety, though he exults in the knowledge that they were privileged to grace a royal and civic banquet. He must know that at such feasts the great majority of dishes are intended more to fill the eye than tickle the palate, and I have no doubt that both Mr. Waters and myself would make a more successful "Bite" at a good fair-sized Royal George than we should at a monster Salwey. At any rate, my little "Bite" has given him a chance to express himself in a more orthodox manner, for which he says "he is not sorry;" therefore, if he is grateful I am proud in having made so successful a—YORKSHIRE BITE.

TWO DISTINCT ORCHIDS.

At the Royal Horticultural Society's Exhibition in the Temple Gardens last May a plant was shown amongst the Orchids of *Grammatophyllum Measuresianum*, a new and very distinct species of much promise. It had fair long racemes of flowers fully 4 feet in height, and formed a remarkably effective specimen. The

FIG. 69.—GRAMMATOPHYLLUM MEASURESIANUM.

flowers are nearly 4 inches in diameter, white, with a greenish tinge, and regularly dotted with rich purplish brown—a peculiar combination of tints. The plant is free in growth and flowering, and is now in Mr. R. H. Measures' collection at The Woodlands, Streatham. A first-class certificate was awarded when it was shown at the Temple, and the woodcut (fig. 69) was prepared to show the flower full size, and the raceme in miniature.

*Bulbophyllum amplum* (fig. 70) is a totally different Orchid, and if we had a few more in the genus like it there would be little doubt but that they would become favourites. It has unusually large flowers for a *Bulbophyllum*, the sepals and petals creamy yellow dotted with bright red; the lip is broad and somewhat ovate in form, of a rich maroon tint. The plant was shown by Sir Trevor Lawrence, Bart., M.P., Burford Lodge, Dorking, at one of the October meetings at Westminster last year.

## ORCHID SALES.

It appears that the Orchid sales are becoming more numerous than ever, and the metropolitan auction rooms are frequented by many amateurs and others. The sale of *Dendrobium Phalaenopsis* at Cheapside last week was a great surprise, for the room was crowded throughout the afternoon, and a brisk competition caused the prices to rise to large figures. As much as 28 guineas was paid for exceptionally good specimens, and we are informed that the total was about £2000, the largest amount yet realised for imported Orchids at one day's sale in the City. The *Dendrobiums* were remarkably strong, some of the pseudo-bulbs being nearly 4 feet in length and proportionately stout. The "Golden-eyed Idol" did not seem to be in much demand, for it was disposed of for the modest sum of a guinea.

## CHOICE DESSERT PLUMS.

[A paper by Mr. G. BUNYARD, read at the meeting of the Horticultural Club, Hotel Windsor, Oct. 13th, 1891.]

AN ideal dessert Plum is a fruit that possesses flavour in a highly concentrated form which shall require no outside addition to render it agreeable to the palate. I therefore propose in the following paper to treat only of those which possess this character in a marked degree. It will be necessary to divide them in various classes, though as in all natural subjects, in some cases these will overlap and blend with others. First, Green Gages; second, Yellow and Green Plums; third, Red and Purple Plums; fourth, Purple Gages; fifth, Damsons.

## GREEN GAGES.

*The Old Green Gage*.—Still one of the most delicious of Plums, and in its perfection is not excelled by any others.

*The Late Green Gage*.—Similar in all respects to the original, but is about few days later.

*Guthrie's Green Gage*.—More oval in shape, of brisk sweet flavour, and handsome in appearance.

*Bryanston Gage*.—Somewhat larger than the type, and forms a healthy standard tree; its fruit ripens gradually, it has rather more of Plum flavour than the Green Gage, but is rich and refreshing; rather late.

*Reine Claude de Bavay*.—A large late Gage, fine in appearance, and nearly equal in flavour to the Green Gage. As a sub-section in the Green Gage class I would here include the Transparent Gages, for which we have to thank Messrs. Rivers of Sawbridgeworth.

*The Early Transparent*.—A vigorous grower, and bears profusely.

*The Transparent Gage*.—A sturdy, but irregular, grower, difficult to form into a well-shaped tree. Its fruit is of the Green Gage shape, pale lemon in colour, marked with red dots and stripes, with russet tinges, and is, when fully ripe, a perfect sweetmeat. It is somewhat apt to crack on the tree, but these in perfect fruits are often most delicious in flavour. The late Transparent Gage is a great addition to this class, as it is nearly a fortnight later than the Transparent.

## YELLOW AND GREEN PLUMS.

*Denniston's Superb*.—A medium sized fruit, and is the earliest Gage to ripen. The fruit is oval, mottled with yellow and green; its flesh is tender and true, flavour delicate and refined. It is a profuse bearer, and a capital substitute for Green Gages in jam making. The tree is of moderate growth, and will succeed well in any form. One of the earliest to ripen in August.

*Oullins Golden Gage*.—A very handsome pale yellow Plum of large size. This ripens early in August. It is a valuable garden Plum, and of rich half Gage flavour. It is rather apt to crack, and as a standard does not bear till about ten years old, after which it crops regularly, and is most valuable as an early Plum.

*Jefferson's*.—One of the largest dessert Plums. Long oval in shape, orange yellow in colour, marked with red spots near the stalk; it is a very rich flavour, and a good regular bearer, succeeding in any form. In fact, one of the most reliable Plums we have. It possesses a somewhat thick skin, and on that account is valuable for bottling, and less liable to attack from wasps.

*Bonne Bouche*.—A somewhat similar Plum to Jefferson's but later. It is an admirable grower, produces fruit somewhat like Golden Drop in shape, very rich, sweet flavour and juicy.

*Coe's Golden Drop*.—One of the most useful late Plums, frequently hanging upon a wall until late in October. This only succeeds as a standard in some localities.

*Guthrie's and McLaughlin's Gages*.—Good varieties of rich flavour, more properly classed here than in the Gages.

#### RED AND PURPLE PLUMS.

*De Montfort*.—A medium-sized oval fruit which ripens very early on a wall, and, in fact, is the earliest dessert Plum. Its colour is a curious mixture of green, red, purple and violet, and it is a little known variety well worth cultivation. Its flesh is handsome greenish and peculiarly rich in flavour.

*Stint*.—This new seedling of Messrs. Rivers, a small red Plum, transparent in appearance and the earliest of all dessert Plums to ripen; it is refreshing in flavour.

*Prince of Wales*.—A sweet early Plum of the Orleans race, purplish red in colour, juicy and pleasant in flavour, very free bearer and worth a good place on a wall.

*Kirke's Blue*.—A large violet Plum, rich full flavour; it requires a wall, as it seldom bears freely in any other form. Its appearance renders it indispensable in a collection.

*Angelina Burdett*.—A small delicious fruit of great richness, not so sweet as Green Gage, but of a peculiarly agreeable flavour; it is, however, a sparse bearer, but rather late and useful.

*Tickworth Impératrice*.—A very small late Plum, valuable for October desserts when grown on a wall, where it shrivels and becomes delicious.

#### PURPLE GAGES.

*Comte Althaus Gage*.—A medium-sized purple red Plum with greenish markings, a very nice flavour and profuse bearer. This will probably prove one of our most reliable kinds.

*Red Gage*.—Reine Claude Rouge. A small round fruit of a singular colour, which when fully ripe and partially shrivelled is most delicious.

*The Blue or Purple Gage*.—Reine Claude Violette. This is similar to the red, except that its skin is a different colour. It is equally rich and a valuable dessert Plum.

This exhausts all those with which I am familiar. Purposely I leave out Washington, though a grand Plum when well coloured, but it bears so indifferently that others are preferable, and the same remarks apply to Boddaert's Gage. We have not yet found any of the Japanese Plums to bear fruit, but they are forming good trees, and a new departure may be found in them, but I think in the comparatively flavourless Myrobalan type, as judged by the foliage, it will be understood that dessert Plums are a matter of taste, and in a scarce season many classed as kitchen sorts will be used. The season of Plums commences early in August with Stint, Denniston's Superb, and De Montfort, followed by Oullins Golden, then a large number ripen, and the season is closed by Coe's Golden Drop and Impératrice at the end of September and early in October. This year they are fourteen days later than usual.

#### CULTURAL HINTS.

A few hints on culture may be added. The only objection to fruit grown upon pyramids and open trees is that the rains wash off that pretty frost-like bloom which adds so greatly to their appearance. The flavour is generally better when grown in the open. A wall, however, allows some of the early kinds to be grown for very early dishes on warm walls, and to extend the season by placing some on north walls, but a satisfactory mode of culture is to grow them in pots in a cold orchard house where they can be produced in great perfection and with very little trouble. As I hope some other member of the Club may give us a paper on their culture in this form I need not enlarge upon it here. I feel, however, that in the restricted growth thus induced we get a hint as to their treatment in other forms, and I would strongly advise all wall trees, pyramids and cordons, to be frequently lifted and root-pruned, this will check that overcrowded and hard pruning which prevent the formation of fruit buds.

Plums are among the most useful of fruits, as they can be used half grown (say thinnings) cooked in various forms, bottled, and as a conserve as "Plum cheese," as well as for dessert. It may be added the Early Damson, Frogmore Prolific, the late small Prune Damson, and Bradley's King, are rich and well worthy of the dessert.

#### FLOWERING TREES AND SHRUBS.

[Read at a meeting of the Chiswick Gardeners' Association, October 9th, 1891, by Mr. H. DUNKIN, gardener to the Earl of Warwick.]

IN the many nurseries of this country we have such variety of flowering trees and shrubs that it is somewhat surprising to find so few private gardens in which a really good collection is established. In far too many instances large masses of common evergreens, such as Laurels,

Box, and Yew, are planted without any attempt being made to give variety and brightness. True, these have their uses, and are always desirable for planting under the shade of trees, or where quick growth is required to shut out unsightly objects or create secluded spots; but after due allowance has been made for these facts, there is still abundance of room for the more varied and skilful arrangement of shrubberies. Wherever these are situated in an open position in which choice shrubs appear likely to thrive, the common ones should be very sparingly planted, reserving them for the background, or positions where they are not much seen. My ideal of a well-planted shrubbery is one in which evergreens of various types are judiciously intermixed according to their habit of growth and the varied colours of their leaves, deciduous and flowering trees and shrubs being dotted about at irregular intervals, so that at every season of the year infinite variety of colour is produced, beginning in the early spring months with those harbingers of coming beauty, Daphnes and Ribes, which put forth their refreshing flowers before the tender leaves unfold; these to be followed by Cydonias, Deutzias, Almonds, Cerasuses, Berberises, gorgeous masses of Rhododendrons and Azaleas, Spiræas and Hibiscuses, and a host of others. At the same time changing leaf colourings of such a variety of trees and shrubs are in themselves a constant source of delight. First the pale green of the opening leaves create a lovely scene, then as they gradually develop and assume a deep green colour they look rich and striking

FIG. 70.—BULBOPHYLLUM AMPLUM.

under the influence of bright sunlight; and again, as the dull days of autumn come the bronze and yellow shades of colour which deciduous trees present are to many a greater attraction than the verdant beauty of spring.

I have in the course of my gardening career seen many fine gardens with pleasure grounds abounding in noble specimens of Conifers in great variety, but in very few instances have I seen places which were not lamentably deficient in flowering trees and shrubs. This is to be regretted, for however stately and imposing the noble proportions of sombre-hued trees may be, we want also some bright cheerful bits of colour to relieve the eye, and arouse into enthusiastic admiration those natures which are not easily stirred by arboreal beauty alone. There is much more interest in pleasure grounds which abound in flowering trees and shrubs, as well as gigantic specimens which possess no floral beauty, than can be found in gardens which are planted in the style which is so common. We have a rich store of plants to select from, and there is room for all. By all means let us have grand spreading Cedars, picturesque Firs, stately Oaks, and noble Piceas, but their beauty will be enhanced by a liberal admixture of flowering trees and shrubs. For the greater convenience of all I will divide my subject into three heads, viz., Azaleas, Rhododendrons and American plants; evergreen trees and shrubs; and deciduous trees and shrubs.

#### AZALEAS, RHODODENDRONS, AND AMERICAN PLANTS.

It is generally admitted that all plants catalogued under this heading succeed best in peat soil, and it is always a safe proceeding to plant them in peat, but I know of localities in which they succeed admirably in a stiff yellow loam, but it is not wise to plant extensively in any soil but peat until it has been clearly ascertained that the plants will thrive in other soil that may be at command. Where the expense

of obtaining peat is great, good sweet leaf soil with a little of the natural soil added, answers in many cases remarkably well. The great point to be observed is to tread it firmly at planting time, leave the surface firm, and do not disturb it by hoeing or digging afterwards.

As special preparation of the soil is needed, it is a good practice to plant in beds and masses; and, moreover, the majority look best when seen in masses, but in the case of Rhododendrons, the plan of planting a few of the strong-growing varieties singly on lawns, or near, but not under, the shade of other large trees, I would specially recommend, as when so treated they develop into grand specimens and make a strong feature at flowering time. In the case also of both Azaleas and Rhododendrons, four or five plants grouped together in the foreground of shrubberies are very effective. Andromedas and Kalmias are charming when associated in beds and edged with hardy Heaths. The varieties of Ericas most useful for this purpose are *E. vagans alba*, *E. v. carnea*, and *E. v. rubra*. Among Andromedas the best I know are *A. floribunda*, *A. speciosa*, *A. formosa*, and *A. japonica*. Rhododendrons and Azaleas are so numerous that want of space prevents my enumerating them; but in ordering plants, if the selection is left to respectable trading firms, satisfaction is invariably given.

#### EVERGREENS.

Following in alphabetical order the first evergreen flowering shrub which I wish to call attention to is the well known *Arbutus Unedo*. Flowering as it does in October and November, at a time when the fruit of the previous year is ripe, it serves to brighten the grounds at a season when but few are in flower in the open air. Certainly none is so distinct in appearance as this *Arbutus*, with its pendent scarlet fruits, small white flowers, and deep green leaves. I now come to that delightful class of plants which produce flowers of so many attractive shades of yellow and orange, I allude to the Berberises, a family which I have a special liking for, not only on account of the beautiful colour of their flowers, but also because of their elegant habit. In this respect *B. stenophylla* is the most beautiful, though strange to say it is not so much grown as some of the others. When once its long arching, slender shoots are seen, studded with drooping yellow flowers, it is not soon forgotten. *B. japonica* and *B. nepalensis* are fine varieties, having large leaves, the stems being surmounted with clusters of yellow flowers. *B. Darwini*, *B. duleis*, and the various forms of *Aquifolia* are all extremely useful types. *B. Darwini* and *B. stenophylla* should either be planted singly on lawns or in prominent positions in shrubberies, where they have room to develop their fine branching habit. *Buddleia globosa* is a choice tree, bearing pretty orange yellow flowers. It requires the protection of a wall or a very sheltered position, and rather light porous soil; in such a position it survived the late severe winter here. As also did

*Choisya ternata*, which is a great acquisition amongst outdoor shrubs, producing deliciously scented white flowers, equal in point of merit to Orange blossom. Another very uncommon and beautiful shrub is the Gum Cistus (*Cistus landaniferus*), bearing white cup-shaped flowers not unlike single Roses; and its companion *C. landaniferus maculatus*. These, like the two preceding, require a warm sheltered position with a south aspect. *Cratægus Pyracantha* and *P. crenulata* are useful for covering walls or fences, principally on account of the scarlet berries they produce in the winter; but their flowers are pretty though not showy. *Daphne Laureola* should find a place in every ornamental garden on account of the sweet scent the flowers emit, especially in the evening.

Among *Escallonia macrantha* and *rubra* are the best I am acquainted with, and prove useful for cutting purposes. A particularly useful shrub for supplying cut flowers at the present time is *Ligustrum lucidum*. It produces large panicles of white flowers, which are supported above small green shining leaves. *L. ovalifolium* is another good Privet which flowers in August. *Magnolia grandiflora*, with its large creamy white scented flowers and noble leaves, is grand for planting against a wall having a south aspect; and although well known could not be left out of this list. *Ulex europea flore-pleno* (the double Furze) is very effective for planting in the front of other shrubs, as it is of dwarf habit, and when covered with its yellow flowers is bright and attractive. This closes my list of evergreen flowering trees and shrubs, which might be greatly extended, but I have brought to notice only those that I know to be good and well worthy of extended cultivation.

#### DECIDUOUS TREES AND SHRUBS.

Among these some of the most beautiful of all flowering trees are found, and I have no hesitation in saying that when these are well selected and judiciously planted among evergreens they are capable of creating when in flower one of the most striking features about places where the grounds are extensive. They are also useful for supplying abundance of flowers for cutting.

*Abelia rupestris* is the first in this class which I would bring to notice. Although not perfectly hardy it will withstand our most severe winters in sheltered places. Its small pink sweetly scented flowers are now in full beauty, and though not particularly showy are decidedly attractive.

Many varieties of the *Amygdalus* family are extremely showy when in flower, and as they produce their flowers in the early spring months they are worthy harbingers of rich floral feasts to come. Among the first to flower is the Bitter Almond (*A. communis amara*), the showy rose-coloured flowers of which are generally produced in March. *A. communis dulcis* (the Sweet Almond), *A. c. flore-pleno*, and *A. nana*,

the latter being of dwarf habit, are some of the best varieties. Among deciduous Berberises the several varieties of *B. vulgaris* are the most useful; *atropurpurea* and *fructu lutea* bear purple and yellow flowers respectively. *Calycanthus florida* (the Allspice) should be freely planted in every extensive garden, on account of the delicious odour the flowers emit.

*Catalpa syriaca* is a beautiful tree, which ought to be grown more extensively. Its habit of growth is similar to that of the Tulip Tree, the flowers being produced in panicles, somewhat after the style of those of the Horse Chestnut. The time of flowering is August, and fine specimens of these beautiful trees are grand when growing singly on lawns.

*Cerasus* (Cherry).—The numerous varieties of this are exceedingly showy, and so well known that no further comment is needed here. *Cercis siliquastrum* (Judas Tree) in some places grows into a fine tree, from 20 to 30 feet in height. Its bright purple flowers are produced in May. The wood is also beautifully veined with black. *Chimonanthus fragrans* is conspicuous among flowering shrubs on account of producing its pale yellow flowers in the depth of winter, and is always highly prized where grown.

*Cratægus* (Hawthorn).—The numerous varieties of these showy trees are so well known as to need but little description here, but I am sure my hearers will agree with me that few more lovely plants dot the landscape in the month of May than shapely examples of these hardy trees when their pendulous shoots are wreathed with red, pink, or white flowers.

*Cydonias* are showy for covering walls, but in many cases they are pruned too closely. If long shoots are laid in freely each year they become thickly studded with flowers in the early spring months. This fine shrub is perfectly hardy, and as far north as Lincolnshire it thrives admirably when grown as a bush in an open position. *C. japonica*, *alba*, and *rosea* are each good varieties.

*Cytisus biflorus* and *C. purpureus* are two beautiful deciduous kinds, quite hardy, and the yellow Broom, *C. scoparius*, is bright and showy. I must make a special plea for *Daphne Mezereum* with its pretty red flowers, as it is one of the earliest shrubs to flower in the spring, and is perfectly hardy, but unfortunately not very extensively grown. There are, I believe, autumn flowering varieties, but I have had no experience with them.

*Deutzias*.—These shrubs are very useful, the pearly whiteness of their flowers, which are produced in great profusion, render them particularly suitable for cutting purposes. *D. corymbosa*, *D. crenata*, *D. crenata flore-pleno*, *D. candidissima* and *gracilis* are all good, the last named being of much dwarfer habit than the other varieties.

*Forsythias suspensa* and *viridissima* are charming yellow flowered subjects of elegant habit of growth, suitable alike for covering walls and for growing as bushes in shrubberies, or as isolated specimens in conspicuous positions. The flowers, being produced in March, are especially welcome.

I find that my paper is becoming unduly long, while I have yet many to deal with. I will, therefore, confine myself to giving a list of those subjects which I wish to bring before you, giving their dates of flowering. This list I will append below; but before doing so I will pen a few lines about two others not generally known. The first is *Paulownia imperialis*, which forms a handsome tree, in habit of growth similar to the *Catalpa* already mentioned, but the leaves are larger and downy, flowers pale violet with dark spots on the inside. The late Mr. Kitley of Bath was, I believe, the first to flower this in England.

The Macartney Roses, *Alba Simplex* and *Rosea Simplex*, are not often met with; but they are fine for training against walls in warm positions. We have a thriving plant flowering here at the present time which is greatly prized, and wherever grown are certain to be appreciated.

In conclusion, let me urge upon my hearers the great pleasure and many benefits to be derived by planting a greater diversity of flowering trees and shrubs than is generally done wherever they are engaged in the formation of pleasure grounds, and in the innumerable instances where large masses of evergreens already exist which possess no special feature, except it be a large expanse of monotonous greenness.

#### VEGETABLES AT HIGHCLERE.

WILL "Observer" say in what respect the notes on vegetables at Highclere do not denote Mr. Pope's connection with either the growing or the showing of them? Surely because one or two dishes were omitted from a collection which "Observer" thinks ought to have been there, does not warrant the inference that what information I there gave on his methods for the benefit of Journal readers was not correct. To the experienced in matters of vegetable showing the reason for the omission of the kinds quoted will be obvious. As I am not in the habit of imparting "assumed" information I can afford to pass over the opening paragraph. Why Mr. Pope had no Turnips in his collection at Edinburgh I am unable to say, it did not occur to me to ask. The reason Cucumbers are more appreciated during September than in August is not difficult to answer—simply because they are not so easily obtained. Where space is limited for their growth the plants which have borne during the summer become a little exhausted by September, and consequently do not produce fruit up to exhibition form nearly so freely. This, no doubt, was the reason why there was an apparent necessity to "comment" on their absence from his collection at Edinburgh. I have not studied the prize list of the show in question, therefore cannot

judge as to the conditions there stipulated, but even judging from "inference" there was no occasion for strong "comments," as to the omission of Cucumbers, because I fail to see how Mr. Pope was "sailing near the wind," as "Observer" infers. Because the second list of prizes for collections of vegetables were not to contain "Cucumbers or Tomatoes," that is no reason why the first list should do so.

We do not usually expect Lady Downe's Grapes ready for the table before early in November, which is fully four months after the period quoted by "Observer," therefore the "parallel" drawn is some distance from the mark. Relative to the Parsnips which were staged a very short time before the stated time when they "are a strong dish." If Parsnips are not in season during September, how is it that such a Society as the Edinburgh Association offer prizes for them alone? I presume Mr. Pope follows the line adopted by sensible men in making up his collection—viz., that a good dish of any one kind if a little out of season (which after all is a matter of opinion) is preferable to a bad "seasonable" one.

I am quite aware that a dish of Globe Artichokes can be cut from the same plants year after year, but in what month? I would ask. Certainly not fit for show in September. "Observer" here displays a want of practical knowledge, or he must know that the same ten-year-old roots will not give heads up to exhibition form in September after having fruited since the early part of July. The reason Mr. Pope included Leeks of such inferior quality as "Observer" describes in his collection is obvious to all I should say, which in spite of their inferiority as Leeks could not have been so extremely bad after all, or the collection would not have been placed where it was by competent Judges, as I presume the adjudicators were. It would indeed be a curious collection of twelve varieties of vegetables which did not contain a single dish to make some "wonder."—THE RAMBLER.

**EVENTS OF THE WEEK.**—To-day (Thursday) the Fruit Show and Conference will be continued at Manchester, the Conference opening at twelve noon. On Tuesday, October 27th, the Royal Horticultural Society's Fruit, Floral, and Orchid Committees will meet in the Drill Hall, James Street, Westminster, at twelve noon; and in the afternoon Mr. H. J. Veitch will give an address on "The Autumn Tints of Trees." The National Chrysanthemum Society's Floral Committee will meet in the Royal Aquarium, Westminster, at 2 P.M. on Wednesday, October 28th. Messrs. Linden of Brussels advertise a sale of "200 plants in flower of the true *Cattleya labiata autumnalis*" at Messrs. Protheroe & Morris's Rooms, Cheapside, October 30th next, which will, no doubt, attract a large number of purchasers. Messrs. Protheroe also advertise sales of Orchids for Friday, October 23rd; Church Fields Nursery Stock, at Cheshunt, on October 28th and 29th; and Nursery Stock at Havant on the same days.

— **ROYAL HORTICULTURAL SOCIETY.**—The next meeting of the Floral, Orchid, and Fruit Committees will be held in the Drill Hall on Tuesday, October 27th, when the Society holds its usual display of new and rare plants, besides which special prizes are offered in the schedule for cooking and dessert Apples and Pears, as well as for varieties of Grapes. Intending competitors should at once communicate as to the nature of their exhibits to the Superintendent, R.H.S. Gardens, Chiswick. In the afternoon at three o'clock Mr. Harry J. Veitch, F.L.S., will read a paper on "Autumn Tints," and specimens of trees, shrubs, or other plants indicating the season will be welcome as illustrations.

— **THE WEATHER.**—The gale last week was very destructive, much damage to trees being reported from many districts around the metropolis and elsewhere. Large trees were uprooted in many cases, and fruit was swept from the Apple and Pear trees in exposed gardens. Heavy rains have also prevailed, with intervals of bright weather, and exceedingly clear nights. Slight frost has been experienced in some places sufficient to blacken the Dahlias, but this has not yet been general.

— **THE CRYSTAL PALACE SHOW.**—Mr. R. Silk, gardener to J. Abernethy, Esq., C.E., Whiteness, Margate, sends us an exhibition card, from which it appears he was awarded the first prize in the class for the best flavoured Pears. In our report the name of the first prize-winner, which was taken from the Crystal Palace Company's official prize list, was given as Mr. W. A. Cook of Compton Bassett. Willingly we make this correction.

— **NITRATE OF SODA AS A STIMULANT.**—I do not wonder at the results obtained from the use of nitrate of soda on Cucumbers and Celery, as described by Mr. H. Dunkin, page 321. I have long had a high opinion of it as a manure. This year I tried it with dissolved bones in two parts to one of nitrate upon Apple trees, and with capital results. About the middle of July a good dressing of this mixture was spread on the surface, washing it in with clear water. The leaves quickly assumed a deep green colour, and had a leathery substance, making good growth, but not too rampant. Fruit of Lord Suffield on trees so stimulated swelled rapidly to a much greater size than hitherto. One fruit weighed exactly 1 lb., which is heavy for this variety, as it is not a weighty Apple for its size. Many other varieties show a similar increase in the size of their fruit. One tree especially of Tower of Glamis exhibits a marked improvement, both in its foliage and the quality of fruit borne. This tree had not been a success previously, but the application of so stimulating a manure as nitrate of soda seemed to give new life to this tree.—E. MOLYNEUX.

— **WARE AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY.**—At the usual fortnightly meeting, held on the 14th inst., an excellent paper was read by Mr. H. Brown on "Exhibition Onions." Practical hints were given on growing Onions generally, as well as how to grow them for exhibition, and some very fine Ailsa Craig Onions were shown by Mr. Brown. A good discussion followed, and the usual vote of thanks brought the meeting to a close.

— **THE HORTICULTURAL CLUB.**—The first monthly dinner and conversazione for the season 1891-92 was held on Tuesday, Oct. 13th, at the Club rooms, Hotel Windsor. Owing to the tempestuous weather the attendance was smaller than usual. The subject for discussion was Choice Dessert Plums, a paper on which was sent by Mr. Geo. Bunyard, who through illness was unable to attend. The paper was read by Mr. Charles T. Druery, and an interesting conversation followed, during which many interesting facts were brought forward by Messrs. Cheal, Soper, Cousens, Walker, &c., and a vote of thanks was given to Mr. Bunyard for his paper, which will be found in another part of our paper.

— **A MOTH TRAP.**—A simple but most effective contrivance for trapping the female Apple Moth is used by Mr. Hobson, the Chairman of the Sutton Coldfield Gardeners' Association, in his garden at Sutton. It consists of a strip of zinc made into a circular form, and is covered with calico fastened round the sides and tied at the top around the stem of the tree. It is really a crinoline, and open at the bottom. The interior is partially filled with a composition made of pitch and any fatty matter, such as kitchen fat or oil, of sufficient consistency to remain in the trap, and the female moth in climbing the stems cannot escape, but is a prisoner in the sticky substance. These should be applied in September; and in one week thirteen female moths, several snails, and a score or two of earwigs were caught in one trap. As these traps can be made at a very trifling cost their use should be general.

— **A FRIENDLY STORM.**—A correspondent, Mr. M. Birt, writes from near Godalming:—"Tis an ill wind that blows nobody good." In January, 1887, an Apple tree on a sloping lawn was blown flat down, and so remained under snow, often frozen for nearly three weeks. It was then raised, broken, tended, and has given its beautiful Blenheim Orange fruits yearly, still leaning considerably to one side, propped up by two supports. During the late gale the wind raised the tree, dragging with it the beam and strong pole, raising the former clear off the ground, and as the trunk returned dropping it down and forcing it safely into the ground, leaving the tree upright. The beam had been fastened by a large iron pin or bolt, driven at the edge of it in the grass, and the beam is now 18 inches from the pin. The tree settled into its original position so firmly that instead of standing as if on a mound, it is now in a slight depression.

— **GARDENERS' ASSOCIATIONS.**—One of these societies was formed at Sutton Coldfield, near Birmingham, some four or five years since, is an affiliated branch of the Birmingham Society, it numbers about forty-five members, owns a select library of gardening books, with powerful microscopes, and has a balance of £8 or £10 in the bank. The autumn session was opened on the 6th inst. by A. W. Wills, Esq., J.P., so well known in the Midlands for his collection of Orchids, with an instructive illustrated lecture on the "Use of the Microscope." The programme for the autumn season comprises "Lessons from my Garden," "Plant Physiology," "Entomology," "Fruit-growing for Profit," "A Night with the Microscope," "The Chrysanthemum," "The Culture of the Mushroom," "Notes on some Garden Favourites,"

"The Kitchen Garden," and "Flowers of Fame." Meetings are held once a week, exhibits invited, and questions are freely asked and answered. The Society is doing good work, and is very popular in the district.

— THE CHICAGO EXHIBITION.—It is said that half a million Pansies, one hundred thousand Roses, and millions of other flowers, including every known variety and species, will be seen at the Exposition. The horticultural exhibit will be on a scale never before attempted in the history of the world. Mr. Thorpe, of the floriculture division, estimates that the equipment of the horticultural building, including the purchase price of plants, will be 350,000 dols., and the total expense of the display 750,000 dols. The floriculturists of the country will give a large share of the plants. Ten of the 16 acres of ground on the wooded island will be planted with flowers. The shores of the island will be left wild for scenic effect, and the waters around the margin of the island will be bright with Water Lilies and other aquatic vegetation, while the interior of the island will be planted with Roses, Rhododendrons, and Lilies, besides a vast variety of wild flowers, which are at present preserved in a nursery on the island.

— INARCHING LATE GRAPES ON MUSCAT OF ALEXANDRIA.—Your correspondent, Mr. Craig, page 306, asks for the experience of others in the above named matter. I have inarched and budded Madresfield Court on Muscat of Alexandria, which is a success, producing fine berries and colouring fairly well. Gros Maroc does fairly well; in fact I have had some fine Grapes from a rod budded on Muscat of Alexandria, but I think the scion is too strong for the stock. The scion is very fruitful, but the stock is not quite so fruitful as before the Gros Maroc was worked on it. I likewise have Golden Champion inarched on the same with good results, and lastly Gros Colman. In this case the scion seems to absorb all the fruitful principle of the Vine, and has done so for the past two years. The rod of Gros Colman shows enough for two crops, and the rod of Muscat side by side has been barren. Although the Gros Colman has been very good I do not think it good enough to render a Muscat of Alexandria so unfruitful, and at pruning time I shall be much tempted to sever the connection.—R. MAHER, *Yattendon Court, Newbury.*

— RAINFALL IN HAMPSHIRE.—Although a considerable amount of rain has fallen here during the past week we have not registered as much as last year at the same time. Last year on the 9th October 23.11 inches of rain had fallen, while up to the same date this year 22.98 inches is recorded. The year 1890 was regarded as being under the average; therefore, we still have a quantity to make up. Although the rain seems pretty continuous, a great amount does not fall in a short time if I except the 6th of the present month, when the record was 1.19 inch. As showing the great variability of the rainfall at certain times of one year, I may instance the first nine days of the present month as compared with the same period of last year, when but 0.23 inch was recorded, which fell in two days. This year 2.44 inches is the recorded amount, and out of the nine days three were dry. Quoting from last year's register, we have but 1.20 inch to make up for the present month. Last year, in the month of October, we had twenty dry days, and upon seven others but 0.30 inch fell. Where much preparation is required for tree planting the present rains are a great boon, rendering the soil thoroughly moist, so that an early start can be made.—E. M.

— THE "American Garden and Forest," in reporting a meeting of the POMOLOGICAL SOCIETY IN WASHINGTON says that "The most entertaining discussion followed an address by Mr. Meehan on the 'Influence of Heredity and Environment in the Origination of New Fruits.' Mr. Meehan spoke without notes for half an hour very forcibly to prove the baselessness of the notion that any change in varieties could be produced by their surroundings, and he fortified his arguments with a wealth of illustrations drawn from human history as well as from plants and animals under domestication. Dr. Riley attacked the position of Mr. Meehan with great vigour, and Professor Bailey added that he was unwilling to allow it to be placed on record that the American Pomological Society held heterodox opinions on so capital a point, and cited numerous examples of variation in plants which he attributed to their environment. Mr. Meehan replied with great good humour that his critics evidently did not understand what was meant by the term environment; and then Mr. Fernow added that if there was doubt as to the meaning of the term environment there was also ambiguity in the use of the term variation, which might be structural or functional, and it was necessary to know whether we were talking about morphological variation or biological variation. The discussion

became enveloped in a haze of uncertainty, as it appeared that none of the gentlemen were quite sure what the others were talking about, and it finally closed in a thick fog. It was very instructive and interesting, however, to the laymen."

— PECULIARITIES OF HYBRIDISM.—Mr. Oberswetter, Austin, Texas, says in *Meehan's Monthly*:—"I find in Baker's handbook of the Amaryllideæ, the most recent authority on this order of plants, that it is not yet recorded by science that a hybrid between a *Crinum* and *Amaryllis* (*Hippeastrum*) was ever raised; but I find pleasure to inform you that I succeeded in raising a hybrid between *Crinum Kirki*, pistillate, and a hybrid *Hippeastrum* as pollen bearer. The plant was raised this spring. The seed I obtained last year, but did not germinate till last spring. I have been trying for years to cross these two genera, but never succeeded, so that I thought Nature had interposed insurmountable barriers. Last year I tried simply to cross different species of *Crinums*, and when giving pollen to the stigma of a *Crinum Kirki*, the thought occurred to me that it would not do any harm if I put *Hippeastrum* pollen on the stigma before administering the *Crinum* pollen. I had about five grains of seeds, but owing to mismanagement only two plants came up this spring, one a *Crinum* pure and simple with long leaves; the other had a different habit from the start; the first two leaves are not more than an inch long, but broad, ovate, and acute. Then a perfect leaf was developed over 4 inches long, nearly an inch broad, folded doubly over in vernation, so that it looks somewhat plicate. The leaves are much harder to the touch than the leaves of its twin plant, appearing as if glazed, light bright green, very upright, bluntly, cordate, acute. Since that first fully developed leaf it has just perfected another, longer, but of the same proportions."

— IN MEMORIAM—CHARLES SIMMS.—A name very little known even amongst those who cultivate the flower, in the management of which he was such an adept—the Tea Rose, but no one who has ever visited the garden of Birch Vicarage but has had something to say to "Charley." He was but a lad, but he was a born rosarian, and I have never seen a better judge or a more accurate observer. He was quiet and unobtrusive, did not bluster if his employer was beaten, and was the first to acknowledge it when fairly done. So good was his judgment that if Mr. Burnside was away at a show, and wanted to exhibit at another without going home, it was quite sufficient for him to write to Charley and tell him to put up a box of eighteen or twenty-four. It would be done without a mistake; there was no fear of duplicates or wrong flowers being put in, and experienced as Mr. Burnside is as a grower and exhibitor, he has often told me that he could thoroughly rely on him. To his employer the loss will be irreparable. Such lads are few and far between. Once, indeed, poor Charley did make a mistake when Mr. Burnside was going to exhibit at the Tea and Noisette exhibition. In his confusion he left the box of "spares" behind him at the railway station near Birch, and it is quite certain he flogged himself about it, although his kind and considerate master took it calmly enough. It was a very great shock to me to receive a note from my friend Mr. Burnside that the poor fellow had died under the effect of chloroform previous to an operation he was to have undergone, and so passed away a young life full of promise, but, who knows, perhaps saved from the evil to come.—D., *Deal.*

#### EARLY FLOWERING CHRYSANTHEMUMS IN 1891.

THE progress in these plants in England this season can only be fitly described as a revolution. The year commenced in February by the reception in this country from France of the catalogues of the French raisers, and chief among them was one from M. Délaux of Toulouse, who sent us not only his usual list of late and early varieties, but a special catalogue of 125 new sorts, said to be early. It almost seemed as if he, seeing that we were beginning to raise some of these sorts ourselves, meant to show us how insignificant we were, and so we may be in that direction, but then perhaps had we not devoted past years to the speciality, he and others might not have thought it worth their while to grow such sorts at all. Rivalry is useful to promote progress, all thanks to our continental friends for their part in the fight. As a matter of course, when we read their flowing descriptions, and think of the many expenses and the labour we have wasted in growing many poor sorts

among the good ones they have sent us, we take what they write not only with a grain of salt, but a good heap of it.

This season has been very unfavourable for their growth and testing in this country, being three weeks or more later than an ordinary one, in consequence of which I think that some which I cannot place as early—that is, flowering before the end of September—may in another year be fairly classed as such. As usual I will deal with the two Shows first. At the Crystal Palace Dahlia Show on the 4th and 5th of September the usual three prizes were offered for groups of early flowering Chrysanthemums, which were taken in the following order:—Messrs. Reid & Borneman first, Mr. H. J. Jones, of the Ryecroft Nursery, Lewisham second, and myself third. In relation to this first prize here and at the Aquarium Show, where also the first prize was awarded to the same firm, it will be well to state that these two groups were not by any means wholly composed of early flowering sorts. If this is allowed to go on, for it was commenced last season, the result would be that others to win the prizes would have to use the late kinds too, and thus pervert the show from its proper uses. It may be as well to name some of the sorts placed in these groups—W. H. Lincoln (Marvel, syn. Spiralis, syn. Mrs. Wellam), Elliot T. Shepherd, Charlie Sharman, Carew Underwood, M. Freeman, and Mrs. Alpheus Hardy. No one would class these plants as early, they were plants that had been forced out of their season. Many growers know that if a piece of an old plant or a young plant struck the summer before is grown that it will flower earlier than a spring-struck plant, and also that if the first bud that appears is kept and all the other side shoots and buds are taken off, that many sorts can be had in bloom early, especially if forced with fire heat; in fact a whole group could be made up in that way by selecting the right sorts which are well-known to experienced growers. A lady or gentleman comes to the show and sets down the names of some that they might decorate their garden next season, and sends an order for a dozen Mrs. Alpheus Hardy, which will not only not bloom early but very often not bloom at all even in a greenhouse, much less in the open garden.

I am rather at a loss to understand how the Judges should in two distinct cases let such a thing pass, but have an idea that Chrysanthemum judges are so much schooled in the matter of the late kinds and judging of individual flowers that they are wanting in appreciation of these sorts. I am attaching no blame to them. I think it is inadvertently done, just as architects apply the pattern of a Greek or Roman temple to a post office in London or an orphan school at Clapton. I admire the Maison Carée at Nîmes as a proper temple for the gods of the Romans, but not as a post office in London. There is an increasing number of new sorts fit for the purpose without forcing late ones, Bouquet de Dame and M. Bahuant for instance, which are both so early that they are unfit for the late shows and fulfil the conditions of growing such are applied to the late sorts.

At the Aquarium Show on September the 9th and 10th Mr. E. Vince of the Highgate Cemetery, north of London, took the second prize for a group; Mr. H. J. Jones of Lewisham third; and Mr. N. Davis of Camberwell had an extra prize for his group. These were all good for the season, but not remarkable, except in the case of Mr. Jones', for having many new sorts of the season contained in it. In the class for cut flowers Mr. Owen of Maidenhead was first, Mr. Ware of Hale Farm Nurseries, Tottenham, London, was second, and Mr. E. F. Such of Maidenhead third. Mr. Owen exhibited for the first time in England several of the new French early sorts—namely, Jules Paquet, Mde. E. Lelfort Pompons, for which he was awarded certificates, the latter being very similar and not any better than the new Pompons, Mde. Albert Colmich and V. Chiquot, all orange coloured, and perhaps V. Chiquot is the best. He had also for the first time as cut flowers M. G. Dubor, a fine orange yellow Japanese, Madame Louis Lionnet, a large incurved pink; M. Zéphir Lionnet, a fine magenta Japanese, Mme. Eulalie Morel, fine cerise Japanese, M. Vauvel, a fine pink Japanese; Vice-President Hardy, very fine orange Japanese, and M. G. Dabor has a slight twist in the centre, and seemed the best of the Japanese exhibited. I should explain that all those fine flowers had been grown on disbudded plants. He also exhibited two very fine crimson flowers of Souvenir de M. Menier, also from disbudded plants, but from my own experience it is not so good when grown naturally. On a visit to Mr. Owen at Maidenhead on September 21st, among many promising seedlings and others I saw some flowers of a new seedling of his raising named N. Molyneux; this is much in the style of E. Molyneux, but purple inside the florets, and with a kind of whitish-grey outer surface. These, of course, were from disbudded plants.

At Mr. Ware's nursery, Tottenham, on September 16th I saw in bloom the new sorts Madame Chauvin, pale magenta Japanese; M. Francis Katzer, a new coloured red orange Japanese; Chevalier Ange de Banderia, a pink Japanese; M. Lemailles, a deep pinkish bronze; and M. Leheureux, a yellow reflexed. I was much impressed on that occasion with a patch of the early Pompon White Lady planted among others in the open field, which bore much finer flowers there than the plants I had formerly grown in pots, and this has demonstrated to me its suitability for the open garden.

I was very fortunate in a visit to the Ryecroft Nursery of Mr. H. J. Jones at Lewisham on the 29th of September, for he had just completed a lean-to structure, with lights and wood about 8 or 9 feet wide and 100 feet long, which he had filled with plants of new and old early flowering Chrysanthemums, mostly in full bloom. There were about 1000 plants here, which formed a grand display, the finest I have ever seen. They were well-grown plants, mostly disbudded, and as they had

only been under glass a day or two had not lost any perceptible colour, which the bright and dark-coloured ones very soon do when housed. This show was a credit to any grower, and much more so in the present case, owing to the great expense and labour in the production of it, due to the number and very high price of the many new and expensive varieties. One had a French list price of 30 francs, and many more prices, ranging 20, 15, and 10 francs each this spring, besides others from other sources than France, but little less dear. I myself have grown many of the best of these, and can well testify to the cost and labour such collections entail.

In an effort to particularise the best and most worthy of cultivation among nearly 150 new sorts of the season one must necessarily fail to some extent, not only on account of the number, but to the fact that in an unfavourable season like this probably we have lost the opportunity of testing which more favourable summers would have afforded. It is possible that unknown merits may be found another season in some of those of which we at present think but little.

I will try and deal with some of the earliest first, and foremost is M. Gustave Grunerwald. I believe this has a great future before it. My own plant had been too weakened to do it justice, and my estimate was low, but on seeing other plants in far apart places found it to be a fine strong sort, though not so coarse and robust as some, still the flowers a kind of light lilac or pink, seemed of no particular merit, and by no means justify M. Délaux's description, which I translate thus: "Here is, without contradiction, the most beautiful and the most remarkable variety of Chrysanthemums that exists." He gives the height at 35 centimetres, or about 14 inches, but I think it will grow generally about 18 inches. The opinion I had formed from the above plants was quite changed one day on a visit to Mr. N. Davis's nursery at Camberwell, for there was a plant in its first bloom showing the most delicate and elegant flower ever seen at this time of the year. The plant was slender with very few leaves and a mass of flower buds on the top besides the flower that was just fully out, which was about 3 to 4 inches across in the form of a half-ball with narrow petals filling up well all over, with just enough curve and twist to add that exquisite refinement which so distinguishes the flower. It was nearly pure white, grown as it was at the very light end of a glass house. I visited this plant on three occasions weeks apart, and it seems to be as M. Délaux states, "Continuellement en fleur." I am not sure how it was that this plant demonstrated so much better the great merit of the variety than the others, but have a strong suspicion that much of it was due to the skill of Mr. N. Davis. For anyone who may have seen Mons. Délaux's engraving of the flower I may say it conveys the idea that the florets are broader and coarser there than in the flower itself, especially in the middle. It is very early, blooming at the beginning of September.

Perhaps the next new plant in importance is Baronne G. C. de Briailles. This is one of the most striking of the early varieties yet seen. It is a very stout robust plant, growing 2 feet 9 inches high, with flowers about 5 inches across, composed of rather broad and stout florets reflexed. The blooms are durable and nearly white, slightly flushed pink at the outer ends of the florets. The blooms come out at different levels, so that no buds need be taken off to let them all expand. It is a good grower, the habit nearly all that can be desired, and it flowers at the end of August.

Vicomtesse d'Avène.—This is a good pinkish lilac incurved variety, very dwarf, and fairly stout, about 20 inches to 2 feet high. Flowers about 3 inches across. Very early, blooming in August. It is of stout woody habit, and very rapid in coming to perfection. Thus a cutting inserted on May 21st was in flower by September 25th.

J. B. Duvoir, not Madame de Dubor, for which the name may be mistaken, is a most beautiful Pompon, perhaps the finest of all the early Pompons, and quite equal to any of the late ones. It is not perfectly white in the open, but is so under glass, and its extreme delicacy of appearance renders it very attractive. The blooms in August were 2½ inches across, very full of florets.

Ami Mezard flowers at the end of July, strikingly novel in appearance, 2 feet high; flowers 4 inches across, composed of broad ribbon-like florets of a blushing pink to yellow; profuse bloomer, and fine stout habit.

Madame Zéphir Lionnet is very fine orange yellow reflexed variety, 2 feet high, flowers 3 inches across; profuse and excellent bloomer; very early, blooms in August.

M. Dupuis is very bright orange yellow, much reflexed, flowers 3 inches across. Plant 18 inches high. This is the best in its line, and with Madame Zéphir Lionnet form the best pair of the kind, and a considerable advance on sorts in cultivation previously, as they both bloom in August.

Réné Chandon de Briailles blooms in July; 2 feet high; flowers 2 inches across; reddish violet striped with white on the petals.

Coral Queen was raised by Mr. Owen; most striking colour of pink coral; Japanese; 3 to 4 feet high, flowers 4 inches across, each one with a good stalk, so that the flowers are not crowded together. It forms in the garden a most striking object, as it is a very free bloomer. It is of good habit, and is an excellent sort altogether. It flowers in September.

Gloire d'Astafort is much the same colour as the above, perhaps the ladies will call it terra cotta. It is a Japanese, flowering at the end of September, of rather slender habit and spare foliage, but good bloomer with long stalks; 4 feet high; blooms 4 inches across.

Ruby King, raised by Mr. Owen, a very fine stout dwarf plant requiring no stick; reflexed crimson; flowers 3 inches across, produced

in immense quantity; 2 feet 6 inches high, and so strong that the stems of my plants 2 or 3 inches above the mould measure five-eighths of an inch in diameter. It flowers at the end of September.

M. Louis Lionnet is a salmon pink or flesh pink Japanese 2 feet 6 inches high; blooms 3 inches across, produced at the end of August.

Le Poète des Chrysanthèmes is a red mauve Pompon, grows 3 feet 6 inches high, of slender habit and spare foliage; profuse bloomer; flowers  $2\frac{1}{2}$  to 3 inches across; blooms at the beginning of August; very good variety, unlike all others.

Silver-mith was raised by myself from seed grown here. Very stout plant and free bloomer; ball like white flowers 2 to 3 inches across; plant 2 feet 6 inches to 3 feet high; good doer and requires no sticks; blooms in August.

Vice-President Hardy is a very fine fire red Japanese, will bloom well all over the plants; excellent habit; 3 feet 6 inches high; flowers 4 inches across, with somewhat drooping petals of a fine transparent shade of colour; blooms end of September.

M. Frédéric l'Usmayer is a very fine reflexed Japanese; orange flushed crimson, 4 feet high; flowers 4 inches across; profuse bloomer in September.

The following are all very early. Madame Gabus, lilac, broad petal; Pompon, 2 feet high; flowers 2 inches across. Raol Chandon de Briailles, pink lilac, 2 feet 6 inches high; reflexed flowers, 3 inches across; robust grower; a little like Pink Christine. Madame Mathilde Cassagneau, large flowered salmon pink, 2 feet high; flowers 4 inches, very much reflexed. M. G. de Dubor, resembling P. Van Geert, 2 feet 6 inches high, with long slender petals; fine orange yellow Japanese.

Rather later than the above but all good sorts are Madame Ve. Pasquier, white and primrose; Gaston de Chandon de Briailles, pink reflexed Japanese; M. Pierre Cassagneau, crimson reflexed Japanese, with slight blue tint; Madame Dufosse, fine red orange Japanese, 3 feet high; Madame Bellau, large pink Japanese, very good, a little like Pink Lacroix; Carrie Denny, orange incurved; Camille Bernardin, purple reflexed Japanese.

I think it desirable that the attention of many cultivators of flowers for that time between the middle of September and the same time in October should be called to the merits of the now not quite new Comtesse Foucher de Careil. It is a Japanese of the brightest orange red, very dwarf and stout, with a flower bearing capacity of the greatest abundance, the whole top of the plant being covered with masses of flowers. It has no equal at the time of year for brightness of colour or profusion of bloom, moreover being at this time a most fashionable and saleable colour. It is so stout and dwarf that it requires little or no support, and yet the branches are well fitted for cutting purposes; besides all this, it is robust, a good doer, as well as good to propagate. Blooming as it does at this time of the year, being too late for the early shows, and not late enough for the late ones, it has not the chance of becoming known as it is worthy to be. I can recommend it with great confidence to all growers.

It is as well also that a little more should be said as to the merits of Arthur Crepey, a new one of last season. It is a most famous sort, resembling in foliage the Desgrange family, from which it is probably a seedling, but this resemblance is only slightly existent in the flowers, they having a distinct reflex form. They are of a primrose or pale yellow colour, but nearly white under glass, and valuable as some relief from the now common prevalence of the Desgrange type; besides the plant is of better habit, each flower stalk being longer, the flowers grown naturally do not come so huddled together, making each separate spray more elegant and charming. Beyond all this it is a much better plant for propagation, making it altogether one of the most desirable varieties ever sent out. It has a further recommendation—viz., that it comes rapidly to maturity from cuttings. For this season, adverse as it was, I had single buds put in on the 3rd of April, plants in bloom on the 20th of August, these being very dwarf and bushy, and the flowers being 3 to 4 inches across, the earliest flowers being out by the end of July.

In conclusion it may be well to say a few words as to the times of the two shows of those early and demi-early sorts. At present the Crystal Palace Show is, say on the 4th and 5th of September, and as that is decided by the Dahlia Show it cannot be moved; but as the Aquarium Show is only one week later it is too soon, because, unless an exhibitor has two sets of plants, those damaged at one show often not being fit for the second so soon after; besides, the time is too short for other sorts to come out. But if the other show were held at the end of September it would give a chance for sorts to be shown which now are not able to be exhibited publicly at all. Thus some excellent sorts are not made known—to wit, Comtesse de Foucher de Careil, which is superb at the end of the month, besides several others, especially now there are so many new sorts. I will try, if possible, to say something more on the October flowers later on.—W. PIERCY, 89, Beadnell Road, Forest Hill, London, S.E.

#### CHRYSANTHEMUM PROSPECTS FOR 1891.

AFTER all the labour and anxiety connected with the culture of the Chrysanthemum I am afraid we are not going to have a good year; the dull damp summer will cause many growers to remember the summer and autumn of 1891 with feelings of disgust. I know here in Grimsby we shall, I think, be below the mark with several varieties. I find there are a quantity of blooms coming deformed, notably Jeanne d'Arc, one of the most constant varieties, plants that are equally as strong as last year showing but poor blooms. Avalanche, another constant variety, seems to be coming only thin. Stanstead Surprise, Mrs. J. Wright, Sunflower, Madame C. Audiguier, Mrs. Beale, Jeanne Délaux, and

several others are coming moderately well. I suppose we have the sunless summer to thank for it. On the other hand some are showing great promise, notably Miss Esmeralda, Puritan, Vivian Morel, likely to be a great beauty; Coronet, also showing great promise. Others most notable are Violet Tomlin, Frédéric Marrouch, W. H. Lincoln, very good; Bouquet de Dame, Eynsford White, and W. W. Coles, all showing good blooms.

The plants around this neighbourhood, as far as the growth is concerned, are the finest ever grown in this locality, and if we had had a good summer, so that they could have their plants well ripened, there would have been some excellent blooms. There will be some as it is, but I do not think they will be so good as they might have been. I have seen good blooms of the new incurved Mr. Robert Cannell, also of Louis Boehmer, which ought to be in every collection. I think next year when it is better known it will be eagerly sought after. Gloire de Rocher is a most charming variety. It has two good qualities, it is constant, also of dwarf habit. I have seen two excellent blooms.

Damp seems to be very prevalent, and I warn all young growers to keep a strict look out. Various remedies have been tried. I know many growers in their endeavours to keep their plants right for a certain show keep them outside too long. No plant ought to stay out any longer than when the bud begins to show signs of opening. If kept outside while they just begin to show their petals you cannot stop damping. I find the best remedy is to put them inside as soon as they begin to open the outer scale that covers the petals. After you get them housed and the blooms begin to expand, give them on dull days a little fire heat, admit plenty of air, and keep the plants at the roots somewhat dry. The wood is very sappy, and too much moisture at the roots leads to certain failure, so again I warn all beginners to be careful.—ONE INTERESTED, Grimsby.

#### CHRYSANTHEMUMS AT CHILWELL.

CHRYSANTHEMUMS at Chilwell will soon be one of the sights of the floral world. The sight is indeed remarkable now, as will be found by whoever may make a journey to see the collection. The chief display is in a light and lofty span-roofed house 100 feet by 30. The banks slope from the eaves to the broad central path, the plants in bloom being about 6 feet in height at the back and 18 inches in front, the end opposite the entrance being furnished in the same way.

Perhaps the most striking variety at present is M. R. Bahuant, a very fine incurved variety, up to Queen of England in form and substance, but with broader and rather shorter florets; colour carmine rose, shaded cerise. It is a strong grower, of good habit, and the blooms seem likely to keep well. Mme. Frédéric Mistral is a very promising novelty, with the form and colour of Alfred Lyne, but a much better flower. Robert Cannell is showing well. The most noticeable of other incurved varieties are the Queen and Princess of Wales groups, while Mrs. Shipman and Barbara are good.

Of new Japanese Flora McDonald, Mistletoe, Yonitza, Mermaid, Evalien Stein, a very long-petalled blush variety, Mattie C. Stewart, Olga, and Progression are the most noteworthy.

Last year's novelties are well represented, the best of which, Alberic Lundén, César Costa, very rich; Gloire de Rocher, Kate Murrell, Louis Boehmer, fine buds; Mlle. Marie Hoste, Mrs. W. Sargeant, a grand incurved yellow; Miss A. Hartzhorn, Vivian Morel, Sylphide, W. H. Lincoln, with fine bold buds; Zillah, Omar, and Ulrich Brunner are admirably represented. The last is an early variety, and was at its best a week ago; colour, carmine shaded violet, very effective as a decorative plant, as it appears to flower freely.

In the general collection of Japanese, Avalanche, Boule d'Or, Etoile de Lyon, Eynsford White, J. Délaux, Marsa, Minnie Palmer, Mrs. A. Hardy (showing colour), Mrs. Irving Clarke, Mrs. Thomson, Mrs. Wheeler, Mrs. F. Jameson, Ralph Brocklebank (improved), Sarah Owen, Stanstead Surprise, Stanstead White, and W. W. Coles, are coming on well, the last named carrying immense buds.

The Reflexed varieties are arranged by themselves, as are the Anemone-flowered, while the Pommpons and singles, which are in large bushes, are mixed. Some trained specimens are arranged at the right and left of the entrance mostly of pyramidal and globular form, Coquette de Castille, W. Holmes, Miss A. H. Bates, St. Michael, and Rosinante are the best.

In another large house, 100 feet long, are big bushes for cutting, besides a large number of plants of the October flowering type, such as the Madame Desgranges family, Madame la Comtesse Foucher de Careil, La Vierge, Mrs. Cullingford, and Roi des Précoces. Noticeable here are two new varieties, Martimas, a lovely shade of pink, and Arthur Crepey, a charming flower, somewhat like Mrs. Burrell in colour, but changing almost to white as the flower ages. It is evidently a seedling from Madame C. Desgranges, but of much better form.

Another house, 90 feet long, is filled with late sorts, Madame Pages, Boule de Neige, Eynsford White, Snowdrop, and Princess Teck, as whites; of the coloured varieties Admiral Symonds is a favourite yellow, and with Tokio, Julie Lagravère, Rubrum Perfectum, St. Michael, and Ville de Hyères, a good supply of flowers will be maintained till after Christmas.

Altogether the display is a gigantic one; indeed the floral pilgrim would have to travel far to find its equal, and then perhaps fail.—A VISITOR.

#### NEW CHRYSANTHEMUMS.

M. R. BAHUANT.—As a new incurved variety of French origin the Chrysanthemum named above attracted some attention last year, and several growers expressed an opinion that it would prove a really valuable

acquisition. Further experience this year has to some extent confirmed this view, but the chief defect seems to be its earliness. At the recent meeting of the National Chrysanthemum Society several exhibitors had good blooms of it, and if it is expected to be at its best in the middle of

a trifle too faithfully depicted in the wood engraving (fig. 71). This was prepared from one of the handsome blooms shown by Mr. Shoesmith at the meeting in question, and for which a first-class certificate was awarded. The colour is described as "carmine rose shaded cerise," it

FIG. 71.—CHRYSANthemUM M. R. BAHUANT.

October it would not be of much service for the ordinary shows during November. Fortunately we have seen plants that are likely to develop their blooms about the right time, so that it will stand a chance of being fairly tested. The florets are broad, and the blooms become of a great size, very solid, but somewhat wanting in refinement, and this is perhaps

is a soft, distinct shade, and the upper surface is of a much richer tint.

BOUQUET DE DAME.—A stand of six magnificent blooms of the white Japanese Bouquet de Dame was shown by Mr. Peter Blair, Trentham Gardens, and a first-class certificate was readily obtained.

The blooms were large, well formed, with broad slightly drooping florets, of great substance, and pure white. The solid white of this variety is very noticeable in contrast with others.

MRS. E. BECKETT.—This and the following variety were grown and shown by Mr. E. Beckett, Aldenham Park Gardens, Elstree, but we understand that they were raised by Mr. Norman Davis from seed he saved himself at Camberwell. The one named above is a Japanese with long twisting drooping white florets, forming a rather effective and distinct bloom (first-class certificate).

EDWIN BECKETT.—This also is a Japanese of an extremely deep rich golden yellow colour, with narrow tapering florets built up into a deep substantial nearly globular bloom. It appears likely to form a good exhibition variety (first-class certificate),

WHITE ETOILE DE LYON.—Mr. H. Cannell sends a bloom under the above designation. The outer florets were much injured in transit, crushed, and almost black, but the central uninjured part of the bloom more nearly approaches white than any we have seen, and may be regarded as the precursor of a pure white variety of the "great" favourite.

CHRYSANthemum MME. JEANNE GAYON.—Mr. Norman Davis sends us a head of this Chrysanthemum bearing twenty single or semi-double blooms, white, with a tinge of purple, and remarks:—"The Chrysanthemum sent is one of Délaux's named Mme. Jeanne Gayon. It is described as being as large as Avalanche and colour resembling James Salter, surpassing the most remarkable of the autumn varieties, &c., price 12 francs. As the flowers have not been disbudded it would be unfair to say what proportions it would obtain, but I fancy in this instance Nature would be preferred to Art."

#### CULTURAL NOTES ON CHRYSANthemUMS.

PROBABLY some of our celebrated growers will reply to the queries of "Y. B. A. Z." and my note can be consigned to the waste paper basket. Yet, as I have had something to do with the growing of Chrysanthemums, and have attended most of the principal exhibitions during the past few years, and have also visited some of the principal gardens where Chrysanthemums are made a speciality, I venture to give my experience.

It is not unusual to answer one question by asking another. Does Fair Maid of Guernsey produce flowers equal to what it used to do? A good bloom has not been produced here, although it has been well tried for successive seasons. If the crown buds are taken, and it generally shows early, numerous other buds are found clustered inside the one selected, making them useless for show purposes. If it will come good it must be had on later growths, yet not terminal. Belle Paule buds are small when they appear, and all growths should be rubbed off as soon as they can be removed with safety. This variety is the worst I know for starting to swell freely.

As I proceed the questions become more difficult, yet as everything has a cause expressions of opinion enable someone to find the "missing link." Had "Y. B. A. Z." named the varieties that show "a few florets then refuse to expand" it might have assisted in solving the problem. In the Japanese Mrs. Beale and Grandiflorum (a thing of the past) frequently do this. In the incurved section do any of the Teck family show that disposition? Doubtless the buds from the first breaks are most promising, but are the early anticipations always realised? I am of opinion that early bud selections of many of the varieties is a mistake; each individual variety must be known, and how far manipulation can be indulged in, for this is the secret of success in timing buds. Varieties that refuse to unfold their florets when they have made their first break and proceeded a foot on their second journey may have the points nipped out and the growths allowed to extend. Over-ripening of the wood or hardening of the buds is the cause of their not swelling freely, and if plants are treated as I have suggested buds will appear nine days or a fortnight later than these, will swell freely, and develop into large deep blooms with broader petals than will those buds taken a fortnight earlier, and which often require the warmest end of the house to induce them to unfold in time for showing.

When I saw the note by Mr. Taylor on Grape stands I thought how applicable it was to Chrysanthemums. All societies do not stipulate as to size; Leicester did not last year, and I believe I have seen large boards at other places. It is certainly desirable that all exhibitors should be placed on the same footing. Sometimes it simplifies judging. Occasionally competing stands of blooms are contrasted instead of each bloom being pointed, and as the one on the small stands cover the boards best a mistake in the awards may occur.

Lastly, Mr. Woodcock, speaking of varieties, advised topping. Mrs. J. Clark—was not Mrs. E. W. Clark meant? I find the former crown bud comes at the right time, while the latter bears out the decision I came to last year, that it is one of a few that must be assisted in its early stages.—SAMUEL BACKHOUSE, *Onslow Gardens, Shrewsbury.*

#### MANURING.

(Continued from page 327.)

ORGANIC matter to a certain extent must be present in all soils for the manufacture of nitrogenous substances needed by the crops. If pasture land the soil adds to its stores of nitrogen, and the gardener's love of turf is due to its containing nitrogenous elements in full quantity for present use and enough for subsequent manufacture; but

turf will not keep on yielding nitrogenous substances for ever, and it is not straining any point when we say that nitrogen cannot be made out of the best loam so as to serve any crop indefinitely. Pasture land will only add to its stores of nitrogen whilst it contains a sufficiency of potash and phosphoric acid. The everlasting use of stable manure on Vine borders fills the soil with an excess of acids, and the crops of Grapes shank at a tremendous rate. Vine borders, like pastures, only assimilate nitrogen when they contain a proper quantity of ash elements—potash, lime, and phosphoric acid. Poverty stricken Vines "jump" when treated with blood manure. Those that are sappy, long jointed in wood, and have an inherent tendency to lack colour and shank in their crops, are revolutionised by dressings of superphosphates. Lawns that will scarcely grow anything but moss will yield abundant verdure in Clover. Bird's-foot Trefoil (*Lotus corniculatus*) will grow on soil which through acidity will hardly support a blade of grass. These facts are the result of causes in the soil or plants. Which? Both! Perhaps, but that is no answer, for the object of chemistry is to explain the natural laws by which plants are governed, so that the gardener and farmer may apply them in their cultures.

To this phase of our subject we now address ourselves, and we shall only premise that the classes of plants with which the cultivator has to deal are:—1, Those which live on the nitrogen of the soil and the nitrogen of manures alone; and, 2, those which can turn to account not only the nitrogen of soils and manures, but also those of atmospheric air. These are the problems science has set itself to teach, and which practice has exemplified to be of uncommon importance. Professor Hellriegel's researches have proved with absolute certainty that the nitrogen of atmospheric air is made use of by certain plants, and assimilated by them, as already described in respect of Clover. Professor Wagner, also, by scientific investigations, has succeeded in solving some important questions relative the use of nitrogenous manures, which clearly define the principles on which they may be applied in manuring garden and field crops. These experiments prove that cereals, Potatoes and Tomatoes, Turnips, and all kinds of Cabbages or Brassicas (including Cress, Mustard, Radish, Seakale, Horseradish, as well as Broccoli and Cauliflowers), Lettuce, also Chicory, Salsafy and Scorzonera, Buckwheat and Rhubarb, are incapable of taking nitrogen from atmospheric air, but consume the nitrogen of the soil and manure, extracting the garden's or farm's store of nitrogen. Vines and all fruit trees are also nitrogen consumers. All these plants require nitrogenous manures to enable them to produce the greatest and best possible crop at the least expense.

Against these nitrogen-consuming plants the gardener and farmer has to set the nitrogen-increasing plants. These comprise Peas, Beans, Vetches, Clover, and all other leguminaceous plants, which take nitrogen from atmospheric air. All plants of that class do not ordinarily require nitrogenous manures, consequently do not diminish the soil's store of nitrogen, nor take from the gardener's or farmer's capital of manure, but augment the one and save the other. They, as explained under Clover, assimilate nitrogen from the atmosphere, and carry it in the form of roots and stubble into the soil. Some of course finds its way, in the shape of hay or fodder, into the stable or stall; but notwithstanding that one crop of these plants, say Clover, is taken off the ground, the soil is left richer in nitrogen by the roots and stubble than had a crop of cereals been taken with manure. This because the Clover is capable of extracting nitrogen from atmospheric air, and thus supplying this valuable substance to the soil gratis. Some parts of the hay crop, with an addition of other manurial elements, finds its way to the soil again, yet this seldom occurs to benefit the same soil in an ordinary system of rotation. Indeed, the agricultural interest demands something more speedy and substantial, therefore the farmer pens sheep on the second crop of Clover, consuming it with or without cake, the mutton is transported, whilst the soil has returned to it its equivalent in nitrogenous yielding substances, and it is in splendid condition for yielding the following year an abundant crop of Wheat. This saves labour, and the green crop eaten on is infinitely superior as manure to double the quantity of fodder eaten off the land, and requiring carting off and on to the land again. One half or more of all stable or farmyard manure is lost as regards its nitrogenous elements in the making. Thus the farmer reduces his manuring with nitrogen to a minimum by manuring the land for cereals with the nitrogen of the air, dispensing to a great extent with the nitrogen of manure dealers, and is able to invest in superphosphates, whereby weight is given to the grain of the Wheat crops.

Nitrogen extracted from the atmosphere enables the cultivator to expend more money on manures that nourish crops which will give the most profitable returns without having nitrogen supplied to them by the soil, and no plant of this class—namely, cereals, roots, and Potatoes, will produce a full yield if in want of nitrogenous nourishment. It is patent, however, that the agriculturist must secure much atmospheric nitrogen by growing much leguminous fodder, and keep many cattle, consuming as much as possible of the crops on the land, reserving no more of these crops for eating off the ground than is absolutely necessary for the winter feeding of stock, for it is easier and far more profitable to transport cattle than bulky crops off and manure on to the land. Growing fodder and feeding off the land is the way not to do it, yet some farmyard manure is an absolute necessity for the growth of Mangolds, Turnips, and Potatoes, but the more of the two former are consumed on the ground the more economical is the system of manuring, because much more nitrogenous manure is put into the soil at much less cost. Growing fodder and feeding cattle with it off the ground is one of the most

extravagant systems of manufacturing nitrogenous manures. Open yards are nitrogen wasters; covered sheds save much nitrogenous matter. One ton of the latter has fertilising value equal to 3 tons of the former. Farmers recognise these facts and limit cattle feeding to absolute necessity as regards doing so, with a view to the manufacture of open yard manure. They consume as much as the climate will allow of fodder on the ground, and they show their abhorrence of carting manure, and at the same time their appreciation of nitrogenous manures by producing them directly on the fields and eating the crops on the ground, or as green manure ploughing them into the soil. This is a very old-fashioned plan as regards Mustard and Rape, which, however, can produce no nitrogenous manure. When eaten on the ground they act in two ways. 1, The fodder is transformed into nitrogenous elements for the support of the succeeding crop; 2, The deep rooting of these plants bring up fresh supplies of potash and phosphoric acid. Therefore the Mustard and Rape when eaten on has a twofold effect—namely, manures the soil with nitrogenous and potassic and phosphoric elements. Ploughing them in as green manures yields very little nitrogen, but provides potash and phosphoric acid. Without these elements in sufficient quantity it is ineffective to manure nitrogen-requiring plants as cereals, Potatoes, and Turnips with nitrates and ammoniacal salts, for a soil deficient in phosphoric acid and potash will make a poor display in the crops by application of nitrate of soda. By ploughing in Mustard or Rape the ground is put in a condition to make the most of nitrate of soda.

On the other hand, Clover, &c., sown into the green cereal crop develop into green manure plants amid the cereal stubble, and these take nitrogen from the atmosphere, and ploughed into the soil in late autumn or early spring decompose, and supply nutriment for a succeeding crop of Potatoes or Turnips, also cereals. This is better than a useless crop of Grasses and weeds allowed to encumber the preceding cereal crop, for they, like Mustard and Rape, have little nitrogenous value, and, unlike them, are too void of nutrition to be eaten by animals, therefore not transformable into nitrogenous manure. But the cereal crop suffers little by Clover sown into it, and animals eat it into the quick, and they put on flesh by the process, whilst they dress the ground with nitrogenous manure. More than that, the ground is kept in cleaner condition. Thus, by employing plants that assimilate nitrogen the cereal crop is not impoverished, but the succeeding crop benefits to the extent of the nitrogen taken from the atmosphere and put into the soil either as green manure but preferably as nitrogenous manure, resultant of eating on by sheep.

Sowing winter Vetches, or Vetches and Peas after harvest, merely grubbing up the stubble and sowing with as little delay as possible secures a good plant before winter, and by ploughing this into the land in spring the future crop of Turnips or Potatoes receive a good supply of nutriment by the decomposition of the Vetches and Peas. That is one way and good, but there is another and better—namely, to pen sheep on the land, give them the bulk of the Tares as fodder, and let them eat the rest on the ground so as to manure the whole ground evenly, affording them a daily supply of cake or Mangolds, and the ground is in capable heart as regards nitrogenous substances for affording nutriment to a crop of Turnips. There is yet another plan, that is, to take the Vetches off the ground and rob the land for the sake of cash, which is a sheer waste of nitrogen, inasmuch as its equivalent in manure is not returned to the soil. Still the Vetch stubble and roots has enriched the soil to the extent of the nitrogen, those parts have implanted in them by that part extracting it from the atmosphere, and it is in the roots and stubble of Vetches and all leguminaceous plants that nitrogen extracted from the atmosphere is chiefly stored.

These are some of the lessons we have gleaned from a close observation of agricultural practice. The fields are open to inspection by every one who cares to look over the hedges separating them from our highways and lanes, and from the crops and the methods of culture pursued all may draw lessons alike interesting, instructive, and useful, especially if the observer has made himself acquainted with the rudiments of agricultural chemistry, which will better enable him to acquire knowledge and understand the crops to which everyone owes existence.

To the gardener these remarks may seem of little importance; but we feel that a majority will agree with us that it is of the greatest importance that the plants we cultivate on empirical lines should be understood from a scientific standpoint. For many years we grew Peas on a south border for early supplies, and followed them with Brassicas that came off the ground in time for sowing with Peas in autumn or spring. This rotation of two dissimilar crops in a season on the same ground succeeded well enough with a dressing of manure annually; but we were then unacquainted with the facts that Science has since taught us that Peas are nitrogen gatherers, and Brassicas nitrogen consumers. Since being made acquainted with the principles of plant nutrition we have sought for plants in other orders that were or appeared nitrogen gatherers, and we are obliged to admit with very indifferent results. The only ones upon which we have been able to fix with any degree of certainty are Cucumbers and Melons in Cucurbitaceæ, and Gardenias in Rubiaceæ. These—Cucumbers, Melons, and Gardenias—are liable to a sickness corresponding to, if not identical with, Clover sickness—namely, attacks of eelworm, *Tylenchus (Vibrio) devastatrix*. The roots of these plants, under certain conditions of soil ingredients, form nitrogenous nodules; but these have no connection with the minute organisms which, as shown by Mr. Warrington of the Rothamsted laboratory, transform ammonia into available plant food—namely, one organism by

oxidation converting ammonia in the soil into nitrites, and the other by a similar process changes nitrites to nitrates, the latter containing a larger proportion of oxygen than the former. The root nodules are simply due, as far as we can make out, to the plants gathering nitrogen from the atmosphere and assimilating it in the plant it becomes stored by some unexplained process in the root nodules. We have noticed similar nodules on sickly Ixoras, also in *Burchellia capensis*; and not infrequently these plants become gouty in the stem next the soil or collar, and they fall a prey to eelworm. Some other plants have a tendency to form nitrogenous nodules on the roots when grown in peat which they do not exhibit when grown in loam, especially where lime prevails to the extent of 5 to 10 per cent.

There is another point—namely, leguminaceous plants seem to assimilate most atmospheric nitrogen where the soil is calcareous, and least where it is of a vegetable nature. If we lime vegetable soils, or those rich in humus, Peas thrive amazingly, by which we assume the minute organisms are called into activity, and converting the lime into nitrate, the Peas are supplied with that substance.

But the question arises, Do Vines, Peaches, and other fruit trees grown under glass extract nitrogen from atmospheric air? We believe the root nodule test to be infallible, and they do occasionally occur on the roots of Vines and fruit trees grown on Plum stocks. We have no desire to see them on any trees under our care, for the simple reason that they are a certain indication of indifferent health.

We have used liquid manure during many years for sprinkling the floors and other available surfaces of plant and fruit houses, and always considered there was advantage in the plan. We saw more chlorophyll in the leaves, the Grapes assumed a deeper purple or black and richer amber, and the Peaches and other fruits grew larger and brighter in colour, and we believed it worth while to practise it because it imparted health to the plants and fruit trees, and enhanced, as we considered, the quantity and quality of their crops. Alas! we did not then know the difference between atmospheric nitrogen and atmospheric ammonia. The latter obtains in the air to the extent of one part in one million, but atmospheric nitrogen forms 79.19 volumes to 20.81 volumes of oxygen, or by weight atmospheric air consists of 23.01 parts of oxygen to 76.99 of nitrogen, and these exist—not as a chemical compound, but as a mechanical mixture. Where, then, is the ammonia vapour doctrine? The Romans believed in it 2000 years ago, and we still practise it, because experience has proved that plants never thrive so well as where gases are being given out by decomposing matter in presence of a due supply of atmospheric air. What favours healthy growth in plants requiring artificial heat so well as that generated by sweet fermenting materials? Some ammonia is being constantly evaporated, and unless excessively present in the atmosphere does not injure, but rather contributes to health and growth, and certainly is inimical to red spider and other insect pests. Of its properties as a source of nitrogen to plants we know absolutely nothing, yet it cannot supply nitrogen in anything like the quantity essential for the swelling and perfecting of profitable crops of fruit, and unless fruit trees and all plants are supplied with potash and phosphoric acid they will make very poor returns for a bounteous supply of nitrogenous manures, with the nitrogen of the air thrown into the same scale.—G. ABBEY.

MR. PRINCE AT LONGWORTH.

THE fine hot weather of the second week in September found me in Oxfordshire; and the warm sun suggesting Tea Roses, and Oxford Mr. Prince, I determined on an expedition to hunt him up, though of course it was too late to see the flowers in proper form. All I knew of his whereabouts was that it was necessary to drive from Oxford, and accordingly I went by an early train one pleasant morning to that ancient seat of learning in the company of a young gentleman of the University, who strongly urged me, if any riding or driving was to be done, to secure the services of a certain quadruped named Brown Sam. The narrated exploits of that noble animal, however, caused me to fight shy of him, and after some inquiries I was fortunate enough to secure a capital little fast-trotting pony and trap for a moderate sum for the day from the King's Arms. I almost regretted afterwards, as we got on so well, that I had not tried to visit Mr. Mattock at Headington the same day. Ten miles, I was told, was the distance to Mr. Prince's grounds at Longworth, and as I rattled along over the splendid granite roads, I wondered over two things: first, why North Berks and also North Oxfordshire are always so much later with their harvest than the midland or eastern counties, and whether it is because the farmers in those parts have a queer habit of sending one man, or a man and a boy, armed with reaphooks, into 12 or 15 acres of Barley; and secondly, how tremendously handicapped a man must be in showing Roses all over England when he is ten miles from a first-class station, and seven from the nearest small one. My little steed made light of the distance, and though I stopped for a while at Kingston Bagpuse, the next village to Longworth, to see my old friend the huntsman of the old Berks, and to admire the horses and hounds about to begin the campaign at five next

morning, I got to Longworth in capital time, and was most hospitably and heartily received by Mr. Prince and his son.

We commenced at once to look at the Roses, and were soon among acres of seedling Briars and tremendously long rows of dwarf Teas. My first impulse was to try and get an idea of the soil by the feeble aid of an umbrella. I need hardly say that after the baking the earth had lately had I did not obtain a very deep insight into its nature by this means, even when supplemented by Mr. Prince's walking stick, but it seemed to be a deep rich loam (very deep he told me), with a little of the reddish tint common in those parts and further north. The rent was very high I was informed, much higher than I should have imagined possible for mere arable land so far from a station. The Roses were of course showing a wealth of bloom; but, alas! I was too late to see them "in character," so much so that sometimes it puzzled all three of us to name a plant. But what a quantity of bloom! And how they "waste their sweetness on the desert air!" for, owing to his isolated position, Mr. Prince told me he was able to do very little indeed in the way of selling blooms, though, as to plants, he had quite a connection even in Spain. Ah! there is something like sunshine there. I should like to see some of his plants in Spain. They could not be less appreciated than they seemed to be at Longworth. There were lovely Roses in cart-loads. We picked a choice specimen, wore it or carried it for a minute or two, and then—really terrible!—threw it down to make room for another. A very beautiful bloom of Madame Chauvry was the first thus to attract attention. This is a strong growing, I suppose a Dijon, Tea, and it seems to me one of the most attractive of the race in colour, recalling the bright tints of some of the favourite buttonhole varieties. Monsieur Furtado, I found, making much better and bigger plants than I expected. I forget whether I have ever had it; at all events I have been without it for some time. It is neat, but not big enough, and I was surprised to hear it was still in demand. A whole row of Jean Ducher in full bloom was of simple pale yellow, hardly a sign of pink anywhere, even on the overblown flowers. I have never seen it so lightly coloured, and should not have recognised it; but perhaps the bright hot weather of the previous days and the buds not being thinned had something to do with it. Marquise de Vivens is a distinct sort, which was new to me. The "bright carmine" is a new colour in Teas, and it seemed likely to be pretty in the bud state, but of not sufficiently good quality for exhibition. Francisca Kruger was beautiful as usual. In the summer for show and in the autumn for lovely half-opened buds this is a very favourite Rose with me. Madame de Watteville was making much better growth as a dwarf than I can get from it. I wanted to see Madame Pierre Guillot, but forgot to ask for it. Mrs. James Wilson was doing well, as it does with me. A friend complains that he cannot distinguish it from Marie Van Houtte, but I find it quite distinct in colour and shape, and remarkably so in habit. Presently I was shown a new Tea Rose, of globular shape and (I am a shocking bad hand at describing colour) generally whitish with a rose centre. It was of course impossible to judge at that time of its capabilities, but I was much interested because Mr. Prince told me he was going to name it "Miss Watson;" and I am sure all rosarians will agree that graceful recognitions like this, and the parallel case of Mr. George Paul calling a good new Rose after his foreman, Mr. Gater, are pleasing and acceptable to all lovers of Roses.

I need hardly say that Souvenir de S. A. Prince was very much in evidence and covered with flowers. Few, if any, I think, will have found any deception in the favourable impression this sport from Souvenir d'un Ami created at first. I have not seen Mr. W. Paul's The Queen, but understand that it is admitted to be practically identical. A few days ago, in the last week of September, I was searching for white Tea Roses for a wedding and a funeral, and all the largest and finest blooms I could find came from this variety. It seems to me to occupy the same position to Souvenir d'un Ami as The Bride does to Catherine Mermet—viz., as an improvement if anything upon the original. H.P. Roses are grown by Mr. Prince in considerable quantity, and principally on the seedling Briar. They seemed good plants, but were naturally showing but few blooms, and those even more out of character and colour than the Tea Roses.

After lunch we went to see the seedling stocks, visiting first a considerable area of fine strong plants which had been budded, and then the newly raised ones. Here I was astonished, for I understood that the seed in this field had only been sown a few months, yet the plants were apparently big enough to bud; at all events I have budded smaller ones. The seed is sown in rows, and the plants are then chopped out and singled like Turnips. It was a splendid crop, and wonderfully uniform in size, strength, and health; there was a general sprinkling of mildew both here and on the budded stocks. Seedlings always seem to me to be more liable to this than cuttings, but not enough to do any harm. We pulled a plant or two, and the roots had gone down capitally.

Soon afterwards we came to the standard Teas. These were very fine, the leaves looking particularly healthy, and I confess I liked their appearance better than the dwarfs. But when we came to a low wall, there were some really famous plants of Teas to be seen. First, and above all, I was struck with Princess of Wales. In growth and size of bloom Mr. Prince had better specimens of this variety, both on the wall and in the open, than any I have seen elsewhere. He had then quite as fine examples of it on the wall as any I have had this year, and the growth was much stouter and stronger than with me. I kept a good look out for Comtesse de Nadaillac, for it is well known that Mr. Prince shows this Rose with a deeper yellow shade than anyone else

can manage. I had heard theories mooted of their being budded on Banksia, and other strange rumours, but I was assured that they were all unfounded; and when I saw a shoot of it against the wall—well, quite long enough and thick enough to form a fashionable walking-cane—it seemed to me merely the case that the stock, the soil, and the treatment suited the variety uncommonly well. The seedling stock appeared to answer particularly well against the wall. Mr. Prince keeps but few cut-backs, but I saw some on the seedling stock, and very strong and healthy they looked. The plants of Marie Van Houtte were veritable bushes. I was surprised to see the union between stock and scion well above the ground, and was told that the distance of an inch was recommended. This, as Mr. Prince's own advice, is well worth bearing in mind.

On asking how they managed to cut and stage for exhibition so far from a station, it was strange to hear that all blooms for show are cut by 7 A.M. on the day preceding, and placed in water in a large cool barn. This may do very well for the Teas, which sometimes in wet weather are even the better for keeping, but seems hard upon the less enduring H.P.'s.

I am sadly afraid that in my enthusiasm and anxiety not to miss anything that was to be seen, I rather tired my kind host, who, as his friends know, is anything but strong since his accident, but I have to thank him for a most pleasant and interesting day, and also for a great box of splendid Roses, which excited much admiration at the house where I was staying.—W. R. RAILLEM.

### THE UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—ANNUAL DINNER.

THE fifth anniversary dinner of the above-named excellent Society was held in the Cannon Street Hotel on Thursday, October 15th last, when there was a large attendance of members and friends to support the Chairman, Harry J. Veitch, Esq., who had been called suddenly to undertake that office in consequence of the unavoidable absence of G. A. Dickson, Esq., of Chester, the appointed Chairman. It is needless to say that Mr. Veitch performed the task in an admirable manner, and entered as thoroughly into the spirit of this meeting as he invariably does at all such gatherings.

The usual loyal toasts having been honoured, the Chairman proposed "The United Horticultural Benefit and Provident Society," and in his opening remarks referred to the strange fatality that had attended the Chairmen at this dinner. Last year Mr. E. R. Cutler occupied the chair, but he had since passed away, as also had Mr. Cavendish, who was then named as the Chairman for 1891. Mr. Dickson was unable to come owing to the serious illness of his mother, and several other gentlemen who had been approached were deterred by similar causes. Having been called to take the post at so short a notice he (Mr. Veitch) hoped they would excuse all shortcomings, but he was always glad to help in such matters, and would, therefore, willingly do his best for them. He then briefly traced the progress of the Society from its foundation in 1865, and observed that for some years the Society was engaged in doing good work very quietly. In 1885, however, it was felt desirable to make the objects and scope of the Society more widely known, and a substantial help was rendered in this direction through the Horticultural Press. Since then it had made great progress. In 1883 there were only 100 members, in 1887 they had increased to 213 with twelve honorary members, while in 1891 the total is 410 with fifty-three honorary members, and during the past year sixty-nine benefit members have been elected, making the largest total in one year. It may be asked, What are the objects and advantages of the Society? and this question could be answered by saying, That it is intended to provide assistance to gardeners in time of sickness and old age, that it is absolutely safe, is governed by very comprehensive rules, and offers many advantages over all other general benefit societies. Members could join between the ages of eighteen and thirty-five, and become entitled to full benefits after twelve months. The payments are in two series—9d. per week to ensure 16s. per week in illness, and 6d. per week to ensure 10s. 6d. in the same way, full benefit payments being made for twenty-six weeks, and after that a reduced rate for an equal period, and then urgent cases may be transferred to the benevolent fund. In addition to this 3s. and 2s. per year is paid to the benevolent fund and also a small annual payment to the management fund. Mr. Veitch then referred briefly to the amounts standing to the credit of members, and which at their decease had been paid to their widows. He also referred to the low rate of sickness, which compared most favourably with other societies, and cited from the letter of an actuary to this effect. He commented favourably upon the general management and the small expenses incurred, and concluded by urging all gardeners to give their cordial support to so excellent an institution, which would become still more useful as the numbers increased. Several donations were announced, including £10 from Mr. G. A. Dickson.

Mr. Nathan Cole responded briefly on behalf of the Society, and Mr. Hudson then proposed the "Honorary and Life Members and Visitors," and pointed out the good service the honorary members rendered the Society, and stated he was glad to find they had the sympathy and support of so many influential friends, but he hoped they would secure the aid of many more. In ten years their members had increased from seven to fifty-three, and they could still advance. Mr. W. Furze and Mr. Jos. Cheal responded, both commending the Society as worthy of all support, and wishing it every success.

Mr. N. N. Sherwood had the next toast—namely, "The Health of the Chairman," which he did in most complimentary terms, very justly observing that Mr. Veitch was always willing to do his utmost for gardeners and gardening. He mentioned the convalescent fund, which he had been the means of starting, and since that £15 had been subscribed. Having invited honorary members to contribute to this special fund, he stated his intention to make his three children annual subscribers of a guinea for that object. Mr. Veitch, in reply, thanked the members heartily for their reception, and said he would be pleased to contribute £25 to the convalescent fund. Mr. Sherwood also proposed the "Officers of the Society," coupled with the names of Mr. Jas. Wheeler and Mr. Collins. Mr. R. Dean proposed "Kindred Societies," for which Mr. G. J. Ingram, Secretary of the Gardeners' Royal Benevolent Exhibition, responded in an excellent exhaustive speech, reviewing the history and progress of the Institution since its foundation; and Mr. J. Laing proposed "The Horticultural Press," which was responded to by Mr. George Gordon. Votes of thanks were also accorded to the donors of plants and flowers—Messrs. J. Laing & Son, B. S. Williams & Son, H. Cannell and Sons; for the fruit to Messrs. Thomson & Sons of Clovenfords, with many others. It should be added that Mr. J. R. Chard, of Stoke Newington, had charge of the table decorations, and employed his artistic arches with excellent effect.

### THE MANCHESTER FRUIT SHOW.

A SPECIAL Exhibition of hardy and other fruits was opened at the Town Hall, Manchester, on October 20th. The fruit generally was exceptionally fine, affording satisfactory evidence of high culture. It was an Exhibition of a very representative character, especially the fruit in the large collections. Of those not for competition was a fine display of 250 dishes of Apples and Pears from Her Majesty the Queen's gardens at Frogmore. General excellence was a characteristic of this display. Among the finest fruits were of Pears Chaumontel, Doyenné du Comice, Beurré Diel, Vicar of Winkfield, Marie Louise, very fine; Flemish Beauty, Beurré Bachelier, and Pitmaston Duchess; and of Apples Mère de Ménage, Striped Beefing, Sandringham, Winter Peach, Dr. Harvey, quite model fruit; Alfriston, very fine indeed; Bismarek, Golden Noble, Frogmore Prolific, a lovely dish of Brown's Codlin of a rich golden yellow, and an attractive dish of the pretty little Fairy Apple.

Messrs. Veitch came next with sixty-six dishes of Pears, and 146 dishes of Apples. The fruit in this collection was really magnificent; so fine were all the dishes that it was not an easy matter to make a selection. This fruit was from trees, pyramids, ready for sale this season. The best Apples were Seaton House, very free bearing; Jefferson, a lovely striped dessert Apple, very large; King of Pippins; Alexander, very fine; Transparent de Courcelles; Benoni, a charming Italian dessert Apple; Barnack Beauty, and King Harry.

In the open class Messrs. G. Bunyard & Co., Maidstone, were first with eighty dishes of Apples, kitchen and dessert kinds. The whole of this fruit was very fine, not an inferior dish in it. The sorts were:—Lord Derby, Dutch Mignonne, Small's Admirable, Lord Grosvenor, The Queen, very fine; Golden Spire, Annie Elizabeth, Jolly Beggar, Rosemary Russet, Potts' Seedling, Hoary Morning, Councillor, Roundway Magnum Bonum, Calville Rouge Précoce, King of the Pippins, Melon Apple, Duchess of Oldenburg, Bedfordshire Foundling, Sandringham, very fine; Northern Dumpling, King of Tomkins County, Ecklinville, Schoolmaster, Swedish Reinette, Brownlee's Russet, Belle Pontoise, Cox's Pomona, Kentish Fillbasket, Lord Derby, Twenty Ounce, Alexander, Golden Noble, Wealthy, Farmer's Seedling, Calville Rouge, Manks Codlin, Gold Medal, Mère de Ménage, Peasgood's Nonesuch, Gloria Mundi, Stirling Castle, Blenheim Pippin, Baumann's Reinette, Golden Reinette, Egremont Russet, Castle Major, Washington, Stone's Apple, Bismarek, Alfriston, Lane's Prince Albert, Tower of Glamis, Gascoigne's Seedling, Seaton House, Old Nonsuch, High Canons, Claygate Pearmain, Cellini, Grenadier, Warner's King, Reinette de Canada, Queen Caroline, Cornish Aromatic, Evagil, Mother, Royal Russet, Beitigheimer, Beauty of Kent, Lady Henniker, New Hawthornden, Graham's Royal Jubilee, Brabant Bellefleur, Bramley's Seedling, Ribston Pippin, Worcester Pearmain, Cox's Orange Pippin, Hormead Pearmain, Tyler's Kernel, and Waltham Abbey Seedling. Mr. John Watkins, Withington, Hereford, was second, and Messrs. J. Cheal & Son, Crawley, Sussex, were third.

For the best fifty dishes of Pears, Mr. John Watkins was first with a well-balanced collection of fair sized fruits; the Earl of Harrington, Elvaston Castle (Mr. J. H. Goodwin, gardener), was second; and Messrs. Bunyard & Co. third, with some fine fruit.

For thirty-six dishes of Apples, kitchen and dessert, Messrs. Rothschild, Gunnersbury Park (Mr. G. Reynolds, gardener), were first with excellent fruit, the Earl of Harrington being second, and C. Lee Campbell, Esq., Glewston Court (Mr. S. T. Wright, gardener), third. In this class an extra prize was awarded to Sir E. G. Loder, Bart., Leonardslee.

For eighteen dishes of Apples C. Lee Campbell, Esq., was first, Mrs. Evans, Moreton Court, Hereford, second, and Mr. Joseph Such, Mount Pleasant, Davenham, third. For twelve dishes of Pears Sir E. G. Loder, Bart., was first with an excellent display, the second prize going to H. St. Vincent, Esq., Westbury-on-Trym, and the third to C. Lee Campbell, Esq.

The Earl of Durham, Lambton Castle (gardener, Mr. J. Hunter), was an excellent first for twenty-six dishes of Apples and Pears grown under glass. This collection was remarkable, as showing what can be done in

the north by the aid of glass. The second prize going to Sir J. W. Pease, Bart., Hutton Hall, Guisborough (Mr. J. McIndoe, gardener), and third prize to Samuel Barlow, Esq., Llandudno (Mr. J. Hilton, gardener). Messrs. J. Cheal & Sons were first for a collection of eighty dishes of Apples and Pears grown under glass. This collection contained many dishes of fine fruit. For six dishes of Pears A. Smith Barry, Esq., Monbury Hall, was first; Mrs. Grundy, Westleigh, being second, and James Watts, Esq., Abney Hall, third.

The Cheshire fruit was really very good having regard to climate, and prizes were taken by C. Sherwin, Esq., Ashbury Hall, Allington; James Watts, Esq., Abney Hall; and Mrs. Grundy in the order named. For Apples grown within twenty miles of Manchester A. Smith Barry, Esq., was first; R. P. Gill, Esq., second; and Mrs. Grundy third.

The display of Grapes was a fine one, some Muscat of Alexandria in a first prize collection of ten bunches being beautifully finished. This prize went to the Earl of Harrington; the other varieties being Gros Colman, Alicante, Alnwick Seedling, and Muscat Hamburg. The second prize went to Messrs. Rothschild, Gunnersbury Park, for a collection showing great cultural skill. These were large bunches of Trebbiano and other good bunches of Alicante, Chasselas Napoleon, Gros Maroc, Black Hamburg, and Muscat of Alexandria. For three bunches of black Grapes C. Lee Campbell, Esq., was a good first with grand bunches of Alicante; the Earl of Carnarvon (Mr. J. Read, gardener) being second; and Sir J. W. Pease third with very fine Gros Colman, rather deficient in colour.

A collection of six dishes of Tomatoes, for which J. F. Campbell, Esq., Woodseat, Utttoxeter, was first (Mr. J. Hollingworth, gardener), had grand fruits of Elvaston Castle, dark red; and Hackwood Park, equally fine. Some clusters of Colchester Black Bullace, exhibited by Mr. A. J. Harwood of Colchester, were worthy of notice. They were dense clusters of fine fruit, having the appearance of Cluster Damson.

### HARDY FRUIT GARDEN.

**ROOT-PRUNING.**—The present is the best time for this operation before vegetation becomes inactive, so that fresh roots may be formed previous to winterly weather setting in, although it may be carried out any time from now until the period when the buds burst again in the spring if the weather is suitable. Root-pruning may easily be carried to excess. It is at best a necessary evil, and should only be resorted to when other means of inducing fruitfulness have failed. Where the top growth can be allowed to extend, and the wood is kept well exposed to sun and air by judicious thinning, a heavy crop of fruit will eventually come, which will reduce the vigour of the tree to reasonable limits, and no further inconvenience will be experienced. The trees will form abundance of fruit spurs and bear well in all favourable seasons, but in the case of fruit trees which persist in growing with excessive vigour and do not bear fruit root-pruning is the only way out of the difficulty. Trees which, from surrounding circumstances, have to be kept to a certain size and are annually cut back to this limit, are very apt to grow vigorously year after year at the expense of fruitfulness. Again, the roots of fruit trees find their way at times into bad subsoils and the fruit becomes poor in consequence; very often the growth of the tree is hindered by the inactivity of the roots from this cause, the leaves become yellow and thin, the flowers are imperfect, and if allowed to continue in this state the tree eventually cankers and dies. Timely lifting and root-pruning will remedy this also, and with good attention in other ways will restore vigour to the trees.

This operation requires considerable judgment and experience. The operator should be well acquainted with the growth and character of each individual tree, and must have a good idea of the balance of power so to speak, in order that he may judge accurately how much root is required to carry a given amount of top with a heavy crop of fruit. This will vary with the character of the soil to a certain extent. A tree in a light and dry soil will need more roots to supply the necessary amount of sap than it would if it were growing where moisture was more easily obtained. In all cases it should be borne in mind that fibrous roots mean fruitful branches, stout fleshy roots mean timber, therefore in removing or root-pruning fruit trees all fibrous roots should be saved.

Commence operations in all cases by digging a trench with a spade some distance from the stem of the tree. This distance should vary with the age and size of the tree, for a young pyramid Apple 10 feet high leaves 3 to 4 feet of ball all round the stem when digging the trench. After this the soil must be worked out carefully from among the roots with steel forks, preserving all the fibrous roots by tying them back as the work proceeds, and covering them from the air as soon as possible, so that they do not become dry and perish. A little moist straw litter or some old sacks are very useful for this purpose. It may not be advisable to do the whole of the ball of roots in one season, and in this case the trench should only be carried half way round. With trees that have been undisturbed for a number of years it is best to spread the work over two seasons, or a serious check will be given to the tree,

which instead of inducing fruitfulness will reduce its strength below fruiting point for two or three seasons. The roots are more easily reached where the whole tree is lifted, but in any case all those which go down into the subsoil must be cut off, taking them back to the fibrous roots, and clean cut all wounds with a sharp knife to induce the formation of fresh fibres as soon as possible. Place some fresh sweet soil over the roots when filling in again, as this also induces fresh fibres, and these will plump up the buds for next season if the operation is completed soon enough before the trees rest for the winter. In laying the roots back again in the hole keep their points from dipping downwards, and distribute them as evenly as possible, both horizontally and vertically. As soon as the hole is filled secure the tree against rocking by the wind if it has been lifted entirely; the best way to ensure this is to fasten some old sacking, or a piece of gutta percha hose split open, around the stem of the tree a little more than half way up, and stretch four wires from this to short stumps in the ground at equal distances apart. The ground over the roots should then have a mulching of straw litter to protect the roots in some measure from frost, and all is complete. Under no circumstances let any manure be incorporated with the soil for fruit trees that have been root-pruned or replanted. All feeding must take place from the surface, which will keep the soil sweet, and induce the roots to come nearer to the top instead of going downwards into the subsoil.

#### FRUIT FORCING.

**VINES.**—*Earliest Vines in Pots.*—Some Grape lovers do not appreciate the thick-skinned varieties, and desire thin-skinned Grapes at all times. In that case it is preferable to take the early supply from Vines in pots than to start the permanently planted Vines at a very early period. Vines in pots produce fruit little inferior to that borne by others planted out, and often better than is produced by those having the roots in outside borders. Success in early forcing is more certain where there is convenience for affording bottom heat, the canes being sufficiently strong, thoroughly ripened, and duly rested. The materials for affording bottom heat—that is, tree leaves and stable litter, should be in course of preparation. The heat to begin with must not exceed 65° about the pots, augmenting it by bringing up the fermenting materials to the level of the pots by degrees, so as to raise the temperature to 70° or 75° when the Vines are in leaf. We advise the pots to be stood on pillars of loose bricks. Let the canes be suspended over the fermenting materials in a horizontal position to induce the buds to break evenly. Sprinkle the canes three times a day, and damp every part of the house at the same time in bright weather. In order to induce regularity of starting, a somewhat higher temperature is necessary at this period than later in the season, 50° to 55° at night, and 60° to 65° by day is not too high to begin with. The Vines to have fruit ripe in April must not be started early in November. Vines in pots not intended for early forcing should be placed under cover, an open shed with a north aspect being suitable, and the pots protected with hay or straw. If placed in cool houses the pots must be protected against frost in severe weather, for the Vines may be injured or destroyed by the soil becoming frozen.

*Earliest Forced Planted-out Vines.*—Those for affording fruit in April must be started at the beginning of November. Have the inside border thoroughly soaked with water at a temperature of 90°, and in the case of weakly Vines a soaking of tepid liquid manure is beneficial, enriching the soil, and conducing a good break by the increased food supply. If the border or floor of the house is covered with leaves and litter in a state of fermentation, occasionally turning the material and adding fresh, the moisture and warmth, also the ammonia-charged atmosphere, are very beneficial to the Vines, and make a considerable difference in the fuel used. The outside border must have a covering of leaves, litter, or fern sloping from the house outwards, and be covered with shutters, tarpaulin, or thatch, so as to throw off the rain and snow. Fermenting material is not indispensable for placing on outside borders, but the warmth is a great aid in keeping the roots active and near the surface. Outside borders, however, are great mistakes for Vines that are forced early year after year.

*Vines for Starting in December.*—Prepare the house for starting, the Vines being pruned when the leaves have fallen, as it contributes to early and complete rest. In pruning two buds are mostly sufficient to leave for affording compact bunches of Grapes. Longer pruning may be practised when the Vines are wanted to give fewer and larger bunches, for it does not answer to allow as many large bunches on a Vine as of medium sized. Large bunches are, as a rule, loose, irregular in size of berry, and do not finish satisfactorily. Medium sized bunches are more regular in form and size of berry, and finish well. If the eyes at the base of the shoots are not plump, three eyes may be left, but this necessitates frequent renewal of the spurs. The Vines should be stripped of loose bark, in fact all that can be removed without stripping them to the live bark, and be washed with tepid softsoap solution—2 ozs. softsoap to a gallon of water. This is all that is necessary where the Vines are free from insects, and where there has been no scale or mealy bug, but infestation by red spider, a solution of softsoap, 4 ozs. to the gallon of water, is strong enough and an effectual remedy. If, however these have any mealy bug or scale a dressing of insecticide must follow, repeating it before the Vines are started. The woodwork must be thoroughly cleansed, if necessary painted, and the walls lime-washed. Remove the surface soil down to the roots and supply fresh lumpy loam with a sprinkling of strained bonemeal and wood ashes intermixed—about a half-pint of bonemeal and a quart of dry wood ashes to each bushel of loam. Though a somewhat dry condition of the

roots is desirable the border must not be allowed to become parched and cracked, affording water if necessary, but not saturating the soil to the extent of making it sodden. Keep the house cool, admitting air freely except when frost prevails. If the house is occupied with plants employ fire heat only to exclude frost.

*Houses of Ripe Grapes.*—A temperature of about 50° artificially is most suitable, losing no opportunity of admitting air when the days are fine, turning on the heat in the morning so as to cause a gentle warmth in the pipes, and so expel damp, turning off the heat at mid-day, or soon after, so as to allow the pipes to cool, and the temperature at night not to be kept above 50°, even less on cold nights; but a slight warmth in the pipes will prevent the deposition of moisture on the berries and prevent "spot," inasmuch as the moisture is condensed on the glass instead of the Grapes. A low night temperature causes the moisture present in the air to be rapidly condensed on the Grapes in the early part of a fine day, when the heat is not turned on early and air admitted, the sun heating the atmosphere much quicker than the Grapes. This must not be overlooked; and during the prevalence of dull weather it will be necessary to keep a gentle warmth in the pipes, the ventilators closed, yet there will be a circulation of air, causing the moisture to settle on the glass, thereby preserving the Grapes from damp.

*Vines Ripening the Wood.*—Vines not yet firm in the wood, the foliage quite green, and the wood not brown, should have the laterals closely pinched, bringing them down by degrees to the principal buds, which will have a tendency to promote rest by admitting more light, especially if air is admitted freely at night, the house being kept rather warm, but not close by day, as that would have a tendency to induce growth. When growth in the laterals is checked the shoots may be shortened to a few leaves above the pruning buds. This will assist the basal buds to plump and the wood to ripen, a gentle warmth being kept in the pipes and air freely admitted.

**PINES.**—Young plants must be afforded liberal ventilation whenever the weather is favourable, avoiding too much moisture in the houses or pits, as over-damping, keeping the atmosphere constantly saturated, is more injurious than beneficial at this time of year. Examine the plants once a week for water, supplying such as require it, for dryness at the roots stunts the growth, and is very pernicious, as the plants seldom, if ever, make free growth afterwards.

Fruiting plants should have a night temperature of 70°, 65° in cold weather, 75° by day, rising to 85° from sun heat, losing no opportunity of closing at 85°, and affording genial surroundings by damping available surfaces. Retain one sucker only to each plant, removing all others. Any suckers appearing on successional plants before the fruit is visible should be removed, except an increase of stock is urgent, when one or more may remain, but it is not a good practice, as the fruit is more or less prejudiced by the suckers.

New beds are usually prepared at this time of year for the reception of young plants. Tan is unquestionably the best material, its heat more regular, and retained longer than any other. Beds formed of it should not be made firm but put together lightly. Oak or Beech leaves are good for furnishing bottom heat over a lengthened period, and a good substitute for tan. Collect the leaves as dry as possible. In forming beds they should be firmly pressed, so that they may not sink too much, and also to regulate the heat; preventing it becomes too violent and soon expended instead of affording a regular warmth over a lengthened period.

**CUCUMBERS.**—Autumn fruiters are now in full bearing. The plants must not be overcropped, therefore cut the fruit when it attains a useable size, also remove early all ill-shapen and surplus fruit. Go over the plants once a week at least, and remove all bad leaves, stopping and tying the growth, laying in no more wood than can have light, cutting away the superfluous shoots. Winter fruiters do best if allowed to advance well up the trellis before stopping them, removing all side growths on the stem up to the trellis, and then train the side shoots right and left of the stem, not too closely, as well developed foliage is very important, particularly in winter fruiting plants. Remove all male flowers, and cut off tendrils as they appear. Add fresh warmed soil as often as the roots have fairly covered the sides of the ridges or hillocks, and if they need vigour use a little soot, and an occasional dusting of the bed with superphosphate will tend to improve the substance of the whole plant.

Maintain a temperature of 70° on mild, 65° on cold nights, 70° to 75° by day artificially, advancing to 80° or 85° with sun heat. Admit a little air at the top of the house on all favourable occasions, but avoid admitting cold air, and never lower the temperature. It is better to shut off the top heat for a few hours when the sun is powerful than ventilate it when the wind is strong or very cold, for it dries the air and causes a chill. The plants will not need syringing except on very fine days, when a light damping is beneficial, but the paths and other available spaces should be damped in the morning and afternoon and on bright warm days shortly after midday, keeping the evaporation troughs charged with liquid manure. Water the beds whenever they become rather dry, not allowing the plants to become distressed or to flag; but before the foliage becomes limp afford a thorough supply of that element or weak warm liquid manure. The water given to the roots must be of the same temperature as the mean of the house, and the soil used for covering the roots should be had inside some time to be warmed before placing it over the beds.

#### PLANT HOUSES.

*The Stove.*—The temperature in this structure should range from 60° to 65° at night according to external conditions. On very mild occasions

a few degrees higher will do no harm, but when the thermometer falls to freezing point outside the temperature must be kept as near the former as possible. If a high temperature is maintained Crotons and other foliage plants are induced to grow, which disfigures them, for there is not sufficient sun to colour their foliage. On all fine occasions the syringe should be used freely to keep the foliage clean. Thrips spread rapidly in a dry atmosphere and red spider will soon establish itself.

*Crotons*.—Young plants that are to be grown for another year should be repotted if they need more root room. It is a mistake to check them by confining the roots in small pots. They will if carefully watered root freely into the new soil if given a temperature a few degrees warmer than advised for the stove proper. Small shifts only should be given at this season of the year, and the plants potted now will be in capital condition for making vigorous growth early in the season. Plants that are growing too tall may be nicked and mossed ready for growing another year. In brisk heat roots are quickly formed, and when severed from the parent they soon become established if plunged for a few days in a close case where slight bottom heat can be given.

*Dracenas*.—Syringing may be practically discontinued. The bed upon which they are standing should be kept moist. Water these plants carefully, if given too much or subjected to too low a temperature the roots will die. Young stock that it is necessary to grow on may be potted. Plants that are damaged in rooms and are needed for stock should be kept in a temperature of 60°, and rather dry at their roots to ripen and harden their stems ready for cutting early in the year.

*Gardenias*.—Repot cuttings that have just been rooted singly and establish them in brisk heat, afterwards giving them ordinary stove treatment. The earliest plants that have flower buds swelling should have a temperature of 65°. Later plants will do in a night temperature 5° lower, provided they are watered with care. Strong stimulants should be avoided, also strong insecticides, after the flower buds once commence forming. Those that have not formed their flower buds may be thoroughly cleaned if mealy bug or scale infest them. Petroleum and water will be found the best solution for this purpose.

*Ixoras*.—These soon fail unless careful treatment can be given them. Good plants often decrease in health and vigour by the treatment they receive during the winter months. The syringe may still be used if a temperature at night of 65° can be maintained. If 5° lower it should only be attempted on the mornings of very fine days. The water used for this purpose should be a few degrees higher than the temperature of the house. The same rule applies to that used for the roots. This must be administered with care, as too much will prove detrimental, while on the other hand an insufficient supply will also be injurious. Keep the plants free from mealy bug and thrips. Young stock intended to flower in small pots will be all the better if they can be arranged where they can enjoy gentle bottom heat, but this must not exceed 70° to 75°.

*Euphorbia jacquiniæflora*.—The wood of those that were rooted late is still soft. They must be exposed to full light and sunshine. The temperature of the structure in which they are placed should not exceed 55° at night or they will continue to grow. The atmosphere should be moderately dry so as to harden them as much as possible. When the wood is soft and the plants are placed into brisk heat the eyes often start into growth instead of forming flowers. The same remarks as regards heat and temperature apply to Poinsettias that are soft and still growing. The earlier plants that have stopped growth and commenced to form their bracts should have a temperature of 65°, in which they will produce finer bracts of better colour than in a lower temperature. Weak liquid manure or artificial manure applied to the surface of the soil will be beneficial.

*Adiantum cuneatum*.—Plants that have been grown cool throughout the summer and the fronds have been gathered will soon start into growth again if placed into a temperature of 60° to 65°. The growth these plants push up will be found useful after the main stock is over. Young plants raised from spores and well established in 4-inch pots may be placed into 6-inch. These in a temperature of 60° will continue to grow, and whether required for furnishing or cutting will be found invaluable.

*Begonias*.—Plants of the manicata section as they are housed from cold frames should not, unless they are needed in flower, be placed in heat. This is a mistake, they will do well for the present in a cool house that can be kept moderately close where the atmosphere is dry. Other winter kinds need an intermediate temperature. They will soon flower freely, and will be found invaluable for cutting. Any that are not needed for the present may be pinched. The varieties of *B. nitida* are useful in the stove early in the year, these if in small pots may be potted, also a good number of *B. Ingrami* that are now in thumb pots. Late struck cuttings or seedlings of varieties of *B. semperflorens* may also be potted if they need more root room.

*Anthurium Schertzerianum*.—Plants that have completed their growth may be removed from the stove to an intermediate temperature to rest. While in this structure be careful not to give too much water. They enjoy a month or six weeks in a lower temperature, and flower more profusely in consequence.

*Anthurium Andreanum*.—One of the most useful plants that can be grown for the stove during the winter. Its large bright scarlet spathes are very attractive, and equally useful in a cut state. The plants for the ornamentation of the stove are most effective in 6 or 7-inch pots. When a large plant can be obtained there is no difficulty in raising a stock.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### PREPARING FOR THE FUTURE.

I HAD just finished my last hive for the winter on October 14th, the day of the great storm, when the barometer in several hours fell more than an inch, running down from 29.40 to 28. The evening was too far advanced before I observed this or I would have taken precautions. Fortunately no hives containing bees were capsized, only a few untenanted ones. On the following morning there were still signs of storms, so I hurriedly loaded full and empty ones with bricks or any weighty material that came to hand until I have all steadied with a stake driven firmly into the ground close to each hive and tied firmly to it, this being more sightly than weighty articles, and more easily secured or separated.

#### ECONOMY AND UTILITY.

I employ no superfluous adornments, nor anything that may hinder easy transit, or that may add unnecessarily to expense. My hives stand complete. Most of them this year are occupied by bees in two body divisions. The third division, and the super protector above it, serve for holding winter packing and supers. The former consists of a piece of woollen cloth next to the frames, and 4 inches of dried grass above. The slips between the frames are left in, there being sufficient opening to allow the escape of moisture. The rest of the space above the packing holds three storeys of empty supers. Those not in outside cases are covered with two or three plies of sacking or woollen material, and that again covered with an oilcloth or felt tarred and limed.

This arrangement permits all the moisture created within the hive to leave before it is condensed within or upon any outer part of the hive, thereby preserving it from decay and the bees from injury. This same arrangement favours under feeding, which I prefer in most cases as being quicker, while the bees sometimes feed more readily from below than from above, and it has the advantage of never causing a current of cold air in the hive, as upper feeders do, which lower the temperature of the hive considerably. The bee-keeper who follows out these or similar plans will be studying his own interest in point of economy and utility.

When I take my bees to the Heather the felt or oilcloth curtain is dispensed with, shade being more essential than warmth at that season, a single piece of sacking around the hive, and an oilcloth on the top, being sufficient. Of course the supers must be well covered. Thus lessening the clothing of the hives there is little to cumber *en route*, and as the alighting boards fold up the hive becomes of very small dimensions, and enables us to take upwards of fifty hives at as little expense and space as a dozen of most of the modern make of hives. That is a large item, and stamps in a stereotyped manner the disadvantage of the cumbrous and expensive modern type of hive.

#### FEEDING.

This is another important point in bee-keeping. My motto has always been never to feed bees if it can be avoided, but unfortunately we are compelled to resort too often to feeding if honey gathering is nil when we expect it would be at the highest. Although I have pointed often, and in the foregoing, some of the evils of top-feeding, my feeders are a combination of top and bottom feeders, and by that means I am enabled to have a portion of the feeder inside the hive permanently. These scoops can be made to hold from 1 to 8 or 10 ozs., and better they be broad than too long, as if the latter, the hive being off the level, the syrup would flow away. The scoops, whether they are broad or narrow, should have a spale float.

We would fain hope that such seasons as we have experienced for years would never recur; but whether or not, there are few

seasons that has not a discontinuance of honey gathering, often too at the most critical time for bees to draw their brood. The queen does not stop laying, although the bees fail to bring them forward, but by the judicious and timely feeding of all the colonies this will be prevented, and instead of depopulated hives at the late honey gathering we have strong ones, which in some seasons makes all the difference between a yield or no yield of honey.

The best method of supplying the syrup, whether it be at home or the moors, is to have the dissolved syrup in a can, from which pour into a bottle and run along all the hives, giving each their allowance to keep up breeding, but nothing more. The time occupied in feeding fifty need not exceed ten minutes. The feeder that does not offer these conveniences is incomplete. I trust those who read these notes will see the propriety and advantage of having their hives in a fit state before the time comes for moving bees about, so that there may be a chance of keeping a moving apiary at a profit.

#### PUNIC BEES.

I have just read the following in *Gleanings*:—"Punic bees, while so highly praised by those who sell them, have strong insinuations thrown out against them by British bee-keepers." The above is simply a misleading statement, and is on a par with much that has emanated from the same quarter. I have praised the Punics because I have proved them to be an acquisition; and as I do not sell anything connected with bees, not even sugar at 20 per cent. profit, I repudiate the statement.

#### BEE SOCIETIES AND ASSOCIATIONS.

If we were to believe the hundredth part of what has been written it would appear that the whole art of bee-keeping had been discovered by a few interested persons. But when we sit down and overhaul our past records the thing is entirely reversed, the greatest amount of good having sprung from the least rewarded and most unostentatious individuals. The country has been canvassed far and near for subscriptions to assist bee-keepers, those who really benefited being the dealers. The greatest part of the money in many cases went to the last named, who, as a rule, had the helm of affairs in their own hands. The greatest cry amongst bee-keepers was the difficulty in disposing of their honey, and yet they were advised to increase their stock, and were told that 3d. per pound was sufficient for it, and that they had no right to expect payment for time spent looking after their bees.

I observe a writer in a contemporary (A Scotchman) complaining of the arbitrary conduct of directors of shows and supposed leaders of bee-keepers, which I am glad to see, as it may revolutionise the existing system, and I gladly advise bee-keepers to be free, and to study their own interest. Establish a system that will prevent middlemen controlling the market and taking from 50 per cent. to 100 per cent. profit, and let the public know that they can be supplied cheaper and better under this system than the old one.

The year 1890 did not yield a plentiful supply of honey in most districts, but in some parts of the West Highlands it did. I took in hand to dispose of some of first-class quality for an acquaintance, but because it was October and the Apple season honey could not be bought. It is rather singular that the winter months being the time most suitable for eating honey Italian warehousemen should prohibit its sale when it is in greatest request.

When the Caledonian Apiarian and Entomological Society was started a market for honey was one of its principal motives, yet when urged to adopt it it was opposed on every side, and this too when there was a honey glut, and some of its members could not command a sale at anything like remunerative prices. There is another strong reason why a co-operative market should be established. Much adulterated honey is sold, and one Edinburgh merchant encourages this, giving to bee-keepers sugar to be con-

verted into comb, which he says is preferred by many to honey proper. This gentleman advises, too, imitating Heather honey by infusing Heather and using the liquid to dissolve the sugar. There is no doubt as to the accuracy of the above, as I had the offer (through a friend) of the sugar, which I respectfully declined to accept, never having allowed sugar to be mixed with the honey in the hive or out of it. Space forbids saying more upon this important topic, but enough has been said to arouse bee-keepers to a sense of their own interests and duties.—A LANARKSHIRE BEE-KEEPER.

#### TRADE CATALOGUES RECEIVED.

James Cocker & Sons, Aberdeen.—*Catalogues of Roses, Perennials, and Herbaceous Plants.*

English Fruit and Rose Co. (Cranston's), Limited, King's Acre, Hereford.—*Catalogue of Roses, Fruit Trees, Forest Trees, and Conifers.*

Frank Cant, Braiswick Nursery, Colchester.—*Rose Catalogue for 1891-1892.*

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Books and Microscopes (F. G.).**—A work that would probably suit you is Johnston and Cameron's "Elements of Agricultural Chemistry and Geology," as, though it is not strictly applied to gardening, it embodies the same principles. It is published by W. Blackwood and Sons, 37, Paternoster Row. Microscopes vary greatly in price and usefulness, but for two or three guineas you could obtain one that would enable you to study as much as you would require.

**Strawberries (Querist).**—We disapprove of the practice of cutting all the leaves off when the plants are trimmed after fruiting. We have known future crops prejudiced by this thoughtless practice, but, on the other hand, we have seen fair yields after the defoliation. A good deal depends on the age of the plants, soil, and season, and if your plants are fairly vigorous you may have a moderately good crop of fruit next year.

**Mildew on Cinerarias (J. B.).**—Leaves that are checked in growth like the small one sent we should burn, but those only slightly affected we should endeavour to save, and we should not like to destroy the plants, at least at present. Try the effect of black sulphur, so holding the leaves that the points of the fine hairs face the application; the sulphur then may fall between them. It is the downy covering that we suspect prevents its reaching the mildew. We should also maintain a drier atmosphere if you can do so. The soil is perhaps fully too rich, and the leaves have not been able to elaborate the crude sap that has been abundantly afforded.

**Walnut Tree not Bearing (P.).**—Walnut trees raised from seed vary greatly, as do Apples and other fruits, both in quality and productiveness. Some Walnut trees bear early and freely, others are many years before they show fruit, and are never productive. The fact of your having to cut dead wood out of the tree suggests that the roots are not in the best of mediums, and the soil may either be too poor or too wet for promoting sound healthy growth, but as we have said some varieties are essentially shy in bearing, and we suspect cannot be made productive. We know trees fifty years old that seldom bear, and never more than the poorest crops of nuts. The price of timber varies very considerably in different localities, and you can best obtain the desired information by consulting one or two local timber merchants.

**Storing Medlars (Dr. W.).**—You have perhaps gathered the Medlars too soon in previous years. Let them remain on the trees so long as the weather continues mild, and even a little frost will do them no harm. If gathered too soon they are apt to shrivel, especially in a very dry place, such as a room cupboard. We have never had any difficulty with them over a period of forty years. They were simply spread on the shelves in a dark fruit room in which the temperature

ranged between 40° and 50°, according to the weather, and the atmosphere, while not distinctly damp, was less dry than that of a living room. Some persons spread the fruits singly on clean sand, calyx side downwards, dipping the stalk end in brine for preventing mould, though we have not found such methods necessary. Try later gathering and a less dry storeroom.

**Trees and Shrubs for Chalk Banks (M. T. R.).**—Of all trees the most likely to succeed is the Beech (*Fagus sylvatica*), which we should use chiefly along with others of the same genus—viz., Fern-leaved and Purple leaved. Birch, as you have found, does fairly. The Hazel, Privet, and Blackthorn will afford the "cover" required. Bird Cherry (*Cerasus Padus*), and the Virginian form (*C. Padus virginiana*), Scotch Laburnum, Mountain Ash, Gold-variegated Elder (common Elder being desirable as shelter). Scarlet-fruited Elder, *Euonymus europæus*, Elms, Exeter and English White Beam, Lime, red-twigged and Snowy Mespilus, may be added if you wish for greater variety. In evergreens, English Yew and common Holly, with *Mahonia aquifolia*, *Hypericum calycinum*, Broom, and common Laurel (in the lowest situations) may be used. Corsican and Austrian Pine would probably succeed, particularly the latter.

**Mushrooms in Cucumber Houses (H. G. O.).**—Mushrooms may be and are admirably grown in structures in the winter that are devoted to Cucumbers and Tomatoes in the summer. The preparation of the manure and routine management are exactly the same as described in the work you possess. The beds may be either flat or ridge shaped, according to convenience, as suggested by the size and form of the house. One grower has them ridge shaped on the floor in a very wide span-roofed structure, and flat in narrow structures, making the beds where the Cucumbers have grown on each side the central path. Highly satisfactory results have been obtained by growing Cucumbers as indicated entirely by turning to account the information given in the book. One grower had a clear profit of £50 last year. He will have more this, as he started sooner, having material prepared ready for making up immediately the Cucumbers ceased bearing profitably. See the example of growing Mushrooms in a vinery on page 113 of the sixth edition of the work in question. A temperature of 50° to 55° is suitable, and the beds must be well covered to prevent evaporation and exclude light. Mushrooms will grow, but more slowly, in a temperature of 45°, and even less in strong beds; also in a temperature of 60° to 65°, when it is necessary to have a supply at a particular time which could not be otherwise obtained; but the higher the temperature above 60°, the sooner, as a rule, are the beds exhausted.

**Neglected Box Edging—Plum Trees Grown from Wall (G. E. B.).**—1, Provided the Box is close enough in the stems at the bottom, so that when cut down there will not be any gaps, it would be the best plan to cut it down in spring, say during mild, moist weather in April or May, better late than too soon, and it will push growths freely from the base, and make a good growth the first summer, trimming off irregularities in July. If gappy there is no remedy but to replant, which may be done in mild weather during the winter, taking off the slips with a portion of roots, and inserting them in the soil to within 3 inches of the tips of the growths, merely cutting off irregularities. Autumn or early spring is the best time to replant Box edgings. The soil should be made firm about the stems, and if dry well watered. 2, The Plum tree has been correctly treated—namely, new growths laid in, and those projecting from the wall shortened, provided those trained in are not nearer than 9 inches apart. This admits of their having the essential light and air, assuring to the growths the benefit of the wall's warmth. 3, The tree that has only three stems nearly 3 inches in diameter may or may not be improved by cutting down. We have cut down several, and they have broken again freely from the old wood, in three years made growth covering a large extent of wall space, and borne finer fruit than on the old branches. It does not, however, answer in all cases, the trees not always breaking well, and in some cases it induces gum in the young growths. 4, There are plain and sound hints on pruning in "Profitable Fruit Growing," which is sold at this office for 1s. 3d. post free, but we think the second edition is nearly exhausted.

**Names of Fruits.—Notice.**—Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only x specimens can be named at once, and any beyond that number cannot be preserved. (*J. R. Nere*).—Not known; worthless. Graft the tree with some good and well-known variety. (*D. M., Ayrshire*).—1, Beurré Diel; 2, Marie Louise; 3, Durondeau. (*F. B. Burbiage*).—1, Beurré d'Aremberg; 2, Beurré Clairgeau; 3, Beurré Diel; 4, Defective specimen; 5, Van Mons Léon Le Clerc. (*F. J. B.*).—1, Yellow Ingestrie; 2, Nonesuch; 3, Cellini; 4, London Pippin; 5, Brabant Bellefleur; 6, Kentish Filltasket. (*A. B.*).—2, Claygate Pearmain; 4, Lady Henniker; 5, Beurré Diel. (*H. E. M.*).—1, Beurré Rance; 2, Possibly Marie Louise on a Quince stock; 3, Marie Louise; 4, Comte de Flandres. (*J. B.*).—Gloria Mundi; trees can be obtained in all good fruit tree nurseries. (*R. Wardman*).—1, Bedfordshire Foundling; 2, Emperor

Alexander, poor specimen; 4, Dredge's Fame; 5, Defective specimen. (*W. R. R.*).—1, Kirke's Fame; 2, Round Winter Nonesuch; 3, Dumelow's Seedling; 4, Bedfordshire Foundling; 5, Northern Greening; 6, Maltster. (*H. H.*).—1, Brabant Bellefleur; 2, Devonshire Queen; 3, Professor; 4, Maltster; 5, Cox's Orange Pippin; 6, Tower of Glamis. (*C. B.*).—We have received two parcels of Apples under these initials, both from Abbots Langley, and we fail to see how the senders can identify their own, therefore the fruits are not named. (*T. T.*).—1, Adèle de St. Denis; 2, Beurré Diel; 3, Beurré d'Amanlis; 4, Beurré Bose; 5, Beurré Clairgeau; 6, Beurré d'Aremberg. (*J. W. Rimmer*).—1, Beurré Diel; 2, Beurré Sterckmans; 3, Broompark; Plum Coe's Golden Drop. (*Henry Pooley*).—1, Beurré Hardy; 2, Figue de Naples. (*Henry Wright*).—Not known; probably local; worthless. (*J. Lyne*).—3, Maréchal de Cœur; the other may possibly be a small fruit of Souvenir du Congrès. (*F. M. M.*).—Both fruits are what you suggest. The Pears are so similar they do not require separate descriptions. (*W. A. Mackenzie*).—1, Alfriston; 3, Cellini; 4, Betty Geeson; 5, Golden Spire; 6, Peasgood's Nonesuch. (*S. Knowles*).—Pear Beurré Capiaumont; 2, Dumelow's Seedling; 3, Golden Noble; 5, Flanders Pippin; 6, Reinette de Canada. (*A. J.*).—1, Lady Downe's; 2, Alicante; 3, Too much bruised; 4, Madresfield Court. The Pear is Beurré Clairgeau. (*John Smith*).—1, Quite rotten; 2, Green Chisel; 3, Grenadier; 4, Lane's Prince Albert. We have now attended to all the fruits that were received up to Wednesday, 20th inst.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*C. D., Wales*).—The plant is *Lycium europæum*, a member of the Solanum family, and some species are known as the South Sea Tea Tree. (*J. A.*).—The plant which you received under the name of *Aerides odoratum* must certainly have come from a rather mixed source, and we are not surprised that you "see a great difference in flowers." It is *Vanda cœrulea*, one of the flowers sent being "doubled" owing to a kind of fasciation.

## DRAINING LAND.

As autumnal tillage draws to a close, and the falling foliage of deciduous trees reminds us that winter is drawing near once more, reference is made to our note book for a reminder of wet spots where the crops failed in the past summer owing to defective drains, as well as of fields with the soil so water-logged that drains are indispensable, and must be had before another season's growth begins.

We may usefully remind our readers that land containing superfluous water, and from which the water does not pass away freely either naturally or artificially, is practically useless for cultivation. It may be worked deeply, manured thoroughly, and cropped carefully, but it will be all to no purpose till drainage relieves it of the accumulation of water, which has not only kept it sodden and sour, but has also kept out air and the warmth which accompanies air circulation in the soil.

Warmth comes to the soil from drainage in another way, too, which all farmers ought thoroughly to understand. Gisborne, in his *Essays on Agriculture*, taught long ago that humid soils were very little benefited by summer heat, because water in a quiescent state is one of the worst conductors of heat. Water warmed at the surface transmits little or no heat downwards. The small portion warmed expands, becomes lighter than that below, and consequently retains its position upon the surface, and transmits no heat underneath. Evaporation is constantly going on, as the moisture constantly rises by capillary attraction to the surface, and so not only is the temperature of the soil low, but that of the atmosphere in contact with the surface is low also.

The undrained soil is thus kept sodden and cold by the water of attraction that is constantly ascending through it and passing off upon the surface by evaporation. Let us understand what this means. Gisborne shows that the evaporation of 1 lb. of water lowers the temperature of 100 lbs. of soil 10°. There is the fact, do not forget it; and remember also, that when by judicious drainage we practically put a stop to such hurtful evaporation, keeping the water of attraction down to the drain level, and drawing off all superfluous water by filtration, we open the pores of the soil to atmospheric action. Every drop of water withdrawn from the soil by filtration leaves a vacuum that is instantly filled by air, the pressure of which upon the surface has been computed at 15 lbs. to each square inch.

There is the theory of drainage placed once more before our readers, and it should be thoroughly mastered, so as to influence our practice beneficially, and enable us to do our work in the best way. There is really nothing in it but what an ordinary mind can grasp and retain, but its importance is obvious enough, and it is worthy of thoughtful discussion. Let the presidents of farmers' clubs and agricultural chambers take for their next subject of discussion the theory and practice of land drainage, and they will find their meetings much better attended than when they are discussing the political aspect of some agricultural question.

Now for the practical side of the question. The depth and distance apart of drains must always depend upon the nature and condition of the soil. To say that all land drains must be 4 feet deep and 30 feet apart is absurd. Happy is the man whose soil and subsoil is amenable to such treatment. We have drained land successfully in that way, but our success arose chiefly from the subsequent deep and thorough tillage of the soil. Taking that as the maximum depth and distance apart it may be modified in very heavy land downwards to 15 feet apart and 2 feet deep. This of course means much more expense, and it should have very careful

consideration beforehand, for it is quite worth while to calculate the cost of clay burning, lime dressing, dressings of coal ashes if they can be had in conjunction with the drainage. Much better is it to open up the soil and ensure its thorough division than to have drains very close together. Let the two processes of cultivation have equal attention, and the result is bound to be satisfactory.

Let calculations be made of the number of pipes required—2-inch for the branch drains and 4-inch for the main drains—and let them be carted on to the land as horses can be spared for the work. The drains should be marked beforehand, and a staff placed for every heap of pipes, the number for each heap being given to the man who receives the pipes from the carter. The branch 2-inch drains should all run downwards to the main 4-inch drain, or to any convenient natural outfall; we have frequently been able to avoid making a main drain by taking the drains into a ditch. In Suffolk especially, where all old ditches on farms are very deep and wide, main drains are seldom necessary.

## WORK ON THE HOME FARM.

Mangolds have now attained full growth, and nothing will be gained by leaving them longer on the land. The risk of damage by frost, too, is so great now that no time should be lost in saving the crop. Let the heaps in the form of long ridges be made close by a hard road at the most accessible and convenient points for use in winter, cover the heaps well with straw, and cover it with enough soil to exclude frost from the roots. In frost of exceptional severity many of the roots in the outer layer are often frozen and spoiled, so that it is quite worth while covering the Mangold ridges with an outer layer of rough litter, such as Sedges, Fern, or hedge clippings, to make all safe. With such an abundance of herbage on pastures the Mangold tops can certainly be spared for ploughing in now, and the sooner it is done after the roots are cleared the better it will be for the land.

Early crops of Swedes should also now be used, or stored in heaps for folding later on. An excellent plan is to place them in small circular heaps equi-distant all over the field, for folding with hoggets in time for Barley or spring Oats. Care should be taken to follow the folds closely with the plough, and not to plough too deeply for such crops.

Late sown crops of Swedes are now small firm roots, and we shall follow our usual practice of leaving them out for the ewes and lambs to be folded on in next February and March. The late Swedes so left out suffered so much from frost in some districts last winter as to be practically useless. But that was such a frost as may not occur again for a life's time. Certainly we shall not let it influence our practice, as we always take care to have the late Swedes sown in a well-drained upland field where the risk of harm is reduced to a minimum.

Early hoggets are now in folds on late white Turnips and Swedes, sown in alternate strips across the field. They have a few hours on pasture also every day, and are all the better for the change. These sheep are having a pint of nibbled Oats per head daily, as well as the roots, and are in forward condition for the butcher. A nice batch of such sheep, and a score or two of steers coming off marsh pasture towards the end of this month, wanting little, if any, finishing for market, is the sort of thing to give a farmer a free hand, and to enable him to avoid corn-threshing till autumn work is over and the corn is in sound condition. That is good management, but then it requires plenty of capital for it to be done in the best way.

## REMARKS.

11th.—Fair morning, with a little sun; wet afternoon and night.  
 12th.—Bright almost throughout, but a shower at 120 P.M., the sun shining meanwhile.  
 13th.—Bright from sunrise to 9 A.M., then overcast to noon; wet afternoon, and heavy rain at night. South-east gale in afternoon and night.  
 14th.—Generally bright, with high wind, but occasional rain squalls, and thunder at 11.20 A.M.  
 15th.—Wet till 9 A.M., and generally overcast till 11 A.M.; thunderstorm at 11.30, with hail and heavy rain, then alternate sunshine and rain squalls; bright afternoon and evening.  
 16th.—Wet till 9 A.M., and generally cloudy in morning; bright afternoon; rain at night.  
 17th.—Bright till about 3 P.M., then overcast, with occasional slight showers or drizzle. Another wet week, with a heavier gale than has recently occurred, and thunder on two consecutive days.—G. J. SYMONS.

NOVEMBER, the best month of the year for planting fruit trees, will soon be here, and a reminder now to planters of two points of special importance in fruit culture, which are often ignored even by old practitioners, but which are worthy of our best attention, will, I hope, prove useful.

They are worthy of prominence, because early planting points to the early establishment of the trees in the soil, while shelter points to the protection of the blossom from the cold scathing winds from the north-east, which are so prevalent in spring, and to that of the fruit from autumnal sou'-westers, which so frequently sweep the fruit from the branches of orchard trees just as it is approaching maturity.

Standing on the northern slope of a Leicestershire valley one evening in the last week of August this year, during a violent gale of wind, I watched with interest the branches of the timber trees dashed together by the fury of the storm, which came rushing up the valley from the south-west, with a noise like the roaring of a high sea. One could not but think of the damage and loss which such a storm must cause as it swept through any orchard in its course—damage which might so easily be avoided, and loss which ought not to be incurred from such a cause.

Why is it that shelter has so little attention in fruit culture? This is a question which I for one cannot answer. The importance of shelter is so self-evident that one would suppose it would have at least equal care with the planting of the fruit trees.

Now the due provision of shelter is a very simple matter. With the planting of an orchard or fruit plantation there should also be the planting of shelter belts enclosing small orchards, enclosing and dividing large ones. The tree best adapted for this purpose is Lombardy Poplar by its erect habit, the rapidity of its growth, and the earliness with which it comes into leaf in spring.

A double row of it, or rather two rows, so planted that each tree forms a triangle with the two nearest it in the other row, makes a tolerably efficient barrier, calculated to break the force of high winds sufficiently to prevent damage to fruit. But when space can be had a belt of three or four rows of Austrian Pines outside the two rows of Lombardy Poplar is most desirable, especially for shelter from cold cutting winds in spring.

I give preference to *Pinus austriaca* for this purpose, both for its dense growth and because trees of it, 6 or 7 feet high, transplant so well that it soon attains a useful height. But it should never be used as a substitute for the Poplar; that is the tree of trees for our purpose, and double rows of it might be made to intersect others in large orchards, dividing the orchards into squares of, say, a hundred feet in diameter, the loss of space being more than counterbalanced by the efficient shelter thus obtained.

For small plots hedges of the Myrobalan Plum answer admirably. It is of a singularly robust vigorous growth, soon affording shelter, for it may be clipped as freely as the common Hawthorn. If space can be had it may be left to grow unpruned in view of obtaining fruit from it in large quantities.

Conjointly with the provision of shelter belts, attention should be given to the selection of fruit trees easy to shelter. The best of all forms for general purposes in fruit farming is undoubtedly the half standard, with its stem of about 4 feet in height; the branches are elevated just sufficiently to render them most

accessible for all purposes of cultivation; they are open to the full action of light and air; the fruit is easily thinned, easily gathered, and easily sheltered from high winds.

In grass orchards only should lofty standards find a place in fruit culture, for there and there only have we a good and sufficient reason for their existence.

It should also, I think, be strongly impressed upon those whom we hope to induce to devote some part of the land they own or hire to fruit farming, that every sunny slope, every sheltered nook is of account in fruit culture. Do we find that such natural advantages have been turned to account? We do not. One could point to a hundred hillsides, valley slopes, and hollows, some with natural barriers to cold winds, others requiring only a little judicious tree-planting to render them perfect for the culture of early soft fruits.

Turn them to full account for this purpose, and the fruit will be ready for market several days—aye, and in some cases even weeks—before that grown under ordinary conditions. This points so certainly to profitable results, that it is certain to have a leading place in fruit farming wherever it is possible.

I am bound to say that the importance of early planting cannot be estimated too highly. So repeatedly have I proved this in my own practice that one wonders it has not long ago had more general recognition. Fruit trees planted early in November make root growth at once. Let us see what this means to the intelligent planter.

His aim in planting early is to have the trees sufficiently established in the soil to promote free, vigorous, unchecked growth in the following spring and summer, so that the tree may take full advantage of the first season of growth after the planting. To enable it to do this in the best way the shoots are thinned if necessary, and shortened to those buds which are in the best position for branch growth.

When the rising temperature of spring causes the buds to swell, to grow, to put forth leaves, stored up sap is drawn from the adjacent wood tissues, and so on downwards to the roots. Then comes the crucial test of the planter's work. If this has been done well and early in autumn the tree will have put forth rootlets bristling with root hairs, through which it takes in food from the soil, and so the demands for sustenance from the soil will be met promptly and fully, branch growth will continue unchecked, and become so robust and vigorous that really fine heads will be formed in the first season of growth. There is no doubt or difficulty whatever about this matter if only the trees are planted early and well, and are pruned at the time of planting, though some experienced cultivators prefer shortening the branches in spring.

If, on the contrary, the trees have none of these cultural advantages, are left unpruned, are planted late, they are practically in a state of stagnation in the following summer. They put forth some leaves, but there is no appreciable growth, a season is lost, nor can any good reason be advanced for this wasted year. There is always due balance and proportion between branch and root growth, and in the early planted trees there is root action as vigorous as that of the branches, so that when growth ceases in the autumn they have plenty of roots to afford ample supplies of food to the branches in the following spring.

There stand the trees, then, pictures of health, models of skilful culture, requiring nothing but a sufficient thinning of branch growth to leave only enough on the tree to form a well balanced head, for these are the main branches, and they must be thinned freely and judiciously.

I have said that to ensure such desirable results the trees must be planted early and well. By this is meant not the simple act of planting only, but fertile well drained soil, keeping the roots moist and as little exposed to the air as possible from the time they are received from the nursery till they are planted. I have frequently had occasion to give the roots a thorough soaking with water as

they came to hand from the nursery before planting or bedding in trenches.

Then, too, there is the careful spreading out of and packing of every root in fine soil; the firm yet gentle pressure of soil about the roots, a surface dressing of manure, and the fastening of the tree to a safe support, so that wind rocking or loosening of the roots in the soil is impossible. All simple matters, but every one of them important factors to success, and which are included in the term to plant well.

I would say in conclusion that the few cultural points I have striven to make clear to you are in a great measure the key to that success which I heartily wish to all who may be induced to begin fruit culture this season.—EDWARD LUCKHURST.—[Read at the Manchester Fruit Conference.]

## THE BRITISH SCHOOL OF GARDENING.

A JOINT Committee of the Worshipful Company of Gardeners and of the Royal Horticultural Society have for some time past been considering the subject of the establishment of a School and College of Technical Horticulture and small husbandry. The Committee have drawn up the following scheme to be submitted forthwith for adoption by the Court of the Worshipful Company of Gardeners and the Council of the Royal Horticultural Society. We should be greatly obliged if you would give publicity to this project, which the Committee venture to regard as one of high national importance.

JAMES CURTIS, *Clerk to the Worshipful Company of Gardeners, 9, Old Jewry Chambers, E.C.*

W. WILKS, M.A., *Secretary Royal Horticultural Society, 117, Victoria Street, S.W.*

*General Objects.*—To impart a higher class of education in the principles and practice of the cultivation of fruit, flowers, vegetables, &c., than is at present obtainable in Great Britain: to

A, Persons wishing to qualify themselves for employment in gardening and garden-farming in this country.

B, The sons of landed proprietors, farmers, and any others who are interested in gardening and garden-farming.

C, Persons who may be desirous to emigrate, or may be already resident in the colonies.

Preference will, however, be given to students of British birth.

*Eligibility of Students.*—No student will be admitted who does not already possess some elementary practical knowledge and experience of gardening or garden-farming. All students will, under ordinary circumstances, be expected to continue their studies for at least two years.

*Employment of Students.*—The object being to impart a thoroughly practical education in gardening, all students must be prepared to devote themselves to the manual as well as to the scientific branches of the work, and to yield implicit obedience to the directors.

*Classes and Lectures.*—Efficient directors will superintend the instruction in the various branches of cultivation, and lectures on the scientific aspects of gardening and garden-farming will be delivered by qualified persons and illustrated by practical demonstrations.

To attain the object in view it is proposed that the Worshipful Company of Gardeners, in conjunction with the Royal Horticultural Society of Great Britain, should secure suitable land where experimental and practical gardening and garden-farming may be carried on, pending which, arrangements are being made to utilise the gardens of the Royal Horticultural Society at Chiswick for the instruction of students in connection with this scheme.

## SCILLA SIBERICA.

FEW bulbous plants are so quickly naturalised as this charming Scilla. The bulbs do not increase so rapidly as either the Snowdrop or the Crocus, but seeds are produced with such freedom that a large stock can be quickly raised. As far as I am aware the whole of the bulbs required for distribution by the wholesale and retail trade are imported. This is to be regretted, for bulbs could be as well grown at home and at perhaps less expense than the Crocus. Home growers will doubtless in time see the wisdom of taking in hand the culture of such bulbs as will flourish well in this country. The seed of the Scilla should be sown as soon as it is ripe in shallow drills on well prepared ground, the drills being similar to those

needed for Onions, only 6 inches apart. The seed must be lightly covered, so that the drills are visible until the end of the season, and the hoe if necessary can then be run between them to keep the ground free from weeds. The seedlings will appear above the ground in spring like Onions, which they closely resemble in a young state. If the seeds are washed bare by autumn and winter rains Nature seems to have provided for these a sufficient covering to protect them from perishing by severe frost. In a natural state they are scattered on the surface, and they can be observed perfectly sound, and commencing germination as soon as the weather is sufficiently warm. The seeds are by no means particular as to soil, for I have seen them germinate freely in gravel walks.

Few bulbs surpass this Scilla when in flower, the colour is charming, especially when the older blossoms are fading or have changed to a lighter shade of blue than the younger ones. The contrast is admirable, and at the same time the lighter flowers add to the intensity of colour in the younger ones. It is at home in the shade, or in the sun, and in all intermediate positions; but in the shade the flowers are later, and form a good succession to those planted in sunny spots; they also retain their deep blue colour for a much greater length of time. It may be planted with advantage in any position in which the Crocus or Snowdrop will flourish. Until a few years ago I had concluded that Scilla siberica displayed itself to the best advantage when planted in masses, but this is not the case, for the flowers of a few solitary bulbs rising above a dense carpet of moss are charming. It is very suitable for the rockery, whether composed of alpine plants or hardy Ferns. It is lovely in the latter, and is not injured by the Ferns, but it brightens such positions greatly when otherwise they would seldom be visited at that season of the year.

If the bulbs are planted on the top of a sloping rockwork, it will in a very few years be one mass of these bulbs. The Scilla must always be planted where it can remain, and increase in its own natural manner. We generally plant too thickly, with the object of an immediate effect. Those not particular in this respect should plant the bulbs thinly. The ground should be kept free from weeds, and a little light soil scattered over the bed in autumn to replace that carried away by weeding and cleaning. The bed will soon become a mass by the seed that will be naturally sown annually. If they are planted in small clumps, and the spade and fork are kept away from them, they will quickly form good-sized patches. The Scilla can be planted with good effect amongst grass, but it must be remembered that this plant retains its foliage for a considerable time longer than the Crocus.

For cultivation in pots this Scilla is very suitable, and perhaps more useful than either the Snowdrop or the Crocus. In effective groups, or the front row of conservatories, it would be difficult to find a plant with which it could be compared for beauty and richness of colour. Its flowers are of the exact colour we frequently require at that season, and if well grown cannot fail to be admired. The Scilla looks best perhaps in 5-inch pots, the pots being filled with bulbs and just covered with soil. It will do well in any light sandy compost. The bulbs cannot be obtained as early as the Snowdrop and Crocus, but they should be potted directly they can be had, and plunged under a few inches of ashes until they have filled their pots with roots. They may then be removed to a cold frame, watered if they need it, and the surface covered with cocoanut fibre refuse, so that the top growth is just covered as well. They will continue growing in this position until severe weather commences, when they should be taken to any structure where the temperature will range about 45°. In this structure they may remain until they commence flowering. Heat will ruin them; they must advance gradually, almost naturally. The extra heat they would receive from the sun in such a structure would do them no harm. If the pots are kept the second year flowers are had earlier than from newly imported bulbs potted for the purpose.—WM. BARDNEY.

## FRUIT AT AUTUMN SHOWS.

THERE is now a considerable array of fruit at most of the Chrysanthemum Shows, this, as far as the majority of professional gardeners are concerned, being quite as attractive as the more showy "mums." Grapes are frequently quite a feature in the displays, and a capital lot of bunches are shown for comparatively small prizes. Bristol is the only schedule I have yet seen where classes are provided for nearly every late Grape in cultivation, and it is a pity this example is not more generally followed. When special prizes are provided for two bunches each of Alicante, Lady Downe's, Gros Colman, Black Hamburgh, Mrs. Pince, any other black variety, Muscat of Alexandria, and any other white variety, there is a good opening for a far greater number of growers than is the case when prizes are offered for collections only, and as a

consequence the competition is much more keen. Five classes are also provided for different varieties of Grapes at Reading, while the Southampton, Birmingham, and Liverpool schedules are fairly comprehensive. When there are not more than two, or at the most three classes for Grapes, exhibitors are at a loss what to stage, and judges scarcely know how to decide. Supposing there is only one class for black Grapes, then Gros Colman, if shown in superior condition, must win. Alicante, no matter how well it may be shown, should take a back place, for the simple reason that it is not particularly high class, or no more so than Gros Colman, and it certainly is the easiest to finish properly; while Lady Downe's, though superior to both in point of quality, is very rarely indeed shown heavy enough to win first honours against all comers. If, therefore, I stage either Alicante or Lady Downe's against first-class Gros Colman, I shall expect to be beaten, and so must other competitors. If Mrs. Pince could be shown at its best, then ought that high-class variety to be put first. Gros Guillaume, Gros Maroc, and Alnwick Seedling are all variously shown in the any other black class, but the former is the most superior in point of flavour, and if shown well coloured should win. Lady Downe's is very frequently shown in the any other black class, and if really good is hard to beat. When we come to the white Grapes matters are more simplified. Muscat of Alexandria shown in a fairly good condition is bound to be first, the next best being Mrs. Pearson. If, therefore, there is a class for any other white Grape, that is a good opening for Mrs. Pearson, Trebbiano and Calabrian Raisin being coarser varieties, and not often seen well coloured. I have frequently shown Golden Queen in the any other white class, but owing to its muddy appearance, which seems to get worse by the time it arrives at a show, it takes prizes on sufferance only, that is to say, when competition is slack. Exhibitors, especially novices, should use more judgment when selecting their Grapes for competition. Too often the largest bunches are selected without due regard being paid to other conditions. I have made the same mistake more than once, only to find that smaller bunches with larger berries, other conditions being equal, were preferred by the judges. There ought to be a marked evenness and cleanness of berries, the removal of a few stoneless or rather small berries greatly improving the appearance of some bunches, and the bloom and colour ought to be as near perfect as possible. Unless these conditions are observed it is useless to compete at many of the leading shows, as it is only the very best of everything that wins prizes nowadays.

Collections of fruit, exclusive of Pine Apples, are provided for at Bristol, Bath, Reading, and a few other shows, and these are usually fairly well shown. A model collection of six dishes would consist of good Alicante or Gros Colman, and either Muscat of Alexandria or Mrs. Pearson Grapes, a Melon, either Marie Louise or Doyenné du Comice Pears, Salwey Peach, and Coe's Golden Drop Plum. Both the latter ought to be available this season, but if not, then a good dish of Cox's Orange Pippin, King of the Pippins, or Ribston Pippin Apples and Medlars would be good substitutes. Medlars, however, are very late this year, and in any case I would prefer Bananas. In some instances two varieties of Pears or Apples are allowed, and this admits of more competing than would otherwise be the case.

It is, however, in the Pear and Apple classes that the strongest competition takes place, the displays at Bath, Bristol, Exeter, and Tiverton being far above the average, and worthy of more notice being taken of them than the much crowded state of the horticultural journals permit. At the first two places collections are principally shown, but at Exeter, in addition to collections, classes are also provided for single dishes of all the best varieties in season, and a most interesting and highly instructive competition invariably results. Not a little in every case depends upon the judgment used in selecting the dishes of the respective varieties, and it is here where the old hands have the advantage. Mere size is not everything. To be certain of winning a prize the fruit must all be as near alike as peas in a pod; size, form, and colour all being studied. One extra large fruit quite dwarfs the rest, therefore let them match as much as possible. Although ripeness is not necessary in all cases, I am yet of opinion that ripe or well coloured fruits gain a point, though wrongly so, perhaps, over green samples, and would advise forwarding in gentle heat many of the late varieties shown in collections in October and early in November. There are two Pears—viz., Marie Louise and Doyenné du Comice, that far surpass all others in point of quality, and when shown at their best ought not to be passed over in favour of the largest fruit of Pit maston Duchess ever shown. When tasting is practised they are bound to win; sometimes one and sometimes the other being preferred, according to the taste of the judges. Beurré Diel, Pit maston Duchess, Duchesse d'Angoulême, Maréchal de Cour, Beurré Bachelier, Doyenné Boussoch, Brockworth Park, Chaumontel, Louise Bonne of Jersey, Huyshe's Prince Consort, Glou Morceau, Easter Beurré, Napoleon, Beurré Bosc, Hacon's Incom-

parable, and such like, are all suitable for collections, and if there is a class for stewing Pears, let General Todtleben, Catillac, and Vicar of Winkfield find a place rather than the dessert sorts. Always stage the heaviest stewing Pears, but let them match well.

Apples are even more numerous shown than Pears, and a remarkably pretty lot of fruit are to be seen at the principal south-western shows already mentioned. Much that has been advanced, as regards selecting, concerning Pears, also applies with equal force to both dessert and culinary Apples. The former ought especially to be as highly coloured as possible, the dull or green varieties being shown in large collections only. They must all be of near one size, and although large Apples are not preferred on the dining table, it is yet advisable to have them of full size for exhibition, always excepting Blenheim Pippin and Peasgood's Nonesuch, both of which are admissible as dessert varieties, and should be of a size and colour to match the rest. What may appear rather large at home dwindle down, that is to say quickly find their level, directly they are staged. As far as a single dish of any variety of dessert Apples is concerned there are none that can possibly equal Cox's Orange Pippin, and this whether the judges taste the fruit or not. It is altogether a model variety, and if kept clear of musty straw, hay, or other contaminating substances is of the best possible quality. Ribston Pippin at its best is a fairly strong opponent, Blenheim Pippin not unfrequently figuring well. These three, King of the Pippins, Margil, and Gravenstein, would be an excellent selection of six dishes, Worcester Pearmain, Braddick's Nonpareil, and Cornish Gilliflower being good reserves. The first prize for a single dish of culinary Apples used at one time to fall to extra fine samples of Blenheim Pippin, but of late years Peasgood's Nonesuch has come to the front. With these two out of the way Warner's King has a good chance, Mère de Ménage, extra good, being a formidable rival. Other good varieties well suited for collections are Stirling Castle, Emperor Alexander, Golden Noble, Cellini, Cox's Pomona, Bismarck, Ecklinville, Kentish Pippin, Prince Albert, Dumelow's Seedling, Royal Somerset, Reinette du Canada, and Tom Putt. By all means let them be of full size, but not large and unshapely; and once more let me add, they must match one another as nearly as possible. Leave those with blemishes of any kind at home, as these cannot be hid from good judges.—W. IGGULDEN.

#### CHRYSANTHEMUM SHOWS.

THE following are the dates of the chief Chrysanthemum Exhibitions to be held during the coming month.

Tuesday, Nov. 3rd.—Pembrokeshire.

Tuesday and Wednesday, Nov. 3rd and 4th.—Brighton, Ipswich, Kent County, Beddington, and Watford.

Wednesday, Nov. 4th.—Dorking and District.

Wednesday and Thursday, Nov. 4th and 5th.—Dalston and District.

Wednesday, Thursday, and Friday, Nov. 4th, 5th, and 6th.—Portsmouth and Ascot (two days). Thursday, Nov. 5th.—Chiswick.

Friday and Saturday, Nov. 6th and 7th.—Crystal Palace, Sydenham.

Monday, Nov. 9th.—St. Neots. Tuesday, Nov. 10th.—East Grinstead.

Tuesday and Wednesday, Nov. 10th and 11th.—Kingston-on-Thames, Horsham, Leeds, and South London.

Tuesday, Wednesday, and Thursday, Nov. 10th, 11th, and 12th.—National Chrysanthemum Society, Royal Aquarium, Westminster.

Wednesday and Thursday, Nov. 11th and 12th.—Birmingham, Bournemouth, Northampton, Swansea, and Croydon.

Thursday and Friday, Nov. 12th and 13th.—Teddington, Wimbledon, and Ware.

Thursday, Friday, and Saturday, Nov. 12th, 13th and 14th.—Pelfast.

Friday, Nov. 13th.—Cheshunt and Hitchin.

Friday and Saturday, Nov. 13th and 14th.—Eccles, Leicester, Sheffield, Tooting, and Monmouth.

Tuesday and Wednesday, Nov. 17th and 18th.—Liverpool, Twickenham,

Wednesday and Thursday, Nov. 18th and 19th.—Spalding. [and Diss.

Wednesday and Thursday, Nov. 18th and 19th.—Hull and Rugby.

Wednesday, Thursday, and Friday, Nov. 18th, 19th, and 20th.—York.

Thursday, Nov. 19th.—Wantage.

Friday and Saturday, Nov. 20th and 21st.—Stirling, Chorley, Bolton, and Stockport. Saturday, Nov. 21st.—Batley.

#### EXHIBITION CHRYSANTHEMUMS.

IN working out the subjoined analysis of last year's show season I have been much struck by the copiousness of the reporting, one variety having been honourably mentioned as first prize winner over, and another just under, one hundred times—a long way the best result achieved since I have kept any record.

Among incurved Mrs. S. Coleman was the only new comer of note; but though standing well for the first season, it occupied a very inferior position to that attained by Miss M. A. Haggas, or even Miss Violet Tomlin when first exhibited. Both appeared in 1889, and have during another year of show existence still further enhanced their reputation as prize winners—the former standing second, and the latter fifth in the list. Before passing to the consideration of other matters, I would like to inquire how it comes about that though this now well-known variety, Miss Haggas, was introduced as recently as 1888, there is no mention of the raiser's name in the last edition of the N.C.S. Catalogue?

Princess of Teck, Refulgence, Novelty, Bronze Queen (John Doughty), Baron Beust, and Eve, all occupy the same position as in the previous season's list, Baron Beust having retained the thirty-first place three years in succession. Those martial spirits, Jeanne d'Are and Lord Wolseley, have exactly exchanged places, while Mr. G. Glenny and Mrs. Dixon reappear after two years' absence. Some few varieties—Mrs. Heale, Charles Gibson (Lady Dorothy), Lord Eversley, and others, for instance—seem slowly creeping upward, but will never attain the front rank. Perhaps it may be well to explain here that varieties bracketed together are declared by the N.C.S. Committee to be inadmissible as distinct.

Among Japanese Etoile de Lyon leads easily with the prodigious record of 106 first prizes, excluding duplicates, while Avalanche, though reported nearly twice as often as in 1889, was unable to repeat its success of that year, and achieve premier honours against so formidable a rival. Sunflower, however, did well, and went up five places; Stanstead White

doing proportionally, even better, by rising eleven; but Mr. Ralph Brocklebank experienced a heavy fall, and Edwin Molyneux was unable to recover the position lost in 1889. We may therefore conclude that there is little likelihood of either ever obtaining pride of place; on the contrary, they will gradually fall more and more out of the running until their disappearance from the list, a fate which must also, even sooner, overtake those once successful veterans Madame C. Audiguier and Jeanne Délaux; indeed, it is becoming increasingly evident that the older Japanese cannot stand against those of more recent introduction, and are slowly but surely being beaten out of the field of competition by the three and four-year-olds. This fact is established by the great success of Mons. Bernard, Sarah Owen, Condor, Stanstead Surprise, Mrs. F. Jameson, Lady Trevor Lawrence, &c., in their second season.

Of varieties appearing for the first time Mrs. C. W. Wheeler is the most conspicuous, Puritan, W. W. Coles, and Volunteer being likely to better themselves considerably during the season which is now fast approaching. As showing how much more frequent are changes in this section than among incurved, it may be noted that Edwin Molyneux and Mr. H. Cannell are the only two which occupy the same position as in 1889.

The prize lists of 1890 seem tame by comparison with those of the previous year, when so many new and magnificent varieties carried all before them at the leading shows. Whether the forthcoming season will be more exciting, or reveal the existence of any novelties capable of ousting the leaders in either class, remains to be seen; the probabilities, however, hardly warrant such a supposition.—B. D. K.

† Three prizes in 1888, four in 1889.

## LOUIS BOEHMER.

MANY of us have been disgusted with Mrs. Alpheus Hardy, and no wonder, for it is one of the worst growers I ever had to deal with. The way it has been spoken of quite justly may have a tendency to act against the newer thorny petalled sort Louis Boehmer. Let no one be prejudiced against the latter, for it is a most excellent plant. Last season I saw one bloom of it, but it was a pity to have shown such a flower, as it by no means represented its merits. I shall perhaps say something on it again, but think this early opportunity should not be lost of calling the attention to its novel and beautiful character.

I have this day (October 23rd) been over to Messrs. Carter's nursery at this place, where they have about three dozen plants just coming into full bloom. They are not quite fully out yet, so there will be an opportunity for anyone to see them who should wish for the next fortnight or three weeks, which will at once demonstrate to any beholder the fine variety it is. These plants were about 4 feet high, and the flowers when only partly out are 7 inches across. When we hear of and see some of the flowers which obtain certificates we little know the extraordinary culture that has been bestowed on the plants, but here is a sort that anyone can easily grow. From the time the cuttings are inserted till they bloom they grow away like the good plants they are. I have now plants from cuttings inserted on the 25th of April, just coming into bloom, and they are only 3 feet high. Messrs. Carter's plants are 4 feet high, which is probably its average stature. It is not only of this moderate height, but it is fairly stout, with excellent foliage. Altogether it seems a famous variety. I may mention for any person who may come from London that Messrs. Carter's nursery is

about fifteen minutes' walk from the Forest Hill Station, L.B. & S.C.R. The Exhibition is, of course, free.—W. PIERCY.

## THE WALKER CHRYSANTHEMUM TUBE.

So many different methods have been devised for elevating and depressing Chrysanthemum blooms on stands for exhibition that it might be thought there was scarcely room for another, distinct in character and efficient. The ingenuity of Dr. George Walker, the well-known amateur florist of Wimbledon, has, however, asserted itself, and he sends us a tube which is the essence of simplicity. The appliance consists of a thin circular tin plate, about 2 inches in diameter, with an oval hole. This plate is fixed to the board and the tube passed through it; in fact, it falls through the longest diameter, but when given a twist either to the right or left a piece of wire soldered on one side bites against the edge of the plate, and the bloom is fixed at the height required. This can be done either by a twist above or under the board as quickly as any person could say "Walker," and as quickly released. Dr. Walker prides himself on the economy, simplicity, and efficiency of his appliance, which he is now advertising, in the belief that it will find favour with exhibitors.

## CHRYSANTHEMUMS AT MAIDENHEAD.

MR. ROBERT OWEN of the Castle Hill Nursery has this season some magnificent plants, including 1000 seedlings of this year's raising, and the same number grown from promising seedlings of last year. The seedlings raised this year are equally as strong as the propagated plants, and include many of a good dwarf habit from which choice novelties

may be expected. The general condition of the plants is of the best, and several new houses have been recently erected for their reception. —H.

#### CHRYSANTHEMUMS IN THE SOUTH.

DURING a stay recently in the county of Hants I had an invitation to drive around a few of the principal "Mum" growing gardens in the southern part of the county, and as that locality in which I was staying has of late years become somewhat noted for large blooms, and as I was somewhat anxious to see what are the prospects for the coming season I readily accepted the invite, and spent several pleasant hours. It was plain to be seen that the "fever" has attained already to a high pitch. The chances of this exhibitor and that grower were largely discussed during the ramble. I have much pleasure in jotting down a few notes collected in a rough manner, but as I have myself a weakness for the autumn queen I find the aid of a good memory is a useful adjunct to a sparsely filled note-book. By-the-by, is not Hampshire rather a noted county for exhibition blooms, and specimens, too, for the matter of that? I remember some few years ago feasting my eyes on some specimens at the Southampton Autumn Show which I thought extra fine. One plant of Dr. Sharpe I shall never forget. This was "caught" just right to the day in point of colour, and what other variety, I wonder, excels this when in that state? The specimen in question could not have had less than 150 blooms on it—aye, and all of passing quality too. I fancy I hear someone saying, "We do not want to hear anything about Dr. Sharpe. It is no use for 'covering the board.' We want to know how the Centenary champions, Messrs. Drover, are 'looking,' and how the Molyneux's are 'shaping,'" so I will get to business. If what I saw during that tour is a criterion to go by, I should say the coming season is likely to be up to the average, in spite of the damp sunless season. The plants on the whole have a good appearance, are rather under the average height if anything, and full of promise for quality when the proper time comes.

The nurseries at Fareham are now well known as belonging to the brothers, Messrs. W. & G. Drover. The number of plants they cultivate are bad to judge when seeing them "packed" away so close as they are in two very long lean-to houses, which are used during the summer time for Roses and Cucumbers, but certainly they do not grow less than 700; and as they appear to confine their attention to Japanese and incurved varieties it gives them a greater scope in the exhibitions. The plants are not remarkable for the extra size of their stems, but they are for the quality of the foliage, which is of that stout character which betokens, not gross immature growth so productive of deformed blooms, but of those remarkable for depth and solidity. The buds appear "kind," and on the whole well "timed." Such as the Queen, the Princess, the Teck, and the Alfred families were looking as well as could be wished. Such well known sorts as Edwin Molyneux, Condor, Stanstead White, Sunflower, Comte de Germiny, and Avalanche were most promising. Louis Boehmer and Mrs. Alpheus Hardy will give blooms worthy of these two novelties.

Amongst new varieties William Tucker stands out quite unique in point of colour, which is simply silvery rose; the flower is large, but would by many be voted "rough," resembling Mrs. Frank Thompson too much, Japanese incurved, the points of the petals being forked or serrated and folding unevenly; the form is the only drawback to an otherwise handsome flower. Secrétaire G. Cassagneau, one of Délaux's introducing, is a promising Japanese, white shaded pink and lilac. M. H. de Fortannier, Japanese, purple shaded claret, reflexed type, full flower. M. Jules Humbert is also a new Japanese variety of promising appearance, violet amaranth, reverse silvery white. It was rather early to judge of new incurved varieties; the only two advancing were Robert Cannell and M. R. Bahuant. The latter is very similar in growth to the "Queen" family, the petals are broad and neatly incurving, but whether it will come deep enough to take a foremost place remains to be seen; the colour is carmine rose.

#### ROOKSBURY PARK.

This, the residence of J. C. Garnier, Esq., has lately sprung into prominence in the Chrysanthemum world. Mr. N. Molyneux is, I learned, a brother to the well known Swanmore gardener of that name. The number of plants cannot fall short of 600; they are full of promise, having a hard look which betokens quality rather than mere size. Most of them are neatly arranged in a long, low Peach house, which affords them ample light. The "Queens" struck me as being especially good, the tallest not more than 6 feet high and the dwarfest about 5 feet, wonderfully even were they altogether. Varieties like Princess of Wales, Mrs. S. Coleman, Barbara, Cherub, and Miss M. Haggas, and others too numerous to mention, give abundant promise. Many newer varieties are being tried apparently. The following are of continental origin and belong to the incurved section. It is yet too early to decide on their merits, but I fancy some will not be required at the end of the season judging by their present appearance. Mdme. F. Mistral reminds one of Refulgence both in habit of growth and colour of the flower. Madame Mante was more like L'Adorable in its formation, but the flower I saw being from an early bud is liable to great variation in form. Manders, rosy white; Marie Pierre, Louis Blancard, Mdme. Dairrier, Mdme. Bonsignour, best described by saying it is a bad Pink Venus; Annie Hoste, of the style of Cherub in every respect but quality. M. Bahuant is promising to incurve neatly. Japanese are largely represented by promising buds of Etoile de Lyon, Mrs. Falconer Jameson, W. W. Coles, Sunflower, Stanstead White, Pelican, and Condor. Newer varieties belonging to this section, and which promise

well, are Anna Hartzhorn, a pure white incurved Japanese; Mrs. Irving Clark, the outer part of the petals pink, inside lilac, a large flower; Mr. Frank Clinton, a pale yellow sport from Lady Lawrence, which ought to be an acquisition; Louis Boehmer is developing good blooms freely; Aida, narrow petals, bronze and yellow; Coronet, golden orange; E. G. Hill, bright golden yellow; Kioto, Thunberg style of flower, and W. H. Lincoln.

#### SWANMORE PARK.

New varieties are largely grown there, as well as several hundred plants of the older favourites. Capital plants in small pots of single, Pompon, and Anemone Pompon varieties are grown, and from their present appearance cannot fail to make a bright and pleasing display later on. In the incurved section the whole "Queen" family have not grown higher than 5 feet, many only 4 feet, which is especially dwarf for that type. Even so low the plants give promise of developing clean blooms, which remark also applies to Princess of Wales, Miss M. Haggas, Cherub, Lady Hardinge, and Prince Alfred. The new French incurved M. R. Bahuant was here in better condition than anywhere else in our tour. The pink striped Queen of England at present remains true to its sportive character; if it continues steadfast it will be a novelty certainly. Amongst the new Japanese Mohawk, crimson maroon, had extra fat buds, auguring well for the future. Louis Boehmer seems everywhere good this year. Mrs. A. Hardy was unfolding its florets in a clean satisfactory manner. Gloire de Rocher, a seedling from Val d'Andorre, orange amber flushed with crimson, varies considerably in height; here it is not more than 3 feet, with others it runs up over 6 feet. Madame Mezzard, white striped delicate rose, opening like Etoile de Lyon, the habit very low. Césaire Costa, poppy red or purple crimson, has long fluted petals, promises to be a good addition to the Japanese class. James R. Pitcher, delicate blush, reflexed Japanese, dwarf growth. Many new kinds were on trial, both incurved and Japanese, and from their present appearance will be heard of later on. Chrysanthemums on walls out of doors are given some attention, and judging from what I saw of them will repay the labour expended on them by a good display of blooms when the bulk of the indoor plants are over.—NORTHERNER.

#### HARDY FLOWERS AT THE ROYAL BOTANICAL GARDENS, MANCHESTER.

THE name of Mr. Bruce Findlay is a "household word" among horticulturists, and I was much pleased when a recent visit to Lancashire enabled me to see the Manchester Royal Botanical Gardens, so ably managed by him as Curator. To my disappointment Mr. Findlay was engaged as judge at a flower show the only day convenient for my visit, and I only saw him for a few minutes previous to my departure. He had, however, very kindly placed me under the charge of Mr. Paul, than whom I could wish for no more competent or obliging guide. As Mr. Findlay informed me previous to my visit, the collection of hardy flowers is not a large one, but all the same I found a good deal to interest me, and I was highly delighted with the Gardens as a whole. As usual in botanical gardens the hardy flowers are arranged, as a rule, according to their natural orders, and, as in all other gardens of a similar kind, there are many plants of no value from a garden point of view. I am rather disposed to agree with those who contend that such plants should be relegated to the herbarium, and only those which are of decorative value grown. There is, however, something to be said on the other side, and I do not feel disposed to quarrel with those who support it. Those of us who grow alpine in quantity may in this matter be careful how we speak, lest we should be accused of living in the proverbial glass houses, and be warned that we should not throw stones.

I feel particularly timorous that in mentioning one of the flowers which I admired a good deal it may be said that it is not of "decorative" value, and that the less said about it the better. Tastes differ, and in admiring *Gratiola officinalis* of Gerard I was glad to find I was not singular in my admiration. I had not seen the plant before, nor can I see it in any catalogues, and I have been at some trouble to find anything about it, not being so fortunate as to possess Gerard's or Parkinson's Herbars. This plant is not the *Gratiola officinalis* of the "Cottage Gardener's Dictionary," nor is it in Maund's "Botanic Garden," where a congener *G. aurea* is figured. It does not seem to be in the edition of "Hortus Cantabrigiensis," edited by Pursch. Joseph Miller, however, in his "Botanicum Officinale," published in 1722, gives a description of the plant which is so clear that I quote it in full. He says:—"Hedge Hyssop is but a small plant, having slender creeping roots, from which spring several square stalks scarce a foot high, with two long narrow sharp-pointed leaves, like common Hyssop, set at every joint, among which come forth the flowers on short footstalks, one at a joint, being small, long, and hollow, not much unlike the flowers of Foxglove in shape, divided at the end into four segments, of a pale yellow colour." He states that it is a native of the Alps and other mountainous countries, and gives Parkinson's name as *G. vulgaris*, "the true Hedge Hyssop," and Bauhin's name as *G. centauroides*, "Hedge Hyssop with Centaury leaves." I cannot discover this *Gratiola* in Philip Miller's "Gardener's Dictionary," and I should be glad to ascertain more about the plant and its whereabouts, as it is worth growing, and its late flowering habit would make it valuable in many gardens and on many rockeries. It was rather past its best when I saw it, but was very pleasing.

Another plant in which I was considerably interested was a dwarf erect purple-flowered *Linaria*. This was unnamed, but I heard an opinion from a good botanist that the plant was *L. Pellissieriana*, which is said, however, to be an annual, while this plant is perennial. It must be observed that some plants named in our gardening and botanical works as annuals prove to be true perennials in many soils. This *Linaria* is apparently a very desirable plant.

Several *Statice*s were grown, among the best of these in flower being *S. dahurica*, pink and white, and growing about 14 inches in height. Other good kinds were *S. Gmelini* and *S. echioides*. *Veronica*s seemed pretty well represented, one which attracted my attention being *V. Michauxi*, a fine plant with a long spike of blue flowers. This seems to have been introduced in 1834, and is probably a native of North America. I had never met with this before, but was much pleased with this member of a family possessing great value for garden purposes. A good plant, too, was to be found in the typical *V. virginica*, of which I had seen the white variety in Mr. Wolley Dod's garden the previous week. Another good *Veronica* is named in Manchester *rubicunda*. I have had this in my garden for rather over a year without name, and several fruitless efforts have been made to find a name for it, and I was glad to have this supplied. I do not know the authority for the name, but the specific title is fairly descriptive of the pinkish tint of this pretty plant, which grows about 18 inches in height in my garden. *V. amethystina*, and several others, were also very pretty.

I was too late in the season to see some of the *Scabiosas* and *Cephalarias*, but what appeared a fine plant of imposing appearance was *Cephalaria leucantha*, a native of the south of Europe, which I see was introduced in 1739. It was past its best, but seemed very like one grown in this neighbourhood under the name of *Cephalaria tatarica* or *Scabiosa elata*, but scarcely so robust in habit nor so large in the heads of flower. When in good condition *C. tatarica* is a fine plant for the back row of a wide border. Another species of similar habit, but dwarfer and smaller in the foliage, was grown as *Scabiosa centaurioides*.

A plant new to me was that named *Hieracium calendulæfolium*, a yellow flowered Hawkweed, which is worthy of attention from those who take an interest in this rather "weedy" genus of plants. Several *Asters* were in flower, but none of particular interest, and in the present condition of affairs as to the nomenclature of this genus one is unwilling to say much about the plants; one, however, named *A. corymbosus* was quite distinct from that grown by Mr. Wolley Dod under that name, and which I have every reason to believe is correct. Mr. Wolley Dod's plant is white with blackish stems, and the Manchester *corymbosus* is purple. Some *Helianthus*es, but not of special interest, were also in flower. A neat little *Chrysanthemum* species, *C. arcticum*, of somewhat slender habit, with pretty blush flowers, was also in flower. There seems to be some confusion in nurseries between *C. arcticum* and one sent out under the name of *C. arcticum*, which latter seems of more robust habit and whiter in flower than the former.

A pretty *Liatris*, known as *L. pumila*, was also in flower, and is worth growing by those fond of this genus, many of the plants in which seem very similar in appearance. *L. pumila* is, as its name would indicate, dwarfer in habit than the others in cultivation. Many other plants in or out of flower must be left unnoticed, and, as was to be expected at that season, there was not much in flower on the rockeries. Among other things were good plants of *Saxifraga paradoxa* (true), *S. majalis*, and a number of others of the various sections of these pretty and interesting plants. *Salix serpyllifolia*, one of the dwarf creeping Willows now attracting some attention from alpine growers, was also in quantity, and among many other plants were *Rodgersia podophylla*, *Aralia racemosa*, *Rhus toxicodendron*, *Phlox canadensis*, *Alyssum spinosum*, and *Anthyllis montana*. In one of the houses was a fine plant of *Symphandra pendula* in beautiful bloom, and making a good pot plant. In the same house was *Eucomis punctata* in flower. This is quite hardy with me, but makes a very interesting and uncommon plant when grown in a pot.

In one of the houses known as the corridor, and which has to be cleared occasionally for flower shows, a very large number of plants of *Francoa ramosa* were planted out, and the fine spikes of this beautiful flower were seen to great advantage among the other plants in the fine structure. Several good arrangements of bedding and other plants were to be seen in the gardens. Unfortunately the *Gladioli*, as in most other places I saw while away, were not doing well on account of the unfavourable season. Of the many interesting and beautifully grown stove and greenhouse plants I do not feel competent to speak. It was, however, a great pleasure to go through the establishment with Mr. Paul, who is so well acquainted with the plants under his charge. The fernery is a most attractive part of the institution, but where there are so many things of interest and beauty with which I have so little acquaintance it will, perhaps, suffice to say that the gardens are silent yet effective witnesses of the skill of those in charge. Despite the unfavourable season, they were bright, and in the highest degree attractive, and I was much surprised to learn that this noble establishment is not in receipt of any Government or Corporation grant. It speaks volumes for the energy and ability of Mr. Findlay and the management in general that the gardens are so well maintained. The people of Manchester have good reason to be proud of their Botanical Gardens, and it is to be hoped that in these days of grants for technical and scientific education, it will not be forgotten that this institution exists, and that its benefits might be extended were more pecuniary support available. I have to express my thanks to Mr. Bruce Findlay and Mr. Paul for their great courtesy and kindness.—S. ARNOTT.

ORCHIDS AT TRANBY CROFT.

I SEND you a note of a few Orchids I saw at Tranby Croft on the 17th of this month. The most striking example in the house was a magnificent spike of that somewhat rare variety *Cattleya aurea*. The blooms were large and well developed; the sepals are about 3 inches long, and of a creamy yellow colour; the lip is broad, tipped with deep magenta, whilst the throat is a marvellous combination of magenta and orange stripes. It is a fine variety, and in my mind well worth cultivating. There were also several good spikes of *C. insigne* Maulei, *Oncidium Forbesi*, *Lælia Perrini*, *Cattleya Gaskelliana*, and *Cypripedium Spicerianum*, whilst two really fine pieces of *Cymbidium Mastersi* and *Lowi* respectively were showing some large and healthy looking spikes. The whole of the plants looked extremely healthy, and showed plainly the careful sympathy and treatment they had received at the hands of Mr. Leadbetter.—IGNORAMUS.

## MILTONIA BLUNTI VAR. LUBBERSIANA.

ON September 8th last, at a meeting of the Royal Horticultural Society, Baron Schröder was awarded a first-class certificate for this beautiful variety of *Miltonia*, which is one of the best of its type, the flower large, the colouring rich, and the general appearance of the flower most striking. Concerning *M. Blunti* itself, of which this is a superior form, Mr. B. S. Williams wrote as follows:—"A very distinct plant—a lovely and elegant thing, as Reichenbach calls it, and which he has named after its discoverer. The plant was exhibited by W. Lee, Esq., Downside, Leatherhead, at

FIG. 72.—MILTONIA BLUNTI VAR. LUBBERSIANA.

the Royal Horticultural Society's meeting in October, 1883. In growth and habit it resembles *M. spectabilis*, between which and *M. Clowesi* it is supposed to be a natural mule. The flowers are as large as those of *M. spectabilis*, with lanceolate acute sepals and oblong-lanceolate less acute petals, both creamy white, with some large brownish lilac or cinnamon-purple blotches chiefly in the centre; the lip, which is oblong-obovate obtuse or subpandurate, like that of *M. spectabilis*, is white or pale rose with purple-violet stripes at the base, where there are two keels, and the short thick column has two large purple-violet wings."

## THE CONFERENCE ON FRUIT CULTURE AT MANCHESTER.

IN connection with the Fruit Show held in the Manchester Town Hall, on October 20th and three following days, by the Royal Botanical and Horticultural Society of Manchester, a Conference was held on the first and second days in the Mayor's parlour. The meetings on both days were well attended, and much interest was evinced in the proceedings.

Lord Derby presided on the first day, and he opened the proceedings with an able speech, in which most points affecting the extension of fruit farming were dwelt upon with his usual ability. In reference to fruit as an article of diet, he said:—It will be admitted that if we can add to the diet of the English labourer, the farmer, and the poorer classes generally, a free use of food which shall be nourishing, wholesome, and agreeable, we shall be doing useful service. We are apt to look too exclusively to meat as a source of nourishment, and both health and economy would be promoted by a more mixed diet.

Of fruit growing, he said, its advantages are obvious, and on the surface. It creates a large demand for labour, because in that industry the human hand cannot be superseded by machinery; it may, under favourable circumstances, give an immense return per acre; the work connected with it is healthy; and inasmuch as fruit is not easily or usually transportable to long distances, or capable of being kept for a long time, it is less exposed to foreign competition than corn or grain of any sort.

The first paper read was that of Mr. E. J. Bailie of Chester, or "The Fruit Growing Movement: Present Day Features and Prospects," in which special stress was laid upon the immense quantity of foreign fruit imported into this country, one reason for which was that it was grown, packed, and placed on market in such perfection as to leave little or nothing to be desired. Stress was laid upon the urgent need for reform in all these matters in fruit culture in this country. He, too, urged the dietetic value of food, the need for practical education in fruit growing, the want of greater facilities for the sale of fruit, and that fruit should be sold by sample and brand.

Mr. W. Crump of Madresfield followed with a detailed account of the raising and pruning of Apples for orchard and estate planting. This has been done at Madresfield for several years on a large scale, and the tenants have evidently taken full advantage of this valuable privilege, 1200 trees having been supplied them last season. This sensible plan has been followed on other smaller estates, where trees have been procured for the tenants from the nurserymen, much good being thus done indirectly by the Madresfield Court scheme.

Mr. T. F. Rivers's paper on orchard house fruit culture had its valuable teaching emphasised by numerous large photographs, which were handed to the audience. In the Fruit Show tangible proof of the value of orchard houses in the north was afforded by the fine fruit from the Lambton Castle (Durham) orchard houses, in contrast with the undersized fruit grown in the open air within twenty miles of Manchester.

On the second day the chair was taken by Sir James Whitehead, Bart., Master of the Fruiterers' Company, and papers were read by S. T. Wright, J. Cheal, and E. Luckhurst.

In a long and exhaustive speech Sir James Whitehead touched upon every important point affecting the extension of fruit farming. He laid especial stress upon the fact that of recent years there has been a very large increase in the consumption of food in this country, and that it is every day becoming more and more an everyday article of food. That within the last twenty years the consumption of fruit per man, woman, and child of the entire population had risen from something like 10d. per head to 3s., and there has not been a corresponding increase of fruit culture in this country, although there has been a very large increase in the cultivation of fruit—not only in the open, but under glass.

He also said that there was every opportunity for the ordinary farmer to add fruit culture to his business, quoting in support of this contention from Mr. John Wright's prize essay on "Profitable Fruit Growing," and from a letter he had received from Dean Hole, who advised the cultivation of fruit to a greater extent by cottagers and by holders of small allotments, and suggested that by means of lectures and otherwise advice should be given to them as to the best trees to plant in the various localities. The great question of the day, said the Chairman, was education. Farmers and cottagers at the present time were almost absolutely ignorant, especially in regard to soils and sites, and they knew but little of the methods of cultivation. What was wanted, as it seemed to him, was that they should have shows from time to time in the great centres throughout the country on the same system as the Royal Agricultural Society, and in connection with these shows lectures should be given and papers read, and, above all things, there should be object lessons, and thus before long the great masses of the people in this country should be educated in this most desirable industry of fruit growing.

After explaining a scheme prepared by the British Fruit Growers' Association, now before the Education Department, for the introduction of practical horticultural instruction into Board schools in rural districts, and dwelling at length upon the question of security of tenure as affecting tenant farmers in fruit culture, Sir James brought his eloquent and eminently practical address to a close amidst the hearty applause of a large and evidently deeply interested audience.

The papers which followed were well received, that of Mr. J. Cheal on "The Condition, Preparation, and After-treatment of the Soil for

Fruit Culture" being of a sound and practical character. Mr. S. T. Wright's paper on "Fruit-growing for Profit" was so excellent that we are glad to say he has promised to send it for publication in the *Journal of Horticulture*. Tangible proof of his skill in fruit culture was afforded by the fruit shown from Glewstone Court Gardens, and his three first prize bunches of Alicante Grapes were not only remarkable for colour, size, and finish, but for the singular uniformity in shape of the large, well-shouldered bunches. Mr. Luckhurst's paper will be found on page 359 this week.

EVENTS OF THE WEEK.—Horticulturists will be busy in the current week, for the Chrysanthemum shows are commencing. On Friday, November 3rd, the meeting to consider the proposed International Fruit Show will be held in the Cannon Street Hotel at 3 P.M., Sir James Whitehead in the chair. Upon the same day Messrs. Protheroe and Morris will hold a sale of *Cattleya labiata autumnalis* in flower, and other Orchids from M. Linden of Brussels. The Chrysanthemum Shows commence on Tuesday, November 3rd, when the Brighton, Kent County, Ipswich, and Watford Society's Exhibitions will be opened, the majority being two-days shows. On Wednesday, November 4th, the Dorking, Portsmouth (three days), and Ascot (two days) Shows will be held. The subsequent fixtures will be found in our Chrysanthemum column.

— PROPOSED LONDON INTERNATIONAL FRUIT SHOW.—Mr. James Douglas, Great Gearies Gardens, Ilford, writes to us as follows:—"I enclose copy of advertisement of proposed International Fruit Show, which has been sent to your paper. Will you please to announce that the meeting is to be held at the Cannon Street Hotel on Friday, October 30th, at 3 P.M., Sir James Whitehead in the chair, and urge all interested in such an exhibition to attend, and be prepared to offer suggestions?" [If the chief societies and organisations combine with this object in view we have no doubt it will be rendered a success. Each Society should be invited to nominate its representatives on the Committee.]

— MYLES MEMORIAL FUND.—It is with much regret we notice the death at Ealing of the Rev. Percy Myles, F.L.S., Editor of *Nature Notes* (the journal of the Selborne Society). Unfortunately he was unable to make any provision for his widow; the Selborne Society has therefore issued a special appeal to all the members, but would also do so generally to any other persons who may feel disposed to contribute to the fund. As many of our readers have doubtless profited by Mr. Myles's admirable "Pronouncing Dictionary" of botanical names, appended to Nicholson's "Dictionary of Gardening," it is hoped that they may like to contribute to the fund. The Rev. Prof. G. Henslow, Drayton House, Ealing, W., will be glad to receive any communications.

— WE are informed that the Municipality of Genoa has voted the sum of 15,000 lire in aid of the INTERNATIONAL BOTANICAL CONGRESS, which is to be held in that city in September, 1892, to celebrate the fourth centenary of the discovery of America.

— THE BEDDINGTON, CARSHALTON, AND WALLINGTON HORTICULTURAL SOCIETY will hold an Exhibition and Conferences on Fruit and Chrysanthemums in the Public Hall, Carshalton, on Tuesday and Wednesday, November 3rd and 4th, 1891. The programme is as follows:—November 3rd, 1891, 6 P.M., Conference on fruit in the small public hall. Subjects: "Planting and Pruning," by Mr. John Wright. "Gathering and Storing Fruit," by Mr. Joseph Cheal. "The Profitable Use of Boundary Fences and Walls in Small Gardens," by Mr. T. W. Sanders. On Wednesday, November 4th, 1891, a Conference on Chrysanthemums will be held in the small public hall. Subjects:—"Culture of the Chrysanthemum," by Mr. Edwin Molyneux, "Chrysanthemums at Home," by Mr. George Gordon; and "Decorative Value of the Chrysanthemum," by Mr. Lewis Castle.

— GARDENING APPOINTMENT.—Mr. David Jones has been appointed gardener to Sir R. R. Wilmot, Bart., Binfield Grove Farm, Bracknell, Berks.

— EXCELLENT arrangements have been made for the establishment of a good system of TECHNICAL INSTRUCTION in Essex. An organising joint committee of the County Council and the Essex Field Club was lately appointed to deal with the question, and funds were placed at its disposal. This body has now issued a preliminary schedule of subjects to be taught. Local technical instruction committees are invited to select from the list one or more subjects which they may deem specially suitable for their respective neighbourhoods. When several such bodies, representing adjacent districts, have chosen a particular subject the organising committee will select a teacher or lecturer, and endeavour to arrange a circuit for him comprising the centres needing his services, apparatus and illustrations being provided by means of the fund for that purpose. By this means the aid of thoroughly qualified and equipped instructors may be obtained by the local committees at a cost considerably less than would be incurred if each centre were to act independently.

— SOME POTATOES.—Your correspondent "B." (page 323) under the above heading calls attention to the good qualities of the Bruce Potato, and I am pleased to endorse his opinion of the same. In a new orchard we have recently made I planted half a ton, and I have had the produce lately lifted, which was 6 tons 3 cwt.—good eating Potatoes, free from disease; 16 cwt. good seed; 5 cwt. of small for pigs—in fact, the Bruce seems to be an improved form of Magnum Bonum, with all its disease-resisting properties.—R. MAHER, *Yattendon Court, Newbury*.

— NOTE ON TWO HARDY DAPHNES.—At page 344 last week Mr. Dunkin, in his excellent paper on flowering shrubs, recommends *Daphne laureola* to be planted for the sake of its sweetly scented flowers. The plant grows wild in this neighbourhood, and so far as my observation goes the flowers do not emit any perfume. It is, however, a pretty evergreen shrub, and thrives well under the shade of trees; but *D. pontica*, which perhaps resembles it somewhat, is, I think, a much more handsome plant, and is moreover exceedingly fragrant in the evening. I doubt not it is the one to which he intended to call attention.—THOMAS SMITH, *Henbury Hill, Westbury-on-Trym*.

— PINUS PYRENAICA.—A correspondent in a former issue (October 8th) writes, that a young tree of this Pine had been killed by frost during the past winter. Was the tree newly planted, and not established? If so this might account for the loss, otherwise it is quite hardy, at least in southern and midland counties. Trees here, in South Bucks, have attained a height of nearly a hundred feet, and withstand the sharpest frost without injury. The heavy and wet condition of the soil had most probably something to do with the loss of the tree in this instance.—H. D.

— A SEEDLING ANEMONE JAPONICA ALBA.—Mr. Andrew Campbell, Ashford Gardens, Cong, Co. Galway, Ireland, writes:—"I am sending for your inspection and opinion blooms and foliage of a seedling *Anemone japonica alba*. The plants are stout, robust growers, not requiring supports of any kind, and are most profuse bloomers, continuing in flower much later than the old variety. Each flower is replaced by a large head of seed, which is brought to perfection. Seeds sown when ripe flower freely the following autumn. Some of the plants are now four years old, and still retain their vigorous habit of growth, with full size and substance of flower." [The specimens sent were very strong, with large flowers, but they had suffered in transit, and did not present any remarkable characters.]

— LIMA BEANS IN CALIFORNIA.—Whatever California undertakes is usually done on a gigantic scale, and this is not less true of her seed crops than of other enterprises there. A few details as to the cultivation of Lima Beans in the Santa Barbara district may interest the seed trade. The quantity of seed used per acre is from 25 to 35 lbs., planted 3 feet apart, from which a yield may be expected of from 1000 to 2500 lbs. per acre. The crop of 1890 was estimated at 1000 car loads of 20,000 lbs. per car. The crop of 1891 is estimated at 2000 car loads, one grower having planted this year in one piece 1300 acres. This crop is estimated at over 100 car loads. Of course these Beans are not trained but allowed to run over the ground, and when in full growth form a waving sea of foliage standing 3 to 4 feet high. In harvesting the crop a V-shaped implement is used, consisting of two boards about 5 feet long and 12 inches wide, shod with steel shear runners and a rolling coulter made from a circular saw is set in the front end of this V. This coulter cuts the Vines, and the two side runners separate them into winrows. The rear of each runner has projecting iron arms with five teeth to shake off the dirt from the Vines.

— THE alleged POWER OF CAMPHOR to awaken seeds or stimulate their germination has been shown by the experiments of M. Henry de Varigny to have no real existence. Various kinds of seed were sown in sand saturated with water containing camphor, as advised by horticulturists, and the germination of all was slower instead of more rapid than that of similar seeds in water without camphor. Germination was even retarded by camphor vapour in the air, the water having no camphor.

— THE USE AND ABUSE OF WATER.—The admission I made at page 331, at having been incorrectly reported upon one or more points raised by "Yorkshire Bite," was intended to convey ample justification for the letter at page 305, though the reference made to my opinion of young gardeners, or how much they will profit, I consider were quite unnecessary, especially so when the fact remains that the primary points your correspondent alluded to were not my preaching; therefore I cannot admit that allusion as a basis of justification. I should be truly sorry if the Journal ever closed its columns to short controversial subjects, as it affords an excellent incentive, as well as a means by which we may all endeavour to put ourselves right, as my courteous friend observes. But unfortunately for me I had not seen the extract referred to at page 305 until after the letter by "Yorkshire Bite" had appeared. This, I trust, he will consider a full and pardonable excuse. It appears to me somewhat strange that "Yorkshire Bite" should doubt the flavour of Peaches from 8 to 11 ozs. while he himself exults in growing Grosse Mignonne at 9 and 10 ozs. Methinks he has lost a "bite" here.—A. WATERS.

— NITRATE OF SODA AS A STIMULANT.—I was pleased to see a note on this subject from Mr. E. Molyneux, who has given us a clear statement of the benefits attending the application of this stimulant to fruit trees. I believe that nitrate of soda has a great future before it, and that the opinion formed of its usefulness has hitherto been greatly underrated by forming hasty conclusions before having given it a fair trial, and by supporting their views by random tests. There are gardeners who would be horrified at the idea of giving nitrate of soda to fruit trees; their active imagination would speedily conjure up in their mind's eye visions of strong shoots, rich green leaves, but no fruit as the result, but they forget that the whole thing may be regulated at will by the amount given and by applying it at the proper season. Trees heavily laden with fruit are in no danger of making too strong a growth however well they may be fed; what they want at such times is a stimulant which will enable them to derive the fullest possible amount of nourishment from the soil, to be converted into an increased weight of fruit. And again, in cases where plants get into a stunted condition nothing seems to give them increased vigour so quickly as nitrate. Its action in such cases is to a great extent explained by recent scientific research, but it seems also to possess a power of recouping the energies of plant life, as yet unexplained. Professor Paul Wagner has published several works on the use of nitrogenous manures, which may with advantage be studied by both gardeners and farmers.—H. DUNKIN.

— LILIUM HARRISI.—Those who have not been successful in flowering in a satisfactory way this fine Lily will do well to depart from the orthodox method of culture, which is to dry off the bulbs after flowering, and then repot them. I was surprised to see some fine plants in flower in the Castle Lane Nursery, Warwick, the other day, and others coming on to succeed them, some with the flower stems a foot long and others just peeping through the soil. These will supply a succession of their fine flowers up till Christmas, after which time the newly imported bulbs will begin to yield flowers. The treatment the plants have received to have them in flower as above stated is as follows:—After flowering in April and May last the supply of water given was slightly reduced till the flower stems died down. From that time the soil in which the bulbs were grown received an occasional watering to prevent the fleshy roots (which it was noticed were still in a growing state) from being injured, this treatment being continued through the early part of the summer, and in due time young flower stems began to make their appearance from the base of the old ones. The supply of water was then gradually increased, and when these shoots had grown a few inches in length a rich top-dressing was given, and with no further trouble except the necessary attention in watering a fine crop of useful flowers was the result, a type of flowers which are very acceptable at all times, but which are rarely met with during the autumn months. It may thus be seen from the above notes that it is possible and indeed easy to flower bulbs of *Lilium Harrisii* twice within twelve months, and Mr. Kitley has certainly hit upon a simple method of accomplishing this feat.—D.

— **AURICULA HOUSES.**—I would like to ask through your columns if your Auricula correspondents who have houses expressly built for their plants will kindly say what is the proper aspect for such, and whether it is possible to grow the Auricula to perfection for show purposes in any one house throughout the year, or is it necessary to remove the plants into the shade in the summer months? I have diligently read everything I can gather on the subject, and find that the old growers placed their frames in different positions according to the season; and coming to modern times, I see that the Rev. F. D. Horner, in a lecture which appeared in the Journal a few years ago, implies that he moves his plants during the summer into a more shaded house. Now have not many of the leading growers had their houses specially adapted, either by position or artificial shading, as to enable them to grow the flower without its being necessary to move the plants at any season of the year? Of course I know all about shading the blooms, but what about the plants in the growing and summer season? If anyone who has experience of an Auricula house will kindly reply I shall feel grateful.—M.

— **BIRMINGHAM GARDENERS' ASSOCIATION.**—The opening lecture of the winter session was delivered by Mr. Harry J. Veitch of the Royal Exotic Nurseries, Chelsea, on the 21st inst., and had consented to open the session after much pressure from Mr. W. B. Latham and other friends. His subject, "A Visit to Greece, with views illustrated by limelight by the aid of a lantern." Sir Thomas Martineau, the President of the Association, presided, and there was a large attendance of members. Admirable pictures were given of Corfu, modern and ancient Athens, various buildings, sculptures, and a host of objects associated with ancient and modern Greece; and the lecture was brimful of interesting and instructive information, interspersed with quaint humorous remarks. The lecture altogether giving intense pleasure to the audience. Starting with maps to illustrate the journey, which extended to about three months, Mr. Veitch revelled in the delight of seeing the innumerable art treasures there, and examples of the marvellous skill of the ancients. A report of the lecture was impossible in a darkened room, and with a long subject before him in a given time, Mr. Veitch had to hurry his remarks; but he is an admirable lecturer, and the "Night with Greece" will long dwell in the memories of those present. The island of Corfu, he said, was a beautiful garden in April, and three millions of Olive trees are growing there for the production of Olive oil, and some of these trees are 500 years old. The horticulture of Greece is of a very limited character, and the cultivation of the Olive is the chief occupation of the people. The *Euonymus*, *Laurustinus*, *Photinia serrulata*, *Pinus halepensis*, and a few other trees and shrubs thrive in Greece; and standard Peaches, Apricots, and Figs grow there. The want of a good supply of water is, however, severely felt.

— **THE Chief Signal Officer of the U.S. Army** has, just before the transfer of the Meteorological Service to the Agricultural Department, issued three atlases, bearing upon the METEOROLOGY of the UNITED STATES, showing—(1) The isobars, isotherms, and winds for each month from January to December for the years 1871-73, a period prior to the regular publication of the monthly charts. The data used include all the materials possessed by the Smithsonian Institution. (2) The probability of rainy days, prepared from observations for eighteen years (1871-88). The average number of such days for all months and for each station has been calculated, and the percentages thus obtained are graphically shown on the charts. The data show great differences of distribution of rainfall in localities not far distant from each other; the influence of the prevailing direction of the wind in increasing the number of rainy days is particularly noticeable in the Lake region. (3) The average monthly cloudiness for the period 1871-88. Cloud observations show indirectly the relative amount of sunshine, as it may be assumed, within reasonable limits, that the complement of cloudiness will be sunshine. The investigation of this element is useful in determining the suitability of certain localities for health resorts, or for the ripening of crops, and the charts may be considered as standard cloud maps of the United States.

— **DR. KING, DIRECTOR OF THE BOTANICAL SURVEY OF INDIA**, has issued a report on the working of the Botanical Survey in Assam and Burmah, for which 2000 rupees are annually allowed, with a view to arranging a plan for working by native collectors. Dr. King visited Assam in the latter half of last year, and found the local authorities ready to afford every assistance. Two native collectors were secured, and set to work near Golaghat, and in the Khasia Hills. The Conser-

vator of Forests also sent a large number of specimens to the Herbarium at Calcutta, and a Eurasian collector was employed for a time in Cachar. Some interesting plants were also obtained from the base of the Eastern Himalayas. Fairly good work was done in Upper Burmah by a native collector, and his specimens are now in course of being arranged at the Calcutta Herbarium. The collecting agencies continue working during the present year.

— **DR. PRAIN**, the Curator of the Herbarium of the Calcutta Botanical Gardens, accompanied the surveying ship "Investigator" during part of her operations in the Bay of Bengal last year. By a special arrangement, Dr. Prain was put down on the Great Coco Island for a few days, and was also enabled to pay short visits to the Little Coco and to Rutland Islands. Except for the visit made by Dr. Prain under similar circumstances the previous year, the Great Coco had not before been explored by a botanist, and the Little Coco and Rutland Islands were this year visited for the first time. Accounts of these visits are to be officially published in due course.—(Nature.)

— **THE Ealing Middlesex County Times** (October 17th) prints the following account of an incident which occurred at "The Grange," the residence of Mr. Yates Neill, Ealing, on Wednesday, October 14th:—"It appears that during Tuesday night a large branch of one of the magnificent Chestnut trees standing in the ground was broken off by the force of the wind, and fell on two stripling Chestnut trees near the wall. On Wednesday morning, the gardener, a man named Parker, was engaged in sawing the detached bough, Mr. Delancey Neill and Mr. Vertie Neill watching the operation. Just before noon, the first-named gentleman saw what appeared to him to be a ball of fire fall, and striking the tree in an oblique direction, alight on the ground within 2 or 3 yards of where the three were standing, whence it rebounded and exploded with a sound like dynamite. Although neither of them was struck, the shock was so great that for a time all three were dazed, Mr. Vertie Neill, indeed, being thrown down, and rolling over two or three times. His brother was the first to recover from the shock, and promptly went to his help, and he was removed to the house, where the feeling of dizziness speedily wore off; and beyond somewhat severe headaches, which lasted for some hours, neither of the gentlemen nor the gardener appeared to have suffered any ill effects. The trunk of the tree struck by the meteor presents the appearance of having been burned in a zigzag direction for a distance of some 20 or 30 feet."

### NEW KIDNEY BEANS.

KIDNEY BEANS are among the most useful crops that can be grown in the kitchen garden. The varieties, Canadian Wonder, Ne Plus Ultra, Negro, and Osborn's Prolific, are well known as useful varieties. It has been my good fortune this year to have had sent me for trial by Mr. Smythe of Basing Park some of his new dwarf Bean, the result of a cross between Ne Plus Ultra and Canadian Wonder, and which this year has obtained three marks in the R.H.S. Gardens at Chiswick. This Bean stands the highest in my estimation of any. It is ready for the table at least a fortnight before any other. It has a fine flavour, is a good cropper, and equally good for forcing. It is being sent out this year by Messrs. J. Veitch & Sons.

Mr. Smythe's new Scarlet Runner is still, in my estimation, one of the best yet raised. The great advantage of this Bean is that it can be grown without stakes, and its yield is almost equal to the long Runner Bean. Its quality is superior to its parents. The reason I mention this dwarf Runner is because in my article on the culture of Beans, two years since, I spoke very highly of it. I have now changed my locality, and find it does equally well on different soils, and I recommend Mr. Smythe to send it out. While on a recent visit there I saw several new Beans, of which, perhaps, more will be heard in future.—G. A. BISHOP, *Wightwick Manor Gardens, Wolverhampton.*

### ARISTOLOCHIA GIGAS.

SOME of the most remarkable flowers in the vegetable kingdom are produced by members of the genus *Aristolochia*, and several have been from time to time figured or described in this Journal, one of the most remarkable that has hitherto appeared in these pages being *A. Goldieana*. Attention is now directed to one which, in some respects, even surpasses that in interest, and certainly in size of the flower. The plant, which is known both as *Aristolochia grandiflora* and *A. gigas*, has for some weeks been flowering in the Victoria Lily house at Kew, and is there trained to the rafters extending over the large central tank. It is of vigorous growth, with heart-shaped, dark green leaves about 6 inches

in diameter. The flowers are about 16 inches across, 20 inches long, terminating in a narrow tail-like appendage about 18 inches in length. The general shape is elliptical, and open or flat, not hooded like some

the plant presents with a dozen or more of these gigantic flowers drooping from the stems.

The engraving (fig. 73) was prepared from a flower shown at a recent

FIG. 73.—ARISTOLOCHIA GIGAS.

species, creamy white, flaked and mottled with bright rosy crimson, with an oval dark maroon centre 6 inches in diameter, giving a peculiar effect to the flower. It can be imagined what a singular appearance

meeting of the Royal Horticultural Society, and is reduced about one-fourth. At the meeting last Tuesday Miss Marie Low exhibited a painting representing the flower of its full size.

## ON KEEPING DAHLIAS.

THE popularity of the Dahlia is deservedly increasing, and as there are numbers who have only the slightest knowledge of how to treat the tubers in order to keep them through the winter months a few notes just at present may be acceptable. That it is possible to keep the tubers in the best condition there can be no doubt, as for many years I have been in the habit of storing a large number—several hundreds—and it is quite exceptional that any are lost. I do not give any particular reason for this, as I believe the method of culture generally has much to do with success in safe wintering. Thus all the tubers are old—that is to say, they are not from cuttings of the same year, as my practice is not to produce my stock from cuttings, but by division of the tubers. The primary reason for doing this was to ensure their safe keeping during winter, as I found that the larger and better ripened the tuber the less danger there was of loss. But I also had the satisfaction of having plants in flower quite a month earlier by this method, and in the case of shy-flowering Cactus sorts this is no mean gain.

With new sorts bought as spring-rooted plants the pots are merely plunged, but deep enough to allow a free growth of roots. Treated thus, these keep as well as the others. When the plants are cut to prepare for removal quite 15 to 18 inches of stem is left, and I like to leave the tubers awhile in the ground after having been cut, so that the dormant buds may be a little more pronounced than if the roots were lifted at once. When they are lifted all the soil that rises with them is left, and I invariably find that the best preserved tubers are those which are stored with soil attached to them.

During winter absolute dryness is essential. Ours are stored in a shed where there is always a little heat, so that no damp is possible. In spring the tubers shrivel somewhat, but I have not noticed that this has been prejudicial. During the month of March if very dry they are watered perhaps two separate times, and by the beginning of April most of them are fairly prominent. I used to defer planting until the beginning of May, but this year I took an opportunity early in April to put out the tubers, setting them much in the same way as "started" Potatoes, and the plants did well, being sturdy, dwarf, and early flowering. I may add that although there is 200 feet super in which the tubers are stored I find it necessary with some of the sorts, such as Glare of the Garden, Juarezi, Chilwell Beauty, and the Old White, of which a large number of each is grown, to bank them up three or four deep, but being always dry they keep perfectly well.—B.

## CIDER.

WE have for some time had what appears to be an excellent little American handbook\* on making cider awaiting notice, and at the present time a few extracts from the work will not be inappropriate. They will also indicate the nature of the book, and those of our readers who desire detailed information on making cider may advantageously consult its pages.

Relative to varieties of Apples and management the author observes:—

"It is a general rule that 'the better the Apple the better the cider;' but this is not to be understood as meaning that the Apples best for eating are always best for cider-making. It is certain, however, that poor, watery, or flavourless Apples can never yield good cider, and it is equally certain that such Apples as the Spitzenberg, Seek-no-farther, Rhode Island Greening, Tompkins County King, and Swaar, all of which are among the best table fruits, do make most excellent cider. But there is another class of Apples, comprising Russets and Crabs, which make the best of cider, and yet are never of the highest quality for table use. They assuredly do attain in time to a condition which admits of presenting them at table, but it is at a season when the other varieties, better liked for that purpose, are generally gone, and the Apple-lover must use Russets and Crabs, or wait another harvest.

"Of whatever variety of Apples cider is made, it is of the greatest importance that the fruit be carried to the highest maturity before that work begins. The French recognise three stages in the maturing process, which they denominate severally 'Maturity of vegetation' (growth), 'Maturity of honeying' (ripening), and 'Maturity of expectation,' which, being rather difficult to define by any synonymous English word, may be best explained by translating the text, "'The "Maturity of expectation" uses or combines the scattered principles to form sugary matter, which thereafter abounds in the Apple.'" Probably the three periods are those known to us as the growing, the ripening, and the sweating

periods or stages; the first and second occurring on the tree, and the last taking place after the fruit is gathered.

"Whenever it is done sweating is of very great importance to the quality of the cider. Its most obvious effect is to reduce weight by evaporation of part of the water of the juice, which is always excessive. By this it produces indirectly an increase in the relative proportion of the saccharines.

"Apples which are not completely grown contain a large quantity of starch, but no sugar. After the fruit is fully grown the starch gradually disappears, and in its place we find Grape sugar. This change constitutes the ripening of fruits, and, as well known, will take place after they are gathered. In this process we have clearly a conversion of starch into sugar by the agency of vegetable acids present in the fruit, a change independent of life.

"Of course the conversion of tissue into saccharine implies a thinning down and weakening of the cells containing the juice, whereby their power to resist pressure is very much reduced, and the Apple becomes softer or 'mellow.' The loss of water at the same time contributes to the same effect.

"Wherever stored after gathering Apples should not be placed in large heaps, nor should they be stored in closed sheds, barns, or bins; but they should be exposed in small piles to the air, wind, and sunshine. They must also be kept perfectly clean, sound, and free from all foreign odours, especially so from mustiness. If allowed to lie on the ground for more time than necessary to gather them they will take an earthy flavour, known in wines as *goût de terroir*, and which will neither leave them nor the cider made therefrom.

"It is no uncommon thing to see Apples collected in heaps on the ground under the trees where they grew, and so left for a week or two before being carted to the mill, where again perhaps they were stored in large closed bins for another equal period, a very sure way indeed to diffuse the earthy and musty flavour with any others they may have acquired, and of thoroughly infecting the whole stock.

"We will suppose our Apples to have been harvested and carefully sweated, and to be now ready for cider-making. They are yet in heaps, each kind by itself, under the trees where they grew. In order to haul them to the mill they must be mixed. Now comes the critical question: How shall they be mixed? It will not do to throw them together indiscriminately; some may be worthless for cider, and be able to damage, if not to destroy, the entire product; and others, if not quite so bad, may possess qualities, or want of qualities, that unfit them for cider, and that the cider will be all the better without. What we are aiming at is high quality in our product. It certainly cannot be obtained by an indiscriminate mixture of all our fruit, regardless of quality. It will not do, even with Grapes, so much richer in wine-producing properties, and surely not with Apples; the greater deficiencies of which, in those respects, demand the more careful judgment, the more skilful blending, and, above all, the most absolute rejection of all those which can in any degree depreciate quality.

"How, then, are we to mix our Apples? Assuredly they should be so mingled that one kind may make up for the deficiencies of another, and that the blend, as it is called, shall be better than the cider made of either one of the varieties alone; in short, so that each shall contribute something toward, and detract nothing from, a complete and generous whole. To do this intelligently it is necessary to know something of the constituent proportions of the various fruits, in order to bring them together harmoniously, and especially to avoid making use of any which are nearly or quite worthless or injurious to our purpose. Good wine is obtained in that way only, and it is the only possible way to obtain good cider.

"Whoever thinks that 'any Apple is good enough for cider' had better not engage in the business. He probably would not know a good article of cider if by any accident he should ever taste one. This book is designed to guide those who intend and desire to make the best, and are to be satisfied with nothing less. Incidentally it teaches how to make the most of imperfect material, but the most perfect product can only be made with the best material. Rest assured that this is eminently true in cider making. Poor material had better be used in other ways, where it can do no harm, and may possibly be made to yield profit; but to use it to deteriorate quality of a product where quality is the first and highest consideration is simple foolishness."

Alluding to the uses of cider, Mr. Trowbridge says:—

"For all purposes for which wine is commonly used, cider, properly made, has much to commend it over many wines. The principal difference between them lies in the lighter alcoholic strength of cider and in the absence therefrom of tartaric acid, which is the principal acid of wine. Tartaric acid combines with lime to form precipitates, or insoluble particles, whenever they are brought into contact. Cider is certainly free from this objection,

\* "The Cider-Maker's Handbook." By J. M. Trowbridge. New York: Orange Judd Co. London: Kegan Paul, Trench, Trübner & Co., Ltd.

since it contains no tartaric acid, the place of which is supplied in the Apple by malic acid. The latter acid is also found in Grape juice, with tartaric, but it has not the power to form precipitates with lime like the tartaric. Malic acid is the principal acid in Cranberries, Rhubarb, Cherries, and also a component of a large number of the most wholesome fruits and plants. Cider should be nothing more nor less than a true Apple wine; that, and nothing else. But, like Grape wine, it may be well or ill made, and it may be agreeable or disagreeable, and yet be pure."

The properties of cider are temptingly portrayed as follows:—

"A pure article of cider, skilfully made from select fruit in perfect condition, should have perfect limpidity and brightness, even to sparkling in the glass; it may vary in colour from a delicate straw to a rich amber colour, more or less deep, but should never be a bright red, nor, indeed, show much of a roseate tinge. It should be fragrant, so that when a bottle is freshly opened and poured into glasses an agreeable fruity perfume will arise and diffuse itself through the apartment, 'with a benison on the giver.' It should be tart, like Rhine wine, and by no means sharp or harsh. It should have a pleasant, fruity flavour, with aromatic and vinous blending, as if the fruit had been packed in flowers and spices. It should have mild pungency, and feel warming and grateful to the stomach, the glow diffusing itself gradually and agreeably throughout the whole system, and communicating itself to the spirits. It should have a light body or substance about like milk, with the same softness and smoothness, and it should leave in the mouth an abiding agreeable flavour of some considerable duration, as of rare fruits and flowers. These qualities are all attainable, but they demand the knowledge and skill which come by practice, thought, assiduous painstaking care, and, above all else, the most rigorous cleanliness. With these and proper material, any intelligent person can make good cider. There is no mystery about it and no secret."

The handbook is illustrated, and the details for making cider are given in its 117 pages.

THE ROSE SEASON OF 1891.

ON all sides we hear of the disappointing character of the harvest. Money articles in the *Times*, reports from correspondents in other papers all tell the same story. There was a goodly prospect in the early summer. May and June brought on everything, but then came a wet July, and the wettest August known for many years, and the hopes of the farmer were considerably diminished. September gave some relief, but on the whole "disappointment" has been the word which most fully describes his position. The same may be said of the flower harvest, and especially of the Rose—a season when everything was three weeks or more behind, when Mr. Horner could not show Auriculas at the usual date because his plants were not in flower, when some of our best Carnation and Picotee growers were prevented from exhibiting from the same cause, when Mr. Lindsell and myself—he partially and I entirely—were prevented from putting in our usual appearance with Gladioli at the Crystal Palace, for at that time I could not to save my life have cut a dozen spikes; and this character of the season very naturally influenced both exhibitors and exhibitions. Take for example two of the most successful exhibitors of 1890—the Rev. F. R. Burnside, who swept all before him in Teas that year, and Messrs. Harkness, who were the winners of the trophy. In the earlier shows of the year they were absolutely nowhere, and it was not until the third week in July that the former showed at all in his usual form, while the latter even then had not his plants in flower. It may be said that they were far north; true, but on the 7th of July I was in the garden of my friend Mr. Lindsell at Hitchin—he grows somewhere about 3000 plants—there were whole quarters without a flower, and he had the greatest possible difficulty in cutting twelve trebles for the Bath Show, and they were indifferent. Some people shake their heads incredulously when we affirm such things. "What," said a west countryman to me, when I was expatiating on the lateness of our season, "and you in the Garden of England!" Yes, in truth, and so it is, we say against all comers, but for all that not so favoured as many places.

Now this perversity of the season led to some very disastrous effects. Some Committees of Rose societies were constrained to alter their dates, and as the Rose exhibition season is a short one this led to more clashing and confusion than was usually the case, and it made the great metropolitan show of the National the worst that they had ever held, with perhaps the exception of that disastrous year 1879. This was seen both in the extent and quality of the exhibition. Large as it seemed to be, it fell far short of those preceding it, while the whole character of the blooms was mediocre. Nothing could show this better than the

fact that where boxes had to be taken in detail, and judged by points, it was very rare that three points could be given to a bloom; and as a consequence, there were no such pleasant memories to look back upon as when some grand box or some magnificent single flower rests on the memory. But I do not think that we must lay all the blame of this on the lateness of the season. I think the terribly severe winter had a good deal to do with it. I took a good deal of pains in the spring to ascertain what had been the effect of the terribly severe frost that we experienced, and for this purpose I wrote to most of the leading growers, especially amongst amateurs, obtaining answers as to the effect on Teas and Hybrid Perpetuals. These, of course, varied much through the differences of soil and situation, but there was a general consensus of fact that they had been very hard hit, that hard pruning was necessary, and that in the case of Teas in most places they had been cut to the ground, while the deaths were not so numerous as might have been expected. Now, where this is the case, it must take a longer time for the Rose to make its growth than when they have not suffered much, and this, I think, was fully borne out by the results of the Hereford Show of the National, where the quality of the flowers was excellent, and making it the very best provincial show that the Society has ever held, and where exhibitors who had made but a sorry appearance ten days before showed admirably. Take, for example, Mr. Burnside, who last year swept all before him at the Palace, but "took a back seat" there this year, yet at Hereford he came out in his usual form, and occupied the foremost place. That Hereford Show was, in truth, a great success, and it is satisfactory to be able to state that its financial results exceeded the most sanguine expectations of the friends who had so pluckily undertaken it.

The carrying off of the challenge trophies is always a matter of interest. This season the nurserymen's trophy fell to Mr. Ben Cant, our veteran Rose exhibitor, who for fifty years has been engaged without intermission, and is now as keen over his flowers as ever. Mr. E. B. Lindsell again carried off the amateurs' trophy, while Mr. Alex. Hill Gray won the Tea challenge trophy and the Boscawen Memorial prize. The Jubilee trophies, which were instituted for the benefit especially of the northern growers, fell to southern men, that for nurserymen to Mr. Frank Cant, and the amateurs' trophy to the Rev. J. H. Pemberton. Indeed, as far as the north is concerned one does not see who is to carry off this latter. The retirement of Mr. T. B. Hall and Mr. E. R. Whitwell removes from us the only large growers in the north, and unless some other amateur steps in to take their place we fear these trophies will always go south.

We fear that it has fared badly with many societies. July is too often a wet month, and that of the present year has been especially so. We all know how many of them live from hand to mouth, and it is to be feared that some of them will be sorely crippled by the wet days they have had to suffer from.

There have been no remarkable records of individual success such as I have had to record in many previous years. Perhaps the most noticeable feature has been the manner in which Mr. Alexander Hill Gray has stepped into the front rank as an exhibitor of Tea Roses. I have long felt and expressed the opinion that he was destined to do this, and the present season has shown that this opinion was correct. Both at Tea and Noisette exhibitions, and at the Metropolitan Show he carried all before him, and his Roses were remarkably fine, especially when we take into consideration the character of the year, although perhaps this was in his favour.

And if there were no remarkable records in prizewinners, I have not much to record as to new Roses. There are many to whom Gustave Piganeau will seem a great gain (great it is as far as size is concerned), but it is not a style of Rose which I value very highly. It has, however, one good quality—it is a very free autumnal bloomer, in this respect resembling Paul Neyron, from which it is said by some to be a sport, while others think it more like Antoine Ducher. There is no more favourite variety with the French for decorative purposes at this season of the year than Paul Neyron, and this probably being of a deeper colour may become equally popular. Messrs. Dickson's fine Rose, Margaret Dickson, has been shown by them in fine condition, and is unquestionably a great gain. Another of their seedlings, Marchioness of Dufferin, was awarded the gold medal of the N.R.S.; it is a light coloured Rose, and one which will be a great favourite; it has also a most delicious perfume. Cleopatra is a very beautiful Tea Rose, with a fine pointed bud, but I think it is questionable whether it will have stuff enough to make it a reliable exhibition Rose. Another Tea Rose of which I entertained a good opinion, was Corinna (Messrs. W. Paul and Son); it is of the character of Princess of Wales, and in a better season would probably be a welcome addition to our Teas. Mrs. Paul (Paul & Son) has not been, of course, largely exhibited as yet, but where seen has been most admired, and its vigorous habit is much in its favour.

And now turning away from Rose exhibiting, with its changes and chances, its ups and downs, successes and disappointments, which has been the character of the past season as far as the Rose garden home enjoyment of the flower is concerned, many things were in its favour; the enemies of the Rose were not in full force—maggots were scarce, and as to the aphid I have not seen a single individual on any of my trees during the whole year. Why this should have been I cannot say, but the same experience has been that of all the Rose growers with whom I have talked on the subject; neither have I seen as much of the red ru or orange fungus, while the absence of mildew has been something remarkable. The weather has been cool, the temperature low, and it is, I believe, the alternations of hot weather, hot sunny days and cold

nights are the fruitful source of this pest. These alternations we have not had, and consequently we have been spared mildew; but with all these advantages the bloom was disappointing, being of such short continuance. I do not think in my own small garden I ever had a better, and I question if ever as good a display of fine flowers; but then it was only for a few days—violent thunderstorms, with deluges of rain, soon took their beauty away, many became gummed, and all soon shed their petals; but they in one way compensated for it. The month of August, so injurious to our cereal crops, just suited the Roses. They made vigorous growth, and when care was taken to disbud the new shoots splendid autumn blooms were obtained. I never myself had a finer bloom, and the Tea Roses were superb. This has been corroborated by others, and although the terrific weather of the second week in October has committed sad havoc amongst them I am yet hopeful that when the weather improves, which I suppose it will do, some late blooms may still be had.

In this brief review of the past Rose season I have, of course, relied solely on my own experience, and given my own views. There may be some who will differ from my conclusions. The conditions of soil and situation may modify them, although I hardly think that they will do so to any great extent; at least, all with whom I have had the pleasure of conversing on the subject have agreed on the correctness of the designation I have given to the season as a most disappointing Rose season.—*D., Deal.*

#### TEA ROSE THE QUEEN.

WE notice that a writer in a recent issue of the Journal alludes to this Rose as "Mr. W. Paul's The Queen." We trust he will pardon our pointing out that this is scarcely correct, as it originated with and was introduced to commerce by the Dingee and Conard Co. of West Grove in the United States, and we think it only fair to our esteemed friend, Mr. A. B. Conard, and his worthy partner that this should be generally known. We (no doubt in common with other English rosarians) ordered it from a circular received in the winter of 1888-9, and the plants reached us early in the spring of 1889. Souvenir de S. A. Prince was not sent out until some months afterwards. The identity of the two varieties seems to be now generally admitted, but there is no doubt as to The Queen having been the first in the market by several months, and considering this fact as establishing a claim to priority of nomenclature, we catalogue the variety under the name of The Queen. We were the first to exhibit The Queen in bloom in this country, as we had previously been in the case of the fine American varieties Sunset and The Bride, but beyond being amongst the earliest purchasers of them, we can lay no claim to introducing them to commerce.—*WM. PAUL & SON, Waltham Cross.*

#### CELOSIA PYRAMIDALIS IN THE AUTUMN.

THIS is one of the best plants in cultivation for decorative purposes at the present time of the year, and indeed it is difficult to imagine any season when their feathery plumes of bright and varied colours are not welcomed; but they are not so much grown for use during the autumn months as during the summer time, and are, therefore, the more highly prized then. Another great point in their favour is that they last a long time in dwelling-rooms; in fact, longer than any other flowering plant that I know. We use them freely for decorative purposes, and have at the present time plants in 4 and 5-inch pots which have been in the rooms for upwards of three weeks, and are apparently none the worse for their long stay. The great secret is to keep them rather dry at the root—one watering before they are really dry will inevitably prove fatal. When arranged in wide ornamental pans or jardinetts, with a base of small and well-flowered Marguerites and an edging of *Isolepis gracilis* and *Panicum*, they are exceedingly effective. They also look well when placed singly in small vases, or when from three to five are placed in a larger vase; they are very telling in suitable positions, and anyone who makes a point of arranging them in various ways will find that they show to advantage much better when placed where they have no background near them—near walls, or in any position where they have not plenty of light around them, the effect is spoilt. Loam, two parts, well decomposed hotbed manure one part, with a liberal admixture of sharp sand, is a suitable compost for them.—*H. D.*

#### ROYAL HORTICULTURAL SOCIETY.

OCTOBER 27TH.

"AUTUMN tints" predominated charmingly at the meeting in the Drill Hall on Tuesday last, not only in the extensive and beautiful collections of varied tree and shrub sprays, but also in the rosy cheeked Apples, which occupied so large a proportion of the table space. Chrysanthemums and Orchids also added their attractions to a display that for the time of year has scarcely been surpassed. Many Fellows and visitors assembled in the afternoon to hear Mr. Harry J. Veitch's entertaining lecture on "Autumn Tints," which was delivered in his customary pleasing manner.

FRUIT COMMITTEE.—Present: Philip Crowley, Esq., in the chair, Dr. Robert Hogg, and Messrs. G. Woodward, T. Francis Rivers,

W. Bates, G. Bunyard, G. Wythes, W. Warren, J. Hodson, H. Balderston, R. D. Blackmore, C. Ross, F. Q. Lane, J. Smith, W. Denning, J. Cheal, J. Willard, A. H. Pearson, A. Dean, and G. Reynolds.

Messrs. Rothschild, Gunnersbury Park (gardener, Mr. G. Reynolds), were successful exhibitors in the two classes provided for six bunches of Grapes each, one being for flavour, as in both the exhibits from Gunnersbury were awarded premier honours. The varieties for flavour were Mrs. Pince, Black Hamburg, Muscat Hamburg, Muscat of Alexandria, and West's St. Peter's, all good compact bunches. In the other class handsome examples were shown of Gros Maroc, Muscat of Alexandria, Mrs. Pearson, and the following:—

*Chasselas Napoléon*.—For this a first-class certificate was awarded, as it was in extremely fine condition. The bunches large but compact; the berries large, oval, white with an amber tint, fleshy, and of good flavour.

Amongst other exhibits were noted well grown brightly coloured examples of Sutton's Perfection Tomato (cultural commendation) from Mr. Debnam, Spring Grove, Isleworth, who also sent a Melon raised from a cross between Hero of Lockinge and Scarlet Premier. P. Crowley, Esq., Waddon (gardener, Mr. W. King), showed a dish of very fine Cox's Orange Pippin (cultural commendation). From the Society's gardens at Chiswick came bunches of the small black out of doors Grape, Miller's Burgundy; and Mr. C. Ross, Newbury, sent fruiting spikes of *Phytolacca decandra*, the American Pokeweed, which has black fruits somewhat like Blackberries, closely set on a spike over a foot in length.

The collections of Apples and Pears were extremely fine, and formed an admirably display. Mr. G. Woodward, The Gardens, Barham Court, Maidstone, had 110 dishes of Apples and Pears (silver-gilt medal); Messrs. J. Veitch & Sons showed 100 dishes and baskets (silver-gilt medal); Messrs. Paul & Son, Cheshunt, had about 100 dishes (silver Banksian medal); Mr. G. Wythes, Syon Gardens, Brentford, showed 80 dishes (silver Banksian medal); Messrs. Peed & Son, Norwood Road, had 50 dishes, but comprising some very fine fruits (bronze medal); and a large collection also came from the Society's Garden at Chiswick.

In the class for six dishes of Apples Mr. G. Sage, Ham House Gardens, was first with fine specimens. For the same number of Pears Mr. Hudson, Gunnersbury House Gardens, took the first place with praiseworthy fruits, and Mr. Sage followed.

FLORAL COMMITTEE.—Present: G. Paul, Esq., in the chair, and Messrs. W. Furze, C. Noble, J. Walker, H. Cannell, H. Herbst, R. Dean, H. B. May, B. Wynne, G. Brycesson, G. Phippen, C. Jeffries, W. H. Poë, C. E. Pearson, F. Ross, and G. Gordon.

The collections of tree and shrub sprays distinguished by the bright and varied colours of their changing foliage or by the possession of attractive berries and fruits were the most important feature amongst the exhibits. Large numbers of Oaks, Maples, Azaleas, *Ampelopsis*, *Berberises*, varieties of *Rhus*, *Liquidambars*, *Andromedas*, *Mahonias*, and others were shown, Messrs. J. Veitch and Sons having the largest display, comprising 120 distinct varieties (silver Flora medal). E. C. Smith, Esq., Silvermerc, Cobham (gardener, Mr. Quarterman), also had a beautiful group very tastefully arranged with a broad marginal band of brilliant red and other fungi upon a moss (silver Banksian medal). Similar awards were granted to R. S. Holford, Esq., Westonbirt, Tetbury, and to Mr. Wythes for smaller collections. Messrs. Cutbush and Sons, Highgate, gaining a bronze medal for a handsome group of *Pernettyas* in fruit and a collection of trees and shrub sprays like the preceding.

Chrysanthemums came next in importance, Messrs. J. Veitch and Sons having a large and effective group of plants representing the chief types and some new varieties, also handsome cut blooms of the Japanese *Vivian* Morel (silver Banksian medal). Mr. G. Wythes also had a tasteful exhibit of cut blooms, including several fine examples, arranged with small Palms and Ferns (silver Banksian medal). Mr. T. S. Ware, Tottenham, sent cut blooms of Chrysanthemums *Vivian* Morel, *La Condamine*, pale pink; and *Amos Perry*, yellow, in the style of Mr. H. Cannell. Mr. H. J. Jones, Ryecroft Nursery, Hither Green, Lewisham, showed plants of "the yellow *Lacroix*," named Mr. C. E. Shea, a free variety, with medium-sized bright yellow blooms and narrow florets. Messrs. Paul & Son sent a plant of the rich crimson Japanese *Alberic* Lunden. Mr. R. Falconer Jameson, Hessle, Hull, sent fine blooms of *M. R. Bahuant* and *Bouquet de Dame* Chrysanthemums, the former of which secured an award of merit, with blooms from other exhibitors. Mr. C. Blick, The Warren, Hayes Common, exhibited an incurved Chrysanthemum named *Madame Durrier*, the blooms neat and well finished, but not deep, the colour a peculiar amber salmon tint. Messrs. Pitcher and Manda, Hextable, showed a collection of cut blooms of Chrysanthemums; and Mr. R. Owen, Maidenhead, had several boxes of blooms, including both English raised and continental novelties, two of which received awards of merit.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq., in the chair, Dr. M. T. Masters, Messrs. J. O'Brien, S. Courtauld, J. Douglas, E. Hill, H. Low, H. M. Pollett, D. B. Crawshaw, T. B. Haywood, F. Sander, and Lewis Castle.

Orchid exhibits were not very numerous, but they included several interesting plants, and two or three small groups. Messrs. Collins and Collins, Willesden, had a graceful arrangement of *Oncidiums*, with Ferns (small silver medal). Messrs. Sander & Co., St. Albans, showed a group of new and rare Orchids, also large healthy imported plants of

*Cattleya labiata* vera in excellent condition (bronze medal). C. Ingram, Esq., Estead House, Godalming (gardener, Mr. Bond), exhibited a group *Cattleya labiata*, var. *Warocqueana* in many varieties, as also did F. Wigan, Esq., Clare Lawn, East Sheen (gardener, Mr. H. Young). Other exhibitors of Orchid plants or flowers were Admiral Cator, Hazlewood, Kings Langley. Messrs. Pitcher & Manda, C. J. Lucas, Esq., Warnham Court, Horsham (gardener, Mr. Duncan), and Mr. H. Tracy, Twickenham.

## PLANTS CERTIFICATED.

*Cypripedium Pitcherianum*, *Williams' Variety* (B. S. Williams and Son).—A particularly handsome *Cypripedium*, with large bold flowers, having a polished shining appearance, and very rich in the colouring. The dorsal sepal is 2½ inches broad, rounded, veined with dark crimson in the centre and at the base, the lower sepal pale green; petals polished with dark reddish central vein, the lip neat and of a dark tint like the petals (first-class certificate).

*Chrysanthemum M. R. Bahuant* (Messrs. R. Owen, Falconer Jameson, and J. R. Pearson & Sons).—The new incurved variety described and illustrated in this Journal last week (award of merit).

*Chrysanthemum Louis Boehmer* (W. Furze, Esq., and Messrs. J. Veitch & Sons and Pitcher & Manda).—The "pink Mrs. Alpheus Hardy," a very distinct and peculiar variety of much better habit than the last named. It is described on page 363.

*Chrysanthemum Mrs. Nisbet* (R. Owen).—A Japanese variety, said to be from English saved seed, and described as very dwarf, not exceeding 3 feet in height. The flowers are of good substance, the florets flat, rich crimson, with a silvery reverse (award of merit).

*Richardia ethiopica compacta* (Messrs. R. Veitch & Sons).—A dwarf, compact growing variety with neat leaves and good sized spathes, useful for culture in pots (award of merit).

*Cypripedium radium* (C. Ingram, Esq.).—An attractive variety with a broad dorsal sepal veined with crimson in the centre, and at the base broadly margined with white like *D. Spicerianum*, the petals small, greenish, undulated at the margin, the lip very dark (award of merit).

*Chrysanthemum William Wells* (W. Wells).—A Japanese variety with pale yellow, deep, well proportioned blooms, the florets narrow and incurving (award of merit).

*Dendrobium O'Brienianum* (Sander & Co.).—A distinct Orchid with long drooping racemes of small creamy-white flowers (botanical certificate).

## SOUTHAMPTON CHRYSANTHEMUM SHOW.

OCTOBER 27TH AND 28TH.

FOR the last two years no Chrysanthemum Show has been held in this town, but a pleasant reunion took place on the above dates, the Exhibition being held in the Victoria Hall, a capital site, affording abundance of light and ample space for visitors to view the exhibits, and a capital Show it was. The cut blooms were arranged on long tables running the length of the building, small Palms and the plants for table decoration being placed in lines down the centre of each. Groups of Chrysanthemums were arranged at the end, and an imposing display of miscellaneous plant groups down one side, and with numerous specimen Palms dotted about the Hall, a pleasing effect was produced. Mr. C. S. Fudge, the energetic Secretary, and his assistant, Mr. H. Dallison, deserve every praise for the arrangements. The entries were numerous in all classes, the exhibits so uniformly good that close competition was the result.

Cut blooms, owing to their greatest numbers, deserve first notice. The premier class was for twenty-four distinct varieties, half to be incurved and the remainder Japanese. Five competed. Mr. N. Molyneux, gardener to J. C. Garnier, Esq., Rooksbury Park, Wickham, Fareham, succeeded in taking first honours by the superiority of his incurved, which were of good size and well finished, the Japanese being rather weak. The names were Condor, Mrs. Irving Clark, Avalanche, Louis Boehmer, Sunflower, Madame J. Laing, Volunteer, W. H. Lincoln, Edwin Molyneux, Puritan, Sarah Owen, and Stanstead White. Incurved: Lord Alcester, Queen of England, Golden Queen of England, Empress of India, Violet Tomlin, Golden Empress, Alfred Salter, Mr. R. Mudie, Jeanne d'Arc, Princess of Wales, Lord Wolseley and Novelty. Mr. J. Agate, Havant, was an exceedingly close second, his Japanese being remarkably heavy and good. Vivand Morel (certificated), Pelican, Mrs. Falconer Jameson, Avalanche, Mrs. A. Hardy, were the most noteworthy. Mr. G. Inglefield, gardener to Sir J. Kelk, Bart., Tedworth, Marlborough, was third. Seven competed in the class for twenty-four in not less than twelve varieties. Mr. Inglefield, with good incurved and Japanese, winning rather easily from Mr. Agate, who staged all Japanese. Mr. Penford, gardener to Sir F. Fitzwygram, Bart., M.P., Leigh Park, Havant, was third.

For twelve incurved, distinct, Mr. N. Molyneux was an easy first with large well-finished blooms of Empress of India, Queen of England, Golden Queen of England, Lord Alcester, Alfred Salter, Golden Empress, Jeanne d'Arc, Violet Tomlin, Princess of Wales, Lord Wolseley, White Venus, and Novelty. Mr. Inglefield second; and Mr. T. H. Crasp, gardener to Lord Wimborne, Canford Manor, Wimborne, third. Mr. Trinder, gardener to Sir H. Mildmay, Dogmersfield Park, Winchester, occupied the premier position for twelve Japanese, with large and brightly coloured blooms of the following:—Avalanche, Mrs. F. Jameson, Stanstead Surprise, Etoile de Lyon, Madame C. Audiguier, Sunflower, M. J. M. Pigny, W. H. Lincoln, E. Molyneux, Condor,

Boule d'Or, and G. Daniels. Mr. Inglefield second; Messrs. Elcombe, Bowsey, third. For twelve blooms in not less than six varieties eleven competed. Mr. Agate first, with a capital stand; and Mr. J. Allen, gardener to Captain The Hon. V. Montague, Wherwell Priory, Andover, second. Anemones were staged in good condition by Mr. Penford and Mr. Agate, the former winning with both Show and Japanese varieties. Mr. Agate staged the only Pompons, but so good were they that the first prize was awarded. Mr. Busby, gardener to F. Millan, Esq., Thornhill Park, Bitterne, was placed first for a group of Chrysanthemums arranged for effect, with plants carrying good blooms and foliage. Mr. H. Innes, gardener to Miss Buchan, Wilton House, Southampton, was second.

The best specimen plants were staged by Mr. E. Rose, gardener to Dr. Aldin, The Firs, Bassett, Southampton, such varieties as Lady Selborne, Bouquet Fait, M. Bernard, and Maiden's Blush being well shown.

Fruit made an imposing display. For three varieties of Grapes, one bunch of each, Mr. N. Molyneux won easily with Muscat of Alexandria, Gros Colman, and Gros Guillaume. Mr. Hall, gardener to S. Montague, Esq., M.P., South Stoneham House, Southampton, was second. Third, Mr. Budd, gardener to F. Dalgely, Esq., Lockerby Hall, Romsey, with very fine Alicante. Mr. Bushby took the premier award in the class for black Grapes. Mr. Trinder was second, and Mr. Inglefield third. For three bunches any white Grapes Mr. Chalk, gardener to G. Read, Esq., Westwood, Wilton Road, Salisbury, staged capital Muscat of Alexandria for the first prize. Mr. Inglefield second, and Mr. N. Molyneux third. Mr. Innes was first for two bunches black, and Mr. J. Allen had a similar position for two bunches any black variety. Mr. Hall had the heaviest bunch of Grapes, Alicante, 4½ lbs. Apples were strong features. For six dishes, distinct, Mr. Bushby first with fine fruit. Mr. Hall second. For four dishes of dessert varieties Mr. Crasp was first with highly coloured fruit, as also were his six dishes of Pears, with which he won the premier award.

Vegetables were as usual a strong feature. For eight varieties Mr. Hall won, Mr. Bushby second; and for six varieties Messrs. Inglefield and N. Molyneux were placed in the order named.

Mr. E. Carr, gardener to W. A. Gillett, Esq., Fair Oak Park, Bishopstoke, staged an admirable miscellaneous group of plants, and was awarded first honours; Mr. W. Peel, gardener to Miss Todd, Sidford Lodge, Shirley, second. Mr. Carr had a good collection of Orchids in the class set apart for them.

Japanese Chrysanthemum Vivand Morel received a first class certificate. It is a full flower, measuring 9 inches in diameter and 6 inches deep, the florets of a semi-drooping character, quite of the Madame C. Audiguier style of colour.

## FRUIT FORCING.

PEACHES AND NECTARINES.—*Earliest Forced Trees*.—Ripe fruit being required in late April or early May, forcing must commence about the middle of November where the houses are planted with such varieties as Hale's Early, Stirling Castle, and Royal George Peaches, along with such Nectarines as Lord Napier and Dryden; but where the trees consist of Alexander, Waterloo, Early Beatrice, Early Rivers, and Early Louise Peaches, with Advance Nectarine, forcing, to have fruit ripe at the time named, need not commence in earnest until the new year. All points considered, there is no better early forcing Peaches than Stirling Castle and Royal George. The house should be closed about the middle of November, using no fire heat unless the weather is frosty. Give inside borders a thorough soaking of water, and if the trees are weakly supply liquid manure, but not too strong, which by the conversion into assimilable plant food taking place in the soil tends to cause activity at the roots, and conduce to a more vigorous expansion of the buds. The house may be kept close, not allowing the temperature to exceed 50° without full ventilation, syringing the trees in the morning and early afternoon of fine days, admitting air abundantly whenever the weather is bright, employing fire heat only to exclude frost, for the slower the trees are excited the stronger will be the blossom. Outside borders should be well protected with about 4 inches thickness of leaves, with a little litter over them to prevent their displacement by wind. Tarpaulin or shutters may be applied at the top to prevent the soil becoming chilled by heavy rains and snow, but they ought not to remain on constantly, merely using them in very inclement and very severe weather.

*Succession Houses*.—The trees are later than usual in casting their foliage, and must not be hurried by removing them forcibly, but admit air freely at night, keeping the houses rather close in the early part of the day, and maintaining a dry atmosphere seek its gradual maturation when the leaves will part freely from the trees. When the leaves are all down unfasten the trees from the trellis, perform any pruning required, cleanse the house thoroughly, paint the woodwork and trellis if necessary, and dress the trees with an insecticide. Secure the trees to the trellis, leaving room in the ligatures for the branches to swell, as tight tying is one of the most prevalent causes

of gumming. Remove the surface soil down to the roots, and supply fresh loam rather stiff, containing about a fortieth part of steamed bonemeal and a twentieth of wood ashes. Give a thorough supply of water to inside borders of houses with fixed roof lights, but it is better to remove the roof lights and allow the borders to become thoroughly soaked by the autumn rains.

Any lifting and root-pruning of trees not in a satisfactory state should be attended to whilst the leaves are upon the trees, not, however, until the foliage becomes mature, and then acting with dispatch. If fresh trees have to be introduced it should be performed when they are safe for removal—namely, when the leaves part readily from them or as soon as they are nearly off the trees. The best description of trees for planting in houses are those three or more years trained to walls or to trellises under glass, and prepared by annual or biennial lifting. Such trees transplant safely with abundance of fibres. Carefully planted they can be forced the first year with every confidence of a crop if not started before the new year, not brought on too rapidly, and not over-cropped. It is always desirable to select trained trees in bearing in preference to planting young trees that are not furnished with some bearing wood, but if young trees must be planted select such as have a well furnished base, free from gum, not very strong in the wood, and that well matured.

*Late Houses.*—The fruit except on a few of the latest trees, is now nearly all gathered, and the wood that has borne fruit and not required for extension should be cut out, as nothing is so prejudicial to late trees as too much wood. If the trees are young and not ripening the wood well, form a trench about one-third the distance from the stem the trees cover in height of trellis, and down to the drainage, so as to detach the roots, and after remaining open a fortnight, fill the trench firmly, adding calcareous matter to the soil if deficient of that substance. This will check the tendency to late growth and induce wood ripening. The surface soil in the undisturbed portion should be removed down to the roots, supplying fresh material, or replacing the old soil after adding some calcareous matter, and give a good watering. The trees will push fresh roots, and ripen the wood, but lifting must not be practised whilst the wood is soft and the leaves green and sappy, or the check will cause the wood to shrivel. Trees judiciously operated upon at the roots invariably set the blossoms well after operations of this character, the roots in lifting being laid in again carefully and kept well up to the surface.

*FIGS.*—*Early Forced Trees in Pots.*—Those intended for affording fruit at the close of April or early in May will now need dressing with an insecticide, softsoap solution 4 ozs. to the gallon of water answering, applying in a tepid state with a brush, being careful when using the solution not to injure the points of the shoots or rub off the embryo fruits. Very little pruning will be necessary, the trees having been regularly stopped during the growing season, but if the growths are too crowded and irregular they may be thinned to render the trees symmetrical. The house in which the trees are forced should have the wood-work and walls washed with hot water, afterwards whitewashing the walls with hot lime and sulphur. A mild bottom heat is almost a necessity to a successful swelling and perfecting of the earliest crop, the pots being raised upon loose bricks pedestal-fashion in the positions they are to occupy in the bed, and the pit filled with Oak or Beech leaves pressed firmly. The depth of the pit needs to be 2½ to 3 feet, with a third of stable litter mixed through the leaves; for leaves alone the depth should be 4 to 4½ feet. Care must be taken to avoid over-heating, not allowing the heat about the pots to exceed 65° until growth takes place. The trees should be started about the middle of November, bringing them forward very gently, keeping the house close and moist by sprinkling twice a day in bright weather, employing fire heat to maintain a temperature of 50° at night, 55° by day, and with sun heat 60° to 65°. The soil in the pots must be brought into a thoroughly moist condition by needful watering.

*Early Forced Planted-out Trees.*—The trees should now be untied from the trellis, and the needful pruning effected. Those with the roots restricted to small borders will only require to have the shoots thinned where too crowded, cutting back growths extended to the limits of the trellis and not necessary for fruit production, so as to allow space for successional growths. Trees that have not the roots restricted will require cutting back at the upper part of the trellis, allowing room for the extension of the lower branches; but luxuriant trees may be root-pruned, or the cutting-out of growths will only tend to render the trees more unfruitful. The trees may be washed with soapy water as advised for trees in pots, and be secured to the trellis loosely. Remove the loose soil, remains of mulchings, point over the surface with a fork, and apply a surface dressing of fresh loam not more than 2 inches thick; sprinkle over that 2 ozs. per square yard of steamed bonemeal, and apply a mulch of partially decayed manure, lumpy yet short. Give a good watering; ventilate freely at all times, except when frost prevails, when keep closed, and turn on heat to exclude it.

*Succession Houses.*—The trees are not ripening their wood well, and it will be wise to turn on the heat in the morning, and admit air only to induce a circulation, throwing the windows open at night, the heat having been turned off at midday. This will assist the maturation of the foliage; but any unfruitful trees must be severely root-pruned, and the roots restricted to moderate sized borders, depending more upon active feeders near the surface, encouraged by light mulchings, than a large extension of roots. These operations must be performed when the leaves give indication of falling. Make the soil firm, employing one-sixth of old mortar rubbish and a similar proportion of road scrapings.

Figs always do better with the roots restricted to moderate sized borders, and are more manageable and fruitful when the roots are confined to limited space than those with an unlimited rooting area. Prune the trees when the leaves have fallen, cleanse the house, put everything into order. Dress trees that have been infested with insects with an insecticide. Scald the woodwork and walls with hot water, keeping it off the trees, yet washing them with a warm soapy solution before applying the insecticide. Keep the house cool and dry, yet exclude frost.

*Late Houses.*—Excessively luxuriant trees should be attended to in lifting and root-pruning as advised above, and Fig trees can hardly have the roots too much restricted for fruitfulness, being also more under control, and can be fed according to requirements. Trees in unheated houses should have free ventilation, and when the leaves fall the trees must be unloosed from the trellis, be tied together in convenient bundles, and made safe against frost with some straw or fern over them, encasing the bundles in mats. In heated houses this is not necessary, but the trees in those must not be exposed to severe frost, or they are liable to be injured, therefore a little warmth will be necessary in severe weather. Trees in cool houses should have the roots protected by a covering of dry material.

#### PLANT HOUSES.

*Zonal Pelargoniums.*—Plants that have been protected for some weeks from heavy rains will come quickly into flower if placed in a temperature of 60°. If possible give them a span-roofed structure, where they can be arranged close to the glass. Apply a little artificial manure to the surface of the soil, and the roots will quickly come to the surface and take possession of it. Water in the morning carefully, and throw about no more water than is really necessary. Admit air daily to prevent the foliage and blooms damping. Few plants are more useful for supplying cut flowers in abundance than Pelargoniums during the dull days of autumn. The season has been unfavourable for ripening their wood, but plants that were potted firmly and kept in a small size should be promising. Place a good number of young plants into 5-inch pots for flowering early in the year; pot firmly, water with care, and keep the plants slowly moving in an airy structure, where the temperature does not fall below 45° to 50°; pinch the shoots if they need it for the last time.

*Cinerarias.*—The earliest plants will soon come into flower if placed in any structure that does not fall below 50°, and can be kept moderately close. These plants will bear slight forcing if a close, confined atmosphere is not attempted. Throughout November and December a few with blue flowers are especially serviceable, and are telling in the conservatory amongst Roman Hyacinths, Solanums, Pelargoniums, Chrysanthemums, and similar plants. Repot later plants as they need more root room; once they are checked they quickly produce their flower spikes. It is useless to pot those that are showing flower spikes. If these are not needed in small pots they can be thrown out. It is a good plan to pot a few more than are required for spring flowering, so that those that show for flowering can be thrown out as soon as they are discovered. The latest supplies should be ready for 4 and 6-inch pots respectively. If large specimens are needed, earlier plants that are not showing flower may be placed into 8 and 9-inch pots. Do not allow these plants to suffer by an insufficient supply of water, and keep them cool and on a moisture-holding base. All plants that are well rooted in their pots may have clear soot water every time they need water. Watch for aphides, and fumigate as soon as they are observed.

*Primula oboeonia.*—Place into 5-inch pots all plants intended for spring flowering; grow them in the greenhouse, or a cool frame will do for the present. Early plants will soon come into flower in a temperature of 45° to 50°. Plants raised from seed sown as soon as it was ripe, should be pricked off singly into pans or boxes and grown on a shelf in the greenhouse.

*Chinese Primulas.*—Those intended for spring flowering should be placed into 4-inch pots. Grow these close to the glass in a cool structure, where they will be safe from frost. If stood on a cool moist base growth will only be slow, which should be aimed at, for if drawn up weakly they only flower poorly in spring, and are liable to damp. Admit air liberally to these as well as to larger plants that are not required in bloom for the present. Double varieties should be placed where they can have gentle warmth, and they will commence flowering profusely and yield quantities useful for cutting. A moderately dry atmosphere suits these best. They are very liable to damp in a cool moist atmosphere.

*Callas.*—The main stock of these should enjoy a light but cool house, where they can be well syringed and freely watered. Admit abundance of air to keep them dwarf and sturdy. Where these are appreciated for Christmas select the strongest and most promising, in fact a good number may be picked up that are already showing their spikes. Keep them a little closer, but do not attempt to force them, or their spathes will not develop properly; they can be brought gradually forward, but cannot endure forcing. Give plenty of air, or they will soon run up weakly.

*Bouvardias.*—These only move slowly in a cool house and are liable to damp. Where it is practicable place them in an intermediate structure, where air can be admitted daily. Water carefully and give weak stimulants frequently, or apply artificial manure to the surface to keep their roots moving, which is the secret of a long succession of flower. When well cared for the plants continue to grow and flower, provided they have been well grown and ripened.

*Solanums.*—Where an increase of stock is needed seed may be sown in heat from well-berried plants. Pot singly as soon as they are large enough to handle, and grow them in a temperature of 60°.

*Cyclamen*.—Place into 5-inch pots seedlings that were raised in February and are not needed in flower before the spring. Arrange these close to the glass, where the temperature at night will range about 45° to 50°. Transplant seedlings into pans, and grow them on a shelf close to the glass in a temperature of 60°. Give plants that are flowering clear soot water; if kept in a structure about 55°, and air is admitted freely during the day, they will flower freely and damping will not take place. Be careful these plants do not become dry at their roots.

*Calceolarias*.—Pot these as they need more root room. The earliest plants should be placed into their largest size. Grow them for some time in cold frames. The moist conditions of these structures suit them well. A dry atmosphere is ruinous to these plants, they quickly become a prey to aphides.

*Libonias*.—Remove these from the greenhouse and cold frames into a temperature of 50°. If kept too cool they lose their foliage, and the beauty of the plants is destroyed. If the plants have been well grown and fully exposed to the sun they will be full of bloom, and will quickly develop their small but showy flowers if given gentle warmth.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### THE STRAW HIVE.

THIS was the first thing the modern school attacked as being totally unfit for bee-keeping, and yet was the only one used to demonstrate humane bee-keeping at all bee shows, while never one single manipulation was made to show the superiority of the frame hive to prove how the promised pounds for pence were to be realised. It was freely stated that honey from modern systems would bring to the cottager 2s. per lb. instead of less than half that sum. This sounded well in the ears of novices, while it suited the interests of dealers, but strange to say that price never was realised, but it has been oftener sold at less than the lowest figure mentioned, and simply reversed the argument. For, with all the advantages the frame hive possesses over the straw hive, it is not on record that the frame hive has been more profitable than the straw hive, but the opposite. In the first place the appliances required under the frame hive system cost pounds for shillings under the straw system, while the honey from the latter is often superior to that of the former, which in too many cases contain 30 per cent. of water. Many of the keenest competitions in strained or dripped honey has had the prizes awarded to that from straw hives. This argument is more truthful than may be appreciated by some. The injudicious use of the extractor has had much to do with putting on the market an inferior quality of honey, and the too lavish use of foundation in supers has rendered much of the comb unpalatable. Taking all into consideration the economist will seek in vain for the advantages in that direction, of the greater profit said to be found in keeping frame hives.

Being in possession of the necessary plant for keeping bees on the most approved style, I would not alter my method, nor would I even advise anyone to adopt straw hives before frame hives, neither would I advise anyone to discard straw hives in favour of frame hives when the bee-keeper is satisfied with those he possesses, but rather try and show the best method by which straw hives can be kept and managed properly, and to do this no better plan exists than the one that has been carried out from time immemorial.

Many cottagers made their own straw hives as they now do wooden frame hives, and thereby saved a considerable sum. They appear to have had from a very remote date the value of young queens in stock hives. Few bee-keepers of the ancient school would have entertained the idea of having bees more than a year old, and fewer the notion that queens could be kept profitably up till four or more years. In my early days I never knew any that would have entertained such "modern" notions. Starting with a certain number of hives with their floorboard, costing about 3s. a piece, a very moderate sum compared with frame hives nowadays, not speaking of the extras, and taking particular care of empty new made combs for the subsequent year for hives, and as guides

to supers, which foundation has supplanted. Every stock hive was expected to swarm twice, sometimes the prime swarm was all that issued, and at other times occasionally three swarms issued, so that the average were commonly maintained at one swarm and one cost.

#### OLD COMBS.

These were not tolerated, so that from the stock hive raised from a young queen the previous year, at the end of twenty-one days after the first swarm was driven, the sealed light coloured combs were taken, the seals first taken off, as modern extractors do, and further sliced to the midrib, the contents all falling into a basket suspended on two chairs. The honey as it dripped from the basket fell into a tapered muslin bag, and from it into earthenware jars, considered then as the only utensil honey would keep in. The blackened combs, and those containing pollen and unsealed honey, were either pressed and the contents given to the bees, or made into mead or beer. Sometimes the driven bees were joined to the first swarm after the old queen had been deposed, or to the second, and at other times was allowed to begin in an empty hive afresh, and all three were like the rest, taken to the Heather, when on their return the best combed hive was selected, evenly straight, and at right angles to the entrance, for bee-keepers then in Scotland knew what they were about. Unless when there was an order for bees the three were joined into one, and supers and sealed honey taken for sale, and the nice pieces of comb kept for as already stated. When joining the swarms together pease meal was liberally dusted upon the lots, then by a vigorous riddling motion the whole were thrown together, and the union was complete as it was satisfactory.

#### PREPARING FOR WINTER.

The number of bees was a guarantee against the influence of a low temperature; but in addition to the comfort derived in that way, it was desirable the hive be kept thoroughly dry, so after covering the hive and the crown with "shoes," the refuse from lint, a straw hackle covered all and over the floor while it was lowered a little at the landing, so that no moisture could penetrate the hive. In fairly good seasons I have known close upon 300 lbs. of honey taken from one spring stock hive, and yet that is the hive so much condemned. The wax was considered to be enough for compensation for working and moving the bees to and from the fruit blossom in spring, the Clover in summer, and the Heather in autumn.

#### BEEES TO BE KEPT DRY DURING WINTER.

It will be observed the ancients spared no pains to secure absolute dryness in their hives, but whether this arose from a knowledge of the way damp acted upon the bees or simply from observations that bees suffered when the hive was damp I am not aware, but the evidence before us is conclusive enough that they dreaded the damp in those days even more than the modern bee-keepers do, because we find the former doing all in their power to resist it, while many modern bee-keepers do the reverse, actually encouraging damp within their hives, although they sometimes cry out against it.

The double-eased hive and the waterproof material close upon the frames, as well as the bee-way left between the waterproof and the combs, have all a tendency to create damp within the hives, with the result that there is always a percentage of deaths from the above causes, while in the ancient management of straw hives it was rare for a hive to be lost during winter.

I am opposed to the belief that bees hibernate during winter in the proper sense of the word. Still I am of the opinion that in a comparative sense they do, or rather to a degree only do they become dormant, and the greater the degree of this dormancy the better is the health of the bee maintained, and the lower temperature it will stand. Although the hum of the bee is never silenced, still the damper the interior of the hive is the louder is the hum, and *vice versa*. Doubtless a hive of bees during winter

in a semi-torpid state loses the immediate use of their wings, and other members are similarly affected, but the sting appears active at the moment of death.

Bees become torpid by degrees according to the state of the hive, and even the greater the torpidity the greater the health is maintained. We should, therefore, use every means in our power to reduce damp and currents of cold air in hives to a minimum, for without these conditions bees are always at the mercy of the weather, and we can never say till the winter is past that our bees are safe.

#### STRAW HACKLES.

This is one of my most ancient customs of covering wooden hives, and cannot be very well improved upon. It is certainly superior to any modern double case. I plaited the straw to a card similar to those put behind horses in some stables, only heavier. This was tied round the hives at the top, and an oil-cloth covered all. In this way it lasted for years. Where straw is plentiful the oil-cloth may be dispensed with, as by itself it makes a good protector.—A LANARKSHIRE BEE-KEEPER.

#### TRADE CATALOGUES RECEIVED.

Geo. Cooling & Sons, Bath.—*Catalogue of Fruit Trees, Roses, and Shrubs.*

Little & Ballantyne, Carlisle.—*Catalogue of Trees, Shrubs, &c.*

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Book (F. D. W.).**—The book referred to was Mr. Wright's "Mushrooms for the Million," which does not, however, include anything on Cucumber culture.

**Cultivated Brambles (F. R. S.).**—By far the most productive crops we have seen were of the Parsley-leaved Bramble. We have seen their long growths secured horizontally to wires stretched between tall posts, forming screens or hedges laden with heavy clusters of black fruits in October. Good soil is essential, also well-rooted plants, these to be cut back after planting.

**Herbaceous Border (Perplexed).**—By all means keep off the clay border so long as it remains saturated. If you take advantage of favourable weather in spring, when the soil is friable and some of the plants starting into growth, then reduce the strong plants and encourage the weak with free fresh soil, the results will be as good as if the work were done in the autumn, perhaps better. If there are bulbs in the border spring renovation is advantageous, as their growth is then visible, and there is small excuse for their being injured in digging.

**Galls on Pear Leaf (R. G.).**—These woolly excrescences appear to be the work of a species of *Phytoptus*, or gall mite, belonging to a family the transformations of which are imperfectly understood. It is considered that they are six-legged while young, eight-legged in their mature condition. A number of them of different ages may be observed living in the same gall upon the "happy family" principle. It has been noticed that they will infest one tree year after year, while others of the same kind standing close remain untouched. Their journeys, whenever they occur, are at night, it is believed. No one has suggested any method of checking their propagation, except the removal and destruction of infected leaves.

**Coping for Garden Wall (J. D.).**—No material answers so well for coping as stone, it being of a composition not liable to be injuriously affected by frost nor perish by exposure to the weather. Yorkshire stone and some others are of that description. You could not have anything

better. Cement copings are excellent, but some which are so called are worse than useless because they are composed of too much sand (much of it loamy) and too little cement. Properly constructed they are as durable as stone. Tile copings are very serviceable and cheaper than stone or cement, but they should be  $2\frac{1}{2}$  inches thick, and made in one piece, so as to project over the wall 3 inches or more, and have a groove in them three-quarter inch from the edge to prevent the wet running down the wall, and be sufficiently burnt to resist weather influences. The groove is of very great importance.

**Sowing Orchid Seed (R. S.).**—Experience has shown that there is no method equal to scattering the seed on the sphagnum in which a plant is growing freely and receives proper attention in watering, so that the sphagnum is kept fresh. No attempt must be made to cover the seed, and it must not be displaced by watering. The seed may be sown as soon as ripe, or in early spring. It is delicate work raising Orchids from seed, then establishing the plants, and only experts or very careful cultivators can hope to succeed. If you succeed in raising plants you must be prepared to give them the best attention for about ten years before they will flower. Some seedlings are fifteen years before flowers are produced, and then the varieties may not be superior, but, on the other hand, some may prove of value.

**Annuals and Cactus Dahlias for Exhibition (W. S. S.).**—You do not say whether hardy annuals only are required, or at what time of year they are to be shown. With further information on these two points we shall be glad to give you the advice required. *Centaurea cyanus* is a true annual, but *Mignonette* is not, though it is usually treated as such under cultivation. The value of Cactus Dahlias for exhibition depends upon whether classes and prizes are specially provided for them or not. At the National Dahlia Society's last Show three classes were devoted to them, with prizes ranging from 30s. to 5s. The same Society states that "Dahlia blooms of the show type should be shown on green stands. Stands for twelve blooms should measure 24 inches by 18 inches, the height in front being 3 inches, but at the back 9 inches; and in like proportion for the other numbers to be staged." No special stand is mentioned for the Cactus varieties, but the above will serve as a guide.

**Gros Colman v. Gros Colmar Grape (A Forty-years Reader of the Journal).**—Under the title *Grosse Kölner* the following history is given in Dr. Hogg's "Fruit Manual," fifth edition, page 392. "It was first introduced to this country by the late Mr. Rivers of Sawbridge-worth from M. Vibert of Angers; but finding it did not ripen with the same treatment as Black Hamburgh, he discarded it. It was introduced a second time by the late Mr. Standish of Ascot from M. André Leroy of Angers, and through him its popularity was established; but it is mainly through the successful cultivation of it by Mr. W. Thomson of the Tweed Vineries, that its reputation is so widely extended. The first trace I find of it in Western Europe is in De Bavay's Catalogue of 1852, where it is called Gros Colman; then I find it in that of Jacquemet-Bonnefont of Annonay, for 1855, under the name of Gros Colmar, and both of these are corruptions of *Grosse Kölner*." In pomology, as in botany and other sciences, precedence is given to the oldest name, and according to that rule those who adopt Gros Colmar are undoubtedly incorrect.

**Pears not Swelling (E. W.).**—The cause of the fruit not swelling is scald—*Fusicladium dendroticum pyrinum*, *Fckl.*, which cripples its growth, and infesting the leaves causes them to fall. You have tried lifting and used nearly all artificial manures in the market without any effect other than to make the trees produce more wood. Lifting or judicious root-pruning ought to check the tendency to produce wood, and we advise that to be done without delay. The analysis is very instructive and affords a key to the situation—namely, the phosphoric acid is very low, 14 per cent. fertile clay often contains 0.38 per cent. Potash is represented by 0.43; a Pear soil should be alkaline, some containing 2.73 per cent. of potash. Soda also is meagre. A Pear soil contains, in some cases, 1.98 per cent. Your soil needs phosphatic, potassic, and sodic elements. We advise steamed bonemeal 5 lbs., kainit 3 lbs., mix, and apply at the rate of 4 ozs. of the mixture per square yard—2 ozs. in autumn, and a similar quantity in spring when the buds begin to swell; but none of those will destroy the germs of the "spot" on the trees, therefore we advise spraying them with a solution of sulphate of copper, 1 lb. to 25 gallons of water, as the wood is manifestly soft, otherwise a 10 per cent. solution is recommended when the wood is firm and well ripened, applying it just before or when the buds begin swelling, and spray the trees just before the blossoms expand with carbonate of copper (precipitated), 1 oz. to 12½ gallons of water, keeping well suspended by one person syringing into the vessel whilst another applies it as a spray. Repeat the carbonate of copper in suspension directly the petals have fallen, and afford two more sprayings at intervals of fourteen days from the first spraying after the petals have fallen. Unless the season be wet those will be sufficient, but if very wet repeat at intervals of seven days, continuing the spraying up to the end of June. Precipitated carbonate of copper does not injure the foliage like sulphate of copper solution, Bordeaux mixture, or ammoniacal carbonate of copper solution; but the latter may be used effectively if you first ascertain the safe strength at which to apply by experimenting on a few growths; yet it must be understood that the solution must not be prepared beforehand, but made as wanted, for Bordeaux mixture and all sulphate of copper solutions undergo chemical changes, and unless these are exercised on the fungus the fungicide is useless.

**White Cup** (*Young Subscriber*).—The plant you have under this name is probably *Nierembergia rivularis*, of which we give an illustration in fig. 74. The plant was found by Miers, about the year 1845, growing on the grassy banks of the Rio de la Plata, South America, "the prostrate branches creeping among the grass, above which rise its pretty white flowers." Indeed, under cultivation, and when well established, there are few similar plants that contribute so much in such little space towards the beauty of the rockwork or border as this little gem. Although it seems to prefer a rockery or a similar situation where its roots get curbed, it will do equally well on dry banks or flats, and a large patch I saw on the flat fully exposed was a sight never to be forgotten, so thickly were the large beautiful white cups studded among

FIG. 74.—NIEREMBERGIA RIVULARIS.

the leaves on short stalks like so many *Campanula*-shaped Mushrooms. Those not hardy in the open air may be used with great advantage indoors in the shape of trailing or creeping plants. A hanging basket made with *N. gracilis* as an edging is extremely pretty, besides having the advantage of being permanent. Then there is *N. frutescens*, a strong shrubby species of considerable worth for a greenhouse or conservatory, as it makes fine bushes in a short time, flowering more or less incessantly. *N. rivularis* rarely grows more than an inch or two in height, having long prostrate creeping branches rooting as they spread away from the centre, which requires filling up occasionally. The leaves are alternate, oblong, blunt at the summit, on a long slender stalk; the corolla, shaped like a *Campanula*, is upright, about 2 inches in diameter, pure white, and very handsome. It flowers through the summer, and may be increased by division.

**Names of Fruits.**—*Notice.*—Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*W. S., Derby*).—1, Brown Beurré; 2, Williams' Bon Chrétien; 3, Beurré d'Amanlis; 4, Red Doyenné; 5, Figue de Naples; 6, Beurré Diel. (*C. B.*).—1, Betty Geeson; 2, Lord Suffield; 3, Piles Russet; 4, Worthless; 5, Not known; 6, Dutch Mignonne. (*D. Mackie*).—1, Moorfowl's Egg; 2, Beurré Diel. The Tomatoes are attacked by a fungus, which has been recently illustrated in the Journal. (*James Grant*).—1, Beurré Hardy; 2, Beurré Clairgeau; 3, Uvedale's St. Germain; 4, Spanish Warden; 5, Beurré Superfin. (*J. J. & S.*).—We cannot trace these to any recognised names. We believe them all to be local varieties. (*C. W. D.*).—Beurré Bachelier. (*L. Black*).—1, Chaumontel; others not in condition to be named. (*T. T.*).—1, Ne Plus Meuris; 2, Napoleon; 3, Beurré Clairgeau; 4, Comte de Flandres. (*Capt. Symes*).—2, Blenheim Pippin; 4, Louise Bonne of Jersey; 26, Comte de Lamy; 27, Beurré Sterckmans. (*J. C.*).—1, Marie Louise d'Uccle; 2, worthless; the Fern is *Adiantum Pacoti*. (*W. N. C.*).—1, Autumn Neils; 2, Fondante de Charneu; 3, Sinclair, small fruit; 4, Beurré d'Aremberg; 5, Verulam; 6, Catillac. (*C. H.*).—Trumpington. (*Biddles & Co.*)—Kerry Pippin. (*W. J. Browne*).—1, Herefordshire Costard; 2, Gloucestershire Costard; 3, Herefordshire Beefing; 8, Beurré Sterckmans; 9, Bergamotte Esperen. (*W. S., Frome*).—1,

Beurré Langelier; 2, Marie Louise; 3, Beurré de Coster; 4, worthless, graft the tree; 5, No doubt a local variety. (*Orston*).—1, Louise Bonne of Jersey; 2, Allen's Everlasting. The flower is *Sparmannia africana*. (*W. S.*).—1, Cox's Pomona; 2, Flemish Beauty. (*Perseverance*).—1, Brown Beurré; 2, Beurré d'Aremberg; 3, Josephine de Malines; 4, Nouveau Poiteau; 6, Yorkshire Greening. (*Scottie*).—The Pear is Ne Plus Meuris. The Apples probably local varieties.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*G. M.*).—It appears to be the variety of *Croton* known as *interruptus*, but we cannot be certain about so poor a specimen. (*J. S. T.*).—*Spiraea Bumalda*. (*W. W.*).—1, *Berberis Thunbergi*; 2, *Liriodendron tulipifera*; 3, *Liquidambar styraciflua*. (*S. B.*).—1, *Odontoglossum grande*; 2, *Oncidium Forbesi*; 3, *Cattleya Bowringiana*; 4, *Cypripedium Spicerianum*. (*J. G.*).—We cannot undertake to name Conifers without cones, but names can be had by comparing branchlets with different kinds growing in nurseries. Your questions will be answered another week. (*G. K. W.*).—Such specimens as you have sent cannot be identified.

## TECHNICAL KNOWLEDGE.

To "know all about it" must be very satisfactory to a farmer when sickness comes among his live stock, or blight or disease of any kind appears in his crops, for complete knowledge of the

cause not only enables him to apply the proper remedy but it also induces caution in practice. Always in everything prevention is better than cure. We should soon cease to hear of heavy losses among cattle or other animals of the farm if only to ordinary painstaking were united sound practical and scientific knowledge.

Quite recently, while on a railway journey, we got into conversation with two tenant farmers who were complaining of heavy losses among calves from hoose this autumn. One of them said a neighbour of his had actually lost ten calves, and, according to their account, this sad state of things was very general. "What a pity it is," said we, "that proper means are not taken to prevent such losses." This remark led to inquiry as to what could be done. Now one of these men said he once farmed 2000 acres, at the present time he farms 700 acres, yet he was quite ignorant of the cause and remedy of hoose. He possessed no technical knowledge of a matter of such vital importance, and just drenched any that had the husky cough which so surely betokens the presence of the hoose worms in the bronchial or breathing tubes.

How are such men to be protected against their own ignorance? We are told that County Council lecturers on agriculture are simply telling farmers over again what has been told so well in the Journals of the Royal Agricultural Society of England. Of course they are, and we only hope hard times and heavy losses may bring farmers sufficiently to their senses to induce them to attend the lectures. We would also urge upon the lecturers the importance of demonstration. Take for example the complaint in question. Let the lecturers go to the farms of those who have the good sense to invite them; let them take nosebags, sawdust, turpentine, and carbolic acid, the farmer providing hot water, and let them show the farmers how easily hoose worms are destroyed by inhaling the medicated vapour; only it must be insisted upon that all calves treated shall henceforward till spring or summer, according to weather, be sheltered in clean dry buildings.

Nor must the teaching stop here. The cause of hoose must be explained, and the possibility of prevention made quite clear. Never was there a better time to enforce this lesson. Calves that have been out on pasture since last spring have not thriven; they are low in condition, no matter how well they have been fed with cake or mixed dry food. The low summer temperature, the showery weather, the constant exposure, has proved too exhaustive. So much of the food has been absorbed in keeping up vital heat, that anything like plump, or as graziers term it "fresh" condition, was an impossibility.

In the midlands the dairy lectures have been attended so well, and they are doing so much good, that one feels hopeful the lectures on other subjects will have equal attention. Care must be taken not to make them too complex. They should be clear, fairly simple, and yet sufficiently exhaustive to bring the whole matter before the hearers. The lectures must not be too long either; short pithy lessons always tell best. If the lecturer can fix some fact of importance upon the minds of his hearers each time he addresses them, good work will be done and progress made. Such a reform and improvement in farming as it aimed at will not be effected by a single course of lectures, however excellent they may be. The work must be gradual if it is to be thorough, and the lectures should extend over three winters at least. By that time the importance of the work and its benefit to farmers will be understood, and then it is most probable that no winter will be allowed to pass by without lectures being looked for as a matter of course.

Farmers may be alarmed by the idea that improvement means expense. It means nothing of the sort; on the contrary, it will lead to economy of labour, time, and money. It will lessen expenditure, and will render farming more profitable, more certain in results; more profitable not only in the increasing yield of the

land, but also in the earlier maturity of live stock. Losses from disease or exposure would practically cease with thorough shelter and cleanliness, growth would be accelerated, and the maintenance of condition would be easy enough. Under this improvement, too, although the quantity of food used might not be less, it would be turned to much better account, and the profit upon expenditure would certainly be much higher.

#### WORK ON THE HOME FARM.

Look carefully after dairy cows now, and take them into yards at night with snug deep dry lodges for them to lie down in. Do not turn them out on very cold windy days, but on all fine days they should go out, as there is such an abundance of fresh growth, more rich in nutriment than is usually the case so late in the year. But keep them from cold and wet always, wet from above and wet from below in the guise of sodden litter or overflowing drains. Let all small or delicate cows have a separate yard. Cows are easily trained to go to a particular yard or ledge. Keep the milk of stale cows apart from that of fresh cows, using only the latter for making the butter required for home consumption.

Farm horses should now be kept in the stables at night. To keep them longer out on pasture is dangerous, as the risk of rheumatism from exposure to cold rains and frost is so great. See that horses have due attention after a heavy day on the land or a long journey by road. It is our interest, as it is our duty, to be kind to man and beast. Never forget that when a man comes to the stables late in the day, and possibly with his clothes wet through, the temptation to neglect the horses under his charge is very great.

Have food, water, and bedding got ready for him, and if possible let him have help also to rub down the horses. This is all in the master's interest, and it should also induce better service on the part of the man. It will do so if he has sufficient sense to realise that he is cared for and thought of. A hot bran mash is an excellent thing for a tired horse, and we use it frequently; that and a thorough rub down is a wholesome and refreshing thing before the horse gets its hay and corn. These are all trifling matters eminently worthy of close attention, for it is surprising how much ignorance and stupidity there is about horse management among men who have been with them all their lives. We were recently assured by a very worthy carter that it was particularly good for horses to lie out on pasture now. When pressed for a reason he could give none other than that he had always heard so. In this, as in all other things, the master's eye and judgment must be used for the protection of his property, and the guidance of ignorant though well-meaning men.

#### OUR LETTER BOX.

**Guernsey Cows (W. R. R.).**—The fact of your having bought a cow for £17 proves that they are to be had at low prices if only you watch for sale announcements in the right way. Pray do not forget that dealers of all men are the most unlikely to assist you in obtaining cheap cows. It is entirely a matter for yourself. Ours was a general statement founded upon results of sales, and it is quite possible you may hear of double the amount mentioned being given for pedigree cows or specially selected animals had from dealers.

**BARLEY COMPETITION.**—At the Brewers' Exhibition, London, which opened on Monday last, sixty-one English and twenty foreign competitors exhibited samples of Malting Barley. The first prize and champion cup open to the world were awarded to Webbs' Kinver Chevalier, shown by Mr. A. Tanner, Shrawardine, Shrewsbury; the second prize went to Mr. Estaugh for Webbs' Golden Grain; and the third to Mr. Combes for Webbs' Kinver Chevalier. This is the fifth annual competition that has been held, and on each occasion Messrs. Webbs' Barleys have won similar honours.

#### REMARKS.

18th.—Brilliant morning; cloudy at times in afternoon and evening.  
19th.—Wet from 1 A.M. to 4 P.M.; fair evening, lunar halo.  
20th.—Misty early; fine day, with occasional sunshine.  
21st.—Heavy showers early; bright from 10.30 A.M. to sunset; showers in evening.  
22nd.—Incessant rain from 2.30 A.M. to 9 P.M.  
23rd.—Fine, and generally bright.  
24th.—Fine, with occasional sunshine.  
Temperature still slightly above the average; air damp, and rain in excess.—G. J. SYMONS.

AS will be seen in the report of a meeting on page 392, the proposal to hold a great National and International Fruit Show in the metropolis next year met with a most encouraging reception. The resolution, moved by Mr. Smee, seconded by Mr. Wright, and strongly supported by other speakers—that such an Exhibition be held—was passed unanimously, not a hand being held up against it. The origin of the movement appears to have been very similar to that of the remarkable International Exhibition of 1866. In each case a few friends talked over the matter in an informal way, and provisional committees were subsequently organised to consider the best methods to adopt in carrying out the scheme.

Some of the Judges at the Crystal Palace Fruit Show last month thought the time had come for holding a fruit exhibition of great magnitude, and a deputation was formed to wait on Sir James Whitehead, Bart., to ascertain his views on the subject. It was presumably not in his capacity as Master of the Fruiterers' Company that Sir James was consulted, but as a recognised leader in the fruit movement, an untiring advocate for increasing and improving the supply of home-grown fruit, an eloquent exponent on the subject, and an able administrator. He was the originator of the great Show that was held in the London Guildhall last year, and which, under his guidance, proved a remarkable success. Sir James Whitehead gave such encouragement to the deputation that waited on him in reference to the still greater project that further action was at once decided upon, which resulted in the meeting in question.

As will be seen on perusal of the Chairman's speech a broad and liberal policy was advocated, and an union of effort by societies and organisations invited. All were encouraged to join hands towards the attainment of the object in view, and a hope was expressed that no petty jealousies whatever would arise in connection with the movement. That the meeting was in full sympathy with the Chairman's propositions and expressions was unmistakeable.

Mr. Douglas, a member of the Council of the Royal Horticultural Society, was asked to propose the first resolution, and it is evident he would have gladly done so had it stood alone, but as he had been entrusted with one also from the Royal Horticultural Society, he was bound to ask that it be appended. The first half of this resolution would have met with a joyous reception, and its adoption must have left the Society in a very strong position, but the latter half was wholly unacceptable as being in direct conflict with the broader principle of mutual co-operation which was felt, as if instinctively, the right line to adopt. The R.H.S. resolution found no seconder, and, in fact, could not be formally proposed by Mr. Douglas, who, however, acquitted himself well in what he correctly described as a difficult position. Mr. Bunyard, also a member of the Council, said the resolution did not embody the views that it was intended should be expressed, and suggested the possibility of a clerical error. Not a few friends and Fellows of the Society would be glad if that was so, and most readily condone any accident or mistake in transcription.

Dr. Masters, in a moment of forgetfulness, animadverted on the circumstance that the Royal Horticultural Society had not

been consulted on the subject of the proposed Exhibition. It was impossible that there could have been any such consultation, for the obvious reason that no person nor body was invested with authority to consult or make proposals to any society till empowered to do so by resolution passed at this, the first meeting. The Royal Horticultural Society will, it is presumed, now be approached, as will other organised bodies, national, metropolitan, and provincial, and there can scarcely be a doubt that abundant support will be forthcoming for insuring the success of an undertaking that is intended to be both national and international in character, and which will undoubtedly be of national importance.

The lines of the 1866 International are being followed in other important respects. The management was then entrusted to an independent Committee. Neither the Royal Horticultural nor any other Society was officially connected with it, but the Fellows of the Society gave to it their valuable support. This will occur again, as most of the gentlemen present at the meeting were supporters of the R.H.S., and while fully admitting the good work it had done were avowedly in strong sympathy with the movement that is now inaugurated.

The duration of the Exhibition is also proposed to be practically the same as in 1866. At the appointed time for closing that Exhibition a great loss was incurred, but by extending it three or four days a great profit was insured, out of which the Lindley Library was bought, and £1000 given to the Gardeners' Royal Benevolent Institution. The proposal to benefit the gardening charities by any surplus that may issue from the forthcoming event is certain to be in consonance with the feelings of the great mass of the gardening community.

Assuming that the Thames Embankment site will be available next year advantage should be taken of it, or a great opportunity may be lost for ever. All who are sincere in their wishes to see the United Kingdom—England, Scotland, Ireland, and Wales, with all the isles thereto belonging—become a greater and better fruit-producing nation, will be helpers in this worthy endeavour; and though the project cannot in its nature be particularly identified with any association, it is hoped, as the Chairman said, that "the work will be considered good enough for every man, whether he holds a high position or a lower one in the scale of horticultural science, to join in this cause."

### SPRING BEDDING.

ALL who have to provide a display of spring bedding ought now to be making active preparations to accomplish the object in view. Although up to the present time we have experienced no frost severe enough to injure bedding plants generally, yet, in consequence of heavy rains and lack of sunshine, there is not much beauty remaining among the summer occupants of the flower garden. Even were it otherwise, in view of the approaching winter, it is necessary that the plants intended to provide the spring display should be planted as soon as possible, so that they may become established before severe weather sets in. Not only is this needful for the purpose of enabling them to pass through the winter with the least possible injury, but also to forward their flowering time, as plants that are well established in the autumn have their roots in the right condition to enable them to push into active growth and flower as soon as spring comes.

There is another point which, if well considered, would I think tend to make spring bedding more popular. It is this, that to produce the bright and attractive show in April and May which is found in gardens where spring bedding is well done not a single square of glass is required. This is in marked contrast to the amount of space under glass required for wintering plants used for summer bedding. And yet for bright cheerful colours

many of those used in the spring time would be valuable additions to the summer bedders. Take for instance the grand strains of Pansies now cultivated; these form some of the most attractive summer beds when, as during the past season, the weather is suitable for them. Again we have no summer bedding plant of such a warm, pleasing pink colour as *Silene pendula*. These with white *Silenes*, Wallflowers in variety, *Myosotises*, Primroses, Polyanthus, Daisies, Arabis, *Saponaria calabrica*, Anemones, Hyacinths, Tulips, and Crocuses supply a charming variety, capable of producing a bright, attractive display during April and May, or still earlier in the season, when Snowdrops and Aconites are in flower.

#### PREPARING THE BEDS.

After having definitely settled with what plants the various beds are to be filled, the preparation of the soil will require some consideration, as the whole of them will not need the same treatment. Some of those used for spring bedding have a tendency to grow unduly strong, which not only destroys the balance, but also defers the flowering period. Again, others are greatly benefited by a deep rich soil, this being especially the case with Pansies. The beds devoted to these should receive a dressing of soot, this to be covered with 2 or 3 inches of thoroughly well-decayed manure and leaf soil mixed. The ground should be deeply dug, taking care to effectually incorporate the manure with the natural soil as the work proceeds. Those beds set apart for Primroses, Polyanthus, Forget-me-nots, Daisies, and all bulbous plants are prepared in the same way, as to bring out the flowers in good condition they require liberal treatment. On the other hand, *Silenes* and Wallflowers, if the soil is not heavy and is in good working condition, will be more satisfactory if no manure is given, neither do the beds for these require to be deeply dug. The soil should be forked to a depth of 2 or 3 inches, and when slightly dry on the surface, planted at once. Before digging flower beds the soil should always be thrown away from the edges with a spade. As the digging proceeds the outline of the bed can then be correctly maintained without placing the soil too near the edgings. As soon as the soil is dry enough after having been dug each bed should be neatly raked over, and is then ready for planting.

As a rule, far less pains are taken to arrange plants effectively for spring bedding than is the case with those used for the summer displays, consequently those who give the matter special attention are able to produce delightful and varied combinations. In many flower gardens there are numbers of small or only moderate-sized beds, and a few very large ones. In such cases there is a fine chance to display artistic ability in the method adopted with the bedding arrangements. The great aim should be to produce plenty of variety, at the same time bearing in mind that the arrangement as a whole should be well balanced and in harmony, yet each section of it should, as far as possible, contain some special feature. The small beds can be planted in distinct colours, with or without edgings, as taste may dictate or circumstances render necessary; but where there are numbers of small beds formed into groups, I prefer to have them without edgings, especially in cases where the beds are marked out with Box or Yew. It is then a much more simple matter to arrange the colours satisfactorily, and small beds, or pairs of beds, planted with one distinct colour are exceedingly effective. By following that system it allows a greater variety of plants to be mixed together in the larger beds without causing the arrangements, as a whole, to appear too much of a mixture. Let the system followed therefore be—small beds of one colour, large beds of mixed colours. Where several groups of beds exist, and bulbs are truly used, devote one group entirely to bulbs, such as Hyacinths, Tulips, Crocuses, Snowdrops and Scillas. Covent Garden Blood Red, Sutton's Harbinger, and Belvoir Castle Dwarf Yellow are three fine Wallflowers for a large central bed; the first-named variety edged with a broad band of the latter, and surrounded by an outer row of *Myosotis dissitiflora* has a fine effect.

Small beds arranged alternately with Pansy Countess of Hoptown (white) and Mrs. Grainger (bronze), or Pansy Archie Grant instead of the latter, are particularly striking. Blue King, edged with Yellow King, which is of a beautiful bright yellow colour, creates a brilliant and attractive show. Other fine varieties of Pansies are Lord Beaconsfield, Haynes's No. 2, Holyrood (dark blue), and Countess of Kintore. These can all be effectively used as taste may suggest.

Another class of plants of much value for spring bedding are the *Silenes*. The pink varieties supply a pleasing shade of colour so much wanted to relieve the blues, purples, and yellows, which predominate in plants used for spring. A good combination for a large oblong bed is to plant *Silene pendula alba* as a groundwork, then at intervals of 2 feet mark out small circles, to be filled with *Silene pendula* (pink), the whole bed being edged with a band of

*Myosotis* or blue Pansy. In another case the blue Forget-me-not might be used as a groundwork, and Belvoir Castle Wallflower as dot plants at intervals of 18 inches, the bed being edged with the dwarf white *Silene* or yellow Pansy. Many other admirable combinations might be enumerated, but I have simply given a few illustrations of different methods of planting for the benefit of those who require information.

#### HINTS ON PLANTING AND AFTER MANAGEMENT.

The distance at which the plants should be set apart must be regulated, not alone by the knowledge of the size they usually attain, but also by the size of the plants. The great point is to have the beds well filled, as no kind of vegetation makes much progress during the winter months, and by the time the plants begin to flower the soil in the beds ought to be quite covered. *Silenes* and *Saponaria calabrica* if planted from 6 to 9 inches apart, according to the size of the plants, will form a compact mass in flower. In the case of *Myosotis*, although at planting time the plants should be larger than *Silenes*, the same distance apart will answer well, because they will not spread so much as the *Silenes*. Those who are fortunate enough to have strong roots of Pansies, which were rooted about thirteen months ago, should place them from 10 to 15 inches apart; but where the cuttings were only inserted in July last close planting may be resorted to, from 6 to 9 inches being about the right distance. Wallflowers grow but little from the present till the flowering time, and should therefore be planted so that they just stand clear of each other. I have often noticed the scanty way in which beds of these finely scented flowers are planted, in the belief that they will fill their allotted space by the time they are in flower; the hope has generally been a vain one. Where *Arabis alpina* is used, as it sometimes is for want of a better, place the plants quite closely together. Daisies can be arranged so that only stand just clear of each other. Crocuses and Snowdrops can scarcely be planted too thickly—i.e., in cases where the bulbs have to be taken up annually. Tulips should be planted in rows 9 inches apart, 5 or 6 inches asunder in the rows, and 2 inches deep. Hyacinths require a little more room. After the beds have been planted with bulbs the soil should be mulched with an inch of sifted leaf soil or cocoa-nut fibre. During the spring months, whenever the weather is favourable and the soil dry enough, the opportunity should be taken to work the Dutch hoe among the plants, to loosen the soil, and thus allow the warmth of the sun to penetrate; this has a wonderful effect in bringing about that desirable result—viz., early flowering in spring bedding plants.—H. DUNKIN.

#### THE SNOWDROP.

THE flowering period of this old fashioned bulbous plant is looked forward to with eager expectation, as it reminds us that winter is past and spring is near at hand. The Snowdrop is perhaps the most accommodating bulb that can be grown. It is at home in the driest and most exposed positions; it does equally well in moist places that would prove disastrous to most bulbs; in fact, it flourishes in the most shaded and secluded spots, where many plants would only linger for a time and eventually die. The Snowdrop will succeed in moist places, but on this point do not misunderstand me, for there are positions that are too moist even for the Snowdrop. It thrives luxuriantly in the fen lands of Lincolnshire, but in wet positions when grown on tenacious soils, and the season proves very wet, the bulbs are liable to decay in the ground.

When once planted it would do perhaps for generations in the same place, but under natural methods of planting the time comes when the bulbs are so crowded that they have not room to develop properly, in fact they increase so rapidly that they almost lift themselves out of the ground. The bulbs decrease in size as well as the flowers, and I have known them fail solely through the crowded condition of their bulbs. Although they do well for an almost unlimited time they are greatly improved by lifting and replanting occasionally. Some people have a remote idea of the size the bulbs of the Snowdrop are capable of attaining when planted singly in good soil. I have seen them as large as a Filbert. To define the position in which Snowdrops should be planted or in which they look best is very difficult. I like to see them planted amongst grass under the shade of trees, where the foliage can be left to die naturally. They are effective amongst moss-covered stones or with a small growing Ivy near the margin of walks, even solitary bunches in shrubbery and other borders have a particular charm when no attempt has been made to plant them in a formal manner. There are positions in every garden in which they are capable of adding to its beauty, and often they are most admired in some out-of-the-way corner where summer flowers are never to be found.

The flowers, too, of this early flowering bulb are not only beautiful in their snowy purity, but they are useful and highly appreciated in these days by the inhabitants of our large towns and cities. The price realised for them in the market brings them within the reach of the majority, who are thus able to make wreaths and crosses at a very small outlay. The flowers are very useful for this purpose, but they should not be associated, as I have seen them, with the popular *Adiantum cuneatum*; their own foliage is not unsuitable, but they are charming when used with the bronzed leaves of Ivy or the mottled ones of other kinds. Who has not noticed the care with which bunches are arranged early in the season, and sent to our markets from France? Before the flowers of the single variety are expanded they are arranged so as to show only the very tips of the flower with a few Ivy leaves round them; thus they have the appearance of so many single pips of Lily of the Valley, but pointed much more considerably. Bunches arranged in this fashion are suitable for many forms of ornamentation in which flowers now play so large a part.

The Snowdrop is seldom used for forcing, but is well adapted for that purpose. Failure in forcing the Snowdrop is often due to potting the bulbs too late in the season. They look best in 4-inch pots, and the bulbs should be placed as thickly together as possible and covered at least with an inch of soil. After potting they should be placed in a rather shady corner and covered with an inch or two of ashes to prevent the moisture of the soil in which they are potted from evaporating. The moisture in the soil will soon start the roots into activity. When they are ready for removal from the ashes they should enjoy cold frame treatment. Under these conditions they move forward rapidly, especially when they are placed early in November where they will be free from frost. Nothing is gained by trying to force them; on the contrary, once use heat and they are ruined. Natural treatment must guide the cultivator if he is to be successful. It may not be generally known that if the bulbs after flowering are well cared for, and the pots plunged outside, that they will force better and earlier the second than they did the first year.

The Snowdrop is grown in large quantities for sale in the Fens of Lincolnshire. Fruit growers, market gardeners, and a very considerable number of cottagers are engaged in growing bulbs. For some years they confined themselves to the Snowdrop, but are now engaged in growing a considerable number of other things. The bulbs of Snowdrops are lifted in July, spread out in the sun to dry and harden for a short time, then they are sorted into two sizes—seed, as the small ones are called, and saleable bulbs. The small ones are planted again as early afterwards as possible. Seldom August is passed before they are returned to the ground. They are planted in rows 4 inches apart, and the bulbs about 1 inch apart. They are allowed to stand two years, when they are lifted and sorted again. The plan they adopt is to lift a patch and plant a patch annually. They have no difficulty in selling the bulbs, one large firm at least is in the habit of sending their representative annually to buy them. Seldom growers realise less than 10s. per thousand for them, and during unfavourable years I have known them sold for 13s. Do they pay at this price? is a natural question. Certainly they do; few plants with which they could crop the ground would yield them a better return.

Growers of *Eucharis* may be consoled by the fact that they are not the sole cultivators who are troubled with the bulb mite. Growers of Snowdrops for sale have been known to lose the whole of their stock by the ravages of these troublesome pests.—WM. BARDNEY.

### THE HESSLE PEAR.

I AM sending with this short note a specimen or two of Hessel Pears. There seems to be in Yorkshire a very prevalent notion that the Hessel and Hazel are separate and distinct varieties, notwithstanding that in Dr. Hogg's Manual, Hessel, Hessel, and Hazel are all classed together.

I have noticed on many occasions this Pear, and the conclusion I arrive at is that they are all one, the different soils and positions being responsible for the slight varieties in the fruits. The foliage, bark, and mode of growth in nearly all places are identical, and the chief difference in the fruits themselves is that some are not nearly so russet as others.

The late gales are responsible for the demolishing of what tradition says is the original Hessel Pear tree in England. It was a fine ruin of what must at one time have been a noble tree. I was in conversation a few days ago with a native of this village, considerably over eighty years of age, and he told me that when he was a boy the tree just blown down appeared almost as old then as it does at the present time, so that it must be upwards of 200 years of age. The tree is reputed to have been planted by the Flemish when they took refuge in this country in the sixteenth century. Hessel, as

it was then spelt, was close to the edge of the waters of the Humber, and at that time a thriving port. Such repute, therefore, may be correct.

The Pears numbered 1 I picked from a tree fifty or sixty years old, and a sucker from the original tree. They are much more covered with brown than those marked with figure 2, which I picked in the village about a quarter of a mile away, and which are identical with those grown near Grimston Park. There seems to me to be no apparent difference in the contour of the fruit, neither in the eye, nor in the insertion of the stem, so how the erroneous notion about difference has arisen I cannot conclude. The Pear is one well worth planting. The fruit is readily sold for eating purposes, but is also valuable as a stewing Pear, though it is not generally tried in this way.

Some years ago when fruit crops were proverbially heavier than at the present time many tons of this fruit were shipped from Hull to Aberdeen for use in the manufacture of perry, for which purpose its juicy qualities made it greatly in demand.

This Pear is generally picked in the first week of October, and should be kept for a few days before eating; and if the skin—which has rather an unpleasant taste—be removed, it will be found to rival many of our more pretentious kinds of Pears.—W. CLAYTON, *Hessle, Yorks.*

[Hessle, Hasel, Hazel, and Hessel are merely synonymous terms as applied to this Pear. The first mentioned is correct.]

### IMPROVEMENTS IN MY CULTURE OF AURICULAS.

In the *Journal of Horticulture* for 10th September I gave a full description of my treatment of this beautiful plant during one or two years; but there were objections to that treatment, arising

FIG. 75.—PROTECTION FOR AURICULAS.

from excessive rains in autumn and winter, also from worms in the open border, and slugs and snails above ground. I have given in the accompanying diagram my improved plan of management, which will completely save them from these enemies, besides rendering them very portable.

I have erected a plank of wood (or shelf) on two supports, to carry six or more cheese boxes. In the bottom of each I have several holes for drainage; over these I place old bones instead of crocks. On these I put a quantity of moss litter, such as is used for horses' litter, then I fill up with loamy mould, leaf mould, cow-dung (old), and some sand.

I then place four or five plants, according to their size, in each box. Three-quarter-inch iron wires are bent, as shown in the separate box of the diagram fig. 75, to support the glass handlights. These keep all the rains from the plants, and will at the same time admit sufficient air at all times to keep the Auriculas in health. By being placed some 2 or 3 feet above the ground they will be safe from worms and slugs.

Another advantage is this, the boxes are portable. At this period of the year they are placed in a sunny position, but during the summer months they are placed in a more shady part of the garden. A few days previous to a flower show they may be potted in readiness for exhibition.

This treatment would be very good for the protection of seedling Pansies, Primulas, and many other small or large plants, as well as Auriculas. The handlights must be covered during cold or winter nights with matting or carpets. The handlights may be taken off occasionally for a few hours in the daytime, weather permitting.—WM. MOODY BELL, *Cheltenham.*

## CHRYSANTHEMUM SHOWS.

THE following are the dates of the chief Chrysanthemum Exhibitions to be held during November of which we have received schedules and advertisements:—

Thursday, Nov. 5th.—Dalston and District (second day).  
 Thursday and Friday, Nov. 5th, and 6th.—Portsmouth and Ascot.  
 Thursday, Nov. 5th.—Chiswick.  
 Friday and Saturday, Nov. 6th and 7th.—Crystal Palace, Sydenham.  
 Monday, Nov. 9th.—St. Neots.  
 Tuesday, Nov. 10th.—East Grinstead.  
 Tuesday and Wednesday, Nov. 10th and 11th.—Kingston-on-Thames, Horsham, Leeds, and South London.  
 Tuesday, Wednesday, and Thursday, Nov. 10th, 11th, and 12th.—National Chrysanthemum Society, Royal Aquarium, Westminster.  
 Wednesday and Thursday, Nov. 11th and 12th.—Birmingham, Bournemouth, Northampton, Swansea, and Croydon.  
 Thursday and Friday, Nov. 12th and 13th.—Teddington, Wimbledon, and Ware.  
 Thursday, Friday, and Saturday, Nov. 12th, 13th, and 14th.—Belfast.  
 Friday, Nov. 13th.—Cheshunt and Hitchin.  
 Friday and Saturday, Nov. 13th and 14th.—Eccles, Leicester, Sheffield, Tooting, and Monmouth.  
 Tuesday and Wednesday, Nov. 17th and 18th.—Liverpool, Salisbury, Twickenham, and Diss.  
 Wednesday and Thursday, Nov. 18th and 19th.—Spalding.  
 Wednesday and Thursday, Nov. 18th and 19th.—Hull and Rugby.  
 Wednesday, Thursday, and Friday, Nov. 18th, 19th, and 20th.—York.  
 Thursday, Nov. 19th.—Wantage.  
 Thursday, Friday, and Saturday, Nov. 19th, 20th, and 21st.—The Scottish Horticultural Society, Edinburgh.  
 Friday and Saturday, Nov. 20th and 21st.—Stirling, Chorley, Bolton, and Stockport.  
 Saturday, Nov. 21st.—Batley.  
 Wednesday and Thursday, Nov. 25th and 26th.—South Shields.

## THE SOUTH SHIELDS CHRYSANTHEMUM SHOW.

ARRANGEMENTS have been made for holding a Chrysanthemum Show in the Royal Assembly Hall, South Shields, on November 25th and 26th next, and we learn from a schedule just to hand that substantial prizes, ranging from £5 downward, are offered for cut blooms, specimen plants, groups, and miscellaneous exhibits. A particularly strong local Committee has been formed, with Messrs. Bernard Cowan and H. Hinde as Hon. Secretaries, and the list of patrons and patronesses includes the Mayors and Mayoresses of South Shields and Darlington, with numbers of the principal residents in Durham. This is the most northern Show held in England, and it is rather strange that Newcastle, Alnwick, and Darlington have all tried the experiment, but failed to continue. There is every prospect of a better fate being in store of the South Shields Show, as it is under capital management, and much interest is being awakened in the district. The hall is said to be a spacious one, and is lighted by electricity.

## NOTES ON EXHIBITION PRIZE SCHEDULES.

THE autumn exhibitions, which are mainly intended for the encouragement of Chrysanthemum cultivation, have fairly begun; no less than three southern towns had their fixtures in October. Until the last half a dozen years Chrysanthemum shows in that month were a rare occurrence, but now these southern fixtures are not found to be at all too early; whether it is owing to the earliness of the seasons generally, or the method of cultivating the plants, or to the introduction of early flowering kinds, it is difficult to say. One useful purpose these early fixtures serve—that of lessening somewhat the clashing of dates, which is bad enough now, as the time over which the Chrysanthemum lasts in its perfection is too short. Something over one hundred shows have to be crowded into the small space of one month, which proves what a hold the Chrysanthemum has upon the public, or so many societies could not exist, and it is seldom that one collapses owing to lack of patronage.

I do not perceive any falling off in the interest in the coming campaign amongst the large army of cultivators of all classes. Ample prizes are offered at most of the leading shows, the bulk going to the cut bloom classes, owing, I presume, to the greater interest taken in this section by the subscribers and the general public. The ball was set rolling at Southampton, October 27th, in the Victoria Hall, a capital site for an exhibition of this kind, abundance of light being obtainable. For the last few years this Society has not held an autumn exhibition, which is to be regretted, for at one time the annual gathering there was anxiously looked forward to by all concerned. The schedule contained several substantial prizes in the cut bloom department, five guineas being offered for twenty-four blooms, half incurred and the

remainder Japanese, with proportionate second and third prizes also, and good competition resulted.

The Kent County Society held their Exhibition in the Rink at Blackheath, November 3rd and 4th. Although this Society is but young in years it is regarded as one of the best of the metropolitan meetings fixed. As it is just before other leading gatherings some of the best blooms in the neighbourhood of London find their way to it. Prizes of £8, £6, £4, and £2 were offered for thirty-six blooms in the usual divided way of incurred and Japanese kinds. The schedule contained no less than thirty-seven classes, which provided abundance of scope for both large and small growers, and gave considerable variety to the Exhibition. Amateurs receive much encouragement; a first prize of £3 was offered for twenty-four blooms equal in numbers of incurred and Japanese. Another rising Society not far from London is Watford. Their Exhibition was fixed for November 3rd and 4th also. Numerous prizes were offered. The two sections, incurred and Japanese, are kept apart here. Good prizes were given in each class.

Portsmouth, November 4th, is an important fixture in the south. Probably nowhere else in England can such a site be found for a gathering of this kind, and nowhere are the poor classes encouraged in the same manner that they are here; 1d. only is the charge for the last three hours on the closing night, a treat appreciated. A very comprehensive schedule was issued by the Committee, containing no less than fifty-eight classes for Chrysanthemums alone. Nowhere do specimen plants receive the same encouragement as here. For eight the first prize was £8, and £5 for second, besides others proportionately substantial in the smaller classes. Cut blooms were thoroughly well provided for by thirty-nine classes. For twenty-four Japanese and the same number of incurred in not less than eighteen varieties, and not more than two of one variety, the first prize was a handsome piece of plate value £25, along with a cash prize of £8; second £7, third £5, and the fourth £3. It may be remembered that this trophy was secured by Messrs. Drover, Farcham, last year. Another important class was that for twenty-four blooms, twelve Japanese and the same number of incurred; £5 is the leading prize. Single varieties receive every encouragement here, and thoroughly well do they deserve it, as no one can deny who have witnessed this exhibition of single Chrysanthemums.

The autumn meeting at the Crystal Palace has long been well patronised by Chrysanthemum specialists, and is one of the annual events looked forward to. November 6th and 7th are the dates this year. Sums of £10, £7, £5, and £3 are offered in the leading class for cut blooms, no less a number than forty-eight being required, the wording of which renders competition easier than usual; but eighteen varieties in each section, incurred and Japanese, are stipulated for. Competition in this class is always keen. On the same dates the Bradford Society hold their show, which must be considered an early date for a town situated so far north. Experience has probably taught the management that it is not too early to secure satisfactory results. £10 is there the leading prize offered for forty-eight blooms under similar conditions to many other societies.

The most important of the metropolitan meetings—that of the National Chrysanthemum and the Kingston Societies—are held the week following the Crystal Palace date. Tuesday, Wednesday, and Thursday are the days selected for the former. Whether the holding of a three-days show is to be recommended or not is a matter for future consideration; but I am inclined to think that such an arrangement will not find favour with the majority of exhibitors, and especially when the small prizes compared with other years is taken into account, for there is a great falling off in the value. The principal class is what is known as the Co. class. Forty-eight blooms are required in not less than twenty-four distinct kinds of both incurred and Japanese, the entry to be made in the name of a society. The blooms can be grown by any number of members belonging to the society in whose name the entry is made, a challenge trophy and £10 being for the premier award in this class, the former to be retained by the President of the winning Society for one year, and the cash to be divided amongst the contributors of the blooms. This class is, in my opinion, not calculated to have a long existence, being too complicated. Two other classes are worthy of mention in the schedule—that for forty-eight incurred blooms in not less than twenty-four varieties; £8, £6, £4 are the amounts at stake. The schedule contains a similar class for Japanese blooms. Several good prizes in special classes are given, but the conditions of competition are very much against a big entry that I shall be much surprised if one is received. I allude to the various trade classes. Already I hear complaints from exhibitors of there being nothing worth going for at the N.C.S. meeting. I am pleased to see that this Society are offering prizes for blooms arranged in what is hoped will be an effective manner without the aid of the show boards, which will dispense with much of the dissatisfaction at present expressed by a certain class of would-be reformers in the manner at present practised in "setting up" Chrysanthemum blooms in a cut state.

The Kingston Society have fixed their dates for the 10th and 11th November. The schedule contains but few alterations from previous years. I have often heard the remark that a Society of this class ought to encourage more variety. There is but one reason why the schedule is not extended—viz., want of space in the Drill Hall where the Show is held; the entries in the present classes quite fill the space at command. The leading prize is the challenge vase valued at 25 guineas, with the addition of £5 in cash, for forty-eight blooms distinct, half incurred and the remainder Japanese. Such a class as this affords ample opportunity for testing the skill of a grower. It may be fresh in the minds

of the Journal readers that this coveted trophy was last year won by Mr. C. Beckett, gardener to W. Bryant, Esq., who will no doubt do his best to repeat the feat this year. Ample scope is given to cultivators, as handsome prizes are offered for twenty-four, twelve, and six blooms in both the incurved and Japanese sections.

In point of money value the Birmingham Chrysanthemum Society carry off the palm in the amount offered in one class. Prizes of £20, £15, £10, £5, £3, and £2, is allotted for forty-eight cut blooms, all to be distinct, evenly dividing the incurved and Japanese sections. Similar prizes induced no less than eighteen entries to be made last year, out of which there was but one absentee, and I should not be surprised if even that number is exceeded this season. Other good prizes are available also to the competitor who is sufficiently strong for the dual competition. November 11th and 12th are the dates chosen.

The Liverpool meeting is arranged for the 17th and 18th November, and should secure a large entry. The prize list is not only comprehensive but of considerable value. In the leading class £10 10s. is offered as first prize for four dozen blooms in not less than thirty-six varieties, and to this prize is added a silver cup. For twelve incurved, twelve Japanese, and the same number of reflexed, the latter in not less than six varieties, the handsome sum of 10 guineas, with the addition of a silver challenge vase, is offered for first honour, suitable rewards also for second and succeeding prizes. This is an easy class, and should secure large patronage. Numerous other substantial prizes are offered in an altogether excellent schedule.

On the day following the opening of the Liverpool Exhibition that at Hull commences, and if it is this year as well supported both by exhibitors and the public as in the past it will be in all respects worthy of its great reputation in the Chrysanthemum world. Incurved and Japanese blooms have classes set apart for them separately. Not more than twenty-four of each are required in any class. In that for the first named but eighteen need be distinct; duplicates in six instances are allowed. Surely these easy conditions, and the fact of £10 being offered as first prize, ought to bring out a strong competition. Two dozen Japanese are quoted—the same amount offered, the only distinction is that they must be distinct varieties. Classes of this kind generally secure more entries than where the two sections are combined, although it is perhaps more difficult for the exhibitors themselves, it being considered a harder feat to accomplish to win two first prizes in separate classes than to win one under the combination system. Other good prizes are offered in the open classes, but space forbids of their being detailed. Ten classes are provided for amateur cultivators of cut blooms. In the open classes for plants, whether it be for groups or specimens, ample provision is made to secure keen competition. No less a sum than £27 is offered for first honour in Class 30 of the schedule, which reads as follows:—"A group of Chrysanthemums interspersed with foliage plants arranged for effect in a space of 100 square feet." If this liberality does not secure the desired aim it is useless to cater for exhibits. Table decorations—the only flowers employed being Chrysanthemums with other greenery, epergnes, &c., confined to ladies—have always been a strong feature at this Show, and should continue so if the amounts offered in prizes are an inducement to the fair sex. During the last two years the autumn exhibitions of the Scottish Association in Edinburgh have been so uniformly good that a notice of this sort would not be complete without a reference to this Society's schedule, which contains no less than thirty classes. The principal class is confined exclusively to Japanese blooms—forty-eight in thirty-six varieties; prizes ranging from £20 to £2 are offered. A challenge cup and £5 is temptingly displayed for the benefit of Scotch gardeners only—twenty-four incurved in not less than eighteen kinds, special varieties, six blooms of each—receive much encouragement, as well as branches staged as grown from decorative varieties. November 19th and two following days are chosen.—M.

#### CHRYSANTHEMUM LOUIS BOEHMER.

I SHALL be pleased to learn through the Journal if Louis Boehmer behaves with other growers as it does with me. Each of my plants (I have only three) has been flagging for some time—say three weeks; in fact, from the time the crown bud was taken it is confined to the three leaves attached to the crown, but sometimes only one leaf will flag, other days two, but rarely all three at the same time. The buds are swelling freely, and I find the last to set are swelling fastest. My first bud was taken on the 20th of September, others on the last days of September. Perhaps I should add that the latest buds were terminals in the place of crown buds. These plants are watered and fed the same as the others, and the only plant that has a tendency to flag is *Boule d'Or*, but then it affects the whole of the foliage. Some plants like *Golden Dragon* have always the appearance of wanting water, but the leaf seems half withered at times.

Like "Y. B. A. Z." (page 311) numbers of what I supposed would be crown buds were terminals. The Queens nearly always are, the only exception being *A. Salter*, but this bud in opening very coarse, and what I call scaly, a green calyx being mixed up with the florets. I am inclined to think that when the crown takes the form of a terminal it makes a good clean flower.—THISTLE.

#### JAPANESE CHRYSANTHEMUM VIVIAND MOREL.

THIS variety is coming so good this year that it is likely to be much sought after, being I think the flower of the season. It is a pity there is already one in existence of the same name, although there is not much danger of there being much confusion, as no doubt the other has almost

dropped out of cultivation, but it is worth making a note of. On page 55 of the National Society's Catalogue of 1888 it will be found described. I well remember it, a white reflexed Japanese with a greenish tip to the florets on first coming out, useful only as a decorative variety, but it is not more than two years ago I saw it in a collection.—C. ORCHARD.

#### YELLOW SPORT FROM MDLLE. LACROIX.

UPON a visit to the nursery of Mr. H. J. Jones, at Lewisham, on October the 28th, I discovered he was in possession of the long-expected yellow sport of that beautiful Chrysanthemum *Mdlle. Lacroix*. This is very valuable to all growers, because that variety is not only good for exhibition, but for all decorative purposes and cut flowers. Grown in small pots or large pots, fed well or poorly, it does its work with power to bloom every bud it forms. This sport is very interesting. As is well known, *Mdlle. Lacroix* sported pink in several places a year or two back, and not as many do from white to yellow first, sometimes a pale yellow, as this is then throwing a darker shade, as in the case of the *Madame Desgranges* varieties. It seems as if in time we shall discover some law as to the evolution of these sports. Mr. Francis Galton said in 1885 before the British Association, "The appearance of each new natural peculiarity was a faltering step in the upward journey of evolution, over which in outward appearance the whole living world was blindly blundering and stumbling," but it is by carefully watching and selecting that we should cease to blunder so much, and conserve many variations in living things now lost for want of intelligent watchers and recorders. Now *Mdlle. Lacroix* was on the list of M. Lemoine of Nancy, France, for the first time in 1882, and was probably raised in 1881, so that it has taken nine years to give a yellow sport. The first record I can find as to *Madame Desgranges* was on an old list at Mr. Ware's Nursery at Tottenham, London, where it appears to have come in 1878, as it was on their list of 1879, with only the notice, "Creamy white flowers, large petals, broad." Now let us suppose that it was raised in 1877. In 1885 Mr. Wermig of Woking, Surrey, was selling a yellow sport of this, and as he had a large stock then must have had the sport in 1882 or 1883, and upon this occasion I found in 1884 there were sports into yellow of it in six or seven different places; so that it seems in six or seven years from seed, if sufficient quantity is grown, that a sport is likely to occur. Perhaps someone else will throw any light they can on this that will help us to build up a theory of the law of sports.—W. PIERCY.

#### CHRYSANTHEMUMS AROUND HAVANT.

I HAD previously read a good deal in the Journal about the Chrysanthemums which are grown in the neighbourhood of Havant, but time would not admit of an extended tour amongst them. Mr. Agate, gardener to R. Rawson, Esq., is a large grower, having a thoroughly representative collection of about 800 plants of the large flowering varieties, 200 Pompons, singles and fimbriated varieties, as well as about six dozen seedlings from the best American source. Sown in March last these plants look remarkably well, having generally a splendid habit of growth, their height ranging from 1 foot to 3 feet 6 inches, many of them having very stout leathery foliage, quite of the style of Mrs. Falconer Jameson. Plants of this habit with good blooms are to be encouraged; the time was too early to see hardly any of them in flower. One deserved notice, a pure white reflexed Japanese of good form, the plant not being more than 1 foot high. The "Queens" range from 5 to 6 feet high with promising buds; in fact, the whole collection is characterised by this, the wood having a ripened appearance, the foliage all that could be desired in developing future blossoms. The Japanese vary in height from 2 feet 6 inches to 8 feet, indeed Mrs. Marion Thrower beats *Madame C. Audiguier* in this, having run up to 12 feet. Of new kinds the following were promising:—*Beauty of Castle Hill*, *Archiviste Blanchard*, *Vivian Morel*, very promising variety of the *Audiguier* type of flower, the growth not more than 3 feet 6 inches high, the growth blush mauve; *R. C. Kingston*, dark purple violet rose; *Eugénie Giat*, purple, with silver reverse. Of others rather better known *W. H. Lincoln*, *Bouquet de Dame*, *Kioto*, *Lilian Bird*, *Coronet*, *Louis Boehmer*, and *Mrs. A. Hardy*, the last named was carrying a magnificent bloom.

Emsworth House is the residence of Captain Boyd, is noted for the local successes which blooms from this place has gained for Mr. Woodfine, who grows about 300 plants for large blooms. This year the frost of Whit-Sunday injured the points of the plants which were outside and unprotected at that time. Thinking they would not make due progress after being so badly checked, all were cut down to within a foot of the pot; the consequence is excellent dwarf plants, very suitable for "grouping," being well clothed with very fine dark green foliage and promising blooms for the purpose. *Alfred Lyne*, *Princess Beatrice*, *Emperor of China*, *Princess of Wales*, *A. H. Neve*, *Jeanne Marty*, and *M. Pankouke* were especially promising of extra fine blooms.

At The Oaks, Emsworth, Mr. Gerald Smith takes much interest in the growth of the Chrysanthemums cultivated here so well by Mr. Payne, who, it may be remembered, carried off the Veitch Memorial medal last year given at the N.C.S. Centennial Exhibition for the best stand of Japanese blooms staged without the orthodox cup and tube, and with several inches of stem attached. About 400 plants are grown for large blooms; with but few exceptions belong to the incurved and Japanese sections. The plants are well grown, not too stout, but just that amount of strength and good foliage which betokens blooms of good quality. The incurved are especially clean and bright. The Queen family is well represented by well-built blooms of *Lord Alcester*,

and Queen of England, Violet Tomlin, Princess of Wales, Miss M. A. Haggas, Lord Wolseley, and Mrs. Naish. George Glenn and Mrs. Dixon here find a home in spite of the smallness of their flowers as compared with the present day rage. Such Japanese as Avalanche, Etoile de Lyon, Puritan, Stanstead White, A. H. Neve, M. Bernard, and Annie Clibran represent this section thoroughly well.

Stanstead Park provides space for a considerable number of plants for all purposes. Not less than 700 are grown on the large bloom method, while for late use bush plants are provided. The plants altogether look as well as could be wished; the former are late compared to others in the neighbourhood. Late home decoration is more of a consideration than early exhibition. The growth is somewhat tall, the plants carry large glossy leaves which are characteristic of liberal treatment, and will no doubt result in a fine display later on. The Queen family are grown in considerable numbers, and being arranged together in two long rows make a very heavy display. In addition to these Mrs. Coleman, Princess of Wales, and Jeanne d'Arc are developing finely. Condor, Mr. H. Cannell, Avalanche, Soleil Levant, and Edwin Molyneux promise equally well. On the whole Mr. Hoskins must be congratulated on the promise of a fine show of blooms.

Leigh Park, the seat of Sir F. Fitzwygram, Bart., M.P., is noted for the general sound quality of the Chrysanthemums grown here every year. Not less than 600 plants can there be this season; exceptionally tall they are, which shows the variability of the plants even in a small area. The blooms are developing fast, and appear to be "timed" about right for the different shows when required. Alfred Lyne, Princess of Wales, Miss M. Haggas, Mrs. Coleman, Lord Wolseley, Avalanche, and Sunflower were a few among many that were noteworthy.

The Victoria Park, Portsmouth, has for some years now produced a capital display of Chrysanthemums. Not only large show blooms, but fine groups have been arranged at the Portsmouth Show from the very limited glass space at command of Mr. Hatch, the Park Superintendent. This year is no exception to the rule; good plants again afford much pleasure to the Portsmouth townspeople, who flock in large numbers to see them in the greenhouses in the park. The Anemone section is well represented, fine blooms of M. Panekoucke, Nelson, Sabine, Lady Margaret, and Mrs. Judge Benedict are notable. Space forbids a detailed list of names being given, but I could not omit such as Hamlet, Advance, Sunflower, Puritan, Jeanne d'Arc, and several of the "Queen" family.—NORTHERNER.

#### CHRYSANTHEMUMS IN THE ISLE OF WIGHT.

THE outlook was very promising here in the early part of the season, but the spirits of the cultivators fell with the barometer, for during the storms and gales experienced here last week damping set in fearfully amongst the blooms, both the tips of the late ones and the full flowers of the early blooms being affected. But as the wind changed and the barometer rose the damp to a great extent disappeared, and the hopes of more than one Chrysanthemum grower rose with it. It has certainly been a very pleasant and acceptable change all round. I send a few notes of some gardens I have visited in the neighbourhood.

#### THE CASTLE, ST. HELENS (W. S. RIDLEY, ESQ.)

Here are some well-known plants, some on the natural and others on the bush system. The gardener, Mr. G. Wilkins, is a careful and observant cultivator, getting some timber into his plants, which here in the sunny south ripen well. Unfortunately his houses for flowering are not so well adapted for developing the large buds as others I am acquainted with; they come on much too quickly, but nevertheless produce some fine blooms. Foremost amongst the new Japanese must be placed Vivand Morel, the flower of the season; Gloire de Rocher; Bouquet de Dame, early white; Louise Boehmer; R. C. Kingston, purple, very promising; Kioto, deep yellow, improvement on Mr. H. Cannell; Cæsare Costa, good colour, but showing too much of the dull turnover; Ada Spaulding, blush incurved Japanese; W. G. Drover, good; Lillian B. Bird, large quilled variety, fleshy pink; Etoile de Lyon, President Lincoln, Annie Clibran, Mr. Wellam; Madame Robert Owen, hybrid Anemone, pure white; Lady Lawrence, Wm. Robinson, M. J. M. Pigny, Madame C. Audiguer, Mrs. J. Wright, Edwin Molyneux, and other older Japanese were looking well.

There is not much new in the incurved section but Alfred Lyne, which has come very well and a good colour, but the old-established ones are well represented. The Queen family, especially Lord Alcester, Venus, White Venus, Yellow Perfection, Princess of Wales, Mrs. Coleman, Empress Eugénie, Mrs. N. Davis, Mr. C. Gibson, Isabella Bott, Lord Wolseley, Hero of Stoke Newington, Lady Hardinge, Jardin des Plantes, good. The bush specimens are well grown in the decorative style, with about twenty to fifty blooms on a plant, which show well in the fine large conservatory.

#### YARBOROUGH HOUSE, BRADING (J. J. DARLEY, ESQ.)

This garden is a *multum in parvo*. The outdoor Peach trees in the spring and summer are such as are rarely seen. The huge clumps of old fashioned herbaceous plants are a pleasant feature, and now Chrysanthemums fill the houses, giving evidence, as do the other things, of the ability of the gardener, Mr. George Burt, one of the most genial and hardworking of the old school of gardeners. Mr. Burt is very careful in his selection of varieties, trying most of the new ones two years, and then discarding them if they do not come up to his standard, which is colour, refinement, and freeness of growth, and flower for decorative purposes as a cut bloom, for most all are sent away to London in the

season. The flowers are all distinguished by high colouring and true character of form. Mrs. Alpheus Hardy, as a small plant, looks developing a good flower, and also the counterpart, Louis Boehmer, which I do not think will ever be such a favourite as the white variety. Gloire de Rocher has six fine flowers highly coloured on the plant and looks well. A. H. Neve is striking, being a soft peach colour. Mrs. Irving Clarke, rose, promising flower; R. C. Kingston, purple, coming large; W. W. Coles, brick red; Miss Emma Hartzhorn; Sunset, fine spreading florets, very striking, but I am afraid won't fill up; Vivand Morel, eleven flowers on the plant, large and good colour; Bouquet de Dame, white, very pure; President Hyde, reflexed Japanese, bright yellow, striking. Amongst other older varieties Miss Gorton is a good variety, soft pink; Mr. Matthews, terra cotta; Mr. C. Orchard, a favourite on account of the habit and showy orange colour; Mr. Falconer Jameson, Avalanche, Madame Louise Leroy, Val d'Andorre, M. J. M. Pigny and others are grown well as fine bushes, carrying well developed blooms.

#### CHRYSANTHEMUMS AROUND LIVERPOOL.

The following list of places may be taken as representing some of the leading growers in the Liverpool district. There are many collections grown which do not figure on the exhibition board, some of which I may refer to in some of the future issues; but as the greater portion of the following will be exhibitors this season, they may, perhaps, be taken first:—

#### CAMP HILL, WOOLTON,

The residence of F. H. Gossage, Esq. Here Mr. Jellicoe is much superior in the Japanese class as compared with last year, and the best of which are Avalanche, Criterion, Val d'Andorre, F. A. Davis, Mdle. Paule Dutour, Madame Louise Leroy, Etoile de Lyon, Geo. Daniels, Fimbriatum, Stanstead White, Geo. Atkinson, Sunflower, Stanstead Surprise, Mrs. F. Jameson, and Bouquet de Dame (grand), Condor, A. H. Neve, Volunteer (very fine), Sarah Owen, Madame Laing, and Belle Paule. In incurved Empress types, John Salter and the Tecks all good. Amongst the newer ones E. Delmas promising well. William Lane, a Japanese reflexed, bright crimson, shaded rose, a full solid flower, is remarkably good. Eynsford White, Mr. Jellicoe says, is not worth the room it occupies. Five hundred plants are grown.

#### LINGDALE LODGE, OXTON, CHESHIRE,

The residence of G. Cockburn, Esq., is again to the fore with a grand collection. The blooms are a week later than last season. The Queen family are good. John Doughty, grand in colour and petal, but lacks the size of its parent; Princess of Wales, Mrs. Heale and sports are all good, as is the Teck family, Jeanne d'Arc, Jardin des Plantes, John Salter, Mr. Bunn, Princess Beatrice, Lord Wolseley, and White Beverley will be good. In Japanese Avalanche, Sunflower, Mrs. F. Jameson, Etoile de Lyon, Condor, M. Bernard, Belle Paule, Edwin Molyneux, Mrs. Irving Clarke, Boule d'Or, Mrs. E. W. Clarke, Bouquet de Dame, M. C. Audiguer, La Triomphante, and R. Brocklebank are all good and grand in colour. Alberic Lunden, Florence Davis, W. H. Lincoln, Vivand Morel is grand, being of a pinkish colour, and as large as Etoile de Lyon. Louis Boehmer is a good sized flower, and promises to be a great curiosity. Robt. Cannell is, with Mr. Burden, a poor thin flower.

#### ELM HALL, WAVERTREE.

Mr. A. R. Cox is the gardener here, and there is every promise of some very fine blooms being had just at the right time for the shows. Of the newer varieties, M. R. Bahuant is a grand acquisition. Here are grand blooms with florets of great substance, very solid and perfectly smooth. A free sturdy grower, but Mr. Cox fears its weak point will be its natural earliness; the first selected buds having far more substance than the later ones. The striped sport from Queen of England (which is to be sent out in due course) under the name "Noel Pragnell," is for the third time coming quite distinct, every petal bearing beautiful delicate streaks of purple on a whitish ground. This sport was fixed by Mr. S. Pragnell, Broomfield Lodge, Chelmsford, who sent it to Mr. Cox for trial. It is far more distinct than Lord Alcester and Golden Empress, and should be in the hands of all cultivators. Of the new Princess sport, "Matthew Russell," it is too early to speak, but up to the present stage is exactly the same colour as Mrs. S. Coleman. Beauty of Hull is the colour of H. Shocsmith, but a decided improvement, the petals being as smooth as Mr. Bunn. Oriental is larger than last year. It is a beautiful shade, approaching Venetian red, but the fear is that it will not come up to the present standard of exhibition blooms. What a beautiful Japanese is "Annie Clibran," so free, and the colour so pleasing. Some consider this too small; but as seen here it is a grand front row flower. Lillian B. Bird, Mr. A. H. Neve, W. H. Lincoln, Coronet, Bouquet de Dames (fine), Geo. Atkinson, and W. W. Coles of the newer varieties; and Sunflower, Belle Paule, Criterion, Boule d'Or, Etoile de Lyon (especially fine) of the older varieties, are conspicuous by large buds, which are certain to produce grand results. In incurved, the Princess of Wales types and John Doughty, John Lambert, Empress of India, Golden Empress, Lord Alcester, Alfred Salter, Mrs. N. Davis, Hero of Stoke Newington, Princess Teck, Refulgens, Mr. Bunn and Barbara are all good. In Anemones, Mrs. Judge Benedict, Gladys Spaulding, Lady Margaret, and Nelson are excellent, while the best reflexed are King of Crimsons, Cullingfordi, Chevalier Domage, and the Christines. The growth of the plants is fairly strong, and the wood well ripened, considering the season, but now they are showing signs of mildew to a greater extent than usual. The stock is limited to 500 plants.

## AYMESTRY COURT, WOOLTON,

The residence of H. J. Robinson, Esq., there are some fine plants, not for the large number (for Mr. C. Osborne has only 250 plants) but for the excellent quality throughout. In the Japanese, Mrs. J. Wright, Album Fimbriatum, W. Holmes, Criterion, M. Bernard, Val d'Andorre, E. Molyneux, Stanstead Surprise, L'Automne, Puritan, W. H. Lincoln, W. W. Coles, Etoile de Lyon, Sunflower, Leon Fraché, Boule d'Or, Golden Dragon, Mrs. F. Jameson, A. H. Neve, are promising well, whilst Avalanche is very fine. Mr. Bunn, Refulgens, all the Queen family, Lord Wolsley, and Prince Alfred are the most conspicuous in the incurved section. Mr. Osborne considers Emily Dale Improved much inferior to the old type. Of the new ones, Cesare Costa, a dazzling red flower with large flowers, and Coronet, a light bronzy yellow with narrow florets, are grand additions.

## ALLERTON BEECHES, ALLERTON,

The residence of Henry Tate, junr., Esq. Here Mr. J. Edwards, the gardener, is later than many of his neighbours. I can fully sympathise with him, for I know of no one who suffered so severely from the late storms. I saw the collection some few weeks ago just after one had passed over, and I thought then how much he would suffer. But now the blooms are beginning to open well. The incurved are rather late, but there will be some good Japanese. In the former of the new ones are some very fine flowers of M. R. Bahuant. Vivian Morel bids fair to eclipse Etoile de Lyon, both for size and fine petal; Excellent, of a soft pink colour, is likely to come good; W. H. Lincoln, Alberic Lunden, and Mrs. Irvine Clarke are all very good.

## HIGHFIELD, WOOLTON,

The residence of W. H. Tate, Esq. Although a non-exhibitor we can always look here for an excellent collection amongst Japanese; Avalanche, Yellow Dragon, Mrs. F. Jameson, Mons. W. Holmes, Bouquet de Dame, Sarah Owen, Madame Laing, and Sunflower are very fine of the older varieties. In the newer varieties G. P. Rawson, a double variety, rich buff centre petals, bright nankeen and apricot yellow. Alberic Lunden, brilliant dark carmine, shaded fiery crimson, Mr. Haigh thinks will supersede F. A. Davis. Lilian B. Bird, a lovely variety with long quilled petals; Louis Boehmer, by far the best bloom seen of it this season, and Gloire du Rocher are all excellent. All the Queen types are very fine, as is Refulgens, but the Princess family do not seem to be opening quite so freely as yet.

## CALDERSTONES,

The residence of Mrs. C. MacIver. Mr. Tunnington has capital plants this season. All the Japanese will be good, with the exception of Meg Merrilies and its sports, which are rather thin in substance, which Mr. Tunnington attributes to the cold wet summer. He is of opinion that their day is nearly over, as at the best the cup can be seen through the flowers when staged. This season Belle Paule is above the average, every bud producing fine blooms. The incurved are about the average, Prince Alfred and Lord Wolsley especially fine; Princess of Wales and all its sports, with Princess Teck, Hero of Stoke Newington, &c., are in fine form. The Empress family are looking well, but a little later than usual. Of the new incurved M. R. Bahuant too much praise cannot be accorded to it. Here it is again first-class in every respect, the flower being equal to the very best grown Queen. Its carliness Mr. Tunnington thinks can be remedied by propagating stronger cuttings somewhat later, or later pinching. M. Ulrich Brunner is another variety of great promise and beautiful colour. Eynsford White, Bouquet de Dame, and C. Wagstaffe are, in Mr. Tunnington's opinion, to supersede Elaine. Miss Anna Hartzhorn is a lovely broad petalled silvery white. W. H. Lincoln, W. W. Coles, Mrs. E. W. Clarke, and Puritan are good in every respect.

## DOVE PARK, WOOLTON,

The residence of Mrs. Cope. Mr. Carling is this year particularly strong in Japanese. E. Molyneux, M. Louise Leroy, Puritan, Sunflower, Mrs. Falconer Jameson, Criterion, Annie Clibran, W. W. Coles, Mrs. E. W. Clarke, M. Bernard, and Madame Baco are excellent. Of the newer ones Gloire de Rocher, and Mdle. Marie Hoste, creamy white, streaked and bordered amaranth, are admirable. Mrs. E. W. Clarke and M. E. A. Carrière are varieties of much promise. Of the incurved section the Empress family are fine in form, but a little small, though time may improve them. Novelty is splendid, as are Lady Hardinge, Hero of Stoke Newington, Princess of Teck, and Barbara.

## CROFTON, AIGBURTH,

The residence of Alfred Holt, Esq. Perhaps the finest plants in the neighbourhood are to be seen here. Mr. Forbes has scored some heavy successes in former years and is likely to do so again. All the older kinds of Japanese are doing very well, and Mrs. Alpheus Hardy is very good, so are W. W. Coles, Puritan, and A. H. Neve. In the newer varieties Vivian Morel is grand, Gloire du Rocher, Florence Davis, Louis Boehmer, Mdle. Marie Hoste, Lilian B. Bird, and Mrs. Levi P. Morton, a bright pink, with base of petals pure white. It is rather soon for many of them, but all the incurved will be very fine.

## THE HOLLIES, WOOLTON,

The residence of Thomas Brocklebank, junr., Esq. Mr. Vaughan, the gardener here, will I am told make his *débüt* at the shows this season, and success ought to meet his efforts. The Japanese are grand, especially E. Molyneux, M. Louise Leroy, Boule d'Or, Puritan

(magnificent), Sunflower, Avalanche, Mrs. F. Jameson, M. Bernard Condor, Belle Paule, Stanstead Surprise, Madame Laing, Sarah Owen and Etoile de Lyon. The finest Queens I have seen this year are here with Emily Dale, Lord Alcester, Golden Empress, and Jardin des Plantes

## ALLERTON HOUSE,

The residence of W. H. Shirley, Esq., can boast of a splendid collection, 350 plants being grown for large flowers, and provision made for cutting by an addition of another 150 plants. In the Japanese (and I may say they excel all Mr. Eaton's previous efforts) Sunflower, Puritan, W. W. Coles, Mrs. F. Jameson, Criterion, Edwin Molyneux, Jeanne Delaux, Avalanche, Madame Laing, Sarah Owen, and Madame Baco. Of newer varieties Florence Davis, which is promising to be a fine white variety; Gloire de Rocher, Sunset, W. H. Lincoln, which is certain to become a popular variety, all the Queen family, Princess of Wales, Miss Haggas, Mrs. Coleman, Lord Wolsley (perfection), Barbara, and Tecks are all unfolding flowers of great promise.

## BROMBOROUGH HALL, CHESHIRE,

The residence of R. N. Dale, Esq., can boast of a collection second to none in the country. Mr. J. Gould, the gardener, made a name last year, but bids fair to eclipse all previous efforts. Incurved Queens, Empress, Lord Alcester, Jeannet d'Arc, Lord Wolsley, Prince Alfred, Refulgence, Jardin des Plantes, Lady Hardinge, Mrs. Heale, Violet Tomlin, Miss Haggas, and Princess Teck are very fine. In this section Mrs. Clibran, a sport from Princess Teck, but much earlier, ought to be very good. Japanese—Avalanche, Puritan, Jeanne Delaux, Stanstead Surprise, Stanstead White, Sarah Owen, T. Stephenson, Edwin Molyneux, Mrs. C. H. Wheeler, Mrs. F. Jameson, W. W. Coles, Marsa, Etoile de Lyon, Madame Baco, and Mrs. Beale are all solid blooms with beautiful colour. Gloire de Rocher, M. E. A. Carrière, W. H. Lincoln, and Lilian B. Bird are established favourites already.—R. P. R.

## FINSBURY PARK.

THE display of Chrysanthemums at this place, so well known to cultivators for many years past in the London district is now at its best, and I venture to say as an annual visitor for a considerable number of years past that, taking it as a whole, in no previous year has it been excelled. The plants are dwarfier than usual, displaying their flowers well below the eye of the observer. The flowers as a rule are clean, bright, and well developed; also the plants are carrying plenty of large, healthy, dark green foliage, which forms the best of groundworks for showing the flowers to their fullest advantage. The plants, some 1500 in number, are arranged in the form of a sloping bank down the centre of a long span-roofed house, the plants sloping gently both ways from the centre down to the pathway, which runs along both sides the house, and are fringed next the path by a single row of dwarf Pompons, low bushes which serve admirably to hide the pots of the large flowering ones, and give a finish and completeness to the bank. We have not space to do much in particularising varieties as there noticed, but may say generally that the incurved section, and especially what is known as the "Queen family," are remarkably fine, and I think are scarcely likely to be seen to better advantage in such numbers anywhere this season. Many of the best varieties of Japanese are not yet fully out. Those popular varieties Avalanche and Etoile de Lyon are well represented by numerous plants, and are at their best. Comte de Germiny is always well grown here, and this year is no exception to such rule. Its near ally also in form and colour, Edwin Molyneux, is well represented by some fine flowers.

Near the entrance I noticed a fine flower of the new variety Vivian Morel, a splendid exhibition flower, similar in colour to the well known Mdme. C. Audiguier, but in form of petal, build of flower, &c., more nearly resembling Avalanche. The new variety Louis Boehmer is represented by a vigorous dwarf plant carrying some half a dozen large but as yet unexpanded buds. This bids fair to be a valuable acquisition, much more tractable and not nearly so shy as Mrs. Alpheus Hardy. The appreciation of the public for this fine display, due principally to the energy and skill of Mr. Mardlin (the foreman and grower), is well shown by the house being packed with visitors from early morning until it is closed at dusk.—VISITOR.

## CHRYSANTHEMUMS IN MESSRS. CARTER &amp; CO.'S NURSERY, PERRY HILL.

IN the course of the next week or so this collection, which comprises some 3000 plants, will be at its best. A large proportion have this year been grown on the cut-back principle, as the plants are more elegant in appearance and more convenient for arrangement. One of the principal features is the new pink Ostrich Plum Louis Boehmer, one of the new feathered varieties, the colour being of a soft lilac plum shade. It is quite distinct in every respect from Mrs. Alpheus Hardy, the original white variety, and promises to be a more certain and satisfactory flowerer. Amongst other leading sorts are excellent examples of Ada Spaulding, Agnes Flight, Alice Carter, Bertier Rendatler, Charlie Sharman, Edouard Audiguier, Edwin Molyneux, Elaine, Etoile de Lyon, Jeanne Delaux, Mdle. Lacroix, W. Holmes, Peter the Great, Sunflower, The Sultan, Bronze Queen of England, Empress of India, Lord Alcester, Lord Wolsley, Miss Violet Tomlin, Novelty, Princess of Wales, &c. There is also a collection designated the Oriental Group, originating in America, and containing some interesting forms, together with some forty to fifty continental introductions. Not the least important are Messrs. Carter's seedlings of 1889 and 1890, showing promise of distinct and valuable properties.

**EVENTS OF THE WEEK.**—Chrysanthemum Shows will contribute the principal horticultural events of the present and succeeding week. To-day (Thursday), Nov. 5th, there are Shows at Highgate, Chiswick, and Wandsworth. On Friday, Nov. 6th, the Crystal Palace Show will be opened, and will be continued on Saturday. Monday, Nov. 9th, commences with a Show at St. Neots, followed on Tuesday, Nov. 10th, by a number of shows, some of which are continued over two, and in one case three days. These are East Grinstead, Kingston, Horsham, Royal Aquarium, Leeds, and South London. The Shows commencing on Wednesday, Nov. 11th, are Birmingham, Bournemouth, Northampton, Swansea, and Croydon. On Friday next, Nov. 6th, an important sale of *Cattleya labiata vera* from Messrs. F. Sander & Co. will be held at Messrs. Protheroe & Morris's rooms, when some extra large specimens will be offered.

— **WARE AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY.**—At a special meeting held by this Society recently a very interesting and instructive paper was read by Mr. G. Paul, of the Old Nurseries, Chesbunt, on "Fruit Culture on the West Slopes of the Lea Valley." Mr. Paul's remarks were illustrated by a very fine collection of fruit. About 100 dishes of Apples and Pears having been sent from the nursery. The paper was highly appreciated by a large gathering of members and their friends. A hearty vote of thanks was accorded to Mr. Paul for his able paper, and a vote of thanks to the Chairman brought a very pleasant meeting to a close.

— **GARDENERS' ORPHAN FUND.**—At a largely attended Committee meeting of this charity on Friday evening last it was decided that the anniversary dinner be held in February next, and it was resolved unanimously that Sir James Whitehead, Bart., be invited to preside on the occasion. A letter was read from Mr. Tait of Manchester stating that a local committee had been formed in that busy and wealthy city to represent and support the Fund, the Secretary Mr. Upjohn, or his delegate, being empowered to attend the meetings of the Central Committee in London. It could scarcely fail to be of great advantage to the charity if committees were established on the same basis in other great centres of population. Sums amounting to upwards of £11 were received as the proceeds of money boxes or collections from Bristol, Birmingham, and Birdsall, Mr. Wadds sending £5 7s. 6d. Two donations of £5 each were announced, also £250 as the result of a collection of small sums, mainly by gardeners and friends in various parts of the kingdom. Thus a great deal of good will be done at a very small sacrifice by individuals, and the Committee expressed their obligation to all who had collected and contributed to the Fund.

— **GARDENERS' ORPHAN FUND.**—At Ketton Hall Gardens, where Peaches are so well and extensively grown by Mr. Divers, a praiseworthy example has been set. By the kind permission of Mr. and Mrs. Hopwood the fine collection of Chrysanthemums grown there are open to public view on a small payment being made on Thursdays and Saturdays from 2 P.M. till dusk until November 21st, the proceeds to be devoted to the Gardeners' Orphan Fund. Could not many others where Chrysanthemums are grown follow the example of the energetic Hon. Sec. for the Stamford district, and try and persuade their employers to allow a similar exhibition, if only for one afternoon?—H. W., *Stamford*.

— **GARDENING APPOINTMENTS.**—We are informed that Mr. Albert Baxter, late foreman to Mr. T. H. Crasp, Canford Manor, Wimborne, has been appointed gardener to Henry Lewis, Esq., Greenmeadow, Tongmynlais, Cardiff. Mr. Walter Madge, foreman at Parker's Well Gardens, Exeter, has been appointed to succeed Mr. C. Lock at Culver, Exeter. Mr. Arthur Allsop, who was plant decorator at Trentham, succeeds Mr. Leach at Bryanston House, Blandford.

— **TREES AT RICHMOND TERRACE.**—The London correspondent of a local paper says:—"Richmond Terrace, whence can be obtained a view over the Thames Valley which Sir Walter Scott pronounced to be 'unrivalled,' and which was equally beloved by

Turner, will shortly lose one of its distinguishing beauties. The stately Elms that line the terrace are all internally decayed. Some must come down at once, and the rest, it is feared, cannot last much longer. It was under these trees, readers of 'Pickwick' will remember, that Mr. Tracy Tupman walked with 'a youthful and jaunty air,' which rendered him 'the admiration of numerous elderly ladies of single condition.'"

— JUST as we are going to press we have received a telegram, from which we learn that the PORTSMOUTH CHRYSANTHEMUM SHOW is an extremely fine one. The Jubilee prize of £8 for eight trained specimen plants is won by Mr. Penford, Leigh Park Gardens, Havant. In the class for forty-eight cut blooms Messrs. W. & G. Drover, of Fareham, have won the piece of plate value £25 and £8 in money as the first prize, and are followed by Mr. Payne of Emsworth, Mr. N. Molyneux, and Mr. Agate. Messrs. Drover won the challenge prize last year, and it therefore now becomes their property in accordance with the conditions imposed by the Society.

— MR. HENRY MARDLIN, the well-known Chrysanthemum grower at Finsbury Park, is about to resign the position he has held since the formation of the Park, as foreman and propagator. And Chrysanthemum cultivators ought not to allow him to retire without some expressions of esteem for one who has done so much to popularise our queen of autumn. The public display at Finsbury Park was initiated mainly through his exertions, and save for those of the Temple Gardens, was the first of the kind in the metropolis. The flower loving public of North London, too, will lose in Mr. Mardlin a valuable public servant. —VISITOR.

— **GREENHOUSE FLOORS.**—The builder of my greenhouse (40 by 20) has laid the tiling of floor almost level, therefore causing all water to lie about unless mopped up or allowed to dry, there being no channels or waterways. To relay would be somewhat costly, besides the builder says all greenhouse floors are so laid. I beg to differ. What is your readers' opinion? Any suggestion as to remedy, and as to whether builder's contention is correct, will be esteemed.—W. B. BECKETT.

— **EARLY PLANTING OF APPLES.**—Mr. Luckhurst's excellent paper on the advantage of autumnal planting ought to be convincing, but there are some still, I fancy, who do not believe in trees and shrubs making roots during the winter. The commencement of the great frost last year found me with one Apple tree still unplanted. It was laid in overnight, and in the morning could not be moved. At the earliest possible opportunity, at the conclusion of the seven or eight weeks' frost, we lifted the tree to plant it, and found that several little white roots had actually been formed during the frost.—W. R. RAILLEM.

— **DACTYLIS GLOMERATA VARIEGATA.**—I have previously touched on the great utility of this beautiful Grass for bedding purposes, I now wish to call attention to it as a useful addition to the list of plants suitable for indoor decoration. For this purpose it is one of the best plants in its own particular style that I am acquainted with for use during the winter and spring months. At those seasons of the year suitable materials in small pots for finishing groups of plants, and arranging around larger plants in vases, are not generally plentiful, and as this can be had in quantity then with but little trouble, it is all the more welcome, especially as it supplies a fine variegation of foliage, which is so desirable for intermixing with Ferns and *Isolepis gracilis*, both indispensable plants to the house decorator. Those who are fortunate enough to have a good stock in any position in the open air should, as soon as possible, lift some of the roots, divide them, and place them in pots of various sizes, pressing the soil very firmly, and then plunge the pots over their rims in coal ashes in the open air. In this position they should be left for a few weeks till the growth has thoroughly died. They should then be taken into a structure where they receive gentle heat, and can be kept near the glass. A heated pit or shelf in a warm greenhouse are capital positions for them, there they quickly develop their growth. When this has become a little hardened by a free circulation of air the plants are ready for use wherever required. When once a good stock has been obtained the roots can be thrown away after being used, as this Grass increases so rapidly that a few roots divided in the spring and planted out in a sunny position, are ready for use in the autumn, and one of the chief features of its usefulness is that they only occupy space under glass while they are making growth, and as the spring months advance they may be brought on quickly enough in cold pits.—H. D.

— AT a recent meeting of the Richmond Athenæum the Rev. G. Henslow delivered a lecture on INSECTIVOROUS PLANTS of which the following is a synopsis:—Insectivorous plants are found in at least six distinct families—Examples of methods of capture (picture form)—*Sarracenia*, *Nepenthes*, *Cephalotus*, *Discoidea* (viscid glands)—*Drosera*, *Pinguicula* (traps)—*Dionæa*, *Aldrovanda*, *Utricularia*. The same methods are found in widely different families; hence it is an acquired property—Proofs of absorption and uses to the plant, as especially benefiting the reproductive system—Insectivorous plants compared with parasites—Specialities of each species, *e.g.*, in movement, structure, methods of secretion, absorption and digestion—Identities between the animal and vegetable kingdom in irritability, of protoplasm, mobility, and electrical phenomena—Secretion of acid and digestive ferments—Effects of poisons and anæsthetics, &c.—Suggested origin of the secretion of ferments and the absorption of nitrogenous nutritive matters.

— NOTES AT ROBY HALL.—Whatever may be said in praise of the beautiful *LILIUM HARRISI* is not in the least more than it deserves. Last April I had the pleasure of seeing some of the finest plants I ever remember growing at Roby Hall. Visiting Mr. Jones, the gardener at the Hall, recently, I was struck by the fine specimen of this *Lilium*, some expanding and many in bud. One plant in an 8-inch pot carrying forty fine flowers was very good. These were the same bulbs I had seen in April, and were flowering the second time. By keeping some cool he will be able to have some of them in flower at Christmas, when they will prove a great acquisition.

— MYRSIPHYLLUM ASPARAGOIDES.—For decorative work this very pretty climber cannot be surpassed. Planted in a narrow border, and trained to upright cords about 5 feet long and 2 inches between, and completely covering the back wall of the late vinery, was this plant in perfection. When wanted for decoration the cords are simply cut away, there being not the slightest entanglement when trained this way. The pleasing shade of green shows up remarkably well by gaslight.

— LYGODIUM SCANDENS.—Exactly in the same position in two other vineries, but allowed an extension over the pathway, is this fine old climbing Fern. The finely cut fronds present a very beautiful appearance, and the uses to which they may be put for table decoration are various. It is a very clean Fern, and for clothing back walls of vineries is at once ornamental and useful. A mixture of loam, peat, lime rubbish, and sand forms a good compost in which to plant the two latter, and with an annual top-dressing the plants can be kept in perfect order for a number of years.

— NOTES AT ALLERTON BEECHES.—Standing out like veritable giants are six fine Beech trees, from which the name of the house has been taken. I question if finer could be found in any part of Lancashire. When calling on Mr. Edwards, the gardener to Henry Tate, jun., Esq., I found I had not arrived at the best time of the year to see the specialities grown here, but a few notes hurriedly taken were worthy of record. Orchids are undoubtedly the chief pursuit, and the houses they are occupying are as perfect as it is possible to find them. Made throughout of the best pitch pine they are stained a dark oak colour instead of paint, and are very pleasing. The supports to the stages are resting in zinc trays, which are always kept filled with water, thus making it an impossibility for insects to find a way up to the stage. Leaves underneath the trellis in Orchid houses have been advocated and condemned. Mr. Edwards is a firm believer in their use. He has the trellis made in sections, which can easily be lifted, to keep up a fresh supply of leaves. By this means a uniform moisture is secured, and the zinc trays keep at bay the attack of slugs, &c., if there are any, contained in the leaves, and the plants throughout all the houses were in the very best of health. Some fine *Odontoglossums*, *Lælia Dayana*, and two very healthy plants of *Vanda Sanderiana* growing in teak cylinders, suspended from the roof, and carrying ten and twelve flowers respectively, were conspicuous. Mr. Edwards has six or seven batches of seedling *Cattleyas* and *Cypripediums*, numbering scores of plants. The crosses are from some of the finest varieties, and many of them present scarcely any appearance to the parents. They are being carefully tended. I must leave the Orchids for a future note.

— *LILIUM AURATUM* planted outside was really fine, one bulb having forty flowers, and on another a spike with twenty-eight flowers. They are from English grown bulbs, the imported ones having been failures over and over again. Lemoine's hybrid *Gladiolus* were in full flower. There is no doubt about their being acquisitions, as they had

stood the last severe winter without protection, many of the flowers being as fine as any type of *gandavensis*; and lastly, *Pyracantha præcox*, glowing in all its beauty against the front of the house, and what a contrast to some Ivy growing in close proximity. It is a fine place, and may be dealt with more fully at a future date.—R. P. R.

— THE DUTCH HORTICULTURAL AND BOTANICAL SOCIETY.—At a meeting of this Society, held on October 10th, 1891, the Floral Committee awarded the following:—First-class certificates to Mr. J. T. Van Den Berg, jun., Jutfaas, for *Dahlia variabilis* König Karl and Adrien de Mortillet; to Messrs. Groenewegen & Co., Amsterdam, for *Dahlia* (Cactus) Paul Schelosky and Maid of Kent, and (single) Frau Dr. Sophie Rhoden; to Messrs. E. H. Krelage & Son, Haarlem, for *Dahlia variabilis* Euphrosyne, and *Gladiolus naneeianus* le Grand Carnot; to Messrs. Anton Roozen & Son, Overveen, for *Chrysanthemum* Mrs. Hawkins, *Crinum speciosum*, and *Dahlia* (single) Mr. H. L. A. Obreen; to Messrs. Zoehér & Co., Haarlem, for *Dahlia* (Cactus) Maid of Kent, Centennial, Edmund Weekly, John Bragge, Vosmaer, (single) Frau Dr. Sophie Rhoden, Gertrude, Miss Reamsbottan, and *Purpurea*; to Mr. N. De Zwaan, Utrecht, for *Begonia Baumannii*. Second-class certificates were adjudged to Mr. J. T. Van Den Berg, jun., for *Dahlia variabilis* Albertine; to Messrs. E. H. Krelage & Son for *Dahlia variabilis* Aglaia and Thaleia; to Messrs. Anton Roozen & Son for *Chrysanthemum* Duchess of Fife; to Messrs. Zoehér & Co. for *Dahlia* (Cactus) Amphion and Zulu. A botanical certificate was awarded to Messrs. De Graaff Brothers, Leiden, for *Gladiolus Eckloni*. Votes of thanks were accorded to Mr. J. T. Van Den Berg, jun., for a collection cut flowers of double tuberous *Begonias*; to Messrs. Groenewegen & Co. for a collection of *Dahlias* in twenty varieties; and to Messrs. E. H. Krelage & Son for a collection of *Gladiolus gandavensis* in fifty varieties.

— THE RAINFALL AT WINCHFIELD, HANTS.—The total amount of rainfall in these gardens (Elvetham Park) for October was 7.16 inches. The total for the ten months, 26.65. The heaviest fall was 1.24, on the 7th. Rain fell upon twenty-two days. This is the largest quantity ever registered in one month, an account having been kept for the past eighteen years.—JAMES FOSTER.

— THE TOTAL RAINFALL AT CUCKFIELD, SUSSEX, for the past month was 7.83 inches, being 3.95 inches above the average. The heaviest fall was 1 inch on 22nd. Rain fell on twenty-two days. Highest temperature 64° on 9th; lowest 30° on 31st. Mean maximum in shade, 56°; mean minimum, 42°; mean temperature, 49°. Partial shade readings, 3° above the average. Last five days fine and dry, and land once more workable.—R. I.

— WEATHER IN THE NORTH.—October closed with ten days of fine seasonable weather, the days bright and pleasant, with frosts of from 3° to 9° on the night of the 30th. The first decided frost was on the morning of the 18th, 3°. The grain crops in this quarter have been, with considerable trouble and anxiety, secured in satisfactory condition, and Potatoes are turning out well, with but little disease. Turnips are also being taken in hand, a fairly good crop generally. Many trees are already stripped of foliage, the sharp frosts shortening the autumn display.—B. D., *S. Perthshire*.

— THE WEATHER DURING OCTOBER AT RIPLEY, YORKS.—The first three weeks were very wet, rain falling upon twenty-one out of the first twenty-four days. On the 25th a welcome change set in, and we were favoured with fine weather to the end of the month. Frost occurred upon seven days. Total rainfall for the month, 4.33 inches, which fell upon twenty-two days. The greatest daily fall occurred on the 10th, when 0.65 of an inch was registered. During the last few days the barometer ranged very high; at 9 A.M. on 31st it stood at 30.82, at which point it stands as I write (November 2nd). Mean reading of barometer for the month, 29.83. Mean maximum temperature, 55.1°; mean minimum temperature, 35.8°. Mean temperature of month, 45.5°. Highest maximum temperature, 63° on the 5th; lowest minimum temperature, 27° on the 30th.—J. TUNNINGTON, *Ripley Castle Gardens*.

— REPORT OF WEATHER FROM OBSERVATIONS TAKEN AT HAMELS PARK.—The past month has been of a very deluging character. There has been a continual drizzle with an occasional heavy downpour. We have also experienced some very heavy gales of south-westerly wind, such as I do not remember our having since October, 1881. The heavy rainfall during the past month has been very beneficial in many places, as the water supply was getting very short. There has been almost a total absence of sunshine, and the same may be said of frost until the morning of the 31st, when 6° were registered, which completely

blackened Dahlias and other plants. Rain fell upon twenty-one days during past month. Maximum in any twenty-four hours, 0·60 inch on the 6th; minimum, 0·01 on the 17th. Total for the month, 5·07; against 1·87 of 1890.—E. WALLIS, *Hamel's Park Gardens, Buntingford, Herts.*

— EXCESSIVE RAINFALL IN HAMPSHIRE.—The year of 1891 appeared in September likely to end with amount of rain below the average. Now after such a drenching October that is a thing of the past, and we have already had for this part more than the average. Rain fell here on twenty days; most rain fell on October 6th, when 1·25 inch was registered as having fallen in twelve hours. The next heaviest was on the night of October 19th, when 0·83 inch fell. The total amount for the month was 10·30 inches. We had no frost here until the night of October 28th, when we had 2°. Until that date such tender bedding plants as Coleus and Iresine were looking as well as in August, a rather unusual occurrence. I may state our garden is on a hill, and sheltered by trees.—A. J. L., *near Stockbridge.*

— RAINFALL IN HAMPSHIRE.—Since writing my last note on the rainfall here sixteen days ago we have had sufficient rain to exceed last year's whole total by 1·35 inch, having registered 5·72 inches, making in all for the present month 7·98 inches, which, as far as my memory carries me, is quite unprecedented for any month, and especially October. Up to the present date, 26th, we have had but four dry days as compared with eighteen last year. Last year's rainfall for the first twenty-six days of October was but 0·89 inch. What a difference between the two seasons. Our total now for the year up to date is 28·52 inches, which is really not in excess of our average rainfall. On Thursday we had twenty-four hours' continuous rain.—E. M.

— THE FLOODS IN SOMERSETSHIRE.—It is widely known (writes Mr. R. Harty Dunn, Street, Somerset) that some 80,000 acres of Somersetshire moorland are under water owing to the heavy rains, the recent high tide, and the breaking away of the embankments of the Rivers Parrott and Brue. But it is not so well known that in consequence of this deluge (the like of which has not been witnessed in this generation) a large number of labourers and small farmers are on the brink of utter destitution, and not a few have had to appeal already to the local poor law unions. The Wheat crop, the Potato crop, and in fact everything, including the peat or "turf" industry, upon which these poor people were relying for subsistence now and during the coming winter, have suffered to such an extent as to create quite a local famine. Men can go by water in boats right over the crops which were their sole dependence.

— RAINFALL AT DARTMOUTH.—Mr. T. Gard, The Gardens, The Beacon, Kingswear, Dartmouth, writes:—"I send you a few notes with respect to the rainfall during the past six months, thinking perhaps it may be interesting to you from this locality. I commenced registering the rainfall on the 1st of May last, and the following are the results:—In May 3·04 inches fell on eleven days, in June 3·83 inches fell on ten days, in July 3·72 inches fell on twelve days, in August 7·07 inches fell on fifteen days, in September 2·46 inches fell on twelve days, in October 10·41 inches fell on twenty-four days; the total was 30·53 inches on eighty-four days. The heaviest falls on one day were as follows:—On the 18th August 1·02 inch, on the 21st August 1·98 inch, on the 1st September 1·02 inch, on the 6th October 1·30 inch, 7th October 1·27 inch, and the 19th October 1·25 inch. For this hilly locality the summer has been very beneficial to the growth of all vegetable crops, but I am afraid the lack of sunshine will tell on the rather soft and overgrown wood of the fruit trees. I gathered a good crop of Peaches and fair crop of Plums, but these cracked badly. Apples were a good crop; Pears scarce. October has been a month long to be remembered, as nothing could be done on the ground; but the weather is now much improved—dry, but very cold easterly wind."

— MR. ALBERT BENZ divides GARDEN PANSIES into six classes, according to the manner in which they are coloured. The first class comprises self-coloured flowers—that is, those which have an even shade spread over the whole surface of each of the petals. They may be white, yellow, bronze, mahogany, brown, purple, lavender, violet and nearly all intermediate shades. They can be depended on more largely than the other varieties to come true from seed. Shaded Pansies constitute the second class, in which the flowers have the darkest shade of a given colour at the upper end of the upper petals gradually graded down to a lighter shade toward the bottom end of the lower petal. Others of this class are darkest in the centre and

shade gradually into a lighter tint toward the edge of all the petals. The Three-spotted or Face Pansies include the flowers which show a distinct mask, or face, in their centre—that is, a dark spot on each side of the side petals, and a broad and larger one on the lower petal. This includes most of the English Pansies and the new French Trimardeau, a remarkable sort for the size of its flowers, which are, however, somewhat deficient in substance and richness of colour. The Odier or Five-spotted Pansies have a white, yellow, blue, crimson, or brown colour and a large dark spot on each one of the five petals. To be perfect, these spots, starting from the centre of the flower, should cover two-thirds or three-fourths of its surface, and be of equal dimensions on each petal with a well-defined outline. Cassier and Bougnot have succeeded in improving this class materially in size of flowers and growth of foliage. Edged or Border Pansies have flowers with a narrow, but distinct, edging around the outside of each petal of a colour which contrasts well with the ground colour of the flower. The colour of the border is generally white or gold when on blue, purple, or bronze flowers, and blue or pinkish on white and yellow flowers. The sixth and last class, called Fancy Pansies, have the marble-striped and flaked flowers, which are distinguished by great oddity and beauty in their colouring and marking.—(*American Garden and Forest.*)

THE AUTUMN FLOWERING CATTLEYAS.

A LARGE company of buyers and on-lookers assembled on Friday last at Messrs. Protheroe & Morris's Rooms, Cheapside, to see the consignments of autumn flowering Cattleyas from Brussels, and a beautiful display was provided. Rarely indeed can an exhibition of Cattleyas in flower be seen at the end of October, and all present were agreed as to the value of plants that yield such richly coloured flowers so abundantly. There was a keen competition for some of the finest specimens, and the total amount realised must have been considerable.

Messrs. F. Sander & Co., St. Albans, also announce a sale for next Friday, November 6th, in the same Rooms, of 1000 grand plants of "the old labiata." Some examples of these were shown at the recent meeting of the Royal Horticultural Society, fine vigorous specimens with large pseudo-bulbs and leaves. It is said that some of the masses are 6 feet in diameter.

There can be no question that, under whatever name these autumn flowering Cattleyas are known, they are certain to become extremely popular. If a supply of flowers can be had from now until Christmas—and there seems to be every probability that this will be the case—it is easy to imagine how useful they will prove to many who have large demands for cut flowers to meet during these months. Easily cultivated, freely flowering, and presenting a great range of variation in form and colouring, they have much to recommend them to the attention, not of Orchid growers alone, but also of all who are concerned in plant culture generally.

I have much more to say upon this subject, but space will not permit this week; and a review of the *Cattleya labiata* varieties with especial reference to those which flower in autumn must be reserved for another issue.—L. C.

### STREPTOCARPUS GALPINI, *Hook, f. (MS).*

DURING the past week a handsome new *Streptocarpus* has been flowering in the Royal Gardens, Kew, and we are pleased to be able to give the appended woodcut (fig. 76), prepared from an excellent sketch of the plant natural size. We learn that the seeds of this *Streptocarpus* were received last summer from Mr. E. E. Galpin of Barberton, Transvaal, but only one plant has flowered up to the present, though there are many others advancing which are expected to prove larger in the leaf, and to be even more floriferous than the one represented in our engraving. The leaf is very fleshy, the veins are thick, and the whole is covered with a soft silky pubescence, making surface appear quite silvery. The flowers are

bright purplish blue, with a clearly defined white throat, and they have a very distinct appearance, owing to the corolla being flatter and more shallow than the majority of the forms best known in gardens. As it is very free, and the colour is

and hybrids form an attractive margin to the paths in the succulent house.

We understand that Mr. Watson has already crossed this species with the fine hybrid he succeeded in raising several years ago—

FIG. 76.—STREPTOCARPUS GALPINI.

so bright, it will prove of considerable horticultural value either for culture in pots or for planting out in an intermediate temperature. At Kew the numerous *Streptocarpus* varieties

namely, *S. Watsoni*—and it is probable that another equally valuable race will be obtained. A coloured plate and full botanical description will shortly appear in the "Botanical Magazine."

## POTATO DISEASE EXPERIMENTS.

YOUR reporter, after recapitulating on page 340 part of what occurred on Friday, 16th, at Reading, winds up by stating, "Here is the significant summary, and there cannot be a doubt of its absolute correctness." That it stated the facts is quite right, but had he examined the figures he would have seen that 601 rows were planted with varieties that were injured by the mixture and only 209 rows with those that benefited. Had the rows been equal the result would have been 6 cwt. 0 qr. 14 lbs., and not 11 cwt. 1 qr. 4 lbs., a result quite serious enough, but rather altering the proportion. I must also ask your reporter where he ascertained that the Board of Agriculture recommends the dressings and areas to be dressed that he states he wishes to recall to your readers. I do not hesitate to inform him they never existed outside his brilliant imagination, and I have that assurance from Major Craigie himself, who stated that the pamphlet issued in May containing an account of what had been done in various places was all that had been sent out, and he expressed a wish to see a copy of your paper containing the mythical instructions. The gentleman who reported on the trial evidently never saw that pamphlet, also as evidently did what nearly all the gentlemen of the Press have done, and that is, hashed up Messrs. Suttons' printed report and flavoured it according to taste. I am extremely anxious to learn where he discovered that there is any particular term for the fungoid attack to be most dangerous, as I should be glad to forward particulars to U.S. Agricultural Department, who have been most generous in supplying me with information.

Having made these remarks I wish to state that in no way am I animated by a desire to question that the trial was not made by Messrs. Sutton with an honest desire to benefit the Potato grower. Some of the figures given in the report prove this, as it shows varieties not of their raising in a most favourable light as regards cropping. I was most kindly invited down, and only regretted that some mistake had been made in the preparation or application of the mixture preventing it being a success. I was the last to be prepared to find the mixture positively injurious, and I fancy your readers after perusing what follows will not be surprised I was so. At Sittingbourne, Kent; Cardington, Bedfordshire; Isle of Axholme, Lincolnshire, in South Wales, Devonshire, and Lancashire, the R.A.S.E. have applied three dressings of 2 per cent. mixture to a 2-acre plot of Potatoes. The first dressing was applied to all the plots between June 29th and July 13th; the second from July 15th to July 27th. I have no information as to the third. 75 gallons of mixture per acre was used at the first, and 100 gallons at the second; no knowledge of quantity at the third. Regents were the variety planted at Sittingbourne, Daniels at Cardington. At Sittingbourne the owner of the Potatoes, Mr. Cobb, had 9 acres of Regents dressed twice with a 2 per cent. mixture in the same field as the plot experimented upon by the R.A.S.E. It was put on by his own labourer with an Eclair, under the superintendence of his intelligent bailiff, who had helped Mr. Riley, who made all the experiments for the R.A.S.E. None of the bine upon these several 2-acre plots or upon the 9 acres of Regents was damaged by the mixture. I saw the 11 acres of Regents in Kent on 21st of September. They were then green and growing. Regent bine untreated alongside or treated with  $1\frac{1}{2}$  per cent. of the mixture only, all long killed down by blight. The plots in South Wales and Bedfordshire have now been weighed and show handsome increase per acre over Potatoes untreated. The firm upon whose farm in Bedfordshire trial was made wrote me they are well satisfied with the utility of the mixture. At Sittingbourne and Cardington the R.A.S.E. are trying various strengths of mixture, and at the latter place an experiment with sulphate of iron instead of copper is added. At Bewdley, Worcestershire, Mr. Thomas Harley dressed at the end of August Maincrop, Bruce, and Early Puritan once with 30 per cent solution. Result, no damage to bine, and as far as could be seen improvement over other varieties in fields adjoining.

At Chessington Hall, Surbiton, Mr. H. Chancellor dressed a plot of Hebrons in the wettest part of a large field with 2 per cent. mixture twice, and a plot of Jeannie Deans in the middle of a field once with 4 per cent. on 5th August. On 29th August when I saw them the Hebron bine not dressed was all dead with disease; treated plot untouched and ripening off. The Jeannie Deans were a grand green colour; the same variety alongside untreated all killed down. Both these plots sustained no damage from Bouillie Bordelaise, and upon being weighed gave an increase of some tons to the acre over those not treated.

Deeping St. Nicholas, Spalding. On 3rd July I here applied 2 per cent. mixture to 12 square rods of Maincrop in the middle of an 8 acre field, also to Puritans, Internationals, Myatt's, White Beauty of Hebron, altogether about twenty odd sorts, upon my trial ground of 3 acres, many of the varieties being those that Messrs. Sutton state were damaged by the mixture; so many yards of a row of each variety were treated. I also dressed a plot of Puritans in another part of the farm. On 1st August I repeated the application to all with 3 per cent. mixture, and later on put 3 per cent. again on the Puritans. On 2nd October Maincrop bine treated was still green, the rest of the field all killed down with disease, and only half the crop of treated part. I dug some yards of all the various sorts on the trial ground, found that the mixture had failed to protect all the tubers of some varieties, more especially Internationals, but in every case the crop was double on treated Potatoes. The plot of Puritans when dug had not a diseased tuber, and was double the crop of those alongside not treated, which were half bad. Not a leaf at Deeping St. Nicholas was damaged of any variety. On 18th July I put 3 per cent. mixture on ten varieties on two plots at the end of an oblong piece of Potatoes on my trial grounds at Cliffe, Rochester. On 24th August, on

my return from Lincolnshire, I found all the rows between the plots killed by disease; the bine of both plots were green, though one was slightly more spotted with blight than others. I applied 3 per cent. mixture to both; it saved bine, on that least affected entirely, and it ripened off grandly; other went with disease in places most spotted. In this instance also not a leaf was damaged and the crop increased.

On September 5th I had 2 acres dressed of Reading Giant especially planted late (June 18th) to try the effect of one dressing of 3 per cent. Bouillie Bordelaise put on late in stopping disease. Having a desire to ascertain the cost of application I had mixture applied by ordinary farm labourer. He went the longest way about the work, and took two days and a quarter, quantity applied 260 gallons on 2 acres. I had half a day with the Eclair and reckon I could do an acre in three-quarters of a day. The solution stayed the disease on the bine for some time, and in this case no damage to bine except where the stuff was prepared by labourers from my written directions, and I burnt off the bine of nearly half an acre. I had intended this two acres to be treated before the 5th, but the foreman was short of labour, and it was ten days after I sent copper down that the mixture was put on; by that time all the leaves were spotted. On 11th September I dressed at Branstane, Edinburgh, some Maincrops, Regents, and Abundance, and some Abundance at Easter Duddingston, and Portobello; in the latter case with the energetic co-operation of the Editor of the *N.B. Agriculturist*, who selected the farms most likely to suit my purpose in the North. On the 15th I put the solution on to some Shaws, Reading Giants, and other varieties on my trial grounds at Pancathy Mill, Carnoustie, and on the 16th on to some Imperators on the farm of Balhousie, Carnoustie, near Arbroath; mixture used in the North, 1 lb. copper, 1 lb. lime, to 26 pints of water; object to ascertain if one dressing in Scotland would check disease once it had taken hold. No damage to a single leaf took place, but as far as the top was concerned it did no good.

In 1890 Mr. E. S. Goff of Madison carried out some experiments for Mr. B. T. Galloway, Chief of the Division of Vegetable Pathology, upon the farm of Mr. A. L. Hatch, Ithaca, Richland County, Wisconsin, U.S.A. The farm is light clay loam, is in good cultivation, on the top of a hill, and not far short of 1000 feet above sea level. May, June, and up to July 13th, it was wet; in August, in twelve days, 3.46 inches of rain fell, and in September 2.5 inches in six days. Variety planted Snowflake; mixture 6 lbs. lime, 4 lbs. copper, to 22 gallons water. First application July 3rd, last September 2nd; no damage done to the bine by the mixture. Middle of August treated bine still green, untreated beginning to spot; result of treatment an average gain of 400 odd lbs. upon each of the four 16 rods treated against 16 rods left to Nature.

To give an idea of the rain, some of the sets were washed out of the ground. The foregoing experiments were carried out under different climatic influences; the crops were cultivated in various ways, and give a better criterion of the value of the mixture than Messrs. Suttons', which was of practically one strength three times applied to the Potatoes—exposed to the same climate, on the same soil, and cultivated one way. It is true there were 278 sorts, but a mistake in the preparation or application affected the result on the whole plot, and only those varieties that were strong or got less of the mixture would escape being injured.

As to the value of disease resisters, there are none; all take it more or less. Had the Abundance at Reading been cultivated highly enough to enable a man to live by growing them for market they would have been half bad; and the robust varieties, even when not taking it in the tubers, have the bine killed down by blight, causing want of quality in the crop and lowering its value in the market by 30s. ton or less, according as it is grown on good quality soil or the reverse. Magnums are being sold here now that cook like soap, simply because the bine was blighted before they were ripe. A mixture that will allow the Potato to complete its growth, even if it does not save all the tubers, is well worth applying at a cost of 25s. an acre. I have faith enough to use it next year on 100 acres to Potatoes grown to supply the London market (the cheapest in the world), and not cultivated to sell at fancy prices. —WM. WHITEHEAD COUSINS, *Covent Garden Market*.

[Our reporter appends, by our request, his observations on the foregoing communication as follows:—Mr. Whitehead Cousins' compliment to the brilliancy of my imagination is exceeded by his own. I had no occasion to "imagine" anything, for all I had to do in reference to the dressings (not "areas") recommended, was to copy the mixtures and applications from a document (not Messrs. Sutton's printed report of the trials) now in my possession.

As your correspondent is so sure I had not seen the May pamphlet of the Board of Agriculture, may I suggest it would have been kind of him if he had sent me a copy? Also may I further suggest if this pamphlet was intended to reach the greatest number of cultivators of Potatoes, that a copy ought to have been sent to the *Journal of Horticulture*? No doubt, so far as a very large number of Potato growers are concerned the pamphlet itself is "mythical," for they know nothing about it.

Mr. Whitehead Cousins is good enough to suggest that "nearly all" the gentlemen of the Press are in the habit of "hashing up" reports. If voluminous contributions to various newspapers entitle writers to be regarded as "gentlemen of the Press" he must of necessity be included in the army of hashers.

The report which appears to have offended your correspondent was a record of facts, which he cannot impugn except on the ground that Messrs. Suttons have blundered. They know best about that; their custom is to conduct experiments with the utmost care and to state the

results with great precision. I have more than once heard Dr. Voelcker bear testimony to this, and something more than negative evidence seems requisite for sustaining the allegation. In referring to sulphate and copper and lime dressings generally, I clearly stated they had in "some cases proved beneficial." I had seen this in Mr. Chancellor's experimental plots, and this gentleman kindly promised to send me some particulars in due time. The sulphate of iron was not efficacious with him, nor was the powder; and the sulphate of copper was undoubtedly the reverse of efficacious with the great bulk of Messrs. Sutton's varieties. To suggest otherwise would be hashing of a most contemptible character, for it would amount to a subversion of facts.

These were apparent enough at Reading without the figures. I venture to say that the gentlemen who examined the crops really did know the good from the inferior yields when they saw them on the ground, and it is a little unfortunate that Mr. Whitehead Cousins was not able to attend, and point out to the visitors on the spot the cause of the disparity. If it is true, as he says, "a mistake in the preparation or application" of the mixture "affected the result," the records are obviously worthless.

Mr. Whitehead Cousins states he is "extremely anxious to learn where I discovered that there is any particular term for the fungoid attack to be the most dangerous," adding he would like to forward the particulars to the U.S. Agricultural Department. The information is not wanted for our own Agricultural Department, but the American. Why is this? I should be sorry to presume that either of the Boards were in need of particulars on the subject, as it would be a reflection on their capacity. Mr. Galloway requires none of my aid in respect to fungoid attacks and prevention. He sends me his masterly reports, which have many times formed the basis of articles in this Journal. This, however, does not answer the question of discovery of the disease term. Not myself alone, but numbers of men, who have evidently had longer experience in Potato culture than has your correspondent, know very well the term of greatest danger, and I do not hesitate saying that in the absence of this knowledge much time and material must be wasted if Bouillie or any other applications come into anything like general use, because it or they will often be applied when not in the least required.

Well-trained and observant gardeners know well the conditions and state of growth that predispose to the fungoid attacks on plants, Vines, &c., under glass, and can, if they wish, incite, or with proper means prevent, those attacks. Potatoes grown in a frame divided in two parts have been free from disease in one part, attacked in the other, the variety and the soil being identical, but the character of the growth made to differ through changed conditions artificially produced. Similar conditions provided in a natural way are followed by similar results.

If Mr. Whitehead Cousins had been working among Potatoes from 1845, taking careful notes of observation for more than forty years, and making experiments for testing various theories during that time in a district in which Potatoes are a staple crop, he would scarcely have asked a question of such a rudimentary character. It would be difficult to make the subject clear to him on paper, but easy enough to point out among growing crops in fields or gardens. He will find it out if he continue his experiments, the record of which is interesting, and the knowledge so gained will be of great advantage and save "broth."

His dictum that varied conditions should form the basis for conducting experiments with exactitude, and tabulating results with accuracy is somewhat novel. A number of varieties of Potatoes grown in the same soil, same climate, and the same way, is a fair way for comparison; and if in the course of time something is discovered that acts beneficially under all circumstances so much the better, but initial experiments must be based on as near as possible identical concrete conditions, or variations in results would be ascribed to differing causes. At Reading they can only be accounted for by alleged mistakes.

Mr. Whitehead Cousins is to be congratulated more on his assiduity in the experimental work in which he is engaged than on the appropriateness of his references. He ought to have known that "all" writers are not mere hashers up of what they can get of the work of others, and if he is a Potato dealer, as I am informed he is, his suggestive allusion to "fancy prices," would, to say the least, have been as well omitted. Prices, high or low, have no bearing on the case. Perhaps he knows that crops of Potatoes varying from 10 to 14 tons (Ware) per acre have been secured this year without "broth," and I think he knows one grower at least who has produced them. On the contrary, it is probable that disease ravages might have been materially restricted by the application of remedies properly applied and repeated as necessary at the right time. Yet there can be no doubt whatever that the raising of varieties, substantially of a disease-resisting nature, has been of enormous value to both growers and consumers.

In some cases sulphate of copper, both in liquid and powder form, has been of distinct service applied to Tomatoes, but in other cases there have been practically no results. If its failure is the outcome of blunders, let those be sought for and pointed out in the interests of all who are interested in the subject. It is easy to make mistakes both in working and writing.]

## ROYAL HORTICULTURAL SOCIETY.

OCTOBER 27TH.

SCIENTIFIC COMMITTEE.—D. Morris, Esq., in the chair. Present: Dr. Hugo Müller, Professor A. H. Church, Rev. W. Wilks, Dr. F. Oliver, Mr. McLachlan, Mr. F. D. Michael, and Dr. Masters.

*Primula Mould*.—Mr. Massec reported upon a specimen submitted

to him for examination from Mr. Wolley Dod. The mould in question is *Ramularia primulae*. It has occurred in various parts of Europe, but is believed not to have been previously recorded from Great Britain.

*Water Plant*.—The capsules sent by Mr. Barr from Constantinople were ascertained to be those of *Iris pseudacorus*.

*Pear Spot*.—Mr. Hinds sent a Pear with irregular depressions on the surface, corresponding to a black patch of decay within, and probably of fungus origin. The condition is familiar to Pear growers in the case of certain varieties, but little is known of the inducing causes. It was referred to the mycologists at Kew for further examination and report.

*Wallflowers with Clubbed Roots*.—Specimens were exhibited in which the roots presented a similar appearance to that of "clubbing" in Cabbages. It was suggested that the condition was due to the presence of a Myxomycetous fungus rather than to insect agency. The specimens were accordingly sent to Mr. Lister for report.

*Hunting Spider*.—Rev. O. P. Cambridge reported on a spider received from the Royal Botanic Garden, Kew, on more than one occasion, and called by Mr. Cambridge *Salticus citus*, though possibly identical with *Hasarius adansonii* of Sauvigny. It is a native of Amboina and other parts of the tropics. The Kew example is an adult male; the female is stouter and of a dull brown hue. The species is partially naturalised in the hothouses at Kew, and is interesting from its agile habits.

*Fog Investigation*.—Dr. Francis Oliver announced that he was working with the Manchester Committee, and to whom a moiety of the Government grant had been made over. In or about London six stations were established where definite quantities of air were collected and analysed.

*Miscellaneous Exhibits*.—Dr. Masters showed a cone of *Abies Webbiana* imperfectly branched at an early stage of its existence, so that the apex of the cone was two-lobed, and the whole cone more or less twisted on its own axis from the check to growth experienced by the union of the two branches. The same gentleman showed specimens of *Heuchera* sp., in which not only were leaf buds formed at the apex of the leafstalks, but also along the sides of the withered flower stalks. An examination of the vascular cords of the leafstalk showed that whilst throughout the greater part of their length they were three in number, one central and two lateral, at the apex of the stalk they formed a perfect ring as in a true stem.

## NOTES ON SOME OF THE NEWER ROSES.

It has been a very bad season for testing or giving a definite opinion upon any of the newer Roses, as many of our old established favourites failed to show their best characteristics. Even Marie Baumann, generally considered to be one of the most reliable of all H.P.'s, has this year grievously failed to reach its usual standard with me, and any new Rose which has not come up to our expectations ought, therefore, to be allowed at least another season before it is finally condemned.

### HYBRID PERPETUALS.

*Augustine Guinoisseau* (Guinoisseau, 1889) is fairly spoken of as a white La France. It is not quite white, but sufficiently so to prevent its giving the La France impression at first view. In this it differs much from the two other new forms of La France—Duchess of Albany (W. Paul, 1888) and Duchess of Leeds (Mack, 1888). These are both darker than the type, and cannot, I think, be considered improvements upon it, for those who grow La France for show know that the lovely silvery sparkle of a perfect specimen constitutes its chief charm. One would recognise at once the two darker forms as being related to the type, but less bright, and Duchess of Leeds is also a weaker grower. Augustine Guinoisseau will certainly not supersede the original, as we have many nearly white Roses, but only one La France; in every other respect, however, it has the good qualities of the type, and seems well worthy of culture.

*Edouard Hervé* (E. Verdier, 1884) is not a new Rose, but I mention it here because, though it is well spoken of by those who know it well, it will not do at all with me. The eight or ten plants I have grown capitally, but the blooms are about as poor "as they make 'em," and I will have no more of it.

*Germaine Caillot* (Pernet, 1887) is a Rose of which I have a high opinion. It cannot be called free flowering, as it is a thoroughly dwarf grower, but with robust and stout stems. The petals have a lovely sheen in fine weather, but it is a hopeless sort in such seasons as the past one. It does not like being covered over, and will not stand rain, so 1891 had to do without it. I quite expect to see it shown finely when (if ever) a dry Rose season at last arrives.

*Gloire de Lyonnaise* (Guillot, 1884) is a Rose which was going to be a yellow H.P. After a year or two we heard a bad account of it, and when I had two or three plants I put them in an out-of-the-way place, with no manure and little care. Here, however, they have made better plants, and given finer and better flowers, every year. I have had one or two lovely blooms, quite fit for show if they would "stand," which they

will not do at present. The colour has been a bright paper-white with me, but I saw a half-opened bud at Mr. Frank Cant's, which was decidedly of a pale yellow. It seems to me to be an improving sort.

*Gustave Piganeau* (Pernet & Ducher, 1889) is a Rose which, having been finely shown, has been much talked of, and probably largely propagated this year. For a very full-sized flower it has a better shape than Ulrich Brunner, and a large majority of the blooms seem to come uniformly good. I see it is marked "very vig." in one of the best catalogues, but my two or three plants (maiden) have been of quite moderate growth, and have made but little wood. Undoubtedly a very fine Rose, and one of the best of its year.

*James Brownlow* (A. Dickson, 1889).—A stout, but by no means a free grower with me, that must, I fear, be reckoned as one of the few failures of the Irish firm which has given us so many excellent novelties. It seems a fresh shade of colour, but the few flowers I have had have been coarse and ill-shaped, and "one more chance because of the bad season" is all I can say for it.

*Jeannie Dickson* (A. Dickson, 1890) is of a very different type indeed. As is a handsome lady to a rough coalheaver, so is Jeannie Dickson to James Brownlow. The very leaves seem to speak of refinement, and the blooms are first-class in every way, though possibly wanting in stoutness of centre in hot weather. A fine autumnal, for I cut a lovely specimen on October 5th, and as I survey my budded stocks my sole source of dissatisfaction is that I have not propagated more of this charming variety.

*Lady Arthur Hill* (A. Dickson, 1889) is a fine handsome grower with grand foliage. I have found the blooms a little disappointing, being generally smaller than one would expect from the growth and foliage. This has perhaps something to do with my treatment, for Beauty of Waltham, the seed parent, either does not do justice to me, or I do not to it; at any rate, the result is seldom satisfactory. There is, nevertheless, decided quality in Lady Arthur Hill, the petals being smooth and of stout substance, and the blooms having capital staying powers.

*Lady Helen Stewart* (A. Dickson, 1887) is another Irish Rose of which somewhat the same may be said. It is a good grower, but not so stiff and strong or fine in foliage as Lady Arthur Hill; much darker in colour, and again hardly up to first-class form in size. The blooms of both these Roses are rather inclined to be flat—i.e., they have not the long petals and high centre of Jeannie Dickson.

*Madame Henri Perreire* (Vilin, 1886).—This Rose has been well shown, and I believe it to be good. My plants bloomed at a time when every Rose was much below par, and in an ordinary season I should have been disappointed with it. It is of rather a common colour, but seems sufficiently distinct.

*Madame Joseph Desbois* (Guillot, 1886).—Th's being a white Rose, easily damaged by rain, was quite spoiled this year with me. The petals are fine, though sensitive, and the blooms are of very large size, but rather loose and deficient in staying qualities.

*Mlle. de la Seigliere* (Maindron, 1886).—A very fine grower with me, but the flowers are not of first-class shape, being somewhat of the cupped form. It is a little like Madame Eugène Verdier outside, and that class of Rose will often do injury to a refined stand.

*Marchioness of Dufferin* (A. Dickson, 1891).—I did not see this Rose as shown at Hereford, but I saw those at the Crystal Palace, and I have two plants, one of which has bloomed. Here, again, the perfection of shape seems to be the lacking quality, the "globular form" being carried rather to an extreme in the specimens I have seen. The blooms are of ample size, and the growth seems good, but I fear there is some tendency to mildew.

*Margaret Dickson* (A. Dickson, 1891).—I have seen no blooms of this but those which have appeared in public, but I hope that we shall be able to retain the very high opinion that was generally formed of it last year. It was stated in the last issue of "The Rosarian's Year Book" that the foliage of this Rose, being stout and almost leathery in character, will be certainly a strong resister of mildew. The argument seemed a strange one. I do not think we know anything of mildew that will warrant such a conclusion; on the contrary, the stoutest foliaged Rose we have, Her Majesty, is notoriously the most liable, while Général Jacqueminot and its allies, which have quite thin leaves, enjoy almost as much immunity as any. As a matter of fact, Margaret Dickson is, I fear, decidedly susceptible to mildew. The plants I have have suffered from it, and some strong run-out shoots from budded stocks have been badly attacked. Nevertheless, I quite hope and believe that this Rose will be decidedly our best white H.P.

*Monsieur Trievoz* (Schwartz, 1888).—This is a Rose of good growth and fine foliage, very much like Comtesse d'Oxford. There may be a sufficient variation in colour to mark it as distinct, but I unfortunately missed seeing at their best the two or three good blooms I had.

*Mrs. Paul* (G. Paul & Son, 1891).—I am sorry not to be able to report on this Rose. That it is a grand grower, and a flower unique in its way, may be taken for granted. I have some grown-out shoots which are untouched by mildew.

*Salamander* (W. Paul & Son, 1891).—I was disappointed at seeing no specimens of this Rose at the Crystal Palace this year. I hope it will prove worthy of its name, and able to stand the fire of a hot season.

*Silver Queen* (W. Paul, 1887).—This is much like Queen of Queens to a casual observer, and a good season is required for a better comparison.

*Souvenir de Rosieriste Gonod* (Ducher, 1889).—There is no doubt

whatever as to the power of growth possessed by this Rose. Two great rows of maidens at Mr. B. R. Cant's were a sight for their luxuriance, and a wonder in that they had no sign of a bloom. A large majority of his cutbacks had also failed to flower. It appears to be a capital Rose when you get it, but not celebrated at present for freedom of flowering.

*T. W. Girdlestone* (A. Dickson, 1890).—This will, I hope, be better as a cutback. The growth and foliage are good, and the buds large, but all my blooms were coarse and of poor shape. One promised well, but the rain spoiled it. It is the sort of Rose which is likely to do better as a cutback.—W. R. RAILLEM.

(To be continued.)

## POTATOES.

A NOTE of mine on this subject in your columns last spring caused Messrs. Daniels of Norwich to send me several varieties of Potatoes for trial with the view of testing their adaptability for culture in Ireland. I grew them side by side, giving no special treatment other than that given to older kinds. Our soil is sandy with a decidedly moory tendency. The district is mountainy. Needless to add, I did not taste all in one day, but had them day by day, jotting down my opinion of them as soon as the ceremony was completed. I flatter myself that the cook's abilities are beyond question, and on that score they suffered no injustice.

**DREADNOUGHT.**—A singularly handsome disease-resisting Potato, a good cropper, but as an eating Potato the quality was only second rate; must try it another year.

**KING KIDNEY.**—This proved a fair cropping variety with large tubers, very floury, and of excellent flavour when cooked. A few had hollow centres; a good disease-resisting Potato, admirably suited for culture in Ireland.

**REMARKABLE.**—Certainly a remarkable cropping variety with large and handsome tubers, well adapted for exhibition, and a splendid eating Potato. This kind cannot be too strongly recommended for culture in Ireland, being the very thing for the peasant's "haggard."

**UNIVERSAL.**—An enormous cropper, and a good disease-resister, but does not cook well; I cannot, therefore, advise anyone to plant it extensively. I shall, however, give it another trial.

**THE DANIELS.**—This variety, the result of a cross between Magnum Bonum and White Elephant, gave me an agreeable surprise, as neither of these varieties is of any use here either as disease-resisters or for eating purposes. Their "bairn," however, turned out like them in being an enormous cropper with large tubers of even size and handsome form and not a trace of disease; of first rate quality when cooked, being very floury, first rate exhibition Potato.

**DANIELS' TABLE KING.**—So far I must pronounce this variety the best of all. It is the most floury Potato I have seen in Ireland, and what is of equal importance it is of first rate flavour, very prolific, in size and shape a gem for the exhibition table, while not a diseased tuber was found when lifting them.

**THE BRUCE.**—This is another most excellent all-round Potato that everyone should grow. I hear excellent accounts from gardens in which the staple soil is clay.

**GOLDEN FLOURBALL.**—I must give this variety another trial, although its behaviour this year offers no great inducement to do so. It was a very light cropper, the tubers are very unshapely, but when cooked of excellent quality; no sign of disease among them. At present, however, I would not recommend anyone to grow it unless they have abundance of spare land. This is not a very good year for Potatoes, for although the crop is generally a heavy one the quality in many cases is very indifferent when cooked. Disease is as usual very prevalent among the staple varieties; it is therefore very satisfactory to find the kinds under notice so free of disease. Among the whole of them I do not think we have had a dozen diseased tubers.—R. WELLER, *Glenstal Gardens, Limerick.*

## THE PROPOSED NATIONAL AND INTERNATIONAL FRUIT SHOW IN LONDON, 1892.

A MEETING of horticulturists was held in the Cannon Street Hotel on Friday, October 30th last, at 3 P.M., Sir James Whitehead, Bart., in the chair, to consider the desirability of holding a National and International Fruit Show in London in 1892. There was a good attendance, the following being present—Mr. A. H. Smea, Carshalton; Mr. H. R. Williams of the Fruiterers' Company; Dr. M. T. Masters, Mr. John Wright; Mr. John Laing, Forest Hill; Mr. George Gordon; Mr. G. Bunyard, Maidstone; Mr. J. Douglas, Ilford; Mr. J. Cheal, Crawley; Mr. W. G. Head, Crystal Palace; Mr. H. Cutbush, Highgate; Mr. F. Sander, St. Alban's; Mr. Elphinstone, Shipley Hall Gardens, Derby; Mr. G. Reynolds, Gunnersbury Park Gardens; Mr. J. Hudson, Gunnersbury House Gardens; Mr. Cuthbertson, Rothesay; Mr. B. Wynne, Mr. H. Herbst, Mr. R. Dean, Mr. A. Dean, and Mr. Lewis Castle of the British Fruit Growers' Association, with several others specially interested in the subject who had been attracted to the meeting by the advertisements in the gardening papers.

The following report of the proceedings appears in the *City Press* for October 31st.

Sir James Whitehead, in addressing the meeting, said he had asked those present to meet him in order that they might discuss a very important subject. There would doubtless have been many more present that afternoon if it had not been for other engagements—he alluded particularly to the several friends who were visiting Mr. Haywood in

Surrey. He was, however, placed in a somewhat invidious position, because that meeting was not convened entirely on his own suggestion, but on the suggestion of a large number of horticulturists in various parts of the kingdom, but he felt that he could not do otherwise than call those together who were more interested than himself in fruit culture, which was saying a great deal. (Hear, hear.) They were probably aware that there was an opinion abroad that much was yet to be done in fruit culture, and the schoolmaster was abroad also, for the public were being educated to a great extent through the instrumentality of the united societies, which had done a great deal for the national welfare and the national prosperity. (Hear, hear.) He felt they might now take opportunity by the hand by promoting a national and international exhibition, and if it was the wish of that meeting that this should be done it could be arranged on probably the largest scale ever attempted in this country. (Hear, hear.) The Exhibition which was held in Edinburgh the other day was a very considerable success, but if the meeting decided that there should be a large exhibition held in London that exhibition, he ventured to say, would be an enormous success, and would probably surpass those which had been held before in this or any other part of the world. If the meeting decided upon promoting this exhibition they must commence at once, so that due notice should be given to the growers at home and those who were living in the colonies. It appeared to him desirable that a fresh face should be placed upon the exhibition, compared with the exhibitions which had been held in this country on previous years. In this matter he hoped every association would join hands, that there would be no jealousies whatever; it should not be connected with any particular association, and he hoped the work might be considered good enough for every man, whether he held a high position or a low one in the scale of horticultural science, to join in this cause. (Hear, hear.) As to a site for the proposed exhibition, there were several places where it could be held, such as the Crystal Palace or the grounds of the Royal Horticultural Society; but he was inclined to believe that if they wished to make it a great success it should be held in the heart of London, where railway lines converged, and where anyone residing in London or the suburbs could visit it without difficulty. (Hear, hear.) He knew there was a site on the Thames Embankment belonging to the Corporation, and assuming that the Corporation had not let that site for building purposes, or disposed of it in the interval between the present time and October, he had no hesitation in saying that, as a loyal body, and having shown a disposition to assist in the cultivation of fruit, the Corporation would assist them as far as they could. (Hear, hear.) He had taken one step with a view of sounding those in authority on the matter, and he spoke with some knowledge when he said if a proper application was made at the proper time there would not be much difficulty in securing this site without any cost or charge whatever. But it was necessary that a guarantee fund should be started, not that he expected any deficiency, but they must provide for any such emergency, and he thought he would be able to obtain very considerable guarantees from those who occupied the highest positions in the country. He would himself give a guarantee of £500. (Applause.) As to what should be done with the surplus, if there should be any, it was not a subject the meeting could discuss at the present time, but there were societies which were doing good work in fruit culture, and there were two charities more especially connected with the horticultural community, and therefore in the future it might be considered how far those societies had claims upon them. He did not desire in the slightest degree to occupy any position of prominence with respect to the proposed Exhibition, if it was felt by those present that other steps should be taken, and that someone else should be put forward—"No, no"—as President or Chairman of Committee. He could assure them that he would be willing to take a humble part in the efforts which would be made in bringing about a successful result. He hoped also that all present would pull together heartily, with a desire to promote an exhibition which would be worthy of their united efforts. Sir James then read several letters expressing regret at inability to attend the meeting, one being from the Rev. W. Wilks, the Secretary of the Royal Horticultural Society, who explained that the subject of the advisability of holding a Fruit Show on a large scale in London next year had been discussed by his Council, and the possibility of being able to hold this Exhibition on a vacant site on the Thames Embankment. Letters were also read from Dr. Hogg and Mr. Bruce Findlay, Secretary of the Royal Botanical Gardens, Manchester, promising to give their cordial assistance to the movement. Referring to the letter of Mr. Wilks, Sir James said he had no idea that the Royal Horticultural Society intended moving in this matter, and with regard to the site on the Embankment he had reason to believe that no application had been made to the Corporation by the Society. Whatever was done they should not oppose that Society, because he wished its members to join them in the movement. He had put down a few points which he thought might be considered by the meeting, and these were that the title of the Exhibition should be the National and International Fruit Exhibition; that it should take place in October, and that it should be kept open for nine or ten days, and that the arrangements for carrying out the same should be on the broadest basis—(Hear, hear), and that the Royal Horticultural Society, the Fruiterers' Company, the Royal Agricultural Society, the Gardeners' Company, the British Fruit Growers' Association, and all provincial horticultural societies should be called upon to assist.

A somewhat lengthy discussion ensued, in which various details connected with the proposed Exhibition were discussed. One or two

gentlemen took exception to the title of International, contending that the exhibits should be confined to British home-grown fruits, although they admitted that it was only in a very small way in which foreign-grown fruit took the lead, and that that fact was owing to a better climate abroad.

Mr. Smee then moved the following resolution: "That in the opinion of this meeting it is desirable to take advantage of the prevailing enthusiasm in the cause of fruit culture in order to promote a National and International Exhibition in London next year, and that efforts should be made to combine with it popular lectures and demonstrations for the practical education of the people in profitable fruit culture." This resolution, which was adopted, was seconded by Mr. J. Wright, and supported by Mr. H. R. Williams, Mr. Cheal, Mr. Bunyard, Mr. Herbst, Mr. Cuthbertson, and others. Mr. Williams, in the course of his remarks, referred to the success which had attended fruit culture at Highgate and Hornsey, and strongly condemned any attempt to exclude foreign products, because he felt sure the public would be well able to judge of the superiority of English grown fruit when placed side by side with that imported by the foreigner. (Applause.)

Sir James Whitehead concurred with these remarks.

Mr. Douglas said he had been asked to move the following resolution from the Royal Horticultural Society: "That the Royal Horticultural Society are ready to cordially co-operate in holding a Great National Fruit Show in 1892 on the understanding that the horticultural arrangements of the Show should be left to the Society, whose members comprised nearly all the fruit experts in the United Kingdom."

Sir James Whitehead, however, thought that societies should sink their individuality in this movement. Referring to statistics on English fruit culture, Sir James said he was pleased to see that there had been an increase during the past twelve months in the extent of fruit culture of 13,600 acres, and during the past three years the total increase had been 27,000 acres. (Applause.)

It was afterwards moved by Mr. Laing, and seconded by Mr. Wynne, and resolved that a provisional committee should be appointed to formulate a scheme for carrying out the object of the foregoing resolution, and report thereon at a future meeting. And it was further resolved that the Royal Horticultural Society, the Fruiterers' Company, the Royal Agricultural Society, the British Fruit Growers' Association, the Gardeners' Company, and the other horticultural societies should be asked to co-operate in the movement. One member from each of the above-mentioned societies, and a member of the Corporation and six other gentlemen, will constitute the provisional committee, with Sir James Whitehead as the Chairman.

On the motion of Mr. Williams, seconded by Mr. Crute, a hearty vote of thanks was accorded to the Chairman for presiding.

It was stated before the meeting had dissolved that nearly £1000 was already promised for the Guarantee Fund.

## CHRYSANTHEMUM SHOWS.

HAVANT.—OCT. 29TH AND 30TH.

THE eighth annual autumn Exhibition was held as usual in the Town Hall, and was the most successful yet seen in this town. It would be difficult indeed to find in another town such grand cut blooms as was exhibited here from so small a district, but much encouragement is given to growers in the neighbourhood. The Committee is almost entirely composed of gardeners, ably led by Mr A. Chignell, and right well they do their duty.

Cut blooms demand first notice, owing to their superior quality right through, the competition being exceedingly keen. The premier class was for thirty-six distinct varieties, half to be incurved and the remainder Japanese, and for which a silver cup and a money prize was offered for the best stand, with suitable second, third, and fourth prizes. Although there were but three competitors, the display was remarkably good. Mr. A. Payne, gardener to Mrs. Ernald Smith, The Oaks, Emsworth, was placed first by the superior weight of the incurved blooms in the back row, which were of grand proportions, fresh and neatly staged. The Japanese were good also, though some were rather thin. The names were:—Madame C. Audiguier, Mdle. Laercix, Val d'Andorre, Soleil Levant, Volunteer, Etoile de Lyon, Puritan, Mrs. C. Wheeler, A. H. Neve, Condor, E. Molyneux, Annie Clibran, Sunflower, Madame B. Pigny, Mons. Bernard, Avalanche, W. H. Lincoln, and Stanstead White. Incurved:—Queen of England, Lord Alcester, Jeanne d'Arc, Golden Empress, Lord Wolseley, Empress of India, Mrs. Heales, Violet Tomlin, Miss M. A. Haggas, Prince Alfred (extra fine), Golden Queen of England, Princess of Wales (the best bloom in the stand), Alfred Lyne, Mrs. S. Coleman, Nil Desperandum, Jardin des Plantes, Mr. R. Mudie, and Mrs. Naish. Mr. Agate, Havant, was a capital second, the Japanese being perhaps a trifle better than in the first prize stand. Very fine was Vivian Morel, W. H. Lincoln, A. H. Neve, Sunflower, and Stanstead White. Mr. Fuller, gardener to the Right Honourable J. Matthews, Idsworth House, Havant, was third, having good Japanese also.

Mr. Payne followed up his previous success by securing the leading position for both twelve incurved and the same number of Japanese, distinct, with admirable quality in both sections; the names were Princess of Wales, Lord Alcester, Queen of England, Golden Empress, Prince Alfred, Empress of India, Golden Queen of England, Lord Wolseley, Miss M. A. Haggas, Violet Tomlin, Mrs. Heale, and Mrs. Naish. Japanese—Madame C. Audiguier, Stanstead White, Stanstead Surprise,

Etoile de Lyon, Madame B. Pigny, E. Molyneux, Soleil Levant, Mdle. Lacroix, Annie Clibran, Avalanche, M. Bernard, and Puritan. Mr. Agate followed for second place in the former class; Mr. C. Steptoe, gardener to G. A. Gale, Esq., Horndean, third; and in the latter class Mr. H. J. Parrott, gardener to Mrs. Kincaird Smith, Wood End, took second place; Mr. Agate third.

The Anemone section were well provided for, no less than twenty-four being required in the leading class, and not less than twelve varieties. Mr. Agate was first with large, full centred, highly coloured blooms of Duchess of Westminster (two), Cincinnati (two), M. C. Leboeuz (two), Lady Margaret (two), Miss Margaret (two), Gladys Spaulding (two), E. C. Jukes, Mrs. R. Mudie, Dame Blanche (two), Fabian de Mediana (two), Ruche Toulousaine, Miss A. Lowe, Mrs. Russell, Citrinus (two), and Grand Alvéole. Mr. Steptoe a good second. Mr. Fuller third. Reflexed varieties were well staged by several exhibitors. Mr. Agate had the best—full solid blooms of the leading sorts, Messrs. Steptoe and Parrott following in the order here named. Mr. Agate was the only exhibitor of twelve Pompons—staged three blooms to a spray, and was awarded premier honour, so good were they. Single varieties were extremely well grown and staged by Mr. Agate, this section appearing to create so much interest that we append the names of the first prize stand blooms—Charming, Mrs. D. B. Crane, Effie, Bessie Conway, Oceana, Jenny Lind, Jane, Florence, Miss A. H. Bates, Elegant, and Charming. Mr. Steptoe second. Remarkably fine blooms were staged in the amateurs' division in all the sections, Mr. Horril, Havant, taking the premier awards in most classes.

A class was provided for the most tasteful table decoration of flowers, &c., which created much interest amongst the ladies to whom competition was restricted. With a capital design of lightly arranged suitable flowers, in which single Chrysanthemums and Grasses were the most prominent, Mrs. Conway, Havant, out-distanced her opponents, Mrs. Longcroft and Miss Chignell, who secured awards in the order named.

Groups of Chrysanthemums in pots were staged by three exhibitors, Mr. Fuller taking first place, closely followed by Mr. Roberts, gardener to E. R. Longcroft, Esq., Hill Place, Havant. Mr. Penford, gardener to Sir F. Fitzwigram, Bart., Leigh Park, Havant, had half a dozen specimen plants; not only neatly trained were they but well flowered also, to which a special prize was awarded. For a group of miscellaneous flowering and foliage plants Mr. R. Woodfine, gardener to Captain Boyd, Emsworth House, Emsworth, was first with a choice arrangement of suitable plants; Mr. Fuller second. Table plants were a distinct feature of the Show, so light and richly coloured were they. For six Messrs. Payne and Agate were first and second respectively.

Black Grapes were fairly well shown by Mr. Parrott in the class for two bunches with Gros Colman. Mr. Woodfine second. Apples were strongly represented by large and highly coloured fruit. For six dishes Mr. H. Budd, gardener to R. Sainthill, Esq., Rockbeare, Emsworth; Mr. Marriner, gardener to Colonel Thistlethwaite, Drayton, had the best pairs in six distinct dishes. Mr. Fuller had much the best vegetable in the class for nine varieties.

#### GOSPORT.—OCTOBER 29TH AND 30TH.

A NEAT, well arranged Exhibition of Chrysanthemums and other autumn produce was the fourth held by this Society in the Thorngate Hall. The competition in nearly all classes was keen, the prizes being well contested. Mr. Spencer had all the arrangements well in hand, and everything in readiness for the Judges in good time.

Groups of Chrysanthemums filled one side of the Hall, making a bright display. Mr. F. Davis, gardener to Mrs. Churcher, Gosport, was first with plants carrying medium sized blooms, neatly arranged. Mr. T. H. Watch, 44, Seafield Road, Gosport, second. Mr. G. Hawkins, gardener to E. Saphorne, Esq., Gosport, had the best six specimens, freely flowered and carrying good foliage, not too stiffly trained. Mr. A. Battershall, gardener to A. D. Cave, Esq., Newtown, second. Mr. T. H. Watch won first honours for six Pompons.

Cut blooms were staged in large numbers and of average quality. For twenty-four distinct varieties, twelve of each, incurved and Japanese, there was but one entry, Mr. Hawkins, to whom was awarded the premier prize; the blooms were rather undersized, but clean, fresh, and well staged. In the class for eighteen Japanese, distinct, Mr. Hawkins was first with a most creditable display. Mr. E. Foot, gardener to H. J. C. Martin, Esq., Gosport, second. The first prize for twelve reflexed blooms fell also to Mr. Hawkins for substantial specimens of leading varieties. Mr. H. Lee, Gosport, had the best Anemone blooms in six varieties, with substantial well filled centres, bright in colour; also he had the best Pompons in six bunches. Mr. Hawkins staged a capital collection of single varieties in the class for eight varieties, and took premier award. Bouquets of Chrysanthemums were as usual too stiff and formal to please the most ordinary person in matters of taste.

Apples and Pears made a good display. Mr. G. Hawkins had the best in the former section, followed by Mr. Groom, Stoke Road, but who reversed his position in the latter class, showing large, well coloured fruit of leading varieties. Mrs. Hawkins was the most successful in the vegetable classes, staging good dishes in the collection of nine varieties. Mr. F. Davis second.

#### KENT COUNTY.—NOVEMBER 3RD AND 4TH.

It is pleasing to observe that this Society is in a flourishing condition. The balance sheet from last season shows a balance of £31 to its credit at the bank, the greater part of this being profit on the last exhibition after paying £119 16s. in prizes. As a result of this a liberal

schedule was prepared for the present season, and this produced a most excellent Show in the Rink at Blackheath.

The exhibits were numerous, the competition keen, and the quality good. The blooms, as a rule, were remarkable for freshness and bright colouring, this being due to the early date. From this cause many flowers could be seen throughout all the classes not yet fully developed, especially amongst the Japanese.

The classes round which the most interest centred were first and second in the schedule. Class 1 was for a group of Chrysanthemums arranged for effect in a space not exceeding 50 square feet, and the prizes were £4, £3, £2, and £1. For these five competed, and some good groups were set up, the first prize going to Mr. Payne, gardener to T. Williams, Esq., who had a fine group, high quality of flowers and foliage being combined with excellent arrangement. Second, Mr. J. Rhoden, gardener to J. Vavasseur, Esq. Third, Mr. E. Trollope, gardener to Colonel E. Larking.

Class 2 was for thirty-six blooms, eighteen incurved and eighteen Japanese, distinct, the prizes being £8, £6, £4, and £2. This also brought five competitors, and some especially fine blooms were staged, the first prize being awarded to Mr. J. Doughty, gardener to Mrs. M. Tomlin. The competition between this and the stand from Mr. C. G. Whistle, gardener to — Goschen, Esq., who was awarded second, was very close indeed, only one and a half point dividing them after close scrutiny and careful pointing. The varieties in Mr. Doughty's stand were as follow:—Incurved.—Back row: Lord Wolseley, Lord Alcester, Alfred Salter, Golden Empress, Prince Alfred, and Empress of India. Second row: Miss Haggas, John Doughty, Princess of Wales, Violet Tomlin, Queen of England, and Mrs. Coleman. Front row: Nil Desperandum, Jeanne d'Arc, Lady Hardinge, White Venus, Refulgence, and Princess Beatrice. Japanese.—Back row: E. Molyneux, Avalanche, Stanstead Surprise, W. H. Lincoln, Gloire de Rocher, and Stanstead White. Second row: Maiden's Blush, E. W. Clarke, Boule d'Or, Madame Baco, Vivand Morel, and Mrs. F. Jameson. Front row: Mons. Bernard, Mdle. Lacroix, Madame J. Pigny, G. Daniels, Sarah Owen, and Mrs. Irving Clarke. Especially fine amongst the incurved were Miss Haggas, Violet Tomlin, Lord Wolseley, Golden Empress, and Nil Desperandum. Among the Japanese, E. Molyneux, E. W. Clarke, Sarah Owen, Mrs. Jameson, and Mrs. Irving Clarke. The second prize thirty-six contained in Japanese a grand corner flower (back row) of the new variety Vivand Morel, the finest bloom shown in this class.

The back row incurved in this second prize stand consisted exclusively of varieties of the Queen family, and were all broad petalled, deep, heavy flowers. The third prize in this class was taken by Mr. H. Shoesmith, gardener to M. Hodgson, Esq. Fourth, Mr. Leadbetter, gardener to A. G. Hubbuck, Esq.

In Class 4, twenty-four Japanese varieties, distinct, five competed, and here again the competition was very close, the first prize going to Mr. C. Blick, gardener to M. R. Smith, Esq.; second, C. E. Shea, Esq., The Elms, Foot's Cray; third, Mr. J. Blackburne, gardener to Jno. Scott, jun., Esq. The varieties in the first prize stand were:—Back row: Vivand Morel, Stanstead Surprise, W. H. Lincoln, Madame Maria Hoste, Edwin Molyneux, Etoile de Lyon, Stanstead White, and Mrs. E. W. Clarke. Second row: Mrs. F. Jameson, Avalanche, Madame C. Audiguier, M. Bernard, Sunflower, Alberic Lumsden, Gloire du Rocher, and Comte de Germany. Front row: Mrs. A. H. Neve, Jeanne Délaux, Japonais, Mrs. Irving Clarke, Mrs. J. Laing, Puritan, Louis Boehmer, and Vice-President Darquier. Vivand Morel and Mrs. E. W. Clarke formed two grand corner flowers (back row), and added greatly to the effect of the whole stand.

In the class for twelve incurved seven staged, the first prize going to Mr. E. G. Whittle; the second to Mr. J. Lyne, gardener to H. F. Tiark, Esq.; and the third to Mr. Doughty. With twelve Japanese ten competed. First, Mr. J. Blackburne; second, C. E. Shea, Esq.; third, Mr. J. Doughty. For six blooms of Avalanche eight competed, Mr. J. Blackburne being first with very fine flowers, remarkable alike for large size and extreme purity of colour; Mr. J. Doughty was second; and Mr. E. G. Whittle third. Class 9, six blooms of the Queen family, brought five stands. First, Mr. J. Lyne; second, Mr. E. G. Whittle; third, Mr. H. Shoesmith.

In the various classes for six blooms of one variety there was splendid competition, the quality being remarkably good all through, and forming in the aggregate one of the finest features of the Show. For six yellow Japanese Mr. C. E. Shea was first with Sunflower, Mr. J. Blackburne second with Sunflower, and Mr. Blick third with W. H. Lincoln. For six whites, excluding Avalanche—first, Mr. J. Doughty, with a grand box of Stanstead White; second, Mr. J. Blackburne; and third, Mr. S. B. Wheadon, with the same variety. For six Japanese in one variety, coloured, excluding yellows—first, Mr. C. Blick, with six magnificent flowers of Vivand Morel; second, Mr. J. Blackburne, with Etoile de Lyon; third, Mr. R. Leadbetter, with E. Molyneux. For six incurved, white—first, Mr. E. G. Whittle, with Empress of India. For six incurved, coloured—first, E. G. Whittle, with Blush Queen.

A class was also provided for twelve blooms of the Rundle family, which brought nine competitors, and a most interesting and pleasing display. First, Mr. R. Leadbetter; second, Mr. A. Tomlin; third, Mr. T. Cowdray. Mr. C. Blick was awarded the prize for the premier Japanese bloom in the Show, winning with his grand corner bloom of Vivand Morel. The premier incurved bloom was Mr. E. G. Whittle's Queen of England.

With twenty-four blooms (eight Japanese, eight incurved, and eight reflexed) Mr. R. Leadbetter would have been easily first, but had

unfortunately staged two blooms of Golden Christine, and was thus disqualified. First, Mr. J. Mitchell; second, Mr. A. Tomalin. For twenty-four flowers (twelve incurved and twelve Japanese) H. Fincham, Esq., was well first; G. P. Black, Esq., being second; Mr. R. J. Allen third. With twelve Japanese varieties, distinct—first, Mr. Payne; second, Mr. H. Hazell; third, Mr. E. H. Meggs.

Table plants were a very fine display, excellent in quality throughout. First, Mr. C. Lane, gardener to E. H. Coles, Esq.; second, Mr. H. Hazell, gardener to R. W. Mitchell, Esq.; third, Mr. J. Cooke, gardener to — Park, Esq.

Messrs. J. Laing & Sons (Forest Hill), W. Cutbush & Son, and local florists contributed effectively in furnishing the building with Palms and other plants. The arrangements were excellent, and the conduct of the Show such as could only be effected by able and active officials.

#### BRIGHTON.—NOVEMBER 3RD AND 4TH.

FAVoured by brilliant sunny weather, such as frequently renders "London by the Sea" so delightful a resort when the metropolis is buried in a most depressing gloom, the Brighton and Hove Chrysanthemum Society's ninth annual Exhibition was opened on Tuesday last. The Dome and Corn Exchange near the Royal Pavilion were, as usual, the chosen sites, and whether in number or quality of exhibits, the Show compared most satisfactorily with those previously held. There is always a charming freshness and vitality about these Brighton shows that prove the importance of the town as a horticultural centre, and also testify to the skill of the cultivators in the district. The Society is well managed by practical energetic business men, and the large share of success which has attended their efforts is amply deserved. A Society that can secure 500 entries and an attendance of 10,000 visitors, as was the case last year, is evidently performing appreciated work.

The Corn Exchange is an uncommonly spacious oblong building, and was on this occasion devoted to the groups of Chrysanthemums, the miscellaneous plants, the fruit, and vegetables, with the larger classes of cut blooms. The Dome is a lofty and handsome building adjoining the Corn Exchange, with which it is in direct communication, and has an extremely fine appearance at night when brilliantly illuminated by the electric light. The orchestra was superbly decorated with foliage plants by Messrs. Balchin, tables of cut blooms were arranged round the sides, and behind these are the pyramidal specimen plants with capital effect. The Committee with their Chairman, Mr. Rupert Miller, and the able Secretary, Mr. Mark Longhurst, merit hearty congratulations upon the result of their work and the success achieved.

At the luncheon in the afternoon the customary compliments were paid to the Judges and officers; but advantage was taken of the large gathering of local horticulturists to introduce another more important matter. Special reference was made by several speakers to the foundation of the Brighton and Sussex New Horticultural and Mutual Improvement Society, the schedules of which were distributed on this occasion announcing the first Shows for 1892, to be held on April 5th and 6th, and August 30th and 31st. The Society is under good patronage with a strong Committee, Mr. W. Balchin, jun., as Chairman, Mr. J. Cheal as Vice-Chairman, and Mr. Mark Longhurst as Secretary. It is being well supported, and a successful career is expected. It was explained by Mr. Balchin that the Society was not instituted in any spirit of opposition, but because it was felt that a representative horticultural society was required in the district, and the support accorded and good wishes expressed were so encouraging that they felt assured they were on the right path. Brief speeches to the same effect followed from others, and it was evident that a very enthusiastic feeling prevails with regard to the work the new Society has undertaken.

With regard to the Chrysanthemum Show we can only give a few details this week. The principal class for cut blooms was that for forty-eight, twenty-four incurved, and the same number of Japanese, not less than eighteen varieties or more than two of one sort. In this there was a brisk competition, and six of the eleven entries were very close in merit. Ultimately the premier prize of £10 was awarded to Mr. W. Nevill, gardener to F. W. Flight, Esq., Cornstiles, Winchester, who had an even collection of clean, handsome, well-finished blooms, the incurved not large, but compact and neat, the Japanese excellent, bright and fresh. The varieties were as follows:—*Incurved*.—Miss M. A. Haggas (2), Prince Alfred (2), Mrs. Heale (2), Violet Tomlin (2), Queen of England (2), Mr. Brunlees, White Empress, Golden Queen, Novelty, Princess of Wales (2), Nil Desperandum, Lord Alcester, Jeanne d'Arc, Alfred Lyne, Mrs. C. Coleman, Lord Wolseley, Jardin des Plantes, and Refulgens. *Japanese*.—Stanstead White (2), Mrs. Wheeler, Mdle. Lacroix, E. Molyneux, Album Fimbriatum (2), Sunflower (2), W. W. Coles (2), Sarah Owen, Maiden's Blush, Etoile de Lyon, Avalanche, M. Bernard, W. H. Linden, Alberic Lunden, Bertha Flight, Pink Mdle. Lacroix, Puritan, Boule d'Or, and Stanstead Surprise. A good second was Mr. C. Penford, gardener to Sir F. Fitzwygram, Leigh Park, Havant, who had substantial incurved in his back row, and the blooms altogether were praiseworthy. The third prize went to Mr. M. Russell, gardener to Dr. C. Lewis, Henfield, and the fourth to Mr. Glen, gardener to Mrs. Montefiore, Worth Park, Crawley, all showing well.

For twenty-four Japanese, not less than fifteen varieties or more than two blooms of one sort, Mr. Glen took the lead with substantial bright blooms of the following varieties:—Stanstead White (2), Miss Wheeler, W. H. Lincoln, Sunflower (2), Meg Merrilics, Val d'Andorre, Etoile de Lyon, Mrs. F. Jameson, W. Tricker, M. Bernard, Puritan, Album Fimbriatum, Avalanche (2), Japonais, Madame C. Audiguier,

Baronne de Prailly, Madame B. Pigny, Boule d'Or, Mrs. F. Jameson, E. Molyneux, and Maiden's Blush. The other prizes in this class were secured by Messrs. Phillips (Meopham), Duncan (Warnham Court Gardens), and Standing in the order named. In other smaller classes for cut blooms the entries were numerous, the Japanese, incurved, reflexed, Anemones, and Pompons all being capitally shown, and some of the principal prizewinners were the following:—Mr. T. Glen; Mr. Emery, gardener to G. Megaw, Esq., Avoca; Mr. W. Jupp, gardener to G. Boulton, Esq., Torfield, Eastbourne; Mr. Sayers, gardener to Mrs. Cook, The Hall, Uckfield; Mr. Fowler, gardener to Mrs. Hall, Barrow Hall; Mr. Phillips, gardener to Dr. Baker, The Deodars, Meopham; with Messrs. Russell, Horscroft, Coleman, and Brockway.

The groups and specimen plants occupied considerable space, and were notable either for the tasteful arrangement or the fine quality of the flowers. Fruit—especially Grapes, Apples, and Pears—were excellently represented; vegetables were abundant and good; and miscellaneous plants, with non-competing exhibits, furnished considerable attractions.

#### IPSWICH AND EAST OF ENGLAND.—NOVEMBER 3RD AND 4TH.

THE annual Chrysanthemum Exhibition of this Society took place in the Public Hall, and proved much better than was generally anticipated, some remarkably good groups and fine blooms being staged, and the resources of the building were tested to their utmost to find accommodation.

Groups of Chrysanthemums arranged for effect were a capital feature. The best came from the Rev. H. A. Berners, Harkstead Rectory, Ipswich, whose gardener, Mr. G. Jordan, had fine plants, fresh, well grown and flowered, mainly Japanese; Mr. R. M. Miller, High Wood, Ipswich, was a good second; and two other prizes were awarded. The best collection shown by persons residing in the borough whose rental does not exceed a certain sum per annum, came from Mr. W. Rush, 16, Newson Street, Ipswich, the plants capitally grown and bloomed; Mr. George James, Tower Street, Ipswich, was second. The best collection of twenty plants came from Mr. H. Pooley, gardener to E. R. Turner, Clare Lodge, Norwich. All plants with three or four to seven and eight shoots, well grown and bloomed. Mr. J. G. Marshall, gardener to J. D. Cobbold, Esq., Holy Wells, Ipswich, was second, also with very good plants. Trained plants were somewhat poor, and in the class for four the first prize was withheld. The best single specimen was a plant of Mdle. Lacroix from Mr. Chenery, gardener to J. Limner, Esq., Constitution Hill, Ipswich; Mr. A. Somes, gardener to Major Howey, Woodbridge, was second.

Groups of plants arranged for effect made a pleasing feature. The best came from Mr. Somes, which contained some well bloomed plants of one of the winter flowering Salvias, a fine spike of Vanda cœrulea and other flowering plants, with charming Ferns, Crotons, &c. Mr. W. Beer, 31, Spring Road, Ipswich, was second, and Mr. J. G. Marshall third. Other plants included table plants, Chinese Primulas, and specimen Palms and foliage plants. Among the latter, and awarded the first prize, was a fine plant of Phormium tenax variegata.

The leading class for cut flowers was for twenty-four blooms, twelve incurved and twelve Japanese. Mr. W. H. Lees, gardener to the Duchess of Montrose, Sefton Lodge, Newmarket, was first with a fine exhibit, his incurved blooms being characterised by remarkably high finish. He had Miss M. A. Haggas, Lord Wolseley, John Lambert, Queen of England, Lord Alcester, John Doughty, Mrs. Coleman, Prince Alfred, Princess of Wales, Violet Tomlin, Mrs. Heale, and Jeanne d'Arc. Of Japanese he had very fine examples of Stanstead White, Sunflower, Condor, Mad. C. Audiguier, Avalanche, Gloire de Rocher, Gloriscum, William Lane, Etoile de Lyon, Mons. Bernard, Edwin Molyneux, &c. Second, Messrs. Saltmarsh & Sons, nurserymen, Chelmsford, with good varieties, in the main similar to those staged by Mr. Lees. Mr. Lees also took the first prize with twelve incurved blooms, very good indeed, and generally similar to those named above. Mr. W. Dance, gardener to Mrs. Lowe, Gosfield Hall, Halstead, was second. Mr. Dance had the best twelve Japs, having fresh, well coloured, and massive blooms of Vivian Morel, Sarah Owen, Etoile de Lyon, Boule d'Or, Puritan, Florence Davis, Mad. Baco, Stanstead Surprise, Gorgeous, Japonais, and Mad. J. Laing, &c. Second, Mr. A. Bishop, gardener to R. Burrell, Esq., Witley Hall, Bury St. Edmunds. In the amateurs' class for twenty-four blooms, twelve incurved and twelve Japanese, Mr. Dance was first again with fine incurved—Mrs. M. A. Haggas, J. Doughty, Emily Dale, Improved Golden Queen of England, Violet Tomlin, Princess of Wales, Mr. W. Coleman, and Mrs. Heale; and such fine Japanese as Criterion, Etoile de Lyon, Gorgeous, Vivian Morel, Boule d'Or, Avalanche and Sunflower. Second, Mr. Jordan, gardener to the Rev. H. A. Berners, with some capital blooms. Mr. Lees had the best twelve Japanese shown by amateurs, the flowers unnamed. Second, Mr. Boyles, gardener to R. B. Cabbell, Esq., Cromer Hall.

A silver cup, value 5 guineas, was offered by Mr. William Colchester for twenty-four blooms of Japanese, fed or grown with pure ichthemio guano. This brought a very fine stand of blooms from Mr. Dance of large size and well coloured, the varieties being Condor, Edwin Molyneux, Etoile de Lyon, Ralph Brocklebank, Baronne de Prailly, Mrs. Falconer Jameson, Madame J. Laing, Sarah Owen, Mdle. Lacroix, Comte de Germiny, Mrs. J. Wright, Mrs. E. W. Clarke, Louis Boehmer, Thunberg, Fair Maid of Guernsey, Val d'Andorre, Sunflower and Elaine. Second and third prizes were awarded in this class, though only the cup was offered by Mr. Colchester. There were also classes for amateurs not competing in the foregoing, in which some very good blooms were staged, but time did not admit of gathering up particulars.

A very good display of fruit indeed was staged. The best six dishes came from Mr. H. Rogers, gardener to Lord Rendlesham, Rendlesham Hall, who had excellent Alicante and Muscat of Alexandria Grapes, Coe's Golden Drop Plums, Doyenné du Comice Pears, King of Pippins Apples, and Melon. Second, Mr. J. Sheppard, The Gardens, Wolverstone Park, with a very close collection, but a little weak in Grapes. He had Golden Queen and Alicante Grapes, very fine; Coe's Golden Drop Plums, Louise Bonne of Jersey Pears, Cox's Orange Pippin Apples, and Melon. Mr. F. Cresswell, gardener to Geo. Charters, Stoke Park, had the best three bunches of Alicante. Mr. Sheppard was second with any other black, staging fine Gros Colman. Mr. Jordan was second with Gros Maroc. Mr. Lees was the only exhibitor of three bunches of Muscat of Alexandria; and Mr. Sheppard was first with any other white, having well finished Golden Queen.

Apples, both dessert and culinary, were numerous and very fine, and the same can be said of Pears. Vegetables were a great feature, being of the highest quality. A good collection of Apples and Pears was staged by Messrs. Daniels Bros., nurserymen, Norwich. The Ipswich Chrysanthemum Show always attracts a great company, and the Hall was completely crowded as soon as the Exhibition was opened to the public.

#### WATFORD.—NOVEMBER 3RD AND 4TH.

THE sixth annual Exhibition of the above Society was held in the Agricultural Hall of this town on Tuesday and Wednesday last, and proved in every way an unqualified success. The great improvement in the quality of the exhibits during the past year or two has been most noticeable, especially in the cut bloom classes, the exhibits of Mr. Beckett having acted as a great stimulus to others. On this occasion the cut flowers were better generally than ever seen at Watford, although there was a slight falling off in the groups.

In the open class for twenty-four Japanese Mr. Beckett, gardener to H. H. Gibbs, Esq., Aldenham Park, Elstree, was a good first with a remarkable stand of blooms, consisting of the following:—Viviand Morel (very fine), E. Molyneux, Boule d'Or, Etoile de Lyon, Gloire de Rocher (good), Baronne de Prailly, W. H. Lincoln, Stanstead White, Coronet, M. Bernard, Mrs. E. Beckett (new white), Mrs. F. Jameson, Beauty of Castlewood, Edwin Beckett (yellow, good), Louis Boehmer, Carew Underwood, Miss Neve, Mr. Freeman, Val d'Andorre, Madame Audiguier, Roi des Japonais, Avalanche, F. A. Davis, and Puritan. Mr. Cox, gardener to J. Trotter, Esq., Brickenden Grange, Hertford, was a good second. Third, Mr. Sturman, Queen's Road, Watford, a most enthusiastic amateur grower.

Five competitors entered for twenty-four incurved blooms, Mr. Cox just beating Mr. Beckett by a few points. His blooms were Queen of England, Lord Alcester, John Doughty, Lord Wolseley, John Lambert, Alfred Salter, Golden Empress of India, Jeanne d'Arc, Madame Darrier, Princess of Wales, R. Cannell, Miss Haggas, Violet Tomlin, Nil Desperandum, Mrs. Heale, Mrs. Coleman, Venus, Camille Flammarion, Queen of the Isles, Prince Alfred, Mr. Brunlees, Princess Beatrice, and Refulgens. Mr. Beckett had especially good blooms of Lord Alcester, John Lambert, M. R. Bahuant, and Madame Darrier. Mr. Neve, gardener to C. Van Raalte, Esq., Aldenham Abbey, Watford, third. Mr. Beckett, was successful with similar numbers, members only, first, with a very fine stand. Second, Neve.

The competition was very strong in the class for twelve Japanese, ten lots competing, all being good, C. E. Shea, Esq., Footsray, Kent, coming first with M. Bernard, Stanstead White, Boule d'Or, Viviand Morel, E. Molyneux, Ralph Brocklebank, M. Marrouh, Meg Merrilies, Sarah Owen, Puritan, Sunflower, and Madame J. Laing. Second, Mr. Neve. Third, Mr. T. Lansley.

With six Japanese, one variety, Mr. Beckett came in first with wonderful flowers of Viviand Morel. Second, Mr. Dinsmore, gardener to T. F. Blackwell, Esq., Harrow, with Etoile de Lyon. For a similar number white, Mr. Neve first; second, Mr. Debnam, gardener to A. Pears, Esq., Isleworth; third, Mr. Sturman; all with Avalanche. Some fine flowers were staged, incurved, of one variety, Mr. Neve first with six grand Miss M. A. Haggas; Mr. Cox second with Violet Tomlin. Mr. Turk, gardener to P. Bosanquet, Esq., Berkhamstead, gained first honours for twelve incurved, followed by Mr. Lansley. Mr. Beckett was awarded the prize for the best Japanese bloom in the Show for a magnificent flower of Viviand Morel, and for the best incurved bloom Mr. Brown, gardener to R. Henty, Esq., obtained the award for a very fine Empress of India. In numbers of other classes the competition was very keen, and the blooms generally of good quality, especially the Japanese.

Groups are not quite so numerous as last year. In the open class, to occupy a space of not less than 50 square feet, Mr. Ashdown, gardener to C. R. Humbert, Esq., Dell Field, Watford, is first with a nicely arranged group of good quality. Second, Mr. Tidy, gardener to W. K. D'Arcy, Esq., Stanmore Hall, Stanmore. For a group of similar size, restricted to members only, first Mr. Wilks, gardener to Mrs. Robins, Watford. Second, Mr. Brown, gardener to Lord Esher, Heath Farm, Watford.

Fruit and vegetables are shown in great abundance, especially the latter, and of excellent quality. For twelve varieties of vegetables Mr. Beckett takes the leading position in a very strong competition, this exhibit being so good that it was unanimously awarded the silver medal offered for the best exhibit in the Show. The same exhibitor also was again first for a collection of fruit, having grand black and white Grapes and Pine.

Not for competition.—Several groups were contributed, that from

Mr. Myers, gardener to Lord Clarendon, deserving of special mention, beautiful dwarf Chrysanthemums with Palms and other foliage and flowering plants, altogether a magnificent group. Mr. Darby, nurseryman, Watford, also contributed an extensive collection of both plants and cut flowers. Messrs. Cutbush, Laing & Sons, and several others also sent plants and flowers.

#### FINCHLEY.—NOV. 3RD AND 4TH.

ONE of the most attractive of the shows in the neighbourhood of London is undoubtedly that of the Finchley Chrysanthemum Society. Woodside Hall, North Finchley, in which it is held, is a lofty and well-lighted building, and the method of arrangement is as near perfection as is usually seen. Mr. Linfield and Mr. Bevan, two of the responsible officials, are to be congratulated on it.

The present year's Show was well in advance of its predecessors, both in point of quantity and quality. The chief class for cut blooms was that for thirty-six, eighteen Japanese and eighteen incurved, the first prize being a challenge trophy, to be won twice before becoming the property of the holder. There was a very close fight between Mr. W. J. Burch, gardener to J. Smith, Esq., Mill Hill, and last year's winner, Mr. Gray, gardener to W. B. Brand, Esq., Finchley, but a slight advantage with incurved, combined with better arrangement, gave Mr. Burch the victory. His Prince Alfred, Princess of Wales, Miss Violet Tomlin, and Alfred Salter were excellent blooms. Mr. Gray's Japanese were rather the better, his Edwin Molyneux, Avalanche, and Mons. Bernard being very good. Mr. Walker, gardener to C. Marshall, Esq., was third. Mr. H. A. Page, gardener to F. Crisp, Esq., won with twenty-four, an excellent stand, Messrs. Walker and Rutson, gardeners to H. Newman, Esq., being second and third. The prizes in this class were presented by the President, H. Hamilton, Esq., Messrs. Walker, Page, Gray, W. J. Burch, and D. M. Hayler, gardener to W. Hannaford, Esq., showed incurved and Japanese well in other classes. Mr. Burch had a delightful box of Elaine in the one variety class, and Mr. Gray received the N.C.S. medal for a beautiful half dozen of Avalanche. Mr. Walker, Mr. W. Green, gardener to Miss Wyburn, and Mr. Page showed large Anemones admirably, and in another class Mr. Green had a charming six of Lady Margaret. Mr. Page won with twelve Reflexed, a very good stand.

Mr. Eason, gardener to B. Noakes, Esq., won very easily with three specimens, the varieties being Bouquet Fait, Florence Percy, and Peter the Great, all fine plants splendidly flowered. He won in the single specimen class with a grand plant of Margot. Mr. Billington, gardener to E. Homan, Esq., and Mr. T. Carter, gardener to C. H. Clayton, Esq., had some good plants in other classes. Mr. Carter won with a group, his plants being very well arranged, healthy and finely flowered. Mr. Kine, gardener to Abbott Smith, Esq., was second, and Mr. Hayler, third, an extra prize going to Mr. Sandford, gardener to G. W. Wright, Esq. Messrs. W. Cutbush & Son, and Messrs. B. S. Williams & Son contributed attractive miscellaneous groups not for competition. Messrs. Cutbush's special prizes were won by Messrs. Walker, Rutson and Hayler, and those of W. White'ey, Esq., by Messrs. Hayler, Cook, gardener to J. B. Yute, Esq., and Billington.

#### FRUIT FORCING.

**PINES.**—At this time of year young plants are apt to become drawn and weak through the moisture so prevalent in our climate during the autumn months. As growth advances in young plants they should be placed so as to obtain all the light possible, the growth then is sturdy and well solidified. To effect that the plants must be placed near the glass and should be kept clean. Owing to decomposition the beds of fermenting materials subside considerably; fresh made beds of leaves, even when well trodden down, are apt to settle rapidly. Tan does not sink to anything like the same extent, but in either case attention must be promptly given to raising the plants so that they may have the full benefit of the light, and in doing this take care not to chill the plants or allow them to become overheated at the roots. This is important, for chilled plants start into fruit prematurely, and those burned at the roots become sickly. More injury arises from the plants being shifted about than many are aware. Prepare new beds when necessary, and the best plan, where the extent of glass admits of it, is to free all the pits of the plants, and not return them until the plants are in proper condition. Tan is much the best fermenting material for affording bottom heat to Pines; Oak and Beech leaves are more durable, and the heat from them is milder and lasts longer than any other.

**Arranging the Plants.**—It is a good practice to assist the plants at this time of year according to their respective requirements for the winter. Fruiting plants need the best places for swelling off their fruits properly at a time when natural means will not afford much assistance. The fruiting plants must have a night temperature of 65°, and 70° to 75° by artificial means during the daytime, losing no opportunity of admitting air at 80°, closing at that temperature. Successional plants require a

night temperature of 60°, and 65° by day artificially, advancing from sun heat to 75° or more, but air must be admitted between 70° and 75°. Suckers or stock not in fruiting pots must not be brought forward too rapidly, as they are not prepared to make growth until well rooted and have formed a sturdy base. They will progress satisfactorily in a night temperature of 55° to 60°, and 60° to 65° in the daytime, but avoid chills or anything likely to cause a stunted growth. As regards moisture, fruiting plants require a genial atmosphere at all times, therefore sprinkling available surfaces must be regularly attended to, and the plants will need syringing in a light house during bright weather two or three times a week. Succession plants will only require syringing occasionally, as they will derive essential moisture from the fermenting beds. Suckers will have sufficient moisture in moist pits with recourse to syringing.

**CUCUMBERS.**—Plants that have been in bearing some time can be invigorated by a top-dressing of turfy loam, to which has been added a little superphosphate and about a sixth of charcoal broken up small, surfacing with an inch depth of horse manure. This must not be used fresh or the foliage may be injured by the ammonia. Afford copious supplies of water, but let the soil be getting dry before any is given, then give enough to moisten the bed through, using it at the same temperature as the house. Thin the old exhausted growths and lay in young, by which means the plants will continue fruiting some time longer. The autumn fruiters are now in full bearing, and must not be overcropped, therefore remove the fruit as soon as it attains a fair size, and all deformed fruit when observed. Examine the plants at least once a week for the removal of bad leaves, stopping or cutting away surplus growths, keeping the foliage fairly thin, yet an even spread on the trellis.

Winter fruiters should be allowed advance well up the trellis before stopping them, training the side growths evenly, and not more closely than to allow of the foliage being exposed to light. Stop at a few joints of growth, or one or two joints beyond the show of fruit; but if the plants are weak allow more extension, and crop lightly at first. Remove all or most male flowers, and do not allow tendrils, but remove them as fast as they appear. Keep the bed replenished with soil, adding fresh and warmed as often as the roots appear at the sides of the ridges or killocks.

Maintain a night temperature of 70°, a few degrees less in severe weather, 70° to 75° by day artificially, advancing to 80° and 90° with sun heat. Admit a little air at the top of the house whenever the weather is favourable, affording it, however, without lowering the temperature, it being better to allow the temperature to rise a few degrees over the ordinary sun heat range than admit air to keep the temperature down when the sun is powerful and the external air sharp. Judicious ventilation is, however, highly beneficial in carrying off accumulated moisture and giving solidity to the growths, enabling the plants to tide over the trying ordeal of prolonged severe weather, when plants with thin-textured leaves often succumb. The syringe will only be necessary for damping the paths, walls, &c., in the morning and afternoon in bright weather, which will give rise to the needful moisture, especially where the evaporation troughs are kept charged with liquid manure. On bright afternoons a light bedewing of the plants will be beneficial, but care must be taken to practise it early and not make the foliage tender by its too frequent recurrence. All water used for damping, watering, or liquid manure applied to the roots must be of the same temperature as the house or bed.

#### THE KITCHEN GARDEN.

**BEET.**—This crop will not stand a very severe frost, and must therefore be either protected or stored at once. The leaves are more hardy than the roots, and if the latter are well mounded over with soil, these also will be uninjured in many winters. Lifting and storing, however, is the safest course to pursue, and this should be done as much as possible in dry weather, or when there is less likelihood of injury being done to the roots by reckless lifting or handling, breaking the thongs being followed by bleeding and a consequent loss of colour. Fork rather than pull the roots out of the ground, and trim off the tops, but not too closely, or bleeding from the crown will result. A cool dry shed is the best place for storing, but the roots must be packed in sand or fine soil, crowns outwards, or otherwise premature shrivelling will take place. Shed room being limited store the roots in conical heaps in a cool dry place, where neither rats nor mice are plentiful, covering with straw litter and banking over with a good thickness of poor soil. The Turnip-rooted forms are the worst keepers, and should be the first used. Extra large roots of any variety, and the former are rather numerous this season, to be given to the pigs or cows, these not paying for storing with the rest.

**CARROTS.**—These have ceased to grow, and may well be lifted and stored at once, or otherwise the formation of root fibres may recommence. These, again, should be carefully forked out of the ground, damaged roots keeping badly. Roughly clear off soil, and cut off the tops rather closer to the crowns than was advised in the case of Beet, and store similarly. Late sown crops to be left where they are, as these will continue to increase in size, and can be drawn as required for use. Horn Carrots, notably the Nantes and Guerande, store and keep admirably, and if fully grown should be treated similarly to the Intermediate and Long Orange sections, but if they are still growing leave them undisturbed, as Carrots are always more tender and sweet when cooked soon after being lifted. Those sown late in frames and pits to have plenty of air, and not to be much crowded, or they will form top growth only.

**OTHER ROOT CROPS.**—Parsnips, Salsafy, Seorzoner, Chicory, and Jerusalem Artichokes keep much the best when left in the ground till wanted for use, or as in the case of Chicory till required for forcing. A few of each might be lifted in anticipation of extra severe frosts, but if instead of this a part of the beds were heavily covered with straw litter it would be possible to dig at all times according as required. Main and late crop Tomatoes have been fit for lifting for some time past, but the weather has been all against such work, especially where the soil is of a heavy clinging character. The crops are perfectly safe where they are for some time longer, and dry weather ought therefore to be waited for before lifting the bulk of the Potatoes. It is particularly unwise to trample on heavy or clayey ground while it is in a wet state. When the tubers are forked out of the ground most of those diseased will be easily separated from the rest, and may well be well mixed with fresh lime at once. All the sorting over needed should take place before the tubers are stored, the alternative of deferring this to a convenient time during the winter not having anything to recommend it. Let quite the smallest be placed on one side for the pigs, select rather more medium sized tubers than are usually required for planting, and the rest can be stored separately for consumption during the winter, either in a cool dry shed or in a heap in the open. Warm cellars and dry rooms are quite unsuited for storing Potatoes of any kind, these causing premature sprouting and shrivelling, while if they are placed in cool sheds they must be kept quite dark, and be further protected whenever severe frosts are imminent. If ridges in the open are formed select a dry cool place for these, and cover the tubers first with 9 inches of poor dry soil, and then give a thick thatching of straw, this being a far better plan than placing the straw next to the Potatoes. The tubers intended for planting next season ought from the first to be stored thinly in light and cool positions, warmth and dark promoting an undesirable and most injurious early sprouting. Protect from severe frosts, and take advantage of wet weather to set all the Ashleafs up in trays or shallow baskets, sprouting end uppermost.

#### PLANT HOUSES.

**Allamandas.**—Plants required for early flowering should be kept dry at their roots to harden and ripen them. They will rest better in a temperature of 55° than in the stove, but on no account should they be kept too cool. Water may be withheld until they flag, but do not allow the wood to shrivel. Young plants raised from cuttings in the spring should be kept rather dry until the end of the year, when the unripe wood can be removed and the plants placed into larger pots. The temperature advised will suit these well; they need not be dried to the same extent as older plants, the roots of which will require to be reduced by one-third.

**Dipladenias.**—These should be thoroughly cleaned if infested with insects, and rested in a temperature of 60°. They will bear without injury the temperature advised for Allamandas. Water with care during the period of rest. They may be kept rather dry, but should not become so dry as to injure their roots. When these plants can be planted out where they can enjoy a temperature of 55° during winter and have a warm moist treatment, fully exposed to the sun during the spring and summer, they will be found to grow much more luxuriantly than when confined to pots. Young stock in small pots can be kept slowly advancing; they rarely do well if rest is forced upon them in their early stages. Water them carefully, and keep them in a warm house.

**Amasonia punicea (calycina).**—Keep these growing in a temperature of 60° to 65°; if retarded or starved in their present condition they will fail to develop their crimson bracts and creamy white flowers. If gentle bottom heat can be given them all the better. Water carefully, but do not allow the soil to become dry. This plant requires greater care at this period of its growth to do it well than at any other time.

**Cyanophyllum magnificum.**—If plants with large bold foliage are needed they must not be allowed to suffer by the want of root room. When confined in small pots the foliage at the base soon becomes disfigured. Repot all plants that need it. Use a compost of loam and leaf mould in equal proportions, with the addition of sand. Peat may, where plentiful, be substituted for the leaf mould. Grow these plants in the warmest part of the stove and syringe freely. If thrips exist in the house they are soon attacked if the atmosphere is allowed to become dry. Watch for these pests and destroy them directly they appear on the leaves.

**Tydeas.**—Grow these where water will not fall upon their foliage. They will do well on a shelf in the stove provided they are kept liberally supplied with water. Soot water in a clear state is beneficial to these plants. Gesneras may have the same treatment until they come into flower, when they should be arranged by themselves, or well elevated above other plants in an intermediate structure where the atmosphere is moderately dry.

**Francisceas.**—These should not be kept too warm, a temperature of 55° will suit them well. Keep them on the dry side to ripen and harden their growth. Even a temperature 5° lower will not injure them after their wood is firm if judiciously watered. They can be brought into flower in succession by introducing them into moist heat.

**Bougainvilleas.**—If these have been hardened and kept dry at their roots they may be removed to any cool structure where the temperature does not fall below 45°. A profusion of flowers depends upon the plants enjoying a complete season of rest and thoroughly ripened wood. This plant requires a longer season of rest than is necessary for the Allamanda, and will bear a much lower temperature without the slightest injury, providing its roots are kept dry. If the soil is wet about the roots while in a cool place the plants are almost certain to fail.

# THE BEE-KEEPER.

## HONEY AT THE DAIRY SHOW.

AN exhibition of honey, &c., was recently held at the Agricultural Hall, Islington, in connection with the Poultry and Dairy Show, under the auspices of the Dairy Farmers' Association. The British Bee-keepers' Association gave £10 towards the prize fund, and arranged the schedule of prizes for the honey classes, and otherwise assisted in the arrangements for carrying out the Show. The B.B.K.A. have found that an exhibition of honey, hives, and appliances is not of itself of sufficient interest to attract large numbers of the general public. They have, therefore, wisely made arrangements with the Royal Agricultural Society of England, the Bath and West of England Agricultural Society, and with the Dairy Farmers' Associations for holding exhibitions in conjunction with them. These exhibitions have been a great success, and have done much towards educating the masses in the improved methods of bee culture. The season of the year at which the Royal hold their shows prevents many persons from exhibiting, on account of being too early for the honey harvest of the districts in which they live; and although exhibitions have been held as far north as Newcastle, Scottish exhibitors were conspicuous by their absence. The different county bee-keepers' associations have also taken

FIG. 77.—FIRST PRIZE EXHIBIT OF HONEY.

advantage of the horticultural or agricultural shows for the exhibition of the honey of their counties.

The National Co-Operative Flower Show at the Crystal Palace offer money prizes, and the B.B.K.A. give silver and bronze medals for honey. This Show, held in August last, was a great success in every way. Bee-keepers from all parts of the United Kingdom were represented in the most creditable way. Never have so many samples of splendid honey been brought together in competition, and had our friend "Lanarkshire" seen it he must have admitted that the teaching of bee societies and "modern bee-keepers" had done a great deal towards the perfection arrived at. The price realised for the honey in approximate 1 lb. bottles was 1s. each, the 1 lb. sections of comb honey about the same price.

The illustration (fig. 77) represents the exhibit to which the first prize was awarded in Class 66 for 1 cwt. of beautiful honey, tastefully arranged.

The Judges (Messrs. J. H. Hooker and W. Broughton Carr) made the following awards:—

Class 63, best twelve jars of extracted honey.—First prize, H. W. Seymour, Henley-on-Thames. Second, Jas. Munro, Forfar, N.B. Third, Wm. E. Little, Eastgate Row, Chester. Fourth, Levi Inwood, Uffington. Highly commended, W. Christie-Miller, Chelmsford; Matthew Whittle, Wantage; Major-General H. H. Lee, The Mount, Dinas Powis, Cardiff; Rev. G. W. Banks, Darenth; Thos. Badcock, Southfleet. Commended, A. Mayell, Bradwell-on-Sea, Essex.

Class 64, best twelve 1 lb. sections.—First, Wm. Woodley, Newbury. Second, The Cathedral Dairy Company, Exeter. Third, J. R. Truss, Ufford Heath. Fourth, A. Hounsom, Chichester

Highly commended, Hon. and Rev. Henry Bligh, Hampton Hill. Commended, Spencer Hancox, Wytham Mill, near Oxford; Hy-Wood, Lichfield, Staffs.; W. P. Meadows, Syston, near Leicester; E. J. Oaten, Porthcurnow, Treen, Cornwall.

Class 65, best twelve sections, any size.—First, Geo. Neighbour and Sons. Second, The Cathedral Dairy Company. Third, James Munro. Fourth, W. P. Meadows. Commended, Rev. G. W. Banks.

Class 66, best exhibit of honey in any form, not exceeding 1 cwt.—First, Wm. Woodley. Second, W. Debnam, Chelmsford. Third, The Cathedral Dairy Company. Commended, J. R. Truss, Stamford; H. Harvey, Hanwell, W.; Jabez Sopp, Crowmarsh, Wallingford; Chas. T. Overton, Lowfield Apiaries, Crawley.

In class 63 there were fifty-nine exhibits of beautiful honey (708 bottles in all).

In class 64 there were forty exhibits of 1 lb. sections of comb honey (480 sections). In class 65 there were eleven entries. In class 66 there were thirteen entries each, consisting of nearly 1 cwt. of honey. It will be seen that the honey to which prizes were awarded came from the extreme ends of the kingdom and was not confined to one district.—JOHN H. HOOKER.

## TRADE CATALOGUES RECEIVED.

Dicksons, Chester.—*Catalogue of Forest and Ornamental Trees, Evergreens, &c.*

Fisher Son & Sibray, Handsworth Nurseries, near Sheffield.—*Catalogue of Trees and Shrubs.*

Richard Smith & Co., Worcester.—*General Catalogue of Nursery Stock.*

Wm. Clibran & Son, Oldfield Nursery, Altrincham.—*Catalogue of Roses, Coniferæ, Shrubs, and Fruit Trees, 1892.*

J. E. Bourne, Longton, Staffordshire.—*Lists of Seeds for 1891.*

Frederick Roemer, Quedlinburg, Germany.—*List of Flower Novelties, 1892.*

\* \* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Rainfall (A. J. L.).**—Thanks for your notification. The weight of 1 inch of rain per acre is about 101 tons, and the volume about 23,000 gallons. The heavy October rains will do much good in high and dry localities, but have been calamitous in some low-lying districts.

**Screen for Flower Garden—Planting Hybrid Rhododendrons (J. G.).**—There is no shrub equal to the English Yew "to plant for a close hedge to screen flower garden from drive," and to be kept at a height of 6 to 8 feet. Thuja Lobbi makes a good screen, but it is not so accommodating as regards clipping as the Yew. Hybrid Rhododendrons are perhaps best planted during moist weather in September, or as soon after as the weather is damp, and the ground being then warm they push fresh rootlets. They may, however, be moved at almost any time when the soil is in good condition, as they lift with good balls, but early autumn and early spring are most safe. There is ample time to plant them this autumn; but avoid doing so in severe weather, and when the ground is sodden.

**Plunging Bulbs (S. B.).**—The pots may be placed anywhere in the open air on a layer of ashes or other base impervious to worms, and covered 5 or 6 inches deep with cocoa-nut fibre refuse. This is the best material, and is used by the most successful cultivators of Hyacinths for exhibition; but ashes, leaf soil, or old damp sawdust will answer the purpose very well. The pots should remain buried until they are filled with roots and the crowns have pushed to the length of from half to three-quarters of an inch. In withdrawing them they should not be at once exposed to the full light, but covered with moss or paper funnels for a time till the growths gradually assume a green hue; after this they cannot have too much light.

## HARDY FLOWER NOTES.

THERE are days when the lover of flowers is fain to keep within doors—days when the drip of the rain tells that outdoor work must be left undone, and to those who know of much to do the desire to be “up and doing” becomes difficult to resist. Experience tells us, however, that there is no gain, but loss in such work, when as Longfellow in melancholy words says :—

“The day is cold, and dark, and dreary ;  
It rains, and the wind is never weary ;  
The Vine still clings to the mouldering wall,  
But at every gust the dead leaves fall,  
And the day is dark and dreary.”

It is not fitting, though, that the spell of the dreary day should enthral us, and though, as the same great poet tell us :—

“The hooded clouds, like friars,  
Tell their beads in drops of rain,  
And patter their doleful prayers.”

Let us rouse ourselves from our dullness, and if need be wander into the garden with overcoat and see if these drenched flowers can bring us a message of cheer. Nor need we wander long—nay, from the window itself can be seen something to think of. There, still in flower, is the pure white *Anemone japonica alba*, with petals of virgin whiteness inside, touched on the outside with a blush-like tinge of red, with its many bright yellow anthers, and its button-like boss of greenish yellow. Near by is a plant of the typical *A. japonica*, one of Robert Fortune's introductions, which, although not so chaste as the white variety, is one of our cherished flowers. Fortune, in his “Wanderings in China,” mentions it as follows :—“The flowers which the Chinese plant on or among the tombs are simple and beautiful in their kind. No expensive Camellias, Moutans or other of the finer ornaments of the garden, are chosen for this purpose. Sometimes the conical mound of earth—when the grave is of this kind—is crowned with a large plant of fine, tall, waving grass. At Ningpo wild Roses are planted, which soon spread themselves over the grave, and when their flowers expand in spring cover it with a sheet of pure white. At Shanghai a pretty bulbous plant, a species of *Lycoris*, covers the graves in autumn with masses of brilliant purple. When I first discovered the *Anemone japonica* it was in full flower amongst the graves of the natives, which are round the ramparts of Shanghai ; it blooms in November, when other flowers have gone by, and is a most appropriate ornament of the last resting places of the dead.” If it thus is one of the last tributes of respect and of love paid by the Chinese to their lost friends, we may well also look upon it as one of the last tributes of Nature to the departed summer, and one, too, which has no fleeting summer's life only, but springs afresh from year to year to delight us with its beauty. Nor must we forget these few remaining *Gladioli*, the “Sword Flag” of the old writers ; while most are past some still remain, and need I say I prize them much. Strange is it that so few of the poets speak of them. Lord Lytton, however, says of one of the family :—

“And the small wild Pinks from tender  
Feather Grasses peep at us ;  
While above them burns on slender  
Stems the red *Gladiolus*.”

Is there not a golden lesson here for those of us who are forced to admit that the *Gladiolus* needs some groundwork, some setting in which to place the jewel, something from which the sword-like leaves and tall stems may rise and deprive them of the stiffness inseparable from them as usually grown ? Would not this groundwork of “small wild Pinks” and “tender Feather Grasses” be a charming setting for the bright crimson of *Gladiolus brecheyleyensis*, or the pinks, and salmons, and whites, and purples, and the streaks, and feathers, and spottings with which many of the varieties of *gandavensis* glow ? There are still some fifteen in flower in my garden, mostly seedlings of my own raising, among them a good white, slightly pencilled with purple. The raising of *Gladioli* from seed is so interesting, and withal so easy, that I am surprised it is not more followed by those who have sufficient time on their hands. Here, flowering in a quiet corner at the base of a rockery, is *Primula capitata*. For this flower the rain has no terrors, and gladly do we see its purple coronal surmounting its slender yet strong mealy stem. Very beautiful is this crown of small flowers of deep, almost blue, purple inside and paler purple outside. The leaves are of the usual primrose shape, averaging about 4 inches in length, tooth-edged and mealy underneath. It was originally collected by Hooker in the Sikkim Himalayas in 1849, and was found in gravelly soil at a height of about 10,000 feet. It is one of those flowers which might well share with its congener, the Cowslip, the honour of being a hiding place of the fairies. While it has not the “rubies, fairy favours” of the Cowslip, its tubulous flowers are extremely pretty, and doubtless some native legend is connected with the flower could we but know it.

Flowering freely in the rock garden is *Saxifraga Fortunei*, which, while not showy, is decidedly attractive, its white flowers looking particularly quaint on their tallish red stems above the bright green leaves. It is a native of Japan, and is said to have been introduced in 1863. It belongs to the same section as *S. sarmentosa*, the Mother of Thousands, and is very valuable from its late flowering habit. It is not considered very hardy, but I have grown it in the open without protection for about three years, and I know of a few gardens in which it has proved quite hardy. The *Tritomas* are still in flower, and nothing in the way of rain seems able to quench their flaming torches ; indeed, they seem to enjoy the moisture, and the manner in which their flowers are arranged on their bottle-brush like heads of flower is a great aid to their remaining in flower so long. The rain cannot reach the inside of the flower, and runs off on the outside. On the rockery a fine plant of *Hypericum reptans* still keeps well in bloom. To me there is always something peculiarly attractive in its pale yellow saucer-like flowers. I am an admirer of the genus, and there is a considerable diversity in habit and in the size and style of the blooms. Yet there is none prettier than this little species of *St. John's Wort*. To the beauty of the plant is added the charm of the connection of the *Hypericums* with ancient legends and superstitions. Few flowers are more widely associated with plant lore than the *Hypericums*. The *St. John's Wort* seems to have been a plant celebrated in heathen mythology. The Rev. H. Friend in his “Flowers and Flower Lore” tells us (page 147) that Baldur and Heindal the two “white gods” of Valhalla, who represent the sun, and whose peculiar epithet referred to the brightness of sunlight, were replaced by *St. John*. “Flowers with large sun-shaped discs, either white or golden yellow, were dedicated to Baldur, as the sun god, and it was in this manner that the *Hypericum* became the peculiar property of *St. John*, and as the ‘fuga dæmonum,’ was so powerful in repelling the works of darkness.” The little *H. reptans* is very pleasing hanging over a large stone where its bright green foliage and pretty yellow flowers about an inch across with the thread-like centre so characteristic of the *St. John's Worts*.

From the plant anciently dedicated to the “sun god” of

Scandinavia we naturally turn to the Sunflowers of our days. Like the sun itself their rays are now but few; in truth *Helianthus multiflorus maximus* is the only one still in flower, and although its flowers are at present far from lively looking, yet it lights up a dull corner somewhat. One wonders which of the Sunflowers it was that is the subject of Ovid's mythical legend of Clytie, who was, on being deserted by Apollo, turned into a Sunflower, and of whom Hood rather unfeelingly says—

“ I will not have the mad Clytie  
Whose head is turned by the sun.”

If we are to believe that the original Tournesol followed the sun in its course from east to west, then none of the perennial species I am acquainted with can claim the honour of being the transformed Clytie. The truth is it may not have been a *Helianthus* after all. I am afraid some of the practical readers of the Journal will be saying, long ere this is reached, *cui bono*? It is true none of us are prepared to admit the truth of these myths and legends, but all the same they give an added interest to the plants to which they refer, and flower culture should not be with us a matter only of soils and manures, of pounds, shillings, and pence; but should also brighten us with thoughts of long ago, and of the many quaint fancies regarding the plants cherished by past ages. Even if we can only smile at their legends and myths, is there no good in this? no good in these thoughts in gloomy days when “the world is too much with us”? It seems to me that the more the gardener—professional or amateur—knows of the legends, myths, and poetry of the flowers he grows, the keener will be his enjoyment of them, and the more will their beauty entice him.

But this is a digression, and there are still some flowers to speak of which I am unwilling to leave lest before another opportunity occurs King Frost should have entered the lists, and with his keen sword cut down his beautiful but feeble opponents, I must thus pass on.

A pretty little *Campanula* for the rock garden which has flowered for a long time is one that I have under the name of *C. hirsuta*, but which I have seen elsewhere under the name of *C. mollis*. It has pretty, hairy, heart-shaped foliage, and small drooping open blue flowers with white centre. It seems allied to *C. garganica*, but is not the variety known as *C. garganica hirsuta*, nor is it a variety of *fragilis*, being without the brittleness of the latter. *C. Hendersoni* is still in flower, and is one of the most valuable of the genus on account of its free blooming qualities. *Sedum spectabile* is very bright just now with its bright purple-like flowers, and it is so accommodating a plant that it ought to be met with everywhere. While it will live in a dry, poor soil it is seen to much better advantage in rich soil. If well treated it will develop enormous heads of good colour. It also makes a good pot plant. Brilliant still, and seemingly flourishing in the rain, is the beautiful *Potentilla nepalensis*, not by any means a new plant, having been introduced in 1822, but yet too seldom met with. It is of trailing habit, sending out long stems, which produce fine red-purple flowers at the ends, which are raised above the ground. It is seen to best advantage in a clump, and either on the level ground or the rockery is extremely beautiful. It is also known as *P. formosa*, and I observed it grown under the latter name in the grand collection of hardy flowers at Dickson's Nurseries, Chester, last August. The name *formosa* seems to have the precedence, but *nepalense*, which was, I understand, given by Hooker, seems in more general use. I have already said more than I had intended, but I cannot refrain from mentioning *Corydalis lutea*, which seems as if the rain was congenial to its nature. It has been in flower all the season, and at the end of October was a picture of beauty with fresh green foliage and golden pendent flowers. Other things would call for mention, but I must forbear. Auriculas and Polyanthus are sending up heads of flower, and are pointing out the lesson of hope for the future; hope that when the dark days now drawing nigh are over we shall enjoy a feast of beauty once more.

Thus we begin to realise something of the sublime thought of Keats in his sonnet to Homer:—

“ Aye, on the shores of darkness there is light,  
And precipices show untrodden green;  
There is a budding morrow in midnight.”

—S. ARNOTT.

## SUCCESSIONAL APPLES FOR AMATEURS' GARDENS.

[A paper by MR. W. GOARING, Weald Hall Gardens, Brentwood, read at a recent meeting of the British Fruit Growers' Association, Horticultural Club, Hotel Windsor.]

It is not my intention here in these brief remarks to enter into the system of growing and disposing of our most useful of all hardy fruit from a commercial point of view, but rather to confine myself to those about to plant in their own small private gardens individually. I will endeavour to point out to intending planters the best method of maintaining a constant supply from their own resources, leaving the large trade growers and salesmen to cater for the masses who have no means of growing their own fruit.

In a brief paper of this description it is impossible to enter minutely into the whole business of Apple production, but I will endeavour to place my ideas before you in a simple, practical manner. To make them as plain as possible I will divide my paper into four sections as follows:—1st, Selection of Trees; 2nd, Preparation of Ground, Planting and Pruning; 3rd, Fruit Room and Storing; 4th, Insect Pests, briefly touching upon each of them in the order named.

**SELECTION OF TREES.**—This may at first appear somewhat early in my remarks to refer to this most important point. Upon it depends the foundation of success or failure of the plants. By way of making a commencement it will be well for the intending planter to have a limited number of trees of approved sorts, and treat them well, rather than overstock himself at the commencement. Success with a few will probably result in the careful treatment of a much larger number in future years; but failure through having a larger number than can be skilfully managed will probably lessen the interest originally attached to them. Glowing ideas at first formed will not be realised owing to overwork, the idea of Apple culture for the use and pleasure of one's own family will probably be abandoned never to be repeated. With regard to the number of trees to be planted, much depends upon the means and requirements of the intending planter. Apples may be grown with success in several forms, but the four ways in which I find they answer best are as follows: bushes, espaliers, cordons and standards. For bushes I find the most suitable varieties with me are—for dessert—Early Margaret, hardy and good cropper; Red Astrachan, extremely handsome and a good cropper; Duchess of Oldenburg, hardy, exceptional cropper, handsome, moderately good flavour; King of Pippins, hardy, good grower, and a reliable cropper; Cox's Orange Pippin, undoubtedly the best of the dessert varieties for flavour; Sturmer Pippin, a most excellent late Apple. Worcester Pearmain, a large conical Apple very popular at the present time, bears on the points of the shoots, which must be remembered in pruning.

**For Cooking.**—Keswick Codlin, an old and popular Apple; Stirling Castle, extremely prolific, should be bought on the Crab; Ecklinville, large, and a good bearer; Potts' Seedling, a very heavy Apple, tree exceptionally dwarf and a good bearer; New Hawthornden, an excellent Apple, and good grower; Wellington, an exceptionally useful Apple, good cropper, cooks well, and is in use a very long time, and Lane's Prince Albert.

**For ESPALIERS** I find the following with me are suitable:—

**Dessert.**—Red Astrachan; King of Pippins; Scarlet Nonpareil, tree hardy and good bearer; Cox's Orange Pippin; Sturmer Pippin; Court Pendu Plat, a very late Apple.

**For Cooking.**—Lord Suffield, where the soil is warm; Cellini, sure cropper; The Queen, a handsome new Apple; New Hawthornden; Warner's King, a large heavy Apple; and Wellington.

**For CORDONS** I consider the following a good selection; they do well with me:—

**Dessert.**—Red Astrachan; Kerry Pippin, a useful early Apple; King of Pippins; Cox's Orange Pippin; Lady Sudeley, new and excellent; Sturmer Pippin.

**Cooking.**—Stirling Castle; Warner's King; The Queen; Cox's Pomona, a handsome Apple; Potts' Seedling; Wellington.

**As STANDARDS** I find the undermentioned do well:—

**For Dessert.**—Yellow Ingestrie, an attractive Apple; Worcester Pearmain; Fearn's Pippin, a good Apple, but the trees do not bear quickly; Duchess of Oldenburg; Cox's Orange Pippin; King of Pippins.

**For Cooking.**—Keswick Codlin; Potts' Seedling; Warner's King; Lord Derby, an excellent Apple; Ecklinville; Wellington

and Lane's Prince Albert. Several others might be added, but I have found the foregoing thoroughly reliable.

It is very interesting to have a trial ground in some convenient place. A large selection of approved sorts may be grown there, and will prove very interesting and instructive. Presuming the intending planter to have decided on the number of trees of each form he wishes to plant, his best plan will be to pay a visit to some well-known reliable nurseryman in the late summer months, and personally select his trees, taking due care to have them marked ready for delivery when the lifting season arrives. This plan of personally selecting the trees I regard of the utmost importance, for the following reasons:—You have the choice of the very best trees for sale; by selecting them early you practically insure early autumn delivery; and further, you have a good opportunity of comparing the merits of the different varieties, and forming an opinion on the ground of any new sorts that may have been recently introduced to commerce.

**PREPARATION OF THE GROUND, PLANTING, AND PRUNING.**—In my opinion the most useful of all trees for the moderate sized garden is the bush, which should, with few exceptions, be planted on the Broad-leaved Paradise. They may be conveniently planted by the sides of walks in rows about 6 feet apart and the same distance from the path. The ground should be trenched 10 or 12 feet from the walk and 18 inches deep or thereabouts, according to its nature, and drained if necessary. Holes should be dug at the required distance from each other, and from 12 to 18 inches deep, according to the nature of the soil. If the soil is wet they may be somewhat shallow, and if dry they may be somewhat deeper, but in no case must the tree be planted deeper than it was originally. The holes must be slightly higher in the centre and well covered with slates or brick rubbish to prevent the roots going downwards. At planting time a good stake should be in readiness to drive in the centre of the hole to secure the tree, also some good turfy loam, to induce the formation of fibrous roots. The roots should be carefully pruned with a sharp knife, making the cut on the under side to induce the new fibrous roots to start from the top of the old root, and ultimately become what are termed surface roots. Without these surface roots it will be impossible to succeed, as they are the first to take any nourishment that may be administered to the tree, also the warmth in the summer.

The trees should in most cases be shortened back to a wood bud, pointing outwards, before the end of the current year, in which they were planted. In my opinion, from my own experience, I believe one of the chief causes of canker in newly planted trees is the result of shortening back late in the spring. Severe and untimely pruning, I believe, induces canker if the operation is performed in the spring, when the buds are swelling and the sap is at work. It must either overflow by the wounded surface and cause weakness or it must stagnate, and when it does so, being partly in contact with the air, it becomes vitiated and the bark cankers and shells off, leaving a long dead stump, which requires to be cut off, and even then the wound is difficult to heal over, setting aside the loss of wood, of time, and perhaps the loss of the whole tree.

**ESPAIERS.**—This is a useful and economical type of tree for small gardens. They may be conveniently planted by the side of walks, about 4 feet from the walk, the ground having been previously trenched as for bushes, a post placed at each end of the line to be planted, and others at intervals of about 18 feet along the lines, and a hole as described for bushes dug midway between each of the posts. Strong wires should be strained along the posts at the same distance as the branches are apart on the espalier trees generally. Do not shorten these horizontal branches, but tie them in the full length for the time being; they will help to keep the tree in action, and may be shortened if necessary when the tree is at rest.

**CORDONS** require a more restricted method. A trench should be dug out about 18 inches deep and 3 feet wide, stout posts placed along the line as for espaliers, about 6 feet high; strain the wire tightly along the top, another about half way down, and one along the line of the posts near the ground. Tie long bamboos to the wires at an angle of 45° to 50°, and 18 inches apart. Plant one tree to each bamboo, and secure them as the work proceeds. These bamboos will be found to protect the trees from the wires, and will be found very handy for securing the leaders of the trees to, more especially if maidens are bought. It should be mentioned that the leaders of the trees should not be stopped if they can be induced to form spurs as they proceed in growth.

**STANDARDS.**—These are too often planted in a careless and slovenly manner, but if success is to follow the efforts of the planter the work must be well and carefully done. The ground should be broken up to a depth of 24 inches, good large holes dug for the trees, the injured roots carefully pruned with a sharp knife, and the whole of them carefully distributed in the hole, a stout stake

having previously been placed there in the centre, the tree securely tied to it before it is left, not, as is too often the case, left undone for the time being, and perhaps never done at all. As a result the trees bow to the ground with the wet and wind, and then our amateur cultivators wonder why their trees do not bear fruit. The trees should be shortened back when perfectly dormant, but do not defer the operation till late in the spring, or canker will assuredly follow. No time should be lost in giving all the newly planted trees a good mulching of decayed manure to prevent undue evaporation and protect the roots from frost.

**FRUIT ROOM AND STORING.**—How often, even in large well-known gardens, do we find a poor makeshift structure for the preservation of fruit, after all the expense and trouble of producing it. What credit is it to an employer, what encouragement to the grower? A good room efficiently constructed may be some little outlay at the beginning, but if properly done it will last as long as any of the surrounding buildings. I recently constructed one on the following lines, at the back of a north wall, some 45 ft. long and 12 ft. wide to accommodate fruits from newly planted trees; the ground was taken out sufficiently deep to allow of a doorway, 6 ft. 3 in. deep, at the same time giving a good pitch to the roof which is of thatch. The floor is of concrete throughout; there is abundance of ventilation at each end, and shutters to keep out frost. The windows open outside and the shutters inside. The shelves are of beech wood smoothly planed, with the edges evenly bevelled to prevent the fruit becoming bruised. The shelves on one side are 2 feet wide and 18 inches apart from top to bottom of the room; on the right I have one long continuous bench with bins underneath, to hold fruits in large quantities. From this room we, this year, had fruits until July, and have even now some Wellingtons in good preservation. In storing be careful to pick all fruits as they approach maturity; if they part readily from the tree the gatherer will be all right. Do not become alarmed at a few stray ones dropping from the trees. The period of gathering is a busy and interesting time for the grower, he has then as it were the reward of his labours for the past season. The fruit should be placed gently in shallow boxes with a layer of wood wool at the bottom to prevent them becoming bruised. None that have dropped or are in any way bruised should be placed in the store room with the good ones. Be careful to keep the varieties separate, and arrange the best as near together as possible, it will prove interesting to visitors.

**INSECT PESTS.**—A long paper might be written on this subject alone, as we do not yet appear to have any very definite authority as to the best means of eradicating them. The Royal Agricultural Society of England, in their Journal for June last, published a very interesting description of them, and gave some good sound advice which it would be well for the grower to make himself acquainted with. Speaking from my own experience the best and safest remedy which I have used is softsoap and quassia, one ounce of each to a gallon of water; boil the quassia until it sinks, afterwards adding the softsoap when cooling. A quantity of this mixture should be in readiness to use at once when the pests are first discovered and then at intervals of ten days afterwards for winter moth. Do not wait until they are actively at work, but remember that prevention is better than cure. The same remarks apply to aphides. They must be kept down, otherwise it is impossible for the trees to thrive, and in my opinion it is only by a constant and unremitting use of insecticides that they can be successfully dealt with.

### SHOULD ASPARAGUS BE MULCHED.

UNDOUBTEDLY giving Asparagus beds an autumn dressing of manure is a time-honoured practice, but that does not prove that it is right in all cases. There are plenty of instances where a good dressing of "fat" manure, duly covered over with soil from the sides and alleys between the beds, may be of some benefit, or at any rate are not injurious beyond destroying many side roots, the soil and subsoil be naturally light and well drained. When, however, heavier soils or those of a clayey retentive nature have to be considered, I must most unhesitatingly answer the question as to whether autumn mulching should be practised in the negative. It is my firm belief more Asparagus roots have been weakened or killed outright from excessive moisture during the winter than from any other cause. The roots, if not actually on the surface, defy the sharpest frost; but much moisture, and which is usually accompanied by low temperatures, proves too much for them. A heavy surface dressing of farmyard or other solid manures applied in the autumn have the effect of keeping the ground in a cold saturated state, and from which it will not recover for many months. If the roots do not perish outright they are inevitably weakened by the ungenial state of the soil, and in any case active growth is bound to be late. What, also, is undeniable is the fact that cold saturated ground is the first to suffer in a dry

season, surface-cracking being with the greatest difficulty prevented. Just now the ground is in an exceptionally wet and cold state for the time of year, and no vegetable will suffer from this excess of moisture and absence of sunshine more than Asparagus. To mulch the beds would, in our case at all events, only aggravate the evil, and from personal observation I am of opinion that there is not a single Asparagus bed within a radius of twelve miles that would not be better without than with a mulching of manure. When the surface of the beds are merely cleared of dead Asparagus growths and weeds, not being deeply loosened in any way, very much of the rain that falls passes away freely, the worms' runs greatly assisting in this desirable end; whereas if the surface is loosened it becomes most absorbent, and far wetter and colder in consequence. It is not manure so much as warmth and a moderate amount of moisture that Asparagus stands in need of, and I hold that heavy autumn or early winter dressings of rich manure is both wasteful and, as I have attempted to prove, injurious.

There are yet other objections to be urged against these mulchings of manure. Asparagus needs a free open surface in the spring, but if there is any clay in the composition of the soil excluding frosts it is a sure way of sealing over the surface. Exposed to all weathers, including winter frosts and March winds, the surface becomes well pulverised, and therefore more amenable to the form of surface culture I am about to advocate. Once more, however, let me repeat, no one need be afraid of any injury frosts may do the roots, as I failed to note the loss of a single plant last winter, and yet there was no mulching or protection of any kind afforded. Another advantage derived from leaving the surface of the beds uncovered is the check this must give to slugs. On clayey land especially the latter invariably prove very troublesome, and a mulching of manure gives them just the kind of shelter and breeding quarters that suits them well. I do not assert that slugs are easily caught napping by frosts, but on the contrary, they seem only too capable of taking care of themselves, burying deeply or otherwise working into snug quarters whenever severe frosts are imminent. One thing is very certain—they are always the most plentiful in beds that have been dressed with solid manure.

The question that now arises is this—If the beds are not to be manured in the autumn or early winter months, when are they to be attended to? Well, as I have previously stated, it is not such a vast amount of manure that is required, and in any case better results in most instances attend the application of artificial or special manures than by the use of solid manure. What is the use of applying so much solid manure when its effects are not unfrequently to destroy many roots and to poison the ground? My advice to those who have long adopted the plan I have condemned, unless indeed they are perfectly satisfied with the results, is to discontinue it for at least one season, being content to fork in a liberal dressing of newly slacked lime, three bushels to the square rod being none too much. The late Mr. Shirley Hibberd proved to demonstration that Asparagus is greatly benefited by a free use of lime or lime rubbish mixed with the soil, and most gardeners are well aware what an excellent corrective of sourness and over-richness an occasional surface dressing of lime proves. Salt would appear to be the only fertiliser other than solid manure that many growers think it necessary to use, but it is by no means indispensable; and if the soil is of a clayey nature applications of it are very likely to do more harm than good. It makes the clay run badly, and to hold far more moisture than is good for Asparagus. Guano is a far safer and, in many cases, a much more effective manure, two dressings in the spring, the last being given not later than May at the rate of 2 lbs. to the square rod, answers well, and so do several of the advertised prepared manures. Lightly forked or stirred into the surface there will be no waste, rains washing the quickly soluble parts down to the active roots well spread throughout the sweet and genial soil below. These manures, and the dressing of lime in particular, are very destructive to the slugs, and prevent the loss of many valuable early shoots, as well as the skinning of the stems of late reserved growths.

Asparagus crowns ought not to be located quite up to the surface, a depth of 3 inches or rather more of fine light soil protecting and otherwise improving the young shoots. Instead, therefore, of giving annual dressings of solid manure the better plan is to substitute the artificial or other manures already alluded to, followed by a good surfacing of fine light soil, such, for instance, as sifted old potting soil, leaf soil, spent tan, fine peat, old Mushroom bed manure, soil from the surface of Melon and Cucumber beds, ashes, fine mortar rubbish, all or a portion of them in mixture, drawing the line, though, at anything likely to be full of weed seeds. A liberal dressing of such material will exclude a certain amount of frost, thereby saving many early shoots, the latter and "grass" generally drawing up through

without any check, and he can be readily traced to the crowns and twisted off without injury to later growths. This loose material also proves an excellent preventive of rapid loss of moisture in hot dry weather.—W. IGGULDEN.

## NOTES ON SOME OF THE NEWER ROSES.

(Continued from page 392.)

### TEAS.

*Cleopatra* (Bennett, 1889).—As maiden dwarfs this Rose was disappointing. It very often came with a double centre, which always seems a great pity, and the second growth has been very weak—mere spray. I expect that it will be better, like many others, on standard stocks not too strong.

*Ernest Metz* (Guillot, 1888).—I am in hopes this will do pretty well as a dwarf. It was very little shown this year, but ought to come to the front next season, as it makes comparatively good growth, and a fair amount of buds for propagation can be found.

*Ethel Brownlow* (A. Dickson, 1887).—I am surprised that this is not shown more. The form of the flower is most excellent. It can be grown of sufficient size, and under favourable circumstances it makes good growth, but in this last respect it seems uncertain. I have lately cut some lovely buttonholes of this sort.

*Lady Castlereagh* (A. Dickson, 1888) must surely be dismissed as a failure.

*Madame Hoste* (Guillot, 1887) holds its own well. Of capital growth, large size, good form, and beautiful colour when shaded, its sole reproach is that it is rather too thin for hot weather.

*Madame Pierre Guillot* (Guillot, 1888).—This is too full a Tea Rose to come to any good in such a season as the past one. It appears to have good capabilities, and I hope we may see it in its true character next year.

*Mrs. James Wilson* (A. Dickson, 1889).—An excellent grower, of quite unique habit. My plants have all made strong secondary shoots this autumn. It is something like Marie Van Houtte in colour, but quite distinguishable. I have not, however, had any blooms that merited a higher title than "pretty," as it is not quite up to the mark in size, and barely perhaps of first-class form.

*Princess Beatrice* (Bennett, 1887), which, though hardly of full size, is very fine early in a dry hot time, has unusual "manners and customs" for a Tea Rose. It grows fast and strong early, blooms in June, and—*voilà tout!* The rest of the season it simply exists; a considerable percentage of the plants make no further move whatever, and under any circumstances that I have seen the secondary growth is very weak. In a less degree *Cleopatra* seems to have this habit; it is a very undesirable one, and strangely different from that of Tea Roses in general.

*Sappho* (W. Paul & Son, 1889).—I saw some nice blooms of this Rose at Mr. F. Cant's, but it was too late in the season to form a judgment of its qualities for exhibition.

Of the new Roses shown at the Crystal Palace Mr. W. Paul's *Corinna*, T., was, I thought, well worthy of notice. Some said it was like *Princess of Wales*, but it appeared to me quite distinct. It is not, I find, yet in commerce, and I hope Mr. Paul will show it again for the gold medal. Mr. G. Paul's *C. Gater* (H.P.) was bright, and is, I hope, good; but it looked like a weak grower. Lord Penzance's exhibits of hybrid Sweet Briars were interesting, but I was surprised to see the very little improvement made. Out of (I think) a dozen different hybrids no distinction from the common Sweet Briar was observable, except just the colour. Perhaps there is a desire to keep these hybrids single, but in addition to there being no increase in the number of petals there was no apparent advance in their size or stoutness. He exhibited, however, one hybrid—*Rob Roy*, a seedling from *Village Maid*, which was calculated to attract attention. Four or five flowers of it were shown, and all were very poor except one, and that was quite a good bloom of its sort. It was of the *Marchioness of Dufferin* shape—even, solid, and smooth. Had it stood alone it might have won commendation; but its companions (brothers and sisters) detracted much from its value.

Mr. W. Paul is issuing, from the American firm of Wood & Co., a Rose I have not seen—*Waban*, a darker sport from *Catherine Mermet*. Sports to a lighter shade are generally the best, but it is difficult to see how one from *Catherine Mermet* can be anything but a good Rose. Another American sport from the same variety—*Ruby Gold*, with a most attractive description—a "*Catherine Mermet*" with shadings of *Maréchal Niel* and *Old Gold*, is in one or two catalogues, but from inquiries I have made I think it has not yet bloomed satisfactorily in England. It is all very well to say a Rose is of the shape of our champion Tea (see "*E. M.*'s" analysis), but an actual *Mermet* with yellow shadings and blendings sounds grand indeed. Let us hope it will prove so.

It is gratifying to find an increasing number of English names every year among the new Roses, and that Great Britain with Ireland (long may they be united, at least in their love for the Rose) can now well hold their own against France and the continent.

## ROSE THE QUEEN.

I am sorry to have made a slip as to the raiser of this Rose. I thought it was introduced here from America principally by Messrs. W. Paul and Son, and they have generally been the foremost in presenting us with novelties from the other side of the Atlantic, so that we naturally look upon them as the introducers as far as we are concerned. The Bride is quite established as one of our very best Tea Roses, and I trust that Waban and Ruby Gold may prove equally valuable; but it is a great pity that the white sport from Souvenir d'un Ami should have two names, and if the matter cannot be arranged a new pair of duplicates should at once be added to the list of the N.R.S.—W. R. RAILLEM.

## TOMATOES OUT OF DOORS.

TOMATOES on the open walls have been a success this season. This fruit has become very popular and is in great demand, prices for it are high, and cultivation is extending. As money can be made by its culture every space on a south wall should be used. This has not been a favourable season, but with care we have managed to procure a fine crop of useful size Tomatoes.

The seed was sown on the 11th of February in stove heat; the seedlings were placed two in a pot, and finally in 8-inch pots. The soil was made firm with a stick, and they were also planted firmly when put outside. In April the plants were put in cooler pits and ventilated freely. In May they were placed in a cool greenhouse fully exposed to the sun, and kept there until the first week in June, when they were planted against the open wall, and trained to a single stem.

We have tried hardening them earlier outside, but the cold winds invariably experienced here at the end of May usually injured the plants. By keeping the plants in longer, some are in bloom and even set fruit, before being placed out, and we gathered a few ripe fruits at the end of August.

We have used a quantity, and have gathered the remainder to put on shelves in the houses to ripen. Sutton's Earliest of All is the only variety that we have grown of late years, but Conference will have a trial next year, as a round variety is preferred if found equally good in other respects.—GEORGE HARRIS, *Alnwick Castle Gardens*.

## VIOLAS.

MR. WM. DEAN'S interesting notes on the above in a recent issue will no doubt be welcomed by many, for at this season we generally try to find out any new varieties of merit with a view of improving our collections. I do not, however, think much improvement has been made during the last three years or so, for, as Mr. Dean justly remarks, "The newer varieties have little of the true Viola character, and too much of the Pansy breed is being infused." I do not wonder that "many inquiries are made as to what constitutes a Viola and a Pansy," for they are now so mixed in character that it is hardly possible to distinguish the one from the other; such varieties as Crimson King are neither more or less than an inferior Show Pansy.

We have the properties of the "Show" and Fancy Pansy clearly defined, and both have been so much improved by florists that we may say they have in their respective classes reached the ideal of perfection. This cannot be said of the Viola. Of course it is asserted by some that the Viola is not a florists' flower. But why not? There is no flower more popular or more useful. It has been taken in hand by the florist and improved, but no one has ventured to lay down the properties of a Viola. This in a measure no doubt keeps many from distinguishing them. Mr. Dean remarks, "Botanically both are Violas." True, but they are distinct species, as much so as *Viola odorata*, another species agreeing in the general structure of their flowers.

The present is perhaps a good opportunity of trying the subject under consideration, and those who are interested in the flower will perhaps throw out suggestions as to what constitutes a Viola. My own opinion is that the Viola pure and simple ought to be in character similar to *Viola cornuta*. The rays or pencilling to be the distinguishing feature, and all those that partake of the Pansy breed, and are of various colours, should be termed "Fancies," or hybrids, to distinguish them from the former, in the same way as the Fancy Pansy is distinguished from the "Show" varieties. I consider *Violetta* a true type of Viola, and probably the forerunner of a new and distinct race. It has one very important feature. It is as sweetly scented as the Violet. The seedlings I have raised from *Violetta* are also very fragrant and of the same distinct type, but differing in colour. This year I have been able to harvest a fine lot of seed, which ought to yield some novelties of the same character. It is a curious coincident that *Violetta* is the result of a cross between *V. cornuta* and *Blue Bell*—the two varieties mentioned by Mr. Dean as introduced long ago, and which suggested

the term Viola—as distinguishing a distinct type from the ordinary Pansy, and I believe if we take *Violetta* as our ideal, we will very soon get a collection of Violas that will not only assert a distinguishing feature peculiar to itself, but establish its right as one of the most popular flowers of the day.—GEO. STEEL, *Heatherslaw, Cornhill-on-Tweed*.

CYPRIPEDIUM YOUNGIANUM (C. CORNINGIANUM).

THIS handsome hybrid *Cypripedium*, which is a very distinct type, possesses a somewhat interesting history, for the same cross was made by two different firms, and when the plants obtained produced their flowers each received a special complimentary name.

FIG. 78.—CYPRIPEDIUM YOUNGIANUM (C. CORNINGIANUM).

Under the name of *C. Corningianum* a plant was submitted to the Orchid Committee of the Royal Horticultural Society on August 11th this year, when a first-class certificate was awarded for it. Concerning this, however, Messrs. J. Veitch & Sons, Chelsea, write as follows:—

"The *Cypripedium* referred to was raised by Seden from *C. philippinense* (pollen) and *C. superbiens* (seed). On flowering we named it in compliment to Mr. Corning of Albany, U.S.A.; but we subsequently found upon comparison that it agreed in all its essential characters with *C. Youngianum*, raised from the same parentage, and exhibited by Messrs. Sander & Co. at the R.H.S.

meeting, July 8th, 1890. The name *Corningianum* must therefore be dropped. We have not a plant in flower at the present time, but so far as we can recollect your representation of it is a very good one."

The flower is large, massive, and of a particularly bold appearance; the dorsal sepal broad, white, with greenish and purple prominent veins running from the base to margin. The petals are also broad and drooping, white and green-tinted, with dark crimson or purplish dots, and marginal rows of hairs. The lip is neat in form, greenish, with a polished surface and a light staminode. The white ground of the flower gives it a very distinct effect amongst hybrid *Cypripediums*.

### LEAF SOIL.

I do not think gardeners, as a rule, pay nearly enough attention to the storing of leaves for future use, especially where strong soil has to be managed. It is much more valuable than the bulk of farmyard manure, especially that from the cowhouse for land of the character indicated. I know that here without leaf soil it would be most difficult to succeed with the flower garden were it not for the liberal employment of leaf soil annually. With the aid of this and a small portion of peat we can manage to have a fair show in the beds. *Alternantheras* would not exist in the natural soil here, and to make as free with the use of peat as is desirable would prove an expensive matter.

The yearly decay of leaves in a natural way as described by "H. D." (page 279) make a fairly good substitute for peat for a variety of plants. In the beds devoted to carpet plants we would wish for nothing better than this annual collection of leaves decaying one upon another. When possible we mulch the surface of the herbaceous borders in the autumn with a compost mainly consisting of leaf soil, and which, lightly forked in in the spring, renders the surface in a capital condition the whole of the summer, not only for the benefit of the occupants, but for the ease with which hoeing is accomplished. Alpine plants on the rockery, too, we treat in a similar manner as to the mulching, and that it is beneficial the following season's growth amply testifies.

Then, again, with regard to shrubs and certain species of Conifer, were it not for a free use of leaf soil we should get along badly with the growth of these plants. For instance, the various *Retinosporas*, Hemlock Spruce, and several *Thuias* would scarcely exist in our natural soil. By freely employing leaves partly decomposed we are enabled to reduce the cost of *Rhododendron* cultivation fully one-half of what it would come to were peat even of a poor character solely depended upon. Our calcareous soil would mean a speedy death to these charming plants if used in the smallest quantity for them to grow in, it being a well-known fact that lime in any form is certain death to American plants.—E. M.

### AURICULA HOUSES.

A CORRESPONDENT, "M.," asks a question or two about the culture of Auriculas under glass. If a house is to be built expressly for them, I would have a span-roofed one, with north and south run, and placed where late and early sunshine could have full play upon it; the glass to come down to the level of the pots, and the ventilation to be very thorough in both the roof and sides. "M.'s" principal inquiry is, Whether Auriculas, for show purposes, can be grown in the same house all the year round? and I can answer that they may, even if the house has a full south aspect, and is of a lean-to description. I would not, however, choose one of this sort as an ideal home for the Auricula; nevertheless, the two houses in which I grow mine are of this aspect and formation, in lengths of 20 and 30 feet, and the glass comes down to the level of the pots. The plants on the back stages are some 6 feet from the glass in the rows most distant from it, but they approach nearer and nearer till the foremost on the front stages are pretty close to it. I find no perceptible difference in the growth of the plants at the back or front except this, that those nearest the back wall will turn slightly to the light; but this any plant will do, even in the open air, if there is a wall close behind it. The Auriculas, even on the front stages, will show a tendency to do this, and will incline to the point where the light is brightest in any kind of house. But the effect is easily corrected by occasionally turning the plants round. I have ventilation enough for anything in the lean-to's—for all the sides and fronts open from end to end—and there are long wide ventilating lights in the roofs with only 2 feet of solid glass between.

I did not build these houses expressly for Auriculas, but for several years past my Auriculas have never been removed from them at any season of the year, except some of the seedlings which

have to be planted out in the open ground till they attain to a large or flowering size, when they are potted and brought into the house to stay there if they are worth their room.

I would, however, particularly state that Auriculas in a house of sunny aspect all the year round will require distinctly more attention during summer than they would if from early in May to early October they could have a house with a cool exposure. Granted that care is constant and wise enough in either case, I find that they will do well in either situation, and what may seem rather curious is that I have quite as little autumn bloom in my south aspect houses as I used to have in my north aspect frames.

But situations, like circumstances, alter cases. I have never grown Auriculas out of Yorkshire. In a moorland and mountain air, and in a hotter and drier district, I should prefer having summer quarters for them in a north aspect house.

Points on which Auriculas will require greater watchfulness in houses of a sunny aspect are as follows:—The plants will want shading during bright sunshine from the middle of March till early in October. I do not believe in "permanent" shading for anything. A dull day is the very sunshine of shade-loving plants, and it is too bad to rob them of their richest light. Here the Auriculas are the near neighbours of the cool Orchids, and it is not much extra work to run the shading down over the hardy pets when protecting the complexions of the tender ones.

With Auriculas, as with Orchids, it is a great gain in coolness to have the shading material kept by some easy contrivance from touching the glass by a foot or so. Of course, in bright weather Auriculas must have every inch of ventilation on, unless there be also a high or drying wind. In such case the ventilation should be chiefly in the roof, taking care that the shading material is free of the glass. Green fly, always troublesome with Auriculas, is no less so in a sunny aspect, and will require much persecution, especially in a spell of hot weather. Thrips I have never seen on the Auricula in a cool or northern aspect; but ever since I once saw an attempt made by them on a plant here and there in my houses, I have during summer often added tobacco liquor with a little softsoap, which gives additional efficacy to the water with which I frequently syringe the plants in dry weather through the summer. Thrips attack the upper surfaces of the leaves, and both the inner and outer ones of the young hearts, and so are open to destruction from above by these means. But though syringing with medicated waters will destroy also all green fly reached by it, there are so many that will hide under the broad leaves that I have always found it necessary to dip Auriculas to free them completely from aphids.

Care in ventilation, in shading, in watering, in cleansing, are four things that require special looking to, if Auriculas are kept all the year round in a house with a southern aspect. But of these four points, there is, after all, only one (shading) which is not part also of the treatment of the Auricula under any circumstances.

As for houses "expressly built for" such and such plants, there is not so very much in it! I expect that plant houses change their trade and tenants much as they do shops, and other human tenements. By little internal arrangements for greater heat or coolness, and the display of what he professionally produces, the butcher may follow the baker, and the candlestick maker may come after them both. None of my plant houses were "built expressly for" anything. They have all changed tenants. The present Auricula houses used to be the home of my Peach and Nectarine pyramids in pots, and Fig trees dwarf in stature. These afterwards removed to the Tulip house, when the Tulips had done with it in June, and with the side lights let down, duly ripened their fruits, afterwards wintering in the open ground. One of my span-roof houses was originally a seminary for young Auriculas; for seedlings were brought up there, but now some of the cool Orchids have it, and the seminary is under plain frame lights. So also the East Indian and intermediate Orchid house is a mere continuation of a commonplace-looking structure that I put up for odd things in the way of curious or interesting tropical plants. Originally there was scarcely an Orchid in it, and now there is little else.

I have done without much *expressiveness* in the way of horticultural building. It was robbery by rats, who seriously took to stealing my Auriculas out of frames, that led me to think of the greater security of a house for them, and to make an experiment which I thought would both answer for the plants, and be much more convenient for the cultivator. Mr. Ben Simonite and I started together to grow Auriculas in houses. Of the plan and its safety some doubted, but I believe we were the first to try it.

Perhaps I may just briefly state this, in case the question should ever, at some far-distant day, be thought of floricultural interest when none could answer it for certain. Just as, in one of the late

Albert Smith's amusing books we find that another fact of momentous import has been lost to the world through being no longer traceable to its origin—namely,

"Mont Blanc is the monarch of mountains,  
They crowned him long ago;  
But who they got to put it on  
We don't exactly know!"

—F. D. HORNER, *Burton-in-Lonsdale*.

#### LIST OF SHOWS.

THE following are the dates of the chief Chrysanthemum Exhibitions to be held during November of which we have received schedules and advertisements:—

Thursday, Nov. 12th.—National Chrysanthemum Society, Royal Aquarium, Westminster.  
Thursday, Nov. 12th.—Birmingham, Bournemouth, Northampton, Swansea, and Croydon.  
Thursday and Friday, Nov. 12th and 13th.—Teddington, Wimbledon, and Ware.  
Thursday, Friday, and Saturday, Nov. 12th, 13th, and 14th.—Belfast.  
Friday, Nov. 13th.—Cheshunt and Hitchin.  
Friday and Saturday, Nov. 13th and 14th.—Eccles, Leicester, Sheffield, Tooting, and Monmouth.  
Tuesday and Wednesday, Nov. 17th and 18th.—Liverpool, Salisbury, Twickenham, and Diss.  
Wednesday and Thursday, Nov. 18th and 19th.—Spalding.  
Wednesday and Thursday, Nov. 18th and 19th.—Hull and Rugby.  
Wednesday, Thursday, and Friday, Nov. 18th, 19th, and 20th.—York.  
Thursday, Nov. 19th.—Wantage.  
Thursday, Friday, and Saturday, Nov. 19th, 20th, and 21st.—The Scottish Horticultural Society, Edinburgh.  
Friday and Saturday, Nov. 20th and 21st.—Stirling, Chorley, Bolton, and Stockport.  
Saturday, Nov. 21st.—Batley.  
Wednesday and Thursday, Nov. 25th and 26th.—South Shields.

#### CALLS AT CHRYSANTHEMUM NURSERIES.—ST. JOHN'S, PUTNEY.

CALLING here on the morning of the 2nd inst. I was fortunate in finding that veteran grower, Mr. Geo. Stevens, at home and busy amongst his favourites preparing for contest, but he was still sufficiently at liberty to extend a hearty greeting and warm welcome to a brother florist and Mum grower, and to show all he has in plants and flowers. Our friend G. S. is, as is well known, the hero of many a close contest in the show tent, and judging by the appearance of his plants and flowers he is likely this year to add fresh laurels to his crown. He has a grand lot of plants both for grouping and cut flowers in the best possible condition, very strong, with large dark green foliage, and large, fresh, very brightly coloured flowers. E. Molyneux, W. H. Lincoln, Avalanche, Wm. Holmes, Elaine, &c., are represented by great banks. The two first named are remarkably fine, better I have never seen. For late flowering great batches are grown of Ethel, Yellow Ethel, Golden Gem, and Princess Blanche. The last named is a favourite with Mr. Stevens, and he grows it finely. Incurved flowers are very fine, especially the Princess of Wales family. I noticed also some grand flowers, deep, massive, and very brightly coloured, of Sunflower (Japanese). Unfortunately the damp fiend has taken possession of many of his very best flowers, and is doing much mischief.

Chrysanthemums are not alone the flowers our friend does well, as is instanced by a long span-roofed house filled with a grand display of *Coelogyne cristata* and *Cypripedium insigne*, forty to fifty very large specimens of each for supplying cut flowers at Christmas in the most robust health, and all showing promise of a grand lot of flowers.

#### MR. N. DAVIS'S NURSERY, CAMBERWELL.

Many a pilgrimage is made to these well-known Chrysanthemum grounds by exhibitors and cultivators in quest of new varieties, and this season, at least, such pilgrims will not return unrewarded. Mr. Davis has a very fine collection of novelties now in bloom, both English and foreign raised, including many good seedlings raised by himself and flowering now for the first time. Vivian Morel, probably the best of last season's new continental varieties, is represented by some score or more plants carrying grand exhibition flowers. There will certainly be a great demand by exhibitors for this fine variety when it is more known. Comte F. Lurani is a very promising new Japanese of French origin which Mr. Davis thinks will also become a popular exhibition variety. The bloom is large, reflexed, with broad, somewhat drooping petals; colour a very pleasing bright pink, each petal edged with a broad stripe of light flesh colour. May Tomlin is a larger, brighter, and much improved Princess of Wales, a sport from that variety, and

will be in demand by exhibitors. Florence Davis is represented by some fine flowers. It is a grand addition to our best white varieties, and might fairly be termed a white Sunflower, as it has much of the build and character of that popular variety. Miss Haggas Improved is a sport from Miss Haggas of a much deeper and more decided tone of yellow. Miss A. Hartzhorn is a grand white, very pure in colour, and with fine broad waxy petals. It is a deep full flower, fine for exhibition, and very distinct. W. K. Woodcock is a seedling from Val d'Andorre, and similar in colour to that variety. It is an immense, deep, and very full flower, and will make a fine exhibition variety. The habit, like its parent, very vigorous but dwarf.—W. K. W.

#### THE WALKER CHRYSANTHEMUM CUP AND TUBE.

DR. GEORGE WALKER sends an illustration of this invention that was referred to on page 363 of our issue of the 29th ult. The appliance has been exhibited before and commended by the National Chrysanthemum

FIG. 79.

Society, and at the Crystal Palace. A sharp twist of the tube in the oval collar causes the wire to bite against the edge, and thus the blooms are fixed in any desired position.

#### ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 10TH.

It was not unnatural perhaps that the Drill Hall should present a somewhat bare appearance on this occasion in view of the numerous Chrysanthemum shows. The duties of all of the Committees were exceptionally light.

**FRUIT COMMITTEE.**—Present: Messrs. P. Crowley (in the chair), J. Lee, R. D. Blackmore, G. Bunyard, G. W. Cummins, J. Willard, C. Ross, W. Warren, T. J. Saltmarsh, G. Cliffe, G. Wythes, J. Hudson, G. Reynolds, Q. Lane, H. Balderson, G. Norman, J. Smith, Harrison Weir, W. Bates, and Dr. Hogg.

A collection of Pears came from the Society's garden at Chiswick, and there were sundry other dishes, Messrs. W. Paul & Son receiving a vote of thanks for a small collection of Apples and Pears. A cultural commendation was awarded to Mr. Myles, gardener to Lady Hutt, Apple Towers, Ryde, for a new Grape named Appley Towers, Gros Colman × Alicante. A first class certificate was awarded to

*Apple Chelmsford Wonder* (Messrs. Saltmarsh & Son).—A handsome and promising late culinary variety, large, skin clear yellow tinged with red on the more exposed side. An award of merit was made to

*Apple Atalanta* (Mr. C. Ross, gardener to Lieut.-Col. Eyre).—A bright yellow variety tinted with crimson. It is from Scarlet Nonpareil, and is said to be a strong and healthy grower and good bearer.

A collection of Carrots came from Chiswick, and Messrs. Dobbie and Co. received a bronze Banksian medal for Leek Dobbie's Champion and Parsley Dobbie's Selected, the former having fine stems blanched from 12 to 15 inches.

**FLORAL COMMITTEE.**—Present: Messrs. W. Marshall (in the chair), B. Wynne, H. Herbst, H. Cannell, J. Bennett Poë, H. H. D'Ombraïn, C. E. Pearson, W. Watson, C. Jeffries, T. Baines, C. T. Drucry, G. Paul, and John Fraser.

The exhibits here were very few. Messrs. Carter & Co. exhibited stands of new Chrysanthemums, and Messrs. Cannell & Sons staged blooms of Louis Boehmer, for which they received a Banksian medal. A collection of well-flowered Chrysanthemums came from the Royal Gardens, Kew. Messrs. Dobbie & Co., Rothesay, exhibited a charming stand of striped Marigolds. A dwarf, compact-growing *Richardia* named *æthiopica compacta* was sent by Messrs. Paul & Son, Cheshunt. From the Botanical Gardens, Cambridge, came *Porana paniculata*, an Indian plant now flowering for the first time, bearing loose clusters of highly perfumed flowers, and *Aristolochia grandiflora*. Mr. G. Wythes, Syon House Gardens, exhibited *Bignonia venusta*, and Messrs. Veitch and Sons Java *Rhododendrons* (vote of thanks). Mr. Smith, gardener to R. E. Warburton, Esq., Northwich, sent *Croton Mrs. Ussher*. The following received first-class certificates:—

*Stapelia gigantea* (Mr. C. Wood, gardener to Lord Hylton, Mersham).—A small specimen of the giant Carrion Flower, bearing two large expanded blooms.

*Gerbera Jamesoni* (Cambridge Botanic Garden).—A brilliant vermilion coloured species; the flowers gathered from the foot of a south wall overhung by glass.

*Rhopaloblaste hexandra* (Messrs. B. S. Williams & Son).—A valuable addition to the list of decorative Palms, the leaves finely divided and graceful.

The following received awards of merit :—

*Chrysanthemum Miss Bella Wilson* (Messrs. J. Carter & Co.).—An incurved of the Violet Tomlin type, deep rose suffused with grey.

*Chrysanthemum Holborn Rose* (Messrs. Carter & Co.).—A Japanese, with large well-formed bright rose flowers.

*Aster grandiflora* (Messrs. Barr & Sons).—Large deep violet-blue flowers, valuable because late.

*Chrysanthemum Col. W. B. Smith* (Messrs. Cannell & Sons).—A very distinct Japanese of the R. Cannell type; colour old gold tinged with bronze.

A silver Banksian medal was awarded to Mr. Wythes for a group of Chrysanthemums, and prizes for plants went to Messrs. E. Vince, Highgate Cemetery, and J. Weston, gardener to D. Martineau, Esq., Clapham Park.

ORCHID COMMITTEE.—Present: Messrs. H. J. Veitch (in the chair), H. M. Pollett, Hugh Low, E. Hill, F. Sander, H. Ballantine, Henry Williams, J. O'Brien, T. B. Haywood, A. H. Smee, and Dr. Masters. The display of Orchids was the most interesting in the hall. Mr. F. Sander exhibited *Cypripedium Malyanum* (Crossianum × Spicerianum). Messrs. B. S. Williams & Son, Upper Holloway, had a choice collection, including seedling *Cypripedium Adonis*, *C. Scegerianum*, *C. insigne aureum*, *C. punctatum violaceum*, *C. Dauthieri*, *C. Arthurianum*, *C. insigne albe-marginata*, *C. Morganiae*, *Cattleya Warocqueana*, and *C. labiata vera*. Messrs. Paul & Son, The Old Nurseries, Cheshunt, had a very interesting collection of *Cypripedium insigne* in varieties. Mr. H. M. Pollett showed *Cattleya labiata vera* and varieties of *C. Warocqueana*. The following received first-class certificates :—

*Cypripedium insigne Sanderæ* (Baron Schröder).—Petals and lip greenish yellow, dorsal sepal broadly margined with ivory white.

*Phaius × maculato-grandifolius* (Messrs. Veitch & Sons).—A garden hybrid. Sepals and petals bronzy salmon, lip brownish chocolate, throat veined with the same colour.

*Dendrobium Lecanum* (Messrs. F. Sander & Co.).—A new species. Flowers borne at the summit of long growths, sepals and petals white suffused with soft magenta, lip and throat bright velvety purple.

EVENTS OF THE WEEK.—The rush of the Chrysanthemum Shows is abating somewhat, but there are still some important events to be recorded. To-day (Thursday) the Aquarium, Birmingham, Bournemouth, Northampton, Swansea, and Croydon Shows will be closed, and Shows will be opened at Teddington, Wimbledon, Ware, and Belfast. On Friday, November 13th, Shows will be held at Cheshunt and Hitchin, Eccles, Leicester, Sheffield, Tooting, and Monmouth. In the approaching week exhibitions will be held on Tuesday and Wednesday, November 17th, at Liverpool, Salisbury, Twickenham, and Diss. Messrs. Protheroe & Morris announce several sales of bulbs and Orchids for the current week, amongst them being a sale of choice Orchids from Messrs. F. Horsman & Co., Colchester, on Friday, November 13th.

COUNTY COUNCIL APPOINTMENT.—Mr. Lewis Castle of the *Journal of Horticulture* and Hon. Secretary of the British Fruit Growers' Association, has been appointed chief instructor in horticulture by the Technical Education Committee of the Hampshire County Council. Mr. W. Palmer, late gardener to W. F. Hume Dick, Esq., has also been engaged in the same county, and the position he vacates at Thames Ditton House, Thames Ditton, has been filled by his former foreman, Mr. Waite.

PRESENTATION TO MR. OWEN THOMAS.—We learn that Mr. Owen Thomas was presented with a handsome silver-plated inkstand and a pair of candlesticks previous to his finally leaving Chatsworth with his family. This was subscribed for by the men (sixty in number) who worked under him, for the past seven and half years. This expression of respect and good feeling must have been most gratifying to Mr. Thomas, who has now assumed his new duties at Frogmore.

AT the ordinary meeting of the ROYAL METEOROLOGICAL SOCIETY, to be held at 25, Great George Street, Westminster, on Wednesday, the 18th instant, at 7 P.M., the following papers will be read:—"Report on the International Meteorological Conference at

Munich, September, 1891," by Robert H. Scott, M.A., F.R.S.; "On a New Self-recording Rain Gauge," by W. J. E. Binnie, B.A., Student Inst. C.E.; "On Wet and Dry Bulb Formulæ," by Prof. J. D. Everett F.R.S.; "Results of Meteorological Observations made at Akassa, Niger Territories, May, 1889, to December, 1890," by Frank Russell, F.R.Met.Soc.

BIRMINGHAM CHRYSANTHEMUM SHOW.—The great prize for forty-eight cut blooms at Birmingham Show, which opened yesterday (Wednesday), was won by Mr. Parker, Impney Hall, Droitwich, Mr. Cox, Elm Hall, Wavertree being second; Mr. Coombes, Himley Hall Gardens, Dudley, third; Mr. Gould, Bromborough, fourth; Mr. Blair, Trentham, fifth, and Mr. Townsend, Mytton Hall, sixth. There were sixteen competitors.

GARDENING APPOINTMENT.—Mr. W. Hunt, gardener to the Rev. H. Trotter, Ardington Vicarage, Wantage, Berks, has been appointed to the charge of Sir William Pink's garden at Shrover Hall, Cosham, Hants.

AN ATTRACTIVE FLOWER BED.—One of the most pleasing combinations of colour we have had this season was composed of blue Cornflower and white Mallow. The latter being the taller was planted in front of a long row of Weigela rosca and amabilis mixed, the Cornflower being planted in front of the Malva. Blue and white always associates harmoniously, no matter what flowers are employed. In our case the outer branches of the Mallow were allowed to mingle with the Cornflower with good effect too. Any two flowers which make such an agreeable contrast in the garden are at once appreciated.—E.

MR. JAMES HORNBY, The Gardens, Heslington Hall, York, writes:—"It may interest some of the readers of your valuable paper to learn that there is in the gardens here a specimen of the AGAVE AMERICANA VARIEGATA now in flower. The spike was first noticed early in the month of June whilst the plant stood outdoors. It has attained the height of 19 feet, has twenty-two side growths, containing some 1500 of its greenish yellow flowers. The first flowers opened five weeks ago, and there is still a quantity to open. This noble flower spike is not without its disadvantages, as a portion of the roof of the conservatory wherein it is growing has had to be made higher to enable it to fully develop."

OPEN-AIR TOMATOES AT NASH MANOR.—While on a visit to this old-fashioned but attractive place a short time ago I was surprised to see the crop of Tomatoes growing on the fruit walls there. The plants were trained on a wall facing south between such trees as Peaches, Nectarines, Apricots, &c. They were about 4 feet in height from the ground, completely laden with large even fruits of the varieties Laxton's Open Air, Large Red, and Wheeler's Prolific. Some of the latter were of great size. Every plant had three leaders from the ground, with, I should say, about 8 to 10 lbs. of fruit on every stem. The leaves were kept continually cut away to admit of every ray of sun to the fruit. They certainly reflect great credit on the enterprising gardener, Mr. Tebby.—J. D.

BOUVARDIAS AT HENBURY HILL.—When paying Mr. Smith of Henbury Hill a visit some few weeks since, I remarked the fine Bouvardias he had just lifted and potted from the garden. They were great plants, full of vigour and health, and when in flower must be well worth going many miles to see. I was a few years ago in favour of keeping them in pots until I first saw Mr. Smith's, when I was at once convinced that the planting-out system was far the best, and since then I have practised it with success. If more followed the practice noted in the *Journal* some months past, I am sure more would have fine healthy Bouvardias than is the case at the present time. The culture is simple. After potting, the plants are placed in a cold frame, and many of the finest specimens were only placed on the shady side of a greenhouse. A few miles distant, at Eastwood Park, Mr. Lippiatt adopts the same plan with equal success. I noticed there particularly fine specimens of Bouvardia Humboldtii, some of them masses of beautiful snow-white flowers. Anyone wishing to have fine plants, plenty of flower, and a long continuance, should try the planting-out system in the way already explained.—W. COATES, Darnhall Hall.

IN the *Revue Agricole*, published in Mauritius, M. A. Daruty de Grandpré gives an account of his attempts to raise SUGAR-CANE FROM SEEDS. The seeds were sent from Barbados by the Governor in March, 1890. M. de Grandpré planted them with the greatest care, and after five days was fortunate enough to obtain five minute seedlings out of the hundred seeds used. The young plants he raised did not all

prove equally vigorous, and he was able to save only one, which, at the time when his report was written, had formed a fine clump of twenty shoots with long ribbon leaves. "I believe," he says, "that we may with reason cherish the most sanguine hopes from the propagation of Sugar-cane from seeds—more especially if we try an intelligent system of cross-fertilisation of the varieties we possess—rather than by planting cuttings, which maintain without appreciable alteration the respective characteristics of the parent plants. Thus we shall be able to supplement the weak points in our best varieties of Sugar-cane by crossing them with others which are remarkable for the qualities it is intended to infuse into them, and we shall moreover obtain, by a process of selection, a cane rich in saccharine matter, which will enable us to compete successfully against the highly improved sugar-beet."—(*Nature*.)

— **DAHLIAS FOR CUTTING.**—Having observed in many gardens that no Dahlias are grown, I wish to call the attention of readers to the fact that where large quantities of cut flowers are required I would advise gardeners to grow plenty of the above, especially the Pompon and Cactus varieties. The show varieties are very handsome, but except for exhibition and large vases they are not so useful for cutting as the others. I have this year for the first time grown some of them, and am so satisfied that I intend to grow many more another year. Among the Pompons I have a pure white variety known as White Aster, and it can be used in every possible way as a cut flower, for buttonholes, bouquets, wreaths, &c., and I must say I do not think there is a better or more useful outdoor summer flower grown for the purposes above mentioned. Some time ago I witnessed a fine show of Dahlias of all classes at Messrs. Keynes, Williams & Co. of Salisbury, and they have this year some splendid new varieties, especially among the Pompons and Cactus. This year they planted out many thousands of seedlings, so that out of such a number there will be some good sorts for next year. Among the Cactus varieties I observed Kynereith, Baron Schröder, Catherine, Lancelot, and Viscountess Folkestone as being very fine in colour. Also among Pompons, Phoebe, Leila, Whisper, Achilles, and Darkness. Among show varieties, Queen of the Belgians and Hon. Mrs. P. Wyndham and W. H. Williams are splendid varieties.—**VISITOR.**

— **POTATO DISEASE EXPERIMENTS.**—We have a letter from Mr. Whitehead Cousins for which it is impossible to find room this week. He states he is a Potato dealer, middleman, and experimentalist, and asks who our reporter of the Reading experiments is. He is neither a "dealer nor a middleman," but a grower of Potatoes of many years' experience both for home use and commercial purposes in more than one district. Another letter before us suggests that Mr. Whitehead Cousins has in view "the floating of a company for sprinkling Potatoes with copper." Is this so? We know it has been effective in some experiments, but not in others. It is right that both failures and successes be recorded. The Potato supply has been both good and cheap during the past few years. It is only during occasional wet summers that anti-disease dressings will be needed. In a very large collection of varieties, where the Bouillie has been used under scientific authority for public instruction, no benefit whatever will be seen to have resulted when the report is published.

— **THE Times** recently published an interesting article on "OUR POSITION WITH REGARD TO RAINFALL," compiled from the statistics published by Mr. Symens and the Meteorological Office. The rainfall during the month of October was so heavy that in many places the amount up to the morning of the 18th was in excess of the average for the whole month. In London this excess amounted only to 0.3 inch, while at Valentia Island and at Stornaway it amounted to nearly 2 and 3 inches respectively, and the amount which fell during the next few days has greatly increased the excess. But for the ten years ending with 1889 the rainfall over the United Kingdom differed only by 1 per cent. from the average of the last fifty years. The values for the present year, up to the 18th instant (as shown by the last Weekly Weather Report then published), were rather in excess of the average over the southern, midland, and western parts of England, and the north of Scotland, while in the remaining districts there was still a deficiency. For the whole period since the end of 1889 there was only one district, viz. Scotland (N.), in which the total fall was in excess of the average. In Scotland and the midland and south-western counties of England, the deficiency was still very large. The question is asked—Are we likely to have in the years immediately advancing more or less rain than during the last few years? While the question cannot be answered with absolute confidence, the grouping of years into decades or other regular periods eliminates most of the non-periodic variations, and shows whether

any secular alterations are taking place. There is no doubt that since 1887, at all events, the rainfall over England has been much below the average; and a consideration of all the facts leads to the conclusion that such a period of scarcity is very likely to be followed by one of abundance, and that the coming few years will probably be more rainy than those recently experienced, although possibly the increase will not occur in the summer months—at a time when it would be most noticed.

— A GREEK gardener lately expressed the opinion that ORANGES, FIGS, OLIVES, and GRAPES grown in Australia are inferior to those grown at Smyrna and Athens. This having been brought to the attention of the Department of Agriculture, New South Wales, letters were addressed to the British Consuls at Naples and Marseilles asking for a consignment of the best varieties of Grapes, Figs, and Olives grown in Italy and France. On receipt of these cuttings, experiments are to be carried out at the most suitable of the experimental stations about to be established throughout the colony, with a view to the propagation of the finest varieties of the respective fruits. With the same object in view application has been made to Mr. Hardy, of South Australia, for a number of cuttings of various Vines he has cultivated, and to Sir Samuel Davenport, of Beaumont, South Australia, for cuttings of the Olive and Fig trees grown by him. The whole of these cuttings will go to form the standard collections of all the different kinds of fruit which it is intended to establish at each of the experimental stations.

#### NATIONAL CHRYSANTHEMUM SOCIETY, ROYAL AQUARIUM.—NOV. 10TH, 11TH, AND 12TH.

THE National Show of the present year, which, as may be gathered from the dates, extends over to-day (Thursday), may be classed as about on an average with the majority of its predecessors. Cut blooms are extensively shown, and the general quality is excellent. Groups are little if at all below the usual strength, specimen plants about the average. The awards in the principal classes were as follows:—

**Groups.**—The first prize for a group of Chrysanthemums over a space of 100 feet fell to the Palace victors, Messrs. Reid & Bornemann, Sydenham, who have come to the front very rapidly this season. The arrangement was a very handsome one, the plants being healthy, and carrying fine blooms admirably displayed. This firm greatly strengthen their arrangements with dwarf plants well clothed with foliage, and bearing very large flowers. Being leafed from top to bottom no bare stem is shown at the front of the group. A few of the most telling varieties were Stanstead White, Etoile de Lyon, E. Molyneux, Avalanche, Sunflower, Mons. Bernard, and Val d'Andorre. Mr. Geo. Stevens, St. John's Nursery, Putney, was second with a group of taller plants, well arranged in his well-known style; and Mr. N. Davis, Camberwell, was third with an arrangement somewhat in the style of the first prize one, but not carrying such good flowers. Messrs. Reid & Bornemann also won with a smaller group of dwarf plants.

**Cut Blooms.**—The principal class for incurved was that for forty-eight blooms, and Messrs. W. & G. Drover, Fareham, followed up their Palace success by securing the first prize. Their blooms were remarkably fine, being large, solid, and admirably finished. The varieties were as follows—Back row: John Lambert (2), Empress Eugénie, Lord Leicester (2), John Doughty (2), Queen of England, Empress of India (2), Alfred Salter (2), Golden Empress (2), Violet Tomlin, and Queen of England. Middle row: Mrs. S. Coleman (2), Lord Wolseley, Princess of Wales (2), Nil Desperandum (2), Miss Haggas (2), Violet Tomlin, Jeanne d'Arc, Princess of Teck, Robert Cannell, Mrs. Heales, Lady Carey, and Beauty. Front row: Lady Hardinge, Jeanne d'Arc, C. Gibson (2), Mrs. N. Davis (2), Lord Wolseley, Lady Dorothy (2), Hero of Stoke Newington, Mrs. W. Shipman (2), Princess of Teck, Mrs. Heales, Lady Carey, and Empress Eugénie. A few of the front row flowers were somewhat weak. Mr. Doughty, gardener to Mrs. Tomlin, Cranbrook, was second, but some distance in the rear, his flowers running somewhat small. They were well finished and in good condition, a grand bloom of Mrs. S. Coleman, Empress of India, Princess of Teck, Golden Empress, and Queen of England being the best. The third prize went to Mr. R. Petfield, gardener to A. J. Thornhill, Esq., Buckden, for a good, but somewhat uneven, stand; the fourth to Mr. W. G. Ray, Teynham, Sittingbourne; and the fifth to Mr. Agate, Havant. Mr. C. W. Knowles, gardener to Mrs. Egerton, Rochampton, who quite swept the board at Wandsworth, demonstrated his ability still further by winning in the class for twenty-four. His flowers were small, but very neat and fresh. Messrs. Myers, gardener to the Earl of Sandwich, Hinchbrook, Huntingdon, and A. Ives, gardener to E. C. Jukes, Esq., High Barnet, were second and third. Mr. Shoesmith, gardener to M. Hodgson, Esq., Shirley, won with twelve, one of the best stands in the Show, the flowers being large and substantial; Mrs. S. Coleman, Princess of Wales, Violet Tomlin, and Mrs. Heales were splendid. Mr. Douglas, gardener to Mrs. Whitbourn, Ilford, was second with smaller, but well-finished, flowers; Mr. W. H. Lees, gardener to the Duchess of Montrose, Newmarket, was third.

There were some grand flowers in the Company class. The Havant Horticultural Society, represented by Messrs. Agate, Fuller, Penford, Hoskins, and Payne, won the challenge shield with heavy blooms, the Japanese being particularly fine. The incurved were well finished, but some small. The St. Neots Chrysanthemum Society were placed second, very little in the rear, and the Wimbledon Horticultural Society third.

Japanese were magnificently shown. C. E. Shee, Esq., The Elms, Foots Cray, staged a grand forty-eight, and defeated a formidable lot

FIG. 80.—CORDON GOOSEBERRY.

om Messrs. W. & G. Drover. His varieties were as follows:—Back row: Etoile de Lyon (2), Mrs. Jameson, Mons. Bernard (2), Boule d'Or (2), Mrs. E. W. Clarke, Stanstead White (2), W. H. Lincoln, Condor, M. Marrouch, Mrs. C. W. Wheeler, E. Molyneux, and Danae. Middle row: Gloriosum, A. H. Neve, Sunflower, E. Molyneux, R. Brocklebank (2), J. Délaux, Meg Merrilies, W. W. Coles (2), M. J. M. Pigny, Criterion, Vivand Morel, J. Délaux, Mrs. Jameson, and Condor. Front row: Puritan, C. Underwood, Mrs. J. Wright, Sarah Owen, A. H. Neve, Gloriosum, Madame J. Laing, Puritan, Mrs. J. S. Fogg, Lilian Bird, Soleil Levant, Meg Merrilies, M. Marrouch, Annie Clibran, Sunflower, and Mdle. Lacroix. Messrs. W. & G. Drover also had a magnificent stand, the flowers being of great size, depth, and substance. The judging was somewhat severely criticised here. Both first

and second were certainly exceptionally fine stands. The third prize went to W. H. Fowler, Esq., Taunton, and the fourth to Mr. H. R. Brown, gardener to E. Barclay, Esq., Roydon, Essex, both having excellent stands. Mr. Agate won with twenty-four; a good stand, Vivand Morel, Madame Baco, Lilian Bird, and A. H. Neve being the best blooms. Mr. H. R. Brown was second, very little in the rear, and losing only by a little weakness in his front row flowers. Mr. W. H. Fowler was third.

The twelves brought a large number of stands, many being very fine. Mr. Ocock, gardener to Mrs. M'Intosh, Romford, won with a splendid stand, Vivand Morel, Etoile de Lyon, Mrs. Falconer Jameson, Sunflower, and Fair Maid of Guernsey being grand flowers. Mr. W. H. Divers, gardener to J. T. Hopwood, Esq., was second, and Mr. Doughty third, other prizes going to Mr. Douglas, Mr. J. Hughes, and Mr. W. H. Lees.

Some splendid flowers were shown in the one variety class. Mr. Myers had a very fine six of Golden Empress; and Mr. J. Shaw, gardener to Lord Clinton Hope, a beautiful stand of Avalanche, but space will not admit of details. Japanese reflexed were finely shown by Mr. Long, gardener to E. P. Oakshott, Esq.; and Mr. R. C. Nottcutt, Ipswich. The best stand of reflexed came from Mr. Myers; Messrs. G. Carpenter, gardener to Major Collis Browne; and Mr. M. Russell, gardener to Dr. Lewis, Henfield, following. Large Anemones were splendidly shown by Mr. W. Green, gardener to Miss Wyburn; and Mr. Ives. The former had an exceptionally beautiful stand. Mr. Myers had the best Anemone Pompons, and Mr. Turk, gardener to T. Boney, Esq., and Mr. C. J. Salter, gardener to T. B. Haywood, Esq., had some excellent Pompons.

Specimen plants were good. Mr. Brooks, gardener to W. Reynolds, Esq., J.P., won with six trained specimens, very fine plants; and Mr. D. Macdonald, gardener to J. G. Barclay, Esq., with standards. Pompons were shown in fine condition by Mr. J. Weston, gardener to Dr. Martineau. Mrs. Smith, Romford, and Mr. R. Potter, won with epergnes, and Messrs. Perkins & Son, Coventry, with table decorations. They had a very beautiful arrangement, as also had Mr. J. R. Chard. The Floral Committee had not finished their duties when our reporter left, but some promising novelties were shown, which may be referred to later.

Miscellaneous exhibits were extensive. Mr. H. J. Jones had a group of single varieties, which formed a very beautiful display, and also a large stand of new kinds. Messrs. Pitcher & Manda, the United States Nurseries, Hextable, Swanley, Kent, had a number of seedlings, several being markedly beautiful, as also had Messrs. Carter & Co. Mr. Owen, Maidenhead, had an attractive stand of new varieties. Messrs. Cutbush and Son, Highgate, had a display of miscellaneous plants. Messrs. Cannell & Sons, Swanley, had a large and beautiful display of Zonal Pelargoniums and Chrysanthemums. Messrs. Laing & Son of Forest Hill had a large display of cut Chrysanthemums and fruit. There were good exhibits of fruit from Messrs. Cutbush, C. Lee & Son, and Cheal and Son, and a fine display of vegetables.

On the evening of the first day a conference was held, at which Chrysanthemum sports were discussed, the Rev. Professor Henslow dealing with the matter from a botanical, and Mr. Norman Davis from a cultural point of view.

## KINGSTON CHRYSANTHEMUM SHOW.

NOVEMBER 10TH AND 11TH.

THIS renowned Society held its fifteenth annual Exhibition in the Drill Hall, Kingston, on the above dates, and although the National Society's fixtures were on the same days it lacked none of its former prestige, the hall was filled to overflowing, and a large space for extra tables at the ends was requisitioned to take the large number of exhibits. Groups of fresh, clean, and attractive Chrysanthemums brightened the sides of the hall. These, interspersed with miscellaneous groups, made a most charming picture, while in the front of the large orchestra thirty-six grand examples of specimen-trained plants were arranged. The large collection of fruit was also an important factor of the Exhibition. Ladies' table decorations and table plants, Primulas and berried plants, buttonholes, bouquets, and vegetables, assisted in making a grand and magnificent display, reflecting the highest credit in the matter of arrangements on Mr. Woodgate, the Hon. Secretary; Mr. John Drewett, the Chairman of the Committee; and their able coadjutors.

The chief interest of the Exhibition was as usual centered in the champion challenge vase, value 25 guineas, which makes the seventh the Society has offered for twenty-four incurved distinct and twenty-four Japanese, and which was won last year by T. H. Bryant, Esq., Juniper Hill, Dorking. This year six magnificent collections were staged, and the coveted honour fell to Mr. G. Carpenter, gardener to Major Collis Brown, Broad Oaks, Byfleet, for the following:—Incurved, reading from left to right—Golden Empress, Empress of India (good), Miss Violet Tomlin, Queen of England (very fine), Alfred Salter, Lord Alcester (very good), John Doughty, Golden Queen, Empress Eugénie, John Salter, Mrs. Heale, Amy Hoste, Jeanne d'Arc, Mrs. S. Coleman, Jardin des Plantes, Princess of Wales (very fine), Mrs. N. Davis, Lord Eversley, Baron Beust, Barbara, Miss M. A. Haggas, Nil Desperandum, Princess Teck, Mr. Brunlees. Japanese—Etoile de Lyon (fine colour), Avalanche, Stanstead Surprise, W. H. Lincoln, Condor, Mrs. F. Jameson, Baronne de Prailly, E. Molyneux (bright), Yellow Dragon, Madame

Baco, W. W. Coles, Puritan (good), Mrs. Wheeler, Stanstead White, Sunflower, Vivand Morel, Cesare Costa, Volunteer, Louis Boehmer, Criterion, Mdle. Laeroix, J. Délaux, Mr. A. H. Neve, and Monsieur H. Elliott. Mr. W. Meaux, gardener to A. Tate, Esq., Downside, Leatherhead, was a very fair second. Mr. C. Beckett, gardener to T. H. Bryant, Esq., Juniper Hill, Dorking, was a very good third. Mr. J. Quarterman, gardener to C. G. Smith, Esq., Silvermere, Cobham, was fourth, showing a grand Japanese, though neat but somewhat small, in the incurved class.

For twenty-four incurved Mr. W. Mease was deservedly awarded the first prize with fresh and even blooms of John Lambert, Empress of India, Golden Empress, John Salter, Queen of England, Mrs. Coleman (good), Violet Tomlin, Lord Alcester, Mrs. Heales, Empress Eugénie, Mr. Brunlees, Princess Teck, Mr. Norman Davis, Hero of Stoke Newington, Miss M. A. Haggas, Princess of Wales, Mr. C. Gibson, Cherub, Jeanne d'Arc, Barbara, Lady Carey, Mrs. Shipman, Lord Wolseley, and Lady Dorothy. Mr. C. Beckett took the second honours. Mr. E. Coombs, gardener to W. Furze, Esq., Roseland, Teddington, was a very good third, and Mr. T. Caryer, gardener to A. G. Meissner, Esq.,

Reeves, gardener to General Annersley, Oatlands Park, were placed first, second, and third respectively. For six Japanese of one variety, Mr. A. Filgate was placed first with six highly coloured large and fresh blooms of Etoile de Lyon; Mr. Carpenter took the second prize with Edwin Molyneux; and Mr. R. Cawte the third with the same variety. There were eight collections staged here.

In numerous other classes the competition was very strong, and each contained meritorious examples of cultural skill, notes respecting which we are compelled to hold over this week. Fruit was extensively shown, and the first prize collection of Apples from Mr. Tubb, gardener to B. W. Currie, Esq., Minley Manor, was amongst the finest we have seen, especially his dish of Peasgood's Nonesuch.

### CORDON GOOSEBERRIES.

GOOSEBERRIES grown in the form of cordons, and trained either to walls or improvised trellises, are most easily managed and productive.

FIG. 81.—A GOOSEBERRY FENCE.

Aldenhorne, Weybridge, fourth. There were five exhibitors in this class.

Eight collections were staged for twelve distinct incurved, and Mr. A. Filgate, gardener to the Duchess of Wellington, Burhill, Walton, was well ahead of the other competitors, having massive blooms of Empress of India, Golden Empress, Alfred Salter, Lord Alcester, Golden Queen of England, Violet Tomlin, Miss M. A. Haggas, Queen of England, Princess of Wales (fine), Mrs. Heale, Mrs. Coleman, and Jeanne d'Arc. Mr. R. Cawte, gardener to J. P. Robinson, Esq., was second, some of his blooms being remarkably neat; and Mr. H. Cawte, gardener to F. C. Moore, Esq., Lillesworth, Esher, and Mr. C. Slade, gardener to Lady Bowater, being placed third and fourth respectively.

For twenty-four Japanese, distinct, Mr. G. Trinder, gardener to Sir H. Mildmay, Bart., was awarded the premier honours with a fresh and well balanced collection, consisting of Sunflower (grand), Madame John Laing, Stanstead White, Sarah Owen, Volunteer, Mrs. F. Jameson, Madame C. Audiguier, Mrs. Wheeler, Avalanche (very fine), Louis Boehmer (magnificent), Mons. Elliott, Puritan, Boule d'Or, Etoile de Lyon, J. M. Pigny, W. W. Coles, Condor, Lady Lawrence (compact), Mons. Bernard, Maiden's Blush, Edwin Molyneux, Carew Underwood, Mrs. A. H. Neve, and Stanstead Surprise; Messrs. R. Cawte, W. Mease, and C. Beckett sharing the other awards in order of their names. There were seven grand collections in this class running each other very close.

Mr. A. Filgate was placed first for twelve even Japanese, a very even lot. Mr. G. Mileham, gardener to A. T. Miller, Esq., Leatherhead, took the second award; and Mr. John Thorne, gardener to A. E. Flood, Esq., the third; and Mr. H. Cawte the fourth.

With six Japanese Mr. J. Quarterman, Mr. C. Slade, and Mr. J.

What are known as Gooseberry hedges are occasionally seen in gardens as marginal lines to borders, and wherever established and properly managed, give much satisfaction. This method of Gooseberry culture is of the simplest, as both summer and winter pruning can be easily and expeditiously conducted, while the fruit is readily gathered. It has been found also that birds do not do half the damage to the leads of the upright cordons that they do to the ordinary bushes, the comparative immunity in the former case being probably the exposure of the depredators and the less convenient foothold than is found in the bushes. Be that as it may, the fact is as stated. By this method of culture very large crops of fruit can be had on narrow strips of land, and the practice is worthy of extension in appropriate positions in gardens.

Our illustration is the result of a sketch made at one of the meetings of the Royal Horticultural Society, where about a hundred fruiting cordons were exhibited by Messrs. James Veitch & Sons. The enlarged tree is an exact representation, and the fence such as would have been produced had the remainder been trained as shown in the engraving.

For the first few years the young trees can, if desired, be secured to neat stakes, and cross supports of wire, or even laths, provided at convenience. In one instance where laths had been used for a few years, the cordons assumed a rigid habit and became "self-supporting."

## CHRYSANTHEMUM SHOWS.

WATERFORD.—NOVEMBER 3RD.

THE annual Chrysanthemum, fruit, flower, and vegetable Show, with a limited class for farm produce, was held on Tuesday, November 3rd, in the Town Hall, under the auspices of the Waterford Horticultural Society. I was quite unprepared for the Chrysanthemum display, as even in the South of England it is hardly attempted to hold great shows on the first days of November, and this was admittedly a late season. The principal feature was the cup class; the best growers put forward their best blooms, and surprisingly fine some of them were.

A silver cup, value £5, was given to be competed for by Reymond De La Poer, Esq., Kilteronagle, well known as a patron of floriculture in the district, for twenty-four blooms, each different, half Japanese and half incurved. The Society added a second prize of £2 and a third of £1. The cup, after a close scrutiny between the stands of Captain De La Poer and Lord Besborough, Piltown Park, went to the former, the second to the latter, and the third to a new grower, Mr. Robertson, of the well-known firm of Robertson, Ledlie, Crawford & Co. A peculiarity of the cup stand was that it contained four alternate rows of Japanese and incurved. I cannot say that it struck me as being more effective—evidently the object—than the usual method of staging; but I will give the stand as staged. Top row: Japanese—Vivian Morel (splendid), Boule d'Or, Volunteer, W. W. Coles, George Daniels, and M. Bernard. Second row: Incurved—Emily Dale, Jeanne d'Arc (fine), Golden Empress, Empress of India, Lord Wolseley, and Alfred Salter. Third row: Japanese—Etoile de Lyon, Japonais (good), Condor (very large), E. Molyneux, Avalanche, and Sarah Owen. Fourth row: Prince Alfred, Lord Alcester, John Doughty, Queen of England, Jardin des Plantes, and Princess of Wales. Lord Besborough's stand contained in addition: Japanese—Mrs. Falconer Jameson, Fair Maid of Guernsey, Comte de Germiny, Mrs. John Laing, Peter the Great, Maiden's Blush, Stanstead White, Bouquet Fait, Source d'Or, and Soleil Levant; incurved—Nearly the same, as already named, with Alfred Salter, Nil Desperandum, Mrs. Shipman, Gloria Mundi, Lady Hardinge, and Violet Tomlin.

The groups were very effective, filling one side of the vast Assembly Rooms, and should be a feature in every show. The first prize went to C. G. Danny, Esq., May Park; and the second to W. G. D. Goff, Esq., Glenville; the former gentleman being equally successful for plants in pots and specimen plants—notable in the latter exhibits being plants of La Frisure, Hiver Fleuri, and Mrs. George Rundle, which it was evidently difficult to get forward in time, but were very floriferous. In the reflexed, Anemone, Japanese, and Japanese reflexed, Captain De La Poer repeated his success in the cup class. There was nothing new in the reflexed class, but all the Japanese Anemones were fine, particularly Sabine, Jeanne Marty (splendid), Grand Alvéole, Ratapoll, Madame Cabrol (splendid), and Nelson. The exhibits in the fruit, cut flowers, and vegetable classes were in some classes more numerous than hitherto, and in all of superior merit. A collection of farm produce of great size and merit was also a feature of the Show. Much credit is due the Committee under their difficult circumstances, but especially the Hon. Secretary and Treasurer, C. P. Bolton, Esq., J.P., Brook Lodge; and Mr. J. A. Power.—W. J. MURPHY.

WELLS.—NOVEMBER 3RD AND 4TH.

THE shows held by this Society have taken well from the first, and apparently there is no diminution in the interest shown in them, all classes of society well patronising the meeting on both days. The Town Hall was fully taxed to hold all that was sent, for competition or otherwise, there being a capital and extensive display of hardy fruit, as well as the usual round of plants and cut flowers. Everything was well planned and carried out by the Committee, most of whom are practical gardeners, much credit also being due to Mr. A. G. Andrews, the Hon. Secretary, and Mr. R. Isgar, Hon. Treasurer.

Groups, largely composed of Chrysanthemums, are always a feature at Wells, and this time they were more numerous and better than usual, Mr. J. B. Payne, gardener to the Lord Bishop of Bath and Wells, was awarded the first prize for a very excellent and imposing arrangement, comprised in which were numerous remarkably well grown Pomsettias, some good pots of Eucharis amazonica, with Crotons, Ferns, and other plants, while the best represented Chrysanthemums were Golden Dragon, Sunflower, Louis Boehmer, Stanstead White, Avalanche, and Sarah Owen. Mr. Wilkinson, gardener to C. C. Tudway, Esq., was a close second, grand Chrysanthemums being shown in this fine group. The third prize went to Mr. Stokes, gardener to N. McLean, Esq., who also had some fine Chrysanthemums. Smaller groups were very well shown by amateurs, these not often being equalled by this class of growers. Trained plants were neither so numerous nor good as usual, the best display of these and the most prizes being won by Mr. Chislett, gardener to Mrs. Rees Mogg, Glastonbury. The best table plants were shown by Mr. H. Young, gardener to W. S. Hodgkinson, Esq., Wells, Mr. R. Phillips, gardener to J. Baily, Esq., Frome, also showing well.

Cut blooms were scarcely so numerous as usual, though there were ample for the space that could well be devoted to them. There were three entries in the principal class, or that for twenty-four blooms, to consist of equal numbers of Japanese and incurved varieties; and here Mr. J. P. Payne was well first, and Mr. Wilkinson a good second. Mr. Payne's blooms consisted of Japanese.—Back row: Avalanche, W. G. Drover, E. Molyneux, and Etoile de Lyon. Middle row: International,

W. W. Coles, Stanstead White, and E. W. Clarke (very fine). Front row: M. Bernard, Mrs. Wheeler, Val d'Andorre, and Sunflower. Incurved.—Back row: Empress of India, Golden Empress, Queen of England, and Lord Alcester (very good and selected for the certificate of the National Chrysanthemum Society). Middle row: Mrs. Heale, Violet Tomlin, Miss Haggas, and Alfred Salter (very good). Front row: Jardin des Plantes, Mrs. Coleman, Lord Wolseley, and Jeanne d'Arc. In Mr. Wilkinson's stands were very superior blooms of J. Doughty, Mrs. Heale, Princess of Wales, Empress Eugénie, and Japanese Gloire de Rocher, a decided improvement on Val d'Andorre. Mr. Payne was also well first for twelve incurved varieties, Lord Alcester, Queen of England, Empress of India, Golden Empress, Princess of Wales, and Mrs. Coleman being the best represented. Mr. Wilkinson was second. The competition with twelve Japanese varieties was also good, but in this instance local growers were well beaten by Mr. W. Strugnell, gardener to A. R. Baily, Esq., Frome, who had in his back row Puritan, Sunflower (extra good), Etoile de Lyon, and Volunteer. Middle row: W. H. Lincoln, Mrs. Falconer Jameson, Edwin Molyneux, and Avalanche; and front row: G. Atkinson, M. Bernard, G. Daniels, and Sarah Owen; altogether very fine blooms. Mr. Wilkinson was second. The last-named was well first for twelve blooms of Anemone-flowered in not less than six varieties, these consisting of Gluck, Lady Margaret, Jeanne Marty, Sabine, Madame Cabrol, Cincinnati, and A. Chater. For the first time at Wells a class was provided for twelve undressed incurved blooms shown with not less than 12 inches of stem. There was good competition with these, Mr. Wilkinson being well first, both blooms and foliage being remarkably good.

A fairly large room had to be given up to the display of hand bouquets, vases, and baskets of flowers, and autumn foliage, and it is very doubtful if the display made will be excelled anywhere this season. Miss Snelgrove was first for a hand bouquet composed of Chrysanthemums and Fern fronds, and Miss Tatchell second, those made by professional men, though lighter, not being fresh enough. The best vase of Chrysanthemums and greenery was arranged by the Hon. Frances Sugden, Mr. Strugnell also having a very well arranged and imposing vase, and was second, Mrs. L. E. Walter being a good third. The vases of autumn foliage and berries were the great feature of the room, if not of the Show, the taste displayed and the pains taken being conspicuously evident. The Hon. Miss G. Sugden was first, the Hon. Florence Sugden following closely, the third prize going to Mrs. L. E. Walter. There were so many capital baskets of autumn foliage and berries shown that it was considered advisable to award six prizes in the class.

Messrs. Payne, Wilkinson, Phillips, J. Reed, H. C. Salmon, and McKenzie were among the principal prizewinners in the various fruit classes, Apples and Pears being particularly good. Messrs. Jarman and Co., Chard, were highly commended for a grand display of Apples, Pears, Onions, and such like, having fully a hundred varieties of the former, and twenty dishes of Pears. Mr. Brown, Wells, was also highly commended for a somewhat similar exhibit; Mr. Mogford, Wells, being commended for a smaller, though very excellent show of hardy fruit.

PORTSMOUTH.—NOVEMBER 4TH, 5TH, 6TH.

THE seventh annual Exhibition of the Portsmouth Chrysanthemum Society was held in the capacious Drill Hall on the dates named, and was equal on the whole to any previous Show. The arrangements were of the usual satisfactory character. Mr. Power, Hon. Secretary, Mr. B. Miller, Assistant-Secretary, and Mr. Collins as stager, deserving every credit for the way in which so large an exhibition was managed.

Cut blooms formed the most important feature of the Show, 2600 being staged. The principal class was that for forty-eight, half to be Japanese and the remainder incurved in not less than eighteen varieties in either section, and for which a piece of plate, value £25, with £8 added, as first prize: £7 for second, £5 for third, and £3 fourth, were offered. Messrs. Drover having won this trophy last year, and being again successful this time, it now becomes their property. Very fine indeed were both the incurved and Japanese, the back row of the former being especially heavy and well finished. The varieties were:—*Incurved*: Empress of India (2), Lord Alcester (2), Queen of England (2), Emily Dale (2), A. Salter, Prince Alfred, Mr. Robert Mudie (2), Princess of Wales, Golden Empress, Violet Tomlin, Lord Wolseley, Empress Eugénie, Mrs. Shipman, Miss M. A. Haggas (2), Nil Desperandum, Mrs. S. Coleman, Jeanne d'Arc, and Lady Carey. *Japanese*: Etoile de Lyon (2), Pelican, Boule d'Or, Alberic Lunden, Stanstead White (2), Sarah Owen, Sunflower, Mrs. C. Wheeler (2), Madame J. Laing, E. Molyneux (2), M. E. A. Carrière, Mr. Ralph Brocklebank, Mrs. E. J. Clarke, M. Bernard (2), Mrs. F. Jameson, W. H. Lincoln (2), Condor, and Louis Boehmer. Second, Mr. A. Payne, gardener to Mrs. Ernald Smith, The Oaks, Emsworth, with medium-sized neat incurved blooms, and full heavy Japanese. Amongst the latter the following were noteworthy: Mrs. C. Wheeler, Condor, M. Bernard, Etoile de Lyon, Stanstead White, and Sunflower. Mr. N. Molyneux, gardener to J. C. Garnier, Esq., Rookesbury Park, Wickham, was an exceedingly close third. The incurved blooms were ahead of the second prize stand, but the Japanese showed a still greater falling off. Mr. Agate, Havant, was fourth, having good Japanese.

For twenty-four distinct, half to be incurved and the remainder Japanese, five competed. Mr. N. Molyneux was an easy first, having perfectly finished incurved of large size and very fresh, but the Japanese being rather thin. The varieties were E. Molyneux, Mrs. J. Clarke, M. Bernard, Condor, Etoile de Lyon, Gloire de Rocher, Sunflower, Mdme. J. Laing, Stanstead White, Puritan, Louis Boehmer, Avalanche,

Incurved: Lord Alcester, Golden Queen of England, Empress of India, Queen of England, Mr. R. Mudie, Golden Empress, Lord Wolseley, Alfred Salter, Miss M. A. Haggas, Violet Tomlin, Mrs. S. Coleman, and Princess of Wales. Mr. Payne was second with good Japanese, the incurved being rather small. Mr. Penford, gardener to Sir F. Fitzwygram, Leigh Park, Havant, third. For twelve incurved, the last-named exhibitor easily took the premier award with medium-sized neat blooms of Lord Alcester, Queen of England, John Doughty, Empress of India, Nil Desperandum, Mrs. Heale, Mrs. S. Coleman, Princess of Wales, Violet Tomlin, Jeanne d'Arc, Lord Wolseley, and Miss M. A. Haggas, Mr. C. Steptoe, gardener to W. A. Gale, Esq., Horndean, second. Mr. Edwards, Witley Heights, Witley, Surrey, third. Mr. Penford followed up his previous successes by taking first honours for twelve reflexed, twelve Anemone, and twelve Japanese Anemones, in all cases staging full and solid blooms, the principal varieties being the following: Reflexed—King of Crimson, Distinction, Dr. Sharpe, Golden Christine, and Cloth of Gold; Anemones—Miss A. Lowe, Gladys Spaulding, Lady Margaret, George Sands, and Mme. R. Owen; Japanese Anemones—Sœur Dorothee Souille, Jeanne Marty, Minnie Chate, and Fabian de Mediana. Mr. Russell, gardener to Dr. C. F. Lewis, Henfield, Sussex, and Mr. C. Steptoe were second and third in the former class, both staging good blooms. In the Anemone class the two last-named reversed their positions. Mr. H. Adams, gardener to T. S. Edgcombe, Esq., Hinton House, Elm Grove, Southsea, secured second position in the Japanese Anemone class.

With Pompons in not less than eight varieties, three blooms to a bunch, eight competed, making a good display. Mr. Russell secured first prize with capital blooms, the best being Madame Domage, President, Prince of Orange, Wm. Holmes, and Marabout. Mr. Agate, second; Mr. Hatch, gardener to the Victoria Park Committee, Portsmouth, third. A class was provided for fimbriated flowers, twelve bunches, in not less than four varieties, and was one of the most attractive in the Show, so bright were the blooms. Mr. G. Hawkins, gardener to E. Laphorne, Esq., Gosport, was placed first among five exhibitors, the best being Scapin, Massange, Croesus, and Chardonneret. Second, Mr. H. Adams; third, Mr. Hatch. Single varieties formed a class which gave considerable pleasure to the visitors, and especially the ladies, so very fine were they in variety and neatly staged. Mr. Agate was an easy first, having a capital selection, and for the benefit of intending exhibitors or growers of these flowers we append the names—Golden Star, Mr. D. B. Crane, Bessie Conway, Admiral Sir A. T. Symonds, Oceana, Jessie Chignell, Exquisite, Effie, Jenny Lind, Yellow Jane, and Jane. Mr. Hawkins was second, and Mr. Hatch third.

For six Japanese, one variety, Mr. Edwards won with solid blooms of Avalanche; second, Mr. Agate, with the same variety; Mr. W. King, gardener to D. Graham, Esq., Liphook, third. For six incurved, one variety, five competed, the best—large, solid, Empress of India—from Mr. N. Molyneux; Messrs. Edwards and Steptoe following in the order named. Mr. W. Colchester, Ipswich, offered a silver cup for six incurved and six Japanese blooms to have been grown with ichemic guano, which Mr. N. Molyneux secured easily with large firm blooms in both sections. Numerous classes were provided for growers in Portsea Island only, the most important being that for twenty-four, six Japanese, six incurved, six reflexed, and six Anemones. Mr. Hatch secured the premier position with even blooms in all sections; Mr. H. Adams second. The premier incurved bloom in the Show was Golden Queen of England, of magnificent proportions, in Messrs. Drover's cup stand; the premier Japanese being a well-formed Stanstead White belonging to Mr. Penford. Amateurs contributed largely and well in the cut bloom classes.

Plants were staged in large numbers, and of average quality. For eight specimens, four incurved or reflexed and four Japanese, the handsome sum of £8 was offered for first prize, with suitable second, third, and fourth prizes also. Mr. Penford secured the leading award with well-grown plants about 3 feet in diameter, profusely flowered, the best being Mr. Dixon, Mr. G. Rundle, George Glenney, Elaine, Elsie, and Mons. Bernard; Mr. G. Lambert, 14, Gordon Terrace, Whyke Lane, Chichester, second; Messrs. F. & G. Cozens, Rownhams, Southampton, third. For six trained plants Mr. G. Lambert carried off the premier award with healthy plants. The best single specimen, any variety, was one of Elsie from Mr. Penford, having 120 fully developed flowers, a grand plant. A class was provided for twelve plants, distinct, grown and exhibited in 9-inch pots, each plant to carry not more than twelve blooms. Mr. Burridge, North End, Portsmouth, easily secured the premier award with really first-rate plants from 2 feet to 4 feet high, carrying good foliage and fine blooms; Mr. G. Lambert was second.

For the best groups of 50 square feet Mr. Hatch was awarded first prize with plants carrying large blooms, but rather too tall, still he won easily. Mr. Hider, gardener to S. G. Way, Esq., Pottery Works, Portsmouth, second; and Mr. G. Kimber, gardener to the Committee of the Portsmouth Lunatic Asylum, third. For a group of Chrysanthemums interspersed with foliage plants, Mr. J. Burridge received the first prize, although his exhibit was too much crowded. Mr. E. R. Harvey, 63, Hanover Street, Portsea, second, too formal also. Plants for table decoration made a remarkable display, so even and good in quality were those staged. For twelve Mr. Edwards was placed first; Mr. J. Amys, gardener to the Hon. Mrs. Elliot Yorke, Hamble Cliff, Netley, second. Primulas were very fine, Messrs. Burridge and Agate receiving the awards in the order here named.

Two classes were open to ladies only. For the most tasteful arrangement of Chrysanthemums and any kind of foliage, on table 3 feet square, Mrs. Conway, Havant, easily secured leading position with a

light arrangement. Miss B. Ladhams, second. For a glass stand or epergne dressed with Chrysanthemums and other flowers, Miss Kate Goldring, Winchester Road, Southampton, was first with a tastefully arranged stand. Second, Mrs. Conway; Miss Ladhams third. For an epergne dressed with berries and autumn foliage Mrs. Conway somewhat easily secured the premier award with a charming combination of colours. Mrs. Ladhams second—six competing. The class for a bouquet of Chrysanthemums and Ferns was well filled. Mr. B. Ladhams, with a simple yet elegant arrangement of the Japanese variety Sourced'Or, associated with long sprays of dark-leaved Spiræas, &c., having the honour of placing Messrs. Perkins, Coventry, in the second position.

Fruit made an imposing display, the competition being keen and the quality good. For three bunches of black Grapes, any variety, Mr. T. Hall, gardener to S. Montague, Esq., M.P., South Stoneham House, Southampton, was first with Alicante in good condition; Mr. N. Molyneux second. For three bunches of white Grapes Mr. J. Chalk, gardener to G. Read, Esq., Westwood, Salisbury, was an easy first with good Muscat of Alexandria, Mr. N. Molyneux following with the same variety. For two bunches of black Grapes Mr. Chalk secured the leading position.

For thirty dishes of Apples and twenty dishes of Pears, distinct varieties, Messrs. G. Bunyard, Maidstone, secured the coveted award, the following varieties being noteworthy:—Royal Jubilee, Belle Pointoise, Gloria Mundi, Peasgood's Nonesuch, Loddington, Queen, Cornish Aromatic, Washington, Bismarck, and Lady Henniker. Mr. J. Watkins, Pomona Nurseries, Withington, second; Messrs. Cheal, Crawley, third. For sixteen dishes of Apples and eight dishes of Pears Mr. Hall was first with good fruit. Prizes were offered for single dishes of both Apples and Pears, which were contested with spirit. Space forbids of a detailed account of each.

Vegetables were numerous staged, the quality being quite of an average character. For nine distinct varieties Mr. Hawkins was first, Mr. Penford, second; and for six varieties Mr. H. Budd, gardener to R. Sainthil, Esq., R.N., Rockbeare, Emsworth; Mr. N. Molyneux second. Both in extent, quality, variety, and arrangement the display was most creditable to exhibitors and officials.

#### BRIXTON, STREATHAM, AND CLAPHAM.—NOV. 3RD AND 4TH.

THIS old established Society held its thirty-second Exhibition in the Town Hall, Streatham, on the above dates, and proved an undoubted success. There were, as is customary here, excellent and numerous examples of both flowering and foliage plants in addition to Chrysanthemums. Mr. Poulton, gardener to C. T. Cayley, Esq., was awarded the premier position for a collection of Chrysanthemums arranged for effect. They were of very dwarf habit, tastefully set up, and well merited the distinction awarded. Mr. Mursell, gardener to W. Burton, Esq., and Mr. Stevens, gardener to B. F. Smith, Esq., received the second and third awards respectively for highly meritorious collections. For six specimen incurved Mr. Cherry, gardener to Mrs. Gabriel, was first, Golden Queen of England and Empress of India being especially good. Mr. Weston, gardener to D. Martineau, Esq., was placed second; but for six Japanese Mr. Weston turns the tables with magnificent plant of L'Ile des Plaisirs, Madame Bertie Rendatler, Madame de Sevin, Elaine, Mons. Jacotot, and Stanstead Surprise. Mr. Cherry was a very good second, exhibiting Elaine, Madame Bertie Rendatler, Mons. Garnet, Hiver Fleur, and Margot. Mr. Clarke, gardener to W. Griffiths, Esq., staged three grand examples of Mrs. G. Rundle, Dr. Sharp, and Mr. Dixon, which deserved the first prize awarded to him. Specimen Pompons were also well shown, Messrs. Weston and Cherry sharing the honours between them.

In the many cut bloom classes there was keen competition. With twenty-four incurved Mr. Howe, gardener to H. Tate, Esq., was well to the front with a clean and fresh collection, comprising Bronze Queen of England, Violet Tomlin, John Lambert, Princess of Wales, Empress of India, Lord Wolseley, Queen of England, Alfred Lyne, Mr. Coleman, Jeanne d'Arc, Prince Alfred, Jeanne d'Arc, Violet Tomlin, Mrs. Heale, Mrs. Coleman, Princess of Wales, Hero of Stoke Newington, Princess Teck, Mrs. W. Shipman, Miss Haggas, Princess Beatrice, Lady Dorothy, and Jardin des Plantes. Mr. Wildman would have made a very good second, but unfortunately he had staged three Lord Wolseleys when it was stipulated there should not be more than two of any one variety. Mr. J. Stevens, gardener to B. F. Smith, Esq., was placed third, the second award being withheld. In the class for twelve incurved, Mr. Howe was again to the front with large examples of Alfred Lyne, Mrs. Coleman, Bronze Queen of England, Empress of India, Lord Alcester, Violet Tomlin, Princess of Wales, Lord Wolseley, Princess Beatrice, Jeanne d'Arc, Jardin des Plantes, and Mrs. Heale. Mr. Poulton was placed second with a good collection, Empress of India, Princess of Wales, and Alfred Salter being especially noteworthy. Mr. W. Hill, gardener to G. W. Ryder, Esq., was placed third. For six blooms, Mr. Pearce, gardener to Mr. Fletcher Bennetts staged very fine Lord Alcester, Alfred Salter, Violet Tomlin, Prince Alfred, Lady Slade, and Jardin des Plantes, Messrs. Cherry and Sandham sharing the other awards.

There was the same excellence of size, beauty, and freshness throughout the many stands of Japanese as was to be observed among the incurved classes. For twenty-four distinct, Mr. Mursell, gardener to Mrs. Burton, was well ahead with Stanstead White, W. Tricker, Edwin Molyneux, Gloriosum, Louis Boehmer, Beauty of Castlewood, Mrs. Clark, Gloire de Rocher, Golden Dragon, Meg Merrilies, Viviani Morel, Mrs. F. Jameson, Condor, Avalanche, Violet Rose, M. A. Carrière, Cesare Costa, Cleopatra, Mrs. W. Thrower, Mons. Bernard, and Sunflower. Mr. Howe

was a good second, his Etoile de Lyon, Val d'Andorre, Mrs. A. H. Neve, and Sarah Owen were very fine. Mr. Ashby, gardener to H. R. Holman, Esq., was a very creditable third. There were several other good collections staged in this class. For twelve blooms Mr. Howe received the highest award, after a sharp contest, with very fine blooms of Mrs. Jameson, Edwin Molyneux, Etoile de Lyon, high colour; Avalanche, Val d'Andorre, Stanstead White, Madame Baco, Thunberg, and Mons. Bernard. Mr. Mursell was placed second, and Mr. Ousley, gardener to R. Lyell, Esq., third, for meritorious collections. Reflexed were represented by Messrs. Mursell, Poulton, and Stevens, who were placed in the order of their names. Many other worthy exhibits deserve mention, which our space will not allow, but the whole arrangement reflected the highest credit on the executive and their zealous Hon. Secretary, Mr. W. Roupell, who laboured very hard to bring the Exhibition to a successful issue.

#### THE DALSTON AMATEURS' SOCIETY.—NOVEMBER 4TH AND 5TH.

It is well known in the horticultural world that amateurs who apply themselves closely and earnestly to any branch of gardening often excel in the production of plants, flowers, fruits, and vegetables requiring the greatest skill and attention; indeed, it is not an uncommon occurrence in open competition for amateurs to defeat experienced gardeners. This results chiefly from the fact that devoting time and attention solely to one class of production gives the best chance of success in cultivation. This is abundantly proved in the system adopted by market growers at the present time, namely, confining themselves to, and making a reputation for, a few plants, fruits, &c., which become specialties. In floriculture amateurs have done wonderful service, and amongst the Chrysanthemums especially they have taken a prominent place in the ranks of successful exhibitors. Even in the least favourable districts, closely pent populous localities of the metropolis and provincial towns, they have overcome innumerable difficulties, and presented the "Queen of Autumn" flowers in a condition highly creditable to themselves, eminently satisfactory to visitors, and offering every inducement to others to enter the ranks of those who engage in such a delightful, healthful, and admirable recreation.

Knowing what has been, and can be accomplished, in this way, a most agreeable surprise was still afforded by the fourth annual Exhibition of the Dalston and De Beauvoir Town Amateur Chrysanthemum Society, which was opened by Lady Hunter at the Albion Hall on Wednesday, November 4th. The hall is of moderate size, and its resources were taxed to the utmost to find space for the overflowing exhibits contributed in competition and otherwise. Around the sides of the hall were groups of Chrysanthemums bearing abundance of brilliant flowers, while the centre tables were devoted to the cut blooms, which were of satisfactory quality throughout, and in several cases would have taken a good place in much more extensive shows. There was a freshness and diversity which imparted a most pleasing character to the Show, and it is almost needless to say that the Committee had arranged the exhibits to the best advantage.

Glancing hurriedly at the winning contributions we found that in the "Holmes class" for thirty-six plants Messrs. Rolt, Reid, and Powell were the most successful in the order named, the first also taking in addition to the silver-gilt medal a special prize of a portable greenhouse, presented to the Society by "a friend of horticulture." The other two prizes were silver and bronze medals respectively, and the plants in each case were well grown healthy specimens. With twenty-four plants Messrs. W. H. Miles, H. R. Pearce, and J. Mann were the prizewinners, the best twelve plants coming from Messrs. Prentiss, G. C. Young, and F. Pearce, and the best three trained specimens from Messrs. Rolt and Reid.

The cut blooms were most praiseworthy, the Japanese bright and substantial, the incurved neat and refined. Mr. W. H. Miles had the best twenty-four blooms, twelve Japanese and twelve incurved, thus winning the silver-gilt medal and Mr. Toope's excellent heating apparatus, presented as an additional prize. Mr. G. P. Rolt followed closely in this class, and was first with twelve Japanese and twelve Pompons, the latter wonderfully good. Mr. Miles also had the best twelve and six incurved blooms, and six Japanese. In the open classes Messrs. Winter, Kendall, and Nye were the winners for twelve blooms.

Amongst the non-competing exhibits Messrs. J. Laing & Sons, Forest Hill, had a valuable collection of foliage plants and Heaths; Mr. H. J. Jones, Lewisham, sent thirty-six handsome cut blooms; and Mr. C. Gibson, Morden Park Gardens, a well known exhibitor at the leading shows, had twenty-four fine cut blooms, all of which added materially to the interest and beauty of the Exhibition.

Altogether the Society had good reason to be satisfied with the results of their efforts, and it is evidently performing valuable service in the district. The Committee with their Chairman, Mr. Hill, and Secretary, Mr. Butler, deserve especial congratulation upon the work performed, which should give ample encouragement to proceed on the same lines.

#### ISLE OF WIGHT.—NOVEMBER 4TH AND 5TH.

THE seventh annual Exhibition of this excellent and well managed Society was held at the Drill Hall, Newport, on Wednesday and Thursday last week, and proved an unqualified success. The Society has a long list of noble and wealthy patrons, and is under the admirable administration of Dr. Groves, J.P., as Chairman; Dr. Coombes, Treasurer, and Mr. Horace Groves, the Secretary, who, in conjunction with

a practical working Committee, have laboured hard this year as in the past to carry out in an efficient manner the duties devolving upon them.

The schedule of prizes was most representative, and contains sixty-five classes for nurserymen, gardeners, and cottagers. The latter had excellent exhibits, in some cases all but equal with the nurserymen and gardeners. Several pleasing and attractive groups were arranged around the sides of the spacious hall, the premier position for a 40-foot group being taken by Mr. G. Freeland, gardener to F. T. Mew, Esq., Polars, Newport, while Mr. W. Morris, gardener to Captain Eveleigh, Shide was a good second.

Miss Way Buckell, Castlehold House, Newport, secured the first place in the amateurs' groups for a well arranged and neat collection, and Mr. F. J. Tomlinson, Trafalgar Road, Newport, in the cottagers' division. Other prizewinners in the group classes were Messrs. Sanders, Webber, and Taplin. Several collections of very neat trained specimens were staged, the best being exhibited by Mr. E. W. Sheppard, gardener to T. C. Clarke, Esq., J.P., Oakfield, Wooton, and took the highest awards in each of the classes for four incurved, four Japanese, single specimen incurved, and single specimen Japanese. All being very creditable, trained, fresh, and profusely flowered. Messrs. G. Freeland, Sinington, Matthews, Guy, and Miss Blake were the other principal prizetakers for trained specimen plants.

Cut blooms, taken collectively, were numerous, and formed a most important feature of the Show. For twenty-four incurved or reflexed Mr. A. Tolley, gardener to S. E. Ridley, Esq., St. Helens, was awarded first honours with a fresh collection consisting of Violet Tomlin, Golden Empress, Cullingfordi, Empress of India, Prince Alfred, John Lambert, Queen of England, Mrs. W. Shipman, Princess of Wales, Miss Haggas, Jeanne d'Arc, Emily Dale, John Salter, Mrs. Heale, Golden Empress, Madame Teizer, Empress of India, Princess Teck, Hero of Stoke Newington, Miss Haggas, Venus, and Mr. Gladstone. In the corresponding class for twenty-four Japanese blooms, not less than eighteen varieties, Mr. F. Miller, gardener to Mrs. Brooke-Firman, East Cowes, was deservedly awarded the first prize for praiseworthy examples of Edwin Molyneux, Val d'Andorre, Stanstead White, Sunflower (very fine), Avalanche, Etoile de Lyon, Puritan, Jeanne Délaux, Florence Percy, M. Bernard, Madame Baco, Elaine, Duchess of Albany, M. J. Laing, Boule d'Or Gloriosum, Mdle. Lacroix, Sarah Owen, and M. Burnet. Mr. R. Tolley, gardener to Lady Oglander, Nunwell, was a close second. For twelve incurved Mr. Tolley was first and Mr. Sheppard second; while in the class for twelve Japs Mr. Sheppard again secured the highest award.

In the open class for twelve incurved or reflexed and twelve Japanese, all distinct, there was only one good collection, that being from Mr. A. Tolley, whose blooms were all that could be desired. The incurved were Empress of India, Prince Alfred, Princess of Wales, Violet Tomlin, Golden Empress, Queen of England, Emily Dale, Lord Wolseley, M. Bahuant (very good), Mrs. Heale, Miss Haggas, and John Salter. Japanese: M. Bernard, George Daniels, Edwin Molyneux, Etoile de Lyon, Meg Merrilies, Madame Baco, Avalanche, Madame C. Audiguier, Grand Flora, Stanstead White, Mr. H. Cannell, and M. J. Pigny. Numerous other cut bloom classes were represented, also bouquets, epergnes, and baskets, tastefully arranged Primulas, Cyclamens, and fruit, the whole forming a brave display, worthy of the island and those who had worked so ably for its ultimate success.

#### ASCOT.—NOVEMBER 4TH AND 5TH.

For years the Chrysanthemum exhibitions held in the Grand Stand at Ascot have been counted amongst the best in the country; certainly the one in question was a decided success. Nowhere do we see groups of Chrysanthemums better managed than here. Cut blooms, too, are remarkable for their even and superior quality, and demand first notice. The principal class was that for eighteen incurved and the same number of Japanese, all to be distinct, and for which a silver cup was offered to go with a money prize for the best stand. Mr. Lane, gardener to Miss D. Smith, Knap Ride, Ascot, having won the first prize in this class twice before and repeating his previous success again this time, the cup becomes his property. The incurved were models of neatness, large, and timed to the day as regards freshness. The names were Golden Empress, Alfred Salter, Princess of Wales, Jeanne d'Arc, Nil Desperandum, Lady Dorothy, Lord Alcester, Queen of England, John Doughty, Miss M. A. Haggas, Novelty, Violet Tomlin, Empress of India, Golden Queen of England, Lord Wolseley, Mrs. Heales, Lady Hardinge, and Mrs. S. Coleman. Japanese were heavy, bright, and well arranged. The names were Geo. Atkinson, Jeanne Délaux, Album Fimbriatum, A. H. Neve, Madame J. Laing, Stanstead White, Etoile de Lyon, Mons. Bernard, Avalanche, Mrs. F. Jameson, Alcion, Edwin Molyneux, Bertha Flight, Madame C. Audiguier, Japonais, Sunflower, and Marsa. Mr. Page, gardener to Mr. H. P. Leschallas, Ascot, was a good second, although some distance behind the winner. Mr. Hughes, gardener to H. F. de Paravicini, Esq., Bracknell, third.

For twenty-four incurved, distinct varieties, four competed, making a really fine display. So even in quality were the blooms that not more than three and a half points separated the first three stands. Mr. Hughes took premier honours with well-finished examples, large in size, of Golden Empress, John Doughty, Princess of Wales, John Salter, Refulgens, Pink Venus, Queen of England, Golden Queen of England, Alfred Lyne, Mrs. Heales, Jardin des Plantes, Prince of Wales, Empress of India, M. H. Bahuant, Violet Tomlin, Jeanne d'Arc, Novelty, Mr. Brunlees, Lord Alcester, Alfred Salter, Lord Wolseley, Miss M. A. Haggas, Camille Flammarion, and Lady Hardinge. Mr. Tomlinson, gardener to F.

Ricardo, Esq., Old Windsor, was second, and Mr. J. Thorne, gardener to Major Joicey, Ascot, third.

No less than seven competed in the class for twenty-four distinct Japanese, creating a fine display. Mr. Sturt, gardener to N. L. Cohen, Esq., Englefield Green, succeeded, after a close fight, in obtaining the premier award with the following varieties:—Etoile de Lyon, Avalanche, Marsa, Val d'Andorre, Mdle. Lacroix, Holborn Beauty, Japonais, Fair Maid of Guernsey, Ralph Brocklebank, Stanstead Surprise, Mrs. A. Hardy, Annie Clibran, Volunteer, Condor, M. Bernard, E. Molyneux, Puritan, Florence Percy, Mdme. C. Audiguier, Baronne de Prailly, Sunflower, M. J. M. Pigny, and Bertha Flight; Mr. Tomlinson second, and Mr. Hughes third.

For twelve incurved Mr. Paul, gardener to J. C. Bowring, Esq., Ascot, was first with even, neat blooms; Mr. Cole, gardener to E. Hamilton, Esq., Sunningdale, second. For the same number of Japanese, distinct, five entered, the best, a capital lot, coming from Mr. Cole; the Rev. R. M. Macdonald second. For six, any one variety Japanese, ten competed, Avalanche taking first and second prizes for Messrs. Hughes and F. J. Thorne in the order named, Ralph Brocklebank winning the third honour for Mr. Woodhouse, gardener to Miss H. Belcher. The finest six incurved, one variety, were from Mr. Lane amongst eight others, large and solid specimens of Empress of India; Mr. Joy, gardener to Mrs. Entwistle, second with the same variety.

Reflexed are always well staged here. Much encouragement is given to this class, a silver cup being offered for first prize, which was well won by Mr. Cole with a very fine lot of blooms, namely Orion, J. H. Bradbury, Cloth of Gold, Emperor of China, Fred Hart, King of Crimsons, Pink Christine, Felicity, Chevalier Damage, Cullingfordi, and Distinction. Mr. Page was a good second. The premier incurved bloom was Lord Alcester in Mr. Lane's cup stand, and the best Japanese Vivian Morel in that of Mr. F. Debnam, gardener to A. Pears, Esq., Isleworth, both extremely fine blooms.

Groups of Chrysanthemums were remarkable for the even high quality of the incurved blooms especially, and for the dwarf nature of the plants. Mr. Cowie, gardener to V. L. Oliver, Esq., Sunningdale, was the most successful amongst five entries. Mr. May, gardener to the Hon. Lady Isabella Keane, a close second. Mr. Hughes third. Chrysanthemums in pots as specimens call for no comment, being only of moderate quality.

Five groups of miscellaneous plants made an imposing display on one side of the room in which the cut blooms were arranged. Mr. Paul secured the first prize easily, Mr. Thorne following. Primulas were remarkable for their high quality. For six white Mr. Joy was first, as also for six coloured. Mr. Woodhouse staged the finest white Cyclamens. Mr. Lane had the best table plants—a good six.

Fruit was of good quality, Mr. Lane taking first prize for two bunches of white Grapes with really splendid Muscat of Alexandria; while Mr. C. Cooper, Sunninghill, did likewise for two of any black variety with well finished Alicante. Mr. Joy had the best four dishes of dessert Pears. Mr. Fenner, gardener to the Rev. Canon Girdlestone, Sunningdale, had the best kitchen Apples, four dishes. Mr. F. J. Thorne the best dessert sorts.

#### CHISWICK.—NOVEMBER 5TH.

FOR several years the autumn shows at Chiswick have been, like the summer shows in the same place, distinguished by the high quality of the exhibits and their bright general character, so that when it was mooted that possibly the Exhibition this year might not be held owing to several unforeseen and unfortunate occurrences, several good supporters of the Society combined to avert such a local disaster. The result was that Mr. E. Hinton became Secretary in succession to the late respected Mr. Hartland, whose death took place suddenly a few weeks ago, and the Exhibition was held as arranged on Thursday last week. The Vestry Hall, Turnham Green, is not a very spacious building, but it is convenient, and with the aid of several beautiful non-competing groups a most pleasing effect was produced. The cut blooms occupied a table in the centre of the hall, and the specimen plants with the groups were arranged round the sides, every foot of available space being filled.

The chief class for cut blooms was that for twenty-four (twelve incurved and twelve Japanese), and in which Colonel W. P. Talbot, Glenhurst (gardener, Mr. C. J. Waite), won the first prize with fresh even medium-sized blooms of the following:—Incurved: Prince Alfred, Jeanne d'Arc, Lady Hardinge, Lord Alcester, Princess of Wales, Mr. Brunels, Nil Desperandum, Miss M. A. Haggas, Empress of India, Lord Wolseley, Violet Tomlin, and Queen of England; Japanese: Condor, Avalanche, Val d'Andorre, Stanstead White, Mrs. Falconer Jameson, Mdle. Lacroix, Sunflower, Stanstead Surprise, J. Délaux, E. Molyneux, Pink Lacroix, and Madame Baco. The second place was taken by E. P. Oakshott, Esq., Orchard Dene, Ealing (gardener, Mr. C. Long), who had some good fresh blooms; and Mrs. Sanderson, Duke's Avenue, Chiswick (gardener, Mr. R. Wood), was third. The class for twelve incurved included some neat exhibits, E. Tautz, Esq., Castle Bar, Ealing, securing the chief prize, followed by C. M. Tate, Esq., Ranelagh House, Chiswick (gardener, Mr. Aspland). The best six incurved came from Mr. H. Head, Inglewood Gardens, Kew, who also had the leading six Japanese. Mr. Davis staged the first collection of twelve Japanese, and Mr. Waite led with six reflexed blooms, also taking the same position for six Japanese blooms of one variety with capital examples of Stanstead Surprise, and the same exhibitor was first for six Pompons, followed by Messrs. Chadwick and Davis. Mr. Chadwick was first for

six single varieties with very graceful blooms, and successful exhibitors in other cut bloom classes were Messrs. Clark and Avey.

The principal prizes for groups and specimen plants respectively were secured by Messrs. Fromow and Sons, Chiswick, and Mr. Meads, gardener to J. T. Thornycroft, Esq., Eyot Villa, Chiswick, while for fruit Messrs. Waite, Wood, Chadwick, and Lang were the chief prizetakers.

Amongst the non-competing exhibits were handsome groups of Chrysanthemums from the Marquis of Bute (gardener, Mr. May), Nepenthes and other plants from the Duke of Northumberland, Syon House, a miscellaneous group from the Messrs. Rothschild, Gunnersbury Park (gardener, Mr. Reynolds), also from E. A. Watts, Esq., Devonhurst, Chiswick (gardener, Mr. H. Wright), and a most attractive group of Chrysanthemums from the Royal Horticultural Society's Gardens, Chiswick, besides a collection of Apples from the same establishment, and another from Messrs. C. Lee & Sons, Hammersmith.

Altogether the Show was very satisfactory and deserves every encouragement from the residents in the neighbourhood.

#### CAMBERWELL, PECKHAM, AND DULWICH.

NOV. 5TH AND 6TH.

A VERY creditable gathering was made by this Society at the Peckham Public Hall, Rye Lane. No less than ten groups were in competition; that for 100 square feet was arranged by Mr. Witty, Superintendent of the Nunhead Cemetery, who secured the tradesmen's silver challenge cup for a highly meritorious collection, the flowers throughout this large group being remarkable for their freshness. Mr. Elson, gardener to M. Peat, Esq., was a very fair second. Amongst the amateurs the group staged by Mr. M. Falkner, Crawthorpe Grove, East Dulwich, displayed very high taste in arrangement, it being among the best we have seen for the season. Other good collections were staged by Messrs. Snoad, Bolton, Clival, Dominy, Lindley, and Merriden. The cut bloom classes were fairly well filled, the principal prizetakers being Messrs. Stevens, Witty, Elson, Brettinshaw, Merriden, Snoad, Bennetts, Clival, and Glasere.

Two very interesting and attractive collections of British and foreign fruit were arranged and much admired. Mr. Major, Pine Apple Nursery, who staged fine Grapes, Pines, and a splendid bunch of Bananas, was awarded the first prize, and Mr. Fletcher, High Street, Peckham, the second. This latter collection contained several fine dishes of Apples and Pears. Messrs. French and Norman Davis staged groups of Chrysanthemums not for competition. The N.C.S. bronze medal was awarded to Mr. Falkner, and the silver to Mr. Merriden, gardener to Dr. Paul, Camberwell House.

#### PUTNEY AND WANDSWORTH.—NOVEMBER 5TH AND 6TH.

THE Putney and Wandsworth Chrysanthemum Society changed the place of their Exhibition from the Putney Assembly Rooms to the much more roomy Town Hall at Wandsworth this year, and judging by the evening attendance the experiment should be as great a success financially as it was artistically. The exhibits were much better displayed than formerly, while there was more space for visitors.

Cut blooms were not quite up to the usual standard, Mr. M. Sullivan, who used to show so finely, having left the neighbourhood. The difference in quality owing to his absence was very marked, but it left the competition much more open. On several former occasions he practically swept the board of the principal prizes. Mr. Knowles, gardener to Mrs. Egerton, Solna, Roehampton, won with twenty-four incurved, his flowers being of fair size but somewhat lacking in solidity and smoothness; John Lambert, Jardin des Plantes, Lady Hardinge, Golden Beverley, and Empress of India were the best. Mr. Bentley, gardener to Lady Gabriel, Edgecumbe, Wimbledon Park, was placed second for much smaller flowers, and of which the freshness was the best point. Violet Tomlin and John Salter were good. Mr. Knowles won again with twelve, relatively a much better stand than the twenty-four. Jeanne d'Arc was here very fine, and Alfred Salter, John Doughty, Prince Alfred, and Nil Desperandum were all large and good flowers. Mr. Bentley was second, and Mr. Methven, gardener to W. Keiller, Esq., Fernwood, Wimbledon Park, was third. Sixes were weak. There were only two stands, and the first and second prizes went to Messrs. Portbury, gardener to W. N. Froy, Esq., Rippon House, Putney Heath, and Mr. Methven respectively.

The Japanese included the best stand in the Show—namely, Mr. Knowles' first prize twenty-four; these, though not perfect, were a good collection of flowers—Etoile de Lyon, Mons. Bernard, Stanstead White, Madame J. Laing, Condor, Mdle. Lacroix, and Fair Maid of Guernsey, being all very good. Mr. Bentley followed with much smaller blooms, Etoile de Lyon being the only one that approached the true size; the flowers were, however, very fresh. Mr. Knowles had another easy victory with twelve Japanese, showing a really excellent stand, with Edwin Molyneux, Condor, Madame J. Laing, Avalanche, Val d'Andorre, and Stanstead White, very fine. Mr. W. J. Wright, gardener to — Tufnell, Esq., The Grove, Wimbledon, was second with fresh but rather small blooms; and Mr. Bentley third. Messrs. Portbury and Wright were first and second with six.

Mr. Knowles had a very fine stand of Reflexed, though somewhat weakened by a small White Christine, and well deserved the premier award. He was also to the fore with large Anemones. Mr. Bentley won with Pompons, minor prizes in these classes going to Messrs. Pearce and Portbury. There were some good blooms in the classes for single-handed gardeners. Messrs. Page, gardener to H. Chester, Esq., Royston, Putney Hill, and Holmes, gardener to S. Crawshaw, Esq., The

Grange, Putney Hill, had excellent stands. Dr. Walker, 12, Ringfield Road, Wimbledon, was credited with the second prize for twelve incurred in this section, but the name of his gardener was not on the card, and also for twelve Japanese. In the amateurs' division he won easily both with incurred and Japanese, Mr. H. Trengrouse, Miss Toppin, and Mr. J. Terry also receiving prizes.

The groups were perhaps the best feature of the Show. Mr. G. Springthorpe, gardener to R. W. Alexander, Esq., Gifford House, Rochampton, had an admirable one, in which Japanese were the most conspicuous, the plants being healthy, and the blooms very fine. He was awarded the silver cup as first prize, and well deserved it. Mr. J. Dark, gardener to J. Hooker, Esq., Lomond House, Putney, also had a fine group, in which incurred were employed freely, and with excellent effect. This would have won at many shows. Mr. Portbury was third, and Mr. Methven fourth. Trained plants were well up to the average, if not a little above it. Messrs. Springthorpe, Pearce; C. Bentley, gardener to J. Bosworth, Esq.; J. Bentley, Portbury, Grounsell, and Townsend, Providence Nursery, Putney, were the principal prizewinners.

The groups of stove and greenhouse plants, the table plants, the Primulas, and the berried plants were excellent, and the fruit merited a special note, being exceptionally fine. Messrs. Wright and Knowles had some splendid dishes of culinary Apples, Winter Hawthornden, Blenheim Orange, and Alfriston being very fine. Mr. Methven also had some grand fruit of Lord Derby, Mère de Ménage, and Alfriston. Mr. J. Bentley was first with dessert fruit, his King of the Pippins being very fine, and Cox's Orange and Ribston excellent. Mr. Portbury was second, and Mr. W. Tew third. There was some high-class fruit in the unplaced dishes also. Mr. Wilson, gardener to R. Christie, Esq., and Mr. Methven showed Grapes finely, and Pears from Messrs. C. Alexander, J. Bentley, and G. Springthorpe were but little inferior to the Apples.

#### TAUNTON.—NOVEMBER 6TH.

CHRYSANTHEMUM Shows, strange to relate, are not so well supported at Taunton as might reasonably be expected, and although under a new management, or that of the Committee of the Summer Flower Show, with its two excellent Honorary Secretaries, Messrs. Howard Maynard and Alex. Hammett, no better encouragement appears to have been met with. As far as the exhibitors were concerned there was not much cause for complaint, cut blooms and fruit being particularly plentiful and good.

Two good groups of Chrysanthemums and Ferns were arranged, Mr. J. Bishop, gardener to Murray Anderson, Esq., being well first for capital cut-backs, a little too formally grouped though. Mr. H. Mockridge was a creditable second, the background of finely flowered varieties of Chrysanthemums being especially good. Mr. W. Cavill, gardener to H. F. Manley, Esq., had a first for six trained plants, any varieties, these consisting of such old favourites as Mdle. Laeroix, Bertier Rendatler, Elaine, Peter the Great, Lady Selborne, and Dr. Sharp in very good condition. Mr. J. Reed, gardener to F. J. C. Parsons, Esq., was first for six varieties of Ferns, Mr. F. J. Burge being second. Poinsettias were remarkably well shown by Mr. J. B. Payne, gardener to the Lord Bishop of Bath and Wells, and in a well-filled class for table plants Mr. B. T. James, gardener to Sir W. A. Lethbridge, Bart., was first, and Mr. J. Lloyd, gardener to Vincent Stuckey, Esq., Langport, was second. Primulas are always well shown at Taunton. For six plants Mr. J. Shepherd was first, Mr. W. Cavill second, and Mr. J. B. Payne third.

The silver cup value £5 with £3 added, offered for forty-eight cut blooms, twenty-four Japanese and a like number of incurred, eighteen distinct varieties of each, brought out four competitors, all staging creditably. However, the Judges had no great difficulty in awarding the premier honours to Mr. G. Hawkins, gardener to W. H. Fowler, Esq., who had a remarkably good lot, Japanese varieties being best represented. This fine exhibit consisted of Japanese, back row: Etoile de Lyon (2), Florence Davis (fine), R. Brocklebank, Mrs. C. W. Wheeler, Puritan, and Gloire de Rocher. Middle row: W. H. Lincoln, F. C. Kingston, W. W. Coles, Madame Baco, Sarah Owen, Eynsford White, Edwin Molyneux, and Avalanche. Front row: Souvenir de Angélie, Ariel, Aida, Mrs. J. Laing, Eynsford White, Golden Dragon (selected for special prize), Japonaise, Mrs. H. Cannell, and Louis Boehmer. Incurred.—Back row: Golden Empress of India (2), Princess of Wales (received special prize for premier incurred bloom), Lord Alcester, Queen of England (2), Golden Empress of India, Princess of Wales, and Mrs. Coleman. Middle row: Empress of India, Jeanne d'Arc, A. Salter, Lord Wolseley, J. Doughty, Princess of Wales, Lord Alcester, and Miss Haggas. Front row: Violet Tomlin, Lord Eversley, Cherub, Alfred Lyne, Jardin des Plantes, Mrs. Halliburton, Beauty of Hull, and Baron Beust. Mr. J. B. Payne was a good second, having a capital lot of incurred blooms, and a highly creditable lot of Japanese varieties, among which Sunflower, Boule d'Or, and Mrs. W. Clarke were the best. Mr. J. Lloyd was a close third; and Mr. Crossman, gardener to J. Bruton, Esq., Yeovil, fourth. The class for twenty-four Japanese varieties, for which the first prize was £5, was also a good one, though Mr. W. H. Fowler won rather easily, his stands being altogether faultless. The varieties were, back row: Etoile de Lyon, Florence Davis, Ralph Brocklebank, Puritan, Gloire de Rocher, Boule d'Or, Baronne Prailly, and E. Molyneux. Middle row: R. C. Kingston, a large handsome bloom, Souvenir de A. Amiel, Madame C. Audigui, Stanstead Surprise, Madame Baco, Avalanche, and W. H. Lincoln. First row: Louis Boehmer, Sarah Owen, Album Fimbriatum, Soleil Levant, Mrs. J.

Laing, Eynsford White, Mons. Bernard, and Mrs. H. Cannell. Mr. J. Lloyd was a creditable second, his stands comprising excellent blooms of Comte de Germiny, Meg Merrilies, Sunflower, Ralph Brocklebank, Volunteer, and Mons. Bernard. Mr. Crossman was third. With twelve Japanese blooms (this class not being open to exhibitors in preceding classes) Mr. C. P. Burge was well first, having Sunflower, Madame Laing, Moonlight, and A. H. Neve particularly good. Mr. H. Mockridge was second, and J. Golding, gardener to Dr. J. H. Mead, third. Exactly similar positions were occupied by these competitors in the class for six Japanese varieties. Mr. J. Lloyd was the only exhibitor of eighteen incurred varieties, and was deservedly awarded the first prize. Mr. Mockridge was first, and Mr. W. Connolly, gardener to J. R. C. Talbot, Esq., second for twelve incurred varieties. In Mr. Mockridge's first prize stand of six incurred was a very good bloom of John Lambert, Lord Alcester and Miss Haggas also being very fine. Reflexed varieties were not well shown, and the Anemone-flowered were quite neglected by the growers generally. The competition with blooms of any white flowered Japanese variety was close and good, Mr. J. Cording being first with beautiful blooms of Avalanche; Mr. Crossman following with the same variety, some lovely blooms of Eynsford White being passed over by the Judges. With six blooms of any other colour Mr. Crossman was first, with rather coarse Etoile de Lyon. Mr. C. P. Burge being second with richly coloured Sunflower. Other kinds of cut flowers were well shown by Messrs. H. Slocombe, gardener to E. Price, Esq.; C. P. Burge, J. Lloyd, and B. T. James, Sir W. A. Lethbridge, Bart.

A large room was wholly given up to fruit and vegetables, and the exhibits were both numerous and of high quality. For a collection of fruit Mr. J. Lloyd was well first, having Gros Colman, Mrs. Pince, and Alicante Grapes, a Queen Pine Apple, Coc's Golden Drop Plums, Hero of Lockinge Melon, Pitmaston Duchess Pears, Adams' Pearmain Apples, and Nottingham Medlars all in excellent condition. Mr. J. Reed was a creditable second, and Mr. Crossman third. Mr. W. Connolly had very fine Muscat of Alexandria Grapes and took two firsts with these. Mr. J. B. Payne was first for Alicante, and other successful exhibitors of Grapes were Messrs. J. Lloyd, G. Webber, gardener to J. Luttrell, Esq., and J. Reed. The principal prizewinners with Apples and Pears were Messrs. J. Reed, J. B. Payne, J. Laing, J. Crossman, Burge, James, J. Hill, and H. Littermore. With a collection of vegetables Mr. W. Cavill was well first; Mr. W. Greedy, gardener to Major Burton, second; and Mr. J. Bruton third. A capital collection of Apples and Pears was shown not for competition by Messrs. Jarman and Co., Chard.

#### CRYSTAL PALACE.—NOVEMBER 7TH AND 8TH.

THE annual Exhibition at Sydenham is invariably looked forward to as one of the events of the Chrysanthemum season; the substantial prizes offered induce good competition, and exhibitors feel there is some credit attached to "a victory at the Palace" beyond the mere pecuniary compensation. Then, too, there is plenty of space to display the various exhibits to the best advantage; "breathing room," so to speak, which those who have had experience in the cramped quarters assigned to some shows was fully appreciated. The Palace is, in fact, so admirably adapted for horticultural shows of all kinds that it would prove an irretrievable loss to the horticultural world if this institution were ever to be disassociated from such attractions and to degenerate into an establishment of the music hall character.

The Show on Friday and Saturday last was not in some respects the largest we have seen there, but in all-round even quality and close competition it would compare favourably with many of its predecessors. The cut blooms in several of the chief classes were extremely good, and have rarely been surpassed. The groups were excellent, and the specimen plants fully up to the standard. Besides these, several important non-competing exhibits were shown, and the groups of Chrysanthemums grown in the Palace gardens were by no means the least attractive part of the display. One group of the latter, in fact, arranged in a semicircular form near the magnificent Tree Ferns at the opposite end of the building, evoked the admiration of both visitors and Judges.

In the cut bloom classes that for forty-eight always attracts the most interest, and the winning collection well deserved its position, the incurred blooms being particularly handsome, but why the exhibitors disfigured the stands by affixing prominent bright yellow name-cards to the front it is difficult to understand; it was one of the worst examples of bad taste we have seen, and it is to be hoped will not be repeated by them or imitated by others.

Of the seven stands of forty-eight cut blooms, twenty-four incurred and twenty-four Japanese, not less than eighteen varieties each, that from Messrs. W. & G. Drover, Fareham, was first, their blooms being distinguished by their substance and bright fresh colours. The incurred varieties were as follows—Back row: Empress of India, Lord Alcester, Alfred Salter, Emily Dale, Lord Alcester, Alfred Salter, Empress of India, and Emily Dale. Middle row: Mrs. E. Coleman, Prince Alfred, John Doughty, Queen of England, John Doughty, Golden Empress, Lord Wolseley, and Miss M. A. Haggas. Front row: Empress Eugénie, Jeanne d'Arc, Mrs. N. Davis, Violet Tomlin, Mrs. E. Coleman, Princess of Wales, Mrs. W. Shipman, and Nil Desperandum. Japanese—Back row: Etoile de Lyon, W. H. Lincoln, Mrs. C. Wheeler, Etoile de Lyon, Sunflower, Alberic Wunden, Stanstead White, and Mrs. C. Wheeler. Middle row: Sarah Owen, E. Molyneux, Stanstead White, Jeanne Délaux, Puritan, E. Molyneux, Madame Baco, and Mons. Bernard.

Front row: Boule d'Or, Louis Boehmer, Mrs. F. Jameson, Ralph Brocklebank, Mons. Bernard, Pink Lacroix, W. H. Lincoln, and Condor. The second place was taken by Mr. E. Whittle, gardener to C. H. Goschen, Esq., Ballards, Addington, with fine Japanese and good incurved. Mr. C. Gibson, gardener to J. Wormald, Esq., Morden Park, Surrey, was a good third with very neat blooms, the Japanese particularly bright; and Mr. H. Shoesmith, gardener to M. Hodgson, Esq., Shirley Cottage, Croydon.

The competition was very keen with twelve Japanese, and the three leading collections were very close together in merit, only separated by a few points. Mr. J. Douglas, gardener to Mrs. Whitbourn, Great Gearies, Ilford, won first honours with handsome examples of Etoile de Lyon, Avalanche, Sunflower, E. Molyneux, Boule d'Or, Val d'Andorre, Stanstead White, Madame C. Audiguier, M. Bernard, Puritan, Madame Baco, and Ralph Brocklebank. The second place was taken by Mr. J. Hughes, gardener to H. F. de Paravicini, Esq., Heathfield, Bracknell, Berks. Mr. G. Carpenter, gardener to Major Collis Brown, Broad Oaks, Byfleet, was a good third, and there were eight other unsuccessful exhibitors who staged most creditably.

Twelve stands of six Japanese (one variety) were shown. Mr. C. Cox, gardener to J. Trotter, Esq., The Grange, Buckenden, Hertford, leading with grand blooms of Avalanche. Mr. G. Glen, Worth Park Gardens, Crawley, and Mr. Goodacre, Elvaston Castle Gardens, Derby, following closely with the same variety.

In the class for eighteen reflexed and Japanese reflexed there were two exhibitors. Mr. H. Felgate, Burhill, Walton-on-Thames, took the lead with very fresh blooms of Maiden's Blush, Cullingfordi, Temple of Solomon, J. Delaux, Golden Christine, Phidias, Amy Furze, L'Adorable, Fred Hart, King of the Crimson, Peach Christine, President Hyde, Elaine, Cloth of Gold, Dr. Sharpe, Val d'Andorre, White Christine, and Pink Christine. Mr. C. J. Salter, gardener to T. B. Haywood, Esq., Woodhatch Lodge, Reigate, was a close second.

The best stand of eighteen Japanese Anemones came from Mr. W. Green, Hadley Manor Gardens, Barnet, who had excellent blooms of Jeanne Marty, Mrs. Judge Benedict, Gladys Spaulding, Madame R. Owen, Nouvelle Alvéole, Cincinnati, Lady Margaret, Gluck, Fabian de Mediana, Souvenir de Madame Blandinières, George Sand, Nelson, Grande Alvéole, Madame C. Leboeuz, Mdle. Cabrol, Miss A. Lowe, and Acquisition. Mr. Salter was second, and Mr. J. Justice, gardener to C. S. Howitt, Esq., The Firs, Norton, Worcester, was third, both showing well.

With twelve Pompons Mr. Salter was first, showing excellent blooms of Golden Mdle. Marthe, Curiosity, Black Douglas, Elise Jordan, Rosinante, La Vogue, Prince of Orange, St. Michael, Pygmalion, Dupont de l'Eure. Messrs. Bowman and Slade followed closely in the order named. Mr. Salter was also first with twelve Pompon Anemones, very neat blooms, Messrs. Slade and Chadwick being second and third. Mr. W. Green had the best twelve Japanese Anemones, and Mr. Justice was second.

The singles were very attractive, Mr. Carpenter having an excellent first prize stand of twelve, showing Jane, Lady Churchill, White Perfection, Sir T. Symonds, Miss Bates, Lutea, America, Patience, Alba, Yellow Jane, Mary Anderson, and Mrs. Langtry. Mr. Wells of Redhill was second, and Mr. Chadwick third.

Eight stands of twelve incurved were staged, and Mr. Hughes secured the first prize with good blooms of Alfred Salter, Miss M. A. Haggas, John Salter, John Lambert, John Doughty, Mrs. Heale, Lord Wolseley, Violet Tomlin, Queen of England, Jeanne d'Arc, and Empress of India. Messrs. Felgate and Douglas were second and third. The best eighteen incurved were shown by Mr. Goschen, Messrs. Cox and Carpenter being second and third, but the blooms were not so good as in the other classes. With six incurved (one variety) there were ten exhibitors. Mr. H. Turner, gardener to F. Murray, Esq., Woodcote Hall, Epsom, was first with beautiful blooms of Princess of Wales, Mr. Felgate being second for Queen of England, and Mr. Douglas third with Empress of India.

Specimen plants were well shown, and the chief prizes were taken by the following exhibitors:—Mr. E. Cherry, gardener to Mrs. Gabriel, Norfolk House, Streatham; Mr. R. Clark, gardener to W. Griffiths, Esq., 12, Palace Road, Streatham, S.W.; Mr. W. Wesker, Tooting Bee Road, Upper Tooting; Mr. J. Weston, gardener to J. Martineau, Esq., South Road, Clapham Park; Mr. W. Carr, gardener to Mrs. Stephenson Clarke, Croydon Lodge, Croydon; and Mr. G. H. Cooper, Sydenham Road, Croydon.

Groups were excellent, and the prizes went in the order named. Collection, arranged for effect in group not less than 100 square feet, incurved varieties only. (To be faced with Pompon, Ferns, or Palms.) First, Mr. J. Townsend, Providence Nursery, Putney; second, Mr. H. J. Jones, Ryecroft Nursery, Lewisham; and third, Messrs. Mobsby & Sons, 147, Moffat Road, Thornton Heath. Collection, arranged for effect in group not less than 100 square feet, Japanese varieties only. (To be faced with Pompon, Ferns, or Palms.) First, Messrs. Reid & Bornemann, nurserymen, Sydenham; second, Messrs. J. Carter & Co., 237, High Holborn, and Forest Hill, S.E.; and third, Mr. H. Loader, Fairlawn Park Nurseries, Sydenham. Collection, arranged for effect in group not less than 50 square feet, any sort. To be faced with Ferns and Palms. (Amateurs only.) First, Mr. R. Illes, gardener to Rev. C. H. Spurgeon, Westwood, Beulah Hill, Upper Norwood; second, withheld; third, Dr. Hetley, Norbury Lodge, Upper Norwood; extra, Mr. T. W. Wilks, gardener to C. Ralph, Esq., Cranbrook Villas, Fox Lane, Upper Norwood.

Non-competing exhibits were numerous. Messrs. J. Laing & Sons,

Forest Hill, had an extensive and attractive display of Chrysanthemums and 100 dishes of Apples and Pears. Messrs. Cannell & Sons, Swanley, sent a stand of twenty-four fine blooms of Chrysanthemum Louis Boehmer and plants of the dwarf Japanese W. B. Clarke. Messrs. J. Carter & Co., Holborn, showed some beautiful novelties, several of which were certificated.

Other varieties were also found worthy of special awards (certificates or commendations)—namely, the following:—Mr. T. Mursell for the Japanese Kate Mursell; Mr. H. Loader for the Japanese Louis Boehmer; Mr. W. Wells for Kate Wells and May Wells; Mr. C. E. Shea for Japanese W. W. Coles and W. H. Lincoln; Messrs. J. Carter & Co. for Japanese Seedling Holborn Rose, single seedlings Holborn Terra Cotta, Holborn Sunray, Japanese Louis Boehmer, decorative Japanese Mrs. James Carter, Holborn Dragon, Alberic Lunden. Commended, incurved Miss Bella Wilson; Messrs. H. Cannell & Son for Japanese Colonel W. B. Smith and Louis Boehmer; Mr. H. Jones for Japanese Louis Boehmer. Commended:—Dr. Walker's Chrysanthemum Cup and Tube, and Mr. Roberts' Silver Lichen.

#### ST. NEOTS.—NOVEMBER 9TH.

THE annual Chrysanthemum festival in this quaint and quiet town is one of the most stirring horticultural events of the year for the district, and not only are the townsfolk attracted to it in considerable numbers, but many journey a distance from neighbouring counties to be present at so pleasant a gathering. A most commendable earnestness distinguishes the amateur and professional horticulturists, and guided by so genial and energetic a Secretary as Mr. Ratchelous, satisfactory success has been achieved for some years. At the Show under notice substantial progress was manifest, especially in the cut bloom classes, where the competition was extremely keen, and the exhibits very close in merit, a few points only separating the prizetakers. The principal class in which general interest centres was that open to the United Kingdom, in which a silver challenge cup was offered. This was for thirty-six blooms of Chrysanthemums, eighteen to be incurved, in not less than twelve varieties; eighteen to be Japanese in not less than twelve varieties, not more than two blooms of any variety allowed. The prizes were: First, a silver challenge cup value 10 guineas and 60s. in money; second, 30s.; third, 20s.; fourth, 10s. "The challenge cup must be won by the same exhibitor twice in succession, or three times in all, before it becomes his property, but on giving a written acknowledgement for the same the winner for the year (except it be finally won) may hold it up to fourteen days of the next Show, when it must be returned to the Society in perfect condition. The winner of the cup for 1890 was Mr. R. Petfield, gardener to A. J. Thornhill, Esq., Diddington, Huntingdon." There were five entries, and after a most careful consideration the Judges awarded the coveted prize to Mr. Petfield for handsome blooms, of which, however, the Japanese were much the best, and to them he was indebted for his victory, only leading by two points.

The varieties were—Incurved: Queen of England, Alfred Salter, Mrs. Coleman, John Doughty, Empress of India, Prince Alfred, Golden Empress Alfred Lyne, Mrs. Heale, Alfred Salter, Lord Alcester, John Doughty, John Lambert, Violet Tomlin, Empress of India, Queen of England, Golden Empress, and Lord Wolseley. The Japanese were Avalanche, Etoile de Lyon, Ralph Brocklebank, Madame C. Audiguier, Annie Hartzhorn, Mrs. C. W. Wheeler, Boule d'Or, E. Molyneux, Avalanche, Etoile de Lyon, Puritan, M. Bernard, Stanstead White, Baronne de Prailly, Boule d'Or, Mrs. C. W. Wheeler, Meg Merrilies, and Val d'Andorre. Mr. Myers, gardener to the Earl of Sandwich, was a very close second, both incurved and Japanese being extremely fresh, even, and creditable. Mr. R. Adams, gardener to W. P. Hartes, Esq., Market Harboro', was third. Mr. W. H. Lees, gardener to the Duchess of Montrose, was fourth.

Mr. Myers was first with twelve incurved blooms, showing Queen of England, John Lambert, Empress Eugénie, Golden Empress, Alfred Salter, Jeanne d'Arc, Lord Wolseley, Lord Alcester, Princess Beatrice, Empress of India, Prince Alfred, and Mrs. Shipman. Mr. Petfield was a close second, and Mr. G. Cotton, gardener to A. W. Lines, Esq., Hitchin, third with twelve Japanese. Mr. Lees took the lead with fresh, good blooms of the following:—E. Molyneux, Avalanche, Gloriosum, Madame Audiguier, Sunflower, Mrs. Alpheus Hardy, Stanstead White, Gloire de Rocher, Louis Boehmer, Etoile de Lyon, W. H. Lincoln, and Lady Lawrence. Messrs. Petfield and Myers were second and third respectively.

In other cut bloom classes Mr. Myers was very successful, taking the premier prizes for twelve reflexed with excellent blooms, for twelve large Anemones and twelve Pompons; Messrs. Redman and Lees securing second and third prizes in the reflexed class. An admirable group gained the chief award for Mr. Redman, the best specimens really well grown examples both of large flowered and Pompon Chrysanthemums won the honours for Mr. Stone, gardener to R. Cochrane, Esq. With a most tasteful basket of Chrysanthemums Mr. Thomas, gardener to Lord Esme Gordon, won the leading prize in that class, and Mr. Myers gained similar honours for a table decoration, followed by Mr. Thomas.

Miscellaneous plants, fruit, vegetables, and cottagers' productions were well represented in numerous classes.

#### HORSHAM.—NOVEMBER 10TH AND 11TH.

BRIGHT, varied and beautiful in all respects was the Exhibition of Chrysanthemums opened in the Drill Hall, Horsham, on Tuesday last. Very rarely are provincial shows of the same extent found to present such a uniformity of good quality and close competition; it was indeed throughout highly creditable both to the Society and the district. Cut blooms were shown in large numbers and of excellent quality, especially

the Japanese, which were very fresh; the incurved in a few cases had suffered a little, the date being somewhat later than usual. Groups and specimen plants were not largely shown, but the leading exhibits in both cases were uncommonly good. Fruit and vegetables were included in the attractions, and the hall was well filled, much taste being shown in the arrangement. For example, the walls behind the groups and specimen plants were draped with dark maroon cloth, and the result was that the colours were seen to admirable advantage. In another matter an arrangement was noted that might well be imitated elsewhere. The Hon. Secretary, Mr. S. Mitchell, who very closely studies the interests of the Society, has designed a neat name card, which is supplied to all the exhibitors of cut blooms, and which is readily affixed to the fronts of the stands before each transverse row of three blooms, thus avoiding the damage done to the blooms, often resulting from attempts to see the names on labels placed on the boards next to each bloom. "The Mitchell Chrysanthemum name card" is useful, neat, and inconspicuous.

We cannot deal with the numerous exhibits fully this week, but the following must be mentioned. With twenty-four incurved blooms, not less than eighteen varieties, Mr. G. Duncan, gardener to C. L. Lucas, Esq., Warnham Court, was the leading exhibitor, staging even examples of Empress of India (2), Miss M. A. Haggas, Mrs. Heale, Violet Tomlin (2), Queen of England, Venus, Lord Alcester (2), Beethoven (2), John Lambert (2), Princess Beatrice, Prince Alfred, Jeanne d'Arc, Princess of Wales, Jardin des Plantes, St. Patrick, Golden Empress of India, Lord Wolsley, and White Venus. Mr. Sparkes, gardener to C. Allcard, Esq., Wimbleshurst, Horsham, and Mr. W. Wallis, gardener to T. J. Mews, Esq., Hartwell, Hartfield, were second and third respectively, each showing well. Mr. G. Duncan was also first for twenty-four Japanese (distinct), exhibiting capital blooms of Stanstead White, Stanstead Surprise, Golden Dragon, Baronne de Prailly, Sunflower, Madame Baco, Ralph Brocklebank, M. Bernard, Thunberg, Condor, J. M. Pigny, J. Delaux, A. H. Neve, Soleil Levant, E. Molyneux, Avalanche, Madame J. Laing, W. G. Drover, Val d'Andorre, H. Cannell, Etoile de Lyon, Meg Merrilies, and Marsa. Mr. T. Glen, gardener to Mrs. Montefiore, Worth Park, was a close second, and Mr. Sparkes third.

Mr. G. Goldsmith, gardener to Sir E. J. Loder, had the best twelve incurved, followed by Messrs. Pullen and White. Mr. Edwards took the lead with twelve Japanese in an excellent class. Mr. Glen and Mr. Duncan also shared the honours in several other classes.

Mr. F. Edwards, gardener to A. Agate, Esq., Horsham, exhibited the best group, a most tasteful arrangement of well-grown plants; and Mr. Sparkes was first with four specimen plants and a single specimen—handsome contributions.

The chief fruit exhibitors were Messrs. Duncan, Glen, White, and Kemp, who staged Grapes, Apples, and Pears in the various classes. Messrs. Sutton & Sons' prizes for vegetables also brought several fine collections.

#### HARDY FRUIT GARDEN.

**PLANTING.**—Proceed with this as fast as possible now, before winter weather commences. Fruit trees are full of leaf yet, but no harm can possibly ensue from moving them at once, and if replanted without delay they will make fresh roots and thus get a much stronger start in the spring. If new orchards are in contemplation they should have attention first, but do not plant in any low situation, as such places are often liable to a superabundance of water, which induces canker and all kinds of disease, and they are sure to feel the effects of spring frosts much more than higher ground would do. A gentle slope to the south or south-west is the best position if it can be had. Extensive operations in the preparation of the soil are not necessary in the majority of cases. Manure is not required when planting fruit trees, no matter how poor the soil is, as a tree when freshly planted has all its roots severed or otherwise injured, and is not in a position to appropriate rich food; its first business is to make fresh roots, and then after a time it is ready for feeding according to circumstances.

Draining will occasionally be necessary, and should always be completed as soon as the trees are planted if not previously done. The drains should run right up the centre of the spaces between the rows, or they will soon be choked by the roots and be worthless. Anyone can easily tell whether draining is necessary by forming a hole 18 inches deep in wet weather, loosening the bottom slightly with a fork, and leaving it for a few hours. Examine it again after there has been at least four hours' fine weather; if water is standing in the bottom of the hole it is not a suitable site for planting fruit trees, and must either be improved or abandoned. Shelter should also be secured from the north and north-east if possible; if none exists plant Larch and Spruce Firs and a few English Elms or Poplars among them, but these must not be placed too near the fruit trees, or the forest trees will have the lion's share of the nourishment. Apples are not very particular as to what kind of soil they have if the above conditions are secured, but it is not well to plant them in very light or chalky soils, as the fruit in these places

will be very small. Pears will not succeed in such soils either; a good supply of moisture at all times is absolutely essential to their well-being, and a deep alluvial loam suits them best of all. For planting in comparatively dry positions this fruit should always be worked on the Pear stock, and for places where moisture is more abundant the Quince stock is the best for most varieties, especially for dwarf trees and pyramids. In all places much exposed to the wind it is best to grow pyramid or bush-shaped trees instead of standards, as the fruit on these dwarfier trees is more secure if a gale of wind comes.

Plums and Cherries will give good returns in certain places where Apples and Pears would be of no use whatever; these fruits must have a certain amount of limestone or chalk in the soil, or they fail to stone when the time comes. Plums are not so particular as Cherries in this respect, and will succeed in sandy soils where Cherries are often of no use whatever. When planting Cherries it is also advisable to consider whether they can be protected from birds, as in some parts of the country it is quite impossible to get a crop from them owing to the ravages of starlings and jackdaws.

In planting fruit trees let the holes be dug at least a little wider than the spread of the roots, so that all may be laid out evenly all round; do not plant deeper than the trees have been growing previously. The surface line will be plainly marked on each stem. Loosen the bottom of each hole before putting the tree in position, scatter a little sweet-surface soil over the roots in preference to that which has been dug out of the hole; cut off all the ends of the roots smoothly before putting in the tree. Remove all those that strike straight downwards, also all suckers. If the soil is wet do not tread it into the hole, but place it in as firmly as possible with the spade. All newly planted trees should be mulched at once with some short straw, half-decayed leaves, chopped hop bines, or some similar material to keep out the frost and encourage root growth as much as possible. Rich manure is not required, and is mostly wasted if used for this purpose at such times, but that fresh from stables where straw is used for bedding will do capitally. Stake all trees as soon as planted, do not give them a chance to rock about by the wind, churning the soil and straining their roots. Place a piece of old sacking, or gutta percha hose split open, around the stems before tying any strings on, to prevent injury to the bark. If any trees should get their roots frozen place them in a cool shed or cellar until a thaw takes place. Never plant when it is freezing or when snow is on the ground, and never let any roots get dry from any cause when removing and replanting trees.

**VARIETIES TO PLANT.**—In selecting these much depends on soil and situation and the purpose for which they are required. If for market they must be either early or late varieties, large, of good colour, good croppers, and good packers. For private use the aim should be first of all to have a continuous supply, and next to get good flavoured varieties, colour and size being minor considerations. The locality often makes much difference, especially with Apples and Pears. A kind that does well in one part will not succeed in another, and the best way is to notice what does well in the neighbourhood, or to consult some reliable authority. This answers far better than going to exhibitions and taking the names of the finest looking fruit, which is apt to be very misleading.

The following are some of the most useful and reliable varieties:—Apples for kitchen use: Lord Suffield, for warm soils only (if soil is cold plant Keswick Codlin instead); Lord Grosvenor, Ecklinville, Manks Codlin, Golden Noble, Cox's Pomona, Warner's King, Lane's Prince Albert, Stirling Castle, Winter Hawthornden, Blenheim Pippin, Northern Greening, Wellington, Bramley's Seedling, Alfriston. Apples for dessert use: Mr. Gladstone, Williams' Favourite, Duchess of Gloucester, Worcester Pearmain, Wyken Pippin, Cox's Orange Pippin, Herefordshire Pearmain, Golden Knob, Duke of Devonshire, Barnack Beauty.

Plums: Early Rivers, Early Orleans, The Czar, Victoria, Grand Duke, Pershore, Oullins Golden, Kirke's, Jefferson, Reine Claude de Bavay, Purple Gage, Coe's Golden Drop. The last six require a wall in cold districts.

Pears: Beacon, Beurré Giffard, Williams' Bon Chrétien, \*Beurré d'Amanlis, \*Madame Treyve, Fondante d'Automne, Emile d'Heyst, Durondeau (for warm climates only), Louise Bonne de Jersey, \*Doyenné du Comice, Marie Louise, \*Pitmaston Duchess, Passe Colmar, Winter Nelis, Glou Morceau, Bergamotte Esperen, Ne Plus Meuris, Easter Beurré. Those marked (\*) are the hardiest varieties, and do best as standards, and for the latter purpose may also be added Beurré de Capiaumont, Beurré Clairgeau (not rich dessert varieties), Beurré Diel, and Hesse. Cherries: Black—Early Rivers (rather tender), Black Tartarian, and Black Eagle; white—Elton, Governor Wood, Bigarreau Napoleon, Morello, Kentish, Flemish, and Old Morello.

#### FRUIT FORCING.

**VINES.**—*Early Forced Vines in Pots.*—Stout, well-ripened canes, with plump buds, and given a short rest, only answer for early forcing. The Vines require a light, airy, efficiently heated structure, which may be a lean-to facing south, or a span-roof with the ends east and west. A lean-to of 6 feet width will accommodate one row of Vines in front; a span-roof of 10 feet breadth may have plants at each side. If the hot-water pipes are at the front of the lean-to and at the sides of the span-roof the Vines may be stood upon them, placing tiles or slates on the hot-water pipes, and standing the pots upon them. The tiles or slates become warmed and transmit the warmth to the pots, which are kept more or less warm at their base, and the roots are not prejudiced

by the heat. The tiles or slates throw off much of the water or liquid manure supplied to and escaping from the pots, so that there is no risk of a surfeit of steam, and the water running on the floor keeps up a genial moisture as well as affording ammonia to the atmosphere when liquid manure is used. Span-roofed pits or lean-to pits facing south, and having sunk paths in the centre or at the back of lean-to or three-quarter-span, and beds in which fermenting materials may be placed, answer admirably, contingent on their having the necessary hot-water pipes to afford top heat for forcing Vines in pots. Pedestals of loose bricks should be formed in the beds so as to raise the pots to the requisite height and prevent sinking, as would be the case were the pots stood on the fermenting material. This is essential, whether the Vines are trained to trellises at 12 to 15 inches distance from the glass or coiled round stakes where there is no trellis, or the Vines are required for decorative purposes when the fruit is ripe. Vines in pots, and restricted there to afford excellent fruit with judicious feeding, but if weight and quality of Grapes are desired the apertures in the pots should be widened, and some turfy loam placed within reach of the roots. The loam may be placed against or on the pedestals of loose bricks, and the roots will follow the liquid manure given, and the turf hold its manurial elements so that the roots will send up plenty of support for the Vines. Oak or Beech leaves are the best to afford bottom heat. They afford a genial warmth and regular moisture in the early stages, and rich stimulating food when the demands of the Vines are greatest. The house must now be ready, and the plants placed in position. The canes should be kept horizontally, or have the ends depressed, if necessary, to insure their breaking evenly from the base upwards. For early work none is better than Black Hamburg and Foster's Seedling. White Frontignan forces grandly, and Madresfield Court is excellent. Vines started now will afford fruit fit for table in April, or by a little earlier with sharp forcing.

*Early Forced Planted out Vines.*—To have ripe Grapes with certainty early in May, the house must be closed by the middle of the month. This more particularly applies to young and vigorous Vines that do not, as a rule, start into growth so quickly as those that have been forced for a number of years. This applies equally to Vines that have not previously been subjected to early forcing. To produce a soft humid atmosphere, and to economise fuel, a good ridge of fermenting material may be placed upon the floor or inside border and be turned at short intervals, additions being made as the heat declines. Old Vines will not need depressing, but it is a good practice to lower them until the buds break before securing them to the trellis. This is not necessary when the Vines are spur-pruned, unless they are young; then the Vines will need to be brought into a horizontal position over the hot-water pipes or fermenting material where they can be well syringed with tepid water about 10° warmer than the house. The temperature of the house may range 50° at night, 55° by day, and 65° on bright days. The outside border should be protected from wet and frost by a covering of leaves and lights, or by other approved means.

*Houses Cleared of Grapes.*—Attend to the pruning directly the Vines are leafless and the Grapes cut. If the Vines are vigorous, have made stout short-jointed wood, thoroughly ripened, and the buds plump, they may safely be pruned to a couple of buds. If, however, the lowest buds are small, and the Vines have not from similar buds in previous years shown fruit as freely as desirable, or not given bunches as large as desired, the shoots may be left a little longer, pruning, in all cases, to a plump bud or thoroughly ripened wood. The pruning bud should be round (not flat), as that affords a close compact bunch of well set berries with stout footstalks, and these generally finish well. Flat buds usually furnish large uneven bunches of Grapes, the berries setting unevenly and swelling irregularly, rarely colouring satisfactory. Pointed buds, as a rule, are not prolific in Grapes, the "shows" having a tendency to develop into tendrils. The house should be thoroughly washed, the glass cleaned inside and outside. Free the Vines from loose bark, avoiding close peeling and scraping, and cut away all "snags." Wash the Vines with soapy water, 3 ozs. softsoap to a gallon of water, using a brush, and reaching well into every angle and crevice with care and judgment. Limewash the walls, painting the house and trellis if necessary. Remove the mulching or loose soil down to the roots, and place on a couple of inches thickness of fresh loam, mixed with a tenth of quicklime, a quart of steam bonemeal being added to every barrow-load of loam, and about double the quantity (2 quarts) of wood ashes. If the loam be light add some clay marl dried and reduced to powder, mixing it with night soil. If the roots are deep raise them nearer the surface, and lay them in fresh material, such as the following. Turfy loam cut 3 inches thick and chopped up rather small have ten barrow-loads, and add to it one barrowful of old mortar rubbish, two bushels of charcoal broken moderately small, one bushel of wood ashes, half a bushel of soot, and half a bushel of bone meal. If the loam be light add three bushels of clay marl. Incorporate all the ingredients well together. The compost may be used as a surface dressing, as it is good alike as a rooting and feeding area. If the houses must be used for plants they should be kept cool, admitting air freely, not exceeding 40° to 45° by artificial means. Admit air freely on all favourable occasions, and where there are no plants keep the house open in all but very severe weather, a few degrees of frost not injuring the Vines.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### BEES AT HOME.

THE weather up till the 24th October was very unpropitious, and bees carried little pollen, but in the intervals between the rains they did their best, and I never experienced bees having so great a desire to carry pollen as they showed in October. How is this? Had they too little stored for spring use, or have they by the eccentric season been lured into the feeling that spring and finer weather was approaching? Judging by their actions we should be inclined to think so, because some of my stocks have bred to an enormous extent, quite out of the ordinary, but the most remarkable thing is they are making no attempt to kill off.

#### THE DRONES.

These, and the excess of worker brood, indicates in every way they are preparing to swarm. Hitherto, I have believed that bees know the coming weather long before any instrument indicates a change; and to some extent I have wondered if killing, or preserving their drones for long before a change, does not support that belief. A few years since we had drones preserved in the hives till the following spring. A good year followed. And in 1890 they killed their drones in June, and we all know what occurred since then.

When at the Heather I watched anxiously to see the progeny of all my stock hives. One fine day I was pleased to see young bees in every one, and could easily detect the cross or the purity of the breed; one showing the Punic blood, another the Syrian, and another the Ligurian, and so on; for those who are acquainted with the pure races can tell at a glance what the cross is. But on an investigation being made after I had them home not one of them had a laying queen. One Carniolian swarm showed at the moors yellow-banded Syrian bees, and I was about presenting this queen, as I had plenty of crosses, but delayed, and kept it to make up the deficiency of queens in my own apiary. Now instead of this queen producing Syrian crosses there had not been a bee brought forth, nor until the 24th October did I see the progeny of a pure Carniolian queen.

The curious part is what induced the young bees of other queened hives to enter others standing from 20 to 40 yards distant. I cannot understand. It could not be robbing, as it is the old bees that do this; but perhaps the young bees may have been acting as spies only.

#### QUEEN CELLS.

A hive was deprived of all its bees except twelve, and placed in an outhouse for eleven days. When this hive was taken into the house to have the honey extracted, the twelve bees were clustered round a queen cell they had raised in their confinement, and on the capping of the cell being raised a beautiful queen crept out.

#### PUNIC BEES AGAIN.

Although your readers have had my experience pretty fully up to date of these interesting bees, there is still important evidence to give. I have not yet proved that an equal number of Punics and any other variety will surpass the latter in honey gathering; but have proved that the Punics will overtake other varieties in two months' time, although far behind at first. This alone is a valuable trait in the Punic bee, because if some flowers in the field, orchard, and garden depend upon bees for their fruitfulness, then the Punic bee is the most useful.

Of all the bees that have been introduced into this country none has been maligned half so much as the Punic has, and by people who had no experience whatever of them, but who were

morally bound to purchase them, put to test, and speak the truth about them so that all might learn and know. We ought to fall at once into the right track and be of one opinion without so much conflicting evidence so common in this country, as well as in America, not only on the Punic, but on other varieties as well. I have sought in vain for samples of the so-called fine yellow banded Italian bees of America. To say "there is no difference between Carniolians, Italians, Syrians, or Cyprians" is as amusing as it is absurd. Space cannot be afforded for a tithe of what has been said for and against the Punic bees, but the following can scarcely be omitted.

Dr. Miller of America says, "As yet I can only say that in appearance they are decidedly different from all other bees I have seen." Mr. A. L. Root says, "If nobody had told me that they were Punic, I should have unhesitatingly declared that they were ordinary black bees," adding, however, "very likely they are a little smaller than most strains of blacks, but in no respect can I discover at present writing that they are different," and cautions his readers against them by calling to mind the experience of the Cyprians, Holy Lands, Carniolians, &c., all of which I found to be good honey gatherers when managed properly. Mr. E. L. Pratt, also of America, gives his experience of them much as I have found them to be.

Mr. Wm. Cowan gives a very bad account of African bees in general, but says, "We know nothing about the so-called Punic bees," and thinks it "strange that we have never found such a race alluded to" in what he claims "the largest libraries of bee literature in the kingdom." And he further disparages them by giving the lexicon meaning of the word Punic, forgetting in his zeal that the word has other meanings in other languages, and might as easily be construed into great value, as well as faithless and treacherous, winding up with an advice to wait for their own interest what experienced bee-keepers have to say about them, promising that he will "give reliable information when it comes to hand." Mr. Cowan might for once purchase a queen for experimental purposes, as probably he will rely more upon his own than other persons' evidence. Contrary to reports that the Punic bee did not gather honey, and that it was a worthless bee, it has proved itself a good honey gatherer, and I am in the belief that it will prove itself, in a good season, to be a superior bee in every respect. At home it is mild tempered, and does not offer to be spiteful. I observe they will resent an injury, but they do not seem to get all excited at once, never more than one bee attacking at a time, and this was their character at the Heather. Only one bee offered to sting at a time, but another followed, and they were unlike some other varieties, which attack by the thousand as the Syrians sometimes do.

A friend, who has his bees upon the banks of Loch Lomond, and about four miles from Ben Lomond, one of the finest districts in Scotland for bees, failed for many years to get a yield of honey from the Ligurians which the Carniolians has given for the last fifteen years, and he introduced the Punic into his apiary in 1890. This year he has the two varieties standing side by side. As we all know, it has been a poor bee year, yet he has had a good yield from both Punic and Carniolians, being alike pleased with both, the difference being the Punic were handicapped, the queens of his best gatherers being put to depopulated queenless hives in June, and were pitted against swarms and unswarmed stocks. The Punic entered their supers at once, and one of them filled two 20 lb. supers, and another a 24 lb. one of Heather honey; none of these, nor of the Carniolians, is thoroughly sealed, but the latter the more so, but much less in them. My friend said that although both varieties apparently worked equally, he was of opinion had the weather been favourable the Punic would have far excelled, and the appearance of the supers which passed through my hands proved this, and were paragons of beauty and neatness. Propolis, I saw none of it.

It astonishes me very much to hear youthful bee-keepers

speaking of the original British bee, and comparing it in colour similar to the Punic. The former in its purity, probably, they never saw. They are widely different in shade, and there is as great a difference in their hum, the Punic having the highest note of any variety I have heard. As winterers I have had no experience yet with the pure breeds, but the crosses are as good as any, and the best honey gatherers.—A LANARKSHIRE BEE-KEEPER.

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**National Chrysanthemum Society's Catalogue (J. B.).**—We understand that it is not intended to publish a new edition this year, nor have the Committee proposed to issue an appendix or supplement to the existing centenary edition.

**Louis Boehmer and Mrs. Alpheus Hardy Chrysanthemums (W. J. N., and Others).**—We have so many notes descriptive of the constancy of the former as compared with the latter, that we cannot at this time of pressure find space for their insertion. The fact is established that the one is as free as the other is "miffy." It is perhaps true, as "W. J. N." suggests, that "those who recommend smaller pots and lighter compost for Madame Alpheus Hardy than are generally used for other varieties, give sound advice."

**Grubs in Flower Beds (J. H. W.).**—These are the larvae of the common and troublesome weevil, *Otiorhynchus sulcatus*, which feed without any interruption during the autumn and winter months, attacking a great variety of underground stems and roots. The proper application of gas lime to the soil is always serviceable, and a dressing composed of equal proportions of quicklime, soot, and wood ashes has been highly recommended by some who have tried it. Some have advised abundant watering with clear lime water, or the use of a very dilute solution of petroleum with a portion of softsoap added.

**Late Grapes not Finishing Well (W. W.).**—This usually arises through too late starting, overcropping, or a bad condition of the roots. If the first, nothing will be gained as regards the Grapes by sharp firing, and it will do no good after the wood is ripe, but that must be effected under any circumstances, yet it will not prevent the Grapes shrivelling when the leaves fall. When the defect in finish is due to overcropping, relief should be given the Vines by cutting a portion of the crop at the earliest convenience; but where it can be traced to imperfect drainage or bad borders no time should be lost in getting out the old soil, rectifying the drainage, and relaying the roots in fresh compost and near the surface.

**Appointments in Gardens (A Young Gardener).**—It is difficult to fix upon the best time for "a young man to get a situation as second or third in a large establishment," as such are often bespoke long before they become vacant. Many changes are made in late summer, and the most vacancies probably occur in the spring through journeymen then changing, and we should say that from the New Year to April inclusive is the most likely time for you to meet with an appointment. The chief thing is to make your requirement known, and afford evidence of qualifications in proper time to quarters through the agency of which such places as that you seek are filled. Advertising is often a means of securing places of the nature desired, and in some cases it is necessary to give a premium or take a low wage for the privilege of gaining experience.

**Removing Stable Manure and Leaves from a Vine Border (A Subscriber).**—The materials placed on the Vine border ought long ago to have been removed. They should now be cleared away carefully, as the roots will probably have run into them more or less. In that case the roots should be covered with a couple of inches depth of fresh loam, and be covered with a few inches thickness of leaves to keep the soil from freezing, and the lights may be replaced so as to throw off heavy rains and snow. The border ought to be exposed in summer,

NO time should now be lost in potting all shrubs intended for forcing, so that they may be in the right condition to respond to the demands made upon their energies while undergoing the operation. Any plants, or rather shrubs, intended for this purpose I always like to plunge over the rims of the pots in coal ashes in the open air for at least a month before taking them under glass, and if they remain in such a position for a still longer period they are all the better for it. In some cases the shrubs root surprisingly when so treated at this time of the year, in others they make no fresh roots before the influence of a warmer temperature is felt; but in all cases the roots have time to heal their wounds, and therefore be in a position to establish themselves more quickly when taken under glass than they would do if potted and at once given shelter. They also start more freely if subjected to a few sharp frosts before forcing begins, and in the case of that useful shrub for this purpose, *Deutzia gracilis*, a few plants should be kept in pots throughout the summer for the purpose of very early forcing, as if well cared for they may be depended upon to come into flower quickly when taken into a brisk heat as soon as the leaves have fallen. Taking them under glass before this stage has been reached is a mistake, as the points of the shoots start into growth, or rather continue the growth already nearly completed, and prevent many of the back buds from breaking, the natural consequence being that shoots which ought to be perfectly wreathed in flowers are only sparsely furnished with them.

In other cases it sometimes happens that cultivators are sorely puzzled to know why their plants lifted from the open air and placed under glass do not succeed as they expected. Judging from the appearance of the ripened wood all goes well for a time; each shoot in due course shows abundance of white buds, but just as these begin to unfold the greater portion of them turn yellow and fall, or at the best only open imperfectly. This undesirable state of affairs is caused by forcing too soon after potting, and by mutilating the roots too severely in order to place the plants in small pots. It is without doubt a great convenience to have plants, especially those required to be used for decorative purposes, in as small pots as is consistent with their well-being, but when this is carried too far great inconvenience often results.

I have treated this particular plant at some length, because when well done this *Deutzia* is one of the best of all shrubs for forcing. It is therefore all the more important that mistakes in its culture should be avoided. It should also be borne in mind that those plants intended for flowering early in the ensuing season should, after flowering, be placed in a medium temperature to complete their growth, otherwise they will not make such vigorous growth as they should do, but later plants will only require the protection of a cold frame till they are sufficiently hardened to place in the open air. The chief plants should be planted out and allowed to stand for two seasons before being forced again. Any plants that are weak or stunted may be invigorated by being cut down to the ground as soon as they have done flowering. Some cultivators make a practice of treating their whole stock in that way, but I have on many occasions found vigorous plants produce very strong shoots under this system which do not yield nearly so much flower per plant as the unpruned

ones, and I therefore advise pruning to be practised only in cases where additional vigour is required. *D. corymbosa* and *D. crenata flore-pleno* are also good varieties for forcing, but they are much stronger growers and produce larger flowers than the first-named.

Azaleas of the Ghent and mollis types are excellent for forcing; the varieties of the latter are perhaps the most showy on account of the larger flowers they produce, but I have a special liking for the Ghent type, because they possess so many lovely shades of colour, and have, moreover, in many instances a pleasing and uncommon scent. Both types should be largely grown where the cost of purchasing plants is practicable, and if only a few can be bought each year a stock is soon got together, as with proper attention they will serve for forcing purposes for an indefinite time by being planted out in the reserve garden in May or June and allowed to remain undisturbed for two seasons. Those who have a good yellow loam, fairly free from stones, will find these Azaleas may be grown successfully in it; but in the case of ordinary garden soils peat with a little burnt refuse added should be procured to plant them in. *Azalea amoena* is also a pretty kind, which thrives well under the same conditions as those already named. It is generally grown throughout the year in pots, but is quite hardy enough to be planted out in the south of England. Nurserymen grow large quantities of it in the open air, but gardeners are, as a rule, rather sceptical about its hardiness. It is a capital plant for forcing, and will succeed under precisely the same treatment as the Azaleas first named.

Rhododendrons are a useful and beautiful class of plants, alike for flowering in pots and in the open air, and fortunately they will endure fairly hard forcing. True, the trusses are not quite so fine as when the plants are allowed to come forward steadily, but the great aim with flowering shrubs for forcing is to get them in flower early in the spring, and for that purpose they are well adapted and will bear forcing better than many persons imagine. Any of the better varieties are good for pot work, but the early ones are of course preferable. The following varieties supply a good range of colour:—White Gem, very early; Baron Osy, creamy white, dark blotch; Caucasicum, yellowish; Illuminator, rose; Madame Wagner, bright pink; Mirabile, deep rose; Nobleum in various shades of colour; Prince Camille de Rohan, white shaded rose; Vesuvius, deep crimson scarlet.

*Choisya ternata* is especially good in pots when brought on in a greenhouse temperature. Its scented waxy white flowers are always prized; but, unlike the other plants named in this list, it should be grown in pots throughout the year, and taken under glass on the approach of sharp frosts. *Staphylea colchica* is another fine shrub, producing deliciously scented creamy white flowers, requiring the same treatment as *Deutzias*, and I am sometimes not a little curious to know why it is not more generally grown. I think it must be on account of a tendency with many gardeners not to grow anything till they have seen it for themselves. The consequence is many fine plants are only grown in certain localities where enterprising spirits have established them. I can confidently recommend this fine deciduous shrub for forcing. *Viburnum Opulus*, *Prunus sinensis flore-pleno*, and *Weigela rosea* and *alba* are well known to be valuable for the same purpose; and *Ribes sanguineum* and *album*, though not so much employed in that way, are quite as suitable. I have also a belief that the *Cydonias* will bear forcing well, and I intend to try some this season. Should they prove a success they will, on account of their colours, be acquisitions in a list of shrubs for forcing.

The value of plants which have been forced is often greatly lessened by cutting the flowers or using the plants for decorative purposes before they have been properly prepared, the result being that they do not last more than half the time they ought to. All cultivators should therefore have a regular system of placing forced plants and flowers into a comparatively cool structure for a few

days before using them, where they will be guarded from cold draughts, yet receive enough air to harden and render both leaves and flowers less fragile.—H. DUNKIN.

### SULPHATE OF COPPER MIXTURE AND THE POTATO DISEASE.

IN view of the discussion which has arisen regarding the application of the sulphate of copper mixture to prevent the spread of Potato disease, I take the liberty of mentioning that I applied the 3 per cent. solution of sulphate of copper mixed with an equal weight of lime, as per usual directions, to a field of Potatoes (Maincrop and Bruce) about the end of August. Soon after I observed the leaves becoming spotted. Fortunately, there is little disease here among late sorts, and my 1891 experience therefore hardly counts in showing how profitable the remedy may be in a more unfavourable season. A small plot of Early Puritans, badly affected in the tops, was dressed at the same time. These were afterwards lifted quite sound.

One portion of the Maincrops had been accidentally dressed with a large excess of lime, so much as to cause them to appear from a distance almost white; and I was surprised that, though the leaves over the rest of the ground died away during the early part of October, this part remained green until killed by frost on the night of the 29th October, and the crop on it is unusually heavy.

This curious result has led me to examine the history of the remedy, and I find that in the first instance some French experimenter discovered that sulphate of copper would cure an attack of fungus on Vine leaves. This fungus (*Peronospora viticola*) is quite similar in its habits of growth to that familiar to us as Potato disease (*Peronospora infestans*). It is now about seven years since sulphate of copper was first applied to the treatment of Vine mildew, and a great many experiments with regard to the best mode of application has been made. I venture to summarise some of the conclusions already arrived at from M. Vermorel's pamphlet, "Résumé Pratique des Traitements du Mildiou," as it is from the Vine-grower's experience that it was first successfully applied by Potato growers in France.

"Some varieties noticed in America as disease-resisting are attacked by it in France, and *vice versa*." "As a rule, people have been in too great a hurry to pronounce certain kinds safe, or certain remedies sure, because they were efficacious against mild attacks." "The Vines of a kind least susceptible of disease have sometimes been seen quite covered with mildew." "As atmospheric conditions vary greatly from one year to another, a variety attacked one year will not be, *ipso facto*, attacked the following year, whilst a Vine that has hitherto escaped may be so."

Sulphate of copper alone in solutions stronger than half per cent. was found to burn the leaves, and M. Millardet found that the injury was not always in proportion to the strength of the solution. This latter conclusion has led to experiment regarding some substance to mix with the sulphate of copper, and it was found that if an alkali were added the burning action would be prevented; ultimately lime has been generally adopted to mix with the sulphate of copper. It is cheap, easily procurable, and has a small value of its own as a disease preventive. The effect of adding the lime may be chemically stated as causing a double decomposition. The sulphate of copper is changed into hydrated oxide of copper (pale blue colour), and part of the lime is changed into sulphate of lime or gypsum. This hydrated oxide of copper is not very soluble, but as it adheres to the leaves is just sufficiently dissolved by the rain or dew to render them unfit for the germination of the mildew spores.

The formula for Potato disease recommended by the Royal Agricultural Society of England (20 lbs. sulphate of copper, 10 lbs. lime, and 100 gallons water) had been condemned by the French experiments, and M. Aimé Girard, in his work "Recherches sur la Culture de la Pomme de Terre" (Paris, 1891), mentions that in 1890 there were some failures in treating Potato disease with this formula owing to the influence of the rainy season, and he states that it is preferable to increase the amount of the sulphate of copper to 30 lbs., using an equal weight of lime.

In view of the chemical decomposition of the sulphate of copper it will be seen that it is essential that any labourer preparing the mixture for sprinkling should keep the lime well stirred, otherwise there will not be sufficient used to decompose the sulphate of copper, and leaves may be burned. It should also be borne in mind that unless the sulphate of copper and the limewash are each cold before being mixed some of the sulphate of copper will not be turned into the pale blue hydrated oxide of copper, but into the anhydrous oxide, which is of a dark brown colour and quite

insoluble, so that it is useless. The sulphate of copper solution requires frequent stirring to keep it of uniform strength.

It will now be apparent, if care be taken to add sufficient lime and the mixture properly made, the result when sprayed on the leaves covers them with the pale blue hydrated oxide of copper, with some free lime and gypsum, none of which substances are at all injurious to the leaves. Any cases of failure will perhaps now be further investigated, and those who have been affected will be able to secure success in future.

From the experience of French Vine growers it seems as if our best course with the Potato will be to set two or three Potatoes of a kind we know to be weak disease resisters in the ground with the others, then about the middle of July give a 1½ per cent. dressing as a precaution. These two or three sets should have been covered during the spraying, and if watched will afford a signal for a second or full dressing if disease should come.

It may occur to some that it would be almost as well to wait till disease actually shows itself before using the mixture, but my own experience this year was that when I first noticed spots on the leaves there was a violent storm blowing, which lasted over a week, before I could use my sprinkler, and M. Girard mentions that the long-continued rain of July-August, 1890, in the north-east of France made it impracticable to apply the Bouillie Bordelaise at all satisfactorily for a long period, so that the only failures he knew of in 1890 were in that district.—THOMAS HARLEY, *Bevdley*.

### CLIMBING PLANTS FOR NORTHERN DISTRICTS.

HARDY climbing plants are worthy of extended cultivation, as it is a phase of gardening that a great majority of people could if they like indulge in without any very great expense or trouble, except the initial expense of procuring and planting suitable kinds. There are thousands of plots of ground at the base of dwelling houses and other buildings, at the foot of boundary walls, palliades and palings, and various other positions which are admirably adapted and might be utilised, as in numerous instances they are, for the growing of hardy climbers. They would give, rightly managed, satisfaction, pleasure, and enjoyment to the planter or owner, and an equal amount of satisfaction, and even positive delight to those who might see them. There are many advantages accruing from the employment of decorative plants of this kind. When well grown, and not trained in too stiff and formal a manner, they are not only pleasing and ornamental, but obscure rough places and glaring bare frontages with either luxuriant foliage or bright flowers, sometimes both combined. There is something of effectiveness for every season of the year, and some—for instance, the Ivies—are effective throughout the year.

In these notes I hope to succeed in making some useful remarks on the hardiest of evergreen, deciduous, and flowering climbers which may without fear of failure be planted in unfavourable situations, or such as those in the immediate districts surrounding towns, and especially smoky and northern towns.

#### WISTARIA SINENSIS.

First of all I will consider the claims of the Chinese Wistaria as a climbing plant. It is not commonly to be met with in the immediate districts of Sheffield, and when it is, it is generally on the spacious walls of old established residences in the suburbs. On country mansions it is often seen to great advantage, its stout stems, strong shoots, and conspicuous foliage soon covering a large extent of space. It is one of the strongest growing climbers we possess, and will grow from 30 to 60 feet high in favourable positions in rich, light, warm soil of a fair depth. A Wistaria and a Scotch Laburnum planted together produce when in flower a good effect, as they bloom about the same time, and the latter, though a flowering tree independent of any support, is yet quite amenable to training against a wall, where if properly treated it will flower freely.

A position with a south aspect is best for the Wistaria, and for a very lofty position it may be ranked as the best flowering climber that could be mentioned. Its chief drawback is its deciduous character in winter, but planted so, if space permits, that it could be trained to overtop all others, the lower part of the position could be utilised for plants of less height, and of an evergreen character. When not required to cover an extensive space, the Wistaria may be planted, and will do well in ordinary fertile soil enriched with manure at or before, but preferably before the time of planting, which may be done in autumn or spring.

After planting, and just when the topmost buds are beginning to start in the spring, the plant should be pruned back in order to secure the requisite number of branches for furnishing the space

to be occupied. If several are required leave a sufficient number of buds to produce them. If only one branch be needed to run up to a considerable height before the work of furnishing the required space can be attempted, cut back to one or two buds, ultimately selecting the best of these for the leader or main stem, and permit no others to extend until this has reached the space intended to be furnished; then lateral branches should be encouraged in the necessary directions. These will finally constitute the framework of the tree, and from them will issue the flowering shoots yearly at every joint. To avoid overcrowding these shoots should be annually cut back to two or three buds during the winter. For growing over arbours, wire, or iron arches, the *Wistaria* is very suitable, and may be so employed with the certainty of producing a beautiful effect in the course of time.

#### CLEMATISES.

As a flowering climber of quite a different type the *Clematis* must next claim attention. If I can say anything that would induce the more extended culture of these beautiful plants in northern districts, particularly near towns, I should feel amply rewarded for penning these notes. They are easily cultivated, profuse bloomers, and wonderfully showy during their season of bloom, which upon the whole is a pretty extensive one. There are several sections of *Clematis*, the hardiest being the *Jackmanni*, the *montana*, and the *viticella* sections. The *Jackmanni* and the *viticella* sections flower on summer shoots from July to October, and *montana* blooms from May to July on the last year's ripened wood.

*Clematises* are slender in their habits of growth, but they are exceedingly vigorous, and therefore require rich soil to start with at planting time, and regular applications of rich material to the roots by means of mulching every year afterwards. This indicates that a light, poor soil will not grow the *Clematis* well, but a good holding soil that will not permit the manurial substances supplied to pass away too quickly is the material required. In addition to being naturally of a rich and strong nature, the soil should also be of a calcareous nature, or made so by the addition of lime, which is found to be of great advantage.

Young plants of any of the sections may be planted almost at any season of the year, but not if the roots have to be seriously disturbed, and with care in keeping the ball of roots moist, and fed if necessary, the beauty of a plant need not be diminished nor its vigour lessened even if planted from a pot when in full bloom. The best time, however, for planting is either in the autumn or spring. If not thoroughly hardened to exposure choose the latter period and plant as growth commences, but for a thoroughly hardened specimen with vigorous shoots and abundant roots autumn is perhaps the best period of any. Planting being completed, then comes the question, How should the *Clematis* be pruned? A reference to previous remarks on the manner of blooming would answer this; but it will be well, however, to make clear the correct methods of procedure, so that the *Clematis* may be grown and flowered on a few feet of trelliswork or wall, as well as be allowed to ramble over wider spaces, whether of walls, trees, shrubs, hedges, or screens.

All varieties belonging to the *Jackmanni* or *viticella* sections may be pruned in winter or early spring almost close to the ground or to a point near it where there are good bold buds, as it is upon the new wood of the current year that the flowers are produced. That is one method of pruning these varieties, and it is an excellent one for certain positions that require to be clothed with foliage and flowers as low as possible; but if required to clothe higher positions, the upper part only of a wall, the roof of a verandah or porch, or other lofty points, then low pruning is neither necessary nor desirable. But in these cases, however, the same fundamental principles must be kept in mind and adopted with this difference, that instead of pruning the plants to the ground they should be pruned to the main stem, cutting back the principal shoots which issue from it to their boldest basal buds for the purpose of covering the space at a certain point. *Clematis montana* of course does not need this annual shortening, thinning the old wood being the most that is necessary. The last, the easiest, and wildest way of cultivation is never to prune at all, but it is a method which produces a veritable thicket of naked and useless wood through which the rising sap in spring has to make its way, weakened and lowered in vitality by the process before it can produce young shoots, which may eventually flower. Those of the *montana* type will certainly do with less pruning than the others mentioned, but this section should never be allowed to retain crowded shoots or useless wood.

A few words as to the best varieties for hardy climbing purposes. *Clematis flammula*, with white sweet-scented flowers, blooming from July to October, is a good old kind belonging to the *Jackmanni* type. All the varieties of *Jackmanni*, of which there are many, are especially good. The best in the *viticella*

section is *Mrs. James Bateman* of a pale lavender colour. *Clematis montana*, with white vanilla-scented flowers, and *vitalba*, also with white flowers, are both rapid growers, and will soon cover plenty of space. The last named requires pruning on the shortening system. It is the only true species native to England, and is popularly known as the *Traveller's Joy*, because of the peculiar feathery construction of its seed vessels, which are very prominent in winter. It blooms in August.—E. D. S.

(To be continued.)

#### ARISÆMA WRAYI.

AT a recent meeting of the Royal Horticultural Society, from Messrs. B. S. Williams & Son, Upper Holloway, a plant was exhibited of this distinct and rather attractive Aroid, which is evidently well

FIG. 82.—ARISÆMA WRAYI.

adapted for culture in pots. The spathes are neat in shape, and of moderate size; the soft shade of green, the white centre, and the long slender green spadix impart a very graceful appearance to the plant. Sir Joseph Hooker has given the appended remarks upon the genus and this particular species.

"The genus *Arisaema* is a remarkable one amongst Aroids for its wide range in latitude, from the tropics to far into the north temperate zone; and as might be expected from this, the elevation it attains is equally remarkable, from the low-lying equatorial regions of the Malayan Archipelago, to an elevation of 12,000 feet in the Himalaya. And what is very singular in a genus of so wide a distribution, there are no sectional groups of it more characteristic of the colder than of the hotter regions, or *vice versa*. The nearest ally of *A. Wrayi* is the Javanese and Sumatran *A. filiforme*, Blume. *A. Wrayi* itself is a native of Perak, where it was

discovered by Mr. L. Wray, who in 1884 sent herbarium specimens to Kew from Birch's Hill, with the note that the flowers are pale lilac and white, whereas in the cultivated plant they are pale green. In 1888 the same excellent correspondent sent living tubers to Kew, which flowered in January, 1889, and from one of these the accompanying figure was made."

The leaves are divided into five to nine narrow leaflets, about 8 inches long each, the leafstalks and scape being green and white dotted with red, giving a very peculiar effect. The plant, like most of its relatives, requires a warm house, a light open soil, abundance of water when in growth and flower, and a period of rest.

The form of the spathe and spadix is well shown in the woodcut (fig. 82).

### ROYAL HORTICULTURAL SOCIETY.

SCIENTIFIC COMMITTEE.—November 10th.—Present: Dr. W. T. T. Dyer, in the chair; Dr. Masters, Dr. Müller, Mr. McLachlan, Mr. Morris, Dr. Russell, Rev. W. Wilks, Mr. Lynch, Mr. Blandford, Prof. Church, Dr. Bonavia, Mr. Michael, Mr. Pascoe, and Rev. G. Henslow (Hon. Sec.).

*Pear Spot*.—The disease upon Pears brought to the last meeting proved to be due to *Fusicladium dendriticum*, Wallr., a common parasite.

*Hunting Spider*.—With reference to this insect, referred to at the last meeting, Mr. Morris observed that it proves to be very widely distributed. The male appears to be most commonly seen; he had observed it at the gardens of Sir J. Llewellyn at Penllergare.

*Wallflowers with Clubbed Roots*.—Mr. Lister, to whom the specimens were sent from the last meeting, reports as follows:—"I have not studied the life history of *Plasmodiophora Brassicæ* sufficiently to speak with entire confidence with regard to the disease which has attacked the roots of the Wallflowers; but I think there can be little doubt that they are affected by the same parasite as causes the clubbing of Cabbage roots. I enclose a drawing from a section of one of the roots, from which it will be seen that one half has not been attacked, while the other half is much swollen by abnormal growth of all the parts. The cells are larger and rounder than in the sound portion, and among them are vast numbers of larger chambers formed by the breaking down of cell walls, and these are filled with the spores of the *Plasmodiophora*. They are most abundant in the cortex, though both the phloem and the outer part of the xylem are largely affected. The organism would seem to be in the condition described by Zopf, where all the plasmodium (if that word can properly be used in this case) has changed to spores, which would escape when the diseased root rotted away. *Plasmodiophora* is not included by De Barry with the *eu-Mycetozoa*, and Zopf places it with the *Monadineæ*."

*Canonia capensis*.—Dr. Masters exhibited specimens showing interpetiolar stipules and glandular processes, apparently secreting a resinous matter. It was the only instance known in Saxifragaceæ, though similar facts were well known in Cinchonaceæ or Rubiaceæ.

*Pinus halepensis*.—A spray was received by Dr. Masters from Baron von Mueller, bearing both male and female inflorescences, they being usually separated.

*New Insect in St. Helena*.—Mr. Morris read a communication from Mr. W. Grey Wilson, Governor, referring to some insects forwarded (in two stages), which he feared might prove dangerous. They were taken from a Rose bush, the branches of which were densely covered with a large white insect and a small red one. It appeared to resemble some species of *Icridia*. It was sent to Mr. Douglas for examination and report.

*The Injury of London Fog to Plants*.—Dr. Dyer called attention to some discrepancies between the published analyses of the deposits collected at Chelsea and Kew—more particularly in the hydrocarbons—given in Dr. Russell's paper in *Nature*, November 7th, 1891. Thus, the hydrocarbons and organic bases are recorded as 12.3 and 2 per cent. respectively at Chelsea, whereas at Kew they were collectively only 4.8 per cent. Similarly the metallic and magnetic oxides of iron were together, 2.6 per cent., and mineral matter (chiefly silica and ferric oxide) was 31.2 per cent. at Chelsea. These taken collectively at Kew were 41.5 per cent. Dr. Müller did not attach very much importance to these differences; and Prof. Church thought it would be desirable to differentiate more accurately between the silicates. The general opinion was that it would be desirable to collect fresh deposits in the ensuing winter and re-examine them.

*Parana paniculata*.—Mr. Lynch exhibited a spray of this plant of the order Convolvulaceæ, received from India through Dr. Bonavia, who described it in 1885 (*Gardeners' Chronicle*, vol. xxiii, N.S. p. 47). It was the first occasion of its flowering in England. Dr. Dyer complimented Mr. Lynch on its successful cultivation.

*Ixodidae (Ticks) from Antigua*.—Mr. Michael exhibited specimens taken from ponies, and received from Mr. C. A. Barber. They were two females of a *Hyalomma*, probably *H. dissimile*, Koch; which Koch described some thirty years ago from specimens taken in Mexico. The creatures are bred on plants and trees, and attach themselves to passing animals, being then quite small; the male remains so, but the female sucks the blood of the animal and becomes enormously distended. They anchor themselves by their rostra, which are provided with recurved hooks; the *Ixodes* can then withdraw the rostrum and being full-fed,

drops off, matures and lays its eggs on the plants. The specimens sent had sucked and were much distended, but had evidently withdrawn their rostra, as these organs were perfect, whereas the claws with which they were holding on were all torn off.

*Specimen of Agaricus melleus Attached to its Mycelium (Rhizomorpha)*.—Mr. Plowright forwarded specimens with the following communications:—"It is not very long since our British mycologists ridiculed the idea that *Agaricus melleus* was a parasitic fungus, capable of destroying living trees. For many years the heterococious-like history of *Puccinia graminis* was similarly scouted as absurd. This, however, is now a thing of the past. In the specimen of *A. melleus* sent herewith, a group of young specimens are seen in situ attached to the well developed rhizomorphoid mycelium. The specimen was removed from an Ash tree in the park of Hammond Lodge, Terrington, St. Clements, in the month of October last. Such specimens are not easy to preserve; but in the present case this has been accomplished fairly well. The group of *Agarics*, which were quite young, had just emerged through the bark of the tree; by carefully cutting away the bark the mycelium was brought into view between the bark and the wood. A piece of the mycelium 3 or 4 inches square was removed with the *Agarics* in situ. Attached to the under side of the mycelium will be observed two fragments of the wood (Ash) already decayed by the agency of the mycelium."

*Agaricus squarrosus, a True Root Parasite*.—"The parasitic nature of *Agaricus squarrosus* is as well marked as that of *A. melleus*, although this feature in the life history of the fungus has not hitherto, to my knowledge, been pointed out. It attacks Beech, Apple, and Ash trees. The specimens sent herewith were obtained from an Ash tree near King's Lynn. The tree is a fine well-grown specimen growing on the roadside. Last October I observed clusters of *A. squarrosus* growing out of the ground a couple of feet from the stem. On carefully removing the turf I was able to trace the base of the stems of the *Agaric* attached to a compacted mass of white mycelium, earth, and small stones to one of the main roots of the tree. It will be observed that a portion of the woody tissues of the root permeated by white mycelial hyphæ is still attached to the basis of the stems of the cluster of the *Agarics*. Having watched trees attacked by this parasite for some years, it appears that its destructive influence upon the tree it attacks is not nearly so rapid as that of *Agaricus melleus*. This is accounted for by the fact that the mycelium of *A. squarrosus* is not nearly so well developed a structure as that of *A. melleus*. The hyphæ are not compacted into such thick cord-like structures. Still, however, a tree once attacked by *A. squarrosus* is practically doomed. This fungus is very destructive to the Apple trees in the orchards of Herefordshire, where it is a well known pest. It very probably attacks other deciduous trees, but the three above named are the only ones upon which I have observed it growing as a parasite."

Dr. Dyer observed that *A. melleus* is now well known as doing serious mischief through its parasitic habit, and mentioned that where roots are exposed and subject to abrasion by cartwheels, or otherwise, the *Agaric* is known to attack the decorticated place.

### STRAWBERRIES IN SCOTLAND.

THE following notes upon Strawberries, showing when we commenced and finished gathering fruits for the last ten years in midland Scotland may be of interest to some readers.

When commenced.	When finished.	Early variety.
1882 ... June 24th ...	August 12th ...	Black Prince.
1883 ... June 28th ...	September 5th ...	" "
1884 ... June 30th ...	September 3rd ...	" "
1885 ... July 3rd ...	September 1st ...	Garibaldi.
1886 ... July 7th ...	September 4th ...	" "
1887 ... June 15th ...	August 11th ...	Black Prince.
1888 ... July 2nd ...	September 20th ...	Garibaldi.
1889 ... June 25th ...	September 9th ...	King of the Earlies.
1890 ... June 27th ...	August 28th ...	" "
1891 ... July 2nd ...	August 22nd ...	Garibaldi.

Black Prince and King of the Earlies I have discarded, both are too small for table. Black Prince was a sparse cropper in our heavy soil, and King of the Earlies is rather white in flesh for preserving. Captain was tried and found wanting in shapely fruit, 90 per cent. were malformed. I planted 1000 of Noble last autumn, thinking to create a sensation with "noble" fruit before Garibaldi was ripe. In that I was disappointed, because Garibaldi was ripe four or five days before it, and President was ready to gather as soon as it was, all grown side by side. Noble is very deficient in flavour, rather soft in flesh for marketing, and far too dull in colour to be a taking fruit. I shall plant no more of it. I have grown about forty varieties, both late and early, but have found none to approach Garibaldi for an early (it is several days earlier than Marguerite), President for a midseason, and Frogmore Late Pine for a late. In other localities, and on different soils, the trio named may not be all what they have proved themselves to be here, but until a variety has proved itself to be *par excellence*, after a thorough test, there will be no more 1000 plants of it planted by—G. McDougall.

## ON JUDGING.

I THINK I made some remarks in the Journal last year upon the amount of work which the Judges at the Crystal Palace Rose Show had to get through within the hour, and suggested their being helped in the business of looking for duplicates, as they are hardly able to do this also when their task happens to be unusually difficult. My sentiments on this head are not altered, as this year my two colleagues and I had to judge Roses in two classes, which occupied, I estimate, more than 50 yards straight on end of tabling. I did not measure it, but I calculate the distance not only from the fact that a colleague standing at one end looked decidedly out of shot from the other if he had been a partridge, but also from the number of stands I knew were shown, and the usual length of boxes in such classes. It looked a large order, and when we found after preliminary investigation (and that must take some time) that no less than 288 blooms (to the best of my recollection, as fortified by my notes) had to be pointed in one class alone, it seems pretty evident that we could give no guarantee that duplicates had not been passed over, and that no time could have been spared for filling up those cards for judging, which were shown and suggested at the last general meeting. I do not wish at all to complain, and am very pleased and proud to do my best. It is plain that the work in one class cannot well be subdivided, but in order to get it done satisfactorily two things I believe are necessary.

First, is a suggestion I made last year—That when you have, in accordance with the rules, chosen your three-point standard Rose, this should be carried about by one of the Judges for immediate comparison directly there is any difference of opinion. I said, I think, that as one end of a large stand often becomes gradually weaker in setting up as the exhibitor gets short of first-class blooms, so in the time of judging as that end is approached, the ideal or standard of the judge involuntarily becomes lower. I thought, as a rule, in any large stand the tendency with judges would be, if anything, gradually to lower the standard; but the season of 1891 proved an exception. We had considerable trouble to start with in finding a three-point Rose at all, and were obliged at last to select one below our mental ideal; consequently, being naturally somewhat hurried, we were continually raising our standard unconsciously to that of ordinary seasons, and the frequent production of the standard Rose generally showed that we were estimating the disputed bloom too highly. A low standard throughout increases the trouble in judging, for a comparison of mediocrities is always tedious and uncertain. Secondly, though of course this is more important and should be first, it is essential that the judges should be absolutely agreed upon the first principles of judging, or, I need hardly say, it is difficult to get on at all. This is by no means meant as a reflection on my excellent coadjutors at the Crystal Palace, for as the work was done in the time, it is plain we got on very well. Still I would like to have my say. The N.R.S. definitions give the points of a good Rose as “form, size, brightness, substance, and good foliage;” and I have no fault whatever to find with this definition, especially if we may take it that the points are mentioned in order of merit, but I think this ought to have been stated.

Form first of all and above all. I had an idea that this was well understood as the prominent article in the florists’ creed, but from what I have heard I am not sure that it is so. “Size” is defined to “imply that the bloom is a full-sized representative specimen of the variety,” and “brightness” to “include freshness, brilliancy, and purity of colour.” Brightness therefore means what is generally spoken of as colour, since dullness would generally be looked upon as a deficiency in colour. I should put size and brightness as thus defined as of about equal value, but the difficulty with novices generally is that they do not realise the importance of form over colour. Yet I feel sure that the N.R.S. will uphold the value of the one above the other. I do not pretend to know much of art; but it is sufficiently plain, even to one who does not, that form must be above colour, for a drawing may be beautiful without colour, but a painting without shape or drawing cannot. I forbear classical allusions, such as that the Roman word for beauty was *forma*—“form”—and for beautiful, *formosus*—“shapely”—but I have sometimes when judging thought of the well known line—

“O formose puer, nimium ne crede colori”

as very appropriate. Let us rather think of the sneer in our own language, “Beauty is but skin-deep.” It is indeed, if it be dependent only on colour, but not if relying on form, for true beauty is in the shape, the outline, and even in the substance. And when I have seen a three-cornered thing of a Dr. Andry because of its bright flush placed upon an equality with a grand Horace Vernet that has somewhat lost its colour, it has seemed to me like estimating a newly painted gimcrack villa as of equal beauty with a noble old cathedral whose stones have become grimy and time-stained.

Now, though I should be disposed to put size and brightness (as defined) upon an equality, the N.R.S. puts size first of the two. And I am glad of this, because there seems to me to be now a considerable

and increasing tendency to take little heed of the authorised rule that size is a point—and the second point too—in the definition of a good Rose. A show bloom should be developed “in the most perfect phase of its possible beauty,” and I protest against Roses which are not developed and are under-sized, having a full amount of points allotted to them, and I believe my protest to be needed. I take the reason of the apparent preference sometimes shown for smaller blooms to lie in the ignorant statements made against exhibitors that they care only for size; and what I complain of is, I believe, the result of the little bit of mud which is proverbially said to stick out of a handful thrown. I remember seeing a short article in the gardening columns of a well-known paper, headed “Ugly Roses,” and it was all a tirade against size. There are two words, “coarse” and “rough,” which are very easily applied to any particularly fine blooms, and it might well be a temptation to a judge that his reputation for good taste might suffer if he awarded merit to blooms which others spoke of as “coarse.” Let the N.R.S. manfully maintain size (as defined) as one of the important points of a good Rose, for after all it is, and must be, the principal sign of good culture. To have good form without size it is only necessary to have the best varieties, and with many of them it is much easier to get good form (without substance or staying power) from plants that have not been very strongly grown or much thinned; but to have the best of colour you must have the vigour from which size is born. Our principal object in careful culture through many months is to get the health and strength which is legitimately shown in size, and for which we hope to be rewarded; but pretty well-formed buds may be got from an utterly neglected plant of a good sort. And let it be remembered that a show Rose is for show—for the exhibition tent, or for a vase by itself—and that it is not meant for wear or decorative purposes of an ordinary kind.

In nothing should the strict regulations and definitions of a perfect Rose be more sedulously observed than in choosing the medal H.P. or Tea. It should be the nearest approach to absolute perfection, as defined, to be found in the show. It is meant to be the best obtainable specimen of a standard or ideal Rose to serve as a pattern. Yet I remember some years ago a bloom of Général Jacqueminot was chosen at the Metropolitan Exhibition which was a mere spike, with only one or two petals open—of lovely colour certainly, for which alone it was, I believe, avowedly chosen; but it was quite undeveloped, and had no pretension to form. I have also seen elsewhere a Tea Rose chosen that was literally only a buttonhole. We must expect mistakes sometimes, but a medal bloom at a National or affiliated show should not be grievously lacking in any one of the three points required.

I am forgetting, however, that there are five points mentioned; but “substance” is actually included by definition 4 under “form,” though it is not necessarily coincident with “size.” And “good foliage,” I fear, we often do take little notice of. The rosarian’s eye wanders from bloom to bloom, and the foliage is scarcely noticed against the moss, though, of course, any serious defect would be detected. The foliage is pretty sure to be right if the Rose is, and under any circumstances it must, I think, be the last consideration.

In conclusion, I still think it would be fairer to exhibitors and judges, and more satisfactory in general uniformity, if in each class the same length of box or boxes was required from all exhibitors.—W. R. RAILLEM.

## FRUIT CULTURE AND EVAPORATING.

MR. J. G. WILSON, Ledbury, writes as follows in the *Worcestershire Echo* on the Gloucester Fruit Show:—

“I think one of the most interesting exhibits in connection with fruit culture was seen at the above Show, reflecting great credit upon the enterprise of Mr. F. Ricardo of Bromsberrow Place, Ledbury. The exhibit consisted of a variety of fruits—Plums, Pears, and Apples—grown and dried at Bromsberrow by the process known in America as fruit evaporating. The samples shown were in point of appearance quite on a par with any imported from foreign countries, and in flavour evidently superior.

“The subject of profitable fruit culture is at the present time a matter of great interest, and it has been proved conclusively that the best varieties of British grown Apples will fetch considerably more money than the best varieties of American Apples, one grower in Herefordshire this year having realised 30s. per cwt. for his Peasgood’s Nonesuch, when the best American Pippins were realising 19s. 3d. per cwt. But still, though the best varieties will command good prices, there remains the question, What is to be done with a quantity of inferior fruits? The mode practised by our cousins across the Atlantic has been to select the best grown fruits for the fresh fruit markets, and utilising the other by the evaporation process, and thus supplying us with the Apple ringlets and other fruits which we see exposed for sale in our grocers’ and fruiterers’ shops.

“Mr. F. Ricardo has been the first to illustrate to the landowners, farmers, and fruit growers of this neighbourhood the utility of this process in a practical manner; and the thanks, not only of the fruit growing community but of the general public, are certainly due to him for his enterprise, for he has proved that when a glut occurs in one kind of fruit, like there has been this year in Egg Plums, instead of the grower having to part with them at an unremunerative price, he can preserve them and get a good price for them in the winter, when fruit is fetching prices almost prohibitive, or at least quite so to the working classes. Not only will this process save the destruction of enormous quantities of health-giving fruit in times of superabundance

or when the markets are overcrowded; but should other landowners, farmers, and fruit growers adopt the method it must of necessity be the means of improving our rural districts, as it would add a new industry to our almost depopulated villages."

#### LIST OF SHOWS.

THE following are the dates of the remaining Chrysanthemum Exhibitions to be held during November of which we have received schedules and advertisements:—

Thursday, Nov. 19th.—Spalding, Hull and Rugby (second days), and Wantage.

Thursday and Friday, Nov. 19th and 20th.—York.

Thursday, Friday, and Saturday, Nov. 19th, 20th, and 21st.—The Scottish Horticultural Society, Edinburgh.

Friday and Saturday, Nov. 20th and 21st.—Stirling, Chorley, Bolton, and Stockport.

Saturday, Nov. 21st.—Batley.

Wednesday and Thursday, Nov. 25th and 26th.—South Shields.

#### BIRMINGHAM.—NOVEMBER 11TH AND 12TH.

THE thirty-first annual Exhibition was held in the City Hall on the 11th and 12th inst., and must be recorded as a very fine exhibition and a success. In one respect it probably differed from most if not all other exhibitions, for it was three storeys high. The exhibits were so numerous that many, including flowers, fruit, and vegetables, had to be arranged in the basement, while plants occupied the main floor of the handsome hall, the great display of cut blooms being arranged in the gallery above.

The cut blooms were an especial feature, and the liberal prizes of £20, £15, £10, and three following prizes brought sixteen exhibits; others had entered, but owing to so many other exhibitions being on at the time could not attend. Mr. R. Parker, gardener to J. Corbett, Esq., M.P., Impney, Droitwich, was first with a superb forty-eight blooms, twenty-four incurved, and twenty-four Japanese, the latter very fine indeed, the incurved not large but of refined quality. The varieties were:—*Japanese*: Vivian Morel (very fine), Boule d'Or, Etoile de Lyon, E. Molyneux, Sunflower, Avalanche, Baronne de Prailly, F. Davis, Meg Merrilies, J. H. Laing, Golden Dragon, Stanstead White, Gloire de Rocher, Madame C. Audiguier, Ralph Brocklebank, M. Bernard (very fine), Thunberg, Mdle. Lacroix, Madame Laing, and Triomphe de la rue des Châlets (both extra fine), and W. H. Lincoln, Mdle. A. Hoste, Mr. A. H. Neve, and Puritan (all very fine). His incurved varieties were Empress of India, Alfred Salter, Golden Empress, John Doughty, Lord Alcester, Queen of England, Lord Wolseley, Emily Dale, Prince Alfred, Mrs. Coleman, Violet Tomlin, Jeanne d'Arc, Prince of Wales, Miss Haggas, Alfred Lyne, Mrs. Heale, Lord Eversley, Lady Hardinge, Mrs. Shipman, Hero of Stoke Newington, Charles Gibson, Princess of Teck, Mrs. N. Davis, and Princess Beatrice. Second, Mr. Cox, gardener to W. H. Watts, Esq., Liverpool, with a fine forty-eight, consisting of incurved: Lord Alcester, Queen of England, Golden Queen, Mr. R. Bahuant, Golden Empress, A. Salter, Empress of India, Miss M. A. Haggas, Mrs. Coleman, Prince Alfred, Lord Wolseley, Mrs. Heale, Princess of Wales, Violet Tomlin, John Salter, Mrs. Clibran, Nil Desperandum, Princess of Teck, Lady Hardinge, Mrs. Shipman, Refulgens, Mr. Bunn, Jeanne d'Arc, Beauty of Hull. *Japanese*: E. Molyneux, Condor, Boule d'Or, Mdle. C. Audiguier, Etoile de Lyon, Sunflower, George Daniels, Avalanche, Stanstead White, Belle Paule, Jeanne Délaux, Bouquet de Dame, Stanstead Surprise, George Atkinson, W. H. Lincoln, Puritan, Martha Hardinge, Madame Baco, Criterion, Annie Clibran, A. H. Neve, Thomas Stephenson, Madame J. H. Laing, and Val d'Andorre. Third, Mr. Coombs, The Gardens, Himley, near Dudley. Fourth, Mr. J. Gould, gardener to G. R. Dale, Esq., Bromborough. Fifth, Mr. Peter Blair, Trentham Gardens. Sixth, Mr. Townsend, gardener to T. R. Greatorex, Esq., Shrewsbury.

For twenty-four blooms, twelve incurved and twelve Japanese, Mr. Parker was again first in a strong competition with incurved: John Doughty, Empress of India, Queen of England, Lord Alcester, Golden Empress, Violet Tomlin, Jeanne d'Arc, Lord Wolseley, Princess of Wales, Miss Haggas, Mrs. Coleman, and W. G. Heale. *Japanese*: Fanny Davis, very fine; Etoile de Lyon, W. H. Lincoln, very fine; a grand bloom of Vivian Morel, Thunberg, Avalanche, Gloire de Rocher, very fine; Sunflower, Louis Boehmer, very fine; Ralph Brocklebank, Meg Merrilies, and Madame C. Audiguier. Second, Mr. Cox, who had very fine blooms of Mons. R. Bahuant, and Mrs. Coleman (incurved), and fine Japanese also. Third, Mr. Austin, The Gardens, Witley Court. In the class for eighteen distinct, incurved, Mr. Parker was again first with similar varieties to those in his other winning stands. The name of the second winner was not on the card. Third, Mr. Austin, Witley Court Gardens. For twelve Japanese, distinct, first Mr. Austin with Sunflower, Alberic Lunden, very fine; Stanstead White, E. Molyneux, M. Bernard, Puritan, Etoile de Lyon, Japonicum, Avalanche, Crystal Queen, Gloriosum, and

Jules Toussaint. Second, Mr. D. Forbes, gardener to A. Holt, Esq., Liverpool. Third, Mr. Wm. Comfort, gardener to J. A. Everett, Esq., Knowle. In the class for twelve Anemone-flowered, not less than six varieties, Mr. Cox was first with Lady Margaret, Jeanne Marty, Gladys Spalding, Miss A. Lowe, Dame Blanche, and Mrs. Judge Benedict, very fine. Mr. W. Comfort was second with a fine stand of nine varieties, including Nelson and Mrs. Judge Benedict, two fine varieties.

The classes for local exhibitors residing close to or in Birmingham were well filled. In the class for twelve blooms, six incurved and six Japanese, Mr. Brasier, gardener to Sir Thomas Martineau, was first; Mr. Waldron, gardener to G. Cadbury, Esq., second; and Mr. W. H. Dyer, gardener to Mrs. Marigold, third. In the class for twenty-four blooms, twelve of each, Mr. Brasier was again first; Mr. W. Palmer, gardener to Wm. Bown, Esq., second; and Mr. C. Thomas, gardener to F. A. Walton, Esq., third.

Five groups were staged for the four prizes, and there was a very close competition for the first and second places especially. The first prize of £10 was awarded to Mr. W. H. Dyer for a fine display, in which the blooms of his incurved were especially fine; and the second prize fell to Mr. G. Fawdry, gardener to F. Breedon, Esq., for a very even in quality group of well grown plants. Third, Mr. C. Thomas, for an excellent arrangement; and fourth, Mr. A. Cryor, gardener to J. A. Kenrick, Esq.; and four finer groups were never seen at any Exhibition held in the Hall. For smaller groups of Chrysanthemums, with Ferns and Palms—and there were seven exhibits—Mr. Brasier was first, Mrs. Horton second, Mr. S. Gibbs, gardener to J. B. Manly, Esq., Harborne, third; and an extra to Mr. J. Farmer, gardener to W. H. Wynn, Esq.

Birmingham has always been noted for specimen Chrysanthemums, and on this occasion some excellent specimens were staged. In the class for nine plants of large flowering varieties Mr. Dyer was first with well-grown specimens, and well flowered; Mr. Brasier a good second; and Mr. Waldron a good third. For six specimens Mr. Dyer was again a good first, Mr. Waldron second, and Mr. Brasier third. For three specimen Japanese Mr. Dyer, first; Mr. Brasier, second; Mr. Waldron, third. For single specimen large flowering Mr. Dyer was first; and for three specimen Pompons Mr. Waldron was first with three grand specimens.

There was a wonderful display of Primulas, 340 plants being staged in competition in the various classes, and throughout they were superb specimens. In the classes for twelve and six single varieties Messrs. Thomson & Co., nurserymen, won first in each class for what the Judges unanimously pronounced to be the finest lot of Primulas ever seen anywhere. The sorts were Princess Louise, The Queen, whites; Emperor, salmon red; Marquis of Lorne, rosy purple; and Duchess of Fife, an exquisite pink, shaded white, and not yet sent out. Messrs. Thomson & Co. were also first respectively, six double Primulas, grand specimens; and for six Fern-leaved varieties, also very fine. Mr. F. Denning and Messrs. Pope & Sons took second and third positions alternating in the four open classes. In the gentlemen's gardeners' and amateurs' classes there was a strong competition, and for twelve, as well as six plants, an old exhibitor and grower, Mr. Caldecott, gardener to William Mathews, Esq., again maintained his position, Mr. Minard and Mr. Cryor being among other successful exhibitors.

Four very fine exhibits of six stove or greenhouse plants were set up, chiefly ornamental, many of the specimens, especially the Crotons, being grand examples of high-class culture. First, Mr. Waldron with a superb *Cycas revoluta* and Crotons *Andreanum*, *Queen Victoria*, and *majestica*, splendid well coloured specimens, and Palms, &c. Second, Mr. Brazier, with a strong lot. Third, Mr. Fewkes, gardener to T. Clayton, Esq., West Bromwich. Two collections of six Orchids were staged, both excellent exhibits. The first prize exhibit of made-up specimens, staged by Mr. Palmer, gardener to W. Bown, Esq., consisted of *Cattleya Warocqueana*, *Oncidium Forbesi*, *O. Alexandræ*, *O. crispum*, a fine pan of *Cypripedium Spicerianum*, and a large mass of *Odontoglossum grande*. Second, Mr. Burbury, gardener to the Right Hon. Joseph Chamberlain, M.P., with single specimens—viz., *Cattleya Bowringiana* and *Warocqueana* var. *regalis*, very fine; *Odontoglossum grande*, *Oncidium varicosum*, with three fine spikes; *O. Forbesi*, and *Dendrobium formosum giganteum*.

Grapes were fairly well represented. In the class for six bunches, not less than three varieties, Mr. C. Slade, gardener to the Duke of Newcastle, Clumber, was first with Alnwick Seedling, Gros Colman, Gros Maroc, Mrs. Pearson, Muscat of Alexandria, and Duke of Buccleuch. Second, Mr. Goodacre, Elvaston Gardens, with two bunches each of Gros Colman, White Tokay, and Alicante. Third, J. Wilkes, Esq., Stafford. In the class for black Grapes, three bunches, there were nine exhibitors. First, Mr. J. Baker, gardener to J. T. Harris, Esq., Stone, with three medium-sized, of very even, well coloured, and fair in berry of Gros Colman. Second, Mr. Slade, with fine Barbarossa. Third, Mr. W. Wilton, gardener to G. A. Carr, Esq., Grimsby. White Grapes, three bunches of Muscat.—First, Mr. W. Harman, gardener to the Earl of Denbigh, Warwick. Second, Mr. Slade. Third, Mr. Wilton. White Grapes, two bunches (Muscats excluded).—First, Mr. Slade. Second, Mr. J. Wallis, Keele Hall Gardens. Third, Mr. Brasier. For single bunches of black, Mr. Slade was first; and for whites, Mr. Harman, with superbly finished Muscats; and his first prize lot of three bunches of Muscats were also as highly coloured and finished.

There was a strong competition in the classes for Apples. For six dishes of culinary kinds Mr. Goodacre was first, Mr. Reed second, and Mr. Austin third, all very fine in quality. For six dishes of dessert

Apples Mr. Goodacre first, Mr. Austin second, and Mr. Reed third. For eight dishes of Pears, distinct, first Mr. Austin, second Mr. Bannister, Westbury-on-Trym; third, Mr. Goodacre. For four dishes, first Mr. Austin, second Mr. Bannister, third Mr. Parker. First prizes for Apples and Pears by Birmingham district amateurs were won by Mr. Zachary Walker, for two dishes of fine Apples, and by Mr. F. M. Mole, Edgbaston, for two fine dishes of Pears.

There was a strong competition in vegetables for prizes offered by Messrs. Sutton & Sons and Mr. R. Sydenham. From ten to twelve competed in each class, and most of the exhibits were of first-class quality. Of honorary exhibits there were several of a very meritorious character. Messrs. Thomson had a beautifully arranged large group, Messrs. Pope & Sons a group of various plants, and Messrs. Hewett and Sons a nice group, in which a beautiful new *Dracæna*, Prince of Monarch Bey (a very odd name), was conspicuous. Very fine memorial designs in flowers were also staged by Messrs. Pope & Sons, Messrs. Thomson, Mr. Denning, and a very handsome display of "shower bouquets" for brackets, &c., so named from the pendant arrangement of the flowers with coloured foliage. Messrs. Rd. Smith & Co., Worcester, and Messrs. Cutbush and Sons, London, contributed fine collections of Apples and Pears, and Mr. R. H. Vertegans plants in fruit of the Melon Pear. There was a large attendance of visitors on each day.

#### BOURNEMOUTH.—NOVEMBER 11TH AND 12TH.

VERY few societies are able to secure such a commodious building for holding an Exhibition as the Winter Gardens adjoining the Hotel "Mont Dore," Bournemouth, and bright, warm, and beautiful in all respects were the exhibits gathered therein.

Groups formed one of the principal features, and were of uniform good quality throughout. Whether in the open or within a radius of twelve miles from Bournemouth Pier, or whether exhibited by the single-handed gardener or amateur, all were alike praiseworthy, and seldom have we seen such numbers competing in the various sections. In the open class, for which the first prize was a silver cup or money, value £5, the premier prize was awarded to Messrs. Watts & Sons, Bournemouth, for fine blooms admirably displayed. The arrangement was a very handsome one, the plants healthy and fresh, and consisting of about equal parts of Japanese and incurved. Mr. T. H. Crasp, gardener to Lord Wimborne, Canford Manor, and Mr. T. R. Ingram, Parkstone, were awarded equal second prizes. Mr. Crasp's collection contained some of the finest incurved in the Show, but he had several old flowers in front. Mr. Ingram's was an effective arrangement of cut-back Japanese plants, carrying fresh blooms. The schedule stipulated "quality and effect," and, as usual, where such stipulations exist the Judges were placed in a dilemma when two groups are side by side bearing opposite characters.

For groups within a radius of twelve miles and of 50 square feet (first prize a silver challenge cup, valued £6 6s., offered by Messrs. Enoch White & Sons) Mr. G. Shave, gardener to W. W. Moore, Esq., Bournemouth, was a good first; Mr. T. H. Crasp took second honours, and Mr. F. J. Ellis, gardener to L. Forbes, Esq., third. There were seven competitors in this class, and the competition was very close.

For groups of Chrysanthemums 40 feet square, open to single-handed gardeners, Mr. Skeats, Mr. Terry, and Mr. Armfield were placed in the order of their names with fine collections. The amateurs staged seven groups, some of them highly creditable, especially those to which the awards were made. Mr. T. W. Tharle, Holdenhurst Road, Bournemouth, was deservedly placed first, and won the silver cup, value £8 8s., Mr. C. H. Mate and Mr. W. E. Macklin sharing the other awards for bright and attractive collections. Several classes were set apart for specimen plants, and brought some creditable examples.

The cut blooms throughout the Show were commendable for their massiveness, freshness, and bright or clear colours, the chief class being for thirty-six, eighteen Japanese and eighteen incurved, not more than two of a variety, first prize a silver challenge, value £8 8s., offered by Baring Young, Esq., M.P. Mr. G. Garner, gardener to Mrs. Braddyll, was well ahead, and secured the trophy with the following:—Japanese: Edwin Molyneux, Stanstead White, Mons. Bernard, Thunberg, Edwin Molyneux, Etoile de Lyon, Japonais, Puritan, Etoile de Lyon, Mons. Bernard, Mrs. C. Wheeler, two of the deepest and finest Mrs. Alpheus Hardy we have observed this year; Louis Boehmer (good), Boule d'Or, and Mons. Elliott. Incurved: Queen of England, Emily Dale, Lord Alcester, Emily Dale, Alfred Salter, Empress of India, Golden Empress, Alfred Salter, John Salter, Queen of England, John Salter, Miss Haggas, Princess of Wales, Mrs. Coleman, Prince of Wales, and Lord Wolseley. Messrs. Watts & Sons were placed second.

For twelve Japanese, distinct, Mr. G. W. Taylor exhibited a grand stand, with which he secured the first position, consisting of Etoile de Lyon, Ralph Brocklebank, Edwin Molyneux, M. J. Pigny, Japonais, Baronne de Prailly, Mons. Bernard, Stanstead White, Mr. H. Cannell, Meg Merrilies, Mons. Baco, and Triomphe de la rue des Châlets; Messrs. Garner and Watts & Sons sharing the other awards in the order of their names. For twelve incurved Mr. Garner was placed first with Emily Dale, Lord Alcester, Empress of India, Golden Empress, John Salter, Alfred Salter, Lord Wolseley, Queen of England, Princess of Wales, Miss M. A. Haggas, Cherub, and Mrs. Coleman.

The schedule consisted of upwards of eighty classes, nearly all of which were well filled. Fruit and vegetables were both good and very numerous exhibited. Bouquets, shoulder sprays, buttonholes, épergnes, Primulas, and table plants all added variety to the whole, and for which

success Mr. J. Spong, The Gardens, Lindisfarne, the Secretary, had worked very hard. He was ably seconded by Dr. Hitchcock and Mr. J. Swaffield, who are all well supported by a large contingent of workers, in the way of affording interest and subscriptions. The Mayor and the influential residents of the district attended the Show, which was opened by the Hon. Mrs. Dennison, and Mr. W. W. Moore also gave an interesting speech at the opening ceremony.

We are glad to learn that the total number of persons who visited the Show, in addition to those holding complimentary tickets, was about 4000. The sum taken at the doors on Wednesday was £42 10s., and on Thursday £75, making a total of £117 as compared with £105 last year. On Wednesday evening, nearly 1000 persons were admitted after six o'clock, and on Thursday evening after six the place was packed, upwards of 2000 paying the popular price of 3d. for admission.

#### BATH.—NOVEMBER 11TH AND 12TH.

As far as cut blooms are concerned Bath scarcely keeps pace with the times, and are not likely to do so unless they offer better prizes. In all other departments, however, they more than hold their own, plants of all kinds, fruit and vegetables being extensively and remarkably well shown. The Chrysanthemum Show, in common with the four other exhibitions annually held at Bath, is under the management of the Floral Fête Committee, the Secretaries of which are Messrs. B. R. F. Pearson and W. Jeffery.

Trained Chrysanthemum plants were shown very well in several classes, the principal prizewinners being the Rev. E. Handley, Mrs. Jolly, Mr. W. J. Brown, S. P. Budd, Esq., and James Williams, Esq. The silver medal of the National Chrysanthemum Society, offered for the best Chrysanthemum plant in the Show, was easily won by Mr. S. Kerslake, gardener to the Rev. E. Handley, who had a grand specimen of Mrs. G. Rundle fully 9 feet across, and carrying upwards of 300 good blooms. Groups of Chrysanthemums are always good at Bath, the competition being very close again this year. The Rev. E. Handley was first, Mr. W. J. Brown second, Dr. S. P. Budd third, and an extra prize was awarded to Mr. E. G. Peacock.

Collections of plants arranged for effect on a space 10 feet by 4 feet again are invariably good, and were particularly so on this occasion, there being three decidedly choice and very prettily arranged groups in competition. R. B. Cater, Esq., was first, C. W. Mackillop second, and J. T. Holmes, Esq., third. Orchids were well shown by Messrs. Cater and Holmes; fine-foliaged plants by Messrs. E. S. Cole and Son, J. F. Holmes, and C. W. Mackillop; table plants by T. W. Gibson, C. W. Mackillop, and A. R. Baily; Primulas by Messrs. Jerome Murch, C. Fisher, and P. C. Hardwick; and Bouvardias by Messrs. W. Pumphrey and E. Hall, who took the prizes in the order named in each instance.

The first prize for twenty-four blooms of incurved varieties, distinct, was won by Mr. W. Robinson, gardener to Lord Justice Lopes, with a generally good lot. In the back row were Golden Empress of India, Queen of England, Lord Alcester, Golden Queen of England, John Salter, Golden Empress of India, Robert Cannell, good; and Hero of Stoke Newington. Middle row: Violet Tomlin, Mrs. Coleman, Miss Haggas, Princess of Wales, Mrs. N. Davis, Mrs. Heale, Mr. Brunlees, and Jeanne d'Arc. Front row: Beauty, Baron Beust, Princess Teck, Jardin des Plantes, Venus, Cherub, Lord Eversley, and Barbara. Mr. J. Baylis was second, among his being good blooms of Mrs. Coleman, Golden Empress of India, John Doughty, Beauty, and Empress of India. Mr. Wilkinson, gardener to C. C. Tudway, Esq., was third, his best being John Lambert, Lord Alcester, Prince Alfred, and John Salter. For twelve incurved Mr. Baylis was first with a capital lot of blooms, to the best of which, Lord Alcester, was awarded a silver medal for the premier bloom in the Show. The rest were Empress of India, Queen of England, John Doughty, Violet Tomlin, Princess of Wales, Mrs. Coleman, Lord Wolseley, Mrs. Heale, Prince Alfred, Beauty, and Miss Haggas. Mr. Robinson was second, and Mr. J. Attwell, gardener to J. B. Brain, Esq., third. For six incurved Mr. W. Strugnell, gardener to A. R. Baily, Esq., Frome, was well first; Mr. G. Pyman, gardener to Mrs. Gouldsmith, being second; and Mr. J. Hinton third. A fine lot of Japanese blooms were shown. The premier prize for twenty-four varieties went to Mr. Wilkinson, who had in his back row Meg Merrilies, Mrs. C. W. Wheeler, Avalanche, Etoile de Lyon, Stanstead White, Gloire de Rocher, Mrs. F. Thompson, and Kioto. Middle row: Sunflower, Madame Baco, W. W. Coles, Boule d'Or, very fine; E. Molyneux, Puritan, Baronne de Prailly, and Val d'Andorre. Front row: Mons. Bernard, G. Daniels, Louis Boehmer, F. A. Davis, Lady Lawrence, Holborn Beauty, Margaret Marrouch, and Miss Amy Hartzhorn. Mr. Robinson was second, among his being extra good blooms of Fimbriatum, A. H. Neve, Puritan, M. E. Carrière, and Léon Fraiche. Mr. W. Strugnell was well first with twelve Japanese varieties, having fine fresh blooms of Volunteer, Sunflower, Etoile de Lyon, W. H. Lincoln, E. Molyneux, Mrs. F. Thompson, Mons. Bernard, Mr. G. Atkinson, Puritan, Mrs. F. Jameson, Avalanche, and Countess of Lytton. Mr. Robinson was a good second, the blooms of M. E. A. Carrière, Boule d'Or, W. W. Coles, A. H. Neave, and Marsa being most noteworthy; while Mr. Mann, gardener to W. H. Laverton, Esq., Westbury, was a creditable third. Mr. Pym was first for six Japanese; Mr. Tucker, gardener to Major Clarke, being second, and Mr. H. Pocock third. A very well-grown lot of blooms gained Mr. Robinson the first prize for Anemone-flowered varieties, these including Jeanne Marty, Madame R. Owen, Fabian de Mediana, Lady Margaret, Sabina, E. C. Jukes, Judge Benedict, Miss Annie Lowe, and Mr. Charles

Lebosque. Mr. Wilkinson was second, and Mr. Tucker third, a very fine bloom of Ratapoi being shown by the latter.

Fruit is always a great feature at this Show, one large room being wholly given up to it. Alderman Chaffin was first for four bunches of Grapes in two or more varieties, the second prize going to Mr. Nash, gardener to the Duke of Beaufort, and the third to Mr. Attwell. Mr. Nash had some grandly finished bunches of Gros Colman, and was first in that class, Mr. T. Jones being second, and Mr. Pymm third. With Alicante Mr. Jones was first, Alderman Chaffin second, and Miss E. Marriott third. In the class for any white variety Mr. Jones was first, Mr. Peacock second, and Mr. Attwell third. A very fine lot of Pears were shown, and with six varieties of these Mr. Nash was first; Mr. J. Gibson, gardener to Earl Cowley, second; and Mr. W. Bannister third. With four varieties Mr. Evry was first, Mr. Pymm second, and Mr. Milne, gardener to Miss Jarrett, third. Thirty-two competed with one dish of Pears, Mr. Gibson taking first with grand fruit of Pitmaston Duchess, the heaviest weighing 26 ozs. Mr. W. Marsh was second, and Mr. Milne third. The principal prizewinners with Apples were Messrs. Garraway, Stuckey, Pymm, Ricketts, E. Hall, S. King, T. W. Dunn, and J. Hibbard. With six dishes of fruit Mr. W. Nash was well first, Mr. E. Peacock being second, and Mr. E. Hall third.

EVENTS OF THE WEEK.—The Chrysanthemum Shows are nearly all over now, and next week will see the close of the season. To-day (Thursday) a Show will be opened at Wantage, and it is also the concluding day at Spalding, Hull, and Rugby. The York Show is continued to-day and to-morrow (Friday). The Edinburgh Exhibition of Chrysanthemums and Fruit will be opened to-day and continued until Saturday. Stirling, Chorley, Bolton, and Stockport announce Shows for November 20th and 21st. There is one at Batley on November 21st, and the latest fixture of which we have any information is at South Shields on November 25th and 26th. The National Chrysanthemum Society's Floral Committee will meet at the Royal Aquarium, Westminster at 2 P.M. on Tuesday, November 24th. Messrs. Protheroe & Morris advertise their usual sales of bulbs and plants for forcing this week and next; also there is to be a large sale of Orchids, including several novelties, in the Cheapside rooms on Friday, November 20th.

— THE INTERNATIONAL FRUIT SHOW IN LONDON, 1892.—We learn that the Queen has graciously consented to become patron of the International Fruit Show proposed to be held in London in 1892. Sir James Whitehead, Bart., is the Chairman, and it will be remembered that a provisional committee has been formed, partly representative of the principal societies and partly of horticulturists nominated at the preliminary meeting.

— CHRYSANTHEMUMS AND SAILORS' ORPHANS.—We are informed that Mr. Charles Colebrook, nurseryman and florist, Grimsby, who grows 5000 plants of Chrysanthemums, this year made a charge of 6d. to visitors for inspecting his display, and that a substantial sum was realised for the Sailors' Orphan House of the busy seaport. Mr. Colebrook grows all the leading varieties, and his show is stated to have been very fine indeed. The orphan boys' band was in attendance on the occasion.

— CHRYSANTHEMUM AND FRUIT EXHIBITION AT EDINBURGH.—The winter Exhibition of the Scottish Horticultural Association, which is now looked forward to as one of the most attractive events of the year in Edinburgh, will be held in the Waverley Market, from the 19th to the 21st inst., and promises to equal, if it does not surpass, all previous shows of Chrysanthemums held there. The fruit section will be a source of great interest and attraction when it is intended to exhibit a collection of the fruits of the United States. As this is believed to be the first occasion on which such an interesting exhibit has appeared at a horticultural exhibition in Britain, it will be examined and criticised by fruit growers with great care. Intimation has also been received from the Government of Nova Scotia through Dr. George Lawson, Secretary for Agriculture, of their intention to exhibit a display of the Apples for which that enterprising Colony is so famed. Fruit grown in the British Isles and in the Channel Islands is also to be present in considerable numbers.

— HARDY DAPHNES.—I must thank Mr. T. Smith for putting me right in the nomenclature of these fine shrubs. *D. Laureola* and *D. pontica* are both useful and desirable, but to the latter undoubtedly belongs the distinction of emitting the pleasing perfume which I attributed to the former variety.—H. D.

— CHRYSANTHEMUM SHOW AT THE GRANGE, CARSHALTON.—Mr. A. H. Smee during the past week opened his garden for the public to view the display of Chrysanthemums, and on Sunday afternoon nearly 2000 persons visited the establishment. The collecting boxes of the Gardeners' Orphan Fund were placed in prominent positions, and will no doubt result in a substantial contribution to that institution.

— GARDENING APPOINTMENTS.—Mr. James Gibson, for the last two years gardener to John McMaster, Esq., The Holt, Harbledown, near Canterbury, has been appointed head gardener to H. Berkeley James, Esq., at The Oaks, near Carshalton, Surrey. Mr. James Gregory, of the Rangemore Gardens, has been appointed head gardener to Sir Offley Wakeman, Bart., Pevery, near Shrewsbury. Mr. William Ranscm has been appointed head gardener to the [Rev. Douglas Barrey, Ightham Rectory, Sevenoaks, Kent.

— ALTERATION IN THE GARDENS, SANDRINGHAM.—In connection with the extensive alterations which has been carried on since Mr. McKellar took charge of these Gardens, there has just been completed a fine and commodious bothy for the young men, fitted up with all the latest improvements in heating and sanitation, hot and cold water lavatories and bath; and to commemorate the entrance into the new premises the gardener, on Thursday evening last, invited upwards of thirty couples to the dining hall, when a very enjoyable evening was spent.

— SUCCESSFUL PLUM CULTURE.—When upon an occasional visit to Mr. Bruce, gardener to R. Smith, Esq., Brentnham Park, Stirling, in the past summer, I admired nothing more than the appearance of two dozen Plum trees in 14-inch pots growing in a Peach house. Some of the trees matured as many as fourteen dozen fine fruits; they would, upon an average, mature ten dozen each. When seen last they were looking well for another season. When Mr. Bruce took charge of the gardens in the spring of 1890 he found the trees growing in 10-inch pots, and transferred them into those 14 inches in diameter. The staple soil used was good heavy loam and the after treatment has been generous.—G. MCD.

— AMATEURS AND SINGLE-HANDED GARDENERS.—Dr. Geo. Walker of Wimbledon sends a letter couched in pleasantly [satirical] language in reference to the comment on his exhibits contained in our report of the Wandsworth and Putney Chrysanthemum Show. It is not quite clear whether his shafts are directed at the Journal reporter or at the Committee of the Society which promoted the Exhibition, and room cannot be found for his communication owing to the present exceptional pressure on space. It was pointed out in the report that, although winning prizes in the single-handed gardeners' classes, the name of the doctor's gardener was not on his card. He now states that he has no gardener, doing all the work himself from first to last, but he omits to explain how it is that, this being the case, he was exhibiting and taking prizes in a section for gardeners as well as in that for amateurs; this, however, is the real point.
