THIS Orchid has now become so common that it is found in almost every collection of this class of plants. Perhaps no Orchid ever caused such a sensation as this when it was introduced, and it has since become famous. It is one of the Orchids Darwin was especially interested in on account of the exceptional length of the spur, and a plant in bloom always attracts attention.

This wonderful *Angræcum* was found in Madagascar by a French botanist near the close of the last century, and when the history of the plants of Madagascar was published in 1822 *Angræcum sesquipedale* became known to science. Botanists and horticulturists were anxious to introduce it, and many attempts were

FIG. 40.  
CYPRIPEDIUM GODSEFFIANUM.

made, but these were not successful until 1855. Mr. Ellis, a missionary in Madagascar, was fortunate to bring home three living specimens to his garden, where one of them flowered in the spring of 1857. There was still great difficulty in reintroducing the plant, and for many years it was rare and expensive. In its native country it is said to grow on the trunks and branches of trees, where it has abundant light and air, and in the hottest and lowest districts.

The flowers are produced on peduncles 10 to 12 inches long. When they first appear they are green, and this colour continues until the flowers are almost fully developed, when it turns to an ivory white. As the flowers begin to fade they become pale yellow. The flowers are not very fragrant during the day, but at night they have a strong odour, which is not very pleasing. The colour and the fragrance of the flowers at night indicate that they are then fertilised by an insect in its native home. My plant had sixteen large flowers fully developed at one time; these measured 6 inches across, and the spurs were 12½ inches long.

The plant is easy to cultivate. It requires a strong moist heat, and is grown in the stove. It also requires abundance of light, but must be shaded from strong sunlight during the summer. It grows well planted in a basket with crocks and sphagnum moss, and suspended near the roof glass. Water must be given during the

entire year, and to keep down insect pests the plant must be frequently sponged.

Another large *Angræcum* in bloom now is *A. eburneum*. It is a large strong-growing plant, with thick, leathery, strap-shaped leaves. The flowers, although not as large as some of the other species, are produced plentifully on nearly erect flower spikes. The petals and sepals are narrow and green, and the lip cordate and pure white. The flowers are very fragrant, and last for nearly two months. It requires the same treatment as *A. sesquipedale*. It was introduced from Madagascar in 1826.—ROBERT CAMERON (in "Garden and Forest").

## EXPERIENCE IN SUMMER ROOT-PRUNING.

I FEEL sure that it would be interesting to readers of the *Journal of Horticulture* to learn on what grounds the local gardeners and amateurs at their meeting (see page 183) arrived at this strange conclusion—"root-prune in the summer if you wish to kill your trees." I have read papers on this subject at horticultural improvement associations several times during the last fifteen years—at Edinburgh twice, and the enthusiastic savants of the North discussed the matter freely, but none of them, with the sweeping confidence of the Society indicated, volunteered to denounce the practice. I have had much to do with horticultural societies whose object is mutual improvement, and it is surprising to note how readily crude and untenable ideas are adduced. The question of root-pruning is somewhat vague, but "root destruction" is very different from judicious "lifting and pruning." In my youthful days, when I could not practise as I would, I conceived the theories of root-pruning which I have, over a course of thirty years, verified by careful practice. After practising root-pruning for a number of years, between June and September, I now and anon received some censure from the non-experienced in such matters, but had my faith in the practice strengthened by reading of the methods of a distinguished market grower, who examined his trees early in June, mostly Apples, Pears, and Plums, and those which showed any tendency to grossness of growth and unfruitfulness were manipulated at the roots at once. I never heard of the *modus operandi* which this reputed grower of fine trees and immense crops of fine fruit followed, but I did not alter my course which I had followed during so many years. If I lifted unfruitful tree roots in June it was generally at one side first, examining those under the bole of the tree. Any going straight down were removed, lime rubbish or some comeatable material was placed to prevent further mischief in that direction; outward growing fibreless roots were shortened, and those uncovered were replanted in good loam and made firm. Perhaps, when needful, the other side of the tree would be treated in the same manner during August. No growth was made after this during that season, but the wood became firm and spurs were formed; the foliage remained late on the branches, and maturation seemed perfected. Invariably the crop of the following year was excellent. We expect this year of scarcity to have Seaton House, Sandringham (also a capital bearer), Northern Greening Apples, and some others till May in good condition, from old trees hollow in the trunk, some trunks repaired with wood from other trees, rendered dwarf by root and top pruning a dozen years ago. The Seaton House trees, I believe, were planted during the last century.

Young trees are root-pruned or lifted, as may be necessary, to keep them at the size desired, thus avoiding the use of the knife to branches, and having ruthlessly to cut off shoots during the growing season, a practice only conducive to canker in fruit trees. My earliest experience of root-pruning was in Wiltshire and Suffolk while a mere "fledgling," but I have since then practised in other parts of England and in Scotland. In no case have I seen other than the best results from pruning roots as indicated, always gaining a season by getting the trees to rest early in autumn, quite recuperated and fruitful the first year. Piecemeal pruning twice or thrice is what I have confidence in.

As to the work being injurious in the long run, I can only say that trees which have been operated on many years ago are sound, healthy, and fruitful now. Some three years ago I saw a number of Plums on a wall in one of the largest of English gardens which I root-pruned during July, twenty-one ago. They were healthy and fruitful; and to use one other argument, I will refer to Apples, Pears, Plums, Cherries, on walls and in the open ground, which were root-pruned during summer to keep them to a proper size. Reference has been made to them in this and other journals as to their productiveness, and I suppose, after being under well known skilful management since I left them over a dozen years ago, they are likely to be in good condition now. The first year after the trees were planted I unfortunately gave a mulching of well decayed manure which had been swept from streets where salt was carted

daily and dropped about. The manure was stored in quantity before my arrival on the place. This gave a severe check to the trees. Vines and Peach trees under glass were severely dealt with from the same cause.

The trees started to grow in the garden the second year on walls (which were not quite finished by the builder), all making roots long and fibreless, and to counteract this I root-pruned moderately during summer and autumn. The fourth year the walls were covered with branches. Pyramids and standards were also in very promising condition, bearing abundance of fruit. They were reported in "Gardener's Chronicle" the fifth season, which described them as having the fruit (Pears especially) "hanging like ropes of Onions." Each season they improved to my heart's content. The soil was a strong loam mixed with a quantity of marl quite free from manure (except the mulching). In this soil I thinned out of the thickets thousands of trees and shrubs to form the park and ground establishment, and they all grew in the strong soil such as I never had seen plants do before. This was at Impney in Worcestershire. I may add that shrubs were also periodically treated, lifted to keep them dwarf, and I still pursue the same course with choice shrubs (to save the use of the knife) regardless of dates or seasons.—M. TEMPLE, *Carron, Stirlingshire*.

[We commend the above article to our correspondent "H. C." (page 183) as possibly worthy of reading and discussion at a meeting of the "local Gardeners' Society" with which he is connected. We have seen the trees at Impney, and they have been admirably managed from the beginning until now. Instead of having been "killed" by root-pruning the fruits from them have won prizes at some of our best exhibitions. Perhaps "H. C." will favour us with a note on any further discussion on the subject that may ensue at the meeting.]

## ALPINE FLOWERS.

### MAKING AND PLANTING ROCKERIES.

IT can hardly be gainsaid that the cultivation of what are known as Alpines is largely on the increase. It is doubtful, however, if the increased interest taken in these charming flowers is at all proportionate to the development of floriculture generally. This is to some extent due to the fact that alpine flowers are neither so showy individually nor so well adapted for cutting as the more striking blooms of larger growth. While this is so it is no rare occurrence to see the ranks of growers of alpines recruited from the great body of flower lovers by the addition of some whose admiration for the subjects of Flora has taught them to appreciate the more minute beauty of these alpine flowers. It is far more seldom, however, that one sees the alpine grower deserting his favourites for more brilliant beauties; and when this takes place we conclude he has been the victim of some untoward circumstances, or that at the outset some initial difficulties have seemed too great to be overcome.

There is no royal road which leads to success in the cultivation of alpines, and each one has to learn for himself the cause of failure in his own garden; but there are certain things which inevitably lead to success or failure, and among these may be pointed out the construction of the rockwork on which the plants are intended to be grown. It was hopeless to expect the tide of favour for alpines to flow rapidly so long as their cultivation was almost entirely attempted in pots, but it is to be feared that many who experimented with the same plants on rockwork quickly discovered that they had only exchanged Scylla for Charybdis. When grown in pots plants which in nature ramble happily over stones and send their roots far into the crevices of the rocks were "cabin'd, cribb'd, confined" until their life energies became exhausted, and they either dwindled away or dragged out a miserable existence. Worse, perhaps, was the fate of those which were placed on some of the pretentious, or even unpretentious, structures called rockeries which were reared in too many gardens.

Those who are at all familiar with gardening books must have seen in some of those published about the middle of this century some wonderful rockeries on which plants were expected to live and be happy. One must not, however, be too severe on the writers of former days, for although such monstrosities are no longer advocated it is only too true that they are frequently erected. It is difficult for an admirer of these exquisite flowers to write calmly about such rockeries as have been referred to, the very act of writing seems to make one desirous of giving vent to indignation at the folly which condemns so many beautiful plants to an untimely and an unhappy death. Many rockeries have been and are built of a pile of stones without a particle of earth between, and only a thin coating on the surface. Others are composed of a

good proportion of soil, but are so steep that the life-giving moisture runs off as from the roof of a house. Still worse than these, however, are more expensive and pretentious structures built of solid stone or brick and mortar, and without a proper crevice into which a plant struggling for existence can insinuate a root to keep it alive.

A primary essential in the construction of a rockery is a good body of soil. With this stones may be mingled, but there should be no crevices between these which are not filled with earth. In actual practice there are two ways of forming a rockery of this kind, one being to make the mound of earth first, the other to place the soil in position as the building progresses. If, however, the mound can be made first and given a little time to settle, there is less fear of subsidence and consequent displacement of the stones. Its height will depend on the position it occupies, but there is, as a rule, no necessity for its being of great elevation; indeed many alpine will thrive to perfection in a bed only slightly raised above the surface. For several reasons it is desirable that the rockwork should have an irregular outline, having here and there little nooks by means of which shelter or shade may be given to plants requiring special attention in this way. This irregularity of outline adds much to the natural appearance, which is a desideratum in constructions of this kind.

The general form of the rockwork having been decided on and the mound of soil placed in position, the stones may be laid in their places, and here it may be well to say a few words about the most desirable material to use; this is not always available, and often we have to depend on the plants and the modifying influences of time to take away the unsightliness of the slag, bricks, or other artificial looking substances. Personally I do not like a rockery composed of granite, which for some years retains its "new" look, and, besides too often taking from the appearance of the colours of the flowers, is not porous enough to induce the plants to cling to it with their roots. Limestone, when it is not too soft, is suitable and harmonises well with the majority of the plants, but I prefer a grey sandstone which soon becomes weather-stained and from its porousness absorbs moisture, and to which the plants seem to love to cling.—S. ARNOTT.

(To be continued.)

## THE DIFFICULTIES OF SPRING BEDDING.

SPRING bedding is an attractive and delightful aspect of gardening, for when the welcome sunshine begins, after a long absence, to shed its warmth upon us, it is refreshing and cheering to watch the tender leaves and flowers unfold their pristine beauty. But there is unfortunately a dark side to the picture which we have to face—after severe winters—before the contemplated effect can be secured, indeed in some instances the precise effect we have in our mind's eye when planting is destined to remain a vision only. I fear there are innumerable cases in which such will be the case this year.

The abnormally severe frosts recently experienced have wrought terrible havoc in flower gardens where spring bedding is carried out. Many Wallflowers, which are generally regarded as perfectly hardy, have been killed outright. The only types that, with us, have come through the ordeal fairly well are all dwarf; these being only about 6 inches in height, were to a great extent protected by snow, which unfortunately was not of sufficient depth to save those of ordinary types. This ought to be kept in view when sowing seeds to provide plants for next year's bedding; indeed, I think dwarf Wallflowers will before long quite supersede those of the Belvoir Castle and Harbinger types where formal beds have to be filled. *Myosotis dissitiflora* is usually a splendid plant for bedding, as it is much more compact in growth and produces larger flowers than the common form; but unfortunately it is more tender, and judging from present appearances quite half of our plants will succumb. Among the *Aubrietias* there is also a great loss. This generally occurs on the sunny side of the beds, which is doubtless due to the fact that the sun thawed the snow and left the plants exposed to succeeding frosts. *Saponaria calabrica* has proved quite a failure, every plant being killed.

Violas seem to have come through the ordeal by far the best. Young plants set out early in November are quite uninjured; old ones divided and replanted at the same time have not escaped so well, as the centres of the plants are much injured, doubtless because the young growths were somewhat tender. *Silene pendula compacta* has suffered but little, the edges of the leaves being browned, but the hearts of the plants are quite sound.

Anemones of the French and fulgens types are untouched.

The leaves were pushing through the soil just before the snow came, and it seems to have afforded them ample protection. It is during such seasons as this that the value of mixed borders and rockeries is apparent, for many varieties of plants which in the flower garden are ruined, in borders quite as much exposed are but little injured. This, of course, is easily accounted for in this way—border plants are usually left undisturbed throughout the year, whereas those employed for spring bedding in the flower garden proper have to be lifted from their summer quarters and transferred to the flower beds during the autumn, and all gardeners know that the effect of frost on plants or shrubs that have been recently disturbed is much more serious than on others of the same species and varieties whose roots are well established in the soil. Many will, I fear, this year have a forcible lesson taught them in this respect, for where the planting of shrubs was deferred till December last disaster is already apparent.

But I am digressing somewhat from the heading of my notes, so let me return to the subject proper. Perhaps there are many who will be disheartened to see their autumn preparations rendered futile, and will in consequence be inclined to discontinue their attempts at spring bedding, for I remember a reaction of this kind took place a few years ago after a series of severe winters. This, I think, is scarcely the spirit in which to meet the case, and, according to the law of averages, is quite the wrong thing to do at the present climax, for after many hard winters we may reasonably look forward to some milder ones.

All may, however, do much toward rendering failure less likely in the future by making a rigid selection of only such plants as are but little affected by our severest winters. We may then in time carry this selection of the fittest to a point approaching so nearly to perfection as to leave us practically indifferent in this matter to severe winters. Another point to which special attention ought to be given in the future is the oft repeated one—plant early in the autumn. No matter how mild the month of October may be, or how well the summer bedding may look even then, we ought not to be beguiled into a sense of security by appearances, but as soon as October comes round clear the flower beds with no unsparing hand. Then go at the work with energy; manure, dig, and replant as soon as possible, so as to have all planting completed by the end of the month, or if it is found impossible to do this let the planting of the more tender kinds stand over till the spring. This, however, is not a desirable practice on light soils, as the plants suffer should a dry period follow, and there is usually too great a pressure of work in most gardens during the spring months. Cocoa-nut fibre refuse or sifted leaf soil if spread on the ground after planting in the autumn would do much towards protecting the roots of plants from frost.

There is one other way in which a good display may be unflinchingly secured—namely, by employing bulbs largely. Unfortunately but few gardeners are able to spend a sufficient sum annually for this purpose, and there is no other way in which such a feast of brilliant colour can be obtained simultaneously during the spring months.—H. D.

## DAHLIAS.

WHILST a few persons relatively are still interested in Dahlias as florists' flowers, tens of thousands who have gardens love them for their intrinsic beauty as decorative flowers. That is a very different state of things to what existed some twenty years ago, when the Dahlia had both for exhibition and for garden decoration got into very low water indeed. That the National Dahlia Society has done much to help resuscitate a once greatly favoured flower there can be no doubt; and for all it has accomplished it is entitled to the fullest credit. But to numbers of persons the Dahlia owes its popularity more to the introduction into gardens of the beautiful Cactus and single forms than to any mere exhibition merits. No doubt to day the Cactus section is by far the most popular of all, and flowers of the refined varieties rank amongst the most charming of double flowers in cultivation. It is well, therefore, to give to these non-florists' forms that credit which they so much deserve.

The show and fancy sections it is evident have almost, if not quite, attained to their fullest excellence. They show in the best of seedlings very little of advance; indeed, beyond diverse colours or markings it is doubtful whether any real advance from the florists' aspect has been seen in show Dahlias for several years, and it is very difficult to show in what direction farther advance is possible. But whatever may come the blooms will still be large, rounded, massive, and to use a common term, lumpy, at least that is the description frequently applied by those who seek for other forms of elegance and beauty than is found in mere solidity and rotundity. These show and fancy Dahlias, however, have their

admirers, and those who like them can grow, show, and enjoy them. There is in horticulture such wide room for all sorts of tastes that it would be stupid to complain because some found more of pleasure in growing big-flowered double Dahlias than in more elegant forms.

Those who want Dahlias to give colour and gaiety in gardens can hardly do better than grow the Pompon forms, for these are of all the sections the most floriferous. If there be partiality for smallish solid rotund flowers, then these are admirable, too, for cutting. For sale in bunches they are much esteemed, and a few dozens of plants, if of some half dozen of the most pleasing colours, will furnish during the season an immense number of blooms. But for house decoration in a cut state no Dahlias can excel the charming single blooms or the quaint and singularly graceful Cactus varieties. The Pompon forms show little advance; they are almost as good as they can be. The singles also seem to have reached the end of their tether. The flat-petalled round form to which this section speedily attained remains as before, and perhaps it is rather from some sort of revulsion from that round form of flower that a strain called single Cactus Dahlias have been created. At present the best that can be said for these is that they are floral abortions. Not very high praise that; but it is not possible for any person of taste to discover in them so far elements of beauty or attractiveness. Until they develop into semi-double forms there is little hope for them, and even then they will be but inferior examples of the Cactus strain, of which in true doubles we have now such singularly beautiful varieties.

It is almost exclusively in the Cactus section that there is real development. We started with these somewhat coarsely, and ran off into a flat-petalled section that since has been termed decorative, an elastic term, but not out of place, as most of this strain make very effective garden flowers. But the true Cactus ideal so admirably set in the Mexican Juarezi was very largely departed from for some time, and it is only within the past few years that we have got back to the right track and even beyond in elegance and refinement what Juarezi furnished. We may well expect, now that such beauty has been attained, raisers will set themselves to improve the habit of growth which has so far largely characterised the Cactus strain. That process has gone on somewhat liberally so far as other sections are concerned, and the more popular Cactus forms may now follow suit. If we can obtain plants some 2½ to 3 feet in height, carrying flowers as profusely as do the Pompons, and of the most perfect and refined Cactus form, then we shall indeed have made great advance. Some development in that direction has already been seen, and no doubt in a year or two there will be many others of similar dwarfed free-blooming characteristics.

It is yet a far cry to the season of Dahlia flowers, but we are full into the season of propagation. Where ordinary prudence prevailed roots were effectually stored, and the severe frost left them unharmed. No doubt in many directions Dahlia roots have gone the way of Potatoes, being frosted and destroyed, but in the nurseries growths are now being pushed on in warmth, and young plants produced in myriads against the demand that seems likely to be unusually large this spring. In any small garden the same practice should prevail. It is well to make an early start in Dahlia propagation, because not only are much stronger plants for putting out at the end of May thus secured, but many more of them can be had also. Those who cannot propagate from lack of stock roots should send their orders to the florists early, and that will entitle them to demand strong, matured plants in due course. Too often the purchaser has to put up with ill-rooted and immature plants that come direct from cutting pots and heat. These are not at all creditable for any trader to send out, and if, as some untutored persons will do, are planted outdoors at once, they almost assuredly die; or if they be as advised, placed singly in small pots, and stood in a frame, they are even then hardly fit to put outdoors until some three weeks after receipt. Very likely the blame rests chiefly with the purchaser who left his ordering too late, but it should even then not all fall on his shoulders.

It is best where practicable to have young plants sent in their pots, or if the pots be omitted then each ball of soil should be carefully wrapped in soft paper before packing. When received these plants should be placed in pots one size larger than rooted in, be stood in a frame or greenhouse for a week or so, then put outdoors into a warm place, where they can be protected at night for yet another week or so, and then they may be planted safely, because so well rooted and hardened. Those who may prefer to root their own can purchase cuttings now cheaply, but some bottom heat is essential for that purpose. Howsoever obtained, it is desired not only that there may be for all the fullest success, but that Dahlias may once more testify that they are of the most beautiful of garden flowers.—D.

**EVENTS OF THE WEEK.**—The events of interest to horticulturists are now becoming more numerous, as during the next week the Crystal Palace Co. will hold its first spring show on Saturday, March 16th; the Reading Horticultural Society a bulb show on Tuesday, March 19th, and the Royal Botanical Society an early spring show on Wednesday, March 20th.

— **WEATHER IN LONDON.**—Pleasant changes in the weather have taken place during the past week. Rain fell on Saturday last, but with this exception bright sunny days have predominated. On Wednesday morning the weather though bright is somewhat colder, the thermometer in the City registering 38°.

— **THE WEATHER IN THE NORTH.**—Thaw has, with an occasional slight frost in the morning, been continuous during the past week, but has as yet penetrated only a few inches into the soil. The days have been generally cold with N.E. winds. On Sunday the surrounding hills had another coating of snow, and there was a threatening of more on Tuesday morning. Snowdrops are coming into bloom, and Auriculas have made a distinct start.—B. D., *S. Perthshire*.

— **DEATH OF MR. R. B. LAIRD.**—It is with very deep regret that we have to announce the demise of this well known and highly respected horticulturist, which occurred on the 4th inst. at the age of sixty-nine years. The deceased was a member of the firm of Downie and Laird of Edinburgh, and subsequently senior member of the old established house of Laird & Sinclair, Dundee. He was a man of the greatest geniality, and will long be remembered by gardeners and nurserymen throughout the kingdom.

— **COOKING APPLES.**—Mr. T. Francis Rivers has been testing the cooking qualities of certain Apples. From his records prior to last year we note that he found Belle de Pontoise and Calville Blanche excellent in February; Wadhurst Pippin, Gooseberry Apple, and Dumelow's Seedling very good in March; but Rhode Island Greening insipid; Calville St. Sauveur and Bramley's Seedling very good in April; Striped Beefing in May. Last October Rivers' Codlin was found excellent, and it is equally good now. Bismarck is still in good cooking condition, but the flavour is insipid.

— **DEATH OF MR. THOMAS GADD.**—Another gardener of the old school passed away on March 7th at the ripe old age of ninety-one. Mr. Thomas Gadd was well known in Sussex, he having been a large prize-taker at the Brighton and other large horticultural shows. He filled some important situations in the county, the last twenty-seven years of his work being at Denne Park, near Horsham. In March, 1876, exactly nineteen years ago, he was allowed to retire on a substantial pension, kindly granted him by his employers, Mr. and Mrs. C. G. Eversfield, by whom he was much respected.—H. H.

— **ELECTRO-CULTURE.**—The members of the Wolverhampton Gardeners' Mutual Improvement Society met recently, when an interesting lecture was delivered by Mr. G. W. Fairall on electro-culture. The lecturer, in order that his hearers might better understand the subject, gave a brief yet clear and sufficient survey of the history and progress of electricity, emphasising the notable developments made in its application to industry and art. Coming to the subject of the lecture, and dealing with it exclusively, the lecturer, himself a successful horticulturist, stated that so far back as ten years ago he had made experiments on Lettuces, Tomatoes, and other vegetables with the object of ascertaining the value of electricity as an agent in the cultivation of plant life. Although the results of his own experiments were eminently satisfactory, as also those of other and more favoured investigators, it would be unwise to generalise too prematurely on the value and extent of that form of assisted cultivation. Scientists, the lecturer said, were never justified in asserting, generally and positively, conclusions arrived at by the examination of single or few cases under certain and limited conditions. The lecturer dealt in detail with his experiments, and said that electricity could be applied successfully in many cases to the cultivation of plant life, and his position with regard to electro-culture was one of hope for the future, although as yet sufficient and satisfactory data were not known to enable one to generalise with freedom.

— CAPE FRUIT.—R.M.S. "Scot" arrived at Southampton with 726 boxes of fruit, consisting of Grapes, Tomatoes, Apples, Pears, Chilies, and Gooseberries.

— ISLE OF WIGHT HORTICULTURAL IMPROVEMENT ASSOCIATION.—Dr. Groves, J.P., presided at the last monthly meeting of this Society, when Mr. Barkham read a paper on "The General Cultivation of the Vine," and which proved to be most interesting and instructive.

— THE NATIONAL DAHLIA SOCIETY held its annual meeting at the Hotel Windsor on the 7th inst., E. Mawley, Esq., in the chair. Among other business transacted, the meeting, in consequence of the small balance in hand—8s. 6d.—decided to reduce the prizes in several classes to the extent of about £10.

— ROYAL METEOROLOGICAL SOCIETY.—At the ordinary meeting of this Society, to be held at 25, Great George Street, Westminster, on Wednesday, the 20th inst., at 7.30 P.M., a lecture will be given by Mr. W. N. Shaw, F.R.S., on "The Motion of Clouds Considered with Reference to their Mode of Formation," which will be illustrated by experiments.

— CUCUMBERS DAMPING.—Observations indicate that this affection is caused by the fungus *Pythium De Baryanum*, *Hesse*, which is known to produce the same effect in Europe on the assumption that this fungus is the cause of the trouble. Plants affected should be at once removed, with the soil immediately surrounding them, and burned. If this is done as soon as the seedling falls the trouble can be held in check, since the fungus will be destroyed before its productive organs have developed.

— A LOCUST PLAGUE.—In about two days the Indian corn in the Usambara country was devastated by locusts, and a missionary at Magila states that there is not an undevoured corn field within thirty miles of his residence, and unless help is forthcoming from England the Boudei people will die of starvation, for the *Imgiva* root crop is exhausted and the Cassava will not be ready for several months. The rice at the mission stations at Magila and Hologwe has prevented the starvation of many, but it cannot last long, and many deaths are inevitable. The missions have never previously experienced such a scarcity of food.

— ANALYSIS OF THE TULIP.—Mr. Edmund Tonks obliges with the following information in reply to "W. J. P." (page 196):—Dr. Emil Wolff, in his *Aschen Analysen* (Berlin, 1871), gives us the analysis of *Tulipa Gesneriana*, which is the parent of the larger proportion of cultivated Tulips:—Potash, as KO, 34.90; soda, as NaO, 1.02; lime, as CaO, 20.85; magnesia, as MgO, 10.76; iron, as Fe<sub>2</sub>O<sub>3</sub>, 1.13; phosphorus, as PO<sub>5</sub>, 8.06; sulphur, as SO<sub>3</sub>, 3.36; silicon, as SiO<sub>2</sub>, 8.51; chlorine, as Cl, 1.17. This indicates that a soil in which Tulips are to be cultivated successfully should contain sufficient potash, lime, magnesia, phosphorus, and sand, and some of these may have to be supplied artificially. Most soils contain sufficient of the other ingredients.

— THE EFFECTS OF LIGHT ON PLANTS.—Professor Wollny states that yellow light has the greatest power of producing organic substances in plants; red comes next in power, while blue has a remarkably prejudicial effect on the development of the reproductive organs. It is, therefore, clear that the rays which take the least part in metabolism are the most refrangible rays. As the result of another series of experiments, Mons. Villon has just found that the Vine produces a greater weight of Grapes when grown behind glass coloured red violet by manganese, which absorbs the yellow and brown rays. Flowers are also favourably influenced by the same colour, which is, moreover, advantageous to the growth of bacteria, yeast, and silkworms.

— PLANTS FOR THE BACK WALLS OF VINERIES.—I have to thank Mr. W. J. Murphy for his timely note (page 206), in which he supplements my remarks concerning plants useful for the above purpose. I have tried neither of the three varieties of Tea Roses he especially recommends. *Maréchal Niel* I have had a good deal of experience with on vinery walls, but never found it quite satisfactory, as the flowers produced under such conditions were wanting in colour and substance. Climbing *Niphetos* and *Safrano* succeed fairly well, especially if planted near the ends of a house where they receive extra light; but one great objection to all kinds of Roses when growing on vinery walls is that at certain seasons they are so subject to green fly. There is now such great demand for *Smilax*, *Asparagus*, and *Lygodium scandens*, that I think for home use or commercial purposes the majority of gardeners will find them more useful or profitable for vinery back walls than even Roses.—W. C.

— CANTOR LECTURES.—A series of Cantor Lectures on Commercial Fibres will commence before the Society of Arts, John Street, Adelphi, W.C., by Dr. D. Morris, M.A., C.M.G., on Monday next at 8 P.M. The subsequent lectures will be on March 25th and April 1st.

— WE learn that Mr. William Scrymgeour of Shrubland Park, near Ipswich, forester to Lord de Saumarez, and late forester to Sir Herbert Maxwell, M.P., has been appointed a Government forester in the Forest of Dean, and will commence his duties there in the beginning of March.

— MESSRS. WRINCH & SONS, St. Lawrence Works, Ipswich, who are advertisers in our columns, desire to announce that the two ranges of greenhouses they are building for Her Majesty the Queen for the Royal Gardens at Osborne are now erected at their Works (Portman Road), and will be on view on Thursday and Friday next, the 14th and 15th inst., between the hours of ten and one in the morning and three and five o'clock in the afternoon.

— THE WEATHER IN THE SCILLY ISLANDS.—Growers in these islands have experienced heavy losses from the long-continued frost, and at the beginning of the month, when the fields should have been spangled by the white and golden flowers of the *Narcissi*, and all have been bustle at St. Mary's, the fields presented a bare or blackened appearance. In consequence, the steamer which runs between Scilly and the mainland has had very light cargoes, and in some instances farmers have had to reduce their staff of workmen.

— BRITISH LEPIDOPTERA.—The remarkable collection of British Lepidoptera formed by the late Mr. William Machin, was sold recently by Mr. Stevens of King Street, Covent Garden. High prices were paid for the majority of the specimens. An *Iris*, with yellow under wings and the white stripe at a more oblique angle than usual, fetched £3 5s. Six specimens of *Dispar* brought prices varying from £5 5s. to £2 each: Two pairs of *Acis* were sold for £4 10s.; a lot of *Trifoli* for £3 10s., while four pairs of *Illicifolia* made altogether £13 3s. A set of specimens of *Subrosea*, seven in number, fetched as much as £18.

— DUNDEE HORTICULTURAL ASSOCIATION.—At the Technical Institute, Dundee, on the 5th inst., Mr. A. Innes, Coupar Angus, read an instructive paper entitled "A Melon House and a Few Frames." He gave structural details of a Melon house, and followed with the culture of the Melon. He also remarked on the various uses the house could be put to when the Melons are not occupying it. He also gave, in a concise manner, the culture of double and single-flowered Violets in cold frames. A long discussion followed, and a vote of thanks to the Chairman and the essayist were given.

— SPRAYING GARDEN TREES.—In many suburban homes there are only a very few trees, but these need spraying just as much as the trees in big orchards. The question is how to do it most cheaply and conveniently. It may not pay to buy expensive pumps and fixings for these small operations. To owners of garden fruit trees who have command of water under pressure a writer in the "New York Tribune" suggests the following method:—Introduce the spraying mixture by means of a funnel into the ordinary garden hose, filling up the section or sections; attach hose to the supply pipe; adjust the sprayer (generally in use on garden hose) so that the tree is reached throughout, and on turning on the water the spraying solution will be driven steadily out and will be quite under control. When the spray begins to come clear it should of course be turned off at once.

— DEVON AND EXETER GARDENERS' ASSOCIATION.—"Foliage Plants and Their Culture" was the title of a paper read at the meeting of this Society, on Wednesday, March 6th, by Mr. G. Camp, gardener to Mr. E. Byrom, J.P., of Culver, near Exeter. Mr. Camp treated his subject in an interesting and discriminating manner. Confining himself to exotic foliage plants, he gave particulars and hints for culture of a long list, including the *Crotons*, *Dracænas*, *Caladiums*, *Anthuriums*, *Marantas*, *Ananassa*, foliage *Begonias*, *Cissus*, *Palms*, *Pitcher plants*, *Side-saddle plants*, and greenhouse foliage plants. A very interesting discussion followed the lecture, which was illustrated by some finely grown specimens of the plants of which the lecturer treated. A vote of thanks was heartily accorded the Chairman (Mr. Hy. Webber), and the reader of the paper. Mr. Hope, Hon. Secretary, announced that the Spring Show would be held on the 20th inst. On account of the backward season some *Hyacinths* and *Tulips* are a little late, and Mr. Hope asked members to help the Show Committee by sending in contributions of plants for the tables.

— THE OXFORD BOTANIC GARDENS.—These gardens are receiving the attention of the University authorities, and steps have been taken to place them on a footing and in a position befitting the Oxford University. Quite recently a Congregation empowered the Curators of the University to make sundry payments to the Curators of the Botanic Garden, to bring up the total income of the gardens during the next four years to an amount sufficient to defray all expenses.

— LARGE CINERARIAS.—Mr. G. Freeman, The Gardens, Akeley Wood, Buckingham, writes:—"I herewith send for your inspection some Cineraria blooms, and shall be glad of your opinion of them. They were cut from plants measuring 2 feet across and producing upwards of fifty blooms each. They are growing in 32-sized pots." [The flowers were large, ranging between 3 and 3½ inches in diameter, and the colours very rich. They represent excellent culture and a good strain.]

— BRADFORD PAXTON SOCIETY.—Between seventy and eighty members and invited guests sat down to the annual dinner of the above Society on the 28th ult. The company included delegates from the Batley, Wakefield, Morley, and Leeds Societies. Mr. R. Eichel (President) was in the chair, and Mr. J. Collier occupied the vice-chair. From the report read by Mr. H. R. Barraclough (the Hon. Secretary), it appeared that the membership had increased during the past year, bringing the present total to eighty-nine. The papers read during the year had been of a high order, affording much information, especially to young gardeners. The report and balance-sheet were adopted.

— EXPOSITION UNIVERSELLE D'AMSTERDAM.—During the present year there will be held at Amsterdam a universal exhibition, in which horticulture will be included. It has been decided to hold four shows. The first, for Roses and other plants, on July the 6th, 7th, and 8th; the second and third, for flowers, fruits, and vegetables, on July 27th-31st, and September 14th-18th; and the fourth, and apparently the principal one, for fruit and vegetables, on October 10th-17th. In the latter there are classes for all countries, and entries must be in before the 1st of October. Several medals are offered, but the prizes in the ordinary classes are not scheduled. Full particulars may, however, be had from Mons. Isaac Bulk, Chief Secretary of the Horticultural Section, Amsterdam.

— WAKEFIELD PAXTON SOCIETY.—The programme of meetings for the first quarter, session 1895, are as follows:—March 9th, "Methods of Book Illustration, Old and New," with lantern views, Mr. J. Swire; March 16th, "The Pyramids of Egypt," Rev. A. N. Thomas, B.A.; March 23rd, "Migration of Plants," Mr. G. Bott; March 30th, "Observant Habits," Mr. J. Thomas; April 6th, "Trees," Mr. J. W. D. McPherson, B.A.; April 13th, "The Rearing and Preservation of Insects," with specimens, Mr. G. Parkin; April 20th, "Rhubarb," Mr. W. Hudson; April 27th, "The Cultivation of Bulbs for Spring Flowers," Mr. J. G. Brown; May 4th, "The Florist's Carnation and Picotee," Rev. F. D. Horner, Kirkby Lonsdale; May 11th, "The Origin and Development of Plants," Mr. J. Burton; May 18th, "Spring Bedding Plants," Mr. T. Pitts; May 25th, "The Primula," Mr. T. Gartery, Rotherham. Each meeting will commence at 8 o'clock for business, and the lecture at 8.15 prompt. We are glad to see by the financial statement that the funds are in a healthy state.

— GOOSEBERRY TREES AND RED SPIDER.—If Gooseberry trees were much more cultivated on trellises than they are red spider and caterpillar would be easily kept down, and a great deal of room saved in gardens. For a number of years Mr. Beddard, Lord Leigh's gardener at Stoneleigh Abbey, near Warwick, has grown them in no other way, and secures fine crops, which are easily protected by netting and kept clean. There are two long lengths of wire trellis, simply uprights at certain lengths, with stout wires strained along at about 9 or 10 inches apart. One-year-rooted cuttings are planted 10 inches apart, and are trained upright, with a single stem on the cordon system, and the side shoots kept pinched off. Large tubs are placed near at hand for holding lime water, made according to a method and at a strength recommended recently in the Journal, and frequent syringings of the trees are given on both sides, and by this means the under part of the foliage is easily got at. Netting can readily be placed over the top to fall down on each side, and gathering can be done by simply lifting the net. A long north-aspect wall has cordon Gooseberry trees against it, and good crops are also obtained here, but when they are against a wall both sides of the foliage are not so easily got at as on the open trellis, and in the latter case caterpillar, a deadly enemy to the Gooseberry tree, is readily exterminated.—W. D.

— GARDENING APPOINTMENTS.—Mr. C. Cowley, late head gardener to E. Brodie Hoare, Esq., M.P., Tenchleys Park, Limpsfield, has been appointed gardener to W. M. Tidy, Esq., Lynton Crofts, Caterham. Mr. W. Boreham, the experienced foreman under Mr. Moorman at Victoria Park, has been promoted to the position of District Superintendent of open spaces south of the Thames, in the place of Mr. Wilkie resigned. Mr. James Wood, for the last two years head gardener at Oak House, Northenden, Manchester, has been appointed head gardener to Ernest Frank, Esq., Withington Hall, Chelford, Cheshire, and will enter on his duties on the 18th of March. In the issue of February 28th it was stated in error that Mr. J. Brooks had been chosen for this position.

— PARSNIPS PROFITABLE.—In the neighbourhood of South Petherton, Somerset, there are large tracts of fertile ground divided into allotments of various sizes, and principally rented by the working classes. For many years past Parsnips have been quite as extensively grown as Potatoes, and are principally preferred by those who grow for the markets. As a rule they do not pay very well, the growers receiving from 30s. to 40s. per ton for the best roots. This season there is an exceptionally heavy demand for Parsnips, these being among the few vegetables that have survived the severe frosts, and the prices have gone up surprisingly. Those growers who delayed selling are securing about £4 per ton for their roots, and two days after I was at South Petherton I heard of as much as £7 per ton being offered in another parish. Sixteen tons to the acre is a fair estimate, and at £4 only that would mean good business.—W. I.

— CABBAGES.—A LUCKY ESCAPE.—That the effects of the frost on vegetables is more disastrous in the south than the north is only what might be expected when the protective power of the snow is kept in mind. During the intense frost of last month there was not enough snow to cover plantations of young Cabbages in Surrey and the "home counties" generally, and millions of plants were destroyed. In suggesting to Mr. McIndoe of Guisboro', Yorks, when he called the other day, that the northerners would have the advantage this year, he said, "Yes, I suppose we have. I have a bed of 6000 Ellam's & Mein's No. 1 Cabbages, many of them turning in just as fresh when the snow left them as when it covered them six weeks before—not a plant killed. I have also 400 sturdy plants of Veitch's Model Broccoli quite uninjured, except the tips of the leaves that were not covered by the snow. They were grown on firm ground. The Cabbages were raised early in July, and are grown 9 inches apart in rows 1 foot asunder, as we like them small. We can cut at any time, and shall have abundance." Lucky Mr. McIndoe.

— SEAKALE.—I quite agree with "A. D." (page 207) as to the great necessity of having a good stock of the above on hand for winter forcing, and more especially in such a severe winter as this, when so many of the green crops are severely cut up. But I have more sympathy with the old-fashioned method of forcing Seakale than "A. D." appears to have. We annually follow the old system of pots and fermenting material, and have this season had no difficulty in cutting good Seakale since early in December. We were a little later this season than usual, which I attribute to the absence of autumn frosts to give the plants that decided rest so essential to successful forcing. Happily, we have a good supply of leaves and stable manure at command. By using three dozen pots, and as the crowns are cut regularly moving the pots forward (leaving only sufficient of the old fermenting material behind to protect the cut crowns from frost), and working in sufficient fresh material to insure a gentle heat, a regular supply of tender growth is maintained. About 400 new crowns are planted each year, and the same number of old done away with. Some portion of the bed now has been forced six years in succession with good results.—J. FRIEND.

— THE HISTORY OF KEW GARDENS.—Some interesting historical facts respecting the Royal Gardens at Kew appear in the "Kew Bulletin" for February. An arboretum has been for more than a century a feature of the Kew establishment. It is supposed to date its formal commencement from 1762, when "all the Duke of Argyll's trees and shrubs were removed to the Princess of Wales's garden at Kew, which now excels all others, under the direction of Lord Bute." The old arboretum in part still exists near the main gate on Kew Green. The Botanical Garden was opened to the public in 1841, with Sir William Hooker as Director. It comprised only about 11 acres, and included the old arboretum. In 1844, by permission of the Queen, about 47 acres, including the ornamental piece of water in front of the Palm house, was added for the formation of a pinetum. This, it

seems, was too near the smoke of suburban London, and it has lost its distinctive character. But many of the trees planted at this time are now of considerable magnitude. The "Pleasure Grounds and Gardens at Kew" were in the occupation of the King of Hanover for sporting purposes at the time the Botanic Garden was given to the nation. The woods were filled with rough scrub for cover. In 1845 they were placed under the charge of Sir William Hooker, "with the intention that they should be formed into a national arboretum." A plan for the purpose was prepared in 1846 by W. A. Nesfield. The main features were carried out at the time, and the general principle has been worked upon ever since. In 1850 the nursery was formed. In 1870 the new pinetum was commenced.

— GREAT QUINQUENNIAL BULB SHOW AT HAARLEM.—The fifth great quinquennial bulb show will be held by the Royal Bulb Society of Haarlem from March 22nd—26th. The competition is open for members of the Society only; but therefore will be the heavier, as most of the leading firms of the famous bulb district are among the exhibitors. The schedule of prizes consists of 132 entries—viz., twenty for Hyacinths, twenty-two for Tulips, twelve for Narcissi, the other being devoted to all kinds of miscellaneous bulbs and bouquets. Among the medals offered there are twenty-five gold ones, and some hundreds of silver-gilt, silver and bronze medals, and extra premiums. The judges are experienced bulb growers, chosen among those who will not exhibit, and in a number of entries the judging system by points will be adopted. The rules for this examination were given in the programme of the show, and are known therefore by intending exhibitors. The show is to be held in the large music hall with annexes of the "Vereemging" Club at Haarlem, and will be opened on March 22nd, at 1 P.M. Intending visitors from abroad will be heartily welcome, and may find this an exceptional occasion for comparing the various growers' strains, and for observing the advance of bulb-growing during the last five years. The classes for miscellaneous bulbs will specially prove of the highest interest and completeness.

— PROBLEMS IN HORTICULTURE.—There seems to be no end to the problems which confront workers in the higher branches of horticulture. Some men of science in France have, according to the "Garden and Forest," been making a study of plants grown from the seeds produced on grafted plants, and they seem to have demonstrated that the seedlings may partake of the character of the stock as well as of the scion—that is, a seedling from a graft may be, in a certain sense, a hybrid inheriting the qualities both of the plant which is used as a scion and the plant used as a stock. These experiments have been confined to herbaceous plants, and they show that, for example, when a Turnip is grafted on a stock of Garlic Mustard, plants from the seed showed a marked reversion to the wild type, and when this Garlic Mustard was grafted on Cabbage the seedlings showed a likeness to the Cabbage plant, and had a less marked smell of Garlic than the wild plant, combined with something of the odour of the Cabbage leaf. Of course, if this is true, it is not improbable that the same law holds throughout the vegetable kingdom, and when, for example, we cross two varieties of grafted Apples the seedlings may show not only the characteristic of the parent plants, but of the scions on which they grow. In this way a hybrid Apple may have four parents, to each of which it is responsible for some of its characters, not to speak of the qualities it may have inherited from the numerous ancestors of each of these parents.

— THE NATIONAL ASSOCIATION OF CIDER MAKERS.—A meeting of this Association was held at the Art Buildings, John Street, Adelphi, on March 6th. Sir George Birdwood, K.C.I.E., C.S.I., M.D., occupied the chair, a moderate attendance of members and friends being present. The Chairman in his opening remarks said the Association had been formed with the idea of assisting the industry of cider making, and he could see no reason why it should not become the national beverage in England. A most interesting and exhaustive paper on "Cider Making" was read by C. W. Radcliffe Cooke, Esq., M.P., the Chairman of the Consultative Committee of the Society of which he is an indefatigable member. The essayist dealt thoroughly with the whole process connected with the manufacture of cider and perry, from the planting of the orchard and the best varieties of Apples and Pears to grow for the purpose, to the further processes until the liquor is finally put into the barrels or bottles. Several cider makers from the counties of Hereford and Devon also spoke briefly on the subject, and Mr. Cooke, in reply, said it should be the object of English cider makers to produce cider of such a quality of excellence that would drive American and other competitors out of

the market. This he felt sure could be done, and it was the object of the Society to further the interests of this once popular industry so far as was possible, in order that it might again come to the front. A vote of thanks was unanimously given to Mr. Cooke for his instructive paper, and also to Sir George Birdwood for the able manner in which he had presided, after which the meeting was brought to a close.

— THE KEW GUILD.—The annual meeting, held at the Kew Garden Library, on February 28th, was a successful gathering. The chair was taken by the President, Mr. G. Nicholson. Mr. J. Aikman, the Hon. Secretary, read the Committee's report and balance sheet, both of which were unanimously adopted. The oldest Kewite living, Mr. J. W. Thomson of Haywards Heath, has shown his appreciation of the Guild's formation by investing a sum in New Zealand stock that will for all time provide the Guild with an annual payment of £5 5s. A hearty vote of thanks was accorded Mr. Thomson for his generosity. Letters from several prominent "Old Kewites" were read by Mr. Watson, and both these and the meeting evidenced the enthusiasm that prevails and the kindly feeling that exists between those who are or have been connected with the establishment. The journal of the Kew Guild will be published as usual in May, and it is hoped that all members of the Guild will assist in completing the efficiency of the list of past Kewites by sending on the "wanted" addresses where such are known.

— FLORA OF MOUNT KINIBALU.—In the "Kew Bulletin" for October 1892, page 249, it was announced that Drs. H. A. and G. D. Haviland had presented Kew with a valuable collection of dried plants, collected by themselves on Mount Kinibalu, North Borneo. As a matter of fact, however, it should be explained that, although the two cousins travelled together, it was Dr. G. D. Haviland alone who did the botanising. This fine collection has been worked out by Dr. O. Stapf, Assistant for India at the Herbarium, together with all previously collected plants from the same region, published and unpublished, notably those collected upwards of forty years ago by Sir Hugh Low, and by Mr. F. W. Burbidge in 1877. The results appear as the second part of the fourth volume (Second Series, Botany) of the "Transactions of the Linnean Society." This is one of the most important and interesting contributions to geographical botany published during the past year, especially in relation to the migrations of plants. The total number of flowering plants enumerated is 360, which Dr. Stapf estimates may be one-fourth or one-fifth of the whole phanerogamic flora of the mountain, and nearly 60 per cent. of these, so far as at present known, are endemic. The relationship with the Australasian flora are especially interesting.—("Kew Bulletin.")

— TINNED GREEN PEAS.—At the Edmonton Petty Sessions, Messrs. Kearley & Tong, Fore Street, Edmonton, were summoned for selling an article of food, a tin of green peas, which were coloured by the aid of copper, thereby rendering them injurious to health. The evidence showed that the article was purchased on January 10th, and an analysis proved it to contain 7-10ths of a grain of copper, which was equal to 2.75 grains of sulphate of copper. Dr. J. F. Sykes, Medical Officer for St. Pancras; Dr. Dupree and Dr. Luff, analysts to the Home Office, stated that sulphate of copper was a poison, which, if taken into the system in the quantities found in the peas would produce chronic poisoning. The copper was used to make the peas retain their greenness, and the effects would be most injurious, especially to weakly persons. For the defence, it was stated there were 16,000,000 tins of the peas imported annually, and yet no case had proved they had produced any injurious effects. The article was sold in the ordinary course of trade, and if it was poisonous, then the question was essentially a State one, and their importation should be stopped. Several cases were quoted to show that the Courts had held the article was not injurious, and in support of this Mr. Otto Hehner, Public Analyst for Nottinghamshire, was called, and said though there was more than the usual quantity of copper in the sample in question, he did not think it would produce the ill effects suggested by the prosecution. After a hearing lasting over four hours the Bench inflicted a fine of £1 and 20 guineas costs. Notice of appeal was given.

— THE CHARLES COLLINS' FUND.—The Committee of this fund desires to tender its sincere thanks to all who have so kindly responded to the appeal; also to intimate that the fund will be closed on the 20th inst. We are pleased to acknowledge £1 from Mr. Coombes, 3s. from "Yorkshire Bite," 5s. from Mr. G. H. Hurry, and 10s. 6d. from Mr. R. Pinnington and two friends. Any further contributions should be sent to the Treasurer, Mr. G. Gordon, Endsleigh Priory, Park, Kew. We think the total sum now acknowledged is £63 2s. 6d.

## ROSE SHOW FIXTURES FOR 1895.

- June 19th (Wednesday).—York.\*  
 „ 25th (Tuesday).—Cowes (I. of W.).  
 „ 27th (Thursday).—Gloucester (N.R.S.) and Canterbury.  
 „ 28th (Friday).—Exeter.  
 „ 29th (Saturday).—Windsor.  
 July 2nd (Tuesday).—Sutton.  
 „ 3rd (Wednesday).—Croydon, Ealing, and Farningham, and Lee.†  
 „ 4th (Thursday).—Eltham and Norwich.  
 „ 6th (Saturday).—Crystal Palace (N.R.S.).  
 „ 9th (Tuesday).—Wolverhampton.\*  
 „ 10th (Wednesday).—Chelmsford, Hitchin, and Redhill.  
 „ 11th (Thursday).—Helensburgh and Worksop.  
 „ 17th (Wednesday).—Derby (N.R.S.).  
 „ 18th (Thursday).—Halifax.  
 „ 23rd (Tuesday).—Tibshelf.  
 „ 24th (Wednesday).—Chesterfield.  
 „ 25th (Thursday).—Trentham.

\* A show lasting three days. † Show lasting two days.

I shall be glad to receive the dates of other Rose shows than those named above for publication in future lists.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

## THE NAMES OF ROSES.

While perusing a list of Rose names to-day, I was more than usually struck with the number of duplicates to be found. Surely there can be no dearth of names for every Rose grown; then why repeat, and often name a second Rose, sometimes a third, similarly to the well-known old favourite? Doubtless there are some few cases where ignorance of the name having already been appropriated may be an excuse, but I am at a loss to find any in more than one instance.

Comte de Paris is one. Who is to know what Rose is meant when only the name of this is given? Do they mean the Tea or Hybrid Perpetual? Duchess of Edinburgh and Duchess of Connaught are in two classes. Then we have the glaring case of Duke of Connaught, the late Henry Bennett giving this name to a H.T. only two years after Messrs. Paul & Son had so named their grand H.P. In the case of Duchess of Connaught, Mr. Noble followed Mr. Bennett by about the same period only. These instances could be greatly multiplied, and surely these prominent rosarians were not ignorant of the prevailing new Roses. Messrs. Veitch & Sons' Duchess of Edinburgh was well advertised and shown only a year or so previous to Mr. Bennett introducing his H. Perpetual of the same name.

Graziella, a very pretty new Rose of 1893-4, we already had in two other classes, and seeing that they were sent out in 1878 and 1889 respectively it is asking too much of us to believe the raiser of the last Graziella was ignorant of the name being applied to any other Rose. Madame Carnot in 1889 and Madame Carnot again in 1894 are further examples. I can understand the commercial instinct which tempts one to give a new production a popular and well-known name, but surely we can find these without duplication among one flower.

What with synonymous Roses, and the same names applied to totally distinct Roses, we shall become terribly confused. The classification is intricate enough, without such palpably avoidable confusion of which I have tried to point out a few examples. If we go back to 1850-60 we find a Rose called *Impératrice Eugénie* in no less than three classes, and all sent out between the dates named. There was even less excuse then than now, because the plurality of Roses was not so great.—PRACTICE.

## LACHENALIAS.

THE Lachenalias, popularly called Cape Cowslips, belong to the natural order Liliaceæ, and comprise a genus of about thirty species of greenhouse bulbous plants, all natives of South Africa. Of the species enumerated and described in botanical and floricultural works many are rare, a few so much so as to be found only in such establishments as Kew, and not always there in living plants. This may or may not be a disadvantage, for many rare things (and plants are no exception) possess little practical value, and what I have seen of scarce species of Lachenalia compared badly, in a decorative point of view, with the old *L. tricolor*, which was introduced in 1774. This is the Cape Cowslip commonly seen, and sometimes known as *L. quadricolor*.

*L. tricolor* has the leaves in pairs, lorate-lanceolate, spreading (arching over the pots), dark green in colour, and spotted with deep purple or black; flower scape erect, the blooms disposed at the upper part in a graceful manner, bright green, red, and yellow, the whole 9 to 12 inches in height. It flowers in April, and in masses produces an effect unequalled by any plants of similar pretensions as regards size. Its variety,

*L. tricolor aurea*, has pure yellow flowers, and is sometimes found under the name of *L. quadricolor lutea*. It is very beautiful, and as yet somewhat scarce. There is also a variety, or possibly species, named *L. luteola*, with yellow flowers, and this forms a charming basket plant, the leaves depending gracefully, while the colour is unique amongst greenery. Botanists, however, do not recognise it, nor the form of *Lachenalia quadricolor*, which has purple in addition to red in the flowers, and if a synonym of *L. tricolor* is a very distinct and desirable one, being very much scarcer and higher in price. It has spotted leaves like *L. tricolor*, and flowers rather later, *L. tricolor* being the first of the two to flower in the spring. *L. Nelsoni*—a hybrid—has golden yellow flowers, produced in long racemes, and is extra fine. Though dating from 1881 it is still somewhat scarce. The woodcut (fig. 41) represents a well grown pot of this handsome Lachenalia.

*L. pendula* is a strong growing species, with somewhat erect leaves, dark green and slightly spotted, the flowers being of a deep purple, red, and yellow colour, quite an inch long, and are almost too closely set, yet in an exceedingly graceful manner, on a stout and spotted scape.

Lovers of scented flowers may find something like *Heliotrope* perfume in *L. contaminata*. The blooms are white tinged with red, the leaves spotted and numerous, and it flowers with or before *L. tricolor*. *L. fistulosa* also has fragrant flowers, containing colours for the fastidious, the calyx being white tinged with sky blue, brown tipped sepals, and white petals edged with purple. It is very scarce. *L. fragrans* really deserves the name, the twenty-flowered racemes being very fragrant, white at first, but soon becoming reddish. It flowers in May. *L. odoratissima* is the sweetest scented of the genera, and is easily recognised by its blistered leaves. The flowers have white sepals with green tips, and disposed in a somewhat dense raceme. It and *L. fistulosa* were introduced in 1884, but *L. fragrans* dates from 1798. *L. orchioides* reached these shores in 1752, and is perhaps only known in botanical gardens. Its flowers are fragrant and variable in colour, hence the name *L. mutabilis* sometimes given to this species.

There are several other species. *L. glaucina* (glaucina), white and red, or yellow tinged; *L. pustulata*, with whitish flowers and long blistered leaves; *L. pallida* (surely nothing more than a magnified *L. glaucina*, and another *L. pallida*, but a synonym of *L. lucida*), the last having sweet flowers tinged with red or yellow, this being an uncommon species, but the three preceding (not bracketed) and *L. unifolia*, which flowers in March, these being white and in many-flowered racemes, may frequently be met with in botanical gardens and other collections. *L. lilacina* has lilac flowers in an oblong spike, and was introduced in 1884, yet is somewhat rare.

The culture of Lachenalias is easy, the chief points being to employ a rich, open soil, good drainage, water carefully in the early stages of growth or during the winter, yet sufficiently to prevent the leaves flagging, and when they are well advanced afford an abundant supply. Too much light cannot be given with free ventilation, but draughts cripple the foliage, and the drying heat from hot-water pipes is scarcely less pernicious, whilst frost and damp are alien to satisfactory growth and flowering. Growing in frames and outdoors has been advised, where frost can be excluded or prevented from doing harm, but I have yet to find such a place in England for these Cape denizens, and the less of this kind of starveling treatment the better. On the other hand, forcing is inadvisable, as that means keeping up a stock for the purpose. The place for Lachenalias is an ordinary cool greenhouse, fire heat being only used to exclude frost and expel damp, then in a light, airy position Cape Cowslips will thrive, flower finely, and keep in good condition for several weeks.

Now is the time to look out for Lachenalias, see them in flower, make selections, and order bulbs to come to hand not later than August. I ask that special note be made of *L. tricolor*, its variety *aurea* or *lutea*, of *L. Nelsoni* and *L. pendula*. These are indispensable in any well appointed cool greenhouse, and are worth growing in numbers for decorative purposes. The thing is to see and the rest follows.

The bulbs are generally quite dormant at the beginning of August, when they may be turned out of the pots, have the soil removed, and be sorted into three sizes—large, medium and small. Of course this trouble will be saved if dry or loose bulbs are procured, and they will or should be of the first or blooming size, for it is only the strongest that flower the best, whilst the medium sized give some bloom, and the small need growing on for another year to acquire strength for this purpose.

The compost for potting may consist of two parts turfy loam and one part leaf soil or well decayed manure, with about one-sixth of sharp sand. This should be well mixed, the pots or pans being drained with clean crocks, and some of the rougher parts of the compost placed thereon to keep it from clogging. Enough soil should be placed in the pots or pans as to bring it up rather firmly to such height that when the bulbs are introduced their apices will be an inch below the level of the rims. This will allow the bulbs to be covered half an inch deep, that is, buried, and leave that amount of space for holding water. Pots 4½ or 5 inches in diameter are large enough for half a dozen of the strongest bulbs, and pans of double those diameters are better than pots of that size, in addition to holding about four times as many bulbs as the smaller pots. The soil should be pressed rather firmly about the bulbs, and a little sand sprinkled in before introducing them. If the soil be moist and the pots or pans are placed on a bed of ashes kept damp, they will not need any top watering till the bulbs commence growing, or very little, and then only enough must be given to keep the soil moist.

A low pit or house from which frost is excluded is the best place for growing *Lachenalias* in quantity, allowing all the light possible, and free ventilation from 45° or even 40°, anywise full at 50°, for without air on all favourable occasions the foliage becomes drawn, also when

giving excessive supplies of water, yet a full one when needed, and then wait until the soil is becoming dry before repeating. Liquid manure may be given as soon as the flower spikes appear, but it should be clear and not strong, as it lodges in the axils of the leaves. Chemical manure, for the

FIG. 41.—LACHENALIA NELSONI.

kept at a great distance from the glass. Cold draughts, however, must be avoided, as this cripples the leaves and stunts the growth, especially in February and March, when the plants are advancing for flowering. The plants must have the soil moist when they commence growing, not

same reason, must be carefully applied. This answers even better than liquid manure, sprinkling a little judiciously and cautiously between the plants, and washing in. When advanced towards flowering more water is necessary, observing the conditions before named as to when to supply

it, and remember that as the weather becomes warmer more air must be given. As each strong bulb produces from one to four flower spikes, the array of bloom is considerable, and the plants are fit for any decorative purpose, showing to best advantage placed in groups, as masses of wild Hyacinths and Wood Anemones do in woods, or Primroses on banks.

When the flowering is over the plants require liberal waterings for a time, but not unnecessary supplies, and all the sun and air a cool greenhouse or low pit affords. This will secure well-developed bulbs and thorough ripening, the watering being diminished as the maturity proceeds, leaving it off altogether when the foliage turns yellow, and when completely died down store where dryness will be assured until starting time.

The medium sized bulbs should be treated similarly to the large, only placing more in a pot or pan. Like remarks apply to the small bulbs, which if encouraged with liquid manure when in full leafage, and ripened off properly, will do good service the year following.

Ordinarily the plants are simply kept in the pots from year to year, being potted in September or when they commence growing, merely dividing the clusters of bulbs, removing some soil, so as to allow space for fresh with new drainage, then assigning them a light airy position in the greenhouse, from which they are only taken for potting, and giving water as growth and the condition of the soil prompts. Grown in this way the plants give very little trouble, and bloom as certainly at their appointed season, affording a charm to the greenhouse occupants, and enhancing the interest all round. After flowering and ripening off the pots are kept on shelves or other convenient position, where they will receive only sufficient water. To keep a fair amount of moisture in the soil appears to be, in my opinion, better than the "dry as dust" system.—G. ABBEY.

## VEGETABLES FOR EXHIBITION.

### POTATOES.

IN dealing with the Potato it is important to have the sets thoroughly prepared in shallow boxes as soon as possible after the crop is lifted from the open ground. The sets—which should be of uniform size and as large as a hen's egg—should be placed on their ends with the eyes upwards, and put in a cool position where they will be safe from frost, and will receive as much light and air as it is possible to give them. In the early spring they will begin to grow, and on the top of each set will be found one strong stem with probably several weaker ones. These latter should be rubbed off, thus concentrating the sap towards the strong one. If the best results are desired Potatoes for planting, especially for exhibition, should never be clamped or thrown together in a heap, as they are sure to sprout prematurely, this causing the stem to be weak, and the haulm to become a ready prey to the disease. By keeping them in boxes quite cool, with abundance of light and air and one strong stem, an excellent foundation is laid for a crop of exhibition tubers.

The preparation of the soil next demands attention. This is best done in the autumn or early winter by thoroughly trenching to the depth of 2 feet. If the bottom spit is not so good as the top it is better not brought to the surface. If the ground has been manured for the previous crop none will be required, but should it be in poor condition a dressing of leaf soil will be found beneficial. Fresh manure from the farmyard induces soft and sappy growth. It is much better to add to the soil such ingredients as will encourage strong stocky growth, with firm leathery foliage. Probably nothing better can be had for this purpose than a good dressing of wood ashes, and if the soil is heavy and stiff a sprinkling of hot lime just before forking the ground over will be of great service not only in improving the soil but in killing little insects. After the ground has been thoroughly forked over, the lines should be drawn to the depth of 6 inches, and at least 3 feet apart for strong sorts, and 3 inches less for smaller. The sets should not be planted closer in the lines than 2 feet—in fact, 6 inches more would be better for robust sorts. This may seem waste of ground, but one cannot have well-formed tubers when they are planted closer, because the leaves are so crammed together that it is impossible for the sun and air to reach them, and if the leaves and stems are not properly matured it is impossible to have tubers of first-class quality. In many soils it is difficult to get the tubers with clear skins. When this is the case, wood ashes, burnt soil, and a little soot form an excellent mixture to place over the sets when planting. Where the soil is of a light sandy loam this is, perhaps, not required. The soil should be drawn over the sets in the form of a ridge, when nothing more will be required except keeping the ground well stirred and free from weeds till the haulm has reached the height of 9 or 10 inches, when they should be finally earthed up.

When lifting the crop great care is necessary not to prick any of the tubers, nor to rub off the skins. The tubers must be selected of an uniform size, and if the show is near at hand they should be carefully washed, before the soil becomes dry, with soap and water and a sponge. As soon as dry they ought to be wrapped in soft paper and placed in a drawer. As regards varieties much depends on the season at which they are wanted. For early shows Snowdrop and Sutton's Seedling are two of the best, and Satisfaction may be grown for later purposes.

### PEAS AND BEANS.

Many different ways are adopted in growing Peas for exhibition, but none is better than growing them in trenches prepared as if for Celery.

The trenches should not be less than 2½ feet deep and the same in width, and filled with well decayed farmyard manure mixed with part of the soil taken from the trench. If plenty of wood ashes could be had they would be an excellent addition to the soil, as they generally contain potash, which the Pea is much benefited by. Three inches of soil should be placed on the top of the manure, bringing up the trench level with the surface. As regards sowing, much will depend on the time they are wanted; but the careful exhibitor will seldom trust to one sowing of the variety he wants to exhibit, for the seasons vary so much that one sowing might either be too early, or, what is worse still, too late. It is best, therefore, to make two or three sowings at intervals of eight days. Three inches will be quite deep enough for the seed, and the Peas should not be closer than 2½ inches. They require abundance of room to develop, and in allowing this you not only insure as many and more pods, but they are handsome and of better flavour. It is a good plan to pinch out the top of some of the stems after they have made three or four trusses of bloom, as the sap gets checked and larger pods are obtained. Feeding should commence as soon as the pods begin to set, and may be continued as long as flowers are produced. The Pea likes water, and should never become dry at the roots. Soot is an excellent stimulant. If the season is a dry one the lines should be top-dressed with long litter, which prevents the sun from drying up the moisture.

If an exhibitor finds that his Peas are too early he can keep them from eight to twelve days by adopting the following method: Fill a pan full of wet sand, pick off the best pods, and immerse the small stalks only in the sand, taking great care not to rub off the blooms; place the pan in any cool dark cellar, and they will keep there perfectly safe for the time mentioned. A good dish of Peas when well staged should not bear a trace of rubbing. There are many varieties suitable for exhibition, but none seem to find more favour than the Duke of Albany. Sharpe's Queen is also popular.

Runner Beans should be treated like Peas, except in a few details. The seed should be planted about 8 inches apart, and must not be placed outside earlier than the last week in April. If required early they should be sown in pots, placing two or three seeds in each in a cold house or frame, and planted out when about 3 inches high. This will make a difference of from a week to ten days in gathering. Ne Plus Ultra and Sutton's Prizewinner are both excellent varieties.

French Beans should be treated in the same manner as the Runner, only no staking will be required. Ne Plus Ultra and Canadian Wonder are chiefly grown for exhibition.

### CAULIFLOWERS AND BRUSSELS SPROUTS.

The soil for these can scarcely be too rich, at the same time not loose, but moderately firm, or the result will be more leaves than anything else. When trenching the ground two spits deep in the autumn manure may be placed at the bottom of the trench and between the two top spits. For early shows Cauliflower seed is best sown thinly in boxes in light soil about the beginning of March, and as soon as the plants have made their seed leaves and become sufficiently hardened, they should be pricked into a frame with a little hot manure placed at the bottom, and 3 inches of half-decayed leaves and turfy loam. In this compost they will grow well and lift with good balls. When being transferred to their summer quarters the ground should be thoroughly forked over, and for the strong growing sorts, of which Autumn Giant is an example, the lines ought not to be closer than 3 feet, and 2 feet from plant to plant.

Cauliflowers can easily be had from outside sowings, which should be done as soon as the weather will permit in March. The seed should be sown very thinly, and the young plants must not be allowed to crowd each other. After they have made four leaves they should be pricked into other beds and thoroughly watered. When ready for planting out they may be lifted with good balls with a trowel, and placed in their new quarters, a handful of soot and lime being thrown round the stems. This will help to prevent the white maggot, which sometimes does great damage, rendering the plant useless by eating off the roots. Abundance of water should be given when the weather is dry, and liquid manure may be applied with advantage once a week. When the heads begin to form, a strict watch must be kept on the caterpillar, and the only effectual remedy I know of is handpicking.

Good Cauliflowers should be perfectly white; this can only be accomplished by tying the leaves over the head and excluding the light immediately they begin to form. A head can be kept in good condition from ten to fourteen days by pulling up the whole plant and storing away in a dark, cool shed. In my opinion the purity of the curd is improved by so doing. This plan has much to recommend it, especially when they are too early. If left in the open ground the same heads would be useless. The stems should never be cut off before staging at the show, and even then they sometimes come in useful, as they serve as a prop when they require to be placed on the top of each other. For early shows Veitch's Pearl is good, and for later ones nothing can equal Autumn Giant when in good condition.

Brussels Sprouts require the same cultivation as Cauliflowers; only, if the soil is rich, the firmer it is the more solid the sprouts will be. Sutton's Exhibition and the Wroxton are good types for show purposes or general use.—JAMES GIBSON.—(Read at a meeting of the Croydon Gardeners' Mutual Improvement Society.)

(To be concluded.)

## DECORATIVE CHRYSANTHEMUMS.

IN my remarks on decorative Chrysanthemums (page 120) there is a mistake, which I think needs correction. It reads: "I never pinch or stop them, but thin the growths, &c." What I intended to have said is, I never pinch, stop, or thin the growths, but let them grow as they will, &c. I do not think by thinning the growths one could secure the same results as by the system I adopt, and would recommend others to try it.—J. LYNE.

## PRIMROSE HILL CHRYSANTHEMUM SOCIETY.

THE annual meeting of this Society was recently held. Mr. B. Gleadhill, President, occupied his official position. There was a good attendance of members. The report and balance-sheet were read, and showed that the Society was in a most flourishing condition. There had been a large increase of members, honorary members being more than double the previous year. The President generously supplemented his usual munificence by additional special prizes. Votes of thanks were accorded to the President and retiring officers. The election of officers for the new year resulted as follows:—President, Mr. B. Gleadhill; Vice-Presidents, Dr. Forbes, Mr. A. T. Bescoby, Mr. A. M. Wilson, Mr. H. Dearden, and Mr. H. Broomhead, F.R.H.S. Committee—Messrs. W. Tissington, R. Allen, J. Carnell, A. Medley, T. Fletcher, J. Lidster, S. Hurst, W. Halliwell, and T. Beaumont. Chairman, Mr. T. Howe. Judges, Mr. B. Glossop, Sheffield, and Mr. J. Woodfield, Birley Carr. Honorary Treasurer, Mr. C. Drabble, Walkley Bank Road. Secretary, Mr. J. Roberts, in the place of Mr. P. Hallam (resigned). Reference was made to the loss sustained by the Society by the deaths of Messrs. S. Furness and C. Burgon. Members of the Sheffield Chrysanthemum Society and other local societies were present.

## NATIONAL CHRYSANTHEMUM SOCIETY.

THE General Committee of this Society held a meeting at Anderton's Hotel on Monday last, when the newly elected Vice-Chairman, Mr. T. W. Sanders, presided. After the minutes of the previous meeting had been read and confirmed, a letter from Sir Edwin Saunders was read, expressing his thanks at having once more been elected as President of the Society.

It was moved that an illuminated address on vellum be presented to Mr. R. Ballantine on his retirement from the office of Chairman for his valuable services to the Society since the year 1879, and in appreciation of the high esteem in which he is held by the Society. The report of Schedule Sub-committee was then presented, and special prizes were recommended for acceptance from the following donors—Mr. J. Wills, Mr. W. Wells, Messrs. B. S. Williams & Son, Messrs. Sutton & Sons, and Mr. W. J. Godfrey.

The Chrysanthemum catalogue recently compiled and published by Mr. O. de Meulenaere of Ghent was then submitted to the meeting as a valuable addition to the literature of the flower. The compiler, who is a foreign member of the N.C.S., was awarded a silver medal for his work.

The Secretary announced that the total number of members now on the books was 704, made up as follows:—Seventy-nine Fellows, 598 ordinary members, and twenty-seven foreign members. Altogether there are now 114 societies affiliated to the National.

One-third of the Floral Committee retiring by rotation, but being eligible for re-election, resulted in a change of membership, the following gentlemen being appointed—Mr. G. S. Addison, Mr. D. B. Crane, Mr. W. H. Lees, Mr. C. E. Shea, Mr. J. W. Moorman, and Mr. J. (Temple) Wright. Mr. George Gordon was elected Chairman of the Floral Committee in the place of Mr. W. H. Fowler, who is much occupied this year with work of a local nature.

The following dates were fixed for the meetings of the General Committee during the ensuing season—26th August, 30th September, 28th October, 18th November, 9th December, 1895, and 20th January, 1896. The Floral Committee will meet on the 3rd and 25th September, the 8th, 23rd, and 30th October, the 11th, 20th, and 27th November, and the 3rd and 11th December.

With regard to the celebration of the Society's Jubilee in 1896, it was recommended by the sub-Committee, who have had the consideration of the matter, that a four-days show be held with competition on the first and third days; that a Jubilee medal from a special design be struck, and that a banquet and Conference be also held. Amongst other items in the schedule will be a class for Japanese cut blooms, with a first prize of £20 and a gold Jubilee medal; second prize, £15 and a silver-gilt medal; third prize, £10 and a silver medal; and a fourth prize of £5 and a bronze medal. A similar class with the same prizes for incurved is also to be included. A class for single-flowered Chrysanthemums, another for Colonial exhibits, and one for varieties in cultivation when the Society was first established, are also to be provided in the Jubilee schedule.

The Catalogue Revision Committee was then elected, the following gentlemen being appointed to serve:—Messrs. Harman Payne, A. Taylor,

W. H. Lees, H. J. Jones, and D. B. Crane. Mr. J. W. Moorman moved that a hearty vote of thanks be accorded to Mr. Payne for his services as Editor of the "Chrysanthemum Year Book," and to all the contributors to that work. Mr. Crane thought that something more substantial should be done in the case of the Editor, and after some discussion it was resolved that the matter be dealt with at a future date. Upon the motion of Mr. Bevan it was resolved that the Secretary should in future receive the sum of £75 per annum for clerical assistance instead of £50. Two Societies were admitted in affiliation, and several new members were elected:

## THE CHRYSANTHEMUM YEAR BOOK.

So Mr. A. Dean (page 212) is displeased because the Committee of the N.C.S. has not condescended to thank him for his work in connection with this publication, and he suggests that the Editor should be paid for his services. A friend in America has favoured me with a copy of the "American Florist," from which I cull the following comments on the publication in question:—"The Year Book published by the N.C.S. of England has recently come to us for review. It is a paper-bound volume of eighty-eight pages, exclusive of advertisements. The American Chrysanthemum literature offered by this book is certainly open to criticism. We find a list of synonymous Chrysanthemums in America by Mr. T. H. Spaulding (in which, by the way, the very familiar Wanamaker is mis-spelt), in which we find 'Ostrich Plume' given as a synonym of Mrs. Alpheus Hardy. It should be borne in mind that although Mrs. Hardy was widely advertised as the 'Ostrich Plume Chrysanthemum,' the title was never arrogated solely by that one variety; it was used as a descriptive term for all the hairy form, and is still so used. For this reason we think it an error to give 'Ostrich Plume' as a synonym when it is merely an adjective.

"Mr. Spaulding gives Robert Bottomley as the proper name of Lady Trevor Lawrence as the synonym, which should be reversed. In the case of President Spaulding, given as correct name, synonym Charles Sharman, it will be found that Charlie Sharman, President Spaulding, and Gladiator are all synonyms of the variety W. M. Singerley. Mr. Spaulding gives Francis A. Spaulding as correct name, J. S. Dibben and Mattie C. Stewart as synonyms; but M. de Meulenaere entertains a contrary belief, as he gives Mattie C. Stewart and 'Mrs. F. Spaulding' as synonyms of J. S. Dibben. We do not find Francis A. Spaulding in any list of Chrysanthemums to which we have access, there being but six or seven varieties bearing this family name in our authorities, so evidently Francis A. got away.

"Mr. Michall Barker of Cornell University gives some notes on American varieties and methods of culture, but few of our most striking novelties are mentioned. . . . 'A list of twenty-five Chrysanthemum portraits with the papers in which they appeared is given; being restricted to this number of varieties it gives but a small impression of the many illustrated, particularly in America. It seems to us it would have been preferable to omit them altogether rather than to have given such an imperfect list.'"—FAIRPLAY.

## PRIMULAS AT PERRY HILL.

PROBABLY nowhere within the metropolitan area can a finer collection of Chinese Primulas be found than at the Perry Hill Nurseries. It is here that the celebrated Holborn varieties have been and, it is hoped, will continue to be raised. For a great number of years Messrs. J. Carter & Co. have been experimenting, and hybridising with indefatigable zeal and exceptional success to improve the existing strains, not of Primulas alone, but also of many other florists' flowers. In this work perhaps none but themselves know to what extent they have been assisted by their able manager, Mr. Waters. In proof, if such is needed, of this assertion, growers have but to cast back their thoughts to the Holborn Primulas of a decade ago, and then to look at those of to-day. It will readily be seen that they have improved in all respects. The plants are of a sturdier habit of growth, and carry the flowers on stouter footstalks in bold trusses well above the leafage. Look again, and it will be seen that the individual pips are purer in colour, firmer in texture, larger in size, and more shapely in contour. The range of colouration is also very much wider.

Looking at these one would think that the acme of perfection had been reached, but still the work is being carried on with undiminished ardour and sanguine hopes of still further improvements. Let us hope that such will be realised, for any appreciable advance in the quality of these most popular winter flowering plants would be hailed with nothing but pleasure. To those who have been and are working so assiduously, the thanks and gratitude of all plant lovers are due, and will, we doubt not, be readily accorded.

Anyone visiting these nurseries will most likely be struck by the comparatively small size of the plants, for all are grown in 5-inch pots. The object for which the plants are grown, however, must be borne in mind. They are not raised for show purposes nor for decoration, but simply and solely for the production of seeds, and for this purpose all growers will know that young healthy stock is the chief desideratum. Old plants that have flowered profusely do not, as a rule, set their seeds so freely as plants in a younger state. The seeds from which the present plants were raised were sown at the end of July, and are sturdy, vigorous specimens, than which none better could be desired. Evidently the right methods of culture are thoroughly understood, and advantage taken of any detail, however apparently small, that may tend towards success.

All the varieties offered by the firm in its "Vade Mecum," besides many others, are tested at Perry Hill, and the comparisons between the numerous varieties is most instructive, at the same time exceedingly interesting. One can in walking through the structures see at a glance which are the best of their respective colours, and thus make a selection; but as numbers of readers of the *Journal of Horticulture* will probably have been unable to go and see for themselves it will be the object of the writer of these notes to mention those that are especially meritorious, either in floriferousness, colouration, or size and substance of the flowers. Of course, regard must be had for the matter of taste, some persons having a partiality for one colour, and others for another. It may safely be asserted, however, that those mentioned below will give every satisfaction, as being of the highest quality and of the most general utility.

Amongst such a plethora of beautiful varieties it is difficult to know where a start should be made, but we may safely surmise that if the much-discussed Blue is placed at the top of the poll that we will not be far wrong. The Blue is now an established fact, much as it was ridiculed a few years ago, and in Holborn, Iris is almost a paragon. The plants are of strong growth, free in flowering, while the petals are of splendid substance and form. The colour is a real blue, though not perhaps of a celestial hue, but this mayhap will be obtained in the course of a few more years. Such earnest work must eventually, one would think, bring a rich reward, and if the same is done in the future as in the past then indeed will this be the case. Though good, and still in much demand, the Holborn Blue cannot be compared to the one previously named.

A variety that is certain to command admiration is Princess May, which carries shapely blooms of the most delicate rose hue. The substance of the petal is good, and the flowers are moreover very freely borne. It certainly has a great future before it, and will most likely be seen and heard of for a number of years to come. One of the most chastely beautiful is Elaine, with pearly white flowers carried well above the rich green foliage. It is a variety that would be an acquisition to any collection. Holborn Queen is exquisitely soft white in colour, the trusses being very fine both in shape and size. This is unquestionably one of the best white Primulas in cultivation. Hercules is admirably named, for the massive growth and flowers force one to think of wondrous strength. The colour is a very deep, and at the same time, brilliant rose, and the blooms are borne with great freedom.

Numbers of other single forms were seen, but they are far too numerous to permit of an extended notice of each of them. It must not be thought, however, that they are not worth growing, for such is not the case, and those who are desirous of having a complete and up to date collection cannot afford to miss them, or the goal will not have been reached. Amongst these may be mentioned Carter's Scarlet, Single Magenta, Vulcan, Roses Venus, Ruby, and Carmine, all of these being singles, and all well worthy of a place where a thoroughly diversified stock is aimed at.

\* Turning now to the doubles, the same variation of colours with perfect form and substance is readily observable. Again, let the Blue be accorded the premier position. This time, however, such high praise cannot be accorded so far as colour is concerned as the single, but though lacking slightly in this respect it fully makes up for it in others. The shape of the flower is superb, as also is the solid texture of the petals, while they are borne in exceptional abundance. It is called Lilac Queen, and good as it undoubtedly is, it will be ousted as soon as a richer, clearer blue is thoroughly established. Another very beautiful double variety is Snowflake, which is early, free, and of excellent colour.

Richer in hue than either of the foregoing is Carmine Empress. The colour is remarkably pure, and such as always elicits admiration. In addition to this both flower and truss are of the first quality. When the names of the Prince and Princess of Wales are reached something good is very naturally expected, and the hopes are thoroughly realised. The colour of the former is a pure rose, and of the latter white, very pleasingly spotted with rose, the bloom in each case being very handsome.

These notes are necessarily brief, and must now be brought to a close, though they cannot possibly have done justice to the Primulas at Perry Hill. In conclusion, let us heartily congratulate Messrs. Carter & Co. on their work, and express the hope that they may continue to work amongst Primulas for a number of years yet, in which case it is almost certain that many more superb varieties will find their way into commerce through the medium of this world-renowned firm.—NOMAD.

### PRUNINGS.

ADVICE opportunely timed is of twofold value. Last week's number of the *Journal of Horticulture* prompts this reflection. Digesting the matter therein contained arrests some passing thoughts thereon.

"Fragaria" (page 199) gives sound and seasonable advice by pointing out "mistakes in Strawberry forcing," most desirable to know in order to avoid. He says, "As soon as . . . five to nine fruits are set remove the other flowers." From now onwards I think the "stitch in time should save nine." Considering the labour involved, compensation must be looked for in the highest possible return, not necessarily in the number of fruits, but in the weight. My criticism is for the sole purpose of acquiring knowledge from one who is apparently well able to give it. Hence, what should be a fair

average weight of fruit per pot, and what per-centage of plants may be expected from good culture to be worthy of retention at the final stage? Approximate data would be useful to growers. You have, "Fragaria," told us so much that we would like to know more.

"T. F." (page 205) says, "When the Onion bed is prepared . . . sprinkle a good pinch of flowers of sulphur in each drill . . . this will produce a sure crop of Onions and no grub will trouble them." Thanks, "T. F.," the remedy is simple; we shall test it.

I note (page 207) that the Chas. Collins' fund is about to be closed, and sincerely hope that it may close over a large amount of practical sympathy for his bereaved ones.

Mr. Taylor (page 208) discourses pleasantly on Vine culture, and conscientiously criticises earlier practice by the light of later experience. May we all be as expert in Vine culture and as liberal-minded to receive and dispense new ideas.

Fig. 38, *Pentas carnea*, revives memories of an old favourite, which had but one fault, namely—its prevalence to attacks by mealy bug. To this I attribute its going out of date, for of all buggy subjects it is the buggiest. Once infested, cleaning, from its hirsute nature was out of the question. Hence, *Pentas carnea* was frequently pitched out, and is now all but of the past.

In the Rose department there is weeping and wailing. A high death rate must be looked for when returns are published. I hear of heavy losses in the North amongst the standards. In all departments noticeable effects of the late severity are increasing with the sun's power. It could not be otherwise considering the soft, sappy condition of vegetable life when the frost set in.

Mr. Arnott (page 210) timed his notes on Snowdrops when they were most interesting. The thought arises, and cannot be suppressed, that anything not known by this gentleman about hardy plants is not worth knowing.

Queries anent Mushrooms still crop up. To those who read, mark, learn, experience of either success or failure in culture is of value. Those who cannot afford to fail should read Wright's "Mushrooms for the Million," for if they go by Wright they can hardly go wrong.

The article by "G. H. H." (page 212) on *Humea elegans* recalls an anecdote related of an old time gardener, who when seeing his lady making her way for the greenhouse would hurry in and vigorously shake these highly perfumed plants, thus paying respect by offering incense to his employer. *H. elegans* purpurea is more attractive than the type.

"Notes and Comments," by "The Missus" (page 214) are most enjoyable. Presumably her evident love of gardening detracts not from her culinary skill, and such savoury odours arise from her table as to overcome any sensations of the Faughl type from the velvety French Marigolds we all admire, but their odour is by some deemed a drawback to table decoration. Still, "Comparisons are odorous," especially in recalling the troubles of a huntsman (in "Punch") whose hounds "lost the scent through running over that bank o' stinking wilets."

Has Covent Garden Market been removed to the Riviera? One might imagine so in noting the prices quoted, which would afford texts for more than one sermon at the present time, when the question is raised, "What pays to grow?" Taking Cucumbers for instance, the mean price quoted being 3s. per dozen. By what arithmetic could a sum be worked out, including cost of production, carriage and commission, so as to leave a remainder for the grower?—SAYNOR.

### EXAMINATION IN HORTICULTURE.

I WAS pleased to learn from your correspondent, "W. D., Turnford," page 214 in last week's issue, that so many of the successful candidates in the Royal Horticultural Society's examination last year were under the age of twenty-five years, as it reflects great credit on the abilities of youthful competitors; but your correspondent does not mention how many of those forty-nine successful ones obtained first-class certificates, for after all a mere pass or third-class certificate but inadequately satisfies most young candidates' expectations.

"W. D." says, "All who sit might (if their answers were good enough) gain a first-class certificate." Here he puts young gardeners and others on an equal footing with men who have had years of practical experience, and surely as much, if not more, theory than any young man, and expects the latter to pass as creditably as the former an examination in horticulture, composed of questions one-half of which (as he himself admits) relate to practical gardening operations.

If some of our head gardeners, school teachers, and others wish to compete for these certificates let them do so by all means, but let there be two separate grades of examination—a senior grade, without any limit as to age or experience, and a junior grade, candidates for which would be limited to, say, not above twenty-five years of age. Then young men who think they are capable of competing in the higher grade can do so.

I did not expect a difference of opinion *re* the above subject should emanate so vehemently from such a source as from your correspondent who signs himself "A Young Amateur Gardener," who is indeed very liberal in his views respecting this matter, and it would be a pity to prevent such amateurs of his type from competing against, as he himself truly says, some of the chiefs, who give valuable information and notes of experience in the *Journal of Horticulture* week by week.

Perhaps the proposition suggested above would meet with "A Young Amateur's" approbation, as it would still enable those to compete whose cause your correspondent has so much at heart.—A YOUNG GARDENER.

#### THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

ON reading the remarks made by your very interesting correspondent, "E. K., Dublin," on the above subject, I must say that it seems strange that so comparatively few gardeners are found on the list of so useful an institution. I hope now that the subject is opened that some contributors will think it worth their while to deal with a matter of so much importance.

I believe there are many who would enroll themselves as members if they could only have some little to do with the working of it, and it is with this object in view that I would beg to suggest to the management to try and induce in different centres through the country, the many horticultural societies to form branches of the above, all to work to the same rules and in conjunction with headquarters.—P. CLARE, *Blundellsands, Liverpool*.

BEYOND the perusal of the notes which appear at times in the pages of the various gardening publications I know little about this Society, and I may say that I am not alone in this matter, for during my gardening career I have never come in contact with one gardener who could fully explain to me the rules and regulations, or the precise way or manner in which the bounties are distributed; therefore in reply to the question put by "E. K., Dublin" (page 200), "How is it that the G.R.B. Institution is ignored by so many good and capable men?" I have no hesitation in saying that it is because the object of it is not made sufficiently clear. Another reason which may, I think, be cited as having a great deal to do with the increasing unpopularity of this Society is in reference to the way by which the candidates are elected. Gardeners say that they do not agree with the ballot, for why should a candidate because he is a gardener of repute, or because he may have a larger circle of friends than another, capture a greater number of votes, thereby entitling him to the benefits of the Society, whilst a less fortunate man would be debarred from deriving assistance because he is practically unknown in the gardening world?

These are the only reasons I have heard why the Institution does not meet with greater support than it does at the present time. If such cases be correct, could not some way be devised by which all the candidates would be placed on an equal footing? for it is a well-known fact that where there is the least signs of favouritism in connection with an Institution the undertaking must and will most assuredly result in a failure. My knowledge of the Institution, however, and to the way in which its business transactions are carried out, is very limited. I have only penned the above remarks with the hope that someone who is more thoroughly acquainted with the Institution and its workings may take the subject up, and throw a ray of light on it by explaining through the pages of the *Journal of Horticulture* some of the principal rules and objects. I feel sure that if the Society was brought more prominently before the notice of gardeners it would be crowned with much greater success in the future than it has hitherto experienced. I should be glad to know where I could obtain a copy of the Society's rules.—GEO. PARRANT, *Ashby Lodge, near Rugby*.

[Rules can be had from Mr. G. J. Ingram, 50, Parliament Street, Westminster.]

#### ROYAL HORTICULTURAL SOCIETY.

MARCH 12TH.

THE first of the two March meetings to be held at the Drill Hall was a decided success in every way. The display of Orchids was remarkable alike for the diversity, superb quality, and unusual numbers. The exhibits pertaining to the Floral Committee were not so numerous, but the quality was high throughout.

FRUIT COMMITTEE.—Present: P. Crowley, Esq. (in the chair); with Rev. W. Wilks, Messrs. H. Pearson, J. H. Veitch, T. J. Saltmarsh, J. McIndoe, J. Cheal, G. Norman, J. Smith, A. Balderson, G. Wythes, G. Sage, J. Hudson, T. Glen, A. J. Laing, A. Dean, T. J. Miles, and J. Wright.

As will be perceived there were more men to do the work than work to be done on the present occasion—a reverse of the circumstances existing in many, if not most, gardens. The duties of the Committee, however, if light were pleasant—namely, in awarding a vote of thanks to Mr. G. Wythes for a dish of ripe St. John's Figs, produced by a heavily cropped tree in a 10-inch pot; and in examining and tasting Strawberries—*Stevens' Wonder* (fig. 42), which was unanimously awarded a first-class certificate. When we consider the size, freedom, colour, high perfume, and evidently good forcing qualities of this variety, and especially in conjunction with the singularly unfavourable season, this Strawberry must be considered of great value for ripening in February and March onwards.

One of our correspondents, Mr. J. Inglis, who knows what is good, has informed us that he had the pleasure of inspecting 2000 plants of this Strawberry in full bearing on February 21st in Mr. Stevens' Nursery at Hassocks, Sussex, and 50 lbs. of fine fruits had then been sent to market. At that time the plants were each bearing from eight to sixteen berries, many of them weighing from 1 oz. to 1½ oz. Several pots of a similar nature were brought before the Committee, and Mr. Glen, one of the members, observed he had seen plants last year ripening from twenty to thirty fruits, the largest girthing 6 inches.

The plants exhibited were remarkable for their dwarf character, producing tufts of leaves about 3 inches high, the majority of the leaflets only slightly exceeding an inch in diameter, the large scarlet fruits hanging down and resting against the sides of the pots. In general appearance the fruits appeared intermediate between Sir Charles Napier and Noble, yet quite distinct from both. They are as large as Noble, but firmer and decidedly of better flavour. The fruit may be described as large and angular, with a somewhat corrugated surface; skin bright red, in some cases quite pale; the seeds not deeply embedded; calyx segments reflexed. They vary in form, some being nearly conical, but the larger are more of the shape of the one figured, which may be taken as a typical example.

So far as we can learn Mr. Stevens knows nothing definite as to the origin of this variety; it seems to have come "by chance," and no doubt

FIG. 42.—STRAWBERRY STEVENS' WONDER.

the possessor of it felt himself in luck's way when he gathered and sold 600 lbs. of fruit last year, when prices were high, and not less so this year, with his larger stock of plants now in full bearing. Stevens' Wonder Strawberry will be "looked after" for forcing, but the character of the plants exhibited did not suggest rapidity of increase, though in this respect they can only be rightly judged when growing in the open ground.

At the close of the business Mr. A. Dean, in well chosen terms, referred to the death of Mr. George Taber, paying a well deserved tribute to the value of his services and his genial character, concluding by moving the following resolution: "The members of the Fruit and Vegetable Committee, having learned with deep regret of the death of their esteemed and capable colleague, Mr. George Taber of Rivenhall, desires to give to that expression of regret the fullest publicity, and also requests that the purport of this resolution may be embodied in the minutes of the Committee's proceedings." This resolution was seconded by Mr. Saltmarsh, who said he had been acquainted with Mr. Taber for fifty years, and it was passed unanimously.

FLORAL COMMITTEE.—W. Marshall, Esq. (in the chair); with Messrs. J. Fraser, J. Laing, C. T. Druery, H. B. May, H. Herbst, George Stevens, Robert Owen, R. B. Lowe, J. H. Fitt, W. C. Leach, C. J. Salter, J. Jennings, J. W. Barr, Chas. Jeffries, Geo. Gordon, W. Briscoe-Ironside, Chas. E. Shea, J. D. Pawle, R. Dean, Chas. E. Pearson, H. H. D'Ombraim, E. Beckett, H. J. Jones, G. H. Ingleheart, James Walker, Ed. Mawley, Harry Turner, and George Paul.

Mr. J. Fitt, gardener to Earl Cowper, Panshanger, Hertford, exhibited a bunch of Ghent Azaleas, John Weathers (see below). Mr. Fitt also staged a vase of *Calla aethiopica*, the flowers and foliage being exceedingly fine. Messrs. Barr & Son, Covent Garden, staged a fine collection of bulbous flowers, conspicuous amongst which were pots of *Galanthus Elwesi*, *Iris reticulata*, *Scilla bifolia*, and flowers of *Narcissus Odorus*, *Sir Watkin*, *Emperor*, *Horsfieldi*, *Obvallaris*, *Poeticus*, *Ornatus*, and *incomparabilis Cynosure*. *Anemone fulgens* was prominent in the group, as also were plants of *Spiraea japonica multiflora compacta*, which is a compact free-flowering variety of *Spiraea japonica* (silver Banksian medal).

Messrs. W. Paul & Son of Waltham Cross, Herts, exhibited a group of flowering plants consisting of *Clematis indivisa lobata*, *Camellia*

Mathotiana, Imbricata, Madame Cachet, and Adelina Benvenuti. The feature of the group, however, was a number of well-bloomed plants of Messrs. Paul's new winter blooming and bedding Rose, Duke of York. This has the appearance of being a free-flowering variety of graceful habit. The chief beauty is seen in the bud, which is of a delicate blush-pink, deepening to rose as the blooms expand. The same firm also staged a varied collection of cut Camellia blooms, consisting of Conspicua, Mathotiana, both remarkably fine, and Alba plena, Reine des Fleurs, Princess Charlotte, Lady Hume's Blush, Vera, and Exquisite (silver-gilt Flora medal).

Messrs. James Veitch & Sons, Chelsea, were as usual to the front with Amaryllis, exhibiting many beautiful varieties, especially worthy of mention being Mrs. Montefiore and Prince Edward (for which awards of merit were granted), Euryalus, Elatior, Adrastus, and Javotte. A fine basket of Iris reticulata var. Krelagi, tastefully arranged, was staged by Messrs. Veitch (silver Banksian medal). A bunch of single blue Violets Princess Beatrice was staged by Mr. G. Nobbs, Royal Gardens, Osborne, Cowes, for which an award of merit was granted. A bunch of Violet Victoria was exhibited by Mr. Jennings, gardener to Leopold de Rothschild, Esq., Ascot, Leighton Buzzard. Mr. Geo. Bolas, Wirksworth, Derbyshire, exhibited a group of Daffodils, tastefully arranged with sprays of Ivy, for table decoration. Mr. F. Cornish, gardener to Dowager Lady Bowman, Joldwynds, near Dorking, staged plants of a seedling Primula, "Joldwynds," and a profusely flowered plant of Shortia galacifolia, to which a cultural commendation was accorded.

Messrs. Paul of The Old Nurseries, Cheshunt, staged plants of single Roses, Paul's Carmine Pillar and Polyantha grandiflora; and also a pot of the new feathered Canna Dr. Masters, and blooms of Cannas Mrs. Yasher, Comte de Bouchard, and Madame de Greve. An award of merit was granted to Mr. P. Blair, gardener to the Duke of Sutherland, Trentham, for plants of Eucharis Stevensi.

Messrs. John Peed & Sons, Norwood Road, London, staged a group of mixed flowering plants, composed of Cinerarias, Ericas, Primulas, Cyclamens, Lachenalia tricolor, Lilac Mary Lagraye, and Hyacinths, arranged with foliage plants (silver Banksian medal). Messrs. F. Sander and Co., St. Albans, exhibited spikes of Hæmanthus Kalbreyeri. Messrs. B. S. Williams & Son, Upper Holloway, London, staged a basket of Boronia megastigma. Mr. H. Briscoe-Ironside, Burgess Hill, Sussex, sent a plant of Chrysanthemum Stresa, with a fine yellow flower, and well clothed with foliage to the pot.

ORCHID COMMITTEE.—H. J. Veitch, Esq. (in the chair); with Messrs. Jas. O'Brien, De Barri Crawshay, H. M. Pollett, H. J. Chapman, W. H. White, F. Hardy, Chas. Pilcher, S. Courtauld, J. T. Gabriel, E. Hill, T. W. Bond, W. Cobb, J. Douglas, T. B. Haywood, C. J. Lucas, F. Sand, and H. Ballantyne.

Messrs. B. S. Williams & Co., Upper Holloway, arranged a charming group of Orchids margined with Palms and Ferns. The exhibit comprised some grand pans of Cœlogyne cristata alba, Phaius grandifolius, Lycaste fulvescens, Cypripediums Boxalli atratum, Chamberlainianum, Measuresianum, Williamsi, and Morgania, a handsome piece of Dendrobium Wardianum, and others (silver Banksian medal).

A very beautiful collection of Orchids came from Messrs. F. Sander and Co., St. Albans, and comprised some magnificent forms. Amongst the most prominent were Dendrobiums nobile nobilius, nobile albiflorum, Dominianum, nobile Cooksoni, Ainsworthi, and others. Cypripedium Fowlerianum (award of merit, see below), C. Selligerum majus, C. miniatum, Cattleya Trianae virginale, C. albanense superba, Phaius Marthæ, P. Cooksoni, P. amabilis, Lælia Oweniana were also noticeable (silver Flora medal).

Two Cypripediums were sent by Mr. Bond, gardener to C. Lee Ingram, Esq., Godalming. One was a hybrid between Curtisi and hirsutissimum, named Refulgence, and the other a hybrid between Venustum and Ingrami, called Crossianum aureum. Mr. W. H. Young, gardener to Sir F. Wigan, East Sheen, sent a grand specimen of Platyclinis glumacea, and also a plant of Cypripedium Godseffianum superbum. W. Cobb, Esq., Tunbridge Wells, showed a plant of Dendrobium Schröderianum, Dulcote variety. Three plants of Eulophiella Elisabethæ were staged by Mr. J. Hamilton, gardener to Hamar Bass, Esq., M.P., Burton-on-Trent.

Mr. Jas. Cypher, Cheltenham, sent a few Dendrobiums, of which D. Apollo grandiflora received a first-class certificate, and will be found described below. Mr. J. Davis, gardener to J. Gurney Fowler, Esq., South Woodford, sent a few blooms of Cattleya Trianae. From Mr. Johnson, gardener to T. Statter, Esq., Stand Hall, Manchester, came a couple of Cypripediums, and some fine blooms of Dendrobium nobile nobilius.

Sir Trevor Lawrence, Burford Lodge, Dorking, sent a small collection of Calanthes, composed of many excellent varieties, also numerous other Orchids, including Lælia rubescens peduncularis, Masdevallia Schröderianum, Epidendrum Endresio-Wallisi, Masdevallia Fraseri (see below), Sophronitis grandiflora (see below), Cirrhopetalum picturatum, Spathoglottis Lobbi, Pleurothallis Roelzi, and others (silver Banksian medal). E. Ashworth, Esq., Harefield Hall, Cheshire, was adjudged an award of merit for Dendrobium Cassiope Ashworth's variety, and a cultural commendation for D. splendidissimum grandiflorum (silver Banksian medal).

A small exhibit of Orchids came from J. Forster Alcock, Esq., Northchurch, Herts, and a plant of Cypripedium Sallieri Fittianum was exhibited by Mr. J. Fitt, gardener to Earl Cowper, Hertford. D. M.

Grimsdale, Esq., Kent Lodge, Uxbridge, sent two plants of Odontoglossums.

A group of Orchids interspersed with foliage plants was staged by Mr. P. McArthur, Maida Vale, W., and comprised some handsome Dendrobiums, Cattleyas, and Odontoglossums. Thos. Craven, Esq., Ashton-on-Mersey, showed a splendid plant of Dendrobium Wardianum album, and some very beautiful varieties of Odontoglossums. Fred Hardy Esq., Ashton-on-Mersey, showed Cattleya Percivalliana magnifica (see below), Odontoglossum Hardyanum, Cymbidium eburneo-Lowianum giganteum, and others.

A handsome collection of Orchids was sent by Messrs. H. Low & Co., Clapton. Dendrobiums, Cattleyas, Cypripediums, and Odontoglossums were particularly noticeable (silver Banksian medal).

Messrs. J. Veitch & Sons, Chelsea, stand of Orchids was comprised of several choice forms. Awards of merit were accorded to Phaiocalanthe irrorata rosea, Dendrobium enosmum virginale, and Læliocattleya Myra, all of which are described below. Chysis Chelsoni, and several varieties of Cypripediums were also included in this group.

C. J. Lucas, Esq., Warnham Court, Horsham, Sussex, staged a small group of Orchids, amongst which were Cœlogyne spara (botanical certificate), and Mesospinidium vulcanicum.

#### CERTIFICATES AND AWARDS OF MERIT.

*Amaryllis Mrs. Montefiore* (J. Veitch & Sons).—A very handsome Amaryllis with excellently formed flowers of a white tinged green colour. The upper segments are streaked bright salmon (award of merit).

*Amaryllis Prince Edward* (J. Veitch & Sons).—This is a splendid variety with medium-sized deep crimson flowers (award of merit).

*Azalea John Weathers* (J. Fitt).—This is a very fine Azalea of the Ghent type, with rose coloured flowers, each having a yellow lower petal. It is very sweetly scented (award of merit).

*Cattleya Percivalliana magnifica* (F. Hardy).—This is an improvement on the type both in respect to size and richness of colouration (award of merit).

*Cypripedium Fowlerianum* (F. Sander & Co.).—This handsome Cypripedium is the result of a cross between C. Harrisianum superbum and C. bellatulum. The prevailing colour is deep claret, the dorsal sepal having darker veins. The petals are rosy claret sparsely spotted with brown. The pouch is of medium size and dull colour (award of merit).

*Dendrobium Apollo grandiflora* (J. Cypher).—This is the result of a cross between nobile pulcherrima and Ainsworthi splendidissimum. The flowers are exceptionally large and of rich colour. The sepals and petals are white tipped with bright rosy purple, and the inner part of the lip is very deep velvety crimson (first-class certificate).

*Dendrobium Cassiope Ashworth's variety* (E. Ashworth).—This hybrid is of no particular value as a showy kind. The flowers are almost pure white, tipped pale rose, the lip, which is very long, having a crimson throat. D. nobile albiflora and D. japonicum are the parents (award of merit).

*Dendrobium enosmum virginale* (Messrs. Jas. Veitch).—This is the result of a cross between D. intermedium and D. Endocharis. The flower is pure white, moderate in size, the lip being heavily blotched with deep velvety crimson (award of merit).

*Eucharis Stevensi* (P. Blair).—This Eucharis is apparently very floriferous, and has medium-sized, pure white flowers (award of merit).

*Lælio-Cattleya Myra* (J. Veitch & Sons).—This is a bigeneric hybrid between Lælia flava and Cattleya Trianae, the former being the pollen parent. The flower is a delicate cream in colour throughout, the inner portion of the lip being canary yellow veined with rose (award of merit).

*Masdevallia Fraseri* (Sir Trevor Lawrence, Bart.).—The colour of this Masdevallia is very rich crimson flushed magenta, and the flowers are of good size (award of merit).

*Phaiocalanthe irrorata rosea* (J. Veitch & Sons).—This bigeneric hybrid is the result of a cross between Calanthe vestita gigantea and Phaius grandifolius, the former of which is the pollen parent. The character of both parents is readily perceptible both in flowers and foliage. The colour is rose, shading to white at the edges of the sepals, petals, and lip (award of merit).

*Sophronitis grandiflora* (Sir Trevor Lawrence, Bart.).—This Orchid is too well known to need any description here (first-class certificate).

*Violet Princess Beatrice* (G. Nobbs).—This is a very large flowered single form of deep colour, but is somewhat lacking in scent (award of merit).

#### DISEASES OF TOMATOES.

At the afternoon meeting, with Mr. J. Douglas in the chair, an interesting paper on the "Diseases of Tomatoes," compiled by Mr. Collenette of Guernsey, was read by Mr. Weathers in the absence of the essayist. From the description of the diseases which attack Tomatoes in the Island of Guernsey, it was evident that the matter had received careful study by Mr. Collenette, who in the course of his paper stated that out of 36,000 inhabitants of the island 1500 of them gained a livelihood by growing crops for exportation, from which an income of half a million of money was annually realised.

Many people, said he, are of the opinion that the natural soil of Guernsey is favourable for Tomato growing. This, however, is not the case, for with the exception of an unfailing supply of potash obtained from the seaweed, the soil is not so fertile as that of many parts of England. The advantage is gained by the geniality of the climate. The houses are erected on as cheap a principle as possible, and are usually about 120 feet long by 30 feet wide. In spite of the suitability of

the climate the losses suffered from parasites and diseases are often great.

A pest found in almost every house, to a greater or lesser degree, is the common yellow blight (*Cladosporium fulvum*), which can, however, be kept in safe bounds if care is taken. A disease known as "black stripe" appears to have arisen since the introduction of Tomatoes into glass structures, and the only known remedy for this is the instant removal of affected plants. The disease, however, from which growers suffer the greatest losses is known by them as the "sleeping disease," from the fact that often whole houses of plants are attacked beyond recovery before it is found out. The first symptoms noticeable are slight drooping of the foliage and complete stoppage of growth, which takes the appearance of having been frost-bitten. Careful observation shows that the root first suffers by the loss of its fibres, and the time of the leaves commencing to droop may be marked as the period when the roots fail to supply them with nutrition.

In many instances of this kind the plants are not removed until the fruit is ripened. Seeds are generally obtained from this, and from researches made it has been ascertained that fruit obtained from such plants show unmistakable signs of the disease. Seeds should therefore on no account be obtained from affected plants. Amongst the preventive means advised were the use of lime during the fallow, applying 10 to 20 lbs. of green copperas per rod during the fallow, and avoiding organic manure for as long a period as possible.

Another pest is the eelworm, which is too well known to need description. An excellent cure for this (though impracticable in Guernsey) is to thoroughly freeze the soil, or else by the application of lime, sulphate of iron, and seaweed. A hearty vote of thanks was accorded to Mr. Collenette for his interesting and instructive paper, and also to Mr. Douglas, Chairman, for presiding.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

THE twenty-ninth annual general meeting of the above Society was held at the Caledonian Hotel, Strand, London, on Monday evening, the 11th inst. Mr. George Gordon occupied the chair, and after the opening preliminaries called on the Secretary, Mr. Collins, to read the annual report, which was as follows:—

ANNUAL REPORT OF THE COMMITTEE.

The Committee in presenting to the members the annual report and balance sheet for 1894, have much pleasure in stating that the Society still continues to make most satisfactory progress both numerically and financially. Seventy-two members joined the Society during the year, nineteen lapsed, and six died, one of these having joined only a fortnight previously.

The membership now stands at 547; the amounts standing to the credit of the deceased members have been duly paid to their nominees. The sick pay has been more than in the previous year, £117 7s. 8d. having been disbursed to twenty-eight members.

The Chairman, in rising to formally move that the report and balance-sheet be received and adopted, said he was quite sure it would not be necessary for him to speak at any length to insure the motion receiving a hearty reception. The report that had been read by their excellent Secretary (Mr. Collins), and the financial statement presented by their not less excellent Treasurer (Mr. Hudson), were so eminently satisfactory that no strong arguments would be required to induce the meeting to pass them unanimously. He had in the course of his connection with public affairs listened to many annual statements, but he could not call to mind any that could have afforded more gratification to the members concerned than those that had been submitted to them. They impressed him, as he had no doubt they had impressed the members, with the important facts that the affairs of the Society are being managed with singular ability, that gardeners as a body are beginning to understand the principles of the splendid Institution to which they were fortunate in belonging, and that they are showing in a practical manner their appreciation of the advantages it offers to them in making provision for the proverbial rainy day, for old age, and for

Subscriptions to the amount of £821 16s. 3d. have been paid into the Benefit Fund during the year, exclusive of arrears. Both the Benevolent and the Management Funds have proportionately increased, the former having received additional strength by the life membership of Sir Stuart Knill, Bart., and Messrs. Jacob Wrench & Sons. A grant of £10 was made to the widow of the late Mr. Chas. Collins, a case calling for urgent assistance; two other sums amounting to £4 have been paid from the same fund.

The Treasurer's account is also very satisfactory, the chief item in which is the investment of £1000 during the year in the names of the Trustees. The annual dinner resulted in a most substantial gain to the Benevolent and Convalescent Funds. Arnold Moss, Esq., presided, and advocated the claims of the Society in a very clear and efficient manner. The accounts have been duly audited and found correct by Messrs. Gunner, Dixon, and Puzey, whose careful scrutiny deserves the best thanks of the members. The thanks of the members are also due to the officers of the Society for their services; also to those gentlemen who contributed plants, fruits, and flowers for the annual dinner. The Committee urge all the members to use their best endeavours to secure fresh additions to the Society, bearing in mind its motto—"Union is strength."

those who may be left behind should they fall early in the great battle of life.

They would, he said, have gathered from the report and financial statement that there had been a large accession of new members, and a concurrent increase in the balances of the several funds. This advance could not be regarded otherwise than with a feeling of gratification, not so much in the interest of the Society as of the horticultural community, for whose benefit it was founded. The Benevolent Fund, although it had been drawn on to relieve several cases of distress, had increased from £2025 12s. 9d. to £2208, or a gain of nearly £200 during the year. The Benefit Fund had increased from £6232 to £7224, or a gain of nearly £1000. The Voluntary Convalescent Fund, instituted a few years ago, had continued to make satisfactory progress, and the balance had increased from £191 to £259, a gain of £68, although grants were made to several members, who had been struck down by sickness, to enable them to have a change of air, which as we all know is so beneficial to those recovering from illness. The balance of the Management Fund was about the same as last year, and it did not appear

desirable there should be any material increase, for whatever surplus that may be available could probably be utilised to advantage in part to making the Society more widely known, and in part to increasing the remuneration of the Secretary. The total of the several balances was £9835 14s. 6½d., and it was of importance to know that this amount—which largely exceeds the liabilities of the Society—is invested in perfectly safe securities, and is a guarantee that every claim will be met in accordance with the rules.

It would not be necessary for him to discuss in detail either the report or balance-sheet; but there were a few points to which he would like to direct attention. It was of interest to know that there had been a substantial increase in the roll of both classes of members, and that the number of benefit members had increased during the financial year from 487 to 547, or a net gain of 69. It was still more interesting to learn that the contributions of the members to the Benefit Fund amounted to £821 16s. 3d., because that sum, taken in connection with some other figures that are given, brings out in strong relief the distinctive character of the Society, and the remarkable advantages it offers. The contributions to the Benefit Fund, as so well known to members, are applied as far as may be necessary in providing the weekly allowances to members during sickness, and the remainder is added in given proportions, according to the scale, to the deposits of the members standing in the books of the Society, which remain at interest until the members attain their seventieth year. Last year the total amount disbursed in sick pay was £117 7s. 8d., therefore of the total of £821 there was a sum of £704 8s. 7d. available for adding to the deposit account. There is nothing unusual in so small a proportion of the contributions to the Benefit Fund being distributed in sick pay, and in 1893 it was relatively smaller. The annual surplus has invariably been large, as proved by the fact that during the twenty-nine years the Society has been in existence the members' deposits have amounted, after the payment of the amounts belonging to deceased members, to £7224 1s. 6d., the balance of the Benefit Fund at the present time. The interest on the balance of this fund was last year £178 11s. 11d., and as this was £61 4s. 3d. more than was required for sick pay it follows that every penny contributed by members to the Benefit Fund has been an investment for old age.

If the members had belonged to one of the best of the general benefit societies the only advantage that would have been derived from this annual surplus would be the payment of £10, £12, or £15 to their representatives at their death. As illustrating the practical effect of this difference he stated that he was well acquainted with a gardener who joined the Order of Foresters three years before the United Horticultural Benefit and Provident Society was founded, and from that time to this he had paid contributions equal to their lower scale—namely, 6d. per week; and the benefits to which he is entitled are 10s. per week during illness, and £10 at death. On the other hand, a member of the United who joined on the lower scale when the Society was first formed had not only been entitled to 10s. 6d. per week in sickness, and would have a claim on the Benevolent Fund on his reaching his seventieth year, but has now standing to his credit the sum of £51 19s. 1d., or actually £7 14s. 7d. more than the whole of his contributions to the Benefit, Benevolent, and Management Funds. On the higher scale the sum placed to the credit of a member of similar standing would be considerably higher, and as a matter of fact a member has the sum of £78 11s. 3½d., or about £14 more than the whole of his contributions to the Society, the difference in both cases being due to the reproductive power of money when judiciously invested.

Members should impress facts of this kind on the attention of friends who are eligible; they should also point out that should a member be unable to continue his subscriptions he does not lose his deposit, but the amount to his credit is retained until he reaches his sixtieth year, when it is handed over to him. To show how important is this feature it was mentioned that at the present the substantial sum of £702 was standing to the credit of lapsed members. In conclusion the Chairman urged on the members the necessity of availing themselves of every opportunity for making the Society known to their friends, so that a much greater proportion of those engaged in horticultural pursuits might derive advantage from the great and highly beneficent work in which it is engaged.

Mr. W. Marshall seconded the proposition, which was carried amidst applause. Mr. E. G. Wheeler moved that 3000 copies of the report should be printed and circulated, which was agreed to. A proposal was made that in future the balance-sheet should be circulated before the annual meeting, which was left for the consideration of the Committee. Then followed the election of members of the Committee in place of those retiring, and on show of hands the result was as follows:—Mr. E. G. Wheeler, thirty-six votes; Mr. Wood, thirty-one; Mr. Boram, thirty; and Mr. T. Thompson, twenty-three. The Chairman declared these gentlemen duly elected.

Mr. J. Hudson moved that Mr. Collins should be re-elected as Secretary, and in addition to his usual stipend a bonus of £5 should be presented to him; this was seconded by Mr. Wheeler, and carried unanimously. A vote of thanks was proposed by Mr. Cole to the Trustees for their services, and duly carried.

Mr. Heals then moved that a hearty vote of thanks should be accorded to the Treasurer, Mr. J. Hudson; this was carried, and that gentleman replied in a few appropriate words.

A vote of thanks was proposed by Mr. Cole to the Press for the hearty and cordial manner in which they had assisted the Society. This was seconded by Mr. Marshall and carried, and Mr. G. Gordon

replied on behalf of the Press. Mr. W. Marshall, in conclusion, moved that a hearty vote of thanks be accorded to Mr. G. Gordon for the able manner in which he had conducted the meeting, a proposition which was carried with approbation.

At a special general meeting held afterwards a proposal was presented by Mr. Hudson, signed by several others, to increase the sick pay from 10s. 6d. to 12s. per week to members who subscribed at the rate of 6d. per week, and from 16s. to 18s. to those who subscribed 9d. per week, a week to consist of six days instead of seven, as heretofore. Mr. Marshall strongly objected to this proposition on the ground that it would not be feasible unless the subscriptions were raised. An animated discussion followed, and upon a show of hands the proposal was carried by twenty-seven votes to seven, amidst great applause. As no other business was before the meeting this ended the proceedings.

#### FRUIT FORCING.

**Vines.**—*Early Forced in Pots.*—Sufficient water or liquid manure must be afforded at the roots to prevent check through dryness, surfacing the soil with rich material, and if the roots extend beyond the pots feed them there as well. Supply atmospheric moisture by damping the paths and walls in the morning and early afternoon, also before nightfall, keeping the night temperature at 60° to 65°, day 70° to 75°, and 80° to 85° with sun heat, closing early to keep it at 85° or 90° while there is abundance of light. When the Grapes begin colouring still maintain the atmospheric moisture, and feed liberally, as the fruit swells considerably then, but cease the use of stimulants when coloured all over, and to enhance the quality still secure the temperature named with sufficient ventilation constantly to insure a circulation of air, and only give water at the roots to keep the foliage in good condition.

*Early Forced Planted-out Vines.*—In the houses started early in December the fruit is thinned and swelling freely, where top-dressings of the advertised chemical fertilisers have been used, and due moisture maintained in the borders. Steady progress is desirable during the stoning process, and phosphatic and potassic manures more advisable than nitrogenic, yet sufficient of the latter must be provided to secure steady growth, four parts bone superphosphate, two parts muriate of potash, and one part sulphate of ammonia forming a good mixture for siliceous soils, but where calcareous nitrate of soda should be used instead of the sulphate of ammonia. Four ounces of this mixture per square yard, every three or four weeks, will help weakly Vines wonderfully, supplying the top-dressing after properly moistening the soil with water and lightly washing the top-dressing into the border. This will need extra attention near the hot-water pipes for watering, always supplying the liquid at the mean temperature of the house, and if liquid manure is used it is preferable to supply it after the soil has been duly moistened, a watering canful then goes as far as half a dozen when the soil is dry. If the roots are near the surface a light mulching of sweetened short stable manure will be useful in respect of soil moisture, attracting the roots, supplying nourishing food and humus, the latter not being had from chemical fertilisers. Maintain a genial condition of the atmosphere by damping in the morning and at closing time, or early in the afternoon. Ventilate early, but not before 75° is reached, securing with sun heat and moderately increased ventilation a temperature of 80° to 85°, at which keep through the day under favouring external conditions, closing in time to secure a long day's work from sun heat, but not to raise the temperature over 90°, a temperature of 60° to 65° at night, and 70° to 75° by day artificially is suitable.

*Houses Started at the New Year.*—The Vines are in flower or advanced to the thinning, and require a night temperature of 65° to 70°, 5° more for Muscats, 70° to 75° by day artificially, and 80° to 85° or 90° with sun heat. This may be lowered about 5° after the Grapes are set, but whilst in flower the rather warmer atmosphere, kept moderately dry by a little ventilation constantly, is desirable. Shy-setting varieties should be carefully fertilised. Early Vines, with the roots to a great extent in outside borders, even where protected so as to exclude frost, are somewhat backward, and the prospect in some cases not of the best. A slight increase of temperature and a reduced supply of moisture for a short time is usually beneficial in such cases. During bright sunny days with sharp winds great care is required in ventilating, so as to avoid cold currents and sudden changes of temperature, this being effected by admitting air in small quantities at a time; reduce the ventilation in a similar gradual manner.

*Houses Started Early in February.*—The Vines breaking into growth freely require earlier attention in disbudding and regulating than those less free in starting, which is not always a bad sign, as fruitful growths are more tardy in pushing than the free, fruitless wood growths, and in any case it is always advisable to defer disbudding until the best breaks and shows for fruit can be readily discerned, then proceed gradually, and reduce the growths to such number and in such place as can have exposure to light when fully developed, and insure an even balance of growth. Likewise in stopping, too great a hurry may

give an undesirable check to the leaves, but when they are fairly formed at the stopping joint, say the size of a halfpenny to a penny, they may be stopped without prejudice at two or four joints beyond the fruit according to space. The laterals may be stopped at one joint up to the bunches, or be removed altogether, except from the two lowest leaves, those above the fruit being allowed to make two or more joints before being pinched, no more foliage being encouraged than can have full exposure to light, and where the space is limited stopping to one joint of the lateral and sub-lateral growths is most consistent with good results. Raise the temperature to 60° at night, 65° by day from fire heat, and 75° to 80° with sun heat, but this should be secured by the time the Vines come into leaf, as frequently stated in these columns.

**Houses to Afford Fruit in August and September.**—The Vines must now be started, making the inside border duly moist to the drainage, and if the Vines are weakly follow with some rather thick or strong liquid manure, not from minerals or chemicals, but from stables and cow-houses. Failing this, top-dress with blood and bone manure or native guano, something that will supply some amount of humus. On the other hand, if the Vines are quite vigorous enough, and produce somewhat long-jointed wood with thin flabby leaves, use chemical manures, especially silicates, and leave on the surface for watering in. If the soil be of a close and moist nature superphosphate, basic slag, and gypsum would be useful dressings, taking equal proportions and applying a pound per square yard, pointing in lightly. The outside border should receive similar attention, a slight protective material being all that is necessary to exclude frost from the soil at this time of year. A moderately moist atmosphere should be secured by damping the rods and every available surface two or three times a day, maintaining a night temperature of 50°, 55° by day artificially, and 65° with sun.

**Late Houses.**—Late Grapes require all the sun's light and heat that can safely be secured for them from April to September, with such assistance from fire heat as to secure steady development, sustain the progress made, and complete the ripening of the crop in the last named month. The Vines now started will have a chance to produce good sized and highly finished fruit, and such as possess good keeping qualities. Syringe the rods in the morning and afternoon, and damp the paths and borders before nightfall. Maintain the night temperature for these Vines at 50° to 55°; 55° to 60° by day, and 10° to 15° more from sun heat, with rather free ventilation from 65°.

**Vines from Eyes.**—Those rooted from buds in February and potted off should be shifted as soon as the roots reach the sides of the small pots into others 6 inches in diameter, placing them on shelves over hot-water pipes in preference to plunging them in bottom heat. Syringe them in the morning and early afternoon, damping other surfaces in the evening, so as to insure a genial atmosphere. Pinch the laterals at the first leaf, and subsequently sub-laterals as made to the same extent of growth, and if the lead divide into two remove the weakest and worst placed.

**Cut-back Vines in Pots.**—Those for fruiting in pots or planting out in prepared narrow and shallow beds for fruiting next season will be fit for turning out of the soil, and after cutting back any straggling bare roots, place in 7 or 8-inch pots, from which they may be transferred when established to 12 or 13-inch pots, or be planted out in the beds. If these Vines have been plunged in bottom heat they may be returned to it for a short time, otherwise bottom heat is not necessary, the preferable plan being to place the pots on slate shelves over hot-water pipes and train the canes about a foot from the glass, as they cannot have too much light, and it is important that the growth be solidified as made. Turfy loam, rather rough, with a sixth of old mortar rubbish, and a good handful of some approved fertiliser to every bushel of loam, form a suitable compost for Vines in pots. Clean pots and efficient drainage of clean crocks must be employed in the culture of these Vines. Keep moist and close until established, it being better to employ a slight shade in the hottest part of the day than allow the Vines to become stunted in growth.

**Cucumbers.**—Increased light and sun heat necessitates a correspondingly greater supply of atmospheric moisture, therefore damp the house in the morning and evening, syringing the plants lightly in the afternoons of bright days, or if dull damp the floors and walls instead of syringing the plants. A night temperature of 65° is sufficient, allowing an advance of 5° when the external air is mild, 60° being the minimum in the morning when the weather is cold. Get the heat up early after daylight, so as to have a temperature of 70° to 75° between 8 and 9 A.M., ventilating a little at the latter figure, with the prospect of an advance from sun heat, keeping the heat from this at 80° to 90°, and close early so as to secure the latter or even more from that source. Liquid manure may be given once or twice a week, and the evaporation troughs kept charged with it. Liquid manure, however, is best given alternating with top-dressings of chemical manures, Cucumbers requiring phosphoric acid, potash, and nitrogen in large amounts; hence five parts superphosphate, three parts sulphate of potash, and two parts nitrate of soda, mixed and applied at the rate of 4 ozs. per square yard, give good results in growth, fruit, and immunity from animal micro-organisms. Dressings of this nature about every three weeks keep the plants in good health, other conditions being favourable. Thin the fruits well, especially on plants just coming into bearing, stopping the shoots one joint beyond the fruit, removing superfluous growths and bad leaves as they appear, as well as tendrils and staminate blossoms.

**Cucumbers in Pots and Frames.**—The weather has given these complete quietus in some places, and in all the progress has been slow, as it was difficult to maintain the temperature at a point calculated to promote steady growth. Now the weather is more favourable the plants

are improving, and should be encouraged by careful attention to the linings, taking care to avoid rank steam, and be cautious in ventilating, maintaining the temperature advised for Melons. Continue to prepare material for making fresh beds and lining purposes, and sow seeds as successional plants are required.

**Melons in Houses.**—Hot-water-heated structures have proved their advantages over manure-heated pits and frames for forcing purposes, and chambered beds their superiority over rubble ones during the recent severe weather. Any plants shifted into larger pots, and being intended for planting out, should be given their fruiting quarters before they become very much root-bound. Pot later-sown plants when they show the second leaves, employing warm moist soil. Maintain a night temperature of 65° to 70°, 5° less on cold nights; 70° to 75° by day, admitting a little air at 75°, allowing the temperature to rise to 85°, with increased ventilation, advancing to 90°, closing by or before 80° or 85° is reached in declining order, and so as to advance 5° to 10°, sprinkling at the same time all parts of the house below the plants, even lightly sprinkling these on bright afternoons. Keep the bottom heat steady at 80°, or that of the soil 70° to 75°.

**Melons in Manure-heated Frames.**—The plants sown early in February will be fit to plant out, the bed having been made for them and the soil warmed, with a sweet atmosphere secured. Where a successional supply of fruit has to be maintained, and the means are limited to frames, a sowing should be made every fortnight or three weeks up to May, making fresh beds at similar intervals to receive the plants, so as to maintain an unbroken supply of fruit. Maintain a night temperature of 65°, and 70° to 75° by day, this being effected by timely attention to the linings and coverings over the lights at night, admitting air from 75°, but without lowering the temperature or admitting cold cutting air, and keep through the day at 80° to 85°, or even 90°, securing this well on towards night by closing early in the afternoon, having due regard to the safety of the foliage.

#### THE KITCHEN GARDEN.

**Beet.**—A scarcity of other vegetables has increased the demand for Beet, and the supply will in many cases be exhausted too quickly accordingly. In order to avoid a very long break in the supply the attempt should be made to procure some roots from the open ground earlier than usual. The Turnip-rooted or Egyptian form is the first ready for use. Sow seeds at once thinly in boxes, and place in gentle heat to germinate. When the seedlings are about 4 inches high harden, and plant 6 inches apart in rows 1 foot asunder, on a warm border. Protect from spring frosts by means of benders and mats, or a few branches of evergreens, and in this way obtain a number of very acceptable roots long before any sown in the open early next month will be ready for pulling.

**Carrots.**—For reasons already given there is certain to be an extraordinary demand for young Carrots, in fact too few of these are forthcoming in most seasons. If possible supplement those raised in a frame on mild hothed with another sowing, and also sow Nantes Horn in a warm border.

**Jerusalem Artichokes.**—Just now these are doing good service, and there is every likelihood of there being a greater demand for them in other winters. The white-skinned form is considered superior to the old coloured variety. Plant in rows 3 feet apart, running from north to south, in freely worked fertile but not richly manured soil.

**Leeks.**—In not a few gardens Leeks are the only green vegetable alive, and as a consequence fewer than usual will be allowed to run to seed. Very fine samples are sometimes desirable for showing in the late summer and autumn months, the plants being raised under glass. It is, however, during the late winter and early spring months when Leeks are most in demand. Sow immediately in the open thinly in drills 6 inches apart, and plant straight from the seed-bed as soon as the plants are 12 inches high. Musselburgh and Ayton Castle Giant are varieties hardy and good in every way.

**Potatoes.**—No crop better repays for deep cultivation and thorough preparation of the soil than does the Potato. A good depth of soil, not merely with a fine surface and lumps of cold, unworkable soil underneath, but well pulverised all through, is essential. Only a few early rows in warm positions should be planted as yet, deferring the principal work till April; then commence with the later varieties, and finish with the bulk of early and second early sorts.

**Peas.**—Only those who are able to raise a considerable number of plants under glass in pots, troughs, or boxes will be able to gather Peas very early this year. Sowing seeds in the open before the ground was thawed completely would have been no gain. Soaking the seeds in water till they have sprouted before sowing may result in a gain of several days. With the first early sorts may also be sown one or more of such good successional varieties as Gradus, Wordsley Wonder, Perfect Gem, Carter's Daisy, and such taller growers as Telephone, Duke of Albany, Criterion, or other selected varieties. All should be disposed in rows as far apart as the known height of the variety, and in deeply worked, well prepared soil.

**Planting out Peas.**—Any raised under glass must not be kept very long in the boxes or pots, or otherwise premature flowering will result. Those in small pots should be planted intact before they become much root-bound, while those in boxes ought to be shaken nearly clear of the soil so as to save the longest roots, the latter being sunk deeply in trenches formed with a spade at planting time. Plant moderately thick, as it is a quick, heavy crop rather than a more continuous one that is most to be desired, and fix the soil about

the roots. Protect with Fir branches for a time. Wood ashes well mixed with the soil to be occupied by Peas will hasten and sustain growth considerably. Where there is a heavy demand for Peas, raise more early and second early varieties under glass and duly plant out, or there may be a gap in the supply owing to not being able to sow in the open earlier.

**Early Turnips.**—The snow saved some portion of those not stored, but all the same there is every likelihood of an early scarcity. Sow in a rough frame on a very mild hotbed if possible, or between boards on edge on a warm border, protecting with mats at night. The Early Milan, of which there is now a good white form, is the best for present sowing. Sow thinly, and cover with sifted soil. Directly the seedlings are seen dust them with soot and lime and repeat the dose occasionally, or the Turnip beetle will soon make short work of them.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### APPLIANCES.

THESE should be overhauled and put in good order, so that when required there will neither be necessity to search for them nor to put them into condition when there is not time to spare to do so.

#### VARIETIES OF BEES.

It would be very interesting as well as instructive were bee-keepers to note the various characteristics of their bees, their faults or failures, as may be observed throughout the year. I have no hesitation in affirming that the Carniolan is the hardiest of any race of bees; also mild in temper, as well as good and cleanly in storing honey. Strongly do I wish also that some of those renowned bee-keepers who have said so much against Punics were here in a good honey flow to witness the energy of these maligned bees. I hope we may have several honey days in succession the coming summer to test the pure ones. Syrians, like the crossed Cyprians, have also proved good honey gatherers. I have not fed mine for years. The large gathering of 33 lbs. in one day was by crossed Syrians.—A LANARKSHIRE BEE-KEEPER.

#### SEASONABLE NOTES.

A FEW words on the subject and an exchange of opinions may be of interest at the present time. Those who are already bee-keepers will probably take the first opportunity of examining their stocks to see how they have fared during the severe weather which has lasted only too long. Some will have passed through the ordeal without the loss of a single stock; others, through various causes, will have suffered severely, and will be wondering if bee-keeping is really worth the trouble. Find out, if possible, the cause of the disaster, and guard against the same mistake in the future, as the severe weather may not be to blame altogether. It may be a leaky roof, insufficient covering, shortness of stores, or a combination of the whole which has caused the loss of many colonies.

The young beginner, after hearing of some friend or neighbour who has been unfortunate, perhaps in his first year of bee-keeping, may be inclined to throw it up in disgust. To such I would say, Try again. Read what is said week by week on the subject in the *Journal of Horticulture*, ask questions through the same source on anything you do not understand connected with bee-keeping, and after another year's experience bee-keeping may have become a source of both pleasure and profit.

#### SUPERSTITION IN BEE-KEEPING.

In the present enlightened age one would have thought this was a thing of the past, but such is not the case, at all events in this neighbourhood, the midland counties. Some time ago a poor man who owned a few stocks of bees in straw skeps died. I bought the bees, and a few days afterwards removed them. Owing to the severe weather I did not disturb them, but afterwards, being anxious to give them dry floor boards, I lifted them off their stand, and to my surprise found on each of the floor boards a piece of cake, which had formed into a wet mass owing to the moisture that was on the board. On inquiry I find the practice is common among bee-keepers, that on a death in the family the bees must be fed with cake, and a piece of crape be placed on each of the hives. If they omit doing this, they consider the bees will dwindle away and die.

The same people still clang the poker and shovel or anything that will make a great noise at swarming time, under the impression that bees will not settle unless this is done, the straw skep in which they are hived being well saturated with a mixture in which beer and sugar form a part. The only wonder is they stop in the hive at all. I have convinced several that the noise and washing out of the hive is quite unnecessary. The former cannot do any harm,

but the latter is positively injurious, as before swarming, bees fill themselves with honey, consequently they have a great amount of unnecessary labour to clean their hive before they can commence comb-building. No wonder they often fly away to more comfortable quarters.—AN ENGLISH BEE-KEEPER.

## TO CORRESPONDENTS

\* \* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Disbudding Azaleas** (*Know Nothing*).—You have not made the matter clear. If you mean "removing all the wood growths," we do not advise this being done for obvious reasons.

**Examinations in Horticulture** (*T. S. and others*).—All requisite information can be obtained on application by letter from the Secretary Royal Horticultural Society, 117, Victoria Street, Westminster, London, S.W.

**Heating Sloping Houses** (*A. F.*).—There will be no difficulty in heating the structures, provided the boiler is at the lower end. It is not necessary that the pipes be level, but they may "rake" with the house, the flow pipes steadily rising up one side, and the returns falling down the other; but the bottom of the feed cistern must be on a level with the highest part of the piping, and at that part an air pipe with tap should be inserted for insuring circulation.

**Culture of Cardoons** (*G. H.*).—They are grown practically in the same way as Celery, but the rows must be farther apart, because more soil is needed for earthing. In very wet soils they are best sown or planted on the surface, the site being well enriched. The seeds may either be sown in April where the plants are to grow, thinning them to a foot apart, or raised elsewhere, grown sturdily, and transplanted: but they must not be raised too early or drawn in their early stages, or most of them may form flower stems and be of little or no use.

**Mildew on Peach Trees** (*Nemo*).—Your trees are attacked by mildew, and the sooner you apply a fungicide the better. The following preparation is extensively used:—2 lbs. of quicklime, 3 lbs. of sulphate of copper, and 20 gallons of cold water. Dissolve the sulphate of copper in cold water for two hours in one vessel. In another pour a little water by degrees on the lime, mixing it well till it becomes a milky liquid; then pour the latter into the former, stir them well, and add to the 20 gallons of water already provided. It should be applied at intervals of three weeks, and always used fresh.

**Grafting Plum Stocks** (*Rugeley*).—The large Plum stocks would be best grafted on the whip or tongue system, taking care to let the barks join exactly on one side, then you may have a chance of success, though large stocks are very undesirable for grafting, as neither cleft nor crown methods are advisable for the Plum, for the wood is very liable to die back, or the bark becomes dry, so as to prevent union, and very often gumming ensues and is fatal. Of course, you can try inserting the scions under the bark, but it is not a good method for stone fruits, as there is not only danger of failure, but of the grafts being broken off by winds. With such large stocks the better procedure is to try the whip grafting, and if the scions fail secure some young shoots from the stocks and bud these as near the main stem as possible, as in budding standard Roses. The bark on the main stem of such stocks will be too thick for satisfactorily operating on them.

# VEITCH'S

FINEST MIXED

## LAWN GRASS

Carefully prepared from the finest Dwarf Evergreen Grasses only.

Unsurpassed for Making and Improving

# A NEW CUCUMBER

For 1895.

## SUTTON'S PROGRESS.

The result of a cross between Sutton's Improved Telegraph and Sutton's Matchless. The seedling combines the prolific character of the former with the rich dark green colour of the latter. It possesses the highest qualities of an exhibition fruit, and is unsurpassed in flavour.

"CUCUMBER, PROGRESS.—It may be said of the superb fruit of this new Cucumber that unanimously obtained a First-class Certificate at the Drill Hall last week, they were as near perfection as well could be. Those who know what Lockie's Perfection is when well grown will find in Progress identical fruits, but fully six inches longer.—D." *Journal of Horticulture*, May 17th, 1894.

### ORANGES UNDER GLASS.

IT is an easy matter to work up a good stock of young Orange trees. The first step to be taken in this direction is to extract the necessary number of pips from imported Oranges or Lemons in the spring, and sow them thinly in a shallow box filled to within 1 inch of the top with light sandy soil, covering the seeds with some of the same. Water through a rosed can, and place in heat, covering the box with a square of glass, and the latter with a little moss, thereby hastening the process of germination by excluding light and air, and therefore maintaining a more uniform degree of warmth and moisture about the seeds than would otherwise be obtained. When the seedlings are about 2 inches high place them singly in small 60-size pots, giving them a compost consisting of five parts light sandy loam, and one of sweet leaf mould to grow in. Make this moderately firm about the roots in potting, water, and keep the soil moist. Let the plants have a position near to the glass in a warm house to secure sturdy growth. Keep the plants free from the attacks of scale and other insect pests.

By the following spring, that is, twelve months from the time the seeds were sown, the young plants will have stems nearly as large as a lead pencil. These should be cut down to within 1 and 2 inches of the soil as stocks on which to engraft scions taken from established plants of the Sweet Orange. There are several ways of grafting, but that known as whip or tongue grafting is the best. Insert the knife about three-quarters of an inch from the top and cut off a wedge-like slice of wood in an upward direction, nearly halving the stock at the top. Then make a cross downward notch at the base, also corresponding cuts in the scion to enable this latter being tongued into the stock. The stock and scion should be prepared with a sharp knife to insure clean even cuts being made, so that the wood and bark surfaces shall fit closely. Bind with strong matting, then with damp moss as a means of keeping the stock and scion moist by being damped over three or four times a day with the syringe until they become united. The process of grafting takes longer to describe than perform. When the plants have been grafted

stand them closely together in one or more hand-lights rather more than half filled with sawdust or leaf mould in a forcing house. Put the covers on, keep quite close. Shade from sunshine, and damp the plants gently three or four times a day with tepid water until the union of stock and scion is effected. In selecting grafts choose short-jointed, clean, healthy shoots about 2 inches long and the same thickness as the stocks.

As soon as the engrafted plants have made a little growth they should be gradually inured to the full light and atmospheric temperature of the structure in which they are growing, and be afforded a position near the roof glass to encourage and promote short-jointed and consolidated growth. When the plants have made 3 or 4 inches of fresh growth they should be shifted into 3½-inch and 4½-inch pots according to variety and the headway made by the individual plants, affording them a compost consisting of four parts sound fibrous loam, and one of leaf mould and pulverised horse droppings, with a dash of sharp sand added as a rooting medium, afterwards shifting the plants as they require more room at the roots, and until they have attained to the desired size, giving good drainage in every case.

Plants of the Tangierine and Mandarin confined to 6-inch pots are very useful and attractive for decorative purposes in their flowering and fruiting stages. Well-conditioned Orange trees generally bear flowers and fruit in various stages of development at the same time, thereby yielding a pleasing combination of flowers of pearly whiteness and delicious fragrance, green and golden fruits intermingling with handsome shining green leaves. The varieties St. Michael and Maltese Blood, as is pretty well known, produce large fruits of fine quality, the fruits of the Tangierine and Mandarin being much smaller as well as earlier in ripening.

The plants will grow, flower, and fruit freely if given a light well constructed house to grow in, and if a minimum temperature of 50° be observed during the winter months, 60° in spring time, running the temperature up to 80° and 85° during the summer months, air being freely given during the heat of the day, and the soil kept uniformly moist at the roots and the trees damped at closing time, good crops of fruit of high quality may be gathered therefrom during the autumn and winter months. The trees will be greatly benefited by frequent supplies of diluted liquid manure at a temperature of from 75° to 80° being given at the roots while swelling their crops, and by way of a change occasional surface dressings of any of the advertised chemical manures may advantageously be given immediately before applying clear tepid water at the roots.

In shifting the plants into large pots or boxes the turfy loam should be used in a rougher state—that is, in larger pieces—than would be advisable for plants being placed in pots under 12 inches in diameter and depth, adding to each barrowful of the loam a 10-inch potful of fine crocks and small charcoal to insure porosity and a 6-inch potful of soot, the whole being well mixed before being used.

In some Orange houses the central ground space is divided into four parts or beds for the reception of Orange trees by two tessellated pathways crossing each other in the centre of the house, and communicating with one of the same description running between the side and end stages and the central beds. In preparing these four beds for planting the trees in the original soil should be excavated to a depth of 3 feet, 6 inches deep of concrete being laid in the bottom, placing therein and on a level with a surface of the same, rows of gutter bricks at intervals of about 4 feet, sloping to one side into a main gutter connected with a waste water drain outside; and on this concreted bottom lay from 9 to 12 inches deep of brickbats, broken fine on top, covering these with thin turves grass side down, thereby securing perfect drainage for the plants. This done, the remaining space should be filled up with a compost consisting of the ingredients described above, and in the proportion indicated. The soil about the roots should be quite moist before the plants are turned out of the pots. The

balls of earth and roots ought to be pricked round with a pointed stick to liberate any of the latter that may have become matted or root-bound before placing the plants in position at proper distances from one another in the beds. In planting ram the soil firmly about the roots of the individual plants with blunt wooden rammers, afterwards filling up the intervening spaces and treading the same well together. In every other respect the treatment of trees thus planted is the same as that recommended for trees in pots.—H. W. WARD.

## PICTURESQUE GARDENING.

“UNERRING Nature,” in the disposal and treatment of the wildlings, contributes so much enjoyment to her devotees that it is not a matter of surprise to find many of the calling, hedged about by divers rules, lines, and other restrictive agencies, gravitating to the free and unfettered original. That it is so is obvious. That it may not be freely acknowledged to be so is another matter. The bonds of custom and of fashion are rather to be gently loosed than rudely snapped. In one instance at least, a writer, liberal minded yet critically disposed—one who would rather lead a good fashion than follow a bad one—has hit the avocation hardly when stating that the gardener is a man whose chief delight is in rearing thousands of little toy plants to be clipped and pinched into orthodoxy. Yet, probably gardeners—those who have been most patient under this form of tribulation—have been the most eager to escape from the thralldom.

It is not uncommon nowadays to find in some fine old gardening establishments, balloon trellises, pyramidal wire structures, and other instruments of torture, relegated to the relic chamber, yclept the store room; whilst the victims, Allamandas, Bougainvilleas, and a host of tropical visitors festoon the houses at their own sweet will, saving that little wholesome correction needful to assert authority, and prevent the plant houses from being turned into Liberty Hall.

These are signs of the times; visible in the houses, more discernible in the garden, and so much in evidence in many a woodland walk or picturesque part of a demesne, that our critics may be impressed with the idea that the gardener is abroad. As a matter of fact he is very much at home, and never more so than when breaking away from formality and catching the spirit of that witchery, the inimitable worker, Nature, throws over her handiwork. Yet, whilst discipline can allow but little more than a suspicion of freedom in the houses or garden proper, we can, circumstances permitting, go forth into the open, contributing with a free hand at a minimum of expense and labour.

These are but few demesnes, large or small, which do not present opportunities for picturesque gardening. The subject is a broad one, and is neither bounded by the walls of public parks or private places, for it includes many a piece of no man's land by the king's highway. So thought a cottager who beautified “that nasty ugly spot”—viz., a heap of road scrapings near her dwelling by sowing a handful of Nasturtium seeds on it. Unlettered probably in the higher things of gardening, yet imbued with the spirit of beauty in Nature, which despises not the common things giving means to an end. Of such is the kingdom of picturesque gardening.

Yet with us there is a limit to work, if not to thought; work with us must begin at home, though to specially favoured ones it need not stop there. Our immediate concern is to break away from the beaten track, and these are the strongest inducements to do so, for he who loves his plants in the abstract is anxious to do the best he can for them. An observant eye cannot fail to note that on the larger scale, and amid the varied aspects of an estate, there are to be found conditions presenting the ideal of situations for some special plants which are not quite happy in the orthodox bed or border. This is a consideration apart from the more natural surroundings that here obtain, and which with some plants is an essential not to be overlooked. Another point is, that once we are outside of the gardens or kept grounds the bugbear of tidiness no longer pursues, demanding the removal of dead or dying foliage acting as natural protectors during the winter season. Even in those localities with uncongenial surroundings are to be found some sheltered nooks which form veritable sun-traps. Also the other extreme, which, with the happy medium, offer a wide field for the enterprising planter. Once we step out into the possibilities of the natural style a new world of work and beauty is opened up, not necessarily in opposition to formality; each has its place and purpose, and those who feel that it is so, and should be so, have room in their hearts for both.

Considerations have to be entertained, in some cases, of setting forth plants to do or die, for here the watchful eye and ministering

hand come but at intervals, perhaps not at all. Yet it is a thought which need carry one but a little way from the object. Indeed, if but a moiety of the care and anxiety our orthodox work entails could not be lost sight of here it would be fatal to its inception. Order—our interpretation of it—must cease to exist, freedom must reign, and if the foster mother deals unkindly with some kinds submitted by us to her rough and ready methods, neither force nor suasion need be persisted in, for they are out of place in wild gardening.

Yet enthusiasm must not deny that there are two sides to this question. In some cases the gardener may roam the whole estate, viewing the possibilities, yet precluded from acting beyond the sphere of his own dominion here, not daring to cross the frontier. I would say, Go up to the very edge of the boundary and beautify those barren spots which may often be noticed outside of the best kept gardens, and there may be reasons for supposing that where the artistic eye roams the hand may one day be permitted to practise the peaceful art. Other phases there are, too, on this side of the question, which from one cause or other of varying circumstances may elicit the remark, "Not practicable;" we (gardeners) are not free agents in these matters, but he who makes but the smallest contribution strikes a blow for freedom—the freedom of picturesque gardening.

The question of ways and means is too vast to receive but more than a passing glance here. There are, I think, but few who can disassociate the presence of water from the picturesque; from the streamlet to the river, or pond styled by courtesy the lake, which in its more ample proportions is entitled to the designation. In the sequence of things natural where water is there we look for rocks, and given this happy combination we have but to add the bright colours or graceful forms of plant life to complete the picture.

So many of our truly hardy plants are seen at their best advantage in the neighbourhood of water. Those who have seen a bold plantation of the Torch Lily (*Tritoma*) stretching to the water's edge on a promontory or islet, or the feathery Pampas Grass receding in the depths of a valley, cannot but think they are the right plants in the right place. Bamboos, New Zealand Flax, and similar foliage plants so well able to hold their own, are appropriate to the position; whilst on the sunny bank the German Iris, or on the boggy margin *Iris Kämpferi* add their charms to the scene.

Natural rockeries are too often monopolised by the rank growth of indigenous vegetation; or perhaps the reverse obtains, and a barren face may be rendered attractive by veiling it with some of our elegant creeping or trailing plants, whilst clefts and crannies form suitable pockets for the riches of the alpine flora. So, too, may the unsightliness of a disused quarry be converted into beauty, and form the happy home for many plants out of the abundance we possess.

Turning to the woodland walks, and skimming the bulb catalogues, a multitude of lesser sorts suggest their suitability to this position, and larger kinds, such as Lilies or *Hyacinthus candicans*, might well be employed to furnish some cosy clearing 'midst the trees. So may Nature's chief agent in distribution—Man—make such investments as will yield a high rate of interest in the unlimited funds of picturesque gardening.—E. K., *Dublin*.

DENDROBIUM APOLLO GRANDIFLORA.

THE Orchid that attracted the most attention at the Drill Hall on the 12th inst. was *D. Apollo grandiflora*, a flower of which is shown in the woodcut, fig. 43. Opinions were unanimous that this variety, which is the result of a cross between *D. nobile pulcherrimum* and *D. splendidissimum*, was the finest that had been seen, and was almost perfect both as regards size and colouration. The substance of the flower was extraordinary, and Mr. J. Cypher, Cheltenham, who was accorded a first-class certificate for it by the Orchid Committee of the Royal Horticultural Society, is to be congratulated on this superb acquisition. The sepals and petals were pure waxy white, shading to bright rosy purple at the tips. The petals were of great breadth, as also were the sepals. The

colour of the lip is white, with a showy patch of deep violet-crimson covering upwards of one-half of the whole. The size of the lip is almost phenomenal, and is, perhaps, the best point about the hybrid.

LÆLIA CINNABARINA.

IF, as stated by your correspondent (page 223), I have not done justice to this superb species, it is certainly not for lack of admiration personally, as I consider it an exquisitely beautiful Orchid. I cannot call to mind the exact words I used in the short note that was suggested by seeing the plant referred to, or how far I extolled its charms; but from six to ten flowers is certainly a fair average number for this species, though it may and evidently does occasionally produce more. I should, however, be inclined to attribute this to exceptional energy in the individual plant or pseudo-bulb rather than as a characteristic of the variety, for it is well known that Orchids of many kinds frequently produce spikes above the average. Your correspondent is none the less to be congratulated

FIG. 43.—DENDROBIUM APOLLO GRANDIFLORA.

on having grown such a beautiful Orchid so well; and if this is his usual experience with this species I am sure a few notes on his mode of culture would interest many of your readers, including—H. R. R.

ORCHIDS AT HARROW WEALD HOUSE.

THE collection of Orchids at Harrow Weald House, the residence of H. Grinling, Esq., is a very good one, and in the experienced hands of Mr. W. Rapley is likely to improve. We have received a small box of flowers, comprising some magnificent forms of *Cypripedium insigne* and *barbatum*, *Angræcum sesquipedale*, a superbly coloured form of *Cattleya Trianae*, and a handsome spray of *Cœlogyne cristata*. All the blooms bore unmistakable evidence of excellent management.

CALANTHES AND THEIR CULTURE.

AMONG winter-flowering Orchids there are few, if any, that can surpass *Calanthes* for usefulness, either for the embellishment of the mansion, or the maintenance of a bright and pleasing arrangement of flowers in a somewhat dry, intermediate temperature, flowering as they generally do with us early in October and continuing to keep up a display till the end of February. I am referring more particularly to the deciduous section, including *C. Veitchi*, *C. vestita oculata rubra*, *C. lutea*, and *C. nivalis*. Though there are several grand additions to the above varieties of more recent introduction, they are not sufficiently known, or even obtainable, to be generally grown, the two finest varieties that have come to my notice being *C. gigas* and *C. Schröderi*, both of which look like making strong growers, and each having been awarded first-class certificates.

We have not made such rapid strides in the cultivation of *Calanthes* during the last twenty years as we have in many other sections of Orchid-growing, for we have it on good authority that even previous to the year 1877 growers had produced spikes 6 feet long and pseudo-bulbs 18 inches high, such specimens of good culture being rarely met with. I am inclined to think that the majority of cultivators of the present day attempt to grow them in far too stringent a manner—firstly, in the potting compost not being sufficiently rich for the encouragement of a strong, luxuriant growth; secondly, in the lack of liberal chemical feeding, so

beneficial during the summer and autumn months; and thirdly, resting them in too low a temperature.

I have tried various methods of culture, in pots, pans, and baskets, but much prefer the pot system. As regards compost we have varied our trials, but the mixture with which we have been most successful consists of the following—equal parts good fibrous peat and loam, one part well dried cow manure, and one part, in equal amounts, of charcoal and potsherds, the peat, loam, and cow manure being broken up quite roughly, in size not less than pigeons' eggs, some larger, the charcoal rather less, and the potsherds smaller, though free from dust. I much prefer the crocks to sand, as I find the latter in such an open compost immediately washes into the drainage, doing more harm than good in the preparation of the pots and drainage.

All must be thoroughly clean, as the roots will cling to pots with the greatest tenacity—in fact, it is impossible, when thoroughly active, to take the plants out of their pots without injuring the roots. The size of pots we use is 5-inch for medium single bulbs, 6-inch for large bulbs, and 7 or 8-inch for two or three bulbs. The latter we use very little, the others being most useful generally. In potting we afford about half drainage, on this a thin layer of moss, filling up to the rim with the compost, then placing the bulb in the centre and packing sufficient material around it to keep it in position by pressing only moderately firm. We then place them on shelves, near the glass, in a warm plant house with a minimum temperature of 65° and maximum of 90° or even 100° in bright days by closing early, and maintaining a very humid atmosphere (such as *Dendrobis* delight in when making their growths), giving no water till growth is well on the move.

As the days lengthen and the growth advances they are removed to a three-quarter span pit and elevated on shelves sufficiently below the glass to keep the foliage from touching, shading them as lightly as possible, and increasing the moisture at the roots, syringing well under the foliage. We find ours ready for potting generally early in March. Some cultivators prefer resting them in the old soil, but we prefer shaking them out immediately after the flowering season is over, and storing them in pans of moss on warm dry shelves. (A few weeks ago a writer in one of our gardening periodicals was recommending us to place three good bulbs in a 5-inch pot. Bulbs 1 foot high and 7 inches in circumference would have but little space for future development were that method adopted.)

By the end of June the plants will have well filled the pots with roots, then we commence feeding with liquid manure from the cow-stalls, using it weak at each alternate watering. We also use the same kind of liquid for damping down the last thing at night; it imparts a deeper colour to the foliage, and is objectionable to all insect life, continuing to feed both at the root and in the atmosphere till the flower spikes commence opening, when a gradual reduction takes place, so that by the time the blooms are about half open the moisture is quite withheld, admitting air on all favourable occasions with a standing temperature of about 60°.

I find this the most critical period of their existence, as they are often used for house decoration or arranging with other plants in glass structures, oftentimes subject to cold draughts or moisture, low or stagnant atmosphere, such as I fear is the prime cause of the dreaded spot. With the above treatment we have produced many spikes 5 feet 9 inches long with pseudo-bulbs 12 and 14 inches high, objects of no mean interest and usefulness during the dark winter months.—J. FRIEND.

## FLORAL FACTS AND FANCIES.—8.

MR. FORTUNE was the means of introducing to our gardens many capital species, and one of the best is the Winter Jasmine, *J. nudiflorum*. It has proved well able to stand our ordinary winters, though I fear the recent arctic weather has dealt hardly with it in exposed places. By judicious training it will produce a succession of flowers during the winter months against houses and walls, imparting at a dull season a cheery aspect both to the mansion of the well-to-do and the cottage of the labourer. Fittingly, it is a symbol of grace or elegance, and the familiar white Jasmine represents "amiability." The *Ipomœa*, sometimes called a Jasmine, shows us "attachment," and another, also thus named, properly the *Bignonia*, by contrast "separation." This significance may have been given from the fact that the plant has left its native home, but Mr. Tyas remarks it is in consequence also of its being separated from an elegant humming bird, which is attached to the *Bignonia* in America, building its nest within a rolled leaf, and feasting on the honey yielded by the purple bells.

That a popular flower of very different habit, yet with a name not unlike the last—the *Begonia*—should represent "deformity,"

seems curious. This might have been suggested from the irregular form of the leaves of some species, or by the disproportion they have often to the size of the plant. The Virginian Creeper, which will thrive amid the smokeiest haunts of men, while it spreads itself so rapidly and persistently over any available space, reminds us of "clinging affection." To the Hop, occasionally cultivated in gardens as an ornamental climber upon trelliswork, belongs no pleasant character. Its Latin name associates it with the wolf, and since the time of Pliny it has been a symbol of "injustice," because it was supposed to twine round and also injure trees which could not defend themselves from its attacks. Bad, too, is the repute of the Fumitory, some varieties of which may be seen in flower during the spring; owing to its bitter and nauseous taste it was made a representative of hatred. To the Chinese we owe the favourable meaning of the *Glycine* (*G. sinensis*), a creeper which tells of "faithful friendship," covering walls or trees as it does with a succession of the pale blue and fragrant blossoms.

We are now eagerly expecting the appearance of flowers upon the Almond tree, a welcome intimation that our much-delayed spring is near at hand. The Easterns compared its bloom to the hoary head of an old man; from an unknown date these have been representative of hope under disadvantages. A Greek story connected the Almond with the history of two attached lovers, Demophon and Phyllis, who were obliged to part, but the absence of Demophon was so prolonged that at last the hope of Phyllis failed, and out of compassion the gods transferred her into this tree. But when he did return, though it was winter, the effect on the tree which enclosed Phyllis was such, that it became suddenly covered with flowers. Besides this meaning, the Almond in our cool land is an emblem of "thoughtlessness," for it seems to act regardless of consequences; flowering when it does, the early formed fruits are destroyed by frosts or cold winds, and few reach their maturity. The double meanings that belong to some is a notable feature of flower lore. We have an example in another plant of the spring, the familiar Wallflower. Queen of the Cross tribe it has been styled, one of the favourites of the old troubadours, often growing seemingly wild, yet not, 'tis said, a British native. Charlemagne the Great, warlike though he was, had a taste for flowers, and the Wallflower was a species he recommended and helped to distribute. Possibly, it was introduced to us by the monks, and if not by some Crusader, and it became a type of "lasting beauty," because the pyramids of bloom may be seen in gardens through the greater part of the year. But more than this, the Wallflower decorates decaying masonry, as venerable walls and neglected buildings afford it a home. Fragrant amid desolation, it is a plant "faithful in adversity." As the poet Moir (*Delta*) remarked:—

"It sheds a halo of repose around the wrecks of Time,  
To beauty give the flaunting Rose, the Wallflower is sublime."

Still, something may be said in favour of the garden Rocket, especially the double varieties, with spikes a foot in length. They tell of "rivalry," for the plant seems as if it would excel its relatives of that family. Gerard was proud when he obtained the white and purple kinds from Italy about 1597, and planted them in his Holborn garden; but the Rocket does not take kindly to the neighbourhood of London, though a clay soil is suitable for its culture. Some people retain a liking for this old-fashioned flower, overlooked through the rush of novelties. "Indifference" is proclaimed by the growth of the perennial and evergreen Candytuft; its white scentless flowers disregard the changes of the seasons, and fear neither summer's heat nor winter's cold. The Ten-week Stock illustrates "promptitude," since it runs its course with speed and punctuality. As a family, the Stocks represent "constant sweetness;" they are always fragrant, and continue in bloom till they die off. What is the connection between another old favourite—the *Lunaria*—and "honesty" is not obvious. The Latin name would associate it with the moon, but our forefathers believed that the plant had an influence potent enough to produce honesty amongst the people in whose gardens it grew. The *Arabis*, or Rock Cross, we cultivate for show merely, though plants of this genus were once supposed to have special qualities, as, for instance, to cure heart complaints, or strengthen that organ.

"Ever charming," is the characteristic of the *Cineraria*, which is indeed a flower generally liked, though it has the disadvantage of tenderness, and that of liability to insect enemies. Gerard and Parkinson made a prize of *C. maritima* with its beautiful foliage, attaining the height of 3 or 4 feet, and which they probably obtained from South Europe; it appears to have almost gone out of cultivation. The *Cyclamen* tells us of "diffidence," for the flower stalks bow themselves as if in humility, and as the seeds ripen the plant does not discharge them after the manner of some species,

but the heads bend lower yet till they reach the soil. Not many flowers of spring can compare with the Camellia, and the white variety has the honour of being an example of "perfect loveliness." In the red variety we behold "unpretending excellence;" both hues unite in the hardy C. Pompona, the petals being white touched with red. This received its name from a fancied resemblance to the French head-dress called a pompon. Then we have C. variegata, where a dark red has white blotches. That old border perennial, oddly called the Spiderwort, also Tradescantia, from the worthy gardener of Stuart Lambeth, tells of "transient happiness," for the flowers are said to fade generally on the day they open. Old authors remark that the Hepaticas, when they open, are meant to give us "confidence" that the earth is now quite ready to receive seeds.—J. R. S. C.

## ALPINE FLOWERS.

### MAKING AND PLANTING ROCKERIES.

(Continued from page 225.)

FOR small rockeries the best plan is to construct them in the form of a series of terraces. It is difficult to explain this simple matter without the aid of diagrams, but I shall try to do so as well as possible. At the base of the mound of earth which is to form the foundation of the rockery a row of stones is placed, and the soil then filled up behind, so that the surface of the terrace thus formed is level. These stones, and, indeed, if possible, all those on the rockery, should be well embedded, so that a foot can be placed on them. The edges of the stones should be closely placed together, and the soil firmly packed in. The soil must not be too wet, as it is desirable that it should not be too stiff. Some persons fill up the crevices with cement or lime mortar, but it will be found that this is not beneficial to the plants, which seem to be the better of the drainage afforded by the joints, and when the rockery requires to be rebuilt the cement or mortar renders this difficult to do.

The next step is to lay the stones for the next "terrace," and this should be done in a similar manner to that adopted for the first row. The distance between the two rows of stones is one that depends on the kind of plants it is intended to place on the terrace, and also on various other considerations which will occur to the reader, such as the height of the rockery. When the second row of stones has been laid, the rockery in course of formation will give a section something like this—

A, ground level; B, stones placed to form first terrace; C, flat portion of terrace; D, second row of stones; E, flat portion of second terrace; F, remainder of soil not yet formed into terraces. It will be found better to give the stones a slight incline inwards at the top. This will make them much firmer.

Where a large number of plants are grown in a small space it will be found useful to make separate divisions for nearly every plant. This may be done by placing stones across the flat portions—e.g., from B to D, sinking these a few inches into the soil. By means of these a series of pockets will be formed, and in each soil suited to the respective plants can be placed. Where possible these transverse stones ought to be inserted in such a way that the end next the upper terrace should abut against the point of junction of two stones, so as to keep them in position. Even in rockwork not divided into these "pockets" the insertion of such transverse stones adds greatly to the strength and security of the rockery. The building of the rockery may be carried on in the same manner until the necessary height is attained.

For many gardens, what may be called a rock bed will be found a convenient means of growing alpine without the trouble and expense of erecting a rockery. Like other rockwork it is better to have this bed of an irregular form, and it will be found to give less trouble to keep in order if it is not laid on grass, but in some position where the roots of the grass and similar plants will not encroach. This, indeed, should be the case with all rockwork; but where good reasons exist for placing it on grass a space must be kept clear, or great annoyance and labour will be required to keep the alpine from being overgrown. The rock bed should be elevated

from 9 to 12 inches above the ordinary level at the outer edge, and ought to have a slight elevation in the centre. Where the soil is comparatively heavy the edge of the bed may be a little higher. The edging of the rock bed is composed of stones laid closely together and embedded a few inches below the surface. Disposed irregularly throughout the bed a number of good sized stones or small boulders ought to be placed with their bases inserted a few inches deep in the soil.

Both rockeries and rock beds should be in a sunny position, and away from the drip of trees; unless intended for shade-loving Ferns or the comparatively few alpine which will thrive under the shade of the trees. The shade or partial shade required for some plants can be secured by planting them in nooks provided for the purpose on rockeries or behind boulders in the rock beds.—S. ARNOTT.

(To be concluded.)

## CYCLAMENS.

ONE of the best and most useful plants that can be grown for various decorative purposes during the winter is the Cyclamen. A house full of them in flower, ranging from the purest white to the darkest crimson or purple, with almost every intermediate shade of colour, is a strikingly effective sight. They display a beauty when grouped together in quantity that few, if any other class of plants, are capable of producing.

Cyclamens require fifteen or sixteen months of steady growth to develop into large plants in 7-inch pots. In twelve months some excellent and useful plants can be produced, and where a start is needed seeds may be sown in May or in September in shallow pans, boxes, or pots; the soil, to be composed of loam and leaf mould in equal proportions, with a liberal addition of sand, should be passed through a half-inch sieve, while that used for covering the seeds should be still finer. Before sowing the surface should be made even, so that the seeds can be covered an equal depth. With the soil uniformly moist, under a sheet of glass, germination will soon follow in a temperature of 60°.

When the seedlings have produced their first leaf they should be placed on a shelf not far from the glass, where they will grow slowly, but sturdily. No attempt should be made to hurry them; this means ruin. When large enough they may be carefully transplanted into other pans, about three-quarters of an inch apart, in similar compost, and returned to the shelf. In this position the young plants should be allowed to grow until they have made three or four leaves, then be lifted and placed in small 60-sized pots. When established in these they should be at once gradually inured by the admission of air to a temperature 5° lower. From small 60's the plants can be shifted into larger 60's, and from these into 5-inch, and all the strongest afterwards in 7-inch pots, a size large enough in which to grow plants fully a foot through their foliage. Dwarf sturdy growth must be aimed at, and this is accomplished by a free, yet judicious, admission of air.

In no stage of growth should the soil be allowed to become dry, or the plants will soon be seriously checked. Once the plants are brought to a standstill they cannot be induced to start again very freely into growth. The plants should stand on ashes or other moisture-holding material, and the house during bright weather must be freely damped. Cyclamens delight in being syringed, and this should be practised at least twice a day when the sun begins to gain power in the spring. Whenever the plants display signs of distress during hot weather a slight syringing proves of the greatest of assistance to them. We have found that perfectly clear soot water given occasionally soon imparts a darkness to the foliage which displays the beautiful markings of the leaves to greater advantage.

The soil throughout should consist of loam, leaf mould, sand, and one-seventh of decayed manure passed through a fine sieve. Loam and leaf mould being used at first in equal proportions, the former may be increased each time the plants are potted until it comprises about two-thirds to the one-third of leaf mould. If cow manure can be had for mixing in the compost it is preferable; if not, any well-decayed manure, free from worms, will do.

If aphides attack the plants, which they rarely do if kept growing without a check, they should be fumigated at once with tobacco smoke, as these pests soon disfigure the plants. Once a proper system of growing these plants annually from seeds is practised old plants will not be retained after they have done flowering or seed-bearing. But until a stock has been obtained these may be kept, and if stood outside after flowering for a time, and supplied with water, and then repotted and started into growth in frames, they will yield a good supply of flowers for cutting.—WM. BARDNEY.

**EVENTS OF THE WEEK.**—Again, as in the past week, there are three items of interest to horticulturists during this week. On Friday evening a presentation will be made to Mr. W. G. Head of the Crystal Palace; on Tuesday the Committees of the Royal Horticultural Society meet at the Drill Hall; and the Brighton and Sussex Horticultural Society holds its spring show in the Pavilion and Corn Exchange of that town.

— **WEATHER IN LONDON.**—During the past week the weather in and around London has been most pleasant and spring-like. The sun has shone gloriously on most of the days, and vegetation has made rapid strides since a few days ago. Most of the mornings have been somewhat foggy, but this has soon been dissipated. Tuesday was dull and cooler, a little rain falling in the evening, while at the time of going to press on Wednesday the conditions are the same as those of the previous day.

— **WEATHER IN THE NORTH.**—During the week ending the 19th inst. the weather has been generally dull with occasional showers and gleams of sunshine. Saturday and Sunday, however, were fine throughout. Rain and sunshine alternated on Monday, and Tuesday morning was dull and cold. West wind has prevailed, and the thaw now complete has enabled farmers to be at the plough for several days. Crocuses are making their appearance.—B. D., *S. Perthshire*.

— At the next meeting of the Royal Horticultural Society, which will be held in the Drill Hall, James Street, Victoria Street, Westminster, on Tuesday, March 26th, Mr. T. H. Crasp will read a paper on "Lifting Large Trees and Shrubs" at 3 P.M. The vacancy caused on the Fruit Committee by the lamented death of Mr. Geo. Taber has been filled by Mr. Iggulden's appointment by the Council. The Vegetable Show has now been definitely fixed for September 10th (instead of October 15th), and will be held at Chiswick Gardens, instead of in the Drill Hall as stated in the Society's "Arrangements" for the year.

— **GOOSEBERRY TREES AND RED SPIDER.**—I have read the note by "W. D." (page 228) with much interest, and venture to endorse the valuable advice as to training Gooseberries on the wire trellis plan as practised by Mr. Beddard at Lord Leigh's gardens at Stoneleigh Abbey. At every centre in Warwickshire where I have given lectures on horticulture I have referred to this excellent plan as carried out by Mr. Beddard. Perhaps the worst attack of red spider I ever remember seeing was on the Gooseberry trees trained on the walls at Stoneleigh Abbey Gardens, referred to by "W. D." My opinion was that the walls sheltered the spiders, and the heat of the sun exactly suited their nature. At the present time thousands, even millions, are feeding on the tips of the unopened buds. Now is the time to check the attack while they are at the mercy of insecticides before the foliage shelters them, and before any damage is done. I can confidently recommend Kill-m-right, advertised in your pages for this and other pests, as I have given it several exhaustive trials.—J. HIAM.

— **MR. MARTIN HOPE SUTTON.**—To very few is it permitted, after an active and successful business career, and a life spent in works of usefulness, social, philanthropic and religious, to enter the threshold of fourscore years. An honoured resident of Reading—Mr. M. H. Sutton—has lived to attain his eightieth birthday, the 14th of March, and the pleasurable occasion was on that day duly observed. Mr. Sutton received over 100 letters and telegrams, besides a great number of congratulatory visits from friends in Reading. Addresses were also presented, amongst others, by the Church of England Y.M.C.A.; the Reading and District Gardeners' Mutual Improvement Association, and by the chiefs of departments of the Royal Seed Establishment, from which business he retired in 1888, after being head partner for more than fifty years, leaving it in the hands of the present firm, consisting of his eldest son, Mr. Martin J. Sutton, who has been managing partner for the past twenty-four years, with two other sons, Mr. A. W. Sutton and Mr. Leonard Sutton, and his nephew, Mr. Herbert Sutton. The heartfelt congratulations which Mr. Sutton received on the anniversary will be echoed far and wide, together with the wish that his life may still longer be spared to his family and friends.

— **PRESENTATION TO MR. W. G. HEAD.**—The presentation to Mr. W. G. Head will take place in the Refreshment Department, Victoria Station, S.W., on Friday, the 22nd inst., at half-past six o'clock sharp, on which occasion Mr. Head will be invited to dinner. William Marshall, Esq., in the chair.

— **DEATH OF MR. ALEXANDER ANDERSON.**—We regret to learn that this able horticulturist died on the 9th inst., at the early age of thirty years, from an attack of pneumonia. For about ten years he had been employed at the Royal Botanic Gardens, Edinburgh, and for the last few years as herbaceous foreman. He was an enthusiast in his department, and enjoyed the respect of his fellow employes at that establishment; his death will be deeply regretted by all with whom he came in contact.

— **NEW SHOW HOUSE AT SOUTHWARK PARK.**—We learn that the County Council has erected a large T-shaped house at this park to be used as a show house for the Chrysanthemums. It is at present open as a winter garden, staging having been erected all round, which is filled with fine-foliaged and flowering plants, such as Spiræas, *Dielytra spectabilis*, Primulas, some fine *Imantophyllums*, Hyacinths, Tulips, and other bulbous plants in full bloom. One length of the stage is set apart for a choice collection of succulent plants. The centres of the different sections are filled with a collection of foliage plants which make a splendid display, and appear to take the public attention as a new feature even better than the Chrysanthemum show.

— **THE HORTICULTURAL CLUB.**—The usual monthly dinner and conversazione of the Horticultural Club took place on Tuesday, the 12th inst., at their Rooms, Hotel Windsor, Victoria Street. There was a good attendance of members. The chair was occupied by Mr. C. E. Shea, and there were present the Rev. W. Wilks, Messrs. Cockett, H. J. Pearson, Selve Leonard, C. E. Pearson, H. Briscoe-Ironside, J. Walker, Harry Turner, J. Laing, and others. The discussion was opened by Mr. H. Briscoe-Ironside with an interesting paper on "The Vegetation of the Italian Lakes, Especially that of Lago Maggiore." In the conversation which followed most of the members present joined, and a cordial vote of thanks was accorded to Mr. Briscoe-Ironside, whose paper will be found printed in full on page 255.

— **THINNING YOUNG CROPS.**—Few practices are more profitable in the amateur's vegetable garden than thinning out garden crops as soon as the young plants are above the surface. If the knowledge of the proper sowing of seeds was more widely prevalent, when the number of seeds required to make plants only need be sown, no thinning would be needed; but so many persons sow more seeds, fearing that numbers will fail to grow, and therefore many more seeds are used than is necessary. But sometimes all these superfluous seeds grow, in which case it is desirable that they should be thinned. Not only do the vegetable plants grow larger under these circumstances, but in many cases they come earlier into use.

— **ROYAL GARDENERS' ORPHAN FUND.**—Mr. H. J. Veitch, who will preside at the anniversary dinner of the Royal Gardeners' Orphan Fund at the Hotel Metropole, on Friday, April 5th, has issued the following appeal:—"Having consented to occupy the chair on April 5th next at the anniversary dinner of the Royal Gardeners' Orphan Fund, I am naturally most anxious that it should be a great financial success, and I confidently appeal to all lovers of gardens and gardening to assist me to the utmost of their power to attain this object. From a personal knowledge of the management of the funds of the charity I can confidently speak of the excellent work it is doing. With the exception of about £50 per annum for office expenses the whole of the work of distributing the income is carried on free of cost by the Committee, and therefore almost the entirety of the income is available for the maintenance and education of the orphan children of gardeners until they attain the age of fourteen, at which age it is expected they can begin to earn. At present sixty-four children are assisted by an allowance of 5s. per week, the good done being limited only by the amount of means at the disposal of the Committee; and when I mention the fact that not half the candidates at the last election could be assisted, solely in consequence of insufficiency of funds, I feel sure I shall not now appeal in vain for help to try and permanently increase the income of the charity. It is, I venture to assert, impossible to imagine any position more sad or heartrending than that of a widow left with, in many instances, several young children and with little or no means for their support, the father having been taken off prematurely and before he could make any or only a totally inadequate provision for them. It is such cases which I now ask all who love their garden to assist." We trust the responses to this appeal will be many and substantial.

— MR. ALFRED OUTRAM, who is so well known in connection with the Royal Horticultural Society and gardening generally, has, we believe, been engaged by Messrs. Sutton & Sons as traveller.

— THE CHESHUNT, WORMLEY AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY.—A meeting was held in Wormley Schoolroom on March 14th at 8 P.M., when a paper was read on "Nitrogen, Natural and Artificial Sources of, the Formation of the Different Compounds in the Soil, its Uses in the Plant Nutrition, and its Value as a Fertiliser." The paper was read by Mr. J. Grey, and a discussion followed, in which many of those present took part.

— SHIRLEY AND DISTRICT GARDENERS' AND AMATEURS' MUTUAL IMPROVEMENT ASSOCIATION.—The first annual general meeting of the above Society was held at the Parish Room, Shirley, Southampton, on the 18th inst., the President, Mr. F. G. Spranger, presiding over a fair attendance. The balance-sheet showed an income of £21 7s. 9d., and expenditure £20 6s. 5d. Commencing with thirty members the Association now numbered 111, which was considered very satisfactory progress. Sixteen meetings were held during the past year, and the average attendance was forty-six. The election of the officers and Committee and some alterations of the rules concluded the meeting.

— TEA CULTURE IN THE CAUCASUS.—We learn that the Administration of Imperial Appanages having decided to make experiments in Tea planting in the province of Batoum, in the Caucasus, where the climatic conditions are similar to those of the districts of China and Japan where Tea is grown, will dispatch a committee of agriculturists to Northern India, Ceylon, China, and Japan, in order to study the industry, and to bring back Tea plants and Chinese planters in order to make the attempt. The Administration has also resolved to send Mons. Krasnoff, Professor of Geography at the University of Charkoff, to South America and Mexico, in order to make inquiries as to certain other tropical plants, the cultivation of which would, it is believed, be also practicable in the Caucasus.

— WALLFLOWERS.—I do not quite understand "H. D." (page 225) in his reference to Belvoir Castle and Harbinger Wallflowers, as not being dwarf. The true Belvoir Yellow is the dwarfiest stock of Wallflower in cultivation. I grew it largely for many years, the average height of the plants being 8 inches, and a little higher when in bloom. I do not know of anything dwarfer. Perhaps he has for Belvoir Castle that tall loose form which came from Germany, and was sent out as Golden Gem—a beautiful yellow variety for cutting, but not at all dwarf. Then Harbinger, that is the original stock, was a dwarf compact habited selection of the London Market Blood Red. This latter is no doubt the finest dark crimson Wallflower we have. Strong plants reach to a height of 16 inches in a year, but the average height of moderately grown plants would be about 14 inches. The true Harbinger was about 10 inches. Probably any stock of the Market Blood Red is now sold as Harbinger. Selecting and keeping Wallflower stocks true is a work of immense difficulty. One stock should be a very long way from another, as the rich perfume and striking colour attracts insects, even if the air does not cause an interchange of pollen. Everything in the way of selection is practically settled for this year, and many working hard in that direction will have to start afresh.—D.

— SPURIOUS MUSTARD AND CRESS.—A few weeks ago lovers of Watercress, that best of all natural salads, were scared out of their seven senses by being informed that the herb conveyed into the human interior germs of a positively diabolical sort. So great was the popular fright that many suburban Watercress vendors retired from business, while the owners of beds who had for years made good incomes out of the herb gave up its cultivation. It is now the turn of Mustard and Cress, another charming salad, to be aspersed. In this instance it is the Mustard to which exception is taken by scientific authority. Not that it is yet indicted as a disseminator of microbes; that charge will come, no doubt, later on. The assertion is that the herb now sold by many greengrocers in combination with garden Cress is the product of Rape seed, not of Mustard seed. It can be differentiated from the latter by comparison of the leaves, the Rape being of a darker and duller green, with a downy surface. There is none of the fresh pungency of flavour which characterises the genuine article, while instead of being wholesome Rape is said to be harmful if consumed in large quantities. The reason for substituting it for Mustard is the greater quickness of growth. Rape seed strewn on wet flannel and kept in a warm atmosphere will be ready to cut in a week, whereas the more slowly growing Mustard requires twice that time for maturity. It seems singular that for such

a trivial gain as this the trade should dishonestly palm off an inferior article for a superior. But competition is especially severe we believe in greengrocery, and even the smallest profits have to be diligently sought for.—("Globe.")

— MARIE LOUISE VIOLETS.—Mr. J. Anderson sends us blooms of this Violet taken from plants grown in cold frames. They are large, rich in colour, and deliciously fragrant, and are highly creditable to their grower.

— FINE CYCLAMENS.—Mr. W. Rapley, Harrow Weald House, Stanmore, writes:—"I have enclosed a few blooms of Cyclamens, of which I think the colours very good. All are seedlings of Sutton's mixed strain. The seeds were sown in November, 1893, and the plants were at their best at the beginning of February, and averaged fifty blooms on a plant. I have quite decided not to grow the plants on the second time again if I have the convenience to grow seedlings. I have at the present time about 150 seedlings in thumb pots, and as these are all whites I hope to have a show of white bloom at the beginning of next year." [We must congratulate our correspondent on the excellence of the flowers he has sent us. The diversity of colouration is very rich, and the flowers and foliage are of splendid substance. It is evidently a grand strain of seeds, and the plants to produce such handsome blooms must have been grown in the best possible manner.]

— THE RED CEDAR.—Red Cedar (*Juniperus virginiana*) is the wood of blacklead pencils; and practically the wood in all these indispensable articles, at least in pencils of good quality, is the wood of this tree from Florida, where there are great factories belonging to German manufacturers, devoted to cutting up Cedar wood into pencil stock. Every artist in all the civilised world, every man of letters, every school teacher, all the bankers, lawyers, and other men of affairs, the men and women who control the world, and all the school children who are going to control it, hold every day in their hands a piece of this wood. It would be interesting to know, says a transatlantic contemporary, what proportion of these men and women, the most intelligent and best educated of the human race, knows anything of the origin of these little cylinders of wood, of the character and appearance, and of the name even of the tree that builds them up in its long life of slow accretions.

— BIRMINGHAM AND DISTRICT AMATEUR GARDENERS' ASSOCIATION.—Mr. Wm. Dean gave a most instructive and interesting paper before the members of the Birmingham Amateur Gardeners Association on Wednesday, 13th inst., on "Gardening Mistakes: How to Avoid Them." He dealt with the subject in three sections—flower garden, fruit and vegetable garden, and greenhouse. He said that overcrowding was far too common amongst amateurs, and was responsible for a good many failures. He advocated the addition of fresh soil to the garden every year, and said cleanliness and order should be the rule here, as well as in the greenhouse. Ventilation in the greenhouse should be given freely and early during the warm weather, and watering should be done very carefully. A vote of thanks was passed to Mr. Dean on the motion of Mr. Roe. Acting on a suggestion made in the course of the discussion, it was decided to invite all the members of the Association to assist in compiling a list of hardy shrubs and perennial plants growing in gardens in the district which had perished and survived the exceptional frost, it being thought that such a list would prove a valuable record for those members about to plant shrubs and the like.—WM. B. GRIFFIN, *Hon. Secretary, Alcester Road, Moseley.*

— THE "BOTANICAL MAGAZINE" of March contains the following subjects:—*Heptapleurum venulosum* (Araliaceæ).—This genus is a native to British India and South-eastern Asia. The specimen represented flowered at Kew last year. It is sub-arborescent, and has the branches dotted with white. The polygamous flowers, which are red and small, stand in clusters upon short pedicels and solid peduncles, the whole forming a compact branching panicle, having a decidedly reddish hue. *Disa sagittalis* (Orchideæ).—Eastern South Africa is the home of this genus. The tuber is spindle-shaped and the stem clothed with dark brown membraneous sheaths. The flowers, which are not an inch in length, have a generally white aspect, touched with pale lilac and red. *Veronica loganioides* (Scrophulariaceæ).—This plant comes from the Southern Island of New Zealand, where it is very rare. It differs from any known *Veronica*, and has been designated *Veronica epacrida*. It is a dwarf shrub. The stems are marked below with the circular scars of the fallen leaves, but are red, leafy, and branched above. The white flowers stand upon hairy peduncles with pink anthers

within them. *Weldenia candida* (Commelinaceæ).—This is a plant ranging from 1 to 8 inches in height, with tuberous roots and spreading, recurved leaves, passing into tubular sheaths below, and having scattered tufts of white hairs. The flowers are sessile, set in terminal tufts among the leaves. The tubular calyx, of about an inch in length, is of pale green colour, and the corolla is pure white, projecting to about twice the length of the calyx. It is a native of Mexico. *Schinus dependens* (Anarcardiaceæ).—This shrub, which comes from Chili, rises to about 15 feet. The dark brown branches are rigid and spiny at the points. The flowers are arranged in thick yellow clusters or axillary racemes, and consist of male and female. It is a hardy plant, and flowers in May.

— KEW GARDENS.—Her Majesty the Queen has been graciously pleased to allow the fences excluding the public from the Palace Meadows to be removed. This piece of ground is about  $4\frac{1}{2}$  acres in extent, and when thrown open it will allow visitors a direct, instead of a circuitous, access to the finest part of the arboretum. The Royal Gardens are 251 acres in extent. It is not generally understood that they were originally the private property of the Crown, and not acquired out of public funds. The building used for the herbarium and library was sold to the nation by George IV. Access to the remainder has been step by step conceded to the public by the liberality and munificence of Her Majesty the Queen. The successive stages may be briefly enumerated:—The Botanic Garden, of which Sir William Hooker was appointed Director in 1841, comprised about 11 acres. To this was almost immediately (1842) added between 3 and 4 acres about No. I. House, and the orangery (now No. III. Museum). Soon after (1844), by permission of the Queen, 47 acres, including the piece of water in front of the Palm house, were added from the pleasure grounds for the formation of a pinetum. In 1846 the Royal kitchen gardens (14 acres) were abolished; a third of their area (about 5 acres), called Methold's Garden (it having originally belonged to Methold House, the Director's present official residence), was at once added to the Botanic Garden; another third abutting on the Richmond Road is now represented by the herbaceous ground and the propagating yard for the purpose of which many of the then existing fruit houses are still in use. In 1851, the intervening third, the kitchen garden and paddock, in the occupation of the King of Hanover, reverted to the Crown, and was added by the Queen to the Botanic Garden. The pleasure grounds and gardens at Kew were in the occupation of the King of Hanover for sporting purposes at the time the Botanic Garden was given to the nation. The woods were filled with rough scrub for cover. July 9th, 1845, they were placed in the charge of Sir William Hooker by the Woods and Forests. The intention was that they should be formed into a national arboretum. A plan for the purpose was prepared (1846) by W. A. Nesfield. The main features were carried out at the time, and the general principle has been worked upon ever since. March 30th, 1864, the arboretum was finally thrown open to the public every day of the year, except Christmas Day.—("Kew Bulletin.")

— EDIBLE FUNGI IN SURREY.—Mr. Charles A. Briggs has an interesting article in the January number of "Science Gossip," on the "Edible Fungi of Surrey." Mr. Briggs is struck by the popular ignorance as to the existence of edible fungi—other than Mushrooms—and suggests that instruction in the difference between edible and poisonous fungi and other plants should be given in village schools. "There must," he says, "in every district be someone—clergyman, doctor, or teacher—with sufficient botanical knowledge to enable them to point out the distinctive characters of, at all events, the larger edible species, and the knowledge thus imparted would spread and spread until this blot on our national thrift was removed." With a view of rousing the class with whom it is a matter of prejudice rather than ignorance, Mr. Briggs gives a few notes of species eaten and enjoyed, not by himself alone, but by his whole household during the past year. Mr. Briggs records no less than fourteen species, of which the common Mushroom (*Agaricus campestris*), the Horse Mushroom (*A. arvensis*), the white St. George's Mushroom (*A. gambosus*), the Warty Cap (*A. rubescens*), the *A. vaginatus*, the *A. prunulus* var. *orcella*, the Blewit (*A. personatus*), the Blue Cap (*A. nudus*), and the *Boletus lutens* "may be cooked either in the frying pan, or baked in one of the common enamelled iron dishes now so much used, another dish being inverted over it all the time of cooking, and not lifted or removed until the dish is placed on the table, so as to retain all the flavour and aroma." Besides these Mr. Briggs utilised two of our common Puff-balls (*Lycoperdon plumbeum* and *L. bovista*), which, if "gathered young and eaten very fresh, are delicious when cut in slices, dipped in egg and crumbs, and fried; the *Morchella esculenta*, which

is "most delicious when stewed in a good gravy;" the *Sparassis crispa*, the most gigantic of English fungi, which frequently makes a growth as large as a man's head; and the beefsteak fungus (*Fistulina hepatica*), the flavour of which, however, Mr. Briggs does not much like. The species named are all large and easily recognisable, but there are also many small kinds equally if not more palatable. Mr. Briggs has done good service in calling attention to these neglected foods.

— CASTLETON GARDENS, JAMAICA.—The "Bulletin" of the Botanical Department, Jamaica, for October—December, 1894, contains very interesting notes on the plants cultivated in the Botanic Gardens at Castleton. This serves both as a guide to the gardens and affords useful information on the plants themselves. A plan is added, showing where the plants may be found. These gardens were established about thirty years ago in a picturesque valley in the mountains between Kingston and Annotto Bay. The chief feature of the garden is undoubtedly its fine collection of Palms. These thrive exceedingly well in the moist part of the locality. There are the Sugar Palm (*Arenga saccharifera*), Tucum Palm (*Astrocaryum vulgare*), Cohune Palm (*Attalea Cohune*), Jamaica Ippi-appi (*Carludovica gracilis*), Wax Palm (*Copernicia cerifera*), Æta Palm (*Mauritia flexuosa*), Ivory Palm (*Phytelephas microcarpa*), Jupati Palm (*Raphia tædiger*). Of flowering plants *Amherstia nobilis* has long been established; *Beaumontia grandiflora* forms large festoons across the garden paths, while others, such as *Bignonia magnifica*, species of *Bauhinia*, *Colvillea racemosa*, *Dillenia indica*, *Mesua ferrea*, *Michelia Champaca*, *Napoleona imperialis*, *Spathodea campanulata*, *Victoria regia*, are very luxuriant and attractive. The Mangosteen (*Garcinia Mangostana*) fruited for the first time in Jamaica at Castleton in 1886. With Economic plants the Castleton Gardens are well supplied. They serve as an excellent centre for the propagation and distribution of such plants on the north side of the island, and large quantities are also sent to the Hope Gardens and to Kingston. The three best known Rubber Trees—viz., Para Rubber (*Hevea brasiliensis*), Central American Rubber (*Castilloa elastica*), and Ceara Rubber (*Manihot Glaziovii*) have been established for more than twelve years, and have borne crops of seeds. A very successful plot of Liberian Coffee has been a prominent feature since 1880, and large quantities of seeds are annually distributed in the island. Mr. Fawcett anticipates that the export of coffee from Jamaica ought soon to be doubled.—("Kew Bulletin.")

— THE INFLUENCE OF TEMPERATURE ON TERRESTRIAL PLANTS.—In an address to the United States National Geographic Society Dr. C. Hart Merriam discusses the influence of temperature on the geographical distribution of terrestrial animals and plants. It is well known that in the northern hemisphere animals and plants are distributed in circumpolar belts or zones, the boundaries of which follow lines of equal temperature; but difference of opinion prevails as to the period during which temperature exerts its restraining influence. Dr. Merriam opens new ground in the address to which we refer. Physiological botanists have long maintained that the various events in the life of plants, such as leafing, flowering, take place when the plants have been exposed to definite quantities of heat, which are the sums total of the daily temperatures above a minimum (6° C.) assumed to be necessary for functional activity, and are termed the *physiological constants* of the particular stages. Dr. Merriam infers from this that there must also be a physiological constant for the species itself; and this *species constant* must be the total quantity of heat required by a given species to complete its cycle of development and reproduction. It follows that not only the mean temperature, but also the total quantity of heat in particular zones must be considered in estimating the influence of temperature on the distribution of plants and animals. Dr. Merriam has constructed a pair of isothermal charts of the United States, of which one shows the distribution of the total quantity of heat during the season of growth and reproduction (*i.e.* the sum of daily mean temperatures above 6° C.), and the other the mean temperatures during the six hottest weeks of the year. By comparing these with a biogeographical chart of the same region, Dr. Merriam concludes, from the striking coincidences which occur, that animals and plants are restricted in northward distribution by the total quantity of heat during the season of growth and reproduction, and in southward distribution by the mean temperature of a brief period during the hottest part of the year. The anomalous intermingling of boreal and austral types which occurs over an extensive area of the Pacific coast of the United States becomes explicable by the establishment of these principles, for here alone is a low summer temperature combined with a high sum total of heat—the two conditions which permit extensive mixture in the same region of northern and southern types.—("Nature.")

— NATAL PINE APPLES.—A small consignment of Pine Apples arrived from Natal a few days since, and the fruits were offered at Covent Garden. Their condition left nothing to be desired, except that, having been gathered before they were ripe, and being brought over in cold-air chambers, many of them had a green and discoloured appearance. Consequently this experimental shipment did not prove altogether a pecuniary success, only 1s. 3d. to 2s. each being realised.

### THE LATE MR. JOSEPH LAKIN.

By the death of Mr. Lakin on March 4th at the age of sixty-seven years, the little world of floriculture "of the old school," as it is now the fashion to call it, is distinctly the poorer, and his departure from our midst merits a further notice than that contained in the brief paragraph in the issue of the *Journal of Horticulture* for March 7th.

Mr. Lakin from youth was an ardent admirer of all florist flowers, and although for many years prevented by the sterner duties of life from cultivating them to the extent of his desire, yet he never lost his early affection for them. When he was able to retire from the Oxford County Police, in which force he held at the time the position of Superintendent of the Chipping Norton division, his one idea was to devote himself to the cultivation of his favourite flowers.

At the peaceful village of Temple Cowley, near Oxford, he found a congenial home, and soon made the half acre of ground behind his house one of the most interesting gardens in the country. Carnations, Picotees, Auriculas, Tulips, and Pinks were his prime favourites, but room was found for many other garden flowers. He was an enthusiastic and successful raiser of Carnation and Picotee seedlings, and many good new varieties have resulted from his labours. Amongst them may be mentioned:—

Carnations.—Rose flakes: Mrs. May, Lovely Mary, and Erskine Wemyss. Pink and purple bizarre: Miss Annie. Selfs: Annie Lakin and Emma Lakin. Fancies: Cowley Rose, Atalanta and Grandis.

Picotees.—Heavy reds: Isabel Lakin, Ne Plus Ultra, and Mrs. Keen. Light purples: Elizabeth and Sarah Ann.

In Pinks he raised Mrs. Lakin, white self; in my opinion the best variety we possess.

For the Tulip Mr. Lakin had much love, bound up as it was with the associations of his youth, at which time he was on intimate terms with the best Midland growers and raisers, and many a racy old story was he able to relate of these worthies and their doings.

Mr. Lakin loved his flowers, and like a true florist tended them with his own hands as long as he was able. None knew better than he their individual requirements; none appreciated more clearly their capacity for improvement, and the lines on which the improvement ought to proceed. This was the steady light of the true florist, and he had no sympathy with those modern "will o' the wisps" who are doing their best to lead us into floral quagmires. If he had been spared in health and strength he would doubtless have gone on adding to the number of the beautiful varieties which already bear his name.

Humanly speaking it is matter for deep regret to his friends that further length of days was not given to him. Genial and good hearted, Joseph Lakin's memory will remain green in the affections of his friends until they, in their turn, pass away and themselves become memories only.—JAMES W. BENTLEY.

### EXAMINATIONS IN HORTICULTURE.

ON page 234, "A Young Gardener" called my attention to the fact that I did not mention in my reply to his (on page 214) how many of the forty-nine successful candidates (whose ages were under twenty-five) obtained a first-class certificate.

It seems as if "A Young Gardener" thought in the first place that few under the age of twenty-five gained the Society's certificate. When he was shown that more passed under that age than above it, he tries to pass it off by asking the above question, but he will find nothing in this to support him, but just the reverse.

Last year ten candidates gained sufficient marks to be placed in the first class; five of these ten were persons under twenty-five years of age, and only one of the remaining five was a gardener. Does this show that the successful candidates were those whom "A Young Gardener" calls our "chiefs?"

We may go even farther and see who are those which are placed in the second class. Taking the first fifteen for convenience, I find that out of that number twelve are under the above mentioned age (viz., twenty-five).

The examination is as perfect as the Society can make it, and I think it would be very unfair to make any distinction in the ages of the candidates, for there are many gardeners above the age of twenty-five who do not know so much as younger men.

I have generally found that anything which seems hard to do, is so because we know very little about it, and I would suggest that "A Young Gardener" should make up his mind to try for a first-class certificate, and then perhaps he will not find it so hard to secure as he thought it would be.

I may say that the lack of candidates for this examination is probably due to the fact that men know but very little about it. As an example, only two sat at the examination which was held in this district last year; this year I know of thirteen who have given in their

names, and probably some of the Society's certificates may come this way, although we are only "Young Gardeners."—W. D., *Turnford*.

[Young gardeners might take courage from the fact that the medallist last year was an amateur, and the student, only four marks behind him, a schoolmaster.]

I GATHER from what has been published in the *Journal*, and also from what I have heard in other directions, there is an impression abroad that these examinations are of a competitive nature. That is a mistake in a certain sense, for they differ appreciably from Civil Service examinations, that are really competitive, as all the candidates in these are of about the same age, and start from very similar bases.

In the R.H.S. examinations, a well cultured youth of twenty, if he has, proportioned to his age, fair practical knowledge, may often do better than a candidate double or treble his age, because his academical education is to him so helpful in a paper examination. Of course we all have to admit that no mere literary examination can furnish a true test of any person's professional capacity, but at least it does to some extent, because it is very easy for any good examiner, if he be a practical man, to gather from paper answers how far the candidate knew thoroughly what he was writing about, or whether his knowledge was only of the perfunctory order. The practical answer usually goes direct to the subject, even though not always an ideal literary exercise, whilst the very amateurish answer dances, as it were, round the subject hesitatingly, then finally makes a dash, and sometimes misses the mark.

It is of great value that anyone purposing to sit for the R.H.S. examinations should practise the art of answering questions on paper concisely and practically. It is an accomplishment only obtained by practice. Now here is a matter in which head gardeners should be able and willing to assist their juniors efficiently. Let them set on paper every week from now till May some nine or ten questions on gardening; not long ones, but brief and practical, to which all their respective young men should be required to furnish replies. It should be made compulsory by the head gardener. Then he could examine, and point (*i.e.*, award marks of merit for) the answers weekly, and it would be a capital plan if the young men in a garden would set apart at least one evening in a week to hear and discuss each other's answers. The result could not be other than interesting and valuable. It is only by some such literary exercises and preparation that candidates can hope to cut a good figure in the examination returns. I do not approve of the creation of different grades of candidates, whether having regard to age or to occupation; but I do think that when the lists of successful candidates are published both occupations and ages should be stated, as then the youth of twenty years, if somewhat below the man of fifty, would certainly occupy a not less meritorious position. All the same, this youth's greater dexterity in composition and literary style may help him far more than he imagines.

May I tell young gardeners that very many of them have not too well mastered the elementary knowledge called spelling, although that is a defect happily becoming less yearly? Handwriting, too, may or may not be of the best. Then at all times and seasons the art of note-taking is a valuable aid. How many things seen or heard embodying most useful knowledge are soon forgotten, because Captain Cuttle's famous practice is not followed. I have frequently at lectures watched with interest the attempt of members of the class to take notes, but they often signally fail. They come armed with pencil and paper, but seem entirely at a loss to make a note of the salient points of what they hear, and before they can make up their minds how to make a note the lecturer is some way further on. Elementary teachers can do this because they are trained to such work, but the young gardener and the amateur are too often from want of experience quite at sea. Hence the great necessity for practice.

It may interest readers of the *Journal of Horticulture* to learn that in connection with the lectures on gardening being given in the county of Surrey under the Technical Education Committee, the lecturers have framed from out of each separate lecture a series of from ten to twelve questions. Copies of these questions are furnished to each person present. These questions are taken home, and those who care to do so furnish replies to as many as they can during the ensuing week, and return them to the instructor at the next lecture or send them by post. These are all subsequently pointed, and the results will be made known to the various candidates. In this way it is hoped many may be induced by a little training to sit for the R.H.S. examinations.—AN INSTRUCTOR.

AN obstacle in the way of not a few men who would like to enter themselves for the R.H.S. examinations is the formidable array of books recommended to students. Some of these books are of a voluminous character. They cannot be purchased by many young gardeners, and as these think that others, to whom £2 or £3 are of small account, will buy them and "read themselves up," several of those who cannot do so simply hold aloof. I know of six men who, through no fault of their own, thus feel themselves handicapped, and are therefore not likely to enter. It may be foolish, but it is a fact. On the other hand I know of two men who bought all the books, and one of them said they bewildered him. It is certain that neither of these students gained a certificate, so this book question has two sides; but still the recommendation of such works implies their necessity, with the results above stated.—A STUDENT.

[Another correspondent who intends trying for a certificate writes:— "Are there no means of borrowing some of the costly books recommended for the exam.? It would ruin men like myself to buy all of them."]

## MODERN GRAPE GROWING.

## HEATING.

I DO not know that I can suggest any better arrangement of the pipes than that in the Longleat vinery, where there are ten rows placed thus:—One nearly close to the side wall, two side by side about a yard from this, and two others 3 feet from the centre of the house forming the boundary to the path. The other side is a repetition of this arrangement, and each side in every compartment can be worked separately. It is of great importance to have good valves at suitable places both on flows and returns, not only such as will regulate or stop the circulation of heat, but that will also when necessary prevent the passage of water, for in these times we must all be economical, and when a particular vinery is not wanted during the winter for storing tender plants it will do no harm, but rather the reverse, to let the frost in till such time as the Vines require to be started. I am in the habit of doing this, and of course it is necessary to draw the water out of those pipes that are exposed.

It is advisable to so arrange the pipes that there shall be no dips. I have never yet had a case where a dip was necessary, though possibly there may be such. I have in times past arranged some compartments to be heated with flows only and others with returns only, and it is astonishing how accommodating hot water is if you arrange it without dips. By dips, of course, I mean where the pipes dip down and rise again. Let them rise a little here and there, or better still all the way, till they begin to return, and generally make the circuits as short as possible, so as to get the water back to the boiler quickly. I know of one establishment where the reverse of this prevails. In one house particularly there are eight rows of pipes altogether near the front in four pairs, one above another, and incredible as it may appear, the water actually travels the length of the house eight times before it can get back to the main. Supposing the house to be 40 feet long the water has to travel 320 feet, whereas if the pipes were properly arranged it would only travel a little over 80 feet. If my readers can believe such a thing to exist they will not be surprised to learn that all the arrangements are faulty; and although there are only about 3000 feet of pipes to be heated, nearly 1000 feet are underground, and there are three large Trenton boilers fixed to do the work. Of course, one of these boilers would be sufficient if the arrangement was right, but as it is the circulation is not to be depended on when all three are going. There should never be as many as eight pipes together, and the water should never go round the house a second time. If there are five pipes two should be flows and three returns, or *vice versa*, and the flows should be in the coldest places. When mains are outside it is important that they be kept clear of the masonry which surrounds them, otherwise much of the heat will be lost. Ours are covered with an asbestos mixture which effectually prevents any loss.

In the matter of boilers we have been unfortunate. Two were fixed side by side, and leading into one main, to which something over 3000 feet of 4-inch pipe is attached. They were welded upright boilers, having a drum outside and a circle of tubes inside, these tubes being so bent at the lower end as to form elbows, which were constantly in the fire, and this proved to be the weak point. One of them sprang a leak during what should have been a summer month, and all the tubes were found to be nearly burned through at the lower part, although they were perfectly clear of sediment. This boiler was replaced by another of the same pattern, but before the fire was lighted the second one gave way, and then it was determined to try something different.

We have tried something different, and now I believe we shall have cause to rejoice that the old ones did go the way of all boilers. What we now have may be called a tubular top-feeding saddle, with water bars. I do not know how much of its power is due to the plan of fixing, for this is something new to me. It is fixed in a slanting position, being 4 inches higher at back than at front. It is less than 4 feet in length, but it is considerably more powerful than the other two were together, and takes no more fuel than one. It is an adaptation of the boiler that won the gold medal in the contest at Liverpool in 1886. Most boilers, and probably all of them, have their faults.

The ordinary saddle boiler, if large enough to heat 1000 feet, is too slow. It may be all right if kept going constantly, but if you have to light a fire suddenly you are apt to have the frost in the house before the heat gets round. A boiler that will not alter the temperature of the flow pipe in ten minutes after lighting the fire is not good enough, neither is one that will not respond quickly to the stoker on a cold frosty morning. What gardener has not found the want of a quick boiler on a morning when frost has been extra severe, and perhaps has come on suddenly? His stoker on his first visit has found temperatures too low. He rouses up the fire, puts on full draught, and uses the poker freely; he burns an enormous quantity of fuel, most of which goes to form clinkers, yet the temperatures still go down rather than up, and he cannot get his pipes hot till just as the sun shows itself; then they get very hot, and all his efforts to check the fire seem to make them hotter still. It is well known to old practical stokers that the big roaring fire got up quickly not only wastes fuel, burns out boilers, bars, firebricks, and all the surroundings, but that most of the heat goes up the chimney, and that when the inexperienced stoker shuts nearly all the draught off a large fire, red-hot through, with the idea of checking it, he just creates the conditions most favourable to rapid heating of the water.

Perhaps a bright day follows with a cold east wind, and then we know what happens. Instead of being able to bottle up the sunshine and keep the east wind outside, some of the latter has to be admitted

and the former is rendered comparatively useless. There is often a difficulty when heat has to be turned on to extra houses during evening simply to keep out the frost. Many a time I have had to keep pipes slightly warm during a bright day to ensure their working right at night, for if you have one or more houses which require to be kept constantly hot, and you are short of boiler power or have a slow boiler, the water returning from the heated houses will make the return main pipe comparatively hot, and there will be a difficulty in getting the cold water from another house into the return at all. Where everything works easily and there is abundance of power this difficulty is not often a formidable one. To be satisfactory, we must have a boiler that will respond quickly to the stoker, that will be economical, that will heat a small or large quantity of pipes at will, that will make few ashes and no clinkers, and that will keep a tolerably even heat during the night.

I do not say the boiler we now have is perfect, but it comes nearer what a boiler should be than any I have had to do with before. The inside of the furnace is sufficiently wide to hold enough fuel for the night, even when coke is used, without placing it much more than a foot in thickness, so that the fire is never smothered. It has tubes running through the centre, splitting up the fire and entirely preventing the formation of large clinkers. There is no poker required. All that is wanted is a light iron rod turned up at the end to be used underneath the bars when the fire is required to go sharper to dislodge the dust that accumulates there. We take out all, some, or none of this dust, according to the amount of heat required. I have been looking over some of Hood's tables concerning heating, and have come to the conclusion that they are either useless or my understanding is very dull indeed. In the first place he calculates on the assumption that the pipes will be heated throughout to 200°. Now we know this never happens with the low pressure system when there is a considerable length of pipes to be heated—say over 1000 feet, and only for very short intervals in shorter lengths, when the water must be actually boiling.

I find in the Liverpool contest with 500 feet that the premier apparatus, after five hours' hard firing, did actually exceed that temperature but none of the others came anywhere near it; but in the morning after the fires had been banked up for twelve hours, the average temperature of the pipes was just 100° on the winning apparatus, 86° on the second, and 73° on the third. In the 2000 feet contest the highest temperature reached at the point where the thermometer was placed on the flow pipe was 168° after four hours' firing, and it declined to 110° after twelve hours' banking. That of the second competitor declined to 104°, and the third to 88°. True, these contests were in the open air; but they took place just after Midsummer Day, and it would be easier to heat pipes in the open air at that time than it would be to heat them in a house during sharp wintry weather.

I think, then, these figures prove that 200° is much too high a figure to calculate upon; in fact, I believe 100° is too high. Then when we come to calculate according to Hood's tables as to the quantity of pipes necessary for heating each house we find they are faulty in an opposite direction. In Mr. Barron's excellent treatise on "Vines and Vine Culture" he gives a plan of a span-roofed house, which I take to be about 40 by 20 feet. Say its average height is 6 feet, this would give 4800 cubic feet of air space to be heated. If we take the external temperature at 32°, and require a minimum of 70° in the house (the figures given by Mr. Barron), it would take 787 feet of 4-inch pipes heated to 200° according to Hood to secure that temperature, but Mr. Barron only shows eight rows, say 350 feet, and few people would think of having a greater number.

Our Muscat house is 60 by 30 by 9 feet—*i.e.*, 16,200 cubic feet—and would require according to the same reckoning 1814 feet of 4-inch pipes to produce a temperature of 60°, but we have only 790 feet in twelve rows, besides ends, and find it ample. There is no doubt that large houses when well glazed take comparatively less piping than smaller ones. It is a good plan to have plenty of piping, but not more than enough; fifty to sixty feet of 4-inch pipes, if the glazing is fairly good, is sufficient for each 1000 cubic feet of air. We do not expect to be firing away all the time, as if competing for a gold medal. Hard firing cannot be carried on without waste of fuel and injury to the plants and apparatus. And after all, the best of apparatuses will be of little avail if we lack that *rara avis*—a good stoker.—WM. TAYLOR.

## SUMMER ROOT-PRUNING.

I HAVE never seen a better example of the good effects of this practice than the following. In 1893 a merchant requested my opinion as to the cause of some of his standard Pear trees never having borne fruit. They were growing luxuriantly, and I found had since being planted been branch-pruned only. I advised him to cut a trench half round each tree at 3 feet from the stem. This was in midsummer. He put the advice into practice, and last autumn the trees for the first time were laden with fruit. The results of cutting back half the roots was not only a check to growth, but mainly it was a rapid and certain means of producing fibrous roots that immediately in turn re-acted on the rankly grown shoots, causing them to ripen and bristle with fruit buds. No doubt the same results would have followed had the operation been delayed until November, but a year would have been lost, and instead of having Pears in 1894 it would have been the present year before the benefit would have been seen.

I have a number of Apple trees to remove next autumn. One-half the roots are being cut back now, and in summer the other half will be

shortened, and by this means I hope, judging from past experience, to transplant not only with safety but with advantage.

Like Mr. Temple, I have transplanted shrubs at all seasons. Last year I had an opportunity of seeing the wonderful manner that shrubs lifted in full growth appreciate the treatment. Those in question were a group of Golden Yews, which grew so rapidly through the summer as to become quite too close by August. One damp afternoon of that month I had half the number transplanted. In November some specimens were required for a scheme of shrub planting then proceeding. The transplanted Yews were chosen, and each one lifted with a network of short white roots encircling the ball.

The only times that I have known root-pruning to fail has been when the work had been injudiciously done. I have seen both fruit

Perhaps the reason of this is because it is considered a difficult plant to cultivate. It also has the reputation of growing well for a time and then to gradually dwindle away, though the greatest care and attention may be bestowed on it.

I have only one plant. This has been under my care for about four years, being a very small piece when it came. So far it has both grown well and flowered profusely. It is now in a 4-inch pot, and has just ceased blooming, which is a little earlier than usual from the fact of it being in a cool house instead of a cold frame during the long spell of severe frost. The flower stems numbered nearly 100, some bearing two and others three flowers. It seems almost incredible that so small a plant should produce such a number of flowers. I should like to know if it generally flowers so freely.—J. S. UPEX.

FIG. 44.—EUCCHARIS STEVENSI.

trees and shrubs killed, large ones of course, through the cutting back of the whole of the roots, when no more than half ought have been manipulated at a time.—R. P. BROTHERSTON.

#### SOLDANELLA ALPINA.

THIS is one of our choice alpine plants, and with a few other species forms a small genus in the Natural Order Primulaceæ. Alpina is the more common one, and is a very beautiful and interesting plant. Its small leaves are round or kidney shaped, dark green, and leathery, growing in tufts upon the ground. The flower stems are about 3 inches in height, and bear two or three pale blue bell-shaped pendent flowers each, which are cut into linear segments, having the appearance of a thick fringe. Its time of flowering is March or April.

Although this plant was introduced into this country nearly two centuries and a half ago, it appears to be very seldom met with.

#### EUCCHARIS STEVENSI.

THIS free-flowering Eucharis (fig. 44) was staged by Mr. P. Blair, Trentham, at the meeting of the Royal Horticultural Society held at the Drill Hall on March 12th, and on that occasion gained an award of merit. The variety was raised a few years ago by Mr. W. Stevens, gardener to W. Thompson, Esq., Walton Grange, near Stone, Staffordshire, whose name is so well known as a successful cultivator of Orchids. Though several years have elapsed since the variety was raised, this was said to be its first appearance at the Drill Hall. The plant is very similar in habit to Eucharis grandiflora, but the leaves are somewhat smaller. The chief recommendations of Eucharis Stevensi are its free-growing and floriferous habit, and its entire freedom from attacks of disease, which so often play havoc with plants of the older varieties, and such being the case it should become a very useful addition to the Eucharis family.

## SPECIAL PRIZES OF THE NATIONAL ROSE SOCIETY.

THE Hon. Secretaries of the National Rose Society are happy to announce the following list of special prizes which have been placed at the disposal of the Committee for the present year.

**GLOUCESTER.**—The High Sheriff of Gloucestershire a silver cup, value 5 guineas. In local classes Messrs. J. Jefferies & Sons, Cirencester, a silver cup; Rev. F. R. Burnside, a silver challenge cup; the Mayor and Corporation of Gloucester, a silver cup; the English Fruit and Rose Company, prizes for Moss, garden, and single Roses; besides money prizes and medals by the Rev. B. S. Dawson, Messrs. J. Jefferies and Sons, Mr. Conway Jones, Mrs. Gambier Parry, Mr. T. Thorpe, Mr. W. J. Johnstone Vaughan, Mr. T. A. Washbourne, Messrs. J. C. Wheeler and Son, Kingsholm Nursery, Gloucester; and Captain de Winton. All the other prizes in the numerous local classes are provided by the Gloucestershire Rose Society.

**CRYSTAL PALACE.**—Messrs. Harkness & Sons, The Grange Nurseries, Bedale, Yorks, a challenge cup value 25 guineas; the Right Hon. Lord Penzance, a silver cup value 5 guineas; Mr. Frank Cant, Braiswick Nurseries, Colchester, a special prize value £5; the Hon. Mrs. J. Townshend Boscawen, a piece of plate value 3 guineas; Mr. E. Mawley, a piece of plate value 2 guineas; besides money prizes by the Rev. W. J. Mellor, Mr. O. G. Orpen, Messrs. Paul & Son, The Old Nurseries, Cheshunt, the Rev. J. H. Pemberton, and Mr. C. E. Shea.

**DERBY.**—The Right Hon. Sir William Vernon Harcourt, M.P., a silver cup value £10; the Royal Crown Derby Porcelain Company (Limited), a Crown Derby vase value 5 guineas; the Mayor of Derby, a piece of plate value 3 guineas; and a money prize by Sir Thomas Roe, M.P.

## NEW ROSES.

WE used to be taught in our Latin grammar that "experience teaches us," but either it is a lesson which our foreign rosarians have not yet learned, or else there is some mysterious way in which they make a profitable business out of their new seedlings of which we are ignorant. What becomes of those varieties which in such constant profusion are brought forward every year it seems difficult to ascertain. No English amateur ever dreams of buying one, and nurserymen have long since given up the unprofitable game of buying a lot of new Roses of high-sounding descriptions and propagating them freely, only to throw them away, and hence I cannot think there can be much of a market for their wares amongst us; nor do I think that America can fill up the gap caused by the greater caution of our English Rose growers, for as well as I can gather from notices which have appeared from gardening journals, the culture there of Roses is mostly under glass and is confined to a few leading varieties, and in such a system there would not be much opening for novelties; and yet, notwithstanding the very small per-centage of new Roses that remains permanently with us, "the cry is, Still they come."

I have before me now through the courtesy of Messrs. Paul & Son a catalogue of the new Roses to be sent out during the present season; it is issued by Messrs. Soupert & Notting of Luxembourg, and the list amounts to no less than eighty-one flowers! Of these more than one-half are Teas—namely, forty-three, eight Hybrid Teas, seventeen Hybrid Perpetuals, sixty-eight in all; the remaining thirteen are made up of miscellaneous Roses, such as Polyantha, China, Noisette, and Rugosa, so that again as of late years the Tea section is the predominant partner.

In looking over the list two things strike me: first, that the names of some of our most celebrated raisers are absent. Death and other causes have thinned their ranks, and in vain we look for the names of Lacharme, Margottin, Charles Verdier, Guillot, Ducher, and others to whom the Rose world owes so much, for their productions are to be found wherever the Rose is cultivated, and will make their names to be remembered even by those who have never seen them. We still find the names of other older raisers, such as Lévêque, Liabaud, and Nabonnand, but they have not given us such striking results as those I have already mentioned. Another fact is that there does not seem to have been any more common sense in naming the varieties than heretofore. Fancy, for instance, Grande Duchesse héritière Anna Maria de Luxembourg; what would an English gardener make of this? We can only hope that it may not have such merit as to entitle it to be placed amongst our permanent Roses.

Another noticeable fact is that some of our British and American Roses find a place in these catalogues. Thus we have amongst Teas William Paul & Son's Duke of York; in Hybrid Teas, Mr. Geo. Prince's Clara Watson; in Hybrid Perpetuals, William Paul & Son's Clio and Dickson & Son's Marchioness of Downshire and Mrs. Sharman Crawford; in Noisettes, Grey's Alister Stella Grey and William Paul & Son's Lorna Doone. The following are the Teas, with the descriptions given of them by the raisers:—

**ANDRÉ SIBOURG (Renoul).**—A large globular flower, very double, salmon rose colour, bare of petals, the yellow shading off to silvery white; very free flowering and sweet scented.

**BARONNE GASTON CHANDOS (Lévêque).**—A very large full flower,

the colour metallic coppery yellow, shaded with peach and orange in the centre, the reflex golden yellow.

**CHEVALIER ANGELO FERRARIO (Bernaix).**—Very full, large flower, with large petals, firm footstalk, holding itself erect, purplish crimson red colour, lighted up with lighter carmine; a remarkable variety.

**CLAIRE GODARD (Godard).**—Variety with long pointed buds, a large full flower opening well, a pretty pure white colour; an abundant autumn variety.

**COMTE CHANDON (Soupert & Notting).**—A large full flower of a yellow lake (?) colour, with a bright citron-yellow centre, one of the most charming of the race; a cross between Lutea Flora and Coquette de Lyon.

**EDOUARD VON LADE (Soupert & Notting).**—Very large full flower of a bright rose colour; in the centre ochre, the reverse of the petals clear satiny carmine red; cross between Comte de Sembul and Socrates.

**E. VEYRAT HERMANOS (Bernaix).**—A large full flower, with a very pretty bud, yellowish apricot colour with amaranth rose at the backs of the petals; very sweet.

**FIAMETTA NABONNAND, or Papa Gontier, with white flowers (Nabonnand).**—This Rose comes with a grand flaming description, and the raiser thinks it sufficient to excite our admiration to say that it is as good in form and fuller than Papa Gontier; but the colour of this variety, which he describes as satiny white slightly tinted with carmine rose. It is not a sport, but said to be a cross between Papa Gontier and Niphotos.

**FRANCIS DUBREUIL (Dubreuil).**—This is said to be the finest red Tea Rose known, and is described as a full flower of a fine form, opening very readily, perhaps too much so; of a crimson red colour, with the reverse of petals cerise, with a long egg-shaped bud of great beauty.

**GLOIRE DE PUY D'ANGO (Nabonnand).**—A good nearly full climbing Rose of a carmine red colour, and golden in the centre, and very bright and clear.

**GRANDE DUCHESSÉ HÉRITIÈRE ANNA MARIA DE LUXEMBOURG (Soupert & Notting).**—Large full flower, the outside petals large, the inside ones narrower; clear Naples yellow shaded with red, peach red in centre; the reverse of the petals, as well as the buds, which are long, are shining and striped like "Luciole." Sweet and floriferous. Cross between Maréchal Robert and Rubens.

**HARRY LAING (Soupert & Notting).**—A large full flower of a fine form, clear orange-red colour, rosy in the centre, carnation red on the reverse of the petals; cross between Earl of Eldon and La Florifère.

**LOUIS LÉVÊQUE (Lévêque).**—A very large full flower, very well made, with a very long bud of a reddish brick yellow colour, shaded with yellow and golden vermilion.

**LOUIS NEYRET (Reboul).**—Of a dwarf habit, with a large full flower of good shape, the colour of a China Rose, shaded to yellowy orange at the base, the outside of the petals with broad margins of white.

**MADAME CHARLES FRANCHET (Liabaud).**—Large full globular shaped flower of a clear rose colour, shaded with yellow; the petals with broad edges of bright rose colour (a rather new colour).

**MADAME EMILIE CHARRIN (Perrier).**—A long bud, the flower medium in size and full, opening well; large thick petals, of a fine China Rose colour, shading to a brilliant scarlet; very free flowering.

**MADAME GEORGES BOULAND (Lévêque).**—A large full flower, very well made, with a handsome bud; a fine brilliant sulphur yellow colour, very lightly shaded with orange-yellow red.

**MADAME GEORGES DURRSCHMITT (Pelletier).**—An enormous flower, nearly 7 inches across, a globular shape; many and large petals, bright China Rose colour; the reverse of petals scarlet, shaded to clear cerise in the centre; very sweet; cross between Christine de Noué and Madame Falcot.

**MADAME HELOISE MANTIN (Lévêque).**—A very large full flower, of a magnificent shape; a bright citron yellow colour, darker in the centre, and sometimes shaded with peach rose; a very effective variety.

**MADAME JEAN ANDRÉ (Pelletier).**—A large full imbricated flower, with a long bud, of a dark red colour, sometimes striped with bright rose; cross between Van Houtte and Madame de Tarius.

**MADAME JULES SIEGFRIED (Nabonnand).**—Large, full cup-shaped flower, with a long bud of a creamy white colour shaded with flesh colour, darker in the centre; a good climbing Rose; cross between Rêve d'Or and Baronne Henriette de Loew.

**MADAME MUISON (Bernaix).**—A large full flower, with the guard petals large clear yellow shaded with salmon yellow, with back of petals coppery yellow; very sweet. A remarkably new colour.

**MADAME LAURENT SIMONS (Lévêque).**—A very large full flower, of a coppery rose colour shaded with red, and tinted with scarlet red.

**MADAME ROZAIN-BOUCHARLAT (Liabaud).**—A large convex-shaped flower, of a pale yellow tinted with rose colour.

**MADAME THIRION (Puyravard).**—A large flower, white at base, centre dark rose, with the edge of petals silvery white, and shaded with rose on the reverse of petals; seedling from Madame de Chatry.

**MADAME WAGRAM COMTESSE DE TURENNE (Bernaix).**—A large flower with very large buds and of a beautiful shape, and a satiny rose colour and still brighter red when full blown.

**MADAME DENISE DE RESERVAU (Lévêque).**—A large full flower of good shape, of a beautiful white, slightly tinted with yellow colour and shaded bright ochre.

**MDLLE. FRANÇOISE DE KERJÉGU (Lévêque).**—A large full flower, white, but tinted slightly with rose, the centre sometimes peach-red, very light, and yellow at the base. It has a delicious perfume of Violets.

**MDLLE. MARIE CREPEY** (Pernet Père).—A good shaped, large full flower of a yellowish-white colour, edged and glossed with bright red. Seedling from Marie Van Houtte.

**MDLLE. MARIE LOUISE BAGERIE** (Chainey).—A large, full cup-shaped flower of a beautiful chrome yellow colour, the reverse of the petals delicately pencilled with red; in the autumn flowering it is a golden yellow seedling of Gloire de Dijon.

**MADAME BONTOR PONTCARRE** (Lévêque).—A large, good shaped flower of a brilliant light rose colour, shaded with darker red and apricot yellow.

**MISS KATHERINE G. WARREN** (Bernaix).—A large carmine-red flower shaded with garnet shading off to a brilliant China Rose shade; very free flowering.

**MISTRESS MIRABEL GREY** (Nabonnand).—A large, erect, medium full flower not unlike "Papa Gontier," of a dark, velvety, carmine-red colour on the outside, lighter in the centre; seedling of Papa Gontier.

**PRINCESSE MARIE DE ROUMANIE** (Souper & Notting).—A large, good shaped, full flower, the petals large and rounded; a beautiful cream-white colour shaded with pale lake rose, and in the centre very pale vermilion red. A very delicate-coloured flower; cross between Madame Nabonnand and Souvenir d'un Ami.

**PRINCESSE DUROUSSOFF** (Souper & Notting).—A large full flower of a good shape, China Rose colour shaded with light melon yellow; cross between Paul Nabonnand and Madame Falcot.

**ROSE D'EVIAN** (Bernaix).—A very large, full, cup-shaped flower with a long bud of a fine magenta red before opening; the flower fine China Rose colour on the outside of the petals, scarlet on the inside of them.

**SOUVENIR DE FERIKE D'AUTUNOVICS** (Souper & Notting).—A medium-sized flower, very full and imbricated, milk white colour; an excellent variety for cutting. Cross between Madame Maurin and Marie Lambert.

**SOUVENIR DE LAURENT GUILLOT** (Bonnaire).—A large, full flower of a good China Rose colour, peach yellow in the centre, and the edge of the petals tinted with carmine. A very pretty variety.

**THERÈSE BARROIS** (Nabonnand).—A large flower of a perfect shape, rose colour, the reverse of the petals dazzling golden China Rose colour when half opened, golden tint in the centre when full blown; very free flowering.

**VALENTINE GANNET** (Nabonnand).—A very large, erect, full flower with large petals bright clear rose colour, reverse of petals silvery-looking, and slightly tinted with carmine; very free flowering. A fine variety.

**V. VIVO E' HIJOS** (Bernaix).—A novel flower in colour, very full, and outside petals very large; carmine rose colour, lighter in the middle and at the base; the interior petals numerous and irregular, very bright, sometimes golden, sometimes salmony or apricot, and often tinged with carnation. The mixture of red and yellow shades gives this flower a very attractive appearance.

It is of course impossible to guess even what may be the real character of these flowers, nor do the raisers' names give any indication of their quality, and it seems as if all must be left in a state of uncertainty for another season. Many of the descriptions sound very tempting, but we have learned to discount these very largely, and we shall probably not err in doing so now. Sometimes one gets information more or less reliable from some of our English growers, but this year I have had positively none, and I doubt very much whether we shall see many of these novelties amongst us this season. I hope to give in a future number a description of the varieties offered in other classes.—*D., Deal.*

## ROYAL HORTICULTURAL SOCIETY.

MARCH 12TH.

**SCIENTIFIC COMMITTEE.**—Present: Dr. M. T. Masters (in the chair); Mr. McLachlan, Prof. Müller, Prof. Church, Dr. Russell, Mr. Michael, Rev. W. Wilks, and Rev. G. Henslow (Hon. Sec.).

***Dendrobium Wardianum.***—A plant was exhibited by Mr. Hugh Low, lately received from Burmah, remarkable for having four flowers, two on one stem and two on a second stem, each pair of flowers being quite distinct, but arising from the same point, and all four flowers with two lips. Dr. Masters undertook to examine and report upon them.

***Libocedrus decurrens.***—Dr. Masters exhibited specimens received from Mr. Meehan of Germantown, Philadelphia, in which the terminal portions of the shoots had been attacked by some grub. The consequence was that the leaves, instead of being minute with mucronate tips and adherent to the axis, were broad at the base, free and lanceolate; thus bringing about what would seem to be a reversion to a more ancestral state of the foliage.

***Stelis, sp. (?)*, Diseased.**—Dr. Masters showed some Orchid leaves with rows of circular spots, having a central hole, due to some fungus. The specimen was interesting from an historical point of view, because it was figured by Gerarde, "Herball" (page 1168), in 1597, under the name of *Viscum indicum* L'Obelii. Being an epiphyte, this and a *Tillandsia*, called *V. peruvianum* L'Obelii, were supposed to be parasites, like the Mistletoe. Gerarde describes the leaf of this Orchid as having "certaine round eies, such as are in the haft of a knife."

***Chinese Primrose* x.**—Some umbels of flowers were received from Mr. Cannell, stated to be a cross, originally effected by Mr. C. Green, of Reigate, between the original wild form of *Primula sinensis*, from N.W. China, and a garden form of the same plant. The wild form

had never previously been known to be crossed. It is figured in the "Gardeners' Chronicle," March 16th, 1895 (page 327).

***Photos from New Jersey.***—Dr. Masters exhibited a series of photographs illustrative of *Nelumbiums*, *Nymphæas*, &c., growing in the open in ornamental waters, from Mr. S. C. Nash, of Clifton, N.J.

***Pinus cubensis, with Androgynous Cones.***—Dr. Mellichamp of Blufton, Sth. Carolina, forwarded some cones of one particular tree, which apparently produces this phenomenon every year.

***Larch Canker.***—Mr. Rogers sent a very characteristic specimen of this disease caused by *Peziza Wilcommi*. It appears to be due to the attack of this fungus after some injury, and then spreads throughout the tree. When this occurs no remedy can be applied, and the tree must be cut down. If, however, it be perceived early enough the infected part can be cut out, and coal tar or carbolic acid be applied to the wound; the fungus may then be killed and the canker arrested.

***Orchid Leaves Decayed.***—Some *Cypripedia* leaves were sent by Mr. O. O. Wrigley for examination. No fungus was apparent on a superficial examination. They were forwarded to Kew for further investigation.

***Trachymene, fasciated.***—Baron Ferd. Von Mueller sent a specimen of this plant with this common deformity from near Coolgardie, W.A.

## VEGETATION OF THE ITALIAN LAKE DISTRICT, ESPECIALLY OF THE LAGO MAGGIORE.

[Read at the Horticultural Club by Mr. H. BRISCOE-IRONSIDE.]

THIS subject, which Mr. D'Ombrian has honoured me in requesting that I should open this evening, is one which I think should indeed be taken up by the botanist rather than an inexperienced person like myself, as it is overflowing with the most interesting and knotty points, and is in many instances in exact contrast to what we experience here in England; and it occurs to me as being a somewhat startling fact, when one seriously considers the matter, that it is possible to find a climate so very different to ours after a journey of only about thirty hours.

Some of you present, gentlemen, may not be acquainted with that part of Italy to which I am referring, and I must include Switzerland, a small part of the Lago Maggiore being in that country; I will therefore endeavour to briefly describe the seasons and climate. Spring may be considered to open about the middle of February, summer about the middle of April (or generally immediately after the spring rains), autumn say the beginning of September, and winter about Christmas. The winter in ordinary seasons may therefore be roughly estimated at about seven or eight weeks. There are, however, several places in the Lake District where the winter is prolonged.

As is generally the case in all mountainous regions the variations in the temperature and weather are extreme and local, and this is particularly felt in this district—*e.g.*, 8 kilometres from Pallanza, where I resided, Lemons and Oranges flourished entirely out of doors. On the Isola Bella, about 2 kilometres distant, where Oranges are cultivated to a considerable extent, they are protected by wood coverings during the winter, and at Stresa, about 4 kilometres away, artificial heat is necessary.

The soil of the district is extremely sandy and stony, and considering that it does not rain for months at a time, you can imagine what the cultivation of plants and flowers in exposed positions means. I have seen huge trees, the leaves of which have flagged for a considerable period. For pot use I found that the best substitute for a retentive soil was the decayed wood of the Chestnut, which the native women easily procure in large amounts from the woods and carry on their backs. In consequence of the large quantity of silica in the soil the effect of a thunderstorm or heavy rain on land which at all slopes is disastrous, the soil being washed away in large quantities. To meet this contingency it is necessary to construct gulleys and small canals or rivulets with considerable forethought. The less said in the way the Italians fertilise the soil the better, as it is distinctly objectionable to the English idea, and should not, I think, be tolerated. It amply illustrated to me the force of the nigger's explanation on the effect of fertilisers—*viz.*, that directly a plant began to smell it endeavoured to run away.

The chief industry is the cultivation of the Vine. It at first struck me as curious how every native, in whatever sphere of life he was, seemed thoroughly well versed in this subject. I had a little practical experience myself, having some 200 or more Vines in my garden, which included Muscat, Barbera, a red Sweetwater, and an American. This last variety—which the Italians called "Americana"—has a very large and almost globular purple berry, is very fleshy and almost stoneless, and has a flavour somewhat resembling a Black Currant (I believe the strictly technical term is "foxy"). The wine made from it is, however, considered "rough," and is not much drunk by the better classes. It is, nevertheless, very popular in this part of Italy on account of its robust growth, its distinct superiority as a stock for grafting, and also for its greater resistance to the phylloxera. I may remark that the flavour of the berry is perceptible in the sap, which might also account for the less vigorous attacks of the insect.

It may perhaps be of some interest if I mention a few details on the subject of phylloxera, as one of my most intimate friends was the Anti-Phylloxera Delegate appointed by the Government to this district. I thus heard a good deal, and I may add as a further reason for cultivating a closer acquaintance on the subject was that one morning I found a score or so of men disturbing the roots of several of the Vines in my

garden, and were all hard at work with picks and shovels without having given me notice (the Englishman's house being his castle is not so well appreciated in Italy as in England). However, the foreman and I were soon friends, as he told me he had lived in England for some time. Pieces of the roots of every Vine were examined by these rough labourers, and it is remarkable how they are easily able to detect any sign of the pest. I did not feel at all at ease until they had taken their departure, as the remedies employed for preventing the ravages of phylloxera are very severe in Italy. Immediately the disease is discovered the very next day a large troop of men appear with their implements, superintended by the Government Delegate, and inject sulphide of carbon into the ground at about every 2 metres. All parts of the Vine, branches, leaves, and roots are dug up, and placed in heaps and fired. Wherever the injector is inserted everything living within a radius of 2 to 3 metres is effectually destroyed, and nothing will grow, so I was informed, for nearly five years after. The Government compensate to the extent of 30 per cent. on one year's crop.

While I was living at Pallanza the phylloxera was discovered on a very large portion of the Monte Rosso, tenanted by men who had supported their families for many years by the cultivation of Vines and Beans. The Government Delegate was informed that any attempt to interfere with the soil would be resisted by force. At the approach of the Carabinieri and soldiers bells were sounded, and the women and children mustered in great numbers and clung to the invaders, so that they were powerless to do anything. Finally the Government abandoned the affair. Plants are forbidden to be sent out of an infected district, although flowers and cuttings may be sent by pattern post. There is also a great deal of difficulty and trouble in introducing plants into Italy from England, except by pattern post, owing to Great Britain having declined to enter into the Berne Convention.

My friend informed me very seriously that Italy had to thank England for the introduction of phylloxera, and stated that it was traced to some private vineyard in England. Not being in a position to contradict this statement I merely laughed, and replied that it was fortunate for him that England had been so attentive, as otherwise he might not have found employment.

In all good vineyards the Vines are syringed three or four times during the season as a preventive against mildew, which the natives call "Peronospera." The mixture employed usually consists of 6 kilos, or about 13 lbs. sulphate of copper to 100 litres of water, with sufficient lime to give substance. The object of the lime is that the sulphate of copper may not be so easily washed off by rain. I mention this little point, as I have recently observed in the horticultural press other reasons for the use of the lime. The effect of the application is plainly noticeable, as where not used the leaves are more or less withered before the berries are ripe, and in consequence the fruit is impoverished. I may mention that in this district the white Muscat suffered most from Vine mildew, and was, of the four kinds I have mentioned, certainly the least robust.

I observed that Vine mildew and Chrysanthemum mildew were most prevalent in Italy during the two hottest months—viz., July and August, and it has seemed to me as not improbable that the great variations in the temperature during these two months might at least be responsible for the encouragement, if not actually the origin of these diseases.

Vines are usually planted about 10 to 12 feet apart, are allowed four rods, and are trained to closely cut Mulberries, Laburnums, or other trees, or strong stakes supported triangularly, but very frequently they are formed into arched avenues. The berries keep well for months if cut with the foliage and hung in ventilated rooms. After they have been pressed for wine the skins are again pressed into circular shapes and dried in the sun, and are then used by the poor class for firing. The leaves are generally removed from the trees just before they would naturally fall, and are put to various uses; there, therefore, is not much waste in the "Vine," although I observed that the sampling of the produce seemed on rather an extensive scale.

One cannot pass through this district without admiring the trees and their luxuriant growth, and what is particularly striking at first is that they seem to have no rest whatever, for almost as soon as the leaf has fallen the bud appears again, and I suppose that is owing to this continuous and rapid growth that the timber is soft and coarse-grained, and an interesting comparison is seen with the English and Italian Oak, but especially is observable the rapidity of the growth of the Acacia.

An arborist or a lover of trees would find sufficient interest and pleasure for some time in the Isola Madre, about half a kilometre from the shore of Pallanza. This island is of considerable repute for its very choice and rare collection of trees, and is a show place like its sister island, the Isola Bella. I have heard that there is no other such representative collection of tropical trees so near to England as is to be found on this island. The two islands I have mentioned, and also the Isola Piscatori, which is only inhabited by fishermen, are known as the Borromeo Islands and belong to the old Italian family of Borromeo. Conifers, Rhododendrons, and Azaleas are magnificently represented at the Villa Clara Baveno, where Her Majesty stayed in 1879. Magnolias flourish and abound everywhere, and there are some typical examples in the noted Franzosini Gardens. Fratelli Rovelli of Pallanza have also a very fine and extensive collection of trees of all kinds, and are specially famed for their Conifers.

How well the climate and soil suit trees and how easily they grow may be partly seen in an instance which I will quote. I was having a tennis lawn made in my garden, and it was necessary to remove two good-sized Apple trees, the trunks of which were not less than 18 inches

in diameter. My surprise was great when I saw that these two trees were only resting on soil of about 6 inches in depth, the rock being immediately underneath, and that the roots which were only just covered extended for a very long distance. The trees were standards, probably thirty years old, and to see them as it were with their big trunks only just resting on the top of the ground, much impressed me at the time, as it seemed as if the slightest breath of air must of necessity blow them down. They amply conveyed to my mind how beautifully controlled are the laws of gravitation in Nature.

The climate clearly points out the effect of dry *versus* moist air, as flowering plants, which require protection in England, flourish in Italy when there is a stiff and continuous frost, and as a foremost and most simple example I may instance the Camellia. I cannot presume to adequately describe Camellias in bloom in Italy, but once having seen them the effect can never be forgotten. The trees grow to a considerable height, and are smothered with blossom from top to bottom.

Palms thrive in the open, as also the Mimosa, Oleanders, and Bamboos; but those shrubs and plants that are apt to suffer or break their branches from snow are generally protected with straw caps or umbrellas. In this district snow is very capricious, but, roughly speaking, except on the mountains it rarely falls to any great depth or lasts for any time, although I am able to say that this season has been an exceptional one there. When there is a fall of snow, it is at once seen that Bamboos are not lovers of a snowy country, in consequence of the extensive snapping of the canes after only a slight fall. The effect of a fall of snow of any extent is often very disastrous to trees and shrubs by reason of their very luxuriance. Hydrangeas and Salvias are very fine, while the Castor-oil Plant also grows very freely, and produces a very decorative effect.

Roses are luxuriant, although the semi-double and Monthly Roses seem to do best; but the climbing varieties are the most patronised. Maréchal Niel grows freely, but I missed the charming, and if I may say, original shade of yellow of the long and graceful bud as seen in this country. So far as I was able to judge the sun seemed to be too much for the large double flowers, and reds soon lost their colour. A very popular Rose in this district, and one which is often seen on the houses, is I think known as Fortune's Yellow. The flower, although of some size, has not much substance, but its tints are exquisite. A house not far from mine was covered to the roof with this variety, and the effect can be better imagined than described. I believe this variety does not flourish here.

Roses are practically not cultivated, and do not succeed as standards, possibly due to the great heat affecting the trunk; and I would remark, if I may, although I have only a very little practical experience of standards either in the case of Roses or fruit, that it has seemed to me theoretically that there might be the same disadvantage to standards in this country, though from the opposite cause—viz., cold, and I have often desired to ask whether the "canker" of fruit trees is evenly balanced between standards, bush or other systems of cultivation.

Geraniums are not a success, as they go to leaf, and often very little of that; but Cannas are evidently suited to the climate, and are most useful, and require but little attention.

The mountains have quite a little flora of their own, and include such flowers as the Gentian, Edelweiss, and many kinds of Cacti, which blossom profusely.

The growth of grass is remarkable, the crops varying from two to four in a season. I sowed a lawn with seed in the first week of April and at the beginning of the next month the grass had grown 1½ inch in height, but it would have been entirely burnt had I not paid great attention to it. Lawns in Italy will not bear comparison with well kept English grass, the sun perhaps being considerably responsible for this, but rolling, which I never saw a native doing, would have doubtless improved matters. My lawn was the recipient of many compliments entirely due to the roller, but I may state that wherever an Englishman resided his garden was generally a subject of remark. The effect of burning grass, as also the use of wood ashes on a silicious soil, produced a highly satisfactory result.

Vegetables in this district give much trouble, especially to suit an Englishman's fastidious tastes. Even the native sorts do not succeed well in this part, and English varieties, with but few exceptions, are out of the question. The climate suits Melons admirably, but Tomatoes from English seed have a great deal of disease, although the native kinds seemed to be exempt, and were also more bitter in flavour than ours. Maize is extensively cultivated in this part, polenta forming one of the chief articles of food for the poor.

Fruit trees such as Apples, Pears, Plums, Cherries, Japanese Medlars, Apricots, Peaches, and Figs all bear immense crops, depending greatly on the weather of the month of May, the two evils being cold wind and hail (I believe this is also the case in England). In the absence of these, good crops may be expected, although, as with us, Apples and Plums alternate more or less. Figs fruit twice, and are very luscious, as also are Peaches, the fruit being much softer and more juicy than English Peaches, and, what is an important point, are marvellously cheap; but of Grapes it is difficult to speak, as I cannot say whether it is the flavour or the thinness of the skins or the quantity that makes Italian Grapes so much appreciated, but probably it is the *tout ensemble*. They should not, however, be eaten too generously and without care, as they form a very important medicine on the continent, for besides that which is known as the "Grape cure," which I believe is efficacious in consumptive cases, the Grape has other medicinal properties—e.g., I heard from a recognised authority that Grapes eaten in the early morning have a

lowering effect, and were so appreciated by doctors, and that eaten in large quantities they entirely alter one's constitution. The American Grape, to which I have referred already, is not recommended by doctors on account of its heating properties.

A great scourge to fruit trees in this district, particularly to Apples, Pears, Plums, and Quinces, is a bright red caterpillar, which the natives call "bruco rosso," and which if not checked literally mines the trees. The only means of eradicating this insect is to cut into the tree and so get it out. I spent many hours in this amusement, and afterwards had all the trunks limewashed, which seemed effectual, as I was not further troubled myself with these creatures while residing in Italy. Some large trees had, however, been so badly attacked as to be of no further use.

A great plague also was another caterpillar which we frequently see in England. When I took possession of my garden I noticed at the top of some Firs large bags of web, which I had brought down. They contained myriads of these caterpillars, each insect being about 1½ inch long. My man collected seventeen of these bags, and I weighed one, and it turned the scale at 3½ kilos, or rather more than 7 lbs., but I understand this is no unusual weight. To destroy them was not such an easy matter as it appeared. We first of all adopted the plan occasionally followed in destroying wasps' nests—viz., soaking them with petroleum and then setting them alight. But this was of no avail, as the web proved quite fire-proof, and not the slightest visible effect was produced. I then had a big fire made, and the webs opened and turned inside out, and the contents thrown on to the fire, but I never wish to witness again so unpleasant an operation. I suppose we must have overlooked a bag somewhere, for later on in the year I noticed a large Apple tree literally smothered with these caterpillars, and nearly every leaf devoured just before the fruit would have ripened. It was a good Apple year, but the fruit from this tree dropped prematurely. I may add that these bags of web, which were I suppose their hibernating quarters, were frequently to be seen in this part.

Doubtless the almost utter absence of birds in the district accounted for the multitude of insects of all kinds. The poor birds hardly seemed to have a chance, and directly a sparrow was seen it was shot at. Anyone travelling in this part will at once have his attention attracted to the number of little birds, including robins and nightingales, exposed for sale. Moreover, the natives have not the slightest regard to where or how they shoot, and I have an old Panama at home which has saved my headpiece scores of times.

In conclusion, gentlemen, I will say that my little experience of practical or theoretical horticulture was considerably modified during my residence of about three years in Italy, and I will quote an instance as to what I mean. I observed my man one day with several Acacia boughs, of which he was pointing the ends. These branches were from 2 to 3 inches in diameter and perhaps 7 or 8 feet long. On my asking him what he was doing, he replied that the hedge wanted repairing, and that he was putting in a few trees. These boughs, after being well pointed at the end, he pressed into the dry stony ground as far as he could, and his statement was fully borne out, as the following year the boughs were in blossom.

#### ACACIA OVATA.

THE utility of Acacias as winter and spring flowering plants is becoming more and more recognised, and rightly so. There are numbers of varieties all possessing great merits, but none, perhaps, is more useful than the variety portrayed in fig. 45, and of which a correspondent recently sent us a splendid spray, with the request that we should furnish him with the name. The character of the plant is fairly well shown in the engraving, but the spray has necessarily had to be reduced. It is most useful for culture in 48-size pots, being of dwarf bushy habit, and producing its bright yellow flower heads freely. The plant is easily grown, readily forced, stands well, and is altogether exceedingly useful, being more graceful than the early Acacia platytera.

#### A SCOTTISH LADY HORTICULTURIST.

THERE are few more earnest horticulturists in Scotland than Mrs. McDouall, of Logan House in Kirkmaiden parish, Wigtonshire. Throughout the entire year it is a pleasure to me to pay frequent visits to her extensive and beautiful gardens, either in her own company or that of her head gardener, Mr. Gilbert McMicking. There is no season, however exacting the atmospheric conditions, in which flowers are not discoverable there. In the spring the Daffodil, the Crocus, the Hepatica, the Tulip, and Anemone; in the summer, the Rose, the Viola, and the Eastern Lily; in the autumn the Dahlia, the high-towering Hollyhock, and the long-lived Chrysanthemum; in the winter the yellow Jasmine, Viola odorata, and the Christmas Rose. At all periods of the year there are flowers under glass. Nearly a fortnight ago, on February 25th, I was presented by Mr. McMicking with two very fine blooms, grown in the central conservatory, of *Souvenir d'un Ami*, and the white Bank-sian Rose. Mrs. McDouall has always been an enthusiastic Rose cultivator; and her collection embraces all the more celebrated Hybrid Perpetuals, Bourbons, Chinas, Noisettes and Teas. My love of Roses was first created by periodical visits to Logan Gardens; and I well remember that, twenty years ago, my supreme favourites were Duke of

Edinburgh and Beauty of Waltham, two varieties of enduring attractiveness, which have always been splendidly cultivated there. Mrs. McDouall has been adding very largely of late to her stock of Tea Roses and Hybrid Teas; but it is extremely unfortunate for her first experience of many of these, and especially those of recent introduction, that last summer should have proved, for obvious reasons, so unfavourable to their floral development, and that the recent winter should have been one of unprecedented severity.

Mrs. McDouall is, like all true lovers of Nature, very fond of climbing flowers, which are largely cultivated both in the garden and in the conservatories. Among these are the various species of Clematis; *Tropæolum speciosum*, which grows to a great height and luxuriates everywhere; the exquisitely graceful *Ipomœa cœrulea*; and *Lapageria rosea*, which is also much grown by Madame Adelina Patti at Craig-y-Nos Castle. The south wall of the flower garden, which encloses

FIG. 45.—ACACIA OVATA.

the picturesque ruins of Logan Castle, is covered in summer with Clematis montana, Tropæolum speciosum, and those highly ornamental Noisette Roses, Celine Forestier and Rêve d'Or. These and many other stately climbers bloom contemporaneously, creating an impressively artistic effect.

It should also be recorded that the Lady of Logan is a great cultivator of Oriental Lilies, among her possessions in this floral department are *Lilium Henryi*, *L. auratum platyphyllum*, *L. Humboldti*, *speciosum Kraetzeri*, *Martagon album candidum*, *davuricum*, *tigrinum splendens*, *Krameri*, and *L. longiflorum giganteum*, of which the last mentioned is almost identical with the Lily of Bermuda, *L. Harrisii*. These she grows midway between the gardens and the mansion house on circular borders previously monopolised by Azaleas and Rhododendrons, which had to give place to their more admired successors, the natives of Siberia, America, China, and Japan.

Fruits of various kinds are largely cultivated at Logan, among those which succeed best being the Black Hamburgh, Buckland Sweetwater, and Muscat of Alexandria Grapes; the leading varieties of the Peach;

the Guava, a fruit which, in Scotland at least, is too seldom seen; the Sultan, Monarch, Green Gage, and Victoria Plums; the Duke, Early Rivers, and Bigarreau Cherries, and all the more prolific modern Apples and Pears. Mr. McMicking, the superintendent of the gardens, is thoroughly conversant with the subject of fruit cultivation. He had the great advantage when a young man of being assistant to the late Mr. Fowler, head gardener to the Earl of Stair at Castle Kennedy, who made this fascinating form of culture a great speciality, though he was also an authority on tropical plants and flowers. Mr. McMicking's favourite pomologist, many of whose finest creations he has, like myself, been recently acquiring, is Mr. T. Francis Rivers. I have for many years been confident of this, that without a considerable number of the invaluable fruit trees which have originated at Sawbridge-worth, no collection would be complete.

As an instance of Mrs. McDowall's deep interest in fruit culture in all its aspects, it may here be recorded that during last summer she made a pilgrimage to King's Acre, Hereford, distant at least 300 miles from Kirkmaiden, in order to inspect the extensive orchards there; and she has often subsequently spoken of that visit as one of the most interesting within the range of her remembrance. She was also much impressed on that occasion with Mr. Cranston's collection of Roses.

Mrs. McDowall's genial and accomplished husband, who is almost equally interested in horticulture, though the science of astronomy is his predominating theme, is one of the most extensive proprietors in the south of Scotland. His father was colonel of the 2nd Life Guards, and was, I understand, a great favourite of Her Majesty the Queen. He was an eminent agriculturist, and made the desert rejoice and blossom with the Rose, or at least with the scarlet Poppy that grows among the corn. Mrs. McDowall is a daughter of the late Sir Thomas Hepburn, Bart., of Smeaton Hall in Haddingtonshire. She is, like several contemporary horticulturists, among whom is Mr. Harry Turner of Slough, a highly accomplished instrumental musician; and though she plays the piano-forte with infinite expressiveness, she is more deeply attached to the English concertina. Her master passions are music and the love of horticulture. Her life is divided between the daily practice among the destitute and the suffering of unobtrusive beneficence, and the cultivation of those noble and gracious arts.—DAVID R. WILLIAMSON.

### LIVERPOOL NOTES.

ON Saturday evening Mr. T. White presided over a very good attendance of members at the William Brown Street Museum, the subjects for the evening's discussion being "The Cultivation and Judging of the Pea," by Mr. J. Smith, Waterdale, St. Helens, and "Two Methods of Preserving French Beans," by Mr. J. Fairhurst, Aigburth.

#### PEA CULTURE.

Mr. Smith stated that to grow the Pea to perfection it was essential that the ground be well drained and deeply trenched. Notwithstanding the many varieties catalogued, he considered the two best to be Ne Plus Ultra and General Windham. Should it happen that too many were coming in at one time, he advocated stopping two or three times as the case might warrant. He was not in favour of the largest Peas when judging, but preferred a moderate sized, well-filled pod of fine flavour, the latter he considered the greatest point in the test. An interesting discussion followed, Mr. Mercer strongly advocating the dwarf varieties for small gardens, Mr. Stoney favouring the tall growing varieties for abundance of crop.

#### PRESERVING FRENCH BEANS.

Mr. Fairhurst, in referring to this subject, suggested two methods, the first being to procure earthenware jars about 20 inches deep and across. Cut the Beans as usually served to table, placing a layer of them 2 inches deep at the bottom, then 1 inch of salt alternately, until the jar was filled. Place on the top two or three Vine leaves, then cover with a piece of wood or earthenware lid, on the top of which, as pressure, place a heavy stone. In a day or two remove the covering, fill up again with Beans, remove the Vine leaves, covering as before. When wanted for use take out the Beans required for the day, and steep in cold water two or three hours before using.

The second method was to have earthenware bottles with good sized necks, run them through boiling water, then dry thoroughly. Place a piece of sulphur on a plate and set it on fire, placing a funnel over it. Hold the necks of the bottles on to that of the funnel for about a minute to sulphur the bottles inside, corking them to keep in the sulphur. Cut the Beans as mentioned in the first method, and boil for about fifteen minutes with sufficient salt to season, taking care of the liquid. Fill the bottles three parts full of Beans, and the remainder with the liquid. Cork tightly, place in a pan of water, boil for a short time, taking care that no water enters the bottles. A bottle of Beans should be used when opened, as they will not keep for any length of time. The usual votes of thanks were carried unanimously.—R. P. R.

### FORCED STRAWBERRIES.

#### AVERAGE WEIGHT OF FRUIT PER POT.

ON page 234 "Saynor," with that keenness which gardeners have long associated with the name, manages, in a very plausible way, to advance a rather ticklish question for my consideration. It is not an unusual occurrence for Strawberry forcers to record in the horticultural

press the weight of some abnormally heavy crop, but any attempt to define "a fair average crop per pot" has been left for the fertile brain of a "Saynor" to suggest, and a humble "Fragaria" to act on. So now to the talk.

At the commencement I shall take my stand on the conviction that the mere weight of fruit produced per pot gives no definite idea of its value for commercial purposes or for private use. Undersized fruits are not valued by employers, and will only be purchased by the public at very low rates. This points out clearly that our aim must be to produce as many large fruits per pot as the plants are able to perfect. To accomplish this we must confine our attention to crown flowers only; side flowers should therefore be removed as soon as they appear.

In early Strawberry forcing it is generally a difficult matter to induce more than six crown flowers to expand within a few days of each other, and I find that if the plants are kept under conditions favourable for securing fertilisation for only a few days longer to allow other flowers to open the earlier fertilised flowers fail to swell their fruits satisfactorily, the somewhat dry conditions necessary to fertilisation having caused the skins of the young fruits to toughen. Under these circumstances I maintain it is better to be content with a good half dozen fruits than to spoil their chances of developing properly by waiting for other flowers to set.

From the present time onwards the setting of the flowers is a comparatively easy matter, and it is not difficult to obtain from twelve to fifteen fruits on a large per-centage of plants; but these will scarcely ever be uniform in size, and it is a well-known fact that those which are comparatively small when they commence swelling will exhibit the same characteristics when ripe, and I maintain that if nine of the largest and best formed fruits are retained the extra size they will grow to will fully compensate for lack of numbers.

In regard to the weight per pot, if we take such varieties as Sir C. Napier, Noble, or James Veitch, if well grown, but few of the fruits should weigh under 1 oz., and one-third of the number will usually be considerably heavier. Making due allowances for pots having less than nine fruits, and for fruits weighing less than an ounce, my estimate for a fair "average weight of fruit per pot" is 5 ozs., and those who can maintain such an average will be no mean adepts in the art of Strawberry culture.

As to the query, "What per-centage of plants may be expected from good culture to be worthy of retention at the final stage?" the answer to this depends largely on two important matters—viz., the care exercised in selecting the runners at layering time, and the precautions taken not to force the plants on too rapidly in the early stages of growth. If these matters receive due attention, 95 per cent. If they are neglected the per-centage will often fall as low as 70 or 80.

I have given you what you asked for, "Saynor." Now cut it to pieces with your keen-edged blade.—FRAGARIA.

### SPRING SHOWS.

#### CRYSTAL PALACE.—MARCH 16TH.

THE first show of the year at the Crystal Palace was held on the above date, and cannot be termed a great success. The classes provided numbered twenty-eight, but in many of these there were no entries, whilst in others there were only one or two. This is not very encouraging for the Crystal Palace Company, who, with Mr. Head, do their utmost in the way of advertising and offering of substantial prizes; and they certainly deserve far more support. We trust at the corresponding show in 1896 that not only will there be a very much larger number of entries, but that the quality of the exhibits will be much better than was the case this year, when it was, with few exceptions, decidedly below the average. We append a list of the prize-winners in the chief classes in which there were exhibits.

One of the principal classes was for thirty-six Hyacinths, and despite good prizes there were only two competitors, of whom Mr. Jas. Douglas, gardener to Mrs. Whitbourn, Great Gearies, Ilford, was an easy first, though not showing quite so well as he has done in previous seasons. Amongst the varieties staged, the following were noticed as being the best and having the finest spikes and the richest coloured flowers:—Grandeur à Merveille, Garibaldi, Princess Mary of Cambridge, King of the Blues, Etna, Lord Derby, Princess of Wales, Mont Blanc, Captain Boyton, Vuurbaak, Sir Henry Barkley, Electra, Koh-i-Noor, Souvenir de J. H. Veen, Gigantea, La Grandesse, Czar Peter, Charles Dickens, and the Sultan. Messrs. Jas. Winter & Sons, West Norwood, were a very poor third, no second prize being accorded.

The chief Tulip class was for thirty-six, three bulbs in a pot, and here again Mr. J. Douglas secured the premier position. The plants were dwarf, sturdy, strong, and carrying handsomely formed flowers of good size and strikingly rich colours. Particularly prominent were Keyser's Kroon, Ophir d'Or, Duchesse de Parme, Vermilion Brilliant, Joost Van Vondel, Proserpine, White Joost Van Vondel, Fabiola, and Van der Neer. The only other competitor was Mr. W. Howe, gardener to H. Tate, Esq., Park Hill, Streatham Common, who received the second prize. His plants was somewhat tall and leggy, but carrying very creditable flowers; Keyser's Kroon, Chrysolora, Van der Neer, Vermilion Brilliant, and Proserpine were conspicuous.

The same exhibitors as in the previous class were opposed in that for twenty-four pots of Polyanthus Narcissi, and the same order with regard to prizes was maintained. Mr. Douglas' stand comprised Mont Cenis, Grand Monarque, Gloriosa, Adonia (a handsome, free blooming,

yellow variety), Bazelman Major, and Jaune Supreme. The plants were capital examples of good culture. The plants in the second prize stand were fairly good, carrying good numbers of flowers.

Mr. W. Howe was a very fine first with twenty-four pots of Narcissi, Daffodil section, showing Sir Watkin, Princeps, Bicolor Horsfieldi, Telamonius plenus and maximus in magnificent form. Mr. J. Gibson, gardener to E. H. Watts, Esq., Devonhurst, Chiswick, was a highly creditable second.

Decidedly one of the best features of the whole show were the Cyclamens shown by Mr. J. Mowbray, gardener to Major the Hon. H. C. Leggc, Fulmer, Slough, in the class for thirty-six pots, and for which he very deservedly received the first prize. All the plants were dwarf and sturdy, clothed with clean well-marbled foliage, and carrying splendid flowers on stout footstalks well above the leafage. The colours were rich and well diversified. Mr. T. Pestridge, Boston Park Road, Brentford, was a poor second.

The first prize for twelve Amaryllises was gained by Mr. J. Douglas with well-grown plants, conspicuous amongst which were Mrs. Laing, Melpomene, Urania, Thalia, Mrs. Douglas, Erato, Terpsichore, Euterpe, Clio, and Polyphema. Mr. William Howe was second with good examples.

For twelve Cinerarias Mr. J. Douglas was first with fair plants, and Mr. J. Slater, gardener to Mrs. Nothard, York House, Lower Sydenham, was placed second. Mr. W. Barrett, gardener to Mrs. Thornton, The Hoo, Sydenham Hill, was the only competitor in the class for nine trained plants of Mignonette, for which he was awarded the first prize.

One of the chief classes was for a group of flowering and foliage plants to be arranged in an oval space, 12 feet long by 9 feet wide, and faced all round. Messrs. J. Laing & Sons, Forest Hill, were the only competitors, and deservedly took the first prize. Amongst the plants utilised were some fine Orchids, handsome Caladiums, Palms, Ferns, Amaryllises, Clivias, Begonias, Crotons, and Ericas. Unfortunately, the space at disposal did not give Messrs. Laing sufficient scope for the display of their talents in the arrangements of plants, and it is to be hoped that the space will be increased three or fourfold at a future exhibition, when a far better result will be obtained.

The first prize for twelve Hyacinths, distinct, was won by Mr. J. Gibson for a collection consisting of Gigantea, Von Schiller, King of the Blues, Princess Amelia, Koh-i-Noor, La Innocence, Moreno, Lord Derby, La Grandesse, Souvenir de J. H. Veen, Macaulay, and Electra. The second prize fell to Mr. W. Barrett, the best flowers being Lord Derby, King of the Blues, and Sterling Beauty; Mr. John Schumacher, gardener to M. Jacoby, Esq., Lynwood, The Avenue, Gipsy Hill, London, being a close third.

The class for twelve pots of Tulips was only poorly represented, Mr. James Gibson gaining the first prize with a group in which were Ophir d'Or, Keyser's Kroon, Joost Van Vondel, Van der Neer, Proserpine, and Rose Luisante were conspicuous. No second prize was awarded, and the third prize fell to Mr. James Wyatt, gardener to J. Perry, Esq., Bradenhurst, Caterham Valley. For twelve Polyanthus Narcissus in pots Mr. James Gibson was the only exhibitor, and was awarded first prize, the chief varieties being Her Majesty, Gloriosa, Mont Cenis, Jaune Supreme, and Bathurst. In the class for six pots of Lily of the Valley, Mr. C. Lane, gardener to E. H. Coles, Esq., Brentwood, Upper Caterham, Surrey, was first, the pots being exceedingly well furnished.

There were four entries in the class for twelve Cyclamens. Mr. W. Slogrove, Gatton, Reigate, was a good first; Mr. F. Watts, gardener to O. J. Trinder, Esq., Mount Vernon, Caterham Valley, being second, and Mr. C. Lane third. Mr. James Bateman, gardener to Mrs. King, Sydenham Hill, was first for twelve Chinese Primulas with well-flowered examples, Mr. C. Lane being a fair second, and Mr. Spong, gardener to C. D. Lord, Esq., Dunearn, Sydenham Hill, third. Mr. J. Mowbray was first for a table of Cyclamens arranged for effect, and was the only competitor.

The miscellaneous exhibits were not very numerous, but some flowers and plants of good quality were to be seen. Messrs. W. Paul & Son, Waltham Cross, staged a fine collection of Camellia blooms, and also pots of Duke of York Rose. Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, sent a fine group of hardy flowers, comprising Irises, Narcissi, Dog's Tooth Violets, Crocuses, Saxifragas, and Spiræas, amongst others. Messrs. J. James & Son, Farnham Royal, exhibited Cinerarias in superb condition, while Messrs. J. Peed & Son, Norwood, arranged an effective group of flowering and foliage plants, and also showed floral decorations, in which Lichens played a prominent part.

One of the most handsome exhibits in the miscellaneous section was a group arranged by the Crystal Palace Company. It comprised foliage plants principally, but was relieved by Hyacinths, Tulips, Richardias, Clivias, Azaleas, and a few Orchids. It was placed in an oval space, and reflected great credit on those responsible for its formation. From Messrs. J. Laing & Sons came plants of Nicotiana affinis variegata, Bertolonias, and others.

#### READING.—MARCH 19TH.

THE above Society held its spring bulb show on Tuesday at the Queen's Hall, Valpy Street, Reading. The competition in some of the classes was not keen, though the exhibits in most were of a high order.

In the class for eighteen Hyacinths in pots the first prize was gained by Mr. Turton, gardener to John Hargreaves, Esq., Maiden Erlegh, for well-bloomed plants of Duke of Albany, Sutton's Matchless Blue, Sutton's Matchless Yellow, King of the Blues, L'Innocence, King of

the Reds, Sutton's Inimitable, pure white, and others. Mr. Dockerill, gardener to G. W. Palmer, Esq., Elmhurst, Reading, was second with a collection containing good spikes of Princess Mary of Cambridge, L'Innocence, Captain Boyton, and La Grandesse. The third prize fell to Mr. Woolford, gardener to Alfred Palmer, Esq., East Thorpe, Reading. In the class for twelve Hyacinths, Mr. W. L. Walker, Balmershe Road, was awarded first prize, this being the only exhibit in the class.

There was only one entry in the class for six pots of Tulips. Mr. Turton was awarded first prize, his exhibit consisting of Vermillion Brilliant, Pottebakker White, Duchesse de Parme, Joost Van Vondel, Keyser's Kroon, and White Joost Van Vondel. For three pots of Tulips Mr. Woolford, the only competitor, secured the first prize.

Mr. F. Lees, Connaught Road, Reading, gained first prize for six pots of Lily of the Valley, Mr. Dockerill being second, and Mr. Woolford third. The first prize for three Dielytra spectabilis was gained by Mr. Dockerill, the second by Mr. Bright, gardener to J. Karlake, Esq., and the third by Mr. Woolford. For six pots of Spiræa japonica Mr. F. Lees was first, Mr. Willis, gardener to H. J. Symonds, Esq., Caversham, second, and Mr. Turton third. Mr. Bright was first for four Deutzia gracilis, Mr. Dockerill second, and Mr. Booker, gardener to J. B. Monck, Esq., third.

For three Azalea indica Mr. Bright was first, and Mr. Booker second. Six Azalea indica, Mr. Turton was first, there being no other exhibits. Mr. Woolford was first for six Cinerarias, Mr. Willis second, and Mr. Chamberlain third. For three Cinerarias Mr. E. Chance, The Shrubberies, Burghfield, was first, and Mr. Hinton, gardener to Major Babbiscombe, Bath Road, Reading, second.

The first prize for six stove and greenhouse plants was gained by Mr. Turton with Acacia armata, Dendrobium nobile, Imantophyllum miniatum, Azalea amœna, Begonia gigantea, and Phalænopsis Schilleriana. For three Cytisuses, Mr. Bright was first with well bloomed plants; Mr. Chamberlain second, and Mr. Booker third. The first prize for six table plants was won by Mr. Woolford, and the second by Mr. Dockerill, these being the only two exhibits.

Mr. Chamberlain was awarded first prize for six single Primulas, his plants being large and well bloomed. The second prize fell to Mr. Dockerill, and the third to Mr. Willis. Only one exhibit appeared in the class for six double Primulas, for which Mr. Barker was awarded first prize. The class for six Cyclamen were represented by three exhibits, Mr. Woolford gaining first prize, Mr. F. Lees second, and Mr. Booker third. The first prize for a group of flowering plants arranged for effect, in a space not exceeding 60 square feet, was gained by Mr. Woolford with a fine collection, amongst which were Euphorbia jacquiniæflora, Narcissi, Arum Lilies, Hyacinths, Cinerarias, Tulips, and Cyclamens. Mr. F. Lees was a close second with a neat collection; and Mr. Chamberlain third.

The first prize for three Orchids was gained by Mr. Turton for splendidly bloomed plants of Cymbidium Lowianum, Dendrobiums Wardianum and nobile. The second prize fell to Mr. Bright for Dendrobium nobile and Cœlogyne cristata, and the third to Mr. Woolford. Mr. Turton was first for twelve cut Roses.

FRUIT.—Mr. F. Lees gained first prize for six dishes of dessert Apples, consisting of Barnack Beauty, Baumann's Red Reinette, and Riene des Reinettes. Mr. Turton was second with Cockle Pippin, Sturmer Pippin, Northern Spy, and others. For six dishes of kitchen Apples Mr. Turton was first with good fruit of Annie Elizabeth, Alfriston, Rymer, Wellington, Northern Spy, and Norfolk Bearer; and Mr. F. Lees second. Mr. F. Lees was the only exhibitor for three dishes of dessert Pears, gaining first prize with Easter Beurré, Olivier de Serres, and Josephine de Malines. The prize for one dish of Strawberries fell to Mr. F. Lees, who was the only exhibitor.

Miscellaneous exhibits included a fine collection of flowering plants, and floral designs by Messrs. Phillips, Broad Street, Reading; and Mr. Perkins, gardener to Hon. F. D. Smith, M.P., Greenlands, Henley-on-Thames, staged eighteen Amaryllis arranged with Palms and Ferns.

#### ROYAL BOTANIC SOCIETY.—MARCH 20TH.

THE first spring show of this Society was held on the above date, and proved to be of good quality and variety. The corridor was well filled, as also was a considerable amount of space in the large conservatory. The show, as usual, was largely composed of non-competing groups and collections of flowers from various nurserymen. The number of entries in many of the competitive classes for amateurs was small, owing possibly to the fact that these are somewhat restricted. The abundance of floral colour and beauty was exceedingly bright and varied, though if anything was deficient it was elegant foliage plants, which assist so materially in producing a really tasteful effect.

The first prize for a group of Azaleas was awarded to Mr. R. Scott, gardener to Miss Foster, The Holme, Regent's Park, for well-flowered and shapely plants of George Loddiges, Madame Van der Cuyssen, Sigismund Rucker, Duc de Nassau, Helen Carmichael, Stella, and others. Mr. H. Eason, gardener to B. Noakes, Esq., Hope Cottage, Highgate, was second with plants of Stella, Baron de Verie, Sigismund Rucker, Apollo, Countess de Kerchove, and Madame Van Houtte.

Mr. T. S. Ware, Hale Farm Nurseries, was the only exhibitor for a collection of hardy herbaceous plants, obtaining the first prize. Conspicuous in the group were Saxifraga Burseriana, Primula denticulata alba and cashmeriana, Hepatica triloba cœrulea, Fritillaria pudica, and Cyclamen Coum.

The first prize for a group of Cyclamen fell to Mr. T. Pestridge, Boston Park Nursery, Brentford. The plants were well grown and

thickly bloomed, large flowers being prominent on stout footstalks, while the foliage was well marbled and sturdy. For a group of Lily of the Valley in pots Mr. R. Scott was first with plants of only moderate quality. For a group of Amaryllis Mr. H. Perkins, gardener to Hon. F. D. Smith, was awarded first prize for fine spikes of Charles Penny, Countess of Arran, Lady Winifred Gore, Miss Claire Stopford, and others. Mr. Jas. Douglas, gardener to Mrs. Whitbourn, Great Gearies, Ilford, was second, the spikes not being so fine as in the former instance.

Mr. Jas. Douglas was first for twelve Hyacinths in pots, his group consisting of fine spikes of Lord Derby, King of the Blues, Garibaldi, Souvenir de J. H. Veen, Czar Peter, The Sultan, Koh-i-Noor, Sir Henry Barkley, La Grandesse, and Princess Mary of Cambridge, and others. Mr. H. Eason, gardener to B. Noakes, Esq., Hope Cottage, Highgate, was second, and Mr. R. Scott third. For twelve pots of Tulips Mr. Jas. Douglas was again first with splendid plants, the flowers being large and distinct in colour. Mr. R. Scott was second with plants not nearly so good, and Mr. H. Eason third. The best collection of Crocus was staged by Mr. R. Scott, and the second prize was gained by Mr. Jas. Douglas, the latter being first for a group of Deutzias.

*Miscellaneous Exhibits*—Amongst the large number of miscellaneous exhibits Messrs. John Laing & Sons, Forest Hill, staged a fine group of mixed plants, for which a small silver medal was granted. Messrs. J. Peed & Sons, Norwood, staged a collection of flowering plants of bright colour. One of the chief features of the show was the group of Orchids and other plants staged by Messrs. B. S. Williams, Upper Holloway, for which a large silver medal was recommended. Clivias also made a magnificent display in this exhibit. A small silver medal was also recommended to Messrs. Williams for a superb exhibit of floral designs.

Messrs. T. Jannoch, Dersingham, staged Lily of the Valley, the spikes of which were arranged in artistic clumps and pyramids on a ground-work of green moss. A small silver medal was recommended for this group. Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, was recommended a large bronze medal for a highly creditable group of hardy bulbous plants. Messrs. Barr & Son, Covent Garden, staged a good collection of hardy bulbous flowers.

Mr. J. R. Stevens, Clayton Nurseries, Hassocks, was awarded a certificate of merit for plants and fruit of his new Strawberry Stevens' Wonder. A small but creditable group of miscellaneous plants were staged by Messrs. Jas. Veitch & Sons, Chelsea. Messrs. Paul & Son, Waltham Cross, staged Camellias in pots, Rose Duke of York, Clematis indivisa lobata, and stands of Camellia blooms, for which a large silver medal was recommended.

#### HARDY FRUIT GARDEN.

**Protecting Fruit Blossom.**—*Coping and Blinds.*—For affording adequate protection to wall trees when in blossom and during the early stages of the young fruit's development a coping either of wood or glass is most convenient, if not indispensable. In some cases and seasons the coping may be sufficient protection of itself, but the addition is almost invariably required of a light covering of tiffany, woollen netting, or double fish nets. Any of these protecting materials used must be made moveable, so that the trees can be covered or uncovered quickly.

The best method is to depend the material from the front edge of the coping, fixing it there with rings which can run on light iron rods stretching the entire length, though they will necessarily be in sections. The material is thus easily drawn on one side or pulled upwards in favourable weather to admit light and air freely, and to prevent coddling. Before the blossoms of Apricots, Peaches, and Nectarines open it is advisable to shade the trees in bright weather, thus retarding the expansion of the blooms longer than would be possible with full exposure to hot sun. This is all the more necessary when sunny mornings are succeeded by sharp cold periods and frosty nights. When frost is imminent and the trees are in bloom run the protecting material over them at sunset. Should stormy weather prevail in the daytime while the blossoms are expanded keep the protection over them. If not in bloom there is no fear of a few degrees of frost doing harm—in fact, at this time cold weather is a useful check, preventing the influence of warm walls bringing the trees prematurely into bloom.

*Protecting with Poles and Nets.*—In the absence of coping from which to suspend protecting material some light poles placed in front of the trees, one end resting against the top of the wall, the other firmly fixed in the ground several feet away from front of trees, will afford support for netting or other material. A double or triple thickness of fish netting forms admirable protection, and as it admits light and air freely there is no necessity to move it to and fro after once placing it over the trees until it can be dispensed with altogether. Protection need not be afforded within 2 feet of the ground in any case.

**Strawberries.**—Beds and quarters of these will need some attention in clearing away dead and badly discoloured foliage which has suffered from the frost. The removal of this affords space for placing

rich material as a mulching closer round the crowns, radiating from which are to be found the greater bulk of the surface roots. Assistance thus rendered to them aid materially the new growth, strengthening the flower trusses and benefiting the fruit subsequently. If used fairly fresh and strawy, spreading it over the entire space between the plants, it affords a clean resting bed for the fruit when ripe. Previously to applying the mulching, which may be done just as growth commences, it is an excellent plan to darken the soil with soot. In dry soils a dressing of chemical manure, such as nitrate of soda, at the rate of an ounce to the square yard, or 2 lbs. per rod, is very beneficial, as it accelerates the growth and proves of great advantage to the crop. Occasional applications of any of the advertised chemical manures are likewise good. The manurial mulching, however, should not be discarded, as it prevents rapid evaporation from the surface, and the virtues in the manure are gradually washed into the soil and appropriated by the roots.

**Spring-planting Strawberries.**—Late-rooted runners that were planted thickly in beds in the autumn on sheltered borders may now be removed and placed permanently in rows, selecting well prepared and liberally manured ground, so that growth may start freely, the plants developing strong crowns during the summer. Spring-planted Strawberries should not be allowed to flower the first year. If they do so, their energies, which ought to be directed to the production of stout crowns and foliage, are appropriated by the small trusses of flowers and fruit. The result is seen in inferior fruiting the following year, as well as a dwarf stunted growth. It is desirable that the flower trusses should show, so that it is known that the plants are of a fruiting instead of a blind character or barren. The latter ought to be uprooted at the same time as flower stems are broken from the others, because they will never do any good.

Lift each plant with as much soil as will adhere to the roots, planting in suitable sized holes so as not to cramp the loose outside fibres. Make the soil quite firm about them, and afterwards spread a light mulching of stable manure between the rows. The distance apart to plant depends on the variety, the strongest requiring 30 inches, while those of weaker habit may only require 20 to 24 inches between the rows. In order to economise space Lettuce may be sown or planted between the plants the first summer. In addition to cutting away the flower trusses detach the newly produced runners before they extend far.

**Stimulating Raspberries and Currants.**—As these have abundance of fibrous roots near the surface a thick mulching of manure placed on the soil over them will have its virtues speedily appropriated by the multitudinous rootlets which are attracted to it. Liquid manure applied now will descend and feed the lower roots, some of its fertilising virtues being washed and stored in the soil to be drawn upon in the future.

**Planting Fruit Trees.**—All kinds of young fruit trees and bushes ought to be planted as soon as possible, the ground being in good working order and becoming warmed. The operation should be carefully carried out, cutting off the bruised ends of roots and spreading out the latter in light loamy soil near the surface. Afterwards mulch lightly all newly planted specimens, and securely stake those that require it before the winds loosen their hold of the soil.

#### FRUIT FORCING.

**Peaches and Nectarines.**—*Early Forced Trees.*—When the fruits are stoning too high a temperature at night and on dull days is not favourable; cold draughts, sudden fluctuation or depression of temperature, and checks of every kind, such as deficiency of moisture at the roots and parching atmosphere, are even more injurious; therefore maintain as agreeable conditions as practicable. Continue the temperature at 60° to 65° at night and on dull days, 70° to 75° by day with gleams of sun, ventilating from 65°, freely at 70°, and not allowing an advance over 75° without full ventilation, closing at 75° but not so early as to cause the temperature to rise more than 2° or 3° afterwards. Attend to thinning the fruit, it being inadvisable to leave more than twice the number of fruits that are to be left for the crop for stoning, as it is the seed that exerts the greatest strain on the trees. One fruit to every square foot of trellis covered with foliage is ample for the large-fruited varieties, the medium-sized and Nectarines being left a little, but not much, closer. See that the successional shoots for bearing another year are properly tied to the trellis as they progress, stopping unduly vigorous at about 15 inches, or if very gross and likely to interfere with the due distribution of the sap or induce gumming, remove them altogether. If the pinching results in laterals stop them to one leaf or joint, treating sub-laterals similarly, and if extension is wanted the uppermost lateral or most promising may be trained in as a continuation. When the trees are in good order there is little necessity for stopping the growths, they being trained in their full length, allowing space for the development of the foliage in order to solidify the wood as made. Shoots, however, retained to attract the sap to the fruit should be finished after the first stopping at two or three good leaves to one leaf as growth is made.

*Second Early Forced Trees.*—Attend to disbudding, performing it gradually, leaving a promising shoot at the base of the present year's bearing wood, and one on a level with or beyond the fruit, this growth being pinched, unless required for extension, at the second or third good leaf. On extensions in young trees leave shoots on last year's wood at 15 inches to 18 inches distance along them, the shoot at the extremity being trained as a continuation of the primary branch, but only such

numbers as to provide main branches or subsidiary ones at 12 inches apart. Commence tying down early, as when the shoots are allowed to grow to a considerable length they cannot be brought near to the wood they proceed from without danger of breaking. Avoid overcrowding the growths, as it is fatal to fine, highly coloured fruits, and to the sound formation and thorough maturation of the wood of future crops. Thin the fruits by degrees, leaving those well exposed to light and in good place for swelling on the upper side of the bearing wood, always in sufficient quantity for the crop, with some over for contingencies. In no case is it good practice to tax the trees with superfluous fruit after it is of the size of marbles. Temperature 55° to 60° at night, 60° to 65° by day artificially, increasing to 70° or 75° with gleams of sun, but with ventilation from 65°, ventilating freely between 70° and 75°, not allowing it to rise above the latter without full ventilation.

**Houses Started at the Beginning of February.**—The trees are in full blossom or setting the fruits. Continue to fertilise the flowers on late trees when the pollen is ripe and the house freely ventilated, as, unless bees visit the trees, it is not wise to rely on self-fertilisation, and when the house from unfavourable external conditions must be kept close, or with a small amount of air only, practise fertilisation from about 10 A.M. to 1 P.M. After the fruit is all set recourse must be had to syringing in the morning and afternoon of fine days, occasionally only in dull weather, and always sufficiently early in the afternoon to allow the foliage and young fruit to become dry before nightfall. Attend carefully to disbudding, proceeding gradually, and commencing with the most vigorous parts, also to thinning the fruit after it is seen which takes the lead in swelling, not deferring it after the largest are the size of horse beans, removing the smallest first, but avoiding large reductions of fruit as well as of shoots at one time. Temperature 55° at night, 5° less on cold mornings, 55° to 60° by day, ventilating at 60°, freely at 65°, and fully before 70° is reached, a close atmosphere in the early stages tending to lean growths and thin foliage, should be carefully avoided, ventilating a little constantly, and increasing it early in the day.

**Houses Started in March.**—The blossoms are expanding, and syringing after the anthers show clear of the petals serves no useful purpose, but in dull weather causes the discolouration of the flowers and converts the pollen into paste, therefore it should cease with prominence of colour in the flowers, but damping the floors and borders on fine days to maintain a genial condition of the atmosphere. Admit air freely in mild weather, and fertilise the blossoms individually when the pollen respectively is ripe. Maintain a night temperature of 45° to 50°, 55° by day artificially with a slight increase of ventilation, and 65° by sun heat with full air. Leave a little ventilation constantly at the top of the house. Where there is a superfluity of flowers, those on the under side or at the back of the shoots may be removed expeditiously by drawing the hand down the growth. This gives the flowers left a better chance of setting the fruit.

**Late Houses.**—The buds are well advanced in swelling, and when the anthers show in the centres of the expanding blossoms they must be kept in safety and steady progress. Turning on the heat in the early part of the day assists the fruit in setting, advancing the temperature by 8 A.M. to 50° and keeping at that during the day but not more by artificial means, with enough ventilation to promote a circulation of air. Without such means, and during the prevalence of dull cold weather at blossoming time, necessitating closing the ventilators for safety, an atmosphere is produced that converts the pollen into paste, and the setting of the fruit is indifferent or uneffected. The borders should be properly supplied with water, giving sufficient to thoroughly moisten the soil through to the drainage. If there be the least trace of aphides fumigation must be had recourse to before the flowers expand.

**Cherry House.**—After the effectual fertilisation of the flowers the swelling of the Cherries proceeds rapidly, and to assist the fruit in throwing off the decayed parts of the flowers, as well as to refresh the trees and keep insects in check, syringing must be resumed once a day in dull weather and twice daily when the weather is clear, the last syringing being practised in time for the foliage to become fairly free from the water before dusk. Fire heat will only be necessary to prevent the temperature falling below 40° at night, and maintain it at 50° during the day in dull weather. Ventilate at 50°, closing at the same, regulating the ventilation according to circumstances, always having it full at 65°. If green aphides appear fumigate the house, having the foliage dry and delivering the smoke cool. Keep a sharp look out for grubs, which, if let alone, soon spoil the foliage and berries. Stopping will need attention when the shoots have made 4 to 5 inches of growth, the points then being pinched out. Extensions of growth required for furnishing the trees train in full length, removing those shoots that are not required for this purpose or forming spurs, as overcrowding is prejudicial to the current and future crops.

**Figs.**—*Early Forced Trees in Pots.*—The swelling of the fruits must be accelerated by top-dressings of rich material applied to the surface of the soil, and with the layers of turves placed round the rims, or by means of zinc or slate introduced inside the rims of the pots, space is afforded for top-dressings. Heavy and too rich dressings do more harm than good, a little and often being the most eligible method as regards top-dressing with either solid or chemical manures. On the other hand, dribbles of water or liquid manure do little good, but thorough supplies so as to pass through the pots are effective. A genial atmosphere, maintained by syringing twice a day when the weather is bright, is essential for the healthy growth of Fig trees, but avoid keeping the foliage constantly wet, lessening the syringing in dull periods.

Sprinkling the paths, walls, and bed two or three times a day secures a congenial atmosphere, but forcible syringings occasionally are necessary for dislodging red spider, and it must not get ahead, or it will spoil the foliage and crop. A little sulphur applied to the hot-water pipes gives off fumes that keep the pest in subjection. Admit a little air at 70°, increasing it with sun heat to 80°, not allowing an advance over 85° without full ventilation, and close at 80°, after which an advance of 5° to 10° will be beneficial than otherwise. The night temperature may still range from 60° to 65°, 55° in the morning in severe weather being safer than the higher temperature, advancing to 70° or 75° by artificial means in the daytime, except when cold and dull, when the heat should be kept at about 65°. Stop the shoots as required to about five leaves, tying the shoots as the growths advance, so as to keep the heads sufficiently open to admit light and air, preventing overcrowding by judicious disbudding.

**Pines.**—*Suckers.*—The rooting of the recently potted is indicated by the growth, but this must be ascertained by turning a portion out of the pots, and when the bottom heat is excessive the pots be raised, as the roots issuing from suckers or recently started plants are tender and susceptible of injury. A temperature of 85° is ample when the roots reach the sides of the pots, and above this there is danger, therefore raise the pots where the bottom heat is likely to injure the roots by placing some loose tan under and around them, so as to allow the superabundant heat to pass off without injuring the roots, yet according a temperature of 80° to 85° about the pots. Careful watering is necessary, making a close scrutiny of the soil, and then supplying it to such as need a supply at the same temperature as the bed.

When the plants from suckers or those disrooted become established they root rapidly, therefore soil should be prepared for transferring them to the fruiting size of pot, as it is important they be grown on without check by being either too dry or root-bound. Sound fibrous loam is the best material for potting, breaking it up in good sized lumps, pressing it firmly down and round the balls of the plants, watering with tepid water after potting if the soil be dry, as it only ought to be moderately, but if moist water need not be given till the soil needs a supply. Plunge the pots in a bottom heat of 90° to 95° until the roots have ramified through the fresh soil, when 85° is more suitable.

Fruiting plants, and those that are at or near the flowering stage, should have a night temperature of 65° to 70°, 75° by day, with 80° to 90° from sun heat, closing at 85°, and well damping the house at that time. Afford successional plants a bottom heat of 85°, and top heat 5° less all round than for the fruiting plants, ventilating at 80°, and closing at 85°, lightly sprinkling the plants occasionally.

**Strawberries in Pots.**—Until the trusses are showing it is well if the temperature does not exceed 50° by artificial means, and between that and setting 55° is safe, advancing to 65° by day with free ventilation. Abundance of light is absolutely essential until the fruits are set, but afterwards they are liable to become dried, hence they swell best in positions where the sun's rays are not strong at midday, or slight shade may be given under direct exposure for a few hours when the sun is fierce. After the fruit is set and swelling a temperature of 60° to 65° at night, 70° to 75° by day, with an advance from sun heat to 80°, 85°, or 90° is desirable, affording copious supplies of water or liquid manure until the fruit shows indications of ripening, when somewhat drier and more airy atmospheric conditions with diminished supplies of water at the roots will afford large well-swelled fruit of good flavour. Thinning the fruit must be attended to as soon as the setting is completed, removing the smallest and deformed fruit, and on no account must there be insufficient water at the roots during the swelling, but at the flowering stage undue moisture or the opposite extreme is prejudicial, suffice that the soil be kept healthfully moist. The chief object in Strawberry forcing is to secure an early and unbroken supply until those in the open ground come in, and this, where there are a number of houses started at intervals, will admit of its being done without much trouble or change of plants, whilst in others some tact will be necessary to meet the requirements. All plants should now be in position for advancement by gently forcing, or if not they should be brought under glass without further delay. Some may be advanced in houses where there is a gentle heat, and others by placing them in cool houses where they will come on gradually, in all cases examining and rectifying defective drainage, cleansing the pots and surface soil.

#### THE FLOWER GARDEN.

**Rapid Propagation.**—Owing to heavy losses among the stocks of Zonal Pelargoniums, Calceolarias, and Violas, there will of necessity be much more propagation of other kinds of plants to be done in order to make good these deficits. Verbenas, Fuchsias, Heliotropes, Ageratums, Iresines, Colcuses, and such like can be rooted and grown to a serviceable size very quickly, always provided the cuttings are forthcoming in sufficiently large quantities. The surest and quickest way of rooting young tops of any of these plants is to place them thickly in watertight pans or saucers half filled with silver sand, and kept constantly supplied with water. These pans or saucers may be set on the hot-water pipes in a forcing house. Roots will form quickly, and there will be few or no failures. Directly the cuttings are well rooted shift the pans to rather cooler quarters, and before the roots become matted together either place the plants singly in small pots or more in boxes, using a rather light compost, previously warmed, in any case. Under this treatment, the plants being kept in heat, there will be no serious check given to their growth, and the tops will soon be long enough for making into cuttings.

**Tuberous Begonias.**—Seeds sown this year have not germinated quite so well as usual, this being probably due in many instances to the

overheating of the hot-water pipes during the long spell of frosty weather. Directly the seedlings can be moved with the aid of a forked stick prick them out in boxes or pans of fine light soil. Keep in moist heat and shade from bright sunshine. They ought to have yet another move into other boxes or to a mild hotbed. They should not be placed in pots, as they move badly out of these. Medium sized bulbs of last year's raising will develop into fine plants by June, and if it can well be avoided these should not be divided. Larger, older bulbs, arranged somewhat thickly in boxes of rich soil in preference to pots, and placed in gentle heat, will form numerous shoots, and when these are 1 inch or rather less in height the bulbs may be split into several pieces, each with one or more sprouts attached. Coat the cut portions with silver sand, and then place all in boxes or pans of good light loamy soil. Keep in gentle heat, and when they are rooting freely transplant to other boxes or, better still, to beds of good soil over a nearly spent hotbed. In this way strong plants will be prepared for the beds in June.

**Carnations and Picotees.**—Seedlings raised this spring and well grown will flower far more freely than most of the plants raised from cuttings. Where disease weakens or ruins the older plants seedlings ought certainly to be grown, as they need only be expected to flower once owing to every growth developing into a flowering stem. A percentage of seedlings will be single, but if the best strains of border varieties are sown the greater portion will be of superior quality, and some of them well worthy of preservation. A strong dry heat is fatal to a good start, the seeds germinating far more surely in a newly started vinery, or in a frame over a nearly exhausted hotbed. A little later on a cold frame will be found the best place for starting the seeds. Sow thinly in pans or boxes of fine loamy soil, cover with squares of glass, and shade heavily. When the seedlings appear transfer to cooler quarters, and not far from the glass. Pot off singly when 1½ inch high.

**Pinks.**—These may also be raised from seeds as easily as Carnations, and will flower strongly the following season. In this case, again, seedlings will be found more vigorous and produce finer flowers than do those otherwise propagated. Plants of choice varieties in pots may be propagated from now, young side shoots being the best for the purpose. Slip these from the old stems and root them in pans of water as advised in the case of Verbenas and such-like plants.

**Gladioli.**—It is a mistake to keep these too long out of the ground. When planted early in April they usually start strongly, and produce finer spikes of flower than do those planted much later. If wanted extra fine give them the benefit of a root run in good fresh loamy soil, surrounding the corms with sharp sand, and covering with 4 inches of soil. If planted in rows they should be from 12 inches to 18 inches apart, or they may be thinly grouped. A carpeting of Mignonette with Gladioli dotted thinly among this forms an effective bed. The Mignonette may be sown after the corms are planted, or be planted out of small pots a little later on. If it is decided to distribute a few Gladioli in a bed of mixed flowering and fine-foliaged plants, the former ought to be started in 5-inch pots and planted out with the rest.

**Sowing Half-hardy Annuals.**—Asters, Stocks and Zinnias may be sown in quantity during the first fortnight in April in gentle heat, but Marigolds ought not to be sown yet. All will germinate the most surely in gentle heat in boxes covered with glass, this precaution being specially necessary if there are mice about. Shade from bright sun, and keep the soil uniformly moist. Sunflowers may be raised in a similar manner, though the end of April is soon enough to sow the seeds. That time is also quite as early as Balsams should be sown. *Zea japonica*, or Japanese Maize, may well be raised in quantity, as these frequently prove very effective in mixed borders. Sow the seeds singly in 3-inch pots and place in heat.

**Hardy Annuals.**—Where the borders were forked over or dug early in the winter the soil ought now to be in excellent condition for seed-sowing. There are many beautiful things among hardy annuals, and properly grown most of them will flower freely till severe frosts prevail. Prepare circular patches irregularly in mixed borders, making these fine and level. Sow the seeds thinly, and cover with a little fine soil—some brought from the frame ground answering best if the ordinary soil is heavy or lumpy. The plants should never be crowded, but it is well to sow more seeds when plants are required, as losses may occur. The following may be sown now:—Alyssum, *Bartonia*, *Calandrinia*, Candytuft, Cornflower, annual *Chrysanthemum*, *Clarkia*, *Convolvulus*, *Coreopsis*, *Eschscholtzia*, *Godetia*, *Helichrysum*, *Hibiscus*, *Larkspur*, *Linum*, *Malope*, *Mignonette*, *Nasturtium*, *Oenothera*, *Poppy*, *Sunflower*, *Sweet Sultan*, *Tropæolum*, *Virginian Stock*, *Viscaria*, and *Ornamental Grasses*.

these need not be kept in the apiary longer than May. By that time young queens can be easily bred and fertilised in time to supersede aged ones, and with extra breeding space are the best and only means to prevent swarming in storified hives. Hives properly managed on the swarming system, where the honey season does not commence before the middle or end of June, are by far the most profitable; besides, there is no risk of a hive collapsing as a non-swarming one with a worn out queen frequently does.

Our first swarms are those on which we depend for large yields of honey of the finest quality, provided the bees issue several weeks before or at the beginning of the honey flow. In the event of the queen of a swarm relaxing in egg-laying at a time that would affect late honey gathering I depose her, and introduce a young but fertile one as early as possible. My safety cage shows at a glance whether it may be safe to release her or not. Many claims have been laid to "direct introduction," but the fact remains that the term is misleading. There is no safe method of direct introduction. The queen regnant must first be deposed, and the bees have time to realise their loss before it is safe to allow an alien queen in their midst.

#### FASTENING COMB FOUNDATION.

I have pleasure in informing "R. D." that where foundation is fixed with wax in a groove or between a split bar the work may be performed at any time; but where it is done by pressure it is better to postpone the fixing till near the time it is wanted. If done earlier the movement of the wood by contraction, and the absorbing of damp, causes the foundation to part from the bar or section. This causes extra labour, and if unobserved crooked combs.—A LANARKSHIRE BEE-KEEPER.

#### SEASONABLE NOTES.

REPORTS to hand from several districts complaining of the disastrous effect of the past winter all tend to show how severe the losses have been among a great number of bee-keepers. Many of them I am convinced were preventible, and were the instructions that are given in these notes weekly more closely followed, many stocks that have succumbed would now be strong and healthy. I never advise others to do what I do not practise myself. I have proof of the assertion that many colonies might have been saved, as in my own apiary not a single stock has been lost; all are strong and in good condition.

I have never before been so successful in wintering. This is the more encouraging, as I have more colonies than usual this winter, thus showing that the severe weather alone is not responsible for the many losses that have occurred. Such successful wintering is not brought about by any special method. Had my hives all ventilated floor boards I should probably have concluded that it was in their favour; but, with the exception of two, all have solid floor boards. These being loose, bottom ventilation can always be given by propping up the hive or otherwise. Neither is it owing to any particular class of hive; although mine are of the standard size, other hives are probably quite as good for wintering purposes. I prefer to have my hives and frames interchangeable, and for convenience in working and securing the greatest yield of honey with the least amount of trouble, I have found the standard frame hive to answer the purpose better than any other.

Neither do I think it is owing to any special variety of bees, as mine are now all composed of our native black or brown bee as true as it is possible to have them. I consider them better adapted for our changeable climate, being hardy, good workers, and not as liable to the swarming mania as many of the foreign breeds, and, what is of great importance, their freedom from disease. Had bee-keepers in the past been satisfied with our native bee, and reared queens only from their best stocks instead of importing foreign queens in great variety, there would have been a better class of bees for honey gathering in this country (and that is what we require them for), and much greater freedom from disease than at present.

I know other bee-keepers who are beginning to come to the same conclusion. In some parts of the country foul brood is such a terrible scourge that it is almost impossible to keep bees with any amount of pleasure or profit; fortunately it is unknown in this locality, long may it remain so.—AN ENGLISH BEE-KEEPER.

## ABRIDGED PROSPECTUS.

THIS CORPORATION has been formed for the purpose of affording greater facilities in respect of the Insurance of Nursery and Garden Glass against damage by Hail. It will meet a long-felt necessity, and will greatly benefit all owners of Glass Houses.

The enormous growth and strength to which the Nurserymen and Market Gardeners' Trade has attained, and the immense area of Glass now erected and under erection in all parts of the United Kingdom, in the opinion of the Directors, fully justify the formation of this Corporation.

The main feature of the Corporation is that it shall be for the mutual benefit of the Trade; and it is confidently anticipated that the majority of Nurserymen, Market Gardeners, and Owners of Glass Houses will become Shareholders and Insurers.

### PREMIUM.

The Rate of Premium to be charged will be 10/- per cent. on 21 oz. glass (which will be 1/3 per 1000 feet, valued at 3d. per square foot; 1/0½ per 1000 feet, valued at 2½d., and 10d. per 1000 feet, valued at 2d. per square foot), and on 15 oz. glass, 15/- per cent. Special arrangements may be made for the Insurance of Glass of greater weight.

### CLAIMS.

Compensation will be paid on Glass broken by Hail at the rate per foot at which it is insured.

The Memorandum and Articles of Association can be inspected, and Prospectuses, Forms of Application for Shares, and Proposal Forms obtained on application at the Offices of the Corporation.

Agents required in every Town and District in the United Kingdom.

THURSDAY, MARCH 28, 1895.

### DAHLIA ANALYSIS—1883-94.

THE exhibition held by the National Dahlia Society at the Crystal Palace in September last was, taking all the different sections into consideration, one of the largest the Society has yet held. The "Shows" were more numerous than at any exhibition since 1890, while there was a similar advance in the Fancies, which were more largely staged than at any recent show, with the exception of 1892. The display of Pompons was about average. Cactus and Decorative Dahlias were not exhibited in quite as large numbers as in the previous year, but as compared with the earlier records they show a very marked increase, and the same may be said of the singles.

The actual number of blooms and bunches staged at the last five shows is given in the following short table.

	1890	1891	1892	1893	1894
Shows (number of blooms) ..	934	854	879	720	894
Fancies .. .. .	283	286	340	270	301
Pompons (number of bunches) ..	214	193	267	168	192
Cactus and Decorative..	156	158	209	264	246
Singles .. .. .	95	124	138	128	138

In the above statement the number of flowers shown in the classes set apart for three or more blooms of any one variety have not been included.

The unfavourable character of last season is indicated by the inferior records of most of the best Show Dahlias. I refer, of course, to the established varieties. For instance, Mrs. Gladstone, now for the ninth year in succession the premier flower in this section, was staged in fewer stands than at any previous exhibition. William Rawlings, Mrs. Langtry, Willie Garratt, Prince of Denmark, and T. J. Saltmarsh were also indifferently represented. There were, however, a few noteworthy exceptions. James Cocker, the oldest Dahlia in the list, for example, was more frequently to be seen than at any Crystal Palace show since that of 1887. Ethel Britton, another old favourite, also did remarkably well, being oftener staged than at any of the eleven previous exhibitions. Miss Cannell, Burgundy, and Queen of the Belgians likewise appeared in an unusual number of stands.

Turning our attention now to the newer kinds, it will be found that most of these have improved their positions since the last analysis

was issued. Of the four on the table which were distributed in 1890, Duke of Fife has lost two places, but nevertheless still occupies a very good position at No. 17; John Hickling rises from No. 22 to No. 19, Majestic from No. 34 to No. 26, and Alice Emily from No. 50 to No. 47. The year 1891 is altogether unrepresented; but four sorts bear the date of 1892, three of which were much better shown at the last exhibition than at the previous one. The first of these is that grand new white variety, John Walker, which has risen from No. 7 to the second position on the list, and last year appeared in nearly as many stands as the leading flower—Mrs. Gladstone. Next comes Arthur Ocock, which rises from No. 21 to No. 11. Then Arthur Rawlings, which now stands at No. 15, thus gaining seven places, and lastly William Powell, which has fallen from No. 15 to No. 24. No 1893 variety is to be found as yet on the table. Duchess of York, however, although only sent out last year, just manages to secure a footing at the bottom of it, having been staged six times.

Of the fifty Show Dahlias tabulated in this analysis four were introduced previous to 1875—viz., James Cocker (No. 10), Henry Walton (No. 13), Mrs. Harris (No. 35), and John Standish

(No. 37), and are consequently twenty or more years old. Four came out during the next five years, seventeen during the next five, sixteen between 1885 and 1890, while the remaining nine varieties are less than five years old.

The question arises, How do the flowers sent out in recent years compare, in regard to quality, with those previously distributed, as gauged by this analysis? If we divide the last twenty-four years into two equal parts, the average position the varieties raised during the first twelve years of this period would be entitled to occupy would be at No. 27, while those of the last twelve years would stand at No. 25. When the first thirty-six sorts are alone taken into consideration the results come out still more favourable to the "Shows" sent out during the last twelve years. These results are very encouraging, and in the interests of the numerous florists for whom the marvellous regularity of form to be found in the Show Dahlia has a peculiar fascination, it is to be hoped that the present rage for the more generally popular Cactus varieties may not cause our Dahlia experts to relax their efforts to produce new sorts worthy of being placed side by side with their predecessors.

\* New varieties, the positions of which are dependent on their records at the 1894 show only.

In the table of Fancy varieties it will be noticed that Mrs. Saunders and Rev. J. B. M. Camm, both more than twenty years old, continue to run each other very close, the former, however, still retaining a slight lead. Mrs. John Downie follows immediately on their heels, and threatens at any time to spring into the first position. There are few changes in this list since the last analysis was issued as regards the older Fancies.

Of the sorts sent out in 1890, T. W. Girdlestone has risen from No. 13 to No. 7, whereas Buffalo Bill (No. 17) has fallen two places. Comedian, an 1892 variety, has made capital progress, rising from No. 24 to No. 12, or twelve places.

Treating the Fancies in the same way as I have done the Shows, three varieties are found to be twenty or more years old, four between fifteen and twenty, five between ten and fifteen, and eight less than ten years old. The average position which those sent out in the first twelve years would occupy in the analysis would be at No. 12, while those introduced since then would stand at No. 8.

The advance made in the Cactus, as distinguished from the Decorative section, is truly surprising, when we consider the character of the flowers staged a few years ago as Cactus Dahlias compared with those now set up at the early autumn shows throughout the country. At the 1890 exhibition of the National Dahlia Society the leading sorts were Mrs. Hawkins, Empress of India, Panthea, Amphion, Juarezii, William Darvill, William Pearce, and Cochineal; whereas on the list of Cactus Dahlias recently revised by that Society, and now numbering thirty-four varieties, only one of the above finds a place—viz., our old friend Juarezii. Regarded simply as exhibition flowers, some of the new Cactuses are as nearly perfect as they possibly could be. Several of the most beautiful of these have, however, one very serious defect, their stalks are so short that the blooms become hidden in the foliage. Varieties which require considerable thinning out, which are not free-flowering, and which do not hold their flowers well above the foliage, are never likely to become generally popular or suitable for garden decoration. As examples of two choice varieties possessing in a marked degree the habit of growth to be aimed at in the raising of new varieties I may instance Matchless and Bertha Mawley.

In the following select lists the Pompons have been treated in a similar way to the Shows and Fancies in the tables. In the case of the Cactus, Decorative, and Single varieties, however, the average number of times they were staged at the last two shows

alone governs their relative positions in the lists. Those marked with an asterisk are new sorts, and the places they take dependent upon the number of times they were shown at the last exhibition only

POMPONS.—Darkness, E. F. Junker, Phoebe, Tommy Keith,\* Isabel, White Aster (Guiding Star), Whisper, Favourite, Grace, Admiration, Arthur West,\* G. Brinckman, Lilian,\* Red Indian, Lady Blanche, Eurydice, Bacchus,\* Captain Boyton,\* Eva,\* Mars,\* and Sunshine.\*

CACTUS.—Delicata, Kynerith, Juarezii, Bertha Mawley, Countess of Radnor, Lady Penzance,\* Apollo,\* Matchless,\* Robert Cannell, Professor Baldwin, Countess of Gosford, Miss Violet Morgan,\* and Kaiserin.

DECORATIVE.—St. Catherine, Duke of Clarence, Marchioness of Bute, Baron Schröder, Cannell's Favourite, Black Prince, Countess of Pembroke, Amphion, Beauty of Arundel, Harry Freeman, Josephine, Lancelot, Millie Scupham, Mrs. Hawkins, and Robert Mayher.

SINGLES.—Phyllis,\* Victoria, Amos Perry, James Scobie, M.C.C.,\* Gulielma, Miss Roberts, Miss Henshaw, Northern Star, Demon,\* Duchess of Albany, W. C. Harvey, Cleopatra, Miss Glasscock, and Yellow Satin.

My Dahlias were not entirely killed by frost last year until the 1st of December, which is the latest date for their destruction that I have yet recorded during the eighteen years over which my observations extend. During that period the average date for their being destroyed comes out as November 3rd. In 1888 they were killed as early as the 3rd of October. Last year, owing to the cold summer, many Dahlias were not at their best during the exhibition season, but in the latter half of September and throughout October they flowered magnificently, the Single Dahlias especially. How seldom are these Singles seen in perfection, and yet, after all, they are by far the easiest to grow. Their requirements are very simple, for they will thrive in almost any soil, and need little or no manure. It is no doubt because they require so little attention, that none at all is given them. To be successful with Single Dahlias three things are necessary. 1, Only named varieties should be grown. 2, They should be firmly staked. 3, Once a week all the seed pods should be removed from the plants, for nothing checks the flowering of Single Dahlias so much as the formation of these seed pods. Thus treated they will yield such a wealth of blossom as few other plants can compete with, and at a time of year when free-flowering showy plants are much wanted.—E. M., *Berkhamsted*.

\* A new variety, the position of which is dependent on its record for the 1894 show only.

## GERMINATION.

MANY are now busy preparing for and sowing seeds; it is, therefore, very advisable at this season to study something about them, and the changes which they undergo during the process of germination. The first question we might ask is, What is a seed? A seed may be said to consist of three parts—an outer skin called the "testa," which envelops the young plantlet, forming a covering which protects it from injury; 2, an "embryonic plant," which consists of a primary root (the radical), a young bud (the plumule), and one or two seed leaves (the cotyledons); 3, a supply of food, which is stored in the cotyledons, or outside the plantlet, and is known in the latter case as the endosperm.

What are the changes which take place in a germinating seed? The seed when sown under suitable conditions absorbs water; this causes it to swell considerably, and the rapidity of germination may be said to depend a great deal on the quantity of water the seed absorbs; this absorption is a mechanical change. If there be sufficient heat, germination will now take place; the food material stored in the seed is in an insoluble form, consequently it cannot be of any use as such; but there is a nitrogenous ferment (diastase) in the seed, which acts on some of these insoluble compounds (*e.g.*, starch is converted into sugar) and transforms them into soluble compounds, which can be at once used by the growing plant. Many other changes take place which we as yet know but little about, but they are no doubt due to the agency of some kind of ferment. The above process is one of oxidation, carbon dioxide and heat during the process being evolved; the substances formed, if in the cotyledons, pass through the vascular bundle to the growing parts of the embryonic plant, but if it be stored outside the plantlet it becomes soluble and is absorbed by the plant as required, by cells adapted for this purpose. A certain degree of heat is necessary for the processes above named to be carried on; the most suitable temperature for the majority of seeds is from 60° to 80°.

The first noticeable change taking place in the seed is the protrusion of the radical through a minute opening in the testa, known as the micropyle. This grows downwards into the soil and becomes branched, root hairs are developed, and the plant is able to absorb water and contained salts for the purpose of nutrition; by the growth of the radical the testa is split, and the plumule grows upwards to form the future stem; sometimes the cotyledons are carried up, and they carry on the work of assimilation until the foliage leaves are developed—*e.g.*, Mustard, Cress, Tomato, and Cucumbers; in other cases the cotyledons remain in the ground and supply the plant with food till it has developed its first foliage leaves—*e.g.*, Peas and Beans. As soon as the cotyledons are exposed to sunlight and become green they commence to form food material for the plant, so the young plant is nourished in two different ways for a time.

What are the conditions necessary for germinating seeds? The seed should be obtained from a good variety, and in the majority of cases ought to be only one year old. The soil must be in a good mechanical condition and have a fine tilth, so that the young root may penetrate through its particles easily and yet be in close contact with them. Sufficient soil should be used to cover the seeds, but great care is needed that small seeds are not buried too deeply; the soil should be loose enough to allow the air free access, but not too open, to allow of excessive evaporation, or the seeds may suffer for want of water.

How may the conditions of the soil be made most suitable for germination? Clayey soil should be well worked in the autumn, and left in ridges for the action of the frost and air to pulverise it, and it is best, if farmyard manure is going to be applied, to use it in a long state at this time of the year. We should then get the soil in a fine condition, which is so suitable for the sowing of seeds. It is not advisable to ridge sandy soils because of their open character, and farmyard manure should be decomposed and only used in the spring for such soils, or much of its fertilising matters will be washed out.

Anything which will make adhesive soils more porous should be used, such as old mortar, sand, quicklime, and gritty matter generally; while light porous soils may be improved by the application of clay, marl, carbonate of lime, and organic matter. In connection with the use of farmyard manure for seeds, it should never be put too near the surface, for by its decay carbonic acid gas will be formed, which will deprive the seeds of some of their oxygen, an ingredient which germinating seeds cannot do without, and it would also, by the carbon dioxide being in the soil, act injuriously to a certain extent on the young seedlings. Great care must be taken never to work soil when it is wet; and one more point to be noticed is never to beat the surface of the seed bed with the back of the spade. If the soil wants consolidating it can

be done with a rake, for if the spade be used the soil, when dry, will crack, and a too excessive evaporation will take place.—  
W. DYKE.

## PLANT HOSPITALS—A SUGGESTION.

IN the early stages of civilisation hospitals, as far as I have been able to ascertain, were entirely unknown. It may be that owing to the primitive mode of life which the "noble savage" followed, that sickness, except in the form of senile decay, was so rare that such institutions were not needed, or perhaps, as some stirring writers tell us, those in good health were utterly indifferent as to whether the ailing ones recovered or not. Be that as it may, there can be no denying that the march of civilisation, with its great centres of population, has created the necessity for vast buildings in which skilled doctors may bestow on suffering patients the magic blessing of their healing art.

Plant-growing under glass in this country has risen from small beginnings to gigantic proportions more rapidly than has civilisation in any quarter of the globe, and, strange as it may appear to superficial thinkers, to me it seems that plant hospitals have now become as much a necessity in well appointed gardens as hospitals for frail humanity are near all centres of population. Let us now try and find out some reason for this analogy. In each case I think it is accounted for by the unnatural and therefore unhealthy conditions to which so many human beings and plants are subjected during a great portion of their time. The one in shops, factories, mines, and busy cities; the other in dwelling rooms, public halls, and churches. Having so far attempted in my own peculiar way to draw some comparisons between plant and animal life, I must now confine my remarks to matters connected with the former, and leave the latter to the care of the modern "medicine men."

So many plants are now used for the decoration of dwelling rooms, that it is absolutely necessary to proceed on systematic lines to supply the demand. A large number of flowering and fine-foliaged plants, too, in a small state are not worth keeping after they have been used for such decorations. The supply and demand in such instances simply amounts to growing a sufficient number of the necessary size, using them for the purpose for which they were intended, then consigning them to the rubbish heap, and propagating others to succeed them. This course, however, cannot be followed with all decorative plants, as many of them are large and valuable; others are choice, of slow growth, and must be reserved to do duty on future occasions. With plants of this description, a golden rule, of course, is not to let them stay too long at a time in the dry atmosphere of dwelling rooms, but change them frequently. Still, with taking such precautions, and with the best of management in other respects, they will get into a sluggish and unhealthy condition. The usual course followed then is to place them in plant stoves or forcing houses, where they receive the treatment suitable for the general occupants of the house, and invariably take a long time to recover. This, however, is not the only evil. Another one is that their disfigurement quite spoils the appearance of a house principally filled with healthy plants. In gardens where much house decoration has to be done it is a most difficult matter to keep a good show in the glass houses, because so much is taken to the house and spoilt as soon as it has been grown into a suitable size. For this reason it is not possible to form a fair estimate of a gardener's ability by the plants growing in the houses under his charge; you must first know how much house decoration he is called on to perform.

Bearing these numerous matters in mind, I maintain that an improved state of affairs may be brought about by devoting one house entirely to the accommodation of plants in a disfigured or unhealthy state. Such cases then receive exactly the treatment they require to secure a speedy return to health and vigour, and shabby looking plants may at all times be kept out of other structures. The size of a plant hospital should of course depend on the requirements and resources of each establishment, but two things are absolutely essential to success—*viz.*, that beds be provided with abundance of bottom heat supplied by means of hot-water pipes fixed beneath plunging material, and that some system of shading be adopted which may be brought quickly into use at all seasons of the year.

Either a span-roofed or lean-to structure would answer equally well. The sides of the house might be fitted up with beds 3 or 4 feet in width, similar to a well-appointed Melon house, except that the bottom-heat pipes ought to be fixed within a foot or 9 inches of the top of the brick wall enclosing the bed. This would leave ample room for a sufficient depth of cocoa-nut fibre refuse for plunging purposes. Valves ought of course to be fixed so that the amount of bottom and top heat may at all times be regulated at will. If a good part of this bed is enclosed with glass

lights it might often answer as a propagating frame when not wanted for the accommodation of small unhealthy plants; indeed, a plant hospital once started would, in many instances, serve the purpose of a propagating house as well. There would, however, be this distinction between the two. Propagating houses are usually and preferably low and comparatively small structures, but the kind of house I am now treating of must be high enough in some part to give head room for Palms 8 or 9 feet in height, because it is such plants as these that are invaluable for decorative purposes. Yet strange though it be, it is none the less a fact that in very few gardens do suitable places exist where such plants when once unhealthy can be given the most favourable treatment to secure a speedy return to vigour. What they require is bottom heat, a brisk top heat, and plenty of atmospheric moisture, in conjunction with judicious shade. Give these conditions for six months shabby plants will make more progress than they do in a couple of years under the treatment generally accorded them.

To secure the conditions just enumerated without having the narrow bed running round the sides of the house too far from the glass, the roof of our plant hospital should be formed on a rather acute angle. Instead of the usual tile or stone floor one of gravel or clinkers broken in small pieces should be formed, as the necessary atmospheric moisture could be much more easily maintained under such conditions than when floors having a surface which favours rapid evaporation are in use, and appearances would be of very little moment in a plant hospital; the great object of it should be to enable the cultivator to bring sickly plants as speedily as possible to health again. The idea, as I have roughly sketched it out, is perhaps not unworthy of the notice of readers of the *Journal of Horticulture*.—H. DUNKIN.

### MOVEABLE FEASTS.

FLORA and Pomona, whose joint feast days are celebrated by horticulturists at stated intervals under the popular cognomen of flower shows, are, as a rule, fixed long prior to the consummation of the event; fixed as irrevocably as the laws of the Medes and Persians. In the ordinary course of things the wisdom of this pre-ordination is obvious, but considering that most potent factor, the weather, which so often and so seriously mars the best laid plans, it is better to face than to ignore the shady side of the subject. There are times when this is so forcibly brought home to all concerned that the question is raised as to the wisdom of concerting with the season instead of fighting against it, and to make our flower shows moveable feasts. The possibility of doing so is more apparent than the practicability, for doubtless there are prospective complications, yet with a choice of evils it is wise to choose the least.

Exhibitors, even those whose experience is limited to a few years' observation, will readily allow that the subject is an important one. Those who are vitally interested in the welfare of the societies they represent will not deny that it is an anxious one, and to the general public, should an abnormally early or late season result in a poor display, may be traced much of that diffidence in patronising the horticultural field days, for a bad impression is harder to erase than a good one.

In the cycle of the seasons spring, summer, autumn, winter the bill of fare—the schedule—is arranged to levy the heaviest contributions characteristic of each season at a fixed date. Comprised, as exhibitions usually are, of various sections—flowers, fruits, vegetables, and plants—one section alone generally forms a central object, which if by untoward circumstances is so poorly represented as to be practically absent, results in placing that exhibition in the same position as the play of Hamlet with the Prince of Denmark missing. That such occurs at times is an accepted fact.

In looking back instances may be noted in which the leading classes of a spring show have all but resulted in blanks—seasons in which at a fixed date the flowers of spring have well-nigh faded and gone, or what is probably worse, have not arrived. So, in the summer with the Rose show, placing this important floral feast in the anomalous position of being such in name only. Autumn and winter no less illustrate the evil which may or may not be preventible. One thing is certain, whether the seasons are early or late, we must take them as they come, but it does not follow that as we are unable to bend them to our purpose, that our purpose should not bend to them and be made to stretch either way in the same elastic manner.

Whether such can be done is the present question, and a question not presented for the first time. Whether such will be done and any difficulties ensuing be made subservient to the benefits it would confer remains to be seen. It is only during abnormal conditions, of which the present year bids fair to furnish a practical example,

that we can hope for the matter to be entertained. Influences of the season are the direct controlling powers of outdoor vegetation. In some degree we are, in the glass department, independent of the weather, yet not wholly so, and there are times when all the means furnished by skill and anxiety fall provokingly short of the desired object. A severe strain is at times entailed on an exhibitor and his staff with the concurrent anxiety in watching the tardy development of certain plants, due, in best conditions, at a certain date. This feeling is intensified when the opposite extreme occurs, and the same plants are found at their best whilst the important day yet looms in the distance.

An exhibitor can, of course, derive a doubtful satisfaction from knowing his competitors are fellow sufferers; but if they can enjoy this qualified consolation it is not shared by the society, which suffers a great deal in pocket and some little in prestige. With a society sufficiently powerful to draw competitors from the two ends of the kingdom, even beyond, the same conditions do not obtain, for in this case deficiency in the North is compensated by the South, or *vice versa*. It is rather with those societies which draw their support from a circumscribed area that the weak points are felt, and being conscious of this weakness the possibility of curing it is worthy of being entertained.

With some few local societies the moveable system is practised when occasion demands, and found to work satisfactorily. These, perhaps, have not to contend with the same difficulties, the chief of which is probably the use of buildings or grounds, which can only be available at a long notice and for the time pre-ordained. Doubtless this is a problem capable of various solutions. An objection which has been advanced is that altering the date of one exhibition—say a Rose show, might clash with a similar meeting elsewhere. But this is merely a matter for mutual arrangement by the separate committees, and the reasons which affect one apply to both.

Taking the Rose show as a prominent example of the subject, it is not difficult to gauge a month previous to the date fixed on how matters are likely to stand when it comes round, and if put to the vote by the leading exhibitors a consensus of opinion and prompt action would prevent this show being held without the Roses; figuratively, of course, for though the "last Rose of summer" may be present, or the earliest specimen, and with a walk over carry off the prizes, it is highly unsatisfactory. It is indeed sad, as a lady once remarked to the writer, to see a Rose show without Roses.

There could not be any difficulty in making public such alterations as might be decided on when the necessity arises, and doubtless the public would infinitely prefer to have a good feast, though moveable, to a meagre display. Certainly exhibitors would, and the intelligence conveyed on a postcard would come as a welcome relief to many who daily, as the festival approaches, hope where no hope is, and grumble at weather which cannot be cured; at fixed rules which must be endured, when a little time either way would do so much for all concerned, for "Time, like money, is measured by our needs."—E. K., *Dublin*.

### VINES AND VINERIES.

MR. TAYLOR'S article on the above subject in the *Journal of Horticulture*, page 208, opens an interesting and important question on these two heads. That Vines thrive and finish their fruit better in houses that are not too much set to the sun, there can be no doubt at all. The sun never has the same power to burn the foliage in flat-roofed houses. In such a structure the atmospheric moisture is not so quickly dried up, so that the temperature remains more uniform and humid, and is not so sensitive to the outside changes, owing to the presence of a large volume of air of a moist nature that is at all times so beneficial to the general health of the Vines.

To grow Vines successfully in the modern vinery containing large squares of wide glass with few laps and an acute angle of the roof is not so easy a matter. On such a house the sun has a scorching effect, because there is nothing to break its force, and in a short time the atmosphere becomes so dry that to preserve the necessary amount of moisture in the house there is a continual need for damping, too much of which is not advantageous.

The heat that rises in a lean-to house facing due south at midday, when the thermometer registers between 70° and 80° in the shade outside, is quite enough to destroy the best of foliage, for when all is so hot and dry, vapour, after the house has been damped, arises and condenses on the edges of the leaves, which in turn become scorched and soon afterwards crumble up, preventing healthy circulation of the sap. No amount of ventilation will prevent this to a certain degree happening. To open the ventilators widely at the top and bottom in the hope of preventing it, in a measure aggravates the evil, as the current is too strong and creates a draught which carries off the natural moisture and leaves the atmosphere of the house parched, the very opposite of what

is needed. A steady circulation of air is really necessary to the healthy development of fruit and foliage.

I have yet to learn how it is that hothouse builders come to know so much better what kind of houses are most suitable for Vine-growing than a gardener who has spent his life in his calling. Each builder has his idea and patent, but it seems useless to build a house in such a form that afterwards it is necessary to shade it to prevent the sun damaging the Vines. Surely this is short-sighted policy considering the amount of trouble connected with the operation of shading, at a time too when gardeners' hands are full enough otherwise.

With a span-roofed vinery the circumstances of the case are materially changed, the position being due north and south. Even although the angle of the house may be somewhat steep, the sun will not have the same power on the foliage although it shines directly on it in the morning, and as a natural consequence the moisture of the house is not so readily dried up, and by noon, when the sun is at its fullest, it will fall on the ridge, and be equally divided on each side. Thus there is no chance of it doing injury to the foliage, although the glass squares may be of large size. I have just touched on the outside points of this important subject, and should be glad to hear what others have to say.—A. KEMP, *Coolhurst, Horsham.*

### DEATH OF MR. WILLIAM DEAN.

FLORISTS all over the kingdom, as well as secretaries and managers of horticultural societies, and our readers generally, will share with us the deep regret we feel in announcing the death of this genuine florist and estimable man. Pansies, Violas, and Pinks were perhaps the favourite flowers of Mr. William Dean, but all kinds were dear to him, and no one than he was more quick to perceive the merits and defects of the several varieties. Mr. Dean was the originator of the characteristic and expressive name of "Fancy Pansy," and to him more than

to any other man we are all indebted for the beautiful race to which the term applies. Fancy Pansies were at the first and for some time lightly regarded, but they have long since won a leading position, and are grown in increasing numbers yearly.

In 1883 Mr. Dean wrote the history of the "Fancy Pansy" in the *Journal of Horticulture*, and this, with his history of the Show Pansy, is embodied in Mr. James Simkins' (King's Norton, Birmingham) excellent work.\* This work gives beautiful coloured illustrations of early Show Pansies as they were in 1833; also of Mr. Dean's beautiful "Fancies"—Mrs. Dean, Her Majesty, His Majesty, and Harlequin, as sent out by him in 1866. The difference is almost startling, and the last-named varieties show the marvellous

FIG. 46.—MR. WILLIAM DEAN.

advance that had then been made in the Pansy since it was introduced from the cornfields into Lord Gambier's garden at Iver in 1833-4, and improved by his Lordship's gardener—Mr. Thompson. The Pansy is emphatically the flower of evolution. Mr. Dean, always abreast of the times with the flowers of his heart, had of late given much attention to the smaller types as represented in the charming Violas, which are deservedly spreading far and wide. Our departed friend raised many of these from time to time, but the one to which his name may be more particularly and appropriately identified is Dean's True Blue—one of the most floriferous and best of bedders and the favourite of one of the truest florists of his day and generation.

Mr. William Dean had an extremely varied career, as will be admitted on perusal of the following interesting biographical notes, with which we have been favoured by his brother—Mr. Richard Dean of Ealing:—

"My brother William was born on July 8th, 1825, on the Hill Nursery of Mr. William Bridgewater Page, a noted botanist, horticulturist, and landscape gardener of Southampton. My father was foreman at this nursery for a number of years, and William was taken into the nursery when quite young as office clerk, and here he remained until 1843, when he went to Belfast as foreman to Messrs. Scott, Bros., being then just turned eighteen years of age. His youth and nationality combined appeared to have prejudiced the employer against him, and after a year or two in the north he came to London, and obtained employment in the Wellington Road Nurseries of Messrs. E. G. Henderson & Son at St. John's Wood, eventually becoming salesman and traveller. About 1850 he went into business with a Mr. Somerville, as nurserymen and florists at St. John's Wood, but abandoned it towards the end of 1853, going to Slough to take a responsible position in the Royal Nurseries under the late Mr. Charles Turner. There he remained until 1857, when he went to Shipley, Yorkshire, and established what was known as the Shipley Nursery, Bradford, doing a general nursery and seed business.

"In 1859 Mr. Andrew Henderson of the Wellington Road Nurseries sent my brother some new forms of blotched Pansies he had met with on a recent visit to France with a request that he would grow them at Shipley, a London nursery not being favourable to their well-doing, making a stipulation that all the plants obtained should be sent to

London. These Pansies had been raised by a M. Miellez of Lille, and were all named varieties. More came to Shipley in 1860, and more in 1861, all improvements upon the preceding ones, and then the supply failed through the death of M. Miellez. Meanwhile my brother had obtained seed, and in the autumn of 1861 he was able to send out the first batch of English-raised Belgian Pansies, as they were termed in those days. It is to my brother's enterprise we are largely indebted for the family of Fancy Pansies of the present day.

"In 1865 my brother acted as Local Secretary for Bradford and district in furtherance of the International Horticultural Exhibition and Botanical Congress of 1866, and he had the satisfaction of sending up the second largest amount obtained in that way—viz., £78 4s. He was one of the 110 jurors who made the awards at that memorable exhibition, of whom only a tithe remains alive to this day.

"In 1876-77 he sold his business at Shipley, and came to London to take charge of the London branch of the Lawson Seed Company in Southwark Street. When the London branch was given up, he went to Chad Valley, Edgbaston, Birmingham, as manager to Mr. R. H. Vertegans, and subsequently with Mr. Thomas Hewitt, and with Messrs. A. Blizzard & Co., Edge Lane Nursery, Solihull. Then some years ago he settled down in the Dolphin Road, Sparkhill, Birmingham, as florist and seedsman, making a speciality of Pansies and Violas, and was very successful as a raiser of the latter. He originated and carried out to a successful issue the Viola Congress held in the Botanical Gardens, Edgbaston, last year, and prepared the report of its proceedings for publication, and which will always stand as a memorial to his exertions in popularising the Viola. At the time of his death he was assisting Mr. H. A. Burberry in bringing out a new edition of his book on Orchids. As assistant secretary to his friend Mr. Robert Sydenham, he carried out the arrangements of the exhibitions of the Midland Counties' Carnation Society, and assisted in all the exhibitions held in the Botanical Gardens. As a judge at flower shows his services were in request, but his health would not permit of his travelling long distances.

"For years past he had been a martyr to asthma and bronchial affections, which kept him a close prisoner in his house for weeks together during winter. In a letter I had from him a few days ago he spoke very hopefully of an improvement in his health when warmer weather came, but it was destined not to be. His end (on the 23rd inst.), was somewhat sudden and unexpected; to all appearance, pneumonia having set in in an acute form. He was twice married, having a family by each wife; and he leaves a widow and children to mourn his loss."

"In the early part of 1860 he became associated with Mr. E. S. Dodwell and Mr. John Sladden (A.S.H.) in the conductorship of 'Gossip of the Garden,' and carried on the work until it ceased at the end of 1863. He was editor of the 'Florist's Guide,' which succeeded 'Gossip of the Garden,' but it did not get beyond the second year of publication."

Mr. William Dean was a most pleasant and genial man, ever ready to help any who needed his assistance in connection with floricultural matters. His quick pen and great experience rendered him a welcome guest in many a committee tent at flower shows. On such occasions few men worked harder than he, and the more he could do the happier he appeared to be. He was a careful and a just judge of flowers, and though, like most other judges, had occasionally to disappoint exhibitors who were his personal friends, he was never more pleased than when he was authorised to give awards of extra medals or commendations to meritorious productions that were equally recognised by his colleagues. He will be missed at many floral gatherings and by a host of friends who were wont to associate with him, as well as by others with whom he corresponded, for he never seemed to tire of writing about flowers to those who loved them, whether they were strangers or not. Mr. William Dean was in a sentence a real, true, genuine florist and an excellent man, whose name will be held in pleasant remembrance by a wide circle of friends who had the pleasure of his association.

We reproduce an excellent miniature portrait of our deceased friend by favour of Messrs. Dobbie & Sons, Rothesay who had it engraved for one of their publications.

### EXAMINATION IN HORTICULTURE.

MANY difficulties arise over the books to study for the above examination, and as your two correspondents said (page 251), the books mentioned for gardeners' study by the Royal Horticultural Society are very expensive, but they can to a great extent be substituted for others much cheaper. Perhaps a few words about those I found most useful last year may help others who are in a difficulty in the choice of suitable books out of it.

I think the best book to commence the study of horticulture is J. Wright's "Primer of Horticulture," 1s.; afterwards R. P. Wright's "Text Book of Agriculture," 1s. 6d.; and William Oliver's "Elementary Text Book of Botany," 2s. 6d. These, with a certain amount of practical experience and a weekly paper on gardening (similar to the *Journal of Horticulture*), will be found (I speak from experience) sufficient to gain a first-class certificate. Those wishing to extend their knowledge can do so by getting the books recommended by the R.H.S., but I think the above books come within the range of all.

A plan we have started amongst ourselves, which perhaps others do, or might like to follow our example, is for six or seven to each buy one

\* "The Pansy: How to Grow and Show It."

good book, and then lend amongst ourselves. This plan brings us within reach of six good books at the expense of one.—W. D., *Turnford*.

ALLOW me to thank your correspondent, "W. D., *Turnford*," for his kind information given me on page 251 on the above subject. He is, however, labouring under a false impression in presuming that I thought few under the age of twenty-five gained the Society's certificates. Let me assure "W. D." that I was fully aware many young men obtained those certificates, but did not know so many under twenty-five succeeded in gaining first-class ones. Now that we are told young men have as good a chance as others of heading the successful candidate list, and have done so, it is to be hoped that many young gardeners who hitherto, like myself, were under the false impression that age and experience counted for something at those examinations, will now take courage, and by following out the advice given by "An Instructor" last week be among the chosen few when the results of the forthcoming examination are made known.—A YOUNG GARDENER.

### THE ALDBOROUGH ANEMONE.

The Aldborough Anemone (fig. 47) first flowered in the late Rev. J. G. Nelson's garden at Aldborough. The bulb was sent to him by a Mr. Poö, a Greek botanist, and I well remember walking into his garden one morning and finding him admiring the first flower that had opened. The flowers vary considerably in character, some having pointed petals as in the illustration, while others are quite round. My plants are now throwing up numbers of buds, one being in flower. After a favourable winter I do not know a plant that will give so early and brilliant a display of bloom for so long a time. For quite three months it may be had in gorgeous magnificence. Bulbs should be planted in August and allowed to remain in the same borders from two to three years. No other plant should be planted among them to shade the bulbs in the summer. I devote a border in the kitchen garden to them, and plant in rows 15 inches asunder.—WM. ALLAN, *Gunton Park, Norwich*.

### PLANTS WITHOUT EARTH.

COLONEL HALFORD THOMPSON of "Jadoo fibre" fame has sent us a neat pamphlet of thirty-two pages, containing the lecture which he delivered at the People's Palace for East London a short time ago. It is an excellent lecture well worth reading. The more experience the Colonel has with Jadoo the more he is convinced of its value as a light yet sufficient and continuous medium for supporting plants.

That it does support plants is evident from the prizes which have been awarded for plants grown in it, not only those of succulent growth, but Chrysanthemums. Mr. E. Molyneux describes the prize blooms as "remarkable for size, depth, and brightness." It will be admitted if Jadoo will do that it will support most other plants usually grown in gardens. The material appears to be scientifically prepared. It seems to be based on a proposition of Mr. Warrington, that "even where soil is extremely fertile the bulk serves chiefly as a sponge to hold water, and a large part of the elements of plant food in soils is in such a condition that plants are unable to make use of it."

The Colonel then goes on to say, "The object of Jadoo fibre is to provide a sponge not only to hold water but also the chemicals themselves, not locked up but stored in such a way that plants can make full use of them." This is done by boiling peat moss with chemicals which contain the requisite essentials of plant food, then fermenting the mass in a particular way to render the food available. The plants then take it as they want it, and make themselves happy. The results have surprised many persons of great experience in plant culture, including Mr. Veitch of Exeter.

In towns where soil is scarce, heavy, and dear Jadoo is sure to be extensively tried, and as Mr. Molyneux remarks, "it should prove a boon to nurserymen who grow plants for transit as well as for baskets because of its lightness." The plants we have seen exhibited as grown in this material were as healthy as could be desired. Colonel Halford Thompson's lecture can be had for 6d., and no one will be the worse for reading it, but on the contrary many of his remarks are very trite and suggestive. It is published by Messrs. Charles and Edwin Layton, 56, Farringdon Street, London, and can also, we presume, be had from the Jadoo Company, of which Mr. A. Hope is the secretary, at the address given in advertisements.

### THE EXTRAORDINARY GALE.

A TERRIFIC gale of wind swept over Warwick about mid-day on Sunday the 24th inst. Scores of trees on Lord Warwick's estate were either torn up by the roots or broken clean through the trunks. Several of the grand old Cedars in the Castle grounds, whose sturdy trunks and spreading branches have weathered many a previous storm, have, alas! at last succumbed. Torn up at the roots, with enormous balls of earth attached, they now lie a mangled mass of broken limbs and branches. In their time they have been a source of delight to the many visitors who flock to Warwick Castle. In the future naught but the memory of them will be left behind. Fortunately, many thriving young Cedars

are advancing in the Castle grounds, so that in future ages they are likely to form as great a feature as their gigantic companions do now.—W.

IN rural districts great, no doubt, are the depredations caused by the recent gale. In London the experience differs somewhat. Last Sunday, whilst taking a walk, I was suddenly startled by a loud crash close behind me; turning quickly, I found it was only a stray chimney pot coming into contact with mother earth, and had I been but a few paces nearer I doubtless should have assisted in breaking the force of the blow. Feeling thankful, however, that such was not the case, I walked on with gaze chiefly centred on the surrounding roofs, fully satisfied that London streets are not the safest of places on a windy day.—COCKNEY.

ON Sunday, 24th inst., a very destructive gale swept over this neighbourhood, doing a considerable amount of damage. About midday the

FIG. 47.—THE ALDBOROUGH ANEMONE.

wind veered from south-east to south-west, and increased in violence up to 2.30 P.M., when it was blowing a hurricane, uprooting hundreds of trees, some of large dimensions, including Cedars of Lebanon, fine Oaks, Elms, very fine Larch, and Spruce Firs upwards of 80 feet high. Nothing has approached the present gale in severity since the memorable gale and snowstorm of Good Friday in 1876, when so much damage was done to the fine specimen Cedars of Lebanon in Southill Park adjoining.—G. R. ALLIS, *Old Warden Park, Biggleswade*.

A GALE of unprecedented violence was experienced in this locality on Sunday, March 24th. It commenced just before noon, and reached its full force about 1.45 P.M., when in the space of half an hour about forty large trees, mostly Elm and Lime, were uprooted in Drayton Park and thrown to the ground with such force as to splinter them to fragments. The greater part of these giants were from 90 to 100 feet high

with a girth of from 20 to 30 feet, several tons of earth adhering to their roots. No one in the neighbourhood can recollect such wholesale destruction; houses were unroofed, chimneys down, pinnacles blown off the church, and stacks overturned. The full extent of the damage is at present unknown, but it must be very serious.—C. C., *Thrapston*.

**WEATHER IN LONDON.**—In and around London during the past week the weather has been somewhat changeable. On Sunday last a severe gale blew over the metropolis, doing considerable damage in some districts. Cold east winds have chiefly prevailed, though on most days accompanied by bright sunshine. Rain fell heavily early on Wednesday morning, and at the time of going to press the atmosphere was dull, and drizzling rain still falling.

— **THE WEATHER IN THE NORTH.**—There has been little sunshine during the past eight days, and more or less rain has fallen daily. Saturday was very wet, and Sunday disagreeably cold and showery with a keen N.W. wind. Monday, too, was gusty, with cold showers; and Tuesday morning bright, with an inclination to frost. The higher hills are again white with snow.—B. D., *S. Perthshire*.

— **VIOLETS AND THE FROST.**—I enclose a few Marie Louise Violets for your inspection. The frames containing the plants were well covered with mats and short straw, but nevertheless the plants and soil were frozen. Great care was taken to thaw them very slowly, leaving protecting material on, and giving air at the back for about ten days. Whether this precaution paid or not may be proved by the splendid blooms we now have.—G. GREGORY, *Came*. [The blooms sent were highly creditable.]

— **CHESHIRE AGRICULTURAL AND HORTICULTURAL COLLEGE.**—At a meeting of the Agricultural School Committee of the Cheshire County Council on Monday, Mr. William Neild was appointed head gardener and instructor in horticulture at the Cheshire Agricultural and Horticultural College, Saltersford Hall, Holmes Chapel. The appointment is a tangible recognition of the ability of Mr. Neild, and the announcement will afford the highest satisfaction to his many friends in the Altrincham district.

— **MUSHROOM SPAWN.**—"Saynor" (page 234) in one of his prunings makes a reference to Mushrooms. I should like to make a pointed one, and it is this. It is not wise to purchase the cheapest spawn, as it may not be cheap in the end. For several years I bought what I termed cheap spawn, and had good results from it, but last year I procured spawn nearly double the price, and I might say with double the results achieved. One bed we started cutting from the middle of December, and now, March 14th, are still at it, and from the present appearance bids fair to last some time longer. Another point worth notice in the Mushrooms obtained from this spawn is the great amount of flesh compared with those from the previous spawn.—E. M.

— **WALLFLOWERS.**—It is so seldom that the pithy notes penned by "D." exhibit any want of comprehension, that it is a pleasure to enlighten him on a point which he admits he does not "quite understand" (page 249). The reason why I wrote of Belvoir Castle and Harbinger Wallflowers as not being dwarf, is that we have types now which are much dwarfer. "D." speaks of the true type of Belvoir Castle as being 8 inches in height, and when grown in poor firm soil I admit it is quite possible to have them as dwarf as that, but the shoots lengthen so much before flowering commences that the plants are often double that height by the time they are in full beauty. Harbinger and Blood Red have the same tendency in a greater degree, and although I have at various times obtained seeds from several different sources the results were the same; still I have hitherto regarded Belvoir Castle as the dwarfiest Wallflower in cultivation, but I am growing a variety this season which under exactly the same treatment only attains a height of from 4 to 6 inches by the time the plants are placed in the flower garden in October. Hence I do not continue to class our old favourite among the dwarf Wallflowers. The new one I hope to say more about later on.—H. D.

— **LACHENALIA NELSONI.**—Mr. Wm. Allan, Gunton Park Norwich, writes:—"I have just now a mass of bloom of the best of all the Lachenalias, the one raised and named after Mr. Nelson, and which was admirably portrayed in the *Journal of Horticulture* for March 14th, page 231. This very valuable winter and early spring-blooming plant, so far in advance of any of the old varieties, will perpetuate the name of that good and genial man who was so much beloved by all gardeners who were fortunate enough to make his acquaintance." [Magnificent examples of *L. Nelsoni* accompanied this interesting note.]

— **IMPORTATIONS OF ONIONS.**—In 1893 we paid foreigners for Onions imported into England the trifle of £783,405. Egypt sold us Onions to the value of £193,163, Spain £191,655, and Holland £132,255. These were the three largest items. The total quantity imported from all British possessions only came to the value of £2551. We bought from France to the tune of £108,724. The supply received from Germany was much smaller, amounting to £35,140. Last year the value of imported Onions dropped to £765,049. Home-grown Onions used to be a safe-paying crop with fair weather, but prices, says a contemporary, have been so forced down by foreign competition that in 1894 the growers lost heavily.

— **WEATHER AND GARDEN NOTES.**—It will perhaps be interesting to some to learn the effects of the frost on some plants in a smoky locality in Lanarkshire. Not a vestige of green can be seen upon Wallflowers; the Primula tribe is much injured. Aubrietias are healthy, even the tender sorts are not injured. This is probably due to the absence of snow, as these plants suffer when there is snow along with frost, through flakes bringing down the sulphurous acid which abounds in the district. Vegetables are spoiled, yet curiously enough Parsley is safe. The leaves of Strawberry plants are blackened, but the crowns are plump and fresh. Snow does not protect all our plants in smoky districts where there is much sulphurous acid in the atmosphere.—W. T.

— **NECESSITY OF AIR FOR THE ROOTS OF TREES.**—It is a well-known fact, that when plants are growing it is just as necessary to have air for the roots as for the leaves, and the failure to meet desired success is often as much due to compactness of the soil, thereby excluding air, as the want of proper food. Under-draining, for instance, is of more value in furnishing air to the soil than in merely getting rid of the water; because when the water goes away, air fills the places occupied by the water. When plants are not growing—that is to say, when they are in a dormant condition—air is not necessary. Plants will, says "Meehans' Monthly," live under water for weeks, in the winter time, without injury, when to be a couple of days without water when they are growing, would cause their immediate death. This lesson is of immense value to the practical cultivator—it is at the bottom of the greater part of a plant grower's success.

— **ROYAL METEOROLOGICAL SOCIETY.**—At the meeting of this Society on the 20th inst. Mr. W. N. Shaw, F.R.S., delivered a lecture on "The Motion of Clouds Considered with Reference to their Mode of Formation," which was illustrated by experiments. The question proposed for consideration was, How far the apparent motion of cloud was a satisfactory indication of the motion of the air in which the cloud is formed. The mountain cloud-cap was cited as an instance of a stationary cloud formed in air, moving sometimes with great rapidity. Ground fog, thunder clouds, and cumulus clouds were also referred to in this connection. The two causes of formation of cloud were next considered, viz., (1) the mixing of masses of air at different temperatures, and (2) the dynamical cooling of air by the reduction of its pressure without supplying heat from the outside. The two methods of formation were illustrated by experiments. A sketch of the supposed motion of air near the centre of a cyclone showed the probability of the clouds formed by the mixing of air being carried along with the air after they were formed; while when cloud is being formed by expansion, circumstances connected with the formation of drops of water on the nuclei to be found in the air, and the maintenance of the particles in a state of suspension, make it probable that the apparent motion of such a cloud is a bad indication of the motion of the air. After describing some special cases Mr. Shaw referred to the meteorological effects of the thermal disturbance which must be introduced by the condensation of water vapour, and he attributed the violent atmospheric disturbances accompanying tropical rains to this cause. The difference in the character of nuclei for the deposit of water drops was also pointed out, and illustrated by the exhibition of coloured halos formed under special conditions when the drops were sufficiently uniform in size.

— THE reader of the paper on nitrogen, &c., before the Cheshunt, Wormley, and District Horticultural Society was J. Guy, and not by J. Grey, as stated on page 249 of our last issue.

— THE Scilly flower season has now fairly set in; 1136 packages, or about 12 tons, were despatched from St. Mary's, Islands of Scilly, to Penzance a few days ago.

— CORRECTION — CALANTHES AND THEIR CULTURE. — On page 246 your correspondent, Mr. J. Friend, makes a slight mistake in his excellent article, by stating that a few weeks ago a writer was recommending us to place three good bulbs in a 5-inch pot. The advice reads as follows:—"Each piece, now consisting of two or three bulbs each, should be placed in 7 to 9-inch pots, according to size." This, I think, will fairly agree with the advice of our friend.—S. K., *Lymington*.

— VINE MILDEW. — Mons. Louis Sipièrè communicates to the French Academy of Sciences a mode of treatment more easily employed, less offensive, and more economical than the use of sulphur. M. Sipièrè avails himself of lysol by reason of its germicide properties. A solution of five parts in 1000 of water is most efficacious in destroying insects, as well as fungus spores, and is much cheaper than the Bordeaux mixture. Three applications should be made, in the course of the summer, in spring, and early summer.

— TEA CULTURE IN CEYLON. — The Tea growing industry is apparently making rapid strides forward in Ceylon. The output for the current year is estimated at nearly 94,000,000 lbs., and there is no occasion to doubt that these figures will be realised. The planters in the island are all making their fortunes, and the country generally is enjoying a condition of prosperity hitherto unknown. The change is all the more noticeable as it has come so quickly after the dreadful depression brought about by the Coffee leaf disease a few years ago.

— CLETHRA ALNIFOLIA. — Notwithstanding the large numbers of species that bloom successively, so that flowers may be had in abundance for most periods of the year, there is a time, about the end of July, midway between spring and autumn flowers, when scarcely anything is open. One of the best for this spare time is *Clethra alnifolia*. The long spikes of pure white flowers with the bright yellow anthers render it a particular ornament. It is impossible to find anything prettier at that season of the year. It has in addition a delightful fragrance. On account of the scarcity of other flowers at that period it is visited by a very great variety of insects, so that what with butterflies, bees, hornets, and other winged insects of many kinds, the flower has an additional attraction to those which its own beauty affords.—("Meehans' Monthly.")

— SCALE IN AMERICAN ORCHARDS. — The scale insects have not been very troublesome heretofore in the northern and eastern parts of the United States, but one of them has appeared in New York orchards, attacking Plums and other trees, and threatens to become a serious enemy. It may have inhabited certain orchards in small numbers for some time, but it never caused any alarm until within two years, and now it threatens the total destruction of thousands of trees. Mr. Slingerland of Cornell University has been making a study of this insect, and, although its life-history is not yet thoroughly understood, he has discovered enough to enable him to state that it can be destroyed by persistent spraying before spring growth begins. In an illustrated bulletin just issued by the Cornell Experiment Station, Mr. Slingerland explains how it can be distinguished from the San José scale, and gives directions for treating the trees with the kerosene emulsion, so as to prevent it starting in April.

— CLERODENDRON FLOWERS FALLING. — After perusing an article in the Journal of the 7th inst. on *Clerodendrons*, I venture to ask advice as to the reason of my losing so many flowers from my *Clerodendron Balfourianum*. I am an amateur exhibitor, and have three full-sized specimen plants which I can manage to grow and bloom well, but on moving them I lose the flowers. I have often wondered the cause of this, as I see other exhibitors hardly lose a single bloom. I adopt the following treatment. As soon as the plants cease blooming I keep them growing in the stove till January, then dry them off a little, and place in the greenhouse, where they remain till June. This produces favourable results as far as blooming is concerned, but although I have tried hardening them when in flower, and every other remedy I could think of, I can attain no better results, as immediately I shake or carry the plants I am left with but poor results for my labour. I have failed eight years in this, and any advice your experienced readers can tender me through your valuable weekly will be most thankfully received.—AMATEUR.

— THE GROWTH OF IVY.—The Ivy differs from ordinary plants in having rootlets on every stem, thus rendering it almost independent of its main ground-roots. Its notorious killing action upon growing trees when it takes possession of them is mainly due to absorption of their juices. If there is any moisture in stone or brick walls the Ivy will have it.

— STATUE TO MONS. GUSTAVE PLANCHON. — A statue has recently been erected at Montpellier, in the south of France, to commemorate the life and services of this distinguished botanist, to whom, after a study of the Phylloxera on American Grape Vines, was largely due the rehabilitation of the Vines of France after they had been ravaged by that insect.

— THE CULTIVATION OF TOBACCO IN FRANCE is extending, but the quality is ordinary. It is the Tobacco imports from Kentucky and Cuba that enable the various mixtures to be prepared. The Government has just authorised the Department of Lot et Garonne to plant this season 2375 acres with Tobacco, and the number of plants per acre is fixed at 12,000.

— THE FIXATION OF NITROGEN.—This is described by M. Petermann as being effected not only by leguminous plants such as Lupins and Beans, but also by Barley. The latter is attributed to the influence of rain water, which favours the development of certain low forms of vegetable life, and these, after absorbing nitrogen from the air, eventually act as fertilisers to the plant.

— FORCING STRAWBERRIES. — May I be allowed to thank "Fragaria" for his prompt and able answer (page 258) to my "ticklish question" on page 234? But there was really no intention of tickling you, "Fragaria," as a means of extracting knowledge. Yet, no matter the means if the end is gained; and if "the blade" is keen to prune, the propagation of sound information is more readily effected. Fear not "Fragaria," your practical article will bear fruit (not weighed by *avoirdupois*) to others as well as to—SAYNOR.

— CORNISH CROPS.—Cornwall, that forefoot of England thrust far out into the benign south-west, gives us the first-fruits of summer long ere they ripen under our harsher sky. But the weather appears to have been too much even for Cornwall. Mr. G. G. Boswell writes from Marazion that he has been round to all the principal market-gardening centres, and never in his experience has he seen crops killed as they are this year in Cornwall. In large fields of spring Cabbages not one has been left. Hundreds of acres of Broccoli are served the same. Tripoli Onions are cut down close to the earth, scores of acres of Parsley, Lettuce, and other garden produce being destroyed.

— THE HESSLE GARDENERS' MUTUAL IMPROVEMENT SOCIETY. — At a special meeting of the above Society on March 22nd, a paper was read on "Exhibitions, Exhibitors, and Exhibiting," by Mr. Wm. Clayton of Appleton-Roebuck. Exhibitions, he said, have now become so popular that nearly all towns and villages have their flower shows. With a description of the different classes of exhibitors Mr. Clayton passed on to exhibiting, in which he gave some good advice. When practical to do so, cut the blooms on the morning of the show, name correctly, and stage in such a position that it appears at its best advantage. If not successful try again; set your mind on improving your exhibits; cherish and support your hobby, and you will not always be disappointed.—F. L. S.

— FLORAL FASHIONS IN NEW YORK.—The custom once so much in fashion of presenting hand bouquets to ladies to carry at dancing parties is no longer observed. The discomfort attending the carrying about, through an entire evening, of an awkward armload of heavy bouquets, as well as the excess to which the fashion was carried, furnished a very good excuse for its abandonment. Hand bouquets are quite fashionable for theatre parties, however. The form which first came into general use last season, under the name of "shower bouquet" or "English spray bunch," is, says the "American Florist," the most popular, and is well adapted to its purpose, as the flowers are arranged to face all to one side, and the bunch may be laid down without injury to the flowers, as would be the case with a round bouquet. Lilacs make up beautifully in these bunches, either by themselves or in association with a few Roses. White Roses and Lily of the Valley are a favourite combination. More novel and very rich in effect are Acacia and Bridesmaid Roses. Bridesmaid, Meteor, or Testout Roses are used sometimes alone. In this case it takes about three dozen Roses to make the bunch properly. When used with Lilac or Acacia one dozen Roses will be sufficient. Bridesmaid is the most popular Rose in the market for such purposes the present season.

— IRISH SEED POTATOES.—Replying to a question in the House of Commons, Mr. J. Morley said: "The Seed Potatoes Supply Bill provides (as did also the similar Bill of 1890) that seeds shall not be sold for less than the net price paid by the guardians for them, inclusive of the expenses incurred for carriage, storage, and distribution. The price would, therefore, vary in different districts according to the contract price and to the expenses incurred in distribution. No seeds have yet reached Belmullet Union for distribution, but the guardians have entered into a contract for about 100 tons of Irish Champions at £5 12s. 6d. per ton, delivered in Belmullet, and for a small quantity of another kind of seeds at £6 17s. 6d. per ton: To this will have to be added the cost of storage and distribution, and it is not possible at present to say what the price charged to the people will be, but the Local Government Board do not think it will amount to anything like so high a figure as £10 a ton."

— A NOTE.—During a recent call on Mr. G. Clements at Haseley Manor Gardens, Warwick, I noticed that there, as in so many other gardens, the severity of the late winter has left unmistakable marks behind. Many fine shrubs are terribly disfigured, and in some instances killed to the ground line. Fortunately, the grounds abound in choice shrubs and Coniferæ, so that they will not be missed so much as in many places, and Alfred Hewlett, Esq., the generous proprietor, is such an ardent arborist that planting is carried on extensively each year, and perhaps in future times the well wooded park at Haseley will possess some of the giant trees of the district. In the houses things are growing apace under the influence of more genial weather, the conservatory being gay with a host of bulbous plants. The well-arranged fernery has been thoroughly overhauled, so as to keep some of the stronger varieties of Ferns within bounds, and thus allow the weaker ones to develop fully. In the course of a few weeks this fernery will look exceedingly well.—Z.

— THE IRON DUKE AND HIS GARDENER.—In an interesting reference to Walmer Castle a daily contemporary tells the following excellent story:—"No resident at Walmer has left a more lasting impression on the history of the Castle than the Duke of Wellington. He did not seem, however, to make any notable improvements in the structure, and the gardens during his residence fell into a great state of neglect, owing, it is said, to his having given the post of gardener to a veteran sergeant who had fought at Waterloo, but who knew nothing of gardening. 'Do you know anything about gardening?' asked the Duke, when the sergeant came by appointment to Apsley House in the hope of employment. The man replied that he did not. 'Then,' said the Duke, 'go and learn, and come back this day fortnight.' At the second interview the Duke said, 'Go and take the place of gardener at Walmer.' 'But,' stammered the sergeant, 'I know nothing about gardening.' 'Nor do I, nor do I,' retorted the Duke shortly, 'take your place at once.' The only subsequent record of the Duke's interest in the gardens was the planting there of a cutting of the Willow that grew by the grave of Napoleon in St. Helena."

— A PURITAN FLOWER.—No more beautiful flower grows in New England than the Sabbatia, and at Plymouth, where it is especially profuse and luxuriant on the borders of the ponds so characteristic of that part of Eastern Massachusetts, it is held in peculiar affection, and one may almost say reverence. It is locally called "the Rose of Plymouth," and during its brief season of bloom is sold in great numbers in the streets of the town, and used in the adornment of houses and churches. Its name, according to the "Garden and Forest," comes from that of an early botanist, *Liberatus Sabbatia*, but this well-established truth is totally disregarded by local tradition. Almost everyone in Plymouth firmly believes that the title is due to the fact that the Pilgrims of 1620 first saw the flower on a Sabbath day, and entranced by its masses of pinkish lilac colour, named it for the holy day. Indeed, this belief is so deeply ingrained in the Plymouth mind that, we are told, strong objections are made if any other flowers are irreverently mingled with it in church decoration. Yet the legend was invented not more than twenty-five years ago by a man whose identity is still well remembered, and thus it is of even more recent origin than the one, still more universally credited, which says that the Pilgrim fathers landed on Plymouth Rock.

— WINTER BEDDING.—The past severe frost has done much to emphasise the advantage of the employment of small shrubs for the winter and spring decoration of the flower beds. "H. D." (page 225) gives a pitiable experience of the death by frost of hosts of plants usually employed as spring bedders. In this part (Hants) it is the same. Even Wallflowers are killed outright. I never saw the common

Daisies and Plantain amongst the grass so brown. Beds filled in the autumn with small shrubs, like *Cupressus Lawsoniana*, *Cryptomeria elegans*, *Thuja Lobbi*, *Thujopsis borealis*, *Retinosporas* of sorts, *Aucubas*, common Laurels, Box, Ivy, Heaths, and *Euonymus radicans variegata*, are now looking quite fresh, while on the other hand the beds of ordinary spring plants are in a sorry plight. The best of them have more gaps than plants. There is something cheerful about these shrub beds, even in the depth of winter, that renders them pleasing. The point to study in achieving a good effect is to have a sufficient number of well grown, bushy plants, and arrange them somewhat thickly, but not so closely together that each loses its individuality. A stock is easily obtained by rooting a number of cuttings of each annually for a time. The summer treatment is not very difficult either. Those who have not given the plan a trial should lose no time in doing so.—E. M.

— ROYAL BOTANIC GARDENS, REGENT'S PARK.—Special interest attached to the meeting of the Fellows of the Royal Botanic Society held on Saturday last, from the fact that notice of motion had been given with regard to the important question of opening the gardens to the public. Mr. G. W. Bell occupied the chair, and Mr. J. S. Rubinstein moved "That this meeting recommends the Council to issue a circular letter to all the Fellows, in order to ascertain whether they approve or disapprove of opening the gardens to the public by payment on two or more off days in the week." He pointed out that it was absolutely necessary to find some new source of income, and he was surprised that the Council had not deemed it expedient to act upon the previous suggestion he had made in that direction. The Chairman then said that the question raised would receive full and careful consideration, and if it were found possible to carry out the recommendation it would no doubt be done. By some, however, it was thought such a scheme would not raise the Society's income by as much as £10; but if the Council came to the conclusion that the innovation proposed would increase the funds, it would certainly be tried.

— WOOLTON GARDENERS' MUTUAL IMPROVEMENT SOCIETY.—On Thursday evening the last meeting of the session was held in the Mechanics' Institute. Mr. H. Middlehurst presided over a crowded attendance, the subject for the evening's discussion being a prize essay, the prize kindly given by Mr. H. Middlehurst, on "Hardy Bulbous Plants Other than Spring Bedding Varieties," and which was won by Mr. G. H. Webster. The essay was of much merit and listened to with great attention. At nearly every meeting members bring exhibits of choice plants, fruits, and vegetables for instruction to younger members, and at this the Committee unanimously granted a certificate of merit to Mr. R. Todd, gardener to Holbrook Gaskell, Esq., Woolton Wood, for a well flowered specimen of *Cœlogyne cristata* *Lemoniana*, with about 250 flowers, several of the spikes bearing eight flowers each. The usual votes closed the meeting. In conclusion I should like to add that the present season's work has been equal to any of the former ones. The members work really for mutual improvement, and many good lessons are taught. The library, which is one of the best of its kind in the country, is freely used and much appreciated.—R. P. R.

— YUNNAN PLANTS.—An old Chinese correspondent of Kew, Mr. W. Hancock, F.L.S., to whom it is indebted for several small collections of dried Chinese plants, has sent a further collection, comprising about 150 species of flowering plants and 120 Ferns. The specimens are admirable, and often copious. These plants were collected in the neighbourhood of Mongtze, or "Mengtze," as Mr. Hancock writes it. This place is situated in South-eastern Yunnan, just within the tropics; and although the plants were not collected at great elevations (4000 to 6500 feet) they were all of a temperate or sub-tropical type. Like other parts of the vast province of Yunnan, this appears to be exceedingly rich in local species, and there can be no doubt from a cursory examination of the collection that it contains a considerable sprinkling of undescribed kinds. There are probably at least ten new Ferns, a large number considering the wide range of Ferns generally. Among flowering plants a species of *Jasminum*, allied to *J. nudiflorum*, is perhaps the most conspicuous. It has primrose-yellow flowers with broad overlapping petals of great substance, and they are from 1½ inch to 1¾ inch in diameter. There is also a remarkable new species of *Brandisia*, with long terminal racemes of "rich red" flowers. A *Rhododendron* having very large solitary or geminate white flowers is probably new, and several elegant *Cyrtandreae* are different from anything Kew previously possessed. The very large and distinct *Rosa gigantea* (Collett) is also among the plants collected. Some of the most striking novelties will be figured in an early part of "Hooker's Icones Plantarum."—"Kew Bulletin."

BRASSIA LAWRENCEANA.

WHEN this Orchid was exhibited at the Drill Hall at one of last year's meetings it was accorded a first-class certificate by the Orchid Committee of the Royal Horticultural Society. It was staged in splendid condition by R. I. Measures, Esq., Camberwell, and well

CATTLEYS "GOING BACK"—DENDROBIUMS.

PLEASE inform me if Cattleyas and other Orchids in bud when removed from one place to another always go back, or does it indicate that they are removed to an unsuitable place? I have purchased several in bud, but the buds always die, unless they are showing colour. I shall also be glad to know the difference between *D. nobile nobilium* and *D. nobile Sanderianum*, and which is the better of the two.—W. S.

[Certainly not, unless the plants were checked by cold, or the buds bruised on the journey. If this was not so either your house must be unsuitable or the plants have been wrongly treated in some way since. If the plants were removed during the recent severe weather they would doubtless be checked, unless extraordinary

FIG. 48.—BRASSIA LAWRENCEANA.

merited the honour accorded. In Williams' "Orchid Grower's Manual" *B. Lawrenceana* (fig. 48) is described as a handsome species, having long racemes of very fragrant flowers, in which the petals are much shorter than the sepals, which are fully 3 inches long, the lip oblong-lanceolate acuminate and wavy, with two pubescent connate lamellæ truncate in front. The colour of these flowers is bright yellow, tinged with green at the base and spotted with reddish brown. They last three or four weeks in good condition if kept dry.

CYPRIPEDIUM INSIGNE.

I AM enclosing a few *Cypripedium insigne* blooms that have been open since the third week in December. During that time they have done turns for decorations in drawing-room. This is the longest time I have known blooms keep fresh.—W. G. G., *Sennowe*.

[The blooms reached us in wonderful condition considering their age, and it would be interesting to know if any readers have kept them a longer time.]

precautions were taken to prevent this, and you will know whether or not this was the case.

With regard to the *Dendrobiums* mentioned it would be hard to say which is the better, as both are truly magnificent forms. *D. nobile nobilium* is the larger flower, but *D. n. Sanderianum* has the broadest petals, and these are usually white at the base, giving them a very distinct appearance. Both forms are very deeply coloured, the former being the more rose.]

CALANTHE CULTURE.

CALANTHE VEITCHI and its allied varieties are generally acknowledged to be exceedingly decorative, and for early winter blooming few plants can equal them. The flower spikes keep a long time when the plants are placed in vases in a living room, the flowers being equally good as cut blooms.

When left in the hothouses they continue to bloom from three to four months, and no plants are so easy to cultivate where a

little heat is at command. For this reason they should be more extensively grown by amateurs. Where they do not succeed the failure is to be attributed to growing the plants in an unsuitable atmosphere, or using a wrong compost. *Calanthes* require a minimum temperature of 65° to 70°.

The plants like abundance of water when growing vigorously, an open compost, a light position not far from the glass, a little bottom heat in their earlier stages of growth, and a gradual ripening off process, which ends in a state of perfect rest. As soon as the plants have finished flowering water should be withheld, the pots turned on their sides, and placed anywhere out of sight in the stove, where they can remain till the pseudo-bulbs have begun to throw out young shoots, which is a sure indication that it is time to recommence operations.

We then shake out all the old soil, dividing the bulbs, and about the end of March we re-pot them, using 6, 7, and 8-inch pots, which should be clean and dry, but not quite so heavily crocked as for some Orchids. They must be filled nearly to the rim with soil, and the bulbs pressed down to the depth of from 1 to 2 inches, making the soil moderately firm round each bulb. The compost should consist of two parts fibrous loam broken in pieces, one part leaf soil, one part good peat, together with some rough sand and broken charcoal, thoroughly mixed together by the hands. When potted the most suitable place to stand the plants is on a bed or a light airy shelf near to the glass in the stove. Too much water must not be given directly after potting, as the bulbs have no live roots at first, and only just sufficient water is required to keep the compost moist, and it ought to be given through a fine rose in a very careful manner. As the plants dislike cold water either at the roots or on the foliage, it ought to be at about the same temperature as the atmosphere of the house.

Slight shading must be provided from the strong rays of the sun, and air should be admitted on all favourable occasions. By following the above conditions, and with ordinary care, they will grow very freely, and produce fine spikes of bloom. Some we had here during the last winter had flower spikes which measured from 3 to 4 feet, and contained between forty and fifty flowers on a spike.—A. SHUTTLEWORTH, *Bolton*.

## THE FUNCTIONS OF ROOT, LEAF, AND BUD.

HAVING (page 203) dealt as concisely as possible with the functions of roots and leaves, I now direct attention to the nature and functions of those important organs

### THE BUDS.

These organs are intimately connected with the leaves. The leaves nourish them, also give them their form and character, and from the buds the leaves reproduce themselves. Let us take an illustration from the insect world. The leaves are like the caterpillar that feeds until it is perfectly developed; it then forms itself a case, and enters into the pupa or resting state, from whence it emerges a perfect, and perhaps a gorgeous insect. The leaves are the feeding stage, the buds the pupa stage, and the blossom and leaves represent the perfect butterfly.

The buds are indeed wonderful organs, wonderful in their construction and development, in their diversity of form, and in their important object—the perpetuation of the life and the multiplication of the species or variety to which they belong. They possess the property of maintaining their vitality unimpaired, and their tissues comparatively unchanged for a considerable time during periods unfavourable for active growth. The whole process of perfecting and ripening the bud appears to be a preparation for a season of rest. It is a law of Nature that all the created world should be subject to periodical changes. Night and day, winter and summer, cold and heat, light and darkness, follow each other in ever changing relation, certain only in the certainty of variability, yet ever constant in the harmonious adaptability of all organic life to the varied surroundings of a natural state of existence.

In our own country the growing season is during summer, this being followed by a season of torpidity, brought about by the low temperature winter brings with it. In some southern countries the season of rest in vegetation is during a period of extreme heat and drought, and may arise primarily from absence of moisture in the soil and air, but in all the preparation is attained in a similar manner. During the height of the growing season food has been stored up in the tissue of the plant, and before its close abundance of this in the form of starch fills the cells in the immediate neighbourhood of the fruit buds; besides, a quantity has been used up to form the embryo leaves and blossoms, which are the chief characteristic of these buds. As the temperature becomes lower the functions of the leaves are less actively carried on, and ultimately cease. The fibreless cells at the base of the leaves become ruptured, and the leaves drop to the ground, there to decay and return their elements to the soil to feed another year's growth. About the same time the root feeders having completed their work for the season they too decay, and the whole plant enters on its season of rest or torpidity, and so remains virtually unchanged until the time arrives when suitable conditions again exist for it to recommence active growth.

I will now draw attention to a few examples of vegetable buds. They will admirably enforce the lesson of Providence—looking forward,

and providing for the day yet to come, but a long way off. This lesson it is important for every gardener to learn and act upon, and without which he can never thoroughly succeed. The first bud to be noted is called a "bulb," say that of a *Hyacinth*. The plant probably shed its leaves and roots about July—more than six months ago. The bulb is in sound condition, and I question if it has very much changed since the day the ripening process was completed. If we take a sharp knife and divide it vertically through the centre, we find the bloom spike in an undeveloped state, but perfect in the number and position of all its parts. All the cultural skill of all the gardeners in England cannot add one single bell more to that spike between now and the time of its perfect development. The result—at least, the limit of its perfection—was unalterably decided while still growing in those well-watered, well-fertilised, sandy beds of Holland; and not only was the embryo flower spike and leaves formed, but a sufficiency of food was stored around them to carry them through to the period of perfect development of new leaves and roots.

We will next for a moment consider the branches of Pear trees. We may observe three kinds of buds—no, that is wrong, there is only one kind; but they are in three different stages of development. These fat, scale-covered buds are fruit buds, perfect buds. Those higher up on last season's shoot are only partially developed buds, and may either develop into fruit buds or wood buds, but in any case they possess within themselves the characteristic properties of their own particular variety, and are capable of communicating these to a distinct individual life, as in the process of budding or grafting. A seed may, and often does, produce a tree differing widely from its parent; but it is very rare for a tree, or plant produced from a bud, to differ from its parent, even when united to a stock of a very different nature, and is fed by sap taken up by roots belonging to that different stock. How is this? Because that bud had within itself its own characteristic embryo life, and food of its own to start with—food elaborated or manufactured by its own particular leaves according to its own specific wants.

This explains many phenomena not otherwise explicable. We may bud or graft half a dozen sorts of Apples or Pears on one stock differing from all the buds, and of each sort will come true to its kind, having the characteristic shape, time of ripening, colour, and flavour of its own. Again, we may work a Peach on a Cherry, a Plum on an Apple, or a Pear on a Thorn, and all these produce their fruit unchanged, showing that the roots have little or no effect on the variety of fruit for the growth of which they supply the sap.

I have drawn attention to the food stored around the buds before the leaves fall in autumn. Let us consider for a moment the object of this. The buds are mostly situated high up in the tree, at least the fruit buds are; the roots are down in the soil. As the days lengthen in spring, and the sun gains power, the temperature of the air increases faster than that of the soil, and the buds feel the influence of the sun's increased heat before it reaches the roots. It is therefore but natural that the buds should commence growing first. They do begin first, and now we see the reason why the food, in the form of starch, was stored in the buds before the leaves fell in autumn—namely, that there should be something for nourishing the growth until the roots could become active again.

The warm spring showers come and soften the gummy covering of the buds; the heat of the atmosphere expands the water ever present in all vegetable tissues to nearly half of the whole bulk; the buds gradually open and let in the carbonic acid gas, which, acting on the starch, converts it into matter suitable for building up the cellular tissues of the leaves; the leaves and the blossoms begin rapidly to develop, and feed on the store of food at hand. They commence their proper functions and communicate vitality to all parts of the tree, lastly to the roots, and by this time the soil has become warm, and nitrification is going on. They reproduce their feeding hairs, and these fulfil their proper functions in taking up nourishment from the soil.

If it were necessary for me to attempt to prove that growth begins in the bud before it does in the root, I could point out many examples. There are also many exceptions. Look at yonder tree; it was cut down last autumn; it has lain there all winter. In the proper season it will expand the buds and develop its leaves, and even make shoots; but having no roots they will soon wither and die. You insert a Vine eye or a cutting; they will each make several leaves before any roots are produced. Notice your Vines start in spring, particularly those forced by artificial heat; they will break, produce several leaves, and even the bunch may be seen; presently growth seems to cease, the leaves appear thin and ill nourished, the shoots become spindly, and in this state they remain without perceptible progress for days, or even weeks. You wonder what is wrong with them, and begin to fear for your crop; but presently they make a fresh start, and your hope rises with the sap, which has at last come up from the roots, to supplement that food which had been exhausted before the roots were ready to provide a supply. And why were these roots behindhand in their work? Probably the soil in which they were embedded was cold and damp—a most fertile source of mischief—the chief cause of shanking and half the other ills that vegetation is heir to.

I have been trying to explain to you some sort of theory of plant life, and have tried to deduce from it, observations to account for, and prove the motive of our practice; and even if my theory is wrong, that does not prove that the practice on which it is founded is wrong, but rather that I have misunderstood and misinterpreted the means by which certain results have been attained by that practice.

The theory is shortly this: In the decay of natural organic matter—vegetable and animal organisms—the simple elements of which these

bodies are composed are set free; that these elements are again reconstructed into other compounds soluble in water, and in that form are taken up by the roots; that these changes of matter in the soil are promoted by the presence of atmospheric air and heat; that the roots take up these compounds held in solution in the water, and by means of the stem and branches they are conveyed up to the leaves, where by the action of carbonic acid and heat they are once again decomposed, and reconstructed into the forms we see them, as wood, leaves, buds, and fruit; that it is in the leaves alone which determines the specific character of the matter passing through them; that the bud is the storehouse of that characterised matter, the transmitter of unchangeable vitality from one generation of leaves to another, and the starting point of a new life.

Now we come to the practical application of all this. First, we should ever be on the alert to improve our soil by working it, draining or liming it as its nature may require, to bring it into a sweet open condition, so that the atmospheric air and sun heat may freely enter, and nitrification be thus promoted, for there will be various other processes in which oxygen is entering into chemical combination with other elements required in the sap, promoted also. Manure abundantly yet judiciously with artificial manures as specially required, but do not forget that animal manures with decayed vegetable matter, such as we find in farmyards, is Nature's own fertiliser, her richest and her best. Secondly, do not forget the most important time to feed—when the fruit is swelling, when the leaves are healthy and green, under the direct influence of the sun; when the soil is warm and the millions of gaping mouths of the rootlets are ready to take up all you can give them. Then is the time for your rich liquid manure to help to swell the Pears and other fruit growing on warm sunny borders and in forcing houses; while the application of such food at any other time, especially in the winter after the leaves have fallen, is wasteful if not dangerous, for there are no root feeders then to take it up, and thus not only is a great proportion of the manure wasted but the soil is soddened, the temperature lowered, and an unhealthy state engendered without any redeeming advantage.

In conclusion, while I know that all I have said that is true and orthodox, has been better explained before, and if anything is conceived to be erroneous, and leads to closer attention and research for the discovery of errors, the result will be what is so desirable for us all—more knowledge. There is much for all to learn if we would reach perfection in our craft. To our young men I would say, Press on, seek for truth, and "Falter not, but, onwards, upwards, till the goal you win."—H. ELLIOTT.

#### PRESENTATION TO MR. W. G. HEAD.

WE have pleasure in stating that, for the purpose of presenting a testimonial to Mr. W. G. Head, the able Superintendent of the Crystal Palace gardens, a party of enthusiastic horticulturists met at a social dinner held in the Restaurant at Victoria Station, W.C., on Friday evening last. Sixteen friends sat down, and in the unavoidable absence of Mr. W. Marshall the chair was taken by Mr. Richard Dean, who, it is needless to say, fulfilled his duties in a highly creditable manner. After an excellent repast had been disposed of the Chairman read letters from several gentlemen regretting their inability to attend.

The usual toast for Her Majesty having been given, Mr. Dean proposed the one of the evening, that of Mr. Head, and in the course of his remarks said they had invited Mr. Head to join them that evening and accept the small tribute, which took the form of a purse of sovereigns, as a mark of their esteem and regard. They were thoroughly satisfied that he highly deserved it, and it was with the knowledge of the good he had done in the world of horticulture that a small number of friends had amalgamated their efforts and got up the testimonial, which they hoped Mr. Head would receive with the hearty good wishes of all concerned. As a manager of flower shows, all who were in the habit of visiting those held at the Crystal Palace could vouch for his ability, and also for the efficient manner in which he carried out the many duties connected with his responsible charge at the Crystal Palace.

In hastily glancing at the record of a life of usefulness he said that Mr. Head was the son of a small nurseryman, and appeared to have imbibed the parental taste for gardening, as in 1853 he went to Arundel Castle under Mr. McEwen, who afterwards became Superintendent of the Royal Horticultural Society's Gardens at Chiswick. In 1856 he went to Shrubland Park, Ipswich, and in the following year to Drumlanrig, N.B., under Mr. McIntosh, where he remained four years. He then became gardener at Castle Dykes, Dumfries, but on account of failing health returned to the south of England in 1863. After again returning to Arundel Castle as foreman he, in 1857, became one of the staff at Chiswick, and on leaving there took charge of the flower and general decorative department at Kew.

In 1872 he was sent out to Calcutta, and while there formed a new garden and nursery for the Agri-Horticultural Society of India. He remained six years, returning to England in 1878, and soon after succeeded Mr. G. Thompson as Superintendent of the grounds and gardens at the Crystal Palace. In closing his remarks the Chairman said that Mr. Head for his ability as a gardener and kindly disposition as a man, was held in high esteem by all who knew him, and it was with the knowledge of this that had prompted them to make this testimonial.

Several others present also spoke in praise of Mr. Head, who in reply said that he was extremely proud that he had so many friends about him, to whom he wished to express his heartfelt thanks for their great kindness. He felt highly honoured by the friendship of all who had exercised their generosity on his behalf, and he trusted that the same good fellowship would stand for many years to come.

Several other toasts having been given, such as "Horticulture," the "Press," and "Gardeners of England," the health of the Chairman was drunk, coupled with a hearty vote of thanks for the able manner in which he had performed the duties of the chair. Mr. Dean replied briefly, and the company dispersed, a most enjoyable evening having been spent.

#### EARLY FLOWERING BORDER CHRYSANTHEMUMS.

Now that more attention is being paid to improvement in the colour of early flowering Chrysanthemums, we get a much better display in the open border than hitherto. Not only do the plants make that part of the garden gay, but they provide so much material for decorating, when hardy flowers are not numerous, with the exception of Michaelmas Daisies. These charming varieties then come in at a time when most useful, and if the improvement in colour continues I predict a long run of popularity for this section.

Let it be understood, though, that I do not allude to those, for instance, which open their flowers during August, I mean particularly such as bloom during September and October, provided, of course, frost does not injure the flowers prior to the latter date.

Below I give a select list of varieties that I know from experience are suitable for the object in view, I having proved the bulk of them personally, and with such satisfactory results, that I have no hesitation whatever in recommending them to others as producers of blooms in quantity, and with but a minimum of labour expended in culture.

The cuttings should be inserted either singly in small pots or three in a 3-inch pot. By growing the plants as near to the glass as possible in a cool house or frame they keep stocky. Pots 5 inches in diameter provide ample space for the roots until the plants can safely be put in the open ground where they are to flower. All that is necessary in the matter of attention after they are planted is to place a stout stake to each, for the support of its branches, which require no manipulating whatever in the matter of pinching. I find it is better to allow the plants to make free and uninterrupted growth from the time the cuttings are rooted to the flowering period. If the branches are not kept neatly tied to the stake but allowed to hang loosely, they are not only broken but grow crooked, which renders them unsuitable for vase decoration. Chrysanthemums, of this class especially, make a much better display when cut with long stems and clusters of flowers than do short-stemmed single blooms.

To Ryecroft Glory must be given the pride of place, as without any pinching whatever single plants will grow in one season from 3 to 4 feet high and nearly 3 feet in diameter, each carrying 200 blooms and unopened buds. The colour of the reflexed flowers is yellow, heavily suffused with bronze. Comtesse Foucher de Cariel is, out of doors, what Source d'Or is under glass—one of the best of bronze-coloured Chrysanthemums; it grows 3 feet high and 2 feet in diameter, and is a profuse flowering variety. Mrs. Gifford is a Japanese of rather tall growth; with me it grows over 4 feet high. The silvery pink blossoms are freely borne on long stalks, rendering it most useful for filling tall vases. The centre of the flower is deeply flushed with rose, which shades to silvery pink as the florets develop.

Montague.—This belongs to the true Japanese section, and flowers most profusely in the open. The colour is rich purple-crimson when the flowers are opened under glass, but a trifle less brilliant when expanded out of doors. The peduncles in this case are both erect and stiff, rendering it very useful. In height it grows 4 feet. General Hawkes is one of the best of the bright-coloured section of early flowering varieties. The rich crimson-claret petals are reversed with silver; as they are long and inclined to droop this trait adds to its character.

Roi des Précoces is perhaps the finest of all the dark-coloured varieties flowering in the open, not only for its profusion, but for the time the blooms last in good condition. The habit of growth, too, is all that could be desired. Harvest Home is one of Mr. Owen's latest introductions in this section. The narrow crimson petals are tipped with gold at the point, which renders it a striking object, growing 3 feet high. Crimson Queen is a fitting companion to Roi des Précoces in point of colour, being more a velvety crimson perhaps. It is a showy and desirable variety growing but 2 feet high. California has larger blooms than the majority of ordinary early flowering kinds. The ground colour, crimson, is heavily suffused with orange-yellow. From 3 to 4 feet it grows.

Carrie Denny is an incurved Japanese variety. The ground colour (orange amber) is flushed with crimson on the surface, but paler on the reverse of the florets; 3 feet. October Yellow reminds one very

much of Peter the Great both in colour and shape of its blooms, but smaller of course. Rose Queen in colour is a pleasing shade of rose. It belongs to the reflexed section, giving flowers in quantity, growing but 3 feet high. M. Gustave Grunerwald reminds one very much of Vivand Morel as the flowers develop in the open. The colour is a bright lilac pink, fading to almost white with age. Hardly ever does it grow beyond 3 feet; seldom so high.

Maria is distinctly Japanese in type. It was raised by Mr. Piercy, and grows from 3 feet to 4 feet in height. The blooms, although not large, are of a pleasing shade of mauve. Arthur Crepey is perhaps the finest yellow-flowered variety in the whole section; the flowers are borne on stout footstalks, the colour being primrose-yellow, fading to white round the edges. Lady Fitzwygram flowers most profusely all through September, and nearly the whole of October. I know of no Chrysanthemum that gives blooms in greater profusion than this, and being a white variety it is especially valuable. The opening flowers have a tinge of cream in them as they expand; this passes off to a pure white with age; 2½ feet to 3 feet. Madame Eulalie Morel does not grow more than a yard high; the habit is erect, the blooms about 4 inches in diameter, of the true Japanese type, opening in September, cerise in colour, with golden reverse. A very pretty and desirable kind for the border.

Vicomtesse d'Avene commences to open its blossoms in August, and continues until the end of September. The habit is dwarf and stout, the blooms somewhat incurved and of a pink lilac shade. Florrie Parsons is one of Mr. Piercy's raising, and belongs to the reflexed Pompon class; the colour is mauve, fading to lilac with age. Blushing Bride, growing 2 feet high, and of a pinkish lilac colour, completes a varied, useful, and extensive collection. The list may be rather a long one, but I recognise the merits of this section, and therefore give such a selection as to provide for the wants of all classes of cultivators. No mention has been made of the Desgrange family, which is too well known to need comment.—E. MOLYNEUX.

## ROYAL HORTICULTURAL SOCIETY.

MARCH 26TH.

THE second March meeting did not bring such an extensive display as was apparently generally expected, the fruit and vegetable department being the most limited. Orchids were shown in excellent form and very large numbers, while the floral section was fairly represented.

FRUIT COMMITTEE.—Present: Philip Crowley, Esq. (in the chair); with the Rev. W. Wilks, Messrs. T. Francis Rivers, H. J. Pearson, G. W. Cummins, Jos. Cheal, G. T. Miles, J. A. Laing, W. Bates, W. Farr, T. Glen, Jas. Hudson, Geo. Wythes, F. Q. Lane, H. Balderson, J. Smith, W. H. Divers, and J. Willard.

The business of the Fruit Committee was very limited, and only occupied a short time. Mr. G. Wythes, gardener to Earl Percy, Syon House, Northumberland, showed a bunch of Asparagus from permanent beds forced annually with leaves. The stalks were very good, and the cultural commendation was well merited. Mr. Wythes also staged a box of Fig St. John, and received a vote of thanks. Mr. Balderson, Hemel Hempstead, staged three Onions, two Ailsa Craig and one Rousham Park Hero, all of which had been frozen, the last-named being quite sound and the former rotten (vote of thanks). Mr. P. Davidson, Iwerne Minster House, Blandford, showed a dish of Tomato Veitch's Perfection, and received a vote of thanks.

FLORAL COMMITTEE.—Present: John Fraser, Esq. (in the chair); with Messrs. Chas. T. Druery, H. B. May, H. Herbst, Geo. Nicholson, George Stevens, C. J. Salter, R. B. Lowe, Charles Jeffries, J. D. Pawle, Chas. E. Pearson, W. Briscoe-Ironside, Chas. E. Shea, Chas. Blick, James Walker, G. H. Engleheart, and W. Selfe Leonard.

Camellias in pots and stands of cut flowers were exhibited by Messrs. Wm. Paul & Son, Waltham Cross, Herts, the group comprising well bloomed plants of C. M. Hovey, Corallina, L'Avenir, Ninfa Egeria, Princess Charlotte, Marchioness of Exeter, Lady Hume's Blush, Dona Camilla de Faria, Donckelaari, and others. The individual cut blooms were especially fine and varied (silver-gilt Flora medal).

A large and varied collection of hardy bulbous and herbaceous flowers were staged by Mr. T. S. Ware, Hale Farm Nurseries, Tottenham. Many of the exhibits were exceedingly charming; and conspicuous amongst many others were Saxifraga Burseriana, Muscari botryoides, and botryoides album, Primula rosea, Hepatica triloba cærulea, and H. triloba rubra, Scilla sibirica, Iris reticulata purpurea, Polygonatum multiflorum, and Trillium grandiflorum. Amongst the bulbous flowers were Narcissus Barri conspicuus, N. Golden Spur, N. Emperor, N. bicolor grandis, N. Empress, N. Princeps, and Poeticus poetarum (silver Flora medal).

A splendid group of Beaumontia grandiflora blooms was staged by Mr. J. Fitt, gardener to Earl Cowper, K.G., Panshanger, Herts, the trusses and flowers being very fine (silver Banksian medal). Bunches of Ghent Azaleas, flowers of Clerodendron splendens, and plant of Veltheimia viridifolia were also sent from the same establishment. A group of mixed flowering plants, composed chiefly of Hyacinths, Tulips, Narcissi, Cyclamens, Arum Lilies, Clivia miniatum, and Anthurium Schertzerianum, intermingled with Palms and Adiantums, was staged by Mr. Wythes, gardener to Right Hon. Earl Percy, Syon House, Brentford (silver Banksian medal).

Messrs. Barr & Son, Covent Garden, London, exhibited hardy flowers, amongst which were Narcissus Empress, N. Sir Watkin,

N. bicolor Empress, N. grandis, N. Golden Spur, N. princeps, Iris reticulata, Anemone fulgens, Scilla sibirica taurica, Saxifraga oppositifolia, Chionodoxa sardensis, and Megasea Stracheyi (silver Banksian medal). A small but superb group of Amaryllis was staged by Messrs. Jas. Veitch & Sons, Chelsea, composed of Medina, Cupid, Chimère, Splendour, Gorgeous, and Phidias. A finely bloomed plant of Streptocarpus × Gratus was also included in the exhibit, and deserving of a special word of praise. Pots of Mignonette "Bush Hill White," were shown by Messrs. Low & Sons, Clapton (see below).

Messrs. John Peed & Sons, Norwood Road, London, staged a collection of Caladiums and other plants; amongst the former were chiefly noticeable Charlemagne, L'Automne, John Peed, Mercedes d'Argent, Triomphe de Comte, Baron de Rothschild and Ernest Caille (silver Banksian medal). A superb group of Cinerarias was staged by Messrs. J. James & Son, Farnham Royal, Slough. The plants bore traces of excellent culture, being sturdy of habit and crowned with flowers, large in size and of an excellent varied strain (silver Flora medal).

Messrs. B. S. Williams & Son, Upper Holloway, staged plants of Otaheite Orange, single Camellias, Borenia megastigma, and Clivias. The latter were especially worthy of mention, the flowers being large, and consisting of such varieties as C. Scarlet Gem, Model, Surprise, Aurantiaca, Holloway Beauty, Madame Van Houtte, robusta, and Ambroise Verschaffelt (silver Banksian medal).

Mr. H. B. May, Edmonton, exhibited baskets of Clematis in pots. The plants were clothed with blooms and produced a pleasing effect (bronze Banksian medal). Mr. J. Miller, gardener to Lord Foley, Esher, sent a small exhibit of Neapolitan Violets. R. Backhouse, Esq., Sutton Court, near Hereford, sent flowers of Narcissus Incomparabilis Dr. Fell, the size and quality being especially good.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); with Messrs. James O'Brien, H. M. Pollett, Chas. Pilcher, H. Ballantine, De B. Crawshay, H. J. Chapman, E. Ashworth, W. H. White, Jas. Douglas, Ed. Hill, Major Mason, S. Courtauld, H. Williams, and A. H. Smee.

Messrs. F. Sander & Co., St. Albans, staged a very choice collection of Orchids, comprising a large number of kinds, of which Bollea Schröderiana (first-class certificate, see below), Cattleya Schröderiæ, C. Trianae, Odontoglossum Pescatorei, O. facetum, Batemannia peruviana, Dendrobiums, Lycastes, and Cypripedium Lawrenceanum Hye-anum were very prominent (silver Flora medal). A showy collection of Orchids, margined with Palms and Ferns, came from Messrs. B. S. Williams and Son, Upper Holloway. Several plants of Vanda suavis were to be seen, as also were Cypripediums in great variety. Dendrobiums, a basket of Calanthe Sanderiana, and a fine plant of Cymbidium eburneum were also conspicuous (silver Banksian medal). Mr. Billington, gardener to W. R. Lee, Esq., Audenshaw, near Manchester, staged a plant of Dendrobium splendidissimum illustris, said to be a cross between D. Leechianum and D. nobile nobilius. The blooms were of good size and rich in colour.

The group of Orchids shown by Messrs. Hugh Low & Co., Clapton, London, was very bright, and consisted of varieties Odontoglossum Roezli, Cattleyas, Cypripediums, and others (silver Banksian medal).

A small collection of Orchids was arranged by Messrs. Jas. Veitch and Sons, Royal Exotic Nursery, Chelsea. Prominent in this stand were Cymbidium eburneo-Lowianum, Dendrobium Murrhinianum, D. Cybele nobilius (a handsome richly coloured hybrid, resulting from a cross between D. nobile nobilius and D. Findlayanum), D. Cordelia (the result of a cross between D. euosmum Heucopterum and D. aureum), D. atroviolaceum, Oncidium superbiens, Coelogyne cristata potoleuca, several Odontoglossums, and others (silver Flora medal). Mr. Bennett, Rangemore Gardens, Burton-on-Trent, showed a plant of Cypripedium bellatulo-venustum. Blooms of Cattleya Trianae were shown by the Rev. E. Handley, Royal Crescent, Bath; while Mr. Denny, gardener to Sir W. Marriott, Down House, Blandford, exhibited a spike of Odontoglossum Pescatorei.

Dendrobiums in splendid condition and variety were staged by Mr. J. Cypher, Cheltenham. The plants were well grown, profusely flowered, and comprised amongst others xanthinum, nobile pulcherrimum, n. nobilius, n. Statterianum, n. Cooksoni, n. Cypheri, and Wardianum giganteum (silver Banksian medal). Messrs. W. L. Lewis & Co., Southgate, showed a few Orchids, amongst which Cattleyas, Cypripediums, Odontoglossums, and Dendrobiums were observed (silver Banksian medal). De B. Crawshay, Esq., Sevenoaks, showed spikes of Odontoglossums; and Mr. H. Paulton, gardener to C. T. Cayley, Esq., Leigham Court Road, Streatham, staged two magnificent plants of Phaius grandifolius, carrying large numbers of grand flowers.

Mr. H. Holbrook, gardener to E. Ashworth, Esq., Wilmslow, Chelsea, showed five Dendrobiums. One of these was a superb example of D. nobile nobilius, said to be carrying 389 flowers, and on which the tallest pseudo-bulb was 3 feet 9 inches (silver Banksian medal). D. nobile Ashworthæ; a natural hybrid Dendrobium; D. nobile Ashworthi, and D. Schneiderianum (award of merit, see below).

Sir Trevor Lawrence, Burford Lodge, Dorking, staged plants of Dendrobium Tattonianum, D. cruentum, Eulophiella Elisabethæ, Vanda cærulea, Schomburgkia crispa, Cymbidium ensifolium, and Bulbophyllum burfordiense, which may be described as the Goliath of the genus.

Baron Schröder, The Dell, Egham, showed a small group of cut Orchids, comprising some grand spikes of Odontoglossums, Sobralia macrantha, Lycastes, and Cattleyas (silver Banksian medal). An award

of merit was awarded to Mr. B. Dunn, gardener to H. Weetman, Esq., The Hawthorns, Little Heywood, for *Odontoglossum luteo-purpureum amplissimum*, which is described below. The same exhibitor also showed a few other Orchids. An award of merit was accorded to *Cypripedium Olenus*, staged by R. I. Measures, Esq., Camberwell, a hybrid that is referred to below.

CERTIFICATES AND AWARDS OF MERIT.

*Amaryllis Gorgeous* (J. Veitch & Sons).—This variety has well-formed flowers of great substance. The colour is a rich deep crimson (award of merit).

*Bollea Schröderiana* (F. Sander & Co.).—This is a new Orchid that has only recently been introduced. The sepals and petals, with the exception of a very faint flush of rose at the tips, are pure white, the lip being rosy purple (first-class certificate).

*Clivia (Imantophyllum) Model* (B. S. Williams & Son).—The spike of this variety was very fine, the flowers being orange scarlet in colour, and of good form and substance (award of merit).

*Cypripedium Olenus* (R. I. Measures).—This is a hybrid between *C. bellatulum* and *C. ciliolare*, the parentage being quite perceptible. The petals are pale claret with dark brown spots; the dorsal sepal is the same ground colour with green and brown markings, while the lip is a deep claret (award of merit).

*Dendrobium Cordelia* (J. Veitch & Sons).—This is the result of a cross between *D. euosmum Heucopterum* and *D. aureum*, the former of which is the pollen parent. The sepals and petals are cream with a thin rose edge. The lip is a superb feature. The margin is cream, claret crimson throat, blotched and veined pure yellow (award of merit).

*Dendrobium Donnesia* (H. Whiffen).—This is a beautiful form, with narrow paper white sepals and very broad petals of the same shade. The lip, which is very long, is paper white with a pure yellow throat (award of merit).

*Dendrobium Schneiderianum* (H. Holbrook).—This is from a cross between *D. Findlayanum* and *D. aureum*. The sepals and petals are white, flushed rose, while the throat is deep yellow with a crimson base and a rose lip (award of merit).

*Dendrobium splendidissimum illustris* (J. Billington).—This hybrid is the result of a cross between *D. Leechianum* and *nobile nobilius*. The sepals and petals deep rose, shading to white towards the base, while the lip, which is large, is velvety crimson, with a white band and a deep rose tip (award of merit).

*Mimnnette Bush Hill White* (H. Low & Co.).—This variety has very white flowers, the purest we have seen, rather thinly produced on the spike (award of merit).

*Odontoglossum luteo-purpureum amplissifolium* (B. Dunn).—This *Odontoglossum* is very handsome. The sepals are brown with a green tip and a blotch of the same colour at the base. The petals are brown tipped and marked whitish green. The lip is broad, fimbriated, pure white, with a heavy blotch of brown, and bright yellow throat (award of merit).

*Streptocarpus* × *Gratus* (J. Veitch & Sons).—This *Streptocarpus* is remarkably floriferous, the blooms rosy red in colour, with darker markings, being borne on stout footstalks. The leaves are very large (award of merit).

RAPHIOLEPIS OVATA.

“SUBSCRIBER” writes:—“Be good enough to give me, through the medium of the *Journal of Horticulture*, a few particulars of *Raphiolepis ovata*, a plant of which I have had given me, and do not know how to treat it, or what the flowers are like.” It is a shrubby evergreen plant, a flowering shoot being represented in the illustration (fig. 49). In some situations the *Raphiolepis* will pass the winter safely out of doors, especially in the south of England, but it is useful everywhere in conservatories or cool houses, its bold vigorous habit and glossy green leaves always having a good appearance. When in flower it is still more attractive; the large heads of white blooms, being produced at the ends of the branches, are very conspicuous.

CONTROLLING TOMATO DISEASES.

A GREAT deal has been written in the *Journal of Horticulture* at various times about the diseases that attack Tomatoes, and different remedies have been advised. It seems to me, however, that as the Tomato grows in favour so rapidly, and consequently is much more extensively grown every year, diseases seem to spread with equal rapidity, and anything that can be advised for holding such in check is of great importance to the world of horticulture. Being a gardener in a private place I have not grown Tomatoes by the thousand like some, but for several years now I have paid special attention to their cultivation, and have been very successful, not only in growing heavy crops of fine fruit but entirely free from disease, and by your permission I should like to say a few words on the subject.

First of all then I may say that I believe most of these diseases, if not all, may be held in check, if not entirely obviated by cultivation alone, and my experience tends to show that the chief factor in preventing disease is a confined root run. For some years now I have grown nearly all my Tomatoes in 10 and 12-inch pots, potted very firmly, and whilst a few that have been planted out in borders have entirely succumbed to disease, those in the pots have borne heavy crops of fine

fruit to the end of the season. This experience has been in different parts of the country widely separated, so that it cannot be either the soil or the locality that is responsible.

I account for it myself in this way. The Tomato being a very vigorous plant, if allowed a free root run with liberal supplies of liquid manure, would make enormous growth in one season, but the crop would not be a very profitable one. Now it is for the crop that we grow it, and in order to obtain fruit of good quality we allow the plants to make but little stem or foliage compared with what they would naturally form; therefore if we are going to so materially restrict the growth of the plant it seems obvious that we ought to treat the root action likewise, or something must go wrong. Some correspondents have inferred that organic manure is accountable for disease. During the time that I have

FIG. 49.—RAPHIOLEPIS OVATA.

been so successful I can safely say that I have never used chemical manure at all, always employing the drainings of the stable and cow yard. I am going to use chemical manure on some of the plants this year, to see if it will make any difference. I certainly do not see why it should, unless by using it in excess they are injured.

I am well aware that I am not the only one who grows Tomatoes in pots, but it would be very interesting to know if any of your correspondents who have tried this plan have had their plants destroyed by disease. If they have, then it becomes obvious that that is not a preventive. Until, however, someone can come forward and say that their plants in pots all succumbed to disease I shall certainly think there is something in it.

Of course, there are other points of importance to be considered, such as the selection of good seeds and soil, but if desired I would give full cultural details. For the present I think I have said enough, except that I do not advise everybody to go and buy as many 12-inch pots as they wish to plant Tomatoes, and say good-bye to all diseases. I certainly think that if those who are growing for market would restrict the size of their beds to, say, 15 inches wide and about the same depth, insure good drainage, and plant firmly, the Tomatoes would need much less soil, but a little more attention in the way of watering, for which the growers would be amply repaid.—W. S. E.

## SPRING SHOWS.

GRASSEDALE AND AIGBURTH.—MARCH 16TH.

THE fifth annual spring show was opened on the above date at the Parish Room by the Rev. C. Yeld, Vicar of Grassendale, who congratulated the Committee on the increasing prosperity both in funds and membership. There were thirty classes provided, the entries numbering 140. Thanks to the staging Committee, ably assisted by the energetic Secretary (Mr. R. Fawkes), the plants were displayed to great advantage; the room in fact could not have looked more beautiful. Hyacinths and Tulips were shown in good condition, the veteran cultivator, Mr. J. Kelly, gardener to R. Singlehurst, Esq., winning for twelve and six distinct. For six pots, three bulbs in a pot, Mr. J. Grant, gardener to W. S. Gladstone, Esq., won well, also for six double, six single Tulips, and six pots Narcissus. The prize for Amaryllis was worthily won by Mr. T. Johnson, gardener to G. W. Moss, Esq. Mr. Johnson was also granted a certificate for an admirable collection, not for competition, which displayed high cultural skill.

For stove and greenhouse plants, a specimen Fern, and specimen Orchid, Mr. J. Bounds, gardener to A. L. Jones, Esq., took all the firsts, the prize for two Orchids going to Mr. G. Leadbeater, gardener to W. J. Davey, Esq.. Azaleas were bright and in good condition, Mr. J. Kelly winning in both classes. Mr. F. Field, gardener to J. H. Wilson, Esq., and G. Leadbeater winning with hardy and greenhouse Rhododendrons, the latter taking the prize for forced hardy plants. Cinerarias, Primulas, and Cyclamen were superbly shown, Mr. A. Lewis, gardener to T. Neal Esq., being simply invincible. This group of Cyclamen he exhibited were acknowledged by some of the most experienced growers to be perhaps the finest they had seen at any show. Mr. J. Grant was successful with Spiræas and Carnations in pots, Mr. Kelly with Palms and table plants, and Mr. J. Heaton, gardener to R. T. Houston, Esq., with a bouquet.

A pretty feature was the special prize given by Messrs R. P. Ker and Sons for the most tastefully arranged hamper of plants, the hamper not to exceed 3 feet, and which might be carried out at many other places. Mr. Bounds won, and was closely followed by Mr. J. Heaton. Messrs. R. P. Ker & Sons, Aigburth Nursery, were awarded a certificate for a collection of superb seedling Clivias. Throughout the day the attendance was of a most gratifying character.—R. P. R.

BRIGHTON.—MARCH 26TH AND 27TH.

THIS was a much better show than expected, for there were scarcely any classes without several competitors, and many were very closely contested. The benefits of a practical and working Committee were well shown, and a good meeting resulted.

A silver cup was presented by T. Billing, Esq., for a group of miscellaneous plants, and called out some spirited competition. Mr. G. Miles, Victoria Nursery, Dyke Road, was awarded this for a very charming arrangement of Asparagus, Aralias, Amaryllis, Palms, and other plants, the smaller and brighter of which were well shown up by a low groundwork of *A. cuneatum*, the whole being encircled with Primroses. Mr. Meachen, gardener to Mrs. Armstrong, Woodlee, Preston, was second with a very pretty group, but too heavy in arrangement. For a table of plants Mr. Jupp, gardener to G. Boulton, Esq., Eastbourne, was first, closely followed by Mr. J. Hill, gardener to Marriage-Wallis, Esq., Withdeane. For a smaller table, open to single-handed gardeners only, Mr. Anderson, gardener to S. Cowell, Esq., Melodia, Preston Park, and Mr. Wickens, gardener to Mrs. Dawson Rowley, Chichester House, Brighton, were first and second.

Mr. Hart, gardener to A. Head, Esq., Shoreham, was a good first for twelve pots of Hyacinths in a well-contested class; while for six Mr. Wickham, gardener to J. Humphrey, Esq., Highlands, Keymer, won. Tulips were good, but not numerous. Mr. Rapley, gardener to Miss Visick, St. John's, Withdeane, was first for twelve; and Mr. Hart for six pots, also first for six Violets. The twelve Cinerarias from Mr. Murrell, gardener to Mrs. Macdonald, Manor House, Preston, and the nine greenhouse Azaleas from the same place were marvels of good culture. Mr. G. Miles had some beautifully flowered *Azalea mollis*. Pot Roses were not up to the usual standard if we except Mr. Meachen's six plants, which gained first honours. The same grower's *Deutzia gracilis* were grand; as also were his pots of Lily of the Valley, obtaining first in each class. Mr. Hart was first for twelve Narcissus, and Mr. Wickens for six Amaryllis. Callas from Mr. Murrell and Mr. Harper were good, and Mr. Murrell was also first for six double and six single Primulas.

Pots of Strawberries in fruit were shown in good condition, the first prize for six being awarded to Mr. Golding, gardener to H. St. George Voules, Esq., Uplands, Dyke Road, and second to Mr. G. Helman, gardener to Viscount Gage, Firlie Park, Lewes.

An epergne of flowers brought several competitors, and resulted in Mr. E. Meachin just defeating Mr. R. Miller. For twelve varieties of cut flowers Mr. H. Garnett, gardener to R. J. Fletcher, Esq., Withdeane, was deservedly put in front of Mr. J. Gore, Polegate, but the points were close.

As usual, there were many exhibits not for competition, the most noteworthy being a good stand of Azaleas, Boronias, Dendrobiums, Ericas, Hyacinths, and Palms from Messrs. Balchin & Sons, who also decorated the stage; a small collection of fruit and seeds from Messrs. J. Cheal & Sons, seeds from Messrs. Tilley Bros., a complete collection of garden implements from Messrs. Palmer & Co., and a stand of artificial flowers from Madame Hastings, Brighton.

## FRUIT FORCING.

**Vines.—Earliest House.**—If fermenting materials have been employed inside the house they should be removed before the berries commence colouring, retaining about a couple of inches thickness as a mulch, and affording a thorough supply of water or liquid manure, or a top-dressing of some approved chemical manure washed in. The manure supplied at this juncture must be of a sweet nature, and not likely to taint the flavour of the Grapes. This sometimes arises from the late use of soot and other crude substances, and that of a sustaining rather than a stimulating character is most advisable. Phosphatic and potassic manures, which usually contain sufficient nitrogenic elements for the due formation of chlorophyll are valuable, and suffice for the appropriation of the other substances. After the Grapes commence colouring ventilate as freely as possible, and gradually reduce the atmospheric moisture. The temperature should be maintained in the daytime at 70° to 75°, with 10° to 15° rise from sun heat, allowing a decline to 65°, or even 60°, on cold mornings. Allow a moderate extension of the laterals, as this accelerates root activity, favours due supplies of nourishment to the fruit, and aids, rather than hinders, acquirement and retention of colour in Black Hamburgh and other black Grapes. Crowding, however, must be avoided, as the results depend on the amount of matter assimilated and stored.

**Vines in Flower.**—A moderate amount of atmospheric moisture, with a steady circulation of warm (rather drier for Muscats than Hamburgs) air, is desirable when the Vines are in flower, with a temperature of 70° to 75° for Muscats, and 5° less for Black Hamburgs, allowing an advance of 10° to 15° from sun heat. Muscat of Alexandria and Canon Hall Muscat—the two finest Grapes extant—should have the points of the bunches brought to the light, and be lightly brushed over, when the caps of the flowers have parted from the calyxes, with a camel-hair brush, and shortly afterwards pollen, taken from free-setting varieties such as Alicante, be applied to the stigma. All shy-setting kinds ought to be fertilised artificially in this manner, the correct procedure being to brush over the bunches of the latter first, and then apply the pollen with another brush, always operating lightly, and with circumspection.

**Disbudding Vines.**—This, as a rule, should not be attempted until the bunches appear in the points of the shoots; even then it is not advisable to be in a hurry, nor remove a large amount of growths at a time, so as to give a little check as possible, and divert the sap into the shoots retained equally. Reserve no more growths than can have full exposure to light, as crowding is one of the chief causes of disaster in Grape-growing. The bearing shoots should be 15 to 18 inches apart. This gives sufficient space for the exposure of the lateral as well as the principal leaves to light and air, and where the extension system is followed, the canes trained 2½ to 3 feet apart for having bearing shoots the following year on both sides, but for these on the upper side only 15 to 18 inches distance suffices.

**Stopping Vines.**—When the growths have advanced one or two joints beyond the show for fruit the cultivator should exercise judgment in respect of the space, and stop so as to apportion the leafage for due exposure. Where there is space it is better to allow shoots with fruit to extend three or four leaves beyond the bunches before taking out their points, then there must be space for lateral growth, it being preferable to allow the laterals to make two or three leaves before stopping, afterwards pinching as space permits. This applies to growths above or level with the bunch, the object being to secure abundant supplies of nutriment to the clusters. The laterals from the leaves below the bunches may be pinched to one first joint and to one leaf afterwards as growth is made. This secures good results in the current season without prejudice to the prospect for another year. Where the space, on the other hand, is limited, it not being possible to carry out the process without crowding, the bearing shoots may be stopped when the leaf at the point determined on is the size of a halfpenny, one or two joints being allowed beyond the bunch. The lateral, level with or above the fruit, must be pinched to one leaf as growth is made, and those below the bunch can be dealt with in a similar manner. This will secure plump basal buds and admit of close pruning, while the principal leaves have full exposure to light, and there is some amount of lateral growth for sustaining root activity and a fair amount of nourishment and stored matter for meeting contingencies. Under these conditions, combined with clean foliage and judicious management, Grapes may be grown satisfactorily by either method, but there is greater danger of overcropping and consequently indifferent finish by the restrictive than by the freer lateral development.

**Thinning Grapes.**—Free-setting varieties may have the berries thinned as soon as they are out of flower, even such as Gros Colman whilst they are in flower, as then the best berries can be decided on, and those left get all the benefit of the swelling and are larger in consequence. Muscats and other shy-setting varieties should not be thinned until it is seen which berries are taking the lead in swelling,

these only being properly fertilised and will stone and swell perfectly. Allow sufficient space for each berry to attain full development without wedging, yet no more, as loose bunches are even worse than somewhat close but not deformed berries. Thinning is a matter of judgment, being determined by the variety, capabilities of the Vines, and the crops.

**Watering, Feeding.**—In the early stages of growth Vines require a moist soil only, anything like a sodden condition inducing a feeble break and retardation of root formation. Such condition often arises from a rich and close state of the border, for where the soil is open and well drained it can only hold water to the extent of its retentive power, consequently it is always sweet, as fresh supplies merely dislodge such surplus, and may have advantages from a sanitary point of view. When Vines come into leaf they push fresh roots and require water more abundantly, this being determined by the staple and area. A narrow border will require water twice as often as one double the width, assuming the Vines to be equally extended and cropped, and a border of loose materials will require watering much more frequently than one formed of firm retentive materials. The cultivator, therefore, must be guided by the state of the Vines in relation to their rooting medium and area. Examination of the border is the only safe plan, and when water is necessary afford a thorough supply. Surface dressings of the approved chemical manures should be applied after the soil has been duly moistened and then be washed in moderately. About 4 ozs. per square yard is a proper quantity to apply at one time, the first being supplied when the Vines are coming into leaf, another when the Grapes are setting, and afterwards every month or six weeks till the berries change colour for ripening, when the last may be given. This will help the Vines considerably at their most important stages of growth, extra feeding being given to weakly and heavily cropped canes. In the case of outside borders the top-dressing should be applied if possible with a prospect of moderate rains following, so as to get it into the soil, but without danger of its being washed clean away by heavy downpours. Liquid manure should always be applied tepid, never very strong, and preferably after the soil has been made moderately moist. Manure water should be about the colour of beer, or neat stable and cowhouse drainings be diluted with six times the bulk of water. A pound of the advertised fertilisers to 20 gallons of water is usually quite strong enough, about 4 gallons per square yard of such solution as a rule constitutes an average watering. Of course, four times the quantity will be required to bring the soil into a properly moist condition if it has been allowed to become very dry, but such must first be effected by clear water and then follow with the liquid manure. In light soils or with the roots near the surface a light mulch of sweetened horse droppings, say an inch thick, will be of benefit, it being better to apply the light dressing and add to it from time to time than supply a heavier coat. For very light open soils a mulch of cow manure is preferable, as it holds moisture better, and when the roots are working in the surface soil advertised fertilisers can be furnished with great benefit, as they supply nutrient matter in proportion to the amount of humus and counteract its otherwise over-luxuriant tendencies.

**Late Vines.**—Judicious syringings aid the breaking of the Vines, as the flow and diffusion of the sap depends on a moist genial temperature, but excessive sprinkling and a confined atmosphere provokes aerial roots, which betray an indifferent condition at the roots proper. Syringing in the morning, and at closing time or early in the afternoon, suffices for the rods, and damping down before nightfall secures a steady amount of moisture in the atmosphere. A minimum temperature should be secured to the Vines at starting, advancing to 65° from sun heat; but when the buds break the heat should be gradually raised, so as to have it 60° to 65° at night by the time they are in leaf, 65° artificially by day, 70° to 75° with gleams of sun, and 80° to 85° or 90° on bright days, ventilating from 75° and freely above it. Vigorous canes should be depressed, so as to secure an equal break, even depressing refractory canes below the horizontal line to prevent a rush of sap to the upper part until the eyes have started evenly from the base, when the canes may be brought up to the wires. If the canes push more than one shoot from an eye rub off the weakest, leaving one only, deferring further disbudding until the bunches become visible.

**Young Vines.**—Those planted last season and cut back to the base of the trellis at the winter pruning should be encouraged by gentle fire heat—say 55° at night and on cold days, so as to encourage them into growth; give benefit of the summer sun, and allow time for making and completing a good growth. Pinch the laterals at the first joint up to a height of 6 feet, and to one of subsequent growth, above which they may be allowed more freedom, but such growth only favours root development and a sturdy rod formation, and is only desirable in the case of weakly Vines. The laterals must not be allowed to interfere with the principal leaves in any way, which, for the proper assimilation of food, must have full exposure to light, so as to secure plump fruit buds, especially on the lower part of the canes.

**Planting Young Vines.**—When the growths of the canes are an inch or two long they should be transferred to the border. If cut-backs of last year's eyes they may be shaken out and placed in position either before or after they have started to the extent named, the roots being disentangled and spread out evenly in the border, covering the main roots about 3 inches deep, and watering moderately to settle the soil about them. Vines of the present year's raising will not be fit for planting out before May or June, but where the turf system is practised they should be transferred to their permanent quarters before they have rooted beyond the turves: It is a good practice, however, to rub off the first roots appearing outside the turves, which induces a fibrous root

formation quite close to the stem, and when the turves are well occupied with such the sooner they are planted the better. Likewise, Vines in pots must not be allowed to become much root-bound before placing them in their permanent quarters. The Vines require a temperature of 60° to 65° at night, 70° to 75° by day with gleams of sun, and 10° to 15° advance on bright days, maintaining a good moisture by syringing in the morning and afternoon, damping other surfaces as they become dry so as to secure a genial atmosphere. Dormant Vines should be allowed to start naturally, or not be subjected to a higher temperature than 50° to 55° artificially, and 65° by day from sun heat, with free ventilation above that point.

**Vines for Early Fruiting in Pots.**—Cut-backs of last year's raising should receive their final shift into pots 12 inches in diameter, which must be clean and efficiently drained, clean crocks or oyster shells being preferable to half-inch bones. Good turfy loam, with a sixth of old mortar rubbish and a twelfth of charcoal "nuts," form a suitable compost, adding about a quart of soot to each bushel of loam, or half that amount of some approved fertiliser. Pot firmly, using the compost rather rough. Place the pots in a position where they will receive moderate warmth from hot-water pipes in preference to plunging in bottom heat, but in this case the heat should not exceed 80° to 85°, and the Vines not be allowed to remain so long that roots enter the plunging material. Keep the house rather close, and if the weather be bright shade for a few days. It is important that the canes be trained near the glass so as to receive all the light possible and insure the thorough ripening of the wood, which for satisfactory fruit production must be solidified as made. Pinch the laterals at the first joint, and treat subsequent growths similarly, stopping the lead at about 8 feet.

#### THE KITCHEN GARDEN.

**Asparagus.**—Asparagus beds ought to be attended to without further delay. If the old-fashioned plan of giving a heavy dressing of solid manure has been followed, do not rake all off into the alleys, but fork it over and clear away all hard rubbish, leaving the rest in a neat state. When the surface of the beds is bared down to near the crowns the shoots are liable to be killed by spring frosts, and in any case the mulching gives a desirable length of blanched stalk, and also serves to keep the beds moist during a dry summer. Unfortunately, heavy autumnal dressings of manure do harm in most cases where the soil is of a heavy clayey nature, as also does salt on a similar compost. Though applied now at the rate of from 2 ozs. to 3 ozs. per square yard it acts beneficially on lighter soils both as a manure for the Asparagus and a destroyer of weeds. Where the crowns are very close to the surface, now is a good time to give a liberal top-dressing of fresh loamy soil and well-decayed manure.

**Protecting Asparagus.**—There is such a scarcity of fresh vegetables that early Asparagus will be even more acceptable than usual. It is the narrow raised beds that should give the first cuttings, and if well bared to the sunshine growth might be expedited considerably, but this is a far too risky proceeding, as many shoots are crippled either before or just as they are coming through the surface by severe spring frosts. A light mulching of straw litter is of the greatest service in protecting early Asparagus, and it pays well to remove this from the beds every morning, and return it in the evening.

**Planting and Sowing Asparagus.**—The best time to plant Asparagus is when the first shoots are 3 inches or more in length, and those who raise their own plants have, therefore, the advantage. When they have to be bought they ought to be sent for before this growth has been made, or otherwise the chances are the young shoots will be broken and the new root fibres dried up. They need not be planted directly they arrive, but may be spread out on the surface of a warm border and covered with 2 inches or rather less of fine light soil, transplanting to the beds after top and root growth has well commenced. If not already done the beds ought to be prepared for either planting or sowing at once, sowing seeds where the plants are to remain answering well. Where forcing is resorted to an old bed is usually broken up and a new one formed every season. For an early supply form beds 3 feet wide, these to hold either one or two rows of plants. For the main crop the beds may be from 4 feet to 5 feet in width, for three rows of plants dispose from 15 inches to 18 inches apart in each and every case. If seeds are sown now dispose them thinly in shallow drills, and thin out in due course. There is no particular art in growing Asparagus. Where the site is naturally well drained and the subsoil of a gravelly nature all that is needed is a good depth, or say from 12 inches to 18 inches of good soil on this. When beds are formed mark out the site, which should be well drained, allowing alleys 2 feet wide between. Throw out all the good surface soil and break up the subsoil. If the latter is very clayey remove a good portion of this, substituting any free working soil, coarse mortar rubbish, and strawy manure for this. If not very clayey be content to add mortar rubbish, half-decayed manure, and decaying garden refuse. The top soil to be returned to its original position, and will be improved by the addition of fine mortar rubbish, leaf soil, well decayed manure, and such like.

**Rhubarb.**—Just when the crowns are bursting into leaf is a good time to divide and replant Rhubarb. It is the younger clumps that usually produce the finest and most succulent stalks, and some replanting should be done every season. Divisions with one to three crowns attached may be detached from old clumps with the aid of a spade. Replant these in deeply dug, heavily manured ground 3 feet apart each way, and do not pull from them this season. Bare the surface roots of old clumps, manure heavily, and return the soil to the top.

# THE BEE-KEEPER.

## THE APIARY.

My hives are all good condition. The frost is not yet fully out of the ground, and there is as yet a paucity of flowers. Breeding is going on briskly in all the well provisioned hives, their dry interior favouring this, while the foreign element in my apiary gives me better working hives, and consequently a greater yield of honey than I can obtain from English bees. This is my experience of thirty years.

Very few of my stocks require feeding; those which do so will be fed from a tin scoop from beneath. Top feeding, unless during summer in the case of nuclei, I do not approve of. Many beginners, who heeded the teachers of the top-feeding system last autumn, notwithstanding the mild months of November and December, record the loss of their hives; with nicely packed crowns, with porous material and under feeders, the loss would have been avoided. Circumstances could be explained to prove exceptions, but where there are risks it is better to avoid them; at least, such is the experience of—A LANARKSHIRE BEE-KEEPER.

## SEASONABLE NOTES.

A THOROUGH overhaul of all stocks in my apiary shows the fallacy of a severe winter being injurious to bees, also that it is not necessary to have the hives facing due south. Some of mine are in that aspect, others due east, but the majority, for certain reasons which I need not explain here, are facing due west. In this locality the prevailing high and cold winds come from that direction. People are often surprised at the bees doing so well, thus showing that it is not the cold or high winds, which in this case blow direct into the entrances, that is fatal to their well being. In fact, other things being favourable, such as dry well-made hives with ample warm covering on the top of the frames, high winds and cold weather are advantageous rather than otherwise.

Of course, all stocks must be well prepared with ample stores to come safely through a severe winter like the last one, and the nearer one can imitate Nature in this respect the better. Were bees left to themselves, and their stores not interfered with in any ordinary season, there would be numbers of sealed-over natural stores. If the bee-keeper deprives them of that, he should supply them with something of equal value for their requirements throughout the winter.

The most satisfactory way of doing this is to feed artificially as soon as the honey flow is over, as the stores will then be sealed over the same as their natural stores were before they were deprived of them, and the earlier this is done the better. If the honey flow is over with the decline of the White Clover and the Limes, as it is in my case, and is never later than the end of July, I feed at once with the best white cane sugar that can be procured. There are several advantages of doing it thus early, as besides coming nearer their natural supplies, the bees take the syrup more readily than they do later in the season when the nights are getting cold.

Very little, if any dysentery will take place, which in some seasons is very prevalent when bees are fed late, and the weather is too cold for them to properly seal their stores. By working on these lines very few losses will occur in any well managed apiary. I am convinced that it is owing to these small details in management that my bees have wintered so well, and have come out so strong and healthy after being confined to their hives for so many weeks. Some stocks I find have used much more of their stores than others. By moving a frame of stores from those that had enough and to spare to those that were short, has kept all in good condition, and is better than feeding with syrup.

## BEES UNSATISFACTORY.

Enclosed find a piece of comb which I found in a hive in the autumn. Will you inform me through the medium of your valuable paper whether the bees are suffering from foul brood? The bees appear strong and healthy, but do not work freely.

The comb forwarded is not affected with foul brood, and as the bees have not worked satisfactorily I am inclined to think there must be some fault with the queen. When the queen is old and few eggs are being laid, bees will often stay about the hive instead of working freely. In that case it is better to remove the queen at the first favourable opportunity and rear a young one, but this should not be done before May. It would be better to rear a queen from a good working colony than from a stock that has not been satisfactory owing to the queen being aged or otherwise.—AN ENGLISH BEE-KEEPER.

## TO CORRESPONDENTS

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Centrostemma** (*W. Keay*).—The Centrostemmas are nearly related to the Hoyas, but of erect, shrubby habit. They succeed in a cool stove or warm greenhouse temperature, and as a rooting medium prefer a mixture of turfy loam, peat, and crushed lime rubbish. A sunny position is desirable, and the soil should be kept rather dry than very wet during the winter.

**Examinations in Horticulture** (*Thos. Lewis*).—As we have more than once stated, all requisite information can be obtained from the Secretary, Royal Horticultural Society, 117, Victoria Street, Westminster, S.W. The questions are not disclosed till the students assemble in an appointed room, and they must answer them within the time then specified without reference to any books or leaving the room.

**Phenyle for Cucumber Disease** (*J. W.*).—Soluble phenyle will destroy eelworm in the soil, but it will not cure infested plants. The thing is to prevent attacks by thorough disinfection of the soil and structure, and in no other way is it possible to avoid infection. The way to use phenyle is given in our issue of March 14th (page 241), and employed in the manner described is thoroughly efficacious, the stronger solution being used for disinfecting purposes.

**Narcissus Horsefieldi and Similar Varieties, Transferring from Alluvial to Very Sandy Soil** (*J. K.*).—Although *Narcissus* succeed fairly well in light sandy soil, they like something more substantial as a base or subsoil, and can only be kept in satisfactory condition by liberal dressings of manure. On such soil we found nothing better than cow manure, a good dressing (40 tons per acre, quarter of a ton per rod) being given and worked into the soil to a depth of a foot before planting. This supplies humus and nutrient matter, and suffices for a number of years, or until they require taking up for division, assorting, and replanting. We, however, also gave a top-dressing each autumn of thoroughly decayed manure, and the *Narcissus* thrive much better than on heavier and richer soil.

**Potatoes on Very Sandy Soil** (*Radcliffe*).—Potatoes can be grown well on soils that produce fair crops of Carrots, Peas, and Clover. The early varieties, such as Ashleaf, do well, and coming in early bring good returns, while *Magnum Bonum* yields heavily for late use, the tubers being of good quality and even size. Bone and blood manure are excellent for such soils, also native guano, as they supply a certain amount of humus. About 5 cwt. should be used per acre. As the land may contain a fair amount of humus from crop residues, the following may be all that is required:—Kainit, 1½ cwt.; nitrate of soda, 1 cwt.; bone superphosphate, 2½ cwt.; iron sulphate ½ cwt., mixed, per acre, applying at the time of setting. The nitrate of soda should be crushed fine, so as to secure thorough mixture and even distribution. As regards the business matter, you must take what course you think best. It is proverbially difficult for outsiders to advise in such matters.

**Fungus on Tomatoes—Useful Preventives** (*W. M. L. M.*).—1, Employ sufficient fire heat to maintain a somewhat dry atmosphere. 2, Pick off the much-affected leaves and burn them. 3, Spray (not syringe) the plants thoroughly on the under as well as the upper surfaces of the leaves with Bordeaux mixture, using a weak one, say 2 ozs. of sulphate of copper dissolved in half a gallon of water in a vessel by itself; slacking 2 ozs. of quicklime in another vessel, and forming into a thin whitewash; then pour this into the vessel containing the sulphate of copper solution, then add enough water to make 3½ gallons; stir well, strain through a hair sieve, and apply to every part of the plants, coating them evenly with the thinnest possible film of the Bordeaux mixture, also every part of the house. The lime must be quite fresh and the sulphate pure. It may be necessary to repeat the spraying in about a week or ten days. Other methods are—4, Dissolve 1½ oz. of carbonate of copper (precipitated) in a pint of liquid ammonia, and mix 1 fluid oz. to 1½ gallon of water for spraying. 5, Dust thoroughly and frequently with anti-hlight powder. Mr. Robert Fenn keeps his plants perfectly free from the fungus with powder that he obtains from Messrs. Barr & Son, Covent Garden. Whatever may be used must be applied in time as a preventive, as when the enemy establishes itself in the leaves it is obviously master of the position.

Heating House (A. F.).—A flow and return on each side of the house would give sufficient heat for Tomato culture from March to November, inclusive, but there is always an advantage in having ample piping; therefore the additional flow and return would be advisable, and a necessity for winter work. The pipes should be 4-inch, and may be arranged as shown in the sketch on page 136, the boiler being at the lower end of the structure, and the flow and return pipes on each side placed one over the other. The other two pipes may be on the same level or nearly so, following the incline of the ground, having an air tap at the highest point, or on the upper part of the cross piece, similar means being employed on the side pipes, but these should be air pipes and always open.

Packing Fruit (E. C.).—American Apples are sent to this country in barrels, the fruit being firmly pressed down without any packing. Each barrel holds about three bushels. Much fruit is sent from Kent to London in round, very strongly made, bushel baskets. French Plums are sent in deal boxes, differing in size, many being about 2 feet long, 18 inches wide, and 9 inches deep; but choicer fruits are sent in much smaller boxes containing two or three layers of fruit, packed in soft paper shavings, the boxes also being lined with paper, the ornamental or "laced" margin of which is brought very neatly over the fruit, giving the boxes a very attractive appearance. Some of the smaller of these, a foot in length or less, are extremely tasteful, and not a few purchasers consider them worth more than the fruits they contain.

Black Muscat (Hamburgh) Grapes Blackened (J. M.).—The berries just set are not infested by any parasite, but have the cuticle or skin destroyed by some corrosive substance, which appears to be that of the fumes of sulphur. It is not necessary for the Grapes to be near the pipes, as the fumes pervade the house, and are often more disastrous at the top of the structure than near the pipes, as the moisture is greater and it takes most effect in consequence. There is a disease to which this Grape is liable that causes the berries when just set to turn black and drop off. This can be traced to a wet and sodden condition of the soil, the Vines having no roots but the thick woody portions, and much of these decayed. In that case the malady is internal, the berries black or discoloured right through; but in yours the internal tissues are quite healthy, the ovules being fertilised, and even swelling to some extent. We therefore consider the fumes of sulphur have produced the mischief, which does not arise until the berries are set. Perhaps the roots are not in good condition, in which case the mischief would be intensified.

Young Cucumber Leaves and Tendrils Turning Yellow (F. W.).—The symptoms you describe are not those of "yellows," but of eelworm or defective root action, but which we cannot say in the absence of specimens. We have known the appearance you describe follow a check, such as a sudden change from dull and cold to bright weather, also a supply of cold water, or an excessive supply of this making the soil sodden, with a consequent loss of roots, causing the foliage to die back and the growths to become stunted. The sulphate of iron is useful against eelworm, which we fear the symptoms indicate, and you should use kainit at alternate waterings, not employing more than 1/2 oz. in a gallon of water, and apply a gallon of such solution per square yard with a fine-rose watering can. The turfy loam ought to have been disinfected before use, as there is great danger in using fresh-cut loam, and the mixing with fresh horse droppings would aggravate the evil, while the burnt ashes from a smother heap and the old mortar rubble would to some extent counteract it. Possibly by the use of the kainit and sulphate of iron you may overcome the eelworm before it has taken possession of the plants and commenced breeding, when there is no cure.

Vines Flagging (E. B.).—Having regard to the extreme severity of the weather in March, and the consequently cold border, it would have been better for the Vines if they had not been started quite so soon, or been brought on more slowly. The growths have been supported by the nutritive matter that was stored in the buds and stems last summer, and if this is exhausted before fresh root action commences the leaves are bound to flag under the influence of the sun. Maintain a somewhat moist atmosphere by damping the house frequently, and only provide sufficient heat for sustaining health, not forcing growth. Admit no air by the front sashes to dry the atmosphere, and thus increase transpiration from the leaves, and on sunny days, when there are signs of flagging, sprinkle the glass with limewash with the aid of a syringe. By the methods advised we hope you will be able to keep the Vines fresh, and in the meantime every day will bring the roots into more active operation. The border should receive all the sun possible, removing the mulching (if any) to permit this, but casting it on when the sun leaves the border to prevent radiation on cold nights. Heavy mulchings on Vine borders that need the sun's warmth may be injurious at this season of the year.

Moles in an Orchard (Annoyed).—There is no plan equal to trapping, the traps being set in the main runs and in proper form. If the traps are properly set in the main runs, which are usually found in ditches or by the sides, or on banks where they must cross into the enclosure from surrounding land, they are so much concerned about feeding on reaching their foraging ground that they rush headlong into the traps. There is an art in catching moles, and it consists in a study of their habits, and these acquired it is easy to set traps so as to capture them. Poisoned worms have been used for the extermination of moles, the poison being introduced into the body of the living worm, and that dropped in the main run. The poison used is strychnine, but it is not easily introduced to the body of the worm except by experts. Twigs of

common Elder introduced into the main runs will effectively bar the entrance of the moles into the orchard, or even leaves or growing shoots of that tree and dwarf Elder have a similar effect. The moles abhor both. We have kept them from ploughing up flower beds and raising their hillocks on lawns by merely thrusting living (dead are useless) pegs or small stakes into the runs where they entered the ground from the park and woodland adjoining.

Preventing Mildew on Vines (J. B.).—The Vines, if they have not started into growth, may be washed with a 10 per cent. solution of sulphate of iron (green vitriol or copperas), applying it to the rods with a brush. The walls should be whitewashed, using the copperas solution 1 lb. to a gallon of water for mixing with the lime, or a good handful of flowers of sulphur may be mixed with each pailful of limewash. The sulphur will give off some fumes under the action of the sun, which are inimical to mildew. The border may also be sprinkled with the sulphate of iron solution, a 3-gallon wateringcanful being sufficient for 90 3/4 square yards. House sewage would not produce mildew, but in excessive quantity, and applied cold, might favour its development. The blue mould on the cuts indicates a damp atmosphere, and possibly this is the only mildew that has infested the Vines. Indeed we have a strong suspicion that this so-called saprophyte is a parasitic fungus on Vines, as we came across some last year producing growths or conidia bearing hypbæ from living tissue. It would be advisable to keep the Vines rather dry as regards syringing, and use the sulphur on the hot-water pipes very carefully, as it may produce rust in the berries, which is quite as bad as mildew for spoiling Grapes.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (G. E. W.).—Epidendrum vitellinum, good form. (R. D. J.).—1, Senecio Ghiesbreghtii; 2, Cardamine hirsuta; 3, Helleborus olympicus; 4, Daphne Mezereum. (F. G.).—Rhododendron fragrantissimum. (R. B.).—1, Odontoglossum luteo-purpureum; 2, Dendrobium nobile nobilium; 3, Cattleya Percivaliana. (H. R. M.).—1, Doodia caudata; 2, Adiantum capillus-Veneris; 3, Polypodium pedatum. (Sunbeam).—A, Acacia pulchella; B, A. Drummondii.

COVENT GARDEN MARKET.—MARCH 27TH.

TRADE and prices remain substantially the same as before.

FRUIT.

Table with columns for fruit types (Apples, Grapes, Lemons, St. Michael Pines) and prices in s. d. format.

VEGETABLES.

Table with columns for vegetable types (Beans, Beet, Carrots, Cauliflowers, Celery, Coleworts, Cucumbers, Endive, Herbs, Leeks, Lettuce, Mushrooms, Mustard and Cress, Onions, Parsley, Parsnips, Potatoes, Salsafy, Seakale, Scorzonera, Shallots, Spinach, Tomatoes, Turnips) and prices in s. d. format.

AVERAGE WHOLESALE PRICES.—OUT

Table listing wholesale prices for various plants like Arum Lilies, Azalea, Asparagus Fern, Bouvardias, Carnations, Daffodils, Eucharis, Gardenias, Geranium, Lilac, Lilium longiflorum, Marguerites, Maidenhair Fern, Orchids, Pelargoniums, Primula, and Ferns.

FLOWERS.—Orchid Blooms in variety.

Table listing prices for various flowers including Roses (indoor and tea), Yellow, Safrano (English), French yellow, French Red, Smilax, Tuberoses, Violets (English, French, Parme, Ozar, Victoria), and Primulas.

PLANTS IN POTS.

Table listing prices for plants in pots such as Arbor Vitæ, Aspidistra, Azaleas, Cinerarias, Cyclamen, Dracæna, Erica, Euonymus, Evergreens, and Ferns.

STRUGGLING FARMERS.

DICTIONARY definitions of struggling are singularly appropriate in reference to the efforts of farmers to overcome difficulties that are an outcome of circumstances beyond their power to prevent or even to control. Here are some of them. To use great efforts, to strive, to contend, contest, effort to obtain an object, or to avoid an evil. These are generally applicable, and wherever full force has been given in the struggle to the pithy sense which they embody, in combination with judicious change, such earnest efforts have been rewarded by success, which if not full and entire, has at any rate staved off actual failure.

Any effort in this direction is worthy of the attention which it commands, very much in proportion to the degree of success obtained. It is so especially because there is no panacea, no general method of action, no single crop that can take the place of Wheat. If there were, our difficulties would soon be at an end. Instead of resting on its old broad basis, and retaining its clear lines of demarcation between dairy and corn farming, agriculture is now split up into sections or groups in accordance with local requirements, or the prospects of a profitable market for special farm produce. A wise man is he, surely, who, bowing to the inevitable, sets himself to obtain a clear grasp of the situation and its possibilities, and then resolves to adapt his practice to the change which has been forced on him. Had this been done—perhaps we shall do well to say, Had it been possible for ordinary farmers to have done this more generally, there would have been less of distress, less of failure. But such efforts to be successful must be an outcome of more than ordinary ability, springing as they do from a combination of shrewdness, energy, enterprise, and in some instances certainly from a spirit of adventure, tempered by caution.

Let it not be supposed that the immigration of Scotch farmers to south eastern counties was undertaken without due inquiry and deliberation. At the very beginning of the movement it fell to our lot to go over several East Anglian farms with a certain Scotch deputy—one of a group of Scotch farmers intending to come south. The searching inquiry and cross-questioning we had to undergo in connection with the inspection was certainly an experience, and if any of them went wrong subsequently it was not for lack of due precaution.

In connection with this the recent lecture delivered in Glasgow by Mr. Allan C. Young, who came south and settled in Hertfordshire, is both interesting and instructive. He told how Hertfordshire farmers, having sufficient capital, and paying 30s. an acre inclusive of tithes and rates, were doing well; but he insisted on the absolute necessity of sufficient capital. To take a farm of 400 acres with only enough capital for 200, was the direct way to disaster. With a holding well within the scope of his means, at such a rent, the Hertfordshire dairy farmer was, he said, more prosperous than farmers in the west of Scotland. Most of the farmers forming the "Scotch colony" in Hertfordshire have sufficient grass for from forty to 100 cows. Contracts for the milk are made for the summer and winter with London dairy companies or milkmen. The prices mentioned were, for the summer 1s. 2d. per barn gallon, or a shade less than 7d. per imperial gallon, carriage paid to London; and for winter 1s. 7d. per barn gallon. Mr. Young said the winter milk paid best. When he was farming he had an average of 1s. 8d. per barn gallon all the year round, and the profit from his dairy of fifty cows

for the twelve months was £253, or say £5 per cow. This is satisfactory so far as it goes, but the lecturer then went on to the profits of the middleman, saying that for every £100 paid for milk by the consumer £40 only went to the producer, the middleman absorbing £60.

After making due allowance for the risk of bad debts and other losses of retailers, he pointed to the farmers' risk of disease and death among his cattle, and to the aberrations of weather as being as great. The retail trade has gone from the farmer to his serious loss. Single-handed he is powerless to touch it; only by co-operation on a large scale, and in a thoroughly systematic manner, would it be possible to wrest it from the keen retailers, who are now in such active competition for the easily earned profits poured daily into their hands by the heedless, easy going, grumbling producer. We shall return to Mr. Young's lecture in another article.

WORK ON THE HOME FARM.

Small, late-sown Swedes, came through the weeks of 20° or 30° of frost practically unscathed; it was the large, earlier-sown roots that suffered. Of course large roots ought not to be exposed to such risk of harm from frost. Hay, too, is abundant, and with present prospects of rapid growth there should be no difficulty in keeping up condition in store cattle and milk yield in dairy cows.

Glad were we to find that Lucerne had due prominence given it in Mr. Martin J. Sutton's paper, read recently before the Farmers' Club. He recommends drilling 20 lbs. of seed per acre in rows 6 or 8 inches apart in April, and not later than July, or four months, for choice. We have found the earlier sowings answer best, and though some of the highest authorities advise sowing broadcast under exceptional conditions, we never do so, because the crop then becomes so foul with weeds as to be worthless in a year or two. Drill Lucerne wide enough apart to admit of a free use of a horse-hoe between the rows; take especial care to drill in soil free of perennial weeds; hand-hoe two or three times at the outset, and subsequently there should be no difficulty in keeping down weeds.

Mr. Sutton's advice to mow the Lucerne three times, and to fold ewes on the weaker fourth growth, is excellent. Every home farm should have its field of Lucerne near the homestead wherever it is possible. Certainly its culture should not be abandoned till the soil has had a fair trial. Often have we expressed surprise that this splendid fodder crop of such enormous bulk, so persistent in growth, so unaffected by drought, is not in more general cultivation.

Lent corn, as well as fodder crops, has been got in with ease, in a splendid seed bed, the soil, ploughed in the autumn, breaking down fine as coal ashes under the harrows, the drills working so true that seed germination will be speedy, growth quick, and a full, even plant, a certainty.

REMARKS.

17th.—Slightly foggy the greater part of the day.  
 18th.—Fog rather thick till about 10 A.M.; bright sunny day.  
 19th.—Overcast all day; spots of rain after 5 P.M., and showers in evening and night.  
 20th.—Overcast and mild with spots of rain in morning; frequent sunshine in afternoon; dull and drizzly after 6 P.M.  
 21st.—Frequent rain in small hours, and dull and drizzly all morning; sunshine all afternoon.  
 22nd.—Unbroken sunshine from sunrise to sunset.  
 23rd.—Alternate cloud and sunshine in morning, cloudy afternoon; rain in night.  
 Fine mild week, with temperature above the average. It seems difficult to believe that only a few weeks back the maximum temperatures were far below the recent minima. The following shows how rapid the rise of mean temperature has been.

MEAN TEMPERATURE OF WEEK ENDING

February 9th, 22.4°.	March 9th, 37.1°, a rise of 14.7°
" 16th, 26.1°, a rise of 3.7°	" 16th, 43.1° " 20.7°
" 23rd, 34.4° " 12.0°	" 23rd, 43.2° " 25.8°
March 2nd, 36.7° " 14.3°

# VEITCH'S

SUPERB

# GLOXINIAS.

THE FINEST IN CULTIVATION.

## VEITCH'S SUPERB SCARLET.

Saved from our splendid collection of high-coloured scarlet and crimson-scarlet sorts, which mark a decided advance in these shades of colour. Per Packet, 2/6.

## VEITCH'S SUPERB MIXED.

This strain of Gloxinia is of the most profuse flowering character, with the greatest diversity in the colours; flowers large and open, growth vigorous. Saved from our newest and best sorts. Per Packet, 2/6.

## VEITCH'S FINEST SPOTTED.

A charming strain, of very compact growth, and most exquisite in the delicate markings; the flowers are produced in the greatest abundance. Per Packet, 2/6, post free.

For full descriptions of other CHOICE NOVELTIES and SPECIALITIES, see SEED CATALOGUE for 1895, forwarded post free on application.

## FLORISTS' FLOWERS

AND

## HARDY BORDER PLANTS.

FORBES' NEW CATALOGUE for 1895 is enlarged to about 150 pages, and very materially improved, embracing everything—new and old—worth cultivating in the way of FLORISTS' FLOWERS and HARDY PLANTS, with accurate descriptions and prices. Copious notes as to their origin, how and where best to grow, a full index of the common or popular names of HARDY BORDER PLANTS, and a vast mass of other valuable information that cannot be had elsewhere, which renders this the BEST, MOST RELIABLE, and COMPLETE CATALOGUE ever issued on this popular class of plants. Free on Application.

JOHN FORBES, Nurseryman,  
HAWICK, SCOTLAND.

# JACK FROST

Has caused many losses that can be made good in an easy and cheap manner by purchasing the following Bulbs and Plants, which I can strongly recommend as being first class:—

## BEGONIAS, SINGLE,

20,000 Grand Bulbs, Mixed Colours, finest ever offered at the price. 3s. per dozen.

## PELARGONIUMS, SHOW & DECORATIVE.

Fine Plants in Best Kinds, 6s., 9s., and 12s. per dozen.

## ZONAL PELARGONIUMS,

Best Kinds only. 6 for 2s. 6d., 12 for 4s.

## IVY-LEAF PELARGONIUMS.

A very Choice Lot. 6 for 2s. 6d., 12 for 4s.

## DOUBLE PETUNIAS,

Extra fine New Kinds. 6 for 3s. 6d., 12 for 6s.

Send for Catalogue, Free.

# BOX OF SEEDS

WHICH CONTAINS

- 6 varieties Truffant's French Pæony-flowered Aster.
- 6 varieties Dwarf German Ten-week Stock.
- 2 ozs. Mixed Sweet Peas.
- ½ oz. Large-flowered Mignonette.
- 12 varieties showy Hardy Annuals, including Nemophila, Clarkia, Candytuft, &c.
- 6 choice Half-hardy and Tender Annuals, including Balsam, Phlox Drummondii, Portulaca, &c.
- 1 oz. Mixed Tom Thumb Nasturtium.
- 1 oz. Mixed Tall Nasturtium.
- 6 varieties Hardy Perennials and Biennials.
- 6 varieties Everlasting Flowers, suitable for winter bouquets.

This unique assortment will be sent Free by Post to any address in the United Kingdom on receipt of remittance.

THURSDAY, APRIL 4, 1895.

## EARLY FORCED VINES.

THE modern system of growing thick-skinned Grapes for keeping till May or June has rendered the practice of forcing Vines very early almost obsolete, there being few places in which they are started before the new year to afford ripe Grapes by the close of May or early in June. This is a decided advantage so far as the very early forcing of permanent Vines is concerned. Canes making their growth at the dullest period of the year, as must be the case with those started in November to ripen their crops in April or even in May, severely taxes the energies of the Vines, especially after a few seasons.

This may not happen until they have done good service, but it does occur too soon for the profitable production of very early Grapes from planted-out Vines, therefore the potted system is resorted to. Of course, there is nothing new in growing Vines in pots to afford ripe Grapes in April, for it is mentioned by Abercrombie over a century ago, also the forcing of Peaches and other fruit trees in pots, and was carried on successfully by the aid of fermenting material, and fire heat on the flue system of heating. Hot-water heating is, however, most in touch with present requirements, and readily answers every purpose.

The originator of the very early system of forcing young Vines in shallow and narrow beds may be untraceable, but it is not by any means a new method as regards permanent planted Vines, having been practised on the Continent for centuries by means of fermenting material, and in this country in some places by those means and auxiliary aid from fire heat. This, however, is not the point, for Vines will grow almost anywhere where there is a sufficiency of heat, and often much better with scanty fare than high living. The question is that of growing in pots for affording ripe fruit in late March or early in April as compared with those planted out in shallow and narrow beds, fruiting them once and then throwing away.

This is the greatest drawback to the potted as to the annually planted system, as the rearing of the Vines requires two years, and then another for fruiting. Vine eyes rooted one year are not

safe for fruiting the following. Cut-backs only can be relied on, and these must be started early to make the desired growth and ripen it for satisfactory cropping. Vines in pots can be prepared in half the room of those planted, an excellent place for the former being a lean-to pit with about 9 feet of trellis, the pots being stood on slate shelves resting on the hot-water pipes. This is all very well so far, but the Vines in pots are one thing and planted out canes another. We secure a Vine by the potted system capable of producing six to eight bunches of Grapes, averaging  $\frac{3}{4}$  lb. each, and the production seldom exceeds 6 lbs. per Vine.

This is the highest average for Vines started at the beginning of November and ripening the Grapes in late March or early in April. The cost of production is nearly double by the potted system as by the planted, for canes in pots require watering much more frequently, and more nutrient matter escapes from the pots than is retained by the soil. Where labour is no consideration, or in other words where the expenses have not to be curtailed to the lowest possible point, this is not material, but apart from this the results are consequential, as there is as much room needed for fruiting Vines in pots as for those planted.

The planted method requires a house with a south aspect, a lean-to or three-quarter span of 9 or 10 feet width. It may be partly sunk in the ground and have roof lights only. Wooden ventilators in front, opening on the hot-water pipes or below them, are an advantage, and with the usual top ventilation is all that is necessary. Four rows of hot-water pipes in front and two at the back afford the requisite top heat. The bed need not exceed 4 feet in width, the walls being taken up 9 inches thick to within 15 inches of the top, which should be about 18 inches below the front wall plate, the upper 15 inches, being  $4\frac{1}{2}$  inches brickwork in cement. This will form a ledge on each side, and a  $4\frac{1}{2}$  inch wall up the middle, built pigeon-hole fashion, of corresponding height, form the requisite rest for the slate or stone covers. In this chamber, which should not be more than 9 inches deep, two rows of 4-inch pipes, raised clear off the floor and not touching the cover, should be fixed. An inch of clean rubble being placed on the covers and 2 inches depth of old mortar rubbish, such as remains in a half-inch sieve after sifting out the small, affords the requisite drainage, and a thin layer of turves, grass side downwards, makes the drainage secure against clogging. This leaves a depth of 1 foot for soil, and a ridge of  $2\frac{1}{2}$  feet base and 18 inches top breadth along the front, answers for planting in. Good turfy loam five parts, old mortar rubbish one part, and half part each wood ashes and charcoal "nuts," form a suitable compost. If the loam be poor add a part of fresh horse droppings, and about a pint of some approved fertiliser may be allowed to each barrowload of loam. When warmed through the cut-back Vines should be planted, they having been started in January and forwarded for turning out by early February, the long roots being shortened, as it is not bare roots but fibres that are required. The way to secure these is to grow the Vines in turves about 9 inches square and 6 inches deep, cutting the roots extending beyond the turves two or three times during the previous summer to planting, as this insures an abundance of fibrous root formation which is very essential, or grow in 6-inch pots in firm soil and water moderately for a time.

The canes should be placed  $2\frac{1}{2}$  feet apart, and always have any corkscrew-like roots cut back. The Vines will spread rapidly in a suitable temperature—namely,  $60^{\circ}$  to  $65^{\circ}$  at night,  $70^{\circ}$  to  $75^{\circ}$  by day, and  $10^{\circ}$  to  $15^{\circ}$  rise from sun heat, with a genial atmosphere secured by damping the house two or three times a day, and keeping the compost properly moist. Soil must be added to the ridge as the roots show at the sides, and thus supplied they will occupy every inch of it and form numberless fibres provided it be rammed firmly. The canes can be trained 1 foot from the glass, the nearer the leaves are to it, provided they do not touch, the

better. Stop the laterals to one leaf, and sub-laterals in like manner, pinching out the points of the canes at 9 feet, or 1 foot from the extremity of the space.

By June the Vines are as thick as walking sticks and the buds prominent, so that it becomes a question of ripening the wood and plumping the buds, which is sure to happen in the heat of the summer, and the leaves will fall as the growths mature, which can be accelerated by reducing the laterals gradually. Care, of course, must be taken in reducing the lateral growths so as not to start the buds in the axils of the principal leaves, and with this precaution the sooner they are removed after the wood commences to ripen the better. With complete control over the roots, as this system affords, resting can be effected readily, but it should not be induced by flagging, but by diminished supplies of water and atmospheric moisture. The Vines should not be allowed to become too dry during the resting period, and will not start with moderate root moisture if abundance of air be admitted day and night, especially during the latter part of the month of August and through September and October.

When the leaves are all down the Vines should be pruned. This consists of cutting off the end of each Vine to the first plump bud below the stopping of the canes in the first instance, leaving a length of about 8 feet 6 inches. On November 1st forcing can commence in earnest, for the Vines need no preparatory process beyond cleansing the house, washing the canes with tepid softsoapy water, and moistening the soil evenly through. A bottom heat of  $60^{\circ}$  to  $65^{\circ}$  and top heat of  $55^{\circ}$  till the buds start is ample, then gradually raise the former to  $70^{\circ}$  and  $75^{\circ}$ , and the latter to  $60^{\circ}$  and  $65^{\circ}$  at night, and  $70^{\circ}$  to  $75^{\circ}$  by day by the time the Vines are in leaf. The bottom heat causes root action in advance of top growth, and this should be assisted by additions of fresh soil. Thus sturdy well-developed leaves are formed, instead of the puny leafage of potted Vines. Every planted Vine has 10 feet of soil surface available for feeding purposes, and as many cubic feet of rootage. This means something in the shape of results, other conditions being favourable—say six bearing shoots on each side of the cane at 15 inches apart, or twelve bunches per Vine, and all over 1 lb. in weight.

These results double those of the very best early forced Vines in pots, while there is no comparison of the two for appearance, size of berry, and finish.

The early varieties only are available for forcing, Black Hamburgh and Foster's Seedling being perhaps unequalled for this purpose, though there is far too many of this class of Grape grown, and too few of Madresfield Court and Muscat of Alexandria for the requirements of the London season. The Vines may be kept a second year for fruiting, but it is not the way to produce anything better than very early forced potted Vine Grapes, which are too small in both bunch and berry to meet acceptance at the hands of those caring only for sterling value. It is better, therefore, to crop the Vines once and throw them away. This necessitates the employment of two structures and takes all the "gilt off the picture." The same thing is essential for potted Vines, which are readily moved from place to place, and, as a consequence, often receive checks and treatment the reverse of beneficial. Attempting too much usually results in the indifferent performance of the subjects. The structures must be kept for the Vines, no other plants being allowed to interfere with them in any way. There is space in the first year for raising Tomatoes for planting in other structures during the spring and early summer months; the back wall of the house will be available for bearing plants of these in the preparatory year, and in the season of bearing strong Tomato plants can be planted in the bed after the Grapes are cleared without any change of soil, as Tomatoes are an excellent rotation crop after Vines, so that there is really no waste of space or time, but two of the easiest-grown crops in the most remunerative form are duly catered for by a straightforward and practical method.—G. ABBEY.

## CARNATION NOTES.

I HAVE just returned from a two-months stay on the Continent, and find, as was only to be expected, that the unusually severe winter has greatly damaged some of my seedlings, but it has left others wholly uninjured, and I venture to offer to your readers the results of my experience.

I had several classes of seedlings, some from seeds sown in August, 1893, immediately after it was harvested. These were kept through the winter of 1893-1894 in small pots in cold frames, and planted out in what I hoped would be their flowering quarters towards the end of April last year. They were kept well pinched back, and when I left England in January were large bushy plants in the perfection of health and vigour. I came back to find them nearly all dead; indeed I do not believe that more than 4 or 5 per cent. will survive and flower this summer.

Side by side with these were a number of plants from seeds harvested in 1893, and sown in March last year. These were planted out late in May—that is, as soon as they were sufficiently large.

Nothing could be more striking or instructive than the contrast they presented—hardly any of them dead (not above 2 or 3 per cent.), and the vast majority of them entirely unaffected by the terrible winter they have passed through.

The irresistible conclusion therefore is strongly in favour of spring as against autumn sowing for plants that are to be wintered out of doors. I believe it will be found that seeds sown in the autumn produce plants too far advanced and too "woody" to stand severe frost—indeed, many of these plants would have flowered last autumn had they not been kept pinched back.

The experience reminds me strongly of an attempt I made some years ago to grow on layers without allowing them to flower, through a second winter, in the hope that the following season they might give a larger supply of bloom. The experiment was equally unsuccessful, and most of the plants died during the second winter, which was a hard one.

I have had a third class of seedlings under different treatment. Sown in March last year they were planted out temporarily, and in October last were moved into their flowering quarters, which had not been ready for them earlier. These plants have suffered very much, and contrast most unfavourably with those which were planted out early last summer, and have not since been moved.

Last year's layers, even of my new Malmaison varieties, seem little if any the worse for the winter.—MARTIN R. SMITH, *Hayes, Kent.*

BOLLEA SCHRÖDERIANA.

AMONGST the novelties shown at the Drill Hall, Westminster, on the 26th ult., was a splendid plant of *Bollea Schröderiana*, carrying several blooms, one of which is depicted in the engraving, fig. 50. The sepals and petals are pure white with the exception of a very faint blush tint at the edge, while the lip, which is of a peculiar form, is rosy purple. Another point in favour of this plant is the delightful fragrance emitted. It was exhibited by Messrs. F. Sander & Co., St. Albans, and received a well-merited first-class certificate from the Orchid Committee of the Royal Horticultural Society.

BRASSIA LAWRENCEANA.

It has been pointed out to us by Mr. Adolphus H. Kent, Chelsea, that the Orchid we figured under this name at page 275 of our last issue is not *B. Lawrenceana* at all, but a form of *B. bracteata*. Our sketch was, as stated in the last issue, taken from a plant staged by R. I. Measures, Esq., and labelled *B. Lawrenceana*. As such it was certificated by the R.H.S. Orchid Committee, and if it was really *B. bracteata*, it was clearly an oversight to give an award to the plant without, at any rate, first correcting the nomenclature. In Veitch's "Manual of Orchidaceous Plants," vol. ii., pages 124-5, some interesting particulars are given of *B. Lawrenceana*, in the course of which it is stated that this Orchid is only known by figure and description. We should be glad of Mr. Chapman's opinion on the subject.

## MASDEVALLIAS OF THE CHIMÆRA GROUP.

THESE extraordinary Orchids have a wonderful fascination for most cultivators, and if once their culture is taken up with

spirit one never seems to tire of them. A friend to whom I was showing some dried flowers recently somewhat laconically described them as the most wonderful of a wonderful family, and certainly no one can fail to be struck with their fantastic forms or singularly effective colouring. No particular difficulty will be found in growing this section providing their wants are anticipated and attention given to a few simple details.

The house in which they are growing must be kept at as uniform a temperature as possible all through the year. During the summer they must be heavily shaded and a free circulation of air kept up about them. The temperature during this period ought not to rise above 70° if it can be avoided, and the atmosphere must be loaded with moisture. The roots are always active, and must never be dry, or the plants will be weakened, and during summer they must be kept moist almost to saturation.

As the season advances and the sun begins to wane, the plants may be inured to rather more light, but avoiding scorching of the

FIG. 50.—BOLLEA SCHRÖDERIANA.

foliage by exposing them to the sun's direct rays. In the winter they must have the lightest position available, and the full day and night temperature maintained. When very cold fire heat must be turned on sufficient to keep the house at, or near 50°, but the atmosphere must be softened by frequent dampings, or thrips will make their unwelcome presence known by the whitish irregular marks all over the foliage and flowers. If they do put in appearance no time must be lost in effecting a clearance of them, for if left alone for a few weeks they obtain a firm hold on the plants, and owing to their marvellous fecundity, are most difficult to eradicate.

The majority of this group are best grown in shallow wood baskets suspended, as this insures a better circulation of air in summer, and clearer light in winter than when they are grown in pots on the stages. Some large pieces of charcoal may be placed over the bottom rods of the baskets, as the roots like to entwine about them, and it also allows the scapes of those that flower downwards to find their way through the bottom easily. Three parts of clean peat, sphagnum moss to half a part of peat and half of potsherds will be found a good compost; the sphagnum must be kept growing about the roots and the bases of the stems all the year round. If the *Odontoglossum* house is kept from falling below 50° this is by far the best place for the plants during winter, but if, as is unfortunately too often the case, this house is allowed to range between 30° and 40°, then the plants must be removed to warmer quarters, which are, however, usually too dry for these moisture-loving and very sensitive Orchids.

The flower scapes of many of this group produce three or even four flowers in succession, so that it is better not to remove these so long as they are fresh. The typical *Chimæra* grows about 9 inches high and bears leaves 1½ inch broad. The flowers appear at different times in the year from the base of these; the sepals are

about an inch across at the base, concave, the ends narrowing to a caudate point about 6 inches from the base. Inside these are hairy, the ground colour yellow, with irregular blotches of red and purple. The petals and lips are comparatively insignificant, white, the latter slightly protuberant, and serrated on the upper edges.

*M. Backbousiana* is said by some authorities to be a variety of the last named. They are very similar species at all events, the chief difference being in the larger, brighter coloured flowers of *M. Backbousiana* and the longer, more narrowed lip. *M. bella* is a remarkable and beautiful species, bearing its flowers singly on their pendent scapes. The tails of the sepals are about 4 inches in length, greenish yellow, thickly spotted about the triangular bases with reddish purple. This blossoms in the autumn and early winter. *M. Chestertoni* grows about half a foot high, and also blooms in autumn. The flowers are smaller than those named above, and quite distinct, the petals cuspidate, yellowish with purple dots, lip dull red. *M. Nycterina* is often met with under the name of *M. Chimæra*. It is, however, quite distinct, being dwarfier in habit and bearing smaller flowers, tails 4 inches in length, brown with blackish or deep purple spots on the broad portions. The lips and petals as in the last named kind. These are all natives of the mountainous regions of Equatorial America, and are the best known of this section. *M. erythrochaite*, *M. macrura*, *M. Houtteana*, *M. Roezli*, and *M. Wallisi* are all interesting and beautiful plants, well worthy of the best care that can be bestowed upon them.—H. R. R.

### SEED SOWING.

THE late frost penetrated to a depth of 2 feet in places, and it may be well to remember that it must take the sun a considerable time to raise the temperature to its normal height. Last season was most unfavourable for the proper maturation of various seeds, and not a few will fail to germinate in a low temperature. Many old seeds will be distributed, especially among those who go in for cheapness, and these will be at a disadvantage when sown in a cold soil. We all ought to know that quite new, perfect seeds germinate the most quickly and strongly, and the plants resulting are rarely equalled by those coming from old seeds, but in either case not a little depends upon the treatment.

William I., and the various round-seeded early varieties of Peas that were sown as soon as the frost departed may succeed, but the dwarf early wrinkled seeded varieties, and the taller growing Marrow Peas, if sown then, should be examined. If found sound and beginning to sprout no mistake will have been made, but if many of them give signs of perishing no time should be lost in sowing more seeds, and it may even be desirable to sow in pots to prevent a break in the supply. They will transplant readily, and the crops will be materially advanced. At Hatfield Mr. Norman grows an extraordinary breadth of the Dwarf Chelsea Gem every season, a peck or more of seeds being used, and this excellent variety is also extensively grown at Longleat by Mr. Trollope. In both instances many rows are planted out, and under high culture—that is to say, with the aid of well worked, very freely manured borders, this variety attains a height of from 2 feet to 3 feet, and produces enormous crops. Very early sown Broad Beans, hard as they look, often perish in a cold wet soil. It will be well to examine them, and act accordingly.

Kidney Beans are naturally delicate, and though we may have much warm weather before the end of April it may yet be advisable to defer sowing in the open till the end of the first week in May, the earliest rows being formed by plants turned out of pots or boxes late in that month and roughly protected. Runner Beans succeed well under similar treatment. The seeds of these are so liable to fail when sown too early that I counsel keeping them out of the ground till the middle of May, the plants thereby obtained also escaping May frosts.

Onion and Parsnip seeds do not often perish in the ground owing to its coolness. By far the best results, however, attend the exhibitor's practice of raising a few hundred plants of Onions in boxes. These small plants scarcely feel the check of removal. Instead of a few hundreds, thousands of plants should be raised under glass, as they take up very little room, and there would be fewer failures from Onion maggot and mildew. At Mentmore, Mr. Smith grows remarkably fine crops of Onions on the ridges between Celery tranches, double rows on each being planted out. What is done so well in this case ought generally to be imitated. Choice or even ordinary varieties of Onions might yet be sown in pans or boxes and placed in heat with every prospect of a gain of a fortnight. With regard to Parsnips very early sowing is a mistake, unless in the event of some extra fine roots being required for summer shows. Good serviceable crops can be obtained by sowing at the present time and the middle of April is soon enough for

sowing the main crop of Carrots, also Beet, Salsafy, Scorzonera, and Chicory.

We are frequently advised to sow Chou de Burghley early in March, whereas the best time to sow seeds of this winter vegetable is late in April or early in May. Sown much earlier the plants grow to a great size, and the hearts are apt to become much too coarse. Half the seeds of Broccoli distributed in this country are sown too early. Where is the sense of raising hundreds of plants much earlier than the ground can be got ready for their reception? Sow the main and late crops late in April or the first week in May rather than a month or six weeks earlier. Borecoles and Brussels Sprouts require a long period of growth, and in all cases where room can be found for them raise the plants under glass or in a warm border, and get them out early. Not so Savoys. Treat them as advised in the case of Chou de Burghley, and thereby avoid waste and coarseness. Nor ought Tomatoes and Vegetable Marrows to be sown so long before they can be planted out, as generally advised. Starvelings turned out of small pots are a long time in recovering from the check given them. From a month to six weeks is time enough for raising the former, and three weeks ample for the latter.—W. IGGULDEN.

### THE FLORISTS' TULIP.

[By JAS. W. BENTLEY, Hon. Secretary to the Royal National Tulip Society.]

#### CHAPTER VI.—CONTINUED.

(Continued from page 203.)

AS five or six years must elapse before the seedling raiser can see any result of his labours in the form of bloom it is of the highest importance that every care should be taken that he starts well. To start well he must have bestowed considerable thought on the selection of the varieties he intends to use as the parents of his seed, and he must have used every care that his cross-fertilisations have really been carried out in accordance with his wishes. It is hardly necessary to say that chance-saved seed is of no value at all, and should never be used, for the chances are that the only result would be a crop of mongrels, and the grower's disappointment would be intensified by the thoughts of the years wasted (as far as they were concerned) in their production. I do not deny that occasionally a good variety has been raised from chance-fertilised seed, for our most prominent bizarre, Sir Joseph Paxton, is said to have come from a casual pod of seed borne by a plant of Trafalgar, an old-time long-cupped red bizarre; but such a case is so rare as practically to be the exception that proves the rule. As an instance of the value of careful cross fertilisation, my friend the late Mr. Lakin informed me that he was present in Storer's garden when the latter fertilised a bloom of Pilot with the pollen of Shakespeare. Such care was taken on this occasion that from that famous pod of seed nothing but bizarres bloomed, and they were such improvements on what had been grown before that they threw out of cultivation nine-tenths of the bizarres which had formerly been highly prized, and although it is over thirty years since they made their appearance they still hold their own as some of the best bizarres in cultivation.

The length of time which must pass before Tulip seedlings bloom has doubtless deterred many persons from attempting to raise them. I fail to see why this reason should be held good, for although life is at the best uncertain, it is nevertheless quite certain that raising seedlings will do nothing to shorten it, but give it an added interest, and one of its best of pleasures, that of anticipation. Should the grower be gathered to his fathers before his seedlings bloom or break, yet in other hands they may serve to keep his memory green for many a long year.

There is not much difficulty in getting seed from the Tulip, for the parts of reproduction are so prominent, and the flower guards them so well, as to be a notable example among botanists. At night, or in bad weather, the petals shut so closely together that sooner will the stem be broken by the wind than the petals separated, and the formation of pollen thus injured or retarded, although when the weather is genial they open readily, so that the sun may mature the parts necessary to the formation of the seed. When the impregnation of the stigma has taken place the petals fall off and decay, leaving the seed pod to benefit by all the nourishment the stem affords, and to enjoy the light and air uninterrupted by their presence.

In actual seedling-raising I prefer to use breeders when possible for seed bearers, as they are as a rule sturdier and more robust than rectified flowers and bear finer pods of seed, and to take pollen from well marked rectified flowers. In my opinion it is important that seedlings should be raised only from such varieties as are known to break well, and have some special merit which it is desired to retain in an enhanced form in the seedling. It is unwise

to cross two varieties each of which shows prominently the same defect, for fear that the resulting seedlings may exhibit the defect in a more marked degree than their parents, and I think that seed should not be obtained from varieties dull and undecided in colour, flimsy of petal, or impure in any way. It is very important that roses should be crossed only with roses, byblœmens with byblœmens, and bizarres with bizarres, and it is well to divide the bizarres, and to cross reds with reds, and darks with darks. I think it is wise also to consider the relationship of the varieties it is proposed to cross-fertilise, and to choose for the purpose those that have been raised by different growers, as I feel sure a stronger progeny is the more likely result if near relationships are avoided. Perhaps a few instances will make my meaning clearer. I should not cross Dr. Hardy (Storer) with Orion (Storer) because, although two good red bizarres, they are probably raised from the same pod of seed, and therefore too nearly related; I would not use Talisman (Hardy) and Maid of Orleans (Gibbons) because, although from different raisers, they both exhibit the fault of being rather long cupped. I should reject Goldfinder (Hepworth) because, although a brilliant breeder, it invariably breaks badly; Lord Lilford because, although of good form and a handsome feather, it is scarcely ever pure, and Lord Derby (Clegg) because, although handsome in colour and excellent in shape, it has flimsy petals and never breaks well.

Improvements in colour should be an important object with the raiser, and he should endeavour to get the roses more scarlet, the byblœmens blacker or more deep violet, the dark bizarres blacker, and the red bizarres more orange-scarlet in their marking colours than has hitherto been obtained, whilst his aim for the ground colour should be a dazzling opaque white for the roses and byblœmens, and clear brilliant yellows for the bizarres, which may vary from a lemon to orange colour in shade. In the following list of suitable crosses I have had regard to the ideas I possess on this subject, and it may be found useful.

*Roses.*

Rose Hill × Annie McGregor	Annie McGregor × Circe
Rose Hill × Modesty	Mabel × Rose Hill
Mary Jackson × Annie McGregor	Rose Hill × Mrs. Lea

*Byblœmens.*

Talisman × King of the Universe	Elizabeth Pegg × King of the Universe
Queen of the May × King of the Universe	Elizabeth Pegg × Talisman
Talisman × Queen of the May	Queen of the May × Adonis
Chancellor × Salvator Rosa	Bessie × Elizabeth Pegg

*Bizarres.*

*Dark.*

Sir Joseph Paxton × Wm. Lea.  
 Masterpiece × Lord Stanley

 Dr. Hutcheon × William Annibal  
 Dr. Hardy × General Grant

Some of my readers may smile at the idea of bringing back old Polyphemus at this time of day, but I do so in order to get if possible his clear lemon and black, which combination is not at all common in our modern flowers.

The flowers destined to bear the seed pods should be selected before they open, and immediately they do the anthers entirely removed. At this stage the pollen, not being yet ripe, will be invisible on the anthers. The flower should then be lightly filled with cotton wool, to prevent chance impregnation by the wind or by bees, and supported by a stick and lead wire. Every fine day the cotton wool should be removed, and the stigma carefully examined; when ready to receive the pollen it will be found covered with a slight viscous exudation, and probably a tiny opening in its centre be observable. An anther covered with ripe pollen should now be extracted from the flower decided on as the pollen parent, and with it the surface of the stigma gently rubbed until it is plentifully covered with the pollen, and the cotton wool immediately replaced. If the pollen has taken effect the stigma will in a few hours have assumed a rosy hue, and have a velvety rather than viscous appearance.

It is important that healthy pollen be used, and only those anthers which are plentifully loaded and are good in size and shape should be selected. It is a good sign if they move about easily on the point or pivot of the filament, as unhealthy anthers are commonly unable to do this, and have a shrivelled appearance. The petals soon fall and the seed pod begins to swell, and sun and air are very essential at this time; but rain or drip should be kept from the growing pod, which is very liable to decay if wet lodges in the corrugated stigma, particularly in damp and ungenial weather. The pods are ready for gathering when they lose their green fleshy look, and show the seeds like ribs through their wasted

sides. It is most important to thoroughly dry the pods immediately after cutting. A good plan is, after tying an identifying label to each, to hang them up in a warm, dry room for at least a fortnight. I have known the seed killed in several fine pods of my own growing through not attaching sufficient importance to drying.

If any mischief is feared from damp, or if any symptoms of mould or mustiness appear about a pod at any time after it has done growing, it is best to open it and turn out the seeds to dry separately, when some may be saved; but it is wonderful how quickly a very slight dampness will destroy the germ of life in every seed in a pod. When perfectly dry the pod is opened, and the seeds, which are flat and of a light brown colour, easily fall out. If they are good the germ is easily seen near that portion of the seed that has been nearest the stem. A fine pod will often contain as many as 200 perfect seeds. The seeds can be stored away in a dry place in envelopes having the particulars of their parentage written on them until the time for sowing arrives.

DOUBLE VIOLETS.

It is questionable if any flowers give more pleasure at any time during the year than double Violets do in the winter. When we consider that Violets can be had with small cost and labour for over six of the dullest months of the year, it seems strange that they are not even more generally cultivated. Double Violets may well be termed amateurs' flowers, as no artificial heat is required at any time during their existence. All that is needed in the way of protection is complete immunity from frost. This can easily be obtained by the aid of an ordinary two-light garden frame, a sufficient amount of long strawy manure or dry leaves to protect the sides of the frame, and an adequate covering of ordinary garden mats for the glass.

The month of April is the right time to prepare the plants for flowering next season. For affording an uninterrupted succession of bloom some persons grow half a dozen varieties. I grow but one, and am well content with it. The best double Violet is, in my opinion, Marie Louise. The colour is described as rich mauve lavender blue, with a white eye. De Parme is also an excellent variety, free and hardy; the colour pale lavender purple, also with a white eye. Neapolitan, lavender, white eye, is appreciated by some, but is too "flimsy" in its blooms, and its flowering season too short to be worthy of more than ordinary attention. Comte de Brazza, pure white, although flowering abundantly in the spring, does not excite much attention, owing to its shyness during the dull winter months. Lady Hume Campbell has somewhat darker flowers than De Parme, though not so rich as Marie Louise; where variety is approved this is worthy a place. Madame Millett, rosy lilac, is most distinct, being very double, fragrant, and free. This Violet succeeds well in pots, which is a good recommendation. Messrs. Beachey, the well-known Devonshire Violet growers, had well flowered plants in pots of it at the Torquay Chrysanthemum show last November. Another striking variety exhibited by the same firm was Duchess of Edinburgh. The flowers are large, rosette-shaped, and not so pale in colour as Neapolitan.

A salient point in Violet culture is thoroughly prepared plants; without these it is not possible to have even a fair crop of flowers. It is not desirable that the plants should make a superabundance of foliage at any period of their growth. Those with a fair number of leaves and well-developed crowns are most sought after by experienced cultivators. These are the result of planting thinly and restricting the growth to the main stems by the prompt removal of runners or side shoots, as then the energy of the plant is concentrated in the crown of each. Our plants are grown on an east border. The soil being heavy leaf mould, not too advanced in decay, leaves are added freely. In heavy soil roots are not made in sufficient numbers to enable the plants to grow large enough to give the best returns. Plants now flowering will by the end of the month be ready for division; the strongest grown roots may be pulled in pieces of one crown each, weaker roots may have two or three crowns together. The runners growing from the base of the old roots make excellent plants, and are preferable, but they cannot always be had in sufficient numbers. The plants are put out 10 inches apart in rows 1 foot asunder.

Keep the soil between the rows well stirred. Should the weather be hot and dry mulch the surface with decayed leaves to prevent the evaporation of moisture and minimise the necessity of watering. Long spells of drought bring a crop of red spider to the leaves, and this checks the growth, and may ruin the plants. Copious supplies of water at the roots, and frequent syringings with soapy water, are the best means of checking the spread of the destructive pest.—E MOLYNEUX.

## ROSE SHOW FIXTURES FOR 1895.

- June 19th (Wednesday).—York.\*  
 „ 20th (Thursday).—Colchester.  
 „ 25th (Tuesday).—Isle of Wight (Cowes).  
 „ 27th (Thursday).—Gloucester (N.R.S.) and Canterbury.  
 „ 28th (Friday).—Exeter.  
 „ 29th (Saturday).—Windsor.  
 July 2nd (Tuesday).—Diss and Sutton.  
 „ 3rd (Wednesday).—Croydon, Ealing, Farningham, and Lee.†  
 „ 4th (Thursday).—Eltham and Norwich.  
 „ 6th (Saturday).—Crystal Palace (N.R.S.).  
 „ 9th (Tuesday).—Wolverhampton.\*  
 „ 10th (Wednesday).—Chelmsford, Hitchin, and Redhill.  
 „ 11th (Thursday).—Helensburgh and Worksop.  
 „ 17th (Wednesday).—Derby (N.R.S.).  
 „ 18th (Thursday).—Halifax.  
 „ 23rd (Tuesday).—Tibshelf.  
 „ 24th (Wednesday).—Chesterfield.  
 „ 25th (Thursday).—Trentham.

\* A show lasting three days. † A show lasting two days.

I shall be glad to receive the dates of other Rose shows than those named above for publication in the next list, which will be issued early in May.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

## THE WINTER AND ROSES AT ST. MICHAEL'S.

THOUGH the winter has been more severe here than usual, Camellias, Lilies, Rhododendrons, and Tea Roses have been flowering almost perpetually. I think my present visit to St. Michael's will have helped to make known the best Roses, as some of the leading families have procured the same from England, our best Teas having been there previously unknown.—ALEXANDER HILL GRAY.

## A NEW HYBRID ROSE.

MR. JACKSON DAWSON, of the Arnold Arboretum, has raised a hybrid with *Rosa Wichuraiana* as the seed parent, and *Rosa rugosa* as the pollen parent. The plant has the perfectly prostrate habit of *R. Wichuraiana*, lying flat to the ground, but with the vigorous constitution of *R. rugosa*, and large, deep green, glossy leaves. The flowers are, says a transatlantic contemporary, single, nearly as large as those of *R. rugosa*, and of a clear rose-pink colour. If it had no flowers whatever, the lustrous leaves and vigorous habit of the plant would make it desirable.

## INFLUENCE OF THE FROST.

IN my recent communication on this special subject I recorded the injuries which had been sustained by the Roses of Messrs. Croll of Dundee. I am gratified to learn from Messrs. Cocker of Aberdeen that they have suffered but slightly from the effects of the severe frost, though their Roses are much exposed. I have just received an interesting letter from this firm, in which they say, "We have escaped wonderfully; some of the more tender varieties are, of course, slightly cut down. Our escape from such a disastrous winter proves what we have always maintained, that Roses grown in an open situation in a severe climate like ours have advantages, for we believe our nursery is the most exposed in the kingdom. We are strongly of opinion that Roses well grown and not pampered or rushed up with chemical manures, but ripened as they grow, are in the best position to withstand a severe frost like that which we have experienced this winter. The frost has been so general that it will test severely the different modes of culture throughout the country."

My own experience is very similar to that of the Aberdeen rosarians. I have in my garden at least 150 distinct varieties of the Rose, and in many notable instances (as in those, for example, of A. K. Williams, Caroline Testout, Duke of Edinburgh, and Gloire Lyonnaise), and though the vast majority were entirely unprotected, not one of them has been killed, while only a few, such as Ethel Brownlow, Thérèse Levet, and Perle des Jardins have been severely injured, but not destroyed. I have always been strongly opposed, like Messrs. Cocker, to the over-protecting of Teas and Noisettes. Had the leading English and Scottish introducers of them, the rosarians of Waltham, Colchester, and Oxford, proceeded on the principle that these required extraordinary attention during the winter to insure safety and prolong their existence, few of them at this moment would have survived the climate to which during January and February they were subjected. "Tea Roses," says a great authority, Mr. George Prince, "are becoming hardier every year; and varieties such as Catherine Mermet and Princess of Wales, which would have been the first to be covered up a few years ago, are now quite as hardy as Hybrid Perpetuals."

Roses, I have observed, are very like children in this special respect: the more they are exposed to every kind of weather the stronger they become. Treat them as if they possessed delicate constitutions, and

under this treatment we shall certainly find that whatever vitality they may have inherited from their parents will speedily disappear.—DAVID R. WILLIAMSON.

## ROSE NOTES.

FROM all quarters I have had sad accounts of the late frost. Many and wide are the gaps, while more than one correspondent reports his Roses as practically exterminated. Let us hope it is not so bad as this in any case. Spring planting is being done, but it will not be an easy matter to replace some choice and rather delicate sorts, my intention is to fill up with small pot plants of last season's working. Several lists have come to hand in which these are offered almost as cheaply as plants of the same varieties from the open ground, and I certainly prefer a small quantity of well ripened wood to any which has gone through the past winter outside. We do not secure such large bushes, but the whole of the wood is sound, while the greater quantity of fibrous roots are a great advantage. It is the same with climbers; those scarcely strong enough for forcing are excellent to plant in the open now. With strong growers dug from the open ground we derive no advantage whatever during the first season, simply because the wood is not in conjunction with established roots, and the wood, good as it may appear, will practically have to be cut away to the base. A small plant from a pot will give us a few blooms the same season and still produce excellent growth for the following year.

Before the planting season is over I would like to call attention to a matter often overlooked. We select a variety from a bloom seen, and do not sufficiently bear in mind or inquire into its habit of growth and other characteristics. The result of this is often unexpected, as we find a weak grower placed against a high wall, or as a neighbour to a Rose of extra vigour, and consequently utterly out of place. The latter class must have room if we are to see them to advantage, while the former are altogether out of place in such positions. Medium growers, such as Marie Van Houtte, Madame Lambard, and Madame Falcot will do well against low walls and fences, but when we can have so nearly the same colours with extra vigorous growth it is a pity to use the dwarf growers on high walls and buildings. This matter also needs more attention in the Rose border; in fact, it is unwise to plant Roses so indiscriminately as many do; nor is there any excuse for so doing, as all trade lists inform us on the habit of growth. No doubt this indiscriminate and careless planting has caused more than one grand Rose to be banished from a garden, whereas it might have been grown successfully if a suitable site was selected and room allowed according to habit of growth.

Spring mulching needs attention. I am greatly in favour of this in preference to autumn and summer mulching. It is not theory alone, but long practice that keeps me to this plan. But some little consideration in this matter should be given to the class of soil we are working with, a light and porous soil needing more summer mulching than one of a rich and stiff nature. Cultivation of the surface soil is not easy where mulching is indulged in to any extent, and with growing Roses surface-stirring is of great benefit. Keep the spade and spud away, but use the hoe freely. Why should we mutilate the valuable surface roots in such a wholesale manner season after season, as a spade or spud must necessarily do? We profess to encourage these, and yet many injure them annually at this season for want of a little thought.—PRACTICE.

## EXAMINATIONS IN HORTICULTURE.

I FULLY endorse the remarks of a "Young Gardener" on page 134 of the Journal, that there should be two grades—one for seniors, and one for juniors. It seems to me beyond dispute that a thoroughly practical man of thirty years of age and upwards must of necessity possess a greater knowledge of horticulture than a young man from eighteen to twenty-five, whatever his capabilities may be from a literary point of view.

In the first place, what is the object and utility of the examination and the certificate awarded by the R.H.S.? In my humble opinion it should be to test a candidate's ability or proficiency as a thorough practical gardener. It is admitted by an "Instructor," on page 251 of the Journal, that no literary examination can furnish a true test of any person's professional capacity; and it appears to me, from what I can glean from the correspondence on the subject, that it is a literary examination pure and simple.

Your correspondent "W. D., Turnford," says young gardeners might take courage from the fact that the medallist last year was an amateur, and the student, only four marks behind him, a schoolmaster. With all due respect to the gentleman in question I am inclined to think if I required a man to undertake the arduous duties of head gardener I should want one with more practical knowledge than a schoolmaster. I have no doubt such men are well versed in the theory of gardening by what is gained from a multiplicity of books. But a great deal more than this is requisite to make a man master of his vocation.

To my mind a certificate obtained under present conditions is misleading as a true test of a man's actual practical abilities as a gardener. Let a man by perseverance and study obtain a first-class certificate for superior cultivation of fruits, flowers, and vegetables at some of the leading horticultural exhibitions held at various places throughout the country, with a first-class testimonial from his employer for proficiency in the various branches of his calling, and I venture to say that will have more weight with the majority of employers than any first-class certificate granted by the R.H.S. for what I consider a literary examination based on theory.—H. O. H.

**EVENTS OF THE WEEK.**—During the coming week events in the gardening circles are limited to two in the neighbourhood of London. On Friday night the Royal Gardeners' Orphan Fund will hold, at the Hotel Metropole, its seventh annual dinner, when Mr. Harry J. Veitch will preside, while on Tuesday next the Committees of the Royal Horticultural Society will meet at the Drill Hall, James Street, Westminster.

— **THE WEATHER IN LONDON.**—The weather has during the past week been very much colder, with occasional heavy showers and bright gleams of warm sunshine. The wind has been, as a rule, somewhat high, and on most days unpleasantly cold, despite which the growth of trees and shrubs is very rapidly advancing.

— **THE WEATHER IN THE NORTH.**—For a week the weather has been continuously dull, with rain on some part of nearly every day. There were a few watery gleams of sunshine on the 1st inst., and Tuesday morning was dull and cold, with wind from the N.—B. D., *S. Perthshire*.

— **THE next meeting of the ROYAL HORTICULTURAL SOCIETY** will be held on Tuesday, April 9th, in the Drill Hall, James Street, Victoria Street, Westminster, at three o'clock. A paper on Campanulas, by Mr. J. Wood of Kirkstall, will be read.

— **BARR'S DAFFODIL PRIZES.**—We are requested to remind our readers that Barr's Daffodil cup, specially designed by Mr. H. G. Moon, is open for competition at the Royal Horticultural Society's meetings in April and May. The cup is to be judged by points, and each competitor to choose his own time and varieties, but must not exhibit for the cup more than at one meeting, notice in writing to be sent to the Secretary of the R.H.S. in advance of the day of exhibition (which is a Tuesday), stating space needed for the cut Daffodils to compete for "Barr's Silver cup." On the morning of the show the collection should be officially entered, and a card received indicating competition for Barr's Daffodil silver cup. Several silver and bronze medals are also offered at the same meetings for Daffodils, as well as a silver-gilt medal for the best seedling not in commerce, raised in the United Kingdom.

— **LONDON PANSY AND VIOLET SOCIETY.**—We have received the schedule of prizes which are to be competed for at the Crystal Palace on July 6th. We note that twenty-six classes are provided, also that one gold, six silver, and a bronze medal are offered, in addition to money prizes and certificates. The Committee desires to draw the special attention of amateur and professional growers of the Pansy and Viola to the exceptional opportunity which this year's exhibition will afford of spreading the taste for their favourite flower through a much wider circle of the public than has been possible at other shows held by this Society hitherto, inasmuch as that of this year is to be held in the same place and at the same time as the Great Metropolitan show of the National Rose Society, at which it is well known there is always an enormous crowd of spectators and ardent florists from all parts of the kingdom. Therefore the Committee urgently appeals to all who can to make as good a display as possible this year, and we hope there will be a satisfactory response.

— **IVY.**—I am rather sceptical as to the assertion made on page 273, that the clingers or tentacles put forth by climbing Ivy are really roots. To me they have never presented other aspects than being grippers or holders, having remarkable power to attach themselves to objects, whether trees or buildings, and in that way enable the plant to climb all over these objects. We see precisely the same sort of thing on many ordinary climbers, especially on *Ampelopsis Veitchi*; but beyond being clingers, and perhaps to some extent absorbers of moisture, though that is not proved, I never found they played the part of roots. There never was a case in my experience where, the main stems of Ivy being severed, these tentacles served to keep the climbers alive. The killing action on growing trees is less due to the tentacles than to the absolute strangulation of the stems by the fierce embrace of the strong growth of the Ivy. Then, also, where Ivy forms a dense leaf covering little or no external moisture can penetrate, hence the ordinary condition of dryness.—A.

— **BIRMINGHAM BOTANICAL AND HORTICULTURAL SOCIETY.**—We are requested to inform our readers that the Daffodil show, to be held in the Botanical Gardens, Edgbaston, has, owing to the lateness of the season, been postponed from April 9th and 10th to April 24th and 25th. Schedules and full particulars can be had from Mr. W. B. Latham, Botanical Gardens, Edgbaston, Birmingham.

— **"THE NATURAL HISTORY OF PLANTS."**—This publication of Messrs. Blackie & Son is fast approaching completion, only five of the sixteen numbers having yet to come. The eleventh number, which has just reached us, continues to deal with the question of fertilisation in a most exhaustive manner. Prefixed to the volume is a coloured illustration of some of the Alpine flora, and forms a most attractive picture.

— **CATERPILLARS INFESTING LIME TREES.**—Probably the caterpillar inquired about by "A. T." (page 263) as infesting the Lime is that of *Biston hirtaria*, the "brindled beauty," which I have noticed almost defoliate that tree in June some seasons. The moth emerges in April to oviposit upon the trunks, or else it is the geometer (*Hyberniedefoliaria*), sometimes an abundant feeder on Lime; its eggs are laid about November.—J. R. S. C.

— **THE EFFECTS OF THE FROST.**—The effects of the late severe frost are now painfully evident. Portugal and common Laurels will lose a great part of their leaves and young growths. Berberries, Junipers, Rhododendrons, Yews, and *Cedrus deodara*, have all suffered very much where they have been exposed to the wind. Roses on walls are quite safe, and the same may be said of H.P. in the open, but Teas in the open beds have suffered more or less.—R. I., *Sussex*.

— **THE ALDBOROUGH ANEMONE.**—At one of the Drill Hall meetings in the spring of last year I remember seeing a mass of this Anemone exhibited. Mr. Allan then spoke of its wonderful manner of production; what a number of brilliant blossoms are produced from a small space, and for such a long period. Examining the blooms closely I thought them superior to *Anemone fulgens*. Undoubtedly the growth is more robust. This Anemone is in time destined to take a foremost place in early out-of-door plants.—E. M.

— **WINTER BEDDING.**—"E. M.'s" note on this subject (page 274) comes at a time when I am sure 99 per cent. of gardeners will agree to the views expressed as to the great value of small shrubs for filling beds in the autumn. Where this plan is followed all concerned may rest absolutely assured that a good effect will be produced, no matter what the weather may be. Of course they cannot vie in brightness with many of the best spring flowering plants during favourable seasons, but the great point is they can always be depended on to steer clear of becoming eyesores. A few beds planted with these shrubs at various points in a formal flower garden also helps to break up an otherwise flat surface. In short, they have so much to recommend them that I think we should all act on "E. M.'s" timely hint.—H. D.

— **BATTLE OF FLOWERS AT NICE.**—Her Majesty viewed the recent battle of flowers from a space on the Rue du Congrès, placed at her disposal by the municipality. The Queen was received by Comte de Malaussena, the Mayor of Nice, and presented on behalf of the Félis Committee with a pink satin banner and a splendid basket of Violets. Her Majesty remained in her carriage during the proceedings, and the Royal equipage was soon filled with small bouquets thrown from the passing vehicles. The Queen appeared to much enjoy the display, and from time to time returned the bunches of flowers, especially favouring the French officers of the garrison. Both on arriving and when leaving Nice Her Majesty was saluted with the British National Anthem. Miss Van Buren of New York, won the first prize for the best decorated carriage, her Victoria resembling a cornucopia overflowing with flowers:

— **THE EFFECT OF GREEN GLASS ON PLANTS.**—According to the "Kew Bulletin" recent investigations have shown that the green glass used at Kew intercepts about one-half of the effective influence of ordinary sunlight on the processes of plant life. Of late years the increasing haziness of the sky, due to the smoke produced by the rapid extension of London to the south-west, has produced the same effect at Kew as the use of green glass; and it has become obvious that in the future the plant houses must be so constructed as to exclude as little of the available sunlight as possible. Since 1886 the use of green glass has, therefore, been discontinued in all the houses except the Fern houses and the Palm house; and, it having been proved by experiment that even Filmy Ferns thrive better under white than under green light, if direct exposure to the sun is excluded, the use of green glass will now be altogether abandoned at Kew.

— THE BATLEY CHRYSANTHEMUM SHOW is announced to be held on November 17th.

— GARDENING APPOINTMENT.—Mr. T. A. Glover, for the last eight and half years gardener to Ed. Ellis, Esq., Manor House, Wallington, Surrey, has been appointed head gardener to F. Macmillan, Esq., Temple Dinsley, near Hitchin.

— CALANTHE CULTURE.—Permit me to inform "S. K., *Lyminster*" (*re* Calanthe Culture, page 273, in last week's issue of the Journal) that I was *not* referring to his article ancient placing three good bulbs in a 5-inch pot; in fact, I was merely illustrating the system of a writer in one of our contemporaries.—JAMES FRIEND.

— PRESENTATION TO MR. WILSON.—Mr. Wilson, steward and gardener to the Earl of Lindsay, Uffington House, a post he has filled for twenty-six years, was recently presented by his Lordship with a handsome watch and chain, a tripod lamp, also a scarf pin from the Ladies Bertie, on his leaving Uffington for Bank Hall, Tarleton. A silver inkstand formed a gift from the villagers

— MARCH IN MID-SUSSEX.—The first three weeks of March were in this district (Haywards Heath) on the whole favourable for garden work. The frost came slowly out of the ground, and fortunately but little rain fell, so that by the 14th the land was dry and working well. Since the 20th it has been showery, cold and sunless. To-day (April 1st) we had a sharp thunderstorm, which brought a heavy down-pour of hail.

— SUSSEX RAINFALL.—The total rainfall at Abbot's Leigh, Haywards Heath, Sussex, for the past month was 1.76 inch, being 0.32 inch below the average. The heaviest fall was 0.40 inch on the 26th. Rain fell on sixteen days. Total for the quarter, 4.40 inches, which is 2.26 inches below the average. The maximum temperature in the shade was 60° on the 22nd, and the minimum 22° on the 4th. Mean maximum, 48.16°, mean minimum, 34.16°; mean temperature, 41.16°, which is 0.40° below the average.—R. I.

— MARCH WEATHER IN SOUTH WALES.—The following is a summary of the weather here for the past month:—Total amount of sunshine eighty-five hours fifty-five minutes. Maximum, nine hours and a half on the 13th; minimum ten minutes on the 20th. Rain fell on eighteen days, total depth 5.26 inches; maximum 1.63 inch on the 23rd; minimum 0.01 on the 20th. The wind was in the N. and N.W. on twenty-five days. It was a very cold stormy month throughout. Snow fell on five days. There was a very strong gale on the 23rd and 24th, and it has been stormy every day since then.—W. MABBOTT, *Gwernllwyn House, Dowlais, Glamorgan.*

— OVERDOING GARDENING.—"I went to stay at a very grand and beautiful place in the country where the grounds are said to be laid out with consummate taste. For the first three or four days I was enchanted. It seemed so much better than Nature, that I began to wish the earth had been laid out according to the latest principles of improvement. In three days' time I was tired to death; a Thistle, a heap of dead bushes, anything that wore the appearance of accident and want of intention was quite a relief. I used to escape from the made grounds and walk on the adjacent goose common, where the cart ruts, gravel pits, bumps, coarse, ungentleman-like grass and all the varieties produced by neglect were a thousand times more gratifying."—(SYDNEY SMITH)

— MOVEABLE FEASTS.—I do not think "E. K." (page 269) can have had much to do with the management of horticultural societies, of which exhibitions are the primary import, or I do not suppose he would advocate the moving of the day. Managers of societies have too often found to their cost that to alter the date when once fixed is a mistake, and has more than once drifted them into debt and despondency. I have known a date changed, the original turned out a splendid day as regards the weather, and the new one *vice versa*. From an exhibitor's point of view I do not think it is good policy. The cultivator who overcomes difficulties that occur through adverse weather, and is ready on the appointed day, surely deserves much more consideration than he who does not meet the exigencies of the season in the same practical manner. I have attended many Committee meetings where an alteration has been proposed, but it has met with little favour. I never yet saw an exhibition that was an utter failure for the reasons stated by "E. K.," but I have seen Rose shows that were "thin," but simply because too many were held in that particular neighbourhood.—EXHIBITOR.

— HORTICULTURAL CLUB.—We are requested to state that the next conversazione will take place on Tuesday, 9th. The discussion will be initiated by Dr. M. C. Cooke on the Fungoid Diseases of Cultivated Plants, a subject of great interest and importance.

— MODERN GRAPE GROWING—HEATING.—I should feel very much obliged to Mr. Taylor if he would kindly state the name (if any) of the boiler to which he alludes in his article on page 252 of the issue of March 21st, which has given him so much satisfaction; also would he kindly give the name of the firm who supplies them?—W. NEILD.

— THE HESSLE GARDENERS' MUTUAL IMPROVEMENT SOCIETY.—The last meeting of the season was held on March 26th, when a paper was read by Mr. G. Jarvis, gardener to Mrs. Whittaker, Cliff House, on "The Working of Our Society." Mr. Jarvis gave some good advice on this subject, and pointed out the advantages to gardeners of joining societies such as this. One of the great things, he said, derived from these societies by young men was the art of public speaking. A few alterations in the rules were suggested, and that the present rules should be submitted to the Committee to revise, and have ready, for adoption or rejection, by the members at the next general meeting, to be held early in August.—F. L. T.

— EARLY LAXTON POTATO.—This, which seems to have been the most meritorious Potato that the late Mr. Laxton raised, has already, I find, made a great reputation with some extensive market growers at Mitcham, who found it to be last year not only a wonderful cropper, but remarkably early. They have it, I think, under the name of Harrison's Short Top, that well-known Leicester firm having purchased the stock of Mr. Laxton and put it into commerce. The title which heads this note was that by which it was known at Chiswick, where two years in succession it proved to be a perfect wonder amongst first early sorts. It should make a first-rate pot or frame variety, because its top is very short and its crop relatively remarkable.—A. D.

— MUSHROOM SPAWN.—I saw last Christmas in a first-class garden an illustration of the fact that it is not always the cheaper spawn that is worst. A couple of large beds, spawned several weeks, had given a great number of tiny and utterly worthless growths, much to the annoyance and disappointment of the gardener, who preferred to endure in silence rather than make a row about it with the seedsman. Yet this spawn was high-priced, and came from a leading house. It need hardly be said that so soon as this state of things was seen other spawn was obtained from a different source, and fresh beds made up. Still the loss at that time of the year was great. Cannot some means be devised whereby the spawning fertility of the cakes can be tested at once, and before beds are made up? Surely that should be practicable, and thus save such annoyances as that I have mentioned.—D.

— THE BOTANISTS' ILLUSTRATED POCKET-BOOK OF THE FLORA OF SWITZERLAND, THE PYRENEES, AND THE MOUNTAINS OF SOUTHERN FRANCE.—To all lovers of field botanising the need of an illustrated handbook of the flora of the particular region in which they are interested must always have been apparent. Before the rise of cheap illustration, however, there could not be the slightest prospect of this very natural desire being gratified. Such a work must have been too costly and too cumbersome ever to have possessed any practical utility. Even now in England the cost of production is such that a cheap and convenient manual for the purposes of home botanising does not exist in colour. Absence of a sufficient demand is undoubtedly the reason of this, though it is not impossible that the demand may yet be stimulated by some enterprising publisher. In France they manage things otherwise, either owing to special facilities or exceptional enterprise. We have received from Mons. H. Correvon, of the Garden of Acclimatisation at Geneva, a copy of his pocket-book of the flora of the mountainous region of Switzerland and Southern France, published by M. Paul Klincksieck, of Paris. It is quite a handy volume, and possesses the unique distinction for a work of its size, of having 144 plates representing in colour 180 species of plants. These are the most characteristic of the 480 species described in the text, and so excellently are they portrayed that a novice, far from experiencing bewilderment in identifying a plant, must recognise it on sight with a feeling of absolute pleasure. Indeed, so attractive are the pages, that the book if encountered casually by a tourist, might easily arouse a feeling of interest in the flora of the neighbourhood and end by winning another adherent to the cause of botany. We give Mons. H. Correvon our hearty congratulations on the appearance of this useful little work, and trust we may see the day when its antitype will appear in this country.

— CLERODENDRON FLOWERS FALLING.—In reply to "Amateur," page 273, it is impossible to state the exact reason why the flowers should fall from his Clerodendrons without knowing how the plants are treated. The only reason I can assign for it is that they must have received a check either at the roots or in the top growths. If the plants have been growing in a stove temperature till the flowering period, and then placed direct into a greenhouse or conservatory temperature, they will receive a severe check, and the flowers will fall. To avoid this the plants should be placed in the intermediate house for a week or fortnight, after which they may be removed to the greenhouse with impunity, but at no time should they be given cooler treatment than 55°. Another cause of flower dropping may be traced to the application of stimulants to the roots.—GEO. PARRANT, *Ashby Lodge Gardens, Rugby.*

— FISHER, SON, & SIBRAY, LIMITED.—This Company was registered on the 21st ult., with a capital of £50,000, to take over the old-established business of nurserymen, seedsmen, and florists, carried on by the partners in Messrs. Fisher, Son, & Sibray, at Handsworth Nurseries, near Sheffield; Fitzalan Square, Sheffield; Church Street, Rotherham; and elsewhere. An agreement for the sale of the business by Messrs. Charles Fisher, Ernest Edward Sibray, Walter Earl, and others, the late partners in the firm, to Mr. Thomas George Shuttleworth, of Messrs. T. G. Shuttleworth & Son, Church Street, Sheffield, Accountants, on behalf of the Company, is adopted by the Articles of Association. The qualification for Directors is that of holding at least £1500 in the Company, and the first Directors are Messrs. Charles Fisher, Ernest Edward Sibray, Joseph Walker, Walter Earl, and William Atkinson. By the Articles of Association Messrs. Alderson, Son, & Dust, of 40, Bank Street, Sheffield, and Eckington, and Messrs. Sanderson & Co., London, are appointed solicitors to the Company; Messrs. T. G. Shuttleworth & Son are appointed Auditors; and Mr. William Atkinson the Managing Director.

— A RECOLLECTION OF THE LATE MR. JOSEPH LAKIN.—In April, 1873, I was changing my residence from the north to the south of England, and I stayed at Chipping Norton a fortnight on a visit to my wife's relatives; and as I was passing the Police Station I noticed that the class of flowers growing in the garden and climbing Roses must all have been selected with care, and tended by a skilful florist. I asked my friends who was the gardener at the Police Station, and they said that is the superintendent. I said, "Please introduce me to him." Knowing florists' flowers pretty well he made me as welcome as an old friend, and I spent a very pleasant hour looking over Mr. Lakin's choice floral treasures. The season was an early one, and choice Roses as *Maréchal Niel* were blooming freely on the walls of his residence. As we were walking round his house we came into a court-yard where it seems he had a couple of cells for temporary detention of prisoners. Two rough men were blacking the super's boots; they touched their caps. Mr. Lakin said, "What, you here again?" "Yes, Sir. We are too fond of 'em. We can't keep away from you." I inquired who they were, and learnt they are a brace of poachers often there, whom the police had caught during the night.—R. M., *Newbury.*

— DOUBLE WHITE VIOLETS.—I have just received from a friend some beautiful double Violets, amongst which are flowers of *Lady Hume Campbell*, which are very fine, pure white, and double. But it seems so difficult to disconnect this form from several others, so that one seems driven to ask how many really distinctive double white Violets there are in commerce. The *Old White*, sometimes called *Odoratissima*, *Fragrantissima*, and *Queen of Whites*, is very well known. Then we have the one just referred to, *Lady H. Campbell*, *Comte Brassa's White*, *Swanley White*, these two apparently identical, and *Belle de Chantenay*. Are there any more under name, and if so, how much do they differ? Is there any one of the whole that stands out beyond others in the same way that a good stock of *Marie Louise* does amongst coloured varieties? There seems to be an intimate connection in Violets between perfume and colour, as whilst the whites have the weakest scent, the darkest coloured ones are the richest. Then apart from these considerations, popular tastes run most after depth of colour in Violets, whether single or double. I do not know where the great numbers of bunched deep blue singles we see in the streets come from just now, as I fear in the metropolitan district the plants have been nearly killed by the frost. Twenty years ago the Violet trade about London was a remarkable one, but we have rarely had good seasons for the flowers since, and whilst the [foreign competition has been extraordinary, the adverse seasons certainly] have not been due to competition. But bunched Violets may be gathered fresh and run into

London from remote places in a few hours, hence it may be that our present abundant supply of sweet perfumed rich singles of the true Russian are home grown. I trust they may be so.—A. D.

— WHEN TO PLANT POTATOES.—I am not surprised to hear in all directions there is great hesitancy this year shown with respect to the planting of main crop Potatoes. All sorts of growers shake their heads knowingly, and declare they are not going to be caught as last year. They are very wise to be so cautious. We shall not be well out of the wood of the present winter until nearly the end of May, and to plant Potatoes early, even though the ground is just now in such splendid condition for the work, is to court fresh disaster. There can be no doubt but that the bulk of the later division will be planted after Easter. That may result in entirely escaping harm from the latest spring frosts. Even if there be no such frosts to avoid, growth is always stronger and more rapid from later planting. We must not forget that the Potato is still a tender exotic, and even where it escapes frosts often suffers great check because of the prevalence of low temperatures. Except where special protection to the tops can be given, very early planting leads to no gain, and may to considerable loss.—D.

— WAKEFIELD PAXTON SOCIETY.—Mr. H. S. Goodyear presided at a meeting of this Society held on March 23rd, when the essayist was Mr. G. Bott, master of Miss Pilkington's School at Walton, who has in previous years delivered a large number of exceedingly interesting lectures, and on Saturday last he added another to the long and excellent series. His subject was "Migration of Plants," and he dealt with it in a thorough and most interesting manner, and imparted much valuable information to his large and very attentive audience. The lecturer showed the various ways and means by which Nature covers the surface of the globe with vegetation, and explained some of the most ingenious contrivances by which seeds and plants of many kinds are transferred from one part of the world to another and germinate and flourish. This, he explained, was caused by the wind, by animals, birds, and insects. After showing how seeds are conveyed from land to land in the air, in the crops and beaks of birds, the stomachs of animals, the wool of sheep, Mr. Bott concluded by saying that the more they searched and inquired into these matters the more they were struck with the great power of the Creator. A very hearty vote of thanks to Mr. Bott closed the meeting.

— EMIGRANTS' INFORMATION OFFICE, 31, BROADWAY, WESTMINSTER, S.W.—The April circulars of the Emigrants' Information Office and the new annual editions of the handbooks show the present prospects of emigration. A new edition of the handbook to the South African Republic is now ready, and a revised and enlarged edition of the West Indian handbook will shortly be issued. Emigrants to Canada should start now; the only demand is for domestic servants, for experienced farm labourers, and for men able to take up land. In New South Wales there is no demand for more labour, except for domestic servants. In Victoria trade and work are very bad, and further reductions are being made in the salaries and number of civil servants to meet the inadequate revenue of the Colony. As many inquiries are being made about the Mildura Irrigation Colony it is necessary to point out that it is suitable for those emigrants only who have a capital of at least £400 to £500. The Irrigation Colony undoubtedly possesses great possibilities of future success for those who can afford to wait; but at present it is only partially developed, and irrigated fruit land may be bought in other parts of Victoria at less cost, and nearer to railways and markets. In South Australia an Irrigation Settlement has been authorised at Lake Bonney, near the River Murray. The land is to be cut up into blocks of 10 acres each, and to be sold at not more than £22 an acre. Provision is made for a limited number of settlers without capital by engaging them at regular wages of 32s. 6d. a week, out of which £1 a week is retained towards the purchase money for their blocks. In Queensland the demand for ordinary labour seems fully met. For a few experienced farm hands however, and especially for men able to take up free grants or other land, there are considerable openings. In Tasmania the supply of labour is quite sufficient. In New Zealand many trades have been doing well, and country labour for the most part has been fully employed. With regard to Cape Colony a large number of official reports for 1894 were received last quarter. They show with few exceptions that all kinds of labour were plentifully supplied both in the towns and the country. Natal is well supplied with labour. Intending emigrants to Matabeleland and Mashonaland must bear in mind that no one should go to those territories who is not in possession of some small means.

## MODERN GRAPE GROWING.

## THE BORDER.

(Continued from page 252.)

THE principal objects of a Vine border are to protect and keep the roots in position, and to afford a suitable medium for conveying food to the root hairs. The chemical constituents of the soil are of minor consequence compared with its physical condition. You may have a soil with the dozen or more elements and compounds essential to the Vine's prosperity, so beautifully balanced that nothing more could be desired in that way, and yet it may be comparatively sterile.

On the other hand, if you possess a soil which is physically right and contains nothing obnoxious, it is an easy matter to make it fertile and to keep it so. Whatever soil the Vine may succeed in abroad—and I am told it often flourishes well where there is hardly any soil at all—experience teaches us that there is nothing suits our purpose so well as a rather heavy loam, that is a soil containing not less than 30 per cent. of clay in almost invisible particles.

Do not let it be thought from this that I disparage the work of chemists, far from it. There is nothing I devour more greedily than records of experiments made by such men as Messrs. Lawes and Gilbert, and certainly any honours that can be bestowed on the world's benefactors ought to be theirs. But if anyone thinks that by paying a few shillings for an analysis of his soil at the village laboratory, even if the presiding genius should be a Davy or a Voelcker, his fruit-growing is going to be made a matter of rule and thumb, he will find himself woefully mistaken. Analysing a soil is not such an easy matter as it appears to the uninitiated. It requires a good many delicate operations if it is to be done thoroughly; and after all, though the ingredients may be there which would render the soil a fertile one so long as it was a ploughed field, a Vine border has the disadvantage of being very much shut off from the beneficial action of frosts and winds, sunshine and showers, and must to a great extent be dependent on the cultivator.

Analysing manures is by comparison an easy matter, because everyone who has learned the rudiments of agricultural chemistry knows what they should contain, and thanks to our legislators no one need now buy quack mixtures, though they do buy them and will continue to do so. Those having a good soil to deal with, and abundance of energy in themselves, may succeed in spite of the quackery, in the same way that people having a good constitution, make their supper, when they have fancied ailments, off Mrs. Swindle's tincture of soap bubbles, and still live. Of course, the tincture gets the credit of saving their valuable lives for the benefit of humanity at large, and Mrs. Swindle is immortalised.

Sometimes it is difficult to secure a soil that is physically correct, and then recourse must be had to mixing. There is no doubt a natural soil is best if you can get it in proper form, but clay can be dried and beaten into powder so that it shall appear almost like a part of the natural soil itself. On the other hand, if a soil contains too much clay and too little sand, there are many other gritty substances to choose from which will be better than sand for mixing, such as mortar from old buildings or burned clay. If a soil does not contain sufficient clay it is not holding, water passes through it too freely, and remember that every time you water a light, loose soil you wash something out of it.

Also it is not retentive of manure. If you use a chemical fertiliser you apply so much to the square yard according to the printed directions received from the vendor, a small part of which goes to the plants and a large portion to the drains. The worst of it is you have no means of knowing how much is retained by the soil, whether too much or too little. Again, what is called a light soil, if it is sandy, gives a great portion of its moisture to the air in the way of evaporation. A soil which is too heavy also has its drawbacks. It may hold the water too long, and not be sufficiently porous to admit air, consequently it will become sour, so that no roots can grow in it, or, if they manage to do so, will not ripen, and the leaves soon find this out.

It has been my lot to have the two extremes to deal with in the matter of soils. In the kitchen garden at Longleat the soil is so stiff that if worked at all when wet it is injured for years after. One portion, about twenty-eight years ago, had some of the subsoil taken out and burned on it by one of my predecessors. The ground, I have been told, was wet at the time, and the axles of the barrow wheels ran uncomfortably close to the soil. Of course the burned material was placed on the top and dug in, but the ground had not recovered when I last saw it, and probably has not done so now, although I made a practice of keeping a fire going the greater part of every winter outside the garden, burning refuse and clay, and this particular patch must have had at least 4 inches of such material put on it during my superintendence. Such ground when well managed grows enormous crops of splendid quality in a season that is not too wet, but it requires a great deal of humouring.

Now, in this neighbourhood it is altogether different. I see men working the ground immediately after and indeed during heavy rain, and this does not seem to hurt it at all. I have seen the best of farmyard manure placed 8 or 9 inches deep over it, and buried with great difficulty by a man with a spade. Very good Mangold was grown on it, but it would want manuring again the following season. Where grass is grown there is very little of what can be called soil before we come to a yellowish sandy material, loose at first, but a little deeper it takes out and looks like clay. It crumbles when exposed to the air, and its capacity for absorbing and disposing of vegetable manure is something marvellous.

Going deeper we find some clay mixed with the sand, and at 8 or 10 feet come on a very soft bluish clay, and this when dried and pulverised, by the action of frost preferably, or pounded, is what we use principally to mix with our Vine soil.

If a soil that is neither too heavy nor too light can be obtained with the turf on it, all well and good. If not we can do without the turf, and when necessary alter the material to make it of the right density. It is an advantage to have at least a little turfy soil to start the Vines in, but there is no particular need for a large amount of fibry turf; indeed it is apt to make the border too rich in nitrogen, causing at the first rampant growth and large pith. The pith, I believe, is what you make it at first, it never enlarges. The part it plays in the plant's economy is, so far as I am aware, not well understood, but no one likes to see too much pith.

When one is starting Vine-growing in a new place where the soil and surroundings are strange, it is advisable to begin cautiously, for even after a life's experience one is easily out of his reckoning. I would recommend starting with perfect drainage and narrow borders, say 4 or 5 feet in width, and then feel one's way during the next year or two.—WM. TAYLOR.

(To be continued.)

## THE LATE MR THOMAS BAINES.

MISS BAINES favours us with an excellent portrait of her late widely known and much-respected father. It will be recognised by many of our readers as a life-like delineation of the famous plant grower, gardener, and judge, while those who may not have had the privilege of knowing Mr. Baines will be pleased to see what manner of man he was as he went about so actively from show to show in his latter years, and from garden to garden in the course of his landscape work. The portrait is taken from an oil painting by Mr. C. F. Lowcock, who has been very successful in producing a characteristic likeness of Mr. Baines, who was a man of mark in the gardening world in which he worked so long and so well.

## THE LONG FROST AND INSECTS.

SOME of my friends, while emphatic in their complaints as to the damage caused by the long frost to many plants and shrubs, are rather jubilant over the supposed effects it has had upon insect life. It must have killed many, they say, above ground and beneath. I have felt myself obliged to discourage them a little by telling them we do not know just yet; we are unable to judge of its results till the world of insects are once more aroused by the influences of spring. The observations of entomologists on the insect tribes generally tend to the conclusion that the hibernating species can stand severe cold better than mild and moist weather. Certain it is that no amount of cold would injure insects' eggs, nor affect to any great extent such moths and beetles as live in their perfect stage from the winter to spring. About those in the pupal or chrysalis stage there may be more doubt. The species that are usually exposed to all the weather of winter are so seasoned to it, I should say, that a prolongation of frost, or some degrees of extra intensity, would not be likely to touch them. We shall soon be able to ascertain whether the two common white butterflies (*Pieris Brassicæ* and *Rapæ*) which emerge in April to deposit eggs about gardens have had their numbers diminished by death of pupæ.

Amongst the *Noctua* group of fat-bodied moths we have several destructive species which pass the winter as pupæ under the soil, but not buried at any great depth. A familiar example is the too abundant Cabbage moth—*Mamestra Brassicæ*. Possibly some of these have been killed by sudden change of temperature in this way. On two or three days in February the sun shone brightly, melting a layer of snow, the warm fluid then partly entering the earth; but after sunset the temperature fell rapidly, and a sheet of ice formed that would freeze up pupæ near the surface which had been previously thawed by the sun. But there is this to be considered also—that many birds during the winter seek out and eat pupæ, which by the long frost obtained protection from their enemies, the ground resisting the birds' bills and feet. Mild winters are helpful to the birds hunting, not only pupæ but other subterranean insects, and when the mildness is accompanied, as it often is, by heavy rainfalls, that destroys hibernating species by inducing a sort of disease, attended by fungoid growth on the skin.

Gardeners, I know, generally suppose that a cold winter lessens their insect enemies next season. This does not seem to be the case, taking the majority of species, but rather the reverse. Still, the early months of 1895 were exceptional, owing to the severity of the frost, and its prolongation towards the spring, though it is the fact that caterpillars may be so congealed as to chink like stones if shaken in a box, and afterwards recover. Some, of course, could not endure such intense cold. Then, again, we must remember that instinct guides many caterpillars to descend deeper into the earth when frost is approaching, wherein they have much the advantage of our water pipes. Whether any of the caterpillars that pass the winter in a silken abode—the brown-tail, for instance—would strengthen its walls during sharp frost, if awake enough to do so, we cannot tell. Amongst the feeders upon wood, our persistent enemy, the goat caterpillar, destroyer of many ornamental and also some fruit trees, prepares for itself a warm retreat, well lined

with silk and chips, for its security in the winter. Probably a similar plan is followed by the leopard caterpillar, a resident in various trees.

The much smaller caterpillars of several clearwing moths, which pass their life in stems, branches, or twigs, take up a winter position where they will be least exposed to the cold; but they appear to feed all that season—at least, such is the habit of the species infesting the Currant, Pear, and Apple. I expect the winter has seen the death of many of those insects which secrete themselves under loose bark, birds having been very diligent in their researches on tree trunks, after the supply of

spring it feeds upon various plants, such as Lettuces and Strawberries; before hibernation it is often found infesting Hollyhocks, amongst other garden species. The habit of this caterpillar is to hide near the ground during the cold season, and a per-centage, I expect, will have been killed by the snow or frost, though their coats are some protection.

Unshielded, however, is the caterpillar of the Currant moth (*Abraxas grossulariata*), some individuals of which conceal themselves amongst stones or refuse in the winter, while others brave it by simply fixing themselves firmly upon a twig of their favourite bush. Hardy fellows they,

FIG. 51.—MR. THOMAS BAINES.

berries began to fall short. It would be pleasant to think the frost was likely to make a reduction in the number of the aphid hosts of the spring, but I expect it will not; the eggs would not be affected, nor probably the insects, "queen aphides," or other adults which hibernate under the earth or in various nooks, their bodies seem to be well stored with oil.

We will just notice a few species of garden and orchard insects, where the hibernating caterpillars or larvæ of last winter may not have escaped entirely from its effects. A familiar insect at once occurs to us in the caterpillar of the tiger moth (*Arctia caja*), often called the "woolly bear," though not clothed in wool, but black-and-grey silk. During the

as I know from observation, but February, 1895, may have been a bit too sharp for them, though not markedly injurious to our Currants and Gooseberries. Then there is the caterpillar of the angle shades (*Phlogophora meticulosa*), one of the very few caterpillars that feed through the winter, quite exposed to the weather, upon any garden plants that may be accessible, such as young Chrysanthemums, Primroses, and early Peas, a velvety leech-like fellow, brown or greenish, with white lines and dots; some of these I saw about in December, but since then they have disappeared.

Another of the hibernators common in gardens is that to which

some old entomologist gave the odd name of the Gothic (*Nænic typica*), which begins life on the Pear and Plum, or other fruit trees, descending in October to hide amongst Box edging, under dead leaves and stones till April. A ravenous caterpillar is it during the spring, devouring herbaceous plants generally; but we may hope for diminished numbers this April. There is a well-known caterpillar—at least, better known by its doings than by its aspect, for it usually hides under the soil—that of the large yellow underwing (*Tryphæna pronuba*), which feeds on the crowns and stems of many plants from the autumn to May, that may have suffered from the cold or want of food. To name one more species, the social and annoying enemy of some fruit trees, the little ermine moth caterpillar emerges from the eggs in the autumn to winter in small colonies upon the twigs under patches of protective gum which is spread by the mother insect. It has been noticed that the substance is, by some hard winters, made to split or shrivel, when the young caterpillars are exposed to cold, also to the attacks of insect-eating birds.—ENTOMOLOGIST.

### THE LATE MR. WILLIAM DEAN.

MR. RICHARD DEAN obliges us with the following supplementary notes on the career of his late brother and great and much-respected florist. A varied career it is truly, and shows the wide experience of our friend in the work he loved:—

"My inability on the spur of the moment to refer to documents, added to my late brother's singular reticence in regard to some of his undertakings, led me to make one or two mis-statements in regard to his doings, and also to withhold one or two points which, with your permission, I hasten to correct and supply. I find I am wrong in stating that he was once with his old friend Mr. Thomas Hewitt of Solihull. When the London branch of the seed business was closed my brother went to the Heatherside Nurseries at Farnham as traveller and sub-manager. These nurseries, which were on a somewhat extensive scale, were founded by the late Mr. A. Mongredien, the author of 'Trees and Shrubs for English Plantations,' and other works of a social and political character. The above mentioned work is an invaluable reference book. The 'Heatherside Manual of Hardy Trees and Shrubs,' with a preface giving instructions How, When, and What to Plant, issued in 1874-75, was also prepared by Mr. Mongredien. It is a work of 116 pages, and valuable for the many useful suggestions. The death of Mr. Mongredien occasioned great changes, and my brother then established the Heath End Nursery at Farnham, but parted with it after a few years, and then went to the Chad Valley Nurseries, Edgbaston, and from thence to Walsall, where he was in business eight years, and taking up the raising of Violas sent out several new types, among them Queen of Spring, Mrs. Turner, and True Blue, and to him is due the first attempts to obtain a rayless section. From there he went to Solihull as manager of a small nursery belonging to Mr. Power at Edge Lane, and not to Messrs. A. Blizzard & Co., and on leaving there he established himself at Sparkhill, where he died.

"For many nights before his death he had slept in an arm-chair being unable to lie in bed. The doctor visited him on the morning of the 23rd, the day of his death, and did not appear to think any change was in progress. He partook of his tea at half-past five, conversing on domestic affairs; immediately after he was seized, and falling into a comatose state, actually died in his sleep at half-past six, breathing gently and regularly to the last, and seemingly not in any pain."

"He left a widow and six children, all of whom followed him to his grave in Yardley Cemetery on the afternoon of Saturday last, his brother Richard and his son-in-law being also present, and several friends from Birmingham, including Mr. Robert Sydenham, Mr. C. H. Herbert, Mr. W. H. Gabb, and members of the Birmingham Gardeners' Mutual Improvement Society, who carried him to his grave, and a magnificent wreath was sent by the Committee and members, and other floral tributes came from Mr. and Mrs. Beddard, Stoneleigh Abbey, Kenilworth; Mr. and Mrs. Watkins and Mr. and Mrs. Herbert, of Messrs. Thomson & Co., the Welshpool Horticultural Society, the Birmingham Chrysanthemum, Fruit, and Horticultural Society, from the Sutton Coldfield Chrysanthemum Society, a spray from the children of Mr. and Mrs. Herbert, and others."

It was with sincere regret that, on opening the *Journal of Horticulture* last Friday, I learned the sad tidings of the death of that great florist and lover of Nature in all her gentlest and fairest aspect, Mr. Wm. Dean. I had not the gratification of knowing him personally; but friendship, as I know from experience, very frequently exists without the assistance of personal acquaintance; a deep chord of sympathy, the inevitable result of mutual tendency in a common direction, existed between us, which even the awful and mysterious intervention of the impartial "Last Messenger" cannot wholly remove.

For his memory and his influence, which are utterly imperishable, remain like benedictions to bless us still. Of my own delineations of his favourite flower contributed to this Journal he was generously appreciative, and on one occasion he was so kind as to express his regret that he was unable to invite me to the Viola Conference, as he did not at that period know my address. It would have been a great pleasure to me to have been there, if only to have made the acquaintance of this venerable horticulturist, so child-like in his simplicity, so generous in his sympathies, so beautiful in his peaceful, unobtrusive nature, so venerative of all beauty and all goodness in his life. He has fast followed in the footsteps of another friend of mine, whom also, alas! I

had never seen, but whose great kindness in my memory shall always abide—William Thomson of Clovenfords, "King of the Vineyards," whose creations are sufficient to perpetuate his name.

It was my intention to have visited Birmingham on some future occasion on my way to London, that thus I might have the privilege of seeing Mr. Dean's Violas and Mr. Chamberlain's Orchids. Also, before the death of Mr. William Thomson, I had promised to pay a visit to Clovenfords in October, and may do so still, for its present possessor is amply qualified by nature to prove a worthy successor to his gifted father and sustain his reputation as a Vine cultivator.

But who as a writer on the Pansy and Viola is competent to succeed the late Mr. Dean? I fear the leading horticultural journals will suffer in this exquisite department by his death. I hope that Mr. Wm. Cuthbertson of Rothesay, Mr. McLeod of Chingford, and other great cultivators of the Viola, will do their utmost to sustain by their writings the wonderful, yet amply merited, popularity wherewith the lamented florist of the Midlands invested by his genius this fragrant flower, also that the invaluable varieties which owe their origin to Mr. Dean may not be permitted, like many of their predecessors once equally esteemed, to fall into oblivion. I have no fear of this.—DAVID R. WILLIAMSON.

By the death of our old friend I feel to have lost a correspondent who spared no trouble or pains, and entered so thoroughly into all our views and suggestions. I had a letter from him the morning he died. I wanted him to come for our spring show and act as Judge, and it was only on Saturday, the 23rd ult., I had a letter from him saying he could not possibly come, although he would have been so glad if he could have ventured. I do not know when I met so real a gentleman as Mr. William Dean, it was always a great pleasure to meet him at any time.—H. W. ADNITT, *Shrewsbury*.

### THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

AS questions are sometimes asked through the gardening Press for particulars of the G.R.B. Institution, would it not be a good idea to republish Mr. Thomas' letter (a copy of which I enclose)? This explains its principles, and would no doubt do good. I wish gardeners as a body would become members, for my part I cannot understand why they do not.—GEO. SUMMERS.

#### AN APPEAL TO GARDENERS.

HAVING recently been elected a member of the Committee of the above Institution, I hope I may be excused for approaching my fellow gardeners for the purpose of endeavouring to influence their minds in favour of a more general and generous support of its funds. It cannot be said that I am asking others to do what I have not attempted to do myself, as I have contributed in one way or another between £70 and £80 to this good and well managed Institution.

It is difficult to understand why all gardeners do not rally round this splendid property of £29,000, especially when it is said that every shilling of it is their own. One would think that even from motives of selfishness, if from no higher, every gardener would strive to do all in his power to promote its usefulness and prosperity.

There cannot be less than 30,000 gardeners, nurserymen, and others engaged in horticultural pursuits who are, or ought to be, interested in its welfare, and if as many of these as can afford it subscribed their guinea a year, and if the remainder who are unable to do this were to collect small sums amongst themselves annually for the benefit of its funds, the question of old age pensions, as far as it relates to gardeners, would be solved.

Objections have been advanced by many persons against the Institution because it is not founded on the lines and principles of a benefit society, where a member can claim help at any time in case of need. On the surface this may appear to be a reasonable objection, and I am afraid has been the cause of many not subscribing to its funds; but I think on a little consideration that this objection may be proved to be an erroneous one, and especially as in the case of gardeners whose wages are scarcely now stopped in time of sickness, and who, therefore, do not feel the pinch of poverty at this time like mechanics and others who are paid by the hour, and whose pay is stopped when work ceases. As bearing on this point, I may say I have been a member of a benefit society for upwards of twenty years, paying about 22s. a year, and if I am to remain a benefit member I shall have to go on paying that sum as long as I live, and in case of sickness and permanent disability from work, I am entitled to 10s. a week for the first year, about 7s. the second year, and after that I believe the pay is reduced to 3s. per week for life. Let me ask my fellow gardeners who are still sceptical on this point to compare this with the advantages offered by the Gardeners' Royal Benevolent Institution, even from a benefit point of view, where after subscribing a guinea for fifteen years, or £10 10s. down, a member is almost certain to be placed on the pension list if he is of good character and incapacitated from work and in want, receiving without any further cost or trouble to himself £20 a year for life, whether his life be short or long.

Another objection has occasionally been levelled at the Institution—viz., that some gardeners who had subscribed but little, and others who had not subscribed at all, were occasionally elected pensioners. On this point I may say that we must not lose sight of the fact that by far the largest proportion of the property of the Institution has been subscribed

by people out of pure benevolence for the relief of aged and destitute gardeners, and I for my part would be very sorry to see this principle of benevolence infringed upon or curtailed in any way; and I hope and believe it will not be allowed to impose a barrier to prevent subscriptions flowing in. The Committee, as is well known, have introduced a clause into their rules, giving almost absolute certainty of election to those who may have subscribed for fifteen years, and the new rule passed at the special general meeting (December, 1892) will give subscribers substantial advantage over non-subscribers, inasmuch that a subscriber for four years will have fifty votes credited to him, and fifty more added for every year subscribed afterwards up to fourteen years.

My appeal in favour of the Institution, even from a benefit and an investment point of view, will, I hope, commend itself to the judgment of gardeners. But I beg very respectfully to appeal to my brother gardeners from a higher level than a benefit one. That man's life is a poor and a barren life who lives entirely to himself, and nothing noble or good has ever yet been accomplished without a sacrifice of some sort.

The gardeners of the past half century (and others interested in gardening and gardeners) have built up a noble standard of garden charity, which is now shedding gleams of joy and brightness round the declining life of many of our fellow workers who have fallen helpless by the way. Let me, then, appeal to all gardeners and others associated with them in the calling, to rally round this splendid Institution, and to strengthen it with their active support, that all the deserving in our craft may claim a shelter under its wings in the time of adversity and want.—OWEN THOMAS, *The Royal Gardens, Windsor.*

CULTURAL JOTTINGS.

CULTIVATORS of plants for any purpose, but especially for the production of large blooms for exhibiting, will do well to bear in mind three very important details just now seasonable. The first is to lose no time in transferring the earliest plants from the shelves of a cool house to a cold frame. No matter how cool the house may be kept, the plants always exhibit a tendency to "run up" quickly if they remain indoors after March has expired.

The best means of keeping the plants dwarf should be adopted, and early frame treatment is a chief factor in the case. The pots should stand on a thick bed of ashes, and the glass be sound and clean. A position facing the south, and sheltered from north and easterly winds, should be chosen on account of the extra warmth thus gained.

The second point demanding rather more than ordinary consideration is that of judiciously supplying the plants with water. At this time of the year many of them have a tendency to change the colour of their leaves from a deep green to a pale hue, and in some instances they almost turn yellow. An excess of cold water is the main cause of such an unwelcome change. Some cultivators appear to forget the altered circumstances under which the plants are placed. When in the cool airy greenhouse much more moisture passes from the leaves than is the case when the plants are subjected to necessarily damp surroundings in frames. Tepid water only should be employed, from the rain water tank if possible. No plant should receive any till the soil exhibits signs of dryness; when the leaves turn suddenly pale, the roots of such plants have received a check, and cannot carry out their functions.

The third point is the admission of air to the plants in such a manner that they will benefit by the supply. Too often the lights are either tilted on the wrong side or drawn entirely off, exposing the plants to cutting cold east winds. Not only does such injudicious treatment check the growth suddenly, but is a precursor of mildew and aphids. Fresh air is absolutely necessary, but it must not be admitted in sharp currents. Tilt the lights on the opposite side to that from which the wind is blowing, and injury will be averted.—E. MOLYNEUX.

THE CHRYSANTHEMUM YEAR BOOK.

A VERY useful book, which will be looked forward to each year if kept strictly useful and impartial, but trade growers regard one article of nearly six pages as an advertisement in the body of the book, while other advertisers have to pay 21s a page, yet Mr. Dean would have the Committee accord a vote of thanks for that article which any of the other advertisers would gladly have thanked the Committee for granting the space; I for one. Mr. Dean is not in the trade. I commend "Fairplay" for his comments, for I simply like what is right, and have no desire to give offence. Every work is open to criticism, and it helps to make works more perfect in future.—W. WELLS.

PERMIT me to do justice to the N.C.S. Executive. Tardily aroused to the fact, no doubt, by my reminder, this body has at length admitted that it owed something, if but thanks, to those persons who contributed to the Year Book gratuitously, and thus made it so great a success that its profits may range from £20 to £25. Publishers ordinarily would, of course, recognise the value of contributions in a more practical way, especially when from those who are essentially of the literary cult; but there are some on the Executive rather too closely

identified with the Press, who may think that would be setting a vicious example. I have not heard that even the accomplished Editor has received other reward than has been meted out to the contributors, except—mark from heaven, save the mark—"Fairplay." Why do not the members clear out from the Committee its Augean stable of trade selfishness and exhibitor narrow-mindedness, and free it from its old parochial slough which has clung to the Society from its early Hackney days? A truly National Society should have higher aims. In one direction no Society could be better or more ably served than it is in its home and foreign Secretaries, but there the merit ends. Were a few gentlemen of Mr. Shea's type in control it would not have been needful for me to have publicly pointed out that the contributors to the Year Book had been by the Executive treated with contempt and indifference.—A. DEAN.

THE WILLIAM THOMSON MEMORIAL FUND.

SHORTLY after the lamented death of the grand old gardener above named, a project was mooted to raise a fund by which his memory could be kept green by the horticultural community. The proposal is now placed on a wider basis than was first suggested, and after mature consideration the form which the memorial should take has been determined. A large representative Committee has been formed, comprising nearly a hundred English, Irish, Scottish, and Welsh horticulturists, and the following circular has been issued, signed by Mr. J. G. Veitch as Honorary Secretary.

Royal Exotic Nursery, 544, King's Road, Chelsea, S.W.  
March, 1895.

WILLIAM THOMSON MEMORIAL FUND.

DEAR SIR,—A fund is being raised to commemorate the services to horticulture of the late William Thomson of Clovenfords, the sum collected to be given to the Gardeners' Royal Benevolent Institution, and the Royal Gardeners' Orphan Fund. Should a sufficient sum be obtained it is proposed to keep a pensioner in perpetuity on the funds of each Institution. To enable this to be done a sum of £1250 is necessary; a perpetual pension to the G.R.B.I. requiring £750, and that to the R.G.O.F. £500, the power of electing these pensioners being in the hands of the Royal Caledonian Horticultural Society, Edinburgh.

Should a sufficient sum not be obtained for this purpose, it is proposed to divide the amount raised between the two Institutions proportionately.

It is hoped that a very liberal response will be received, not only on account of the esteem in which Mr. Thomson was held, but also on account of the object to which the Fund is to be devoted.

A Committee, the names of which you will find annexed [in the circular] has been formed to collect subscriptions, and I trust you will become a contributor to this very laudable object.—I am, dear Sir, yours truly,  
J. G. VEITCH,

To whom, or to any member of the English Committee, subscriptions may be sent.

We shall rejoice if the amount desired can be raised, both in the interests of aged and needy gardeners and of helpless orphans, equally with the well-merited tribute that will be so appropriately paid to the worth of one of the most accomplished and worthy of British gardeners, who left the world the better for his labours in the cause of horticulture.

The following donations have been promised, the contributors, except those indicated by an asterisk, constituting the Executive Committee for England:—

	£	s.	d.		£	s.	d.

CORN SALAD.

THOSE who still cling to the old custom of sowing a good breadth of this excellent edible, to provide plants for winter and spring use, have this year just cause to congratulate themselves, for Lettuces have been unusually scarce, and the absence of warmth and sunshine will greatly retard the progress of early crops both in frames and the open air. Corn Salad, on the contrary, seems to be as abundant as usual, as beyond suspending growth for a time the late severe winter does not seem to have affected it the least, at least that is the case with our own plants. Throughout the winter we have had plants available for use, and at the present time the growth is quite young and fresh, although I think it would puzzle most gardeners to cut salading of any other kind from the open air at this early date.

Although this Corn Salad, or Lamb's Lettuce, is comparatively little grown now, it always seems to be appreciated at table, and those who have to keep up a regular supply of salading will do well to bear this in mind, and make a sowing when the month of August comes round. It is not often sown in the spring because throughout the summer there is generally abundance of Lettuce. Where it has become an established favourite it is liked occasionally in the summer time, as it helps to make a greater variety for the salad bowl, and moreover

frequently proves useful when Lettuce play us the freak of bolting wholesale, thus breaking, as it were, a few links in our chain of supply.

South or west borders are capital positions in which to sow at the present time. A foot apart is a convenient distance for the rows; then if the seedlings are thinned to 3 inches asunder, every alternate plant should be used in a young state to give the remaining ones room to develop.—A LAMB.

## ROYAL HORTICULTURAL SOCIETY.

MARCH 26TH.

SCIENTIFIC COMMITTEE.—Present: Dr. M. T. Masters (in the chair); Mr. McLachlan, Mr. Morris, Mr. Sutton, Prof. Müller, and Rev. G. Henslow (Hon. Sec.).

*Orchid Leaves Decayed.*—The report from Kew on the specimens brought to the last meeting was as follows:—"Fungi and bacteria are absent from all the specimens, and the disease is entirely physiological, being caused by the substance of the leaf at particular points becoming saturated with water. This causes the formation of numerous oil globules, followed by degeneration of the chlorophyll corpuscles and cell contents. This disease is caused by the activity of the roots being in excess of that of the leaves. Less moisture at the roots, and a free circulation of air with a not too damp atmosphere, is the remedy."

*Dendrobium with Two Lips.*—Dr. Masters had examined a flower of the plant exhibited at the last meeting, and found that the extra lip was accompanied with a bifurcation of the single central cord belonging to a normal labellum, so that it was not due to a fusion of two organs, but to multiplication by chorisism of one.

*Ferns Injured by Mice.*—Mr. McLachlan described the injuries done to Ferns during the hard frost by mice. Mr. Morris attributed it to a want of water, as he had experienced a similar trouble on board ship, when a consignment of Cinchonas and other plants was sent from Jamaica to New Orleans, and was much injured by rats and mice. By placing pans of water among them, however, no further injury occurred.

*Aspidistra Attacked by Fungi.*—Dr. Masters exhibited a leaf much decayed in parts with peculiar black marks on it. It was referred to Kew for examination.

*Odontoglossum cirrhosum.*—A specimen was sent by Mr. Smee, remarkable for the flowers being associated with leafy bracts.

*Hyacinth Malformed.*—A peculiar specimen was sent by Sir Ch. Strickland. The stem was exceedingly slender, the flowers remote, small, double, and campanulate; probably an accidental variation from impoverishment.

*Galls on Leptospermum.*—Dr. Masters showed a specimen of these received from Baron Von Müller from Australia. Mr. McLachlan undertook to examine them.

*Schinus Molle.*—A photograph of a remarkably fine tree, apparently some 25 feet in height, growing in Graham's Town, was shown by Dr. Masters.

*Bulbophyllum burfordiense.*—This remarkable Orchid was exhibited by Sir Trevor Lawrence, Bart. It is probably by far the largest flowering species of this genus. Its peculiarity, however, consists in the absence of petals, as there are only three large green sepals, the posterior one being spotted with white.

## SPINACH.

WHEN it was the other day remarked that, because so close growing, Winter Spinach has largely escaped the destruction wrought amongst other winter leaf vegetables, I had brought to mind two very extensive breadths I had seen on a Surrey farm only a few days before, where an August sowing was decimated, and a later one made in September had stood remarkably well. That fact shows the great value of late sowings for reserve, even if not wanted; for it very frequently happens that not only Spinach, but Onions, Turnips, and Cabbages, when thus sown so late stand hard winters better, but prove invaluable in the spring, when the earlier sowings have been destroyed. If not wanted, at least the sowings cost little, do not occupy much ground, and may then be dug in as a green manure crop. But then it is evident, so far as Spinach is concerned, that, welcome as a late sowing may be to furnish late pickings in April, it is really through the winter months that the need for this leaf product is greatest.

It will be now very interesting to learn whether round-seeded kinds have proved to be hardier or have shown more endurance than have prickly varieties. The breadths that I referred to were of the usual prickly or rough-seeded order, as it has hardly yet entered into the minds of market growers to sow round Spinach for winter use. But very likely many gardeners have done so, and they can, with their now ample experience, tell us which form has withstood the severe winter best. Probably the effects of the winter has led many growers to be quite out of respect for either variety. We may feel the same with regard to many other plants usually esteemed hardy; but it would be most unwise to assume simply because of a great garden disaster that things are to be ever such. We may have no such destruction amongst vegetables again for perhaps twenty years, and if we do then is it too much to hope that horticulture will, ere that time, have so far advanced that disasters of this sort may be better prepared for than they are to-day?

It will be a long time ere in any garden we make such provision against hard weather as shall enable us to have most of our green winter crops under glass. There may indeed be said to exist a certain

amount of absurdity in the suggestion, and yet where is the gardener who to-day would laugh at the proposal if he were the possessor in a big span frame or other protection of a fine bed of Spinach, or dwarf Cabbages, or of late Broccoli, or indeed of anything else of great use, but of which now he has none whatever? Why should our glass protection be so rigidly limited to the ordinary heated house, or the frame ground? How different might have been matters with thousands of gardeners if they had had at disposal, to plant or sow thickly last autumn, numerous light wooden span or lean-to frames; or having on warm borders, beds, or blocks, specially prepared by sowing or planting have, the moment frost became imminent, these frames or protectors dropped over them, and as far as practicable made air-tight. The results would have been most valuable, without doubt. Of course the benefits would have been all the greater were it possible to have these frames gently warmed by a couple of 3-inch pipes, because even so little of warmth allied to the undoubted protection the frames afford, would have done wonders in warding off absolute injury.

Whilst every year we recognise more and more the need of glass for fruit, flower, and Tomato culture, we have hardly given to vegetables the consideration that they merit. Well, the recent winter has taught us a lesson, and it is for us to utilise it. We cannot hope, of course, to cover in whole gardens with glass, much less fields, and for defects in our climate must always suffer; but all the same, in many ways much may be done to check harm amongst our winter vegetable crops. It is worth making a start in that direction with so excellent a kind as good Spinach.—A. D.

## SPRING FLOWERS.

AFTER all, there is no season in the whole year whose flowers are so welcomed and appreciated as those of the spring. It will doubtless be even more so this year. For many weeks the whole country has been snow-covered and ice-bound, and while in this condition it was difficult to bring the mind to think of either spring or its flowers. Happily, this has all now passed away; the sun is gaining power, days are lengthening, birds have commenced singing, and those pleasing harbingers the Snow-drop and Crocus have pushed forward their blooms in spite of severe weather, as if to convey to us the news that winter's chain is broken, and there are better days near at hand.

Ardent cultivators of hardy spring flowers, and happily there are many, will now be turning their attention towards them, and gardens that can boast a goodly collection of these charming species will enjoy a season of unsurpassable beauty months before those where only summer flowers are grown. A great loss sustained by those who only follow the system of summer bedding is the complete exclusion of flowers during the spring. This state of things may be often noticed, and the folly of the system marked in paying a visit to some old-fashioned garden during the month of April. There, perchance, will be found Primroses of numerous colours, sweet Violets, Pansies, Daffodils, blue Anemones, purple Aubrietia, and many others; while the surrounding country lanes and woodlands are gay with Cuckoo Flowers, Anemones, Bluebells, and Violets.

Many much more fashionable and pretentious gardens will on the contrary be found dull and blank at this season of the year, with but little more signs of the spring than were apparent months before. Surely by setting apart a portion for the cultivation of spring flowers, the dull aspect in many instances at this period of the year might be rapidly transformed, and the time when the garden is gay with flowers be extended considerably. The best way of bringing this about is an easy one. That is by procuring a number of plants that are hardy, and will be likely to multiply. All plants are not suitable for these conditions, but there are many that flourish profusely. Much care is necessary in choosing situations for hardy favourites, as some delight in rather dry sunny positions, whilst others revel under conditions of moisture and damp.

Amongst the old-fashioned spring flowers that may be raised from seeds sown the preceding year, none occupies a higher position than the Wallflower. It may be found flowering profusely in almost any garden, even where methods of spring bedding are not strictly adhered to. Easy of cultivation, pleasing in colour, and sweet in scent, in spite of new additions this old-timed favourite will never be displaced. Then there are Polyanthus, Cowslips, Auriculas, Forget-me-nots, and Daisies, all of which supply abundance of flowers for cutting, and are also easily propagated by division.

Bulbs, too, are annually becoming more popular amongst spring flowers, and need we wonder at this? for the brightness of colour of many of them, and the pleasing form of others, must make them general favourites.

It seems needless to dwell upon the many different species of bulbous flowering plants, as they are so well known. Common Daffodils will flourish under almost any conditions, as will the different forms of Pheasant's-eye or Poet's Narcissus, while the more rare varieties of the former, such as Sir Watkin, Horsefieldi, and others, will amply repay for careful cultivation. Tulips of all kinds, single and double, the qualities and properties of which have been admirably described in recent numbers of the *Journal of Horticulture*, are indispensable, with their varying forms and pleasing colour. Hyacinths also claim attention, and will in the future, as they have in the past, play a conspicuous part among the beauties of the spring. Ranunculus in many gardens do not receive the attention they deserve, for if the colours are carefully blended they have no superiors.

Among the hardy plants which many of them require but little attention are *Doronicums* with their bright yellow star-like flowers; *Anemones* of several varieties, all free-blooming and useful; *Saxifragas*, *Primula cortusoides amœna*, and others; *Myosotis*, *Alyssum saxatile*, *Scilla*, and *Aconites*. These are but a few in the great many, each and all of which add so much to the floral beauty of our gardens in the spring.—G. H. H.

SHORTIA GALACIFOLIA.

At a recent meeting of the Royal Horticultural Society Mr. F. Cornish, gardener to the Dowager Lady Bowman, Joldwynds, Dorking, staged a magnificent example of this charming plant and was deservedly awarded a cultural commendation, for it is seldom we see plants of it so profusely bloomed. *S. galacifolia* (see illustration, fig. 52) is a hardy herbaceous perennial of a dwarf tufted habit of growth, with leaves and flowers as represented in the engraving. The latter are pure white, with a tinge of pink when about to fade. It is a native of the mountains of Carolina, and though it has been known for some time is still not widely grown.

VINES AND VINERIES.

AN opinion which differs from another need not be altogether antagonistic. The conclusions which Mr. Kemp, your able correspondent, sustains on page 269 with regard to the damage which the scorching rays of the sun often inflict on the foliage of the Vine under glass can be obviated by an efficient system of ventilation and proper attention, therefore the cause of the injury lies not in the sun, but in the construction more than the position of the vineries, and perhaps also to the overtaxed energies of the cultivator.

It has frequently been observed in lean-to vineries that the scorching of the foliage is generally most severe near to the apex of the house, and under the glass where there is no immediate ventilation, therefore such houses should possess a continuous system of ventilation, and not merely every other light. Horticulturists, as a rule, worship the sun in all its brilliancy, and must have the most favoured position for the vineries, where the first rays of the morning sun are not observed and the meridian bright, and where the temporary gleams of sunset cast the shadows of the glorious fruit along the rafters.

There is no other fruit than the Grape Vine that requires greater skill and more studious attention to bring the produce to anything like perfection, and for that purpose abundance of sunshine, no less than an abundant supply of fresh air on all favourable opportunities, not only to give to the fruit the best colour and highest flavour, but also to give to the foliage a robust, leathery nature. When the Vines have been too much coddled the foliage is apt to be deficient in substance, and the evil of scorching may be intensified.

It is always interesting to read and have something to say about the cultivation of the Grape Vine. Whether this popularity of the Vine arises from the sacred incident of "Noah" being an eminent and successful cultivator of the "generous Vine," or that there be some potent spell about the plant, it is an acknowledged fact that the cultivation of the Vine was well known to the ancients, for do they not say, "Never offer to the Gods wine produced from the Vine unpruned." In the mind's eye one can see the adventurers spying out the land, and their wondrous surprise in beholding the gigantic bunch of Grapes, and their determination to carry it back with them as a proof of the great virtue of the locality, and how to do so without bruise or blemish to the fruit if not the blooms, they hit on the happy medium which is so well known to readers of sacred history.

Modern Grape growers have not sufficient data to prove that they can make a record against primæval culture beyond the deducible fact that the Escholian bunch of Grapes must have been of a most remarkable character, and without information as to colour, weight or dimension, as such it must remain; nor are we told whether the fruit had been fostered by the hands of Nature, or cultivated by some peace-loving member of ancient society, who possibly might have sat at the feet of the great horticulturist. If he did so or not, through course of time he would learn that the mysteriousness of the capabilities of the Vine lay in a careful and studious attention to all the requirements of the plant, and would naturally come to the conclusion that before he could have good fruit, whether on the spur or long rod system of cultivation, the young wood must possess a robust nature and be thoroughly ripened, and for that important factor in good Grape growing to be accomplished, no one can say that we have too much sunshine anywhere in the British islands.—A. M.

THE DESTRUCTIVE GALE.

NEVER do I remember a more damaging wind than occurred about midday on March 24th. In some villages in this neighbourhood hardly a house escaped damage; indeed, with some, the roofs were blown entirely off. In the fen country adjoining, the reports coming in of the sad havoc to buildings are appalling. The Wheat plant in many places is blown out of the light peaty soil that abounds there. Churches and public buildings in the towns have also suffered.

In the gardens here I am sorry to record a heavy loss of fine Conifers.

Large Cedars of Lebanon are completely destroyed, only one left out of many. Three large *Abies princeps*, one 63 feet high, all handsome specimens, were uprooted. A very fine tree of *Abies lasiocarpa*, 65 feet high, with an upright trunk 8 feet round near the base, was completely destroyed; also large specimens of the Californian Cypress, *C. macrocarpa*, several *C. Lawsoniana*, *Pinus pinaster*, large Scotch Pines 60 to 70 feet high, *P. strobus*, and many others.

There are six large specimens of *Libocedrus decurrens*, but only one succumbed. Large trees of Ash and Elm in hedgerows lie about in all directions. Larches of from twenty to thirty years' growth were swept down in a wholesale manner. Many of the trees in the pleasure grounds noted above fell like ninepins. It will be heavy labour to clear away, for many that are left standing are badly broken.

The trees that stood the test of the gale best are the *Wellingtonia gigantea*, for out of 300 large specimens only one has blown aside. One of the best of the Conifers, *Thuja gigantea*, has stood well, not one being

FIG. 52.—SHORTIA GALACIFOLIA.

shifted or broken. It makes fine upright trunks and splendid foliage here. A great many are close on 60 feet high. Others that have stood well are *Taxodium sempervirens*, *Cedrus atlantica*, *C. deodara*, *Salisburia*, *Taxodium distichum*, *Abies Nordmaniana*, *A. amabilis*, *A. Douglasi*, *A. grandis*, *A. morinda*, *Pinus ponderosa*, *P. macrocarpa*, *P. austriaca*, *P. Jeffreyi*, and *P. Coulteri*. Some that were only partly blown over we have raised upright with strong ropes and pulleys and supported with long props.—A. HARDING, Orton Gardens, Peterborough.

HARDY FRUIT GARDEN.

**Grafting Fruit Trees.**—The operation of grafting can be performed somewhat later than usual this season, owing to the protracted rest all fruit trees have had with the severe winter. In consequence the sap takes longer in actively circulating, though with mild, favourable weather it will rise strongly, and probably quickly when once on the move. It is, therefore, imperative that all preliminary details be completed, so that when the opportune moment arrives the scions can

be inserted readily with reasonable prospects of speedy union. The scions, of course, will be in quite a dormant condition, being cut from the trees some time ago and laid-in in moist soil to retard the pushing of the buds. There they should remain until wanted for the purpose of preparing for insertion.

**Preparing Grafting Clay.**—Although prepared grafting wax is frequently used, a mixture of clay and manure is preferred by many. Obtain some good, strong, adhesive clay, freeing it of stones; then beat it into fine particles and make it plastic with water. Keep it moist until grafting time, when add, or it may be introduced at once, equal parts of horse droppings and cow manure to two parts of clay, blending all well together. Rub the horse manure through a sieve, and take out any long straw which may be contained in fresh cow manure, which ought to be employed.

**Heading Down the Stocks.**—Trees should be headed down at once to the point where grafts are to be inserted, especially where strong limbs have to be cut down. Select a position where the bark is smooth, and near the base or origin of branches. On large old trees four or five branches are enough to retain, selecting the best placed. The diameter of the branches is immaterial, as several grafts can be inserted on one, and when it is intended to replace inferior varieties of Apples or Pears by superior on old trees this is the best method, operating mainly by crown grafting, the cleft and notch process also being practised.

**Crown Grafting.**—This is the most common form of renovating old trees, and is applicable wherever branches are over an inch in diameter. If the branches are shortened early in the season a further portion may be removed now, so that the working is carried out with fresh wood and bark.

**Preparing the Stocks.**—With a very sharp knife make a clean slit in the bark, commencing from the top and extending downwards about 2 inches. These slits should not be less than 2 inches apart, and must be made just prior to inserting the scions.

**Preparing the Scions.**—Select well ripened wood of last season's growth with plump dormant wood buds. The central part of shoots is usually the best. A portion with five or six buds may be selected. Cut the base level, then make a sloping cut to it corresponding in length to the slit in the stock. At the point where the cut commences make a transverse incision, thus forming a small shoulder by which the scion when in position will be seated on the stock, holding it there securely. Reduce the length of the scion to four buds, or less if at all weakly.

**Inserting the Scions.**—The scions being in readiness, with a hard wedge-shaped strip of wood the same size and thickness as a scion, lift the bark carefully on each side of the cut in the stock. Withdraw and introduce the scion, pushing it gently into position until seated on the stock, when it can go no further. It is important that the inner bark or layer of alburnous matter meet exactly together, as it is at this point where the union takes place. On stocks of large diameter three scions may be affixed with advantage.

**Securing Stock and Scion.**—Bast matting is the best material to wind round for holding the parts firmly together. This must be effected without binding too tightly. To each scion attach a stick to prevent possible loosening by wind. Apply the grafting clay over all apertures, and cover the top of the stock with a good coating, using a little fine sand on the hands when finishing off so that the clay can be left smoothly completed. Grafting wax is applied with a brush, merely covering all joinings to exclude air, which is essential in effecting a union. The ordinary clay covering when dry frequently cracks. Such openings must be closed as often as made until growth is so far advanced that the clay can be gradually dispensed with.

**Cleft Grafting.**—In this method it is necessary to split the stock down the centre with a chisel and mallet, holding the cleft thus made open with the chisel or a wedge. The scions are cut wedge-shaped and as long as the cleft is deep, about 2 or 3 inches. One may be inserted on each if the branch is of large diameter. When small, the top of the stock is cut sloping, and the scion inserted on the highest side, one only being used. More than two grafts cannot be employed on one branch with this method. They must be made to fit bark to bark along their entire length, so that the alburnous matter or inner vital tissue of both stock and scion approach each other exactly. Then by taking out the wedge in the centre the cleft closes tightly, holding the scions very firmly in position. The greatest disadvantage in this method is the aperture left in the middle of the stock, but this must be covered securely with grafting wax to exclude air and moisture, the outside joinings of stock and scion being treated likewise.

**Notch Grafting.**—This is effected by cutting a triangular notch through the bark and into the wood, the same width as that of the scions to be used. The latter must be cut wedge-shaped down two sides and made to fit truly, binding securely in with matting, afterwards laying or waxing over all joinings.

#### FRUIT FORCING.

**Peaches and Nectarines.**—*Earliest Forced Trees.*—The very early varieties, such as Alexander, Waterloo, Early Beatrice, and Early Louise Peaches, Early Rivers and Advance Nectarines, will soon give indications of ripening, when syringing must cease, and the leaves that shade or overhang the fruit be drawn aside, raising any away from the light, by means of laths placed across the wires of the trellis, so that the apex will be brought directly to it. The ripening of the fruit of these varieties may be accelerated by maintaining a night temperature of 65° to 70°, 70° to 75° by day artificially, and 80° to 85° or 90° through the day from sun heat. In the case of such standard varieties as Hale's

Early, Stirling Castle, and Royal George Peaches, Lord Napier, Elruge, and Goldoni Nectarines, the trees should be allowed time during the stoning process, maintaining the temperature at 60° to 65° at night, 70° to 75° by day with sun heat, and about 65° by day in dull weather, carefully avoiding sudden fluctuations or depressions. Tie the shoots to the trellis as they advance, and regulate the growths for future bearing, so as not to have them too crowded, as by giving the growths ample room the fruit is more exposed to the sun and air, and the wood for another year stouter and better ripened. Basal shoots for next year's bearing disposed to grow more than 14 or 15 inches may have the points pinched out, and the laterals and subsequent growths stopped to one leaf as made. These remarks do not apply to extensions, except as regards the laterals. When the stoning process is over, which may be ascertained by testing a few fruits with a knife, the fruit will require regulating for the swelling period. Very vigorous examples may be allowed to carry a few more than those that are weakly, but on no account unnecessarily tax the trees. Weakly trees should be supplied with nourishing food, such as top-dressings of phosphatic, potassic, and nitrogenic manure, washed in or in solution, not allowing the trees in any case to suffer for lack of moisture at the roots, and keeping the soil uniformly moist by a light mulch of partially decayed manure. This will secure conditions favourable to the swelling of the fruit to a good size, especially if the temperature be raised with corresponding moisture, as advised for the very early varieties.

**Trees Started at the New Year.**—As stoning has now commenced care must be taken to avoid sudden checks by injudicious ventilation, cold air in the daytime and too high a temperature at night. A night temperature of 60° to 65°, 5° less on cold nights, and 65° by day in dull weather, with 70° to 75° from sun heat, will be quite sufficient, and better for the trees and crop than a higher range of heat. Syringe the trees twice a day in favourable weather, so as to keep them free from red spider. Maintain a due moisture at the roots, but avoid stimulating food, as provocatives of growth do not favour stoning, yet weakly trees should have a nourishing dietary of superphosphate and muriate of potash, about three parts the former to one part of the latter, using 4 ozs. per square yard. This dressing may be applied at intervals of three or four, or four or six weeks, as the trees stand in need of nutriment.

**Trees Started Early in February.**—The fruit has set and is swelling satisfactorily. Syringe the trees in the morning and afternoon, which will assist the fruit in swelling and casting off the remains of the flowers, and prevent attacks of red spider and aphides; but avoid heavy syringings, and an occasional one in dull weather will be all that is needed until the foliage is more advanced. Allow a temperature at night of 55° or 60° in mild weather, ventilating from 65°, permitting an advance from sun heat to 70° or 75°, but with full ventilation.

**Disbudding.**—This important operation must be done with care and judgment, commencing as soon as the shoots can be displaced with the finger, and following up day by day until only the growths required for future bearing, attracting the sap to the fruits or for furnishing the trees, are left. A shoot must be retained from the base of the growths now bearing, and another on a level with or above the fruit; the latter not being required for extension should be stopped at the third good leaf and subsequent growths to one as made. In the case of trees extending it will be necessary to leave shoots about 15 inches apart along last year's wood, calculating from the base on the upper or both sides of the growth as space permits, the terminals being trained in their full length, and the growths for forming the main branches being about 1 foot asunder. Avoid close training, as it results in weak overcrowded growth, not nearly so satisfactory as that fully exposed to light and air. Stop laterals on extensions to one leaf, and sub-laterals to a similar extent of growth.

**Thinning the Fruits.**—When the size of horse beans, the fruit will swell or drop. The latter are not fertilised, and the others will have degrees of vigour, which must be utilised by removing the weakest first, commencing with the least vigorous parts of the trees, thinning proportionately less on strong than on weak wood, which will tend to the equalisation of the vigour of the tree. Regard must be had to the position of the fruits, leaving the most promising on the upper side of the growths for receiving most light and air, and the fruit ought not ultimately to be left closer than one to every square foot of trellis covered by the trees, but the smaller varieties and Nectarines may have one to every 9 inches square of trellis covered with growth. The first thinning should be effected when the fruit is fairly set and commencing to swell, the second when the size of marbles, when a few more only need be left than is required for the crop, looking over the trees again when the size of walnuts, then very few indeed over the intended crop should be left, though there must always be a margin for casualties, yet the less the trees are burdened during the stoning process the more likely is that to be satisfactorily effected.

**Syringing.**—This operation may be overdone, and some are worse than useless. It is overdone when the water hangs on the trees for a considerable time, often through the night, destroying their tissue and inducing a soft sappy growth. It is worse than useless when a squirt is given here and there, and so lightly as not to dislodge dust and vermin. Vigorous syringing means the forcible ejection of red spider and aphides from every part of the trees without tearing the foliage into shreds or otherwise damaging it, and this should be done twice a day when the weather is bright, the afternoon syringing being done at closing time, always sufficiently early to allow the trees to become fairly dry before night. If the trees have water hanging from the edges of the leaves in the morning omit the afternoon syringing, which, however, will only be required for very vigorous trees.

**Tying-in the Growths.**—Attend to this early, as it is necessary to give the growths the desired inclination, which must be done carefully so as not to bring the shoots down too sharply, for this may snap off the points or give an undesirable conformation by throttling them. This must be avoided by the exercise of judgment, and in securing the shoots to the trellis sufficient space must be left in the ligatures for the swelling of the growths, otherwise gumming may be induced, as well as the contraction of the growth and consequent danger of breakage.

**Trees Started Early in March.**—Trees in full blossom ought not to be syringed; indeed, it should not be practised after the anthers show clear of the corolla, but a genial condition of the atmosphere be secured by damping the floor and border in the morning and early afternoon on bright days, omitting it altogether in dull, cold moist weather. The night temperature should be 50°, falling 5° in cold weather; 50° to 55° by day, with a rather free circulation of air; and 65° from sun heat, with full ventilation, preventing a vitiated atmosphere by admitting a little air constantly by the top ventilators.

**Latest Houses.**—With the flowers opening and abundant thin them well on the under side of the shoots. Assist fertilisation by shaking the trees daily from the first pollen ripening until the last of the blossoms need attention, selecting the early part of fine days when artificial impregnation is resorted to, which is desirably effected by means of a camel's-hair brush, feather, or some other light substance. Any trees deficient in pollen, as the large-flowered varieties sometimes are, should have some taken from those that afford it abundantly, and this applied carefully to the stigmas will usually afford good results. Maintain a temperature of 40° to 45° at night, 50° to 55° by day, in all cases accompanied by slight ventilation at the top of the house, which must be increased when the temperature reaches 50°, and be full at 65°.

**Unheated Houses.**—The buds of fruit trees in these are fast expanding, yet the house should be kept as cool as possible by free air circulation. Ventilate when the flowers expand at 50°, and increase it with the advancing temperature, not allowing an advance above 65° without full ventilation top and bottom, and close the house at 65° when there is danger of a severe frosty night, but leave on a little air to allow of moisture escaping, not closing entirely until the actual prevalence externally of frost. In mild weather leave the ventilators open when the temperature is over 50°. Where there is an abundance of blossom buds thin them carefully, removing those on the under side of the growths.

**Figs.**—**Earliest Forced Trees in Pots.**—The fruits of Early Violet and St. John's ripen on trees started in November or early in December during April, or under hard forcing in March, and, though poor in size and quality as compared with the luscious Brown Turkey and White Marseilles, are desirable for early dishes. Where ripening commences gradually reduce the atmospheric moisture, and admit air constantly by the top ventilators, as a circulation of rather warmer and drier air is necessary for securing flavour and thorough ripening. When the fruit of the larger varieties commences ripening the supply of water at the roots should be gradually reduced, yet affording sufficient to keep the foliage healthy, withholding it from the fruit and ventilating freely.

**Early Forced Planted-out Trees.**—Fig trees always do best when somewhat restricted at the roots, and surface fibres encouraged and kept active by judicious top-dressings of rich material. Good turfy loam, horse droppings, and old mortar rubbish in equal parts, favour an abundant formation of fibres, and these obtained feeding is an easy matter. To insure uniform moisture a light mulching of decayed manure serves that end and is a source of nourishment, this being added to from time to time so as to keep about an inch thickness. Liberal supplies of water or liquid manure will be necessary to assist in swelling the fruits satisfactorily. Continue to pinch out the points of the shoots for forming spurs, and thin all crowded growths, or preferably prevent these by timely disbudding. Fig trees cannot have too much light, the growths being fully exposed to the sun. The temperature may now be increased to 60° to 65° at night, 70° to 75° by day with gleams of sun, and 80° to 85° or 90° under a cloudless sky. Attend to tying in the extensions and successional growths, allowing space for the shoots thickening.

**Raising Young Trees.**—If it be desired to increase the stock, cuttings may be inserted, selecting well ripened shoots of about 6 inches length, taking them off with a heel or portion of last year's wood attached. They root readily in bottom heat, and are best potted in 3-inch pots. When rooted shift without much delay into 5-inch pots, and when they fill the pots with roots transfer to pots a couple of inches larger, but avoid overpotting. Good drainage is necessary, firm potting essential, and turfy loam, with a sixth of old mortar rubbish and a fifth of thoroughly decayed manure, forms a suitable compost.

**Cucumbers.**—These plants come more to grief than any other, in consequence of the forcing nature of the treatment, the thing being to get as much hulk of the most tempting colour in the least time as practicable. Nitrogen and a close moist and high atmosphere secure these desiderata at least expense, but there are more failures under such régime than a more rational procedure. Plants that have been in bearing all the winter are certainly benefited by nitrogenous substances, which, to be of profit, must be accompanied by a corresponding root action, and there is nothing so favourable thereto as fresh, sweet, rich lumpy compost. The soil, therefore, may be removed with a handfork, clearing away as much of the old as practicable without prejudice to the roots, and fill with the compost described, rammed down firmly. Stopping, training, and cutting out the old growths must be followed up, and abundant waterings given as necessary. Assist plants in full bearing with liquid manure or top-dressings of chemical manures washed in. Earth up the roots occasionally, using warmed compost. Damp the

floors about 8 A.M. and 3 P.M., the foliage being lightly syringed on fine afternoons. There ought not to be any delay in having the blinds ready where that form of shading is adopted, so that they can be employed for an hour or two at midday when the sun is brightest, especially after a period of dull weather, as then it is most needed, and unless given serious consequences may follow.

**Melons.**—In the earlier houses the fruit has set, or is setting, and when the fruits are getting heavy supports must be afforded. Half-inch boards 6 or 7 inches square, with a hole through each corner, and suspended by four pieces of string or wire from the trellis in a slanting direction to prevent water lodging, may be used for the purpose. Remove superfluous fruits and all flowers from such plants, also unrequired growths, stopping and tying as necessary. Afford efficient supplies of water, giving top-dressings of nourishing food or liquid manure, maintaining a free but not luxuriant growth. Maintain a good atmospheric moisture by damping early in the morning and afternoon, syringing the plants lightly on bright afternoons about 3 P.M. Late plants showing fruit should, unless abundant and the plant vigorous, have the first blossoms removed, it being important that the pistillate flowers be nearly of one stage of growth. Secure a somewhat higher temperature and drier atmosphere during the setting, only affording as much moisture at the roots as will prevent flagging. Fertilise the blossoms when fully expanded, stopping the shoots one joint beyond the fruit, but otherwise employ the knife as little as possible during the setting period. In pits and frames a good bottom heat must be maintained, and night coverings employed to retain the requisite temperature.

#### THE FLOWER GARDEN.

**Antirrhinums.**—The dwarf white, yellow, and crimson forms promise to become very popular as hedging plants. They thrive and flower grandly during a dry hot summer, and are quite as effective in a wet season. The best plants are those that have been raised from cuttings in the autumn. They must not be left standing thickly together in rough frames and hand-lights, but should be given more room at once. Bed them out temporarily in fairly good soil and about 4 inches apart each way, when they will be ready for planting by the middle of May. They are grand in masses, and cutting their first strong flower spikes benefits them considerably. Any old plants that have survived the winter should be taken good care of, as they will give an early display.

**Early Flowering Chrysanthemums.**—There are a considerable number of summer and autumn flowering Chrysanthemums which are very effective either in masses or mixed borders. Those who left the whole of their stock in the open ground will most probably have to start afresh. If, however, some of the old plants are still alive these might well be lifted and placed in a cold frame with a view to earlier and better cuttings than can often be had from unprotected plants. These late cuttings should be placed thinly in boxes of fine sandy soil, and given the benefit of gentle heat and shade as required, pinching out the tops as soon as rooted. After they have formed fresh growths harden and plant out in good soil where they are to flower. For planting in beds in succession to Asters, Poppies, Campanulas or other plants that cease to be gay soon after July, the preference may well be given to Madame Desgrange, white, Lady Fitzwygram, an improvement on the latter, and Mrs. Hawkins, yellow. There must be no late stopping of these, and strong branching plants in 8-inch pots should be ready for the beds directly they are cleared of their other occupants.

**Fuchsias.**—Old plants of these in pots and tubs have kept better in cellars than in outhouses, and all that are alive ought now to be growing afresh. If they are to flower in the open it is a mistake to start them under glass, as this is liable to unduly forward them. The young wood must first be shortened back, preferably with pruning scissors, to within one or two joints of where they last started, leaders perhaps having a greater length reserved. If the tops are dead cut them down to where they are alive. When the plants are breaking afresh is the time to repot or retub. Carefully turn out, freely reduce or pick away much of the old soil from the roots, and shorten the latter somewhat, replacing in pots or tubs of much the same size as before. They will then have abundance of a rather rich loamy compost, with a sprinkling of bonemeal in the soil, in which to root. Keep the plants in a sunny sheltered place, and water sparingly at first. Stop the young shoots if taking the lead unduly, or if more growths are required to form a presentable bush.

**Isolepis gracilis.**—Single plants of this elegant Grass are frequently used, and sometimes whole patches, with good effect in summer bedding arrangements. It is small fresh plants that should be used. Roughly shorten some of the latter, divide into small pieces, each with a few roots attached, and place these in threes just clear of each other in 2½-inch pots. Kept in heat till well established, neat little plants will be ready for the beds in June, and which will be certain to grow freely all the summer.

**Cyperus natalensis.**—This succeeds admirably as a hedging plant, and is effective dotted among trailing flowering plants, or even with taller-growing tuberous Begonias. Single plants are not nearly so graceful as small patches, and instead, therefore, of pricking out the small seedlings that come up so quickly and abundantly in heat singly in small pots, lift and repot in patches of not less than three plants. They soon fill the pots with roots, and may be given a small shift so as to have good sized plants for bedding out early in June.

**Dwarf Nasturtiums.**—Dwarf or Tom Thumb Nasturtiums, properly managed, are even more gorgeous than Pelargoniums in a dry

season, and quite eclipse them in showery weather. What they ought to have are sunny open beds or banks, poor soil, and ample room. The surest way to have them regular and even is to raise the plants singly in small pots, late in April or early in May being soon enough to sow the seeds, and then, if eventually planted out a foot apart each way in separate colours, there will be no undue crowding, and a continuous display of flowers be obtained. The seeds may also be sown now, or a little later, where the plants are to flower, allowing for failures, and thinning out where the seedlings come up too thickly.

**Salpiglossis.**—This class of annual is somewhat neglected. The large flowering type dotted thinly among a carpet of Mignonette would look well, and be a novel and cheap bed. Both should be sown now thinly and broadcast, covering the seeds with fine soil, or the Mignonette may be sown now, and the Salpiglossis be raised under glass and planted out of small pots. The dwarf Salpiglossis deserve a bed by themselves, and should be sown at once where they are to flower, raising a few in pots or boxes in readiness for any blanks that may occur.

**East Lothian and other Stocks.**—Ten-week Stocks are very handsome while they last, but are soon over. Not so the East Lothian, Earliest Flowering Autumn, and other intermediate types. If these latter are sown now in gentle heat, and the seedlings duly pricked out in temporary beds or in boxes, they will be ready for the beds late in May or early in June, and given good soil and ample room they will commence flowering early in August.

**Bedding Violas.**—If these were rooted thickly in frames or hand-lights last autumn they ought to be at once temporarily bedded out in good soil, not coddling them in any way. Strong stocky plants ought to be planted in rich soil not later than the middle of May, and if still earlier so much the better.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### FUTURE PREPARATIONS.

WE have not as yet passed through the most rigorous and varied winter ever experienced. The days are still raw and cold, without sunshine, and snow falls and lies deep a few miles distant from us. Flowers come slowly, and bees cannot venture to work on those in bloom.

The present is a critical time for bees and bee-keepers. The season is late; hives are of all grades, some well stocked with bees and well provisioned, others with ample bees and little food. How to bring these hives to a profitable state should be the aim of every bee-keeper. There is something wrong if any hive is not in a normal state of breeding at this date. When all are healthy and in a proper state it is surprising how little difference there is at the commencement of the honey flow between weak and strong hives.

Weak hives and those lacking food may be incited to breed by being properly covered, judiciously fed, and supplied with peameal mixed with honey placed in a scoop on the floor of the hive under the combs. These tend to keep the bees more at home, when otherwise many would be lost through flying in chilly weather. Well provisioned, strong stocks are always worse for artificial aid.

When there are one or more weaklings which lack vigour, and do not come up to a paying strength at the proper time, we take the first opportunity of joining the bees and brood to a stock which swarmed after all queen cells have been destroyed, thereby insuring in eight or ten days a strong stock, which may be supered, or if preferred allowed to swarm.

So far as profit and profitable hives are concerned, it will be understood the management must be with full sized hives. One of the most important factors for bee-keepers to know at a glance, when the bees are working, the strength of the hive, whether full or otherwise, and so long as bee-keepers remain ignorant of these things they cannot reap the full benefit from their bees. Make it an axiom in the apiary that queens deposit 4000 eggs daily, consequently hives ought to be large enough to contain these and the winged bees.—A LANARKSHIRE BEE-KEEPER.

#### STRAW SKEPS VERSUS FRAME HIVES.

THE past winter has given bee-keepers a good opportunity of proving which are the best hives for wintering purposes. Those who keep bees in straw skeps alongside of the more modern moveable frame hives can now compare notes, and prove without a doubt whether any improvement has really been made from a wintering point of view.

When compared with the old-fashioned straw skep, which so many cottagers still cling to, a practical test of this sort is worth a great amount of theory. When one hears of an apiary in which 50 per cent. of the bees are dead, presumably in wooden hives, the cause of which is supposed to be owing to the use of solid floor

boards, one is forced to the conclusion that the cause must be looked for from some other source.

Another bee-keeper writes regretting the loss of nine stocks, eight of these being destroyed by mice. This is very annoying to an enthusiast who must necessarily reside in the town, and whose apiary is in an outlying country district some distance from any dwelling. Had the precaution of reducing the entrance to all the hives by the aid of a piece of zinc, only allowing space for the bees to pass, and if the floor-boards were loose and not ventilated, by slightly plugging up the hive ample ventilation would have been provided, and the stock would in all probability have wintered without any mishap. It is from such failures as these that one may often learn a useful lesson, and guard against similar mishaps in the future.

During the past winter I have experimented with some bees in straw skeps that were not fed last autumn. No. 1 was a first swarm, which collected ample stores, and is still a good weight and very strong in bees. No. 2 was a cast which did not fill the hive more than three parts full of comb, and was short of stores in the autumn. No. 3 was a late cast, and owing to the wet weather, although they were put into a small straw skep, did not half fill it with comb, there being but very little honey. The bees, comb, and honey would not weigh more than 4 lbs., but by judicious feeding these stocks are all alive and doing well, with the prospect of each throwing off a swarm in time to obtain full benefit from the White Clover should the weather be favourable.

Although my stocks in frame hives have without exception wintered well, I am convinced there is no hive equal to the straw skep for wintering weak stocks of bees, but I do not recommend them for any other purpose, as so much larger yields of honey can be obtained by using frame hives.—AN ENGLISH BEE-KEEPER.

#### TRADE CATALOGUES RECEIVED.

W. Clibran & Son, Oldfield Nurseries, Altrincham.—*General Plant List.*

E. H. Krelage & Son, Haarlem, Holland.—*Spring Catalogue.*

Charles Turner, Royal Nurseries, Slough.—*Spring Catalogue.*

## TO CORRESPONDENTS

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Diseased Tomatoes (Challenger).**—If you send a dying plant as soon after you read these lines as possible it shall be carefully examined. A mixture comprising equal parts of peat loam and leaf soil with a little sand will be suitable for the young Ferns. In the absence of peat use more leaf mould.

**White Flowers (Kittie).**—A reply to your letter was published on page 263, March 21st. The letter arrived one post too late for being answered sooner, but we suspect you will have to purchase some flowers for attaining the particular object you have in view in the most satisfactory manner.

**Bunches of Grapes Defective (A. B.).**—There is nothing parasitic on the bunches, nor have they been eaten by anything. They are what is termed "deaf," which is due to imperfect development, and usually accompanies unripe wood, yet imperfect bud formation also occurs on Vines with hard and brown wood. From your description we should attribute the defective bunches to immature wood, and, of course, the only remedy is to take care to ripen it in the current year, so as to have a different result another season. This may be done by keeping the growths rather thin, allowing the principal foliage plenty of space, nothing interfering with the free access of light and air, and keeping the laterals somewhat closely pinched (but not so as to start the basal or pruning buds), which will concentrate the elaborated matter on the buds, and with these well plumped and the wood thoroughly ripened good results would follow.

**Raising Fruit Stocks from Cuttings** (*K. J. B.*).—We consider this an undesirable and unnecessary mode of propagation, as Crab stocks are easily raised from pips or seeds, and Paradise stocks are obtained in half the time and much better by layering than from cuttings, which do not root very freely without a heel. They will root in the open ground, but will do so more certainly under a hand-light.

**Weeds in a Lawn** (*Worried Gardener*).—The weeds sent are not grown annually from seeds blown from adjacent land, but are perennials firmly established, and if they flower scatter their own seeds. The whole should be forked up when the ground and weather are favourable for the removal of every particle of rubbish, which must be burned. The site should then be drained if needed, the surface soil enriched with a compost containing lime and wood ashes or a mixture of bonemeal and kainit made firm, rolled level, then scratched with a rake for forming a suitable tilth for a mixture of lawn seeds, which can be obtained in the right quantity and kinds on your describing the extent of the space to be sown and the nature of the soil to a seedsman or firm. By sowing in genial weather in April a full and close lawn may be had in six weeks. This is the cheapest and best way of forming lawns of a satisfactory character.

**Violets** (*H. M.*).—It is quite true that Violets like pure air and an open position in order that they may produce stout foliage, not large thin-textured leaves to fall a prey to their natural enemy, red spider. They are not good town plants, and do not usually succeed near hot sunny walls in the country. If you have sound loam and an open position, not dry gravelly soil, you might try what can be done in your locality. With good cultural attention we do not see that you should fail. If you cannot grow the plants outdoors in the summer, you cannot have the coveted blooms from frames in winter, unless, indeed, you purchase fine plants in September which have been grown outdoors by someone else, and this for your purpose might not answer. They cannot have too open a site, but the soil must not be dry, and the present month is a good time for planting. See notes by Mr. E. Molyneux (on page 289), who grows Violets abundantly with the greatest ease. He transfers the plants to frames in September. If you have fair success in the first attempt you may expect better results a second season, as there is always something to learn from experience.

**Pelargoniums from Eyes** (*Yorkshire Bite*).—Undoubtedly these plants can be raised from eyes. Take the cuttings from the plant, cut transversely below the lowest leaf, and then, placing the knife about half an inch above the eye, cut the stalk in a sloping direction towards the base of the shoot. The large leaves only are available for forming leaf cuttings. The extremities of the shoots should be inserted, like ordinary cuttings, with one joint in the soil, and the growing point above. The cuttings being made as described, drain the cutting pots effectually, and fill them to within half an inch of the rim with sandy loam, leaf mould, and silver sand in equal parts. A little silver sand is then placed in the pot, a quarter of an inch or so, and the cuttings inserted about half an inch deep, each leaf being tied to a small stick, with matting round the footstalk, to maintain it in an erect position. A slight watering is then given, and the pots plunged in a hot room of 75°, a top heat of 60° or 70° being afforded. The frame having a moist atmosphere, there is little necessity to water; none should be given so long as the soil remains moist, and the less water needed the better, as the great evil is the liability of the footstalk of the leaf to decay, and the consequent destruction of the eye before a callus is formed. Shade is given for a few days, until the leaves are able to bear the sun; and in this position they remain until the shoot from the eye appears, when they are gradually hardened, and finally potted singly in small pots.

**Cucumber Plants and Eelworm—Corrosive Sublimate** (*T. W.*)—1, Corrosive sublimate solution is so dangerous a poison that we only recommend it as a drastic measure, but there are few substances that will destroy eelworm without prejudicing the well doing of the plants. We have given much attention to the subject, and find that though corrosive sublimate destroys the pests, being a thorough soil disinfectant, it has not the beneficial effect of gas liquor, soluble phenyle, sulphate of iron, and kainit. These act as manures as well as destroy eelworm, hence their use is preferable to such as have a more or less ultimate injurious effect upon the soil, and are dangerous to animal life, though we are bound at times to have recourse to such drastic measures, as special cases must have particular treatment. 2, As you have used corrosive sublimate solution, 1 oz. to 15 gallons of water, for Tomatoes without any deleterious effects, you may now treat the plants as you propose, giving them an ordinary watering with the solution whilst the soil is moderately moist, and in sufficient quantity to reach uniformly down to the drainage. For Cucumbers the solution should only be used at half strength (1 oz. to 30 gallons of water), as the roots are more tender than those of Tomatoes, indeed Tomatoes will stand a maximum dose. 3, Beyond the objection to the poisonous nature of corrosive sublimate, there is little to anticipate in the way of harm, as such an infinitesimal dose is not likely to enter into the composition of the fruit to an unsafe extent, but its negligent or excessive use may be attended with serious consequences both in the plant and soil. But the watering will soon wash any small quantities (such as those advised) away or beyond the reach of plants, and only extravagant use is likely to poison the soil. 4, Corrosive sublimate solution in the proportions we have advised will not nullify the beneficent action of gas liquor or soluble phenyle, as there are no bases in either with which the mercury is likely to combine. We particularly ask you to be very careful with the corrosive sublimate, using no more, and that under strict supervision, than is absolutely necessary for effecting the object in view.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*E. H.*)—The flowers sent are all varieties of *Dendrobium nobile*, of which there are dozens of unnamed forms, and yours are included amongst those. (*J. H.*)—The specimen is a *Cœlogyne*, but it is obviously impossible for us to give the specific name. Send a bloom when you have one. (*H. F.*)—1, *Dendrobium fimbriatum oculatum*; 2, *D. primulinum*.

**COVENT GARDEN MARKET.—APRIL 3RD.**

**STRUGGLING FARMERS.**

BURDENS on the land are in no instance so unjust, so oppressive as preferential railway rates. They are an anomaly so unfair, so absolutely dishonest, so opposed to fair dealing, and the common sense of right and justice, that prominence should be given to every fresh instance of them. In his remarkable lecture at Glasgow, to which we called attention last week, Mr. Allan C. Young mentioned the fact of hay now being brought from Africa to London as cheaply as within a radius of thirty miles of the metropolis. This is part of the foreign hay trade to which the great drought of 1893 gave such an impetus. Bales of Timothy hay from Canada were already

on the market, and as the drought grew in intensity the demand for any fodder went on increasing daily. It was a splendid chance for the British farmer, which, alas! very few were able to take advantage of. The lecturer told how large orders were placed in the north, and how a few farmers in the south having hay reaped a little fortune out of it, one farmer in Hertfordshire receiving £6000 and another £4000 for hay alone.

In the winter of that year thousands of cattle were kept alive on a diet of Oat straw and a few roots, many of them having nothing but the straw. The lesson was a severe one, which ought to have had tangible results in efforts for the improvement of pasture. So far as we can see it did nothing of the sort. Pasture is as much neglected as it ever was; there is no systematic culture of it. There is nothing like sustained fertility in ordinary pasture. During the winter it is brown and bare as it ever was; in the spring it is late in growth, that part of it which is reserved for hay may have a slight dressing of so-called manure, which usually is just so much decaying humus containing very little fertilising matter that is available by the growing crop, with the inevitable result that anything like an approach to a fair crop of hay is dependent on rainfall. At the best the hay a short crop—often taken so late that there is no useful aftermath.

It is so difficult to convince even dairy farmers of the certain profit of pasture cultivation—of the advantage to them in so many ways of an annual dressing of manure worthy of the name. Yet it is well known in actual practice that by an annual expenditure of about £1 per acre on pure chemical manure, applied to pasture by the end of February, we are certain of—first of all sustained fertility, next an early growth of herbage, next a hay crop saved by or soon after midsummer, followed by an aftermath of almost equal abundance, and pasture green and fresh-looking all the winter. At the least 2 tons of hay per acre may be taken as the mean crop on land so cared for, as compared with a ton, or often considerably less, on starved land. Then, too, there is the difference between an early crop and an aftermath, and a late crop and only late autumnal growth; between June hay and September hay; between cheap hay of high quality, and dear hay of low quality. The best hay always being the less costly, from being made with such ease and dispatch; the inferior hay, from being exposed to rain from being thrown into haycocks and repeatedly shaken out, being really very expensive. Well did Mr. Young say that the farmer of the present day is chiefly to be found fault with for his want of adaptability to circumstances, and for a narrow-minded prejudice about departing from old customs and embarking on new ones. Such grave accusations from a practical man cannot be ignored. They were not made lightly, and certainly were intended for the benefit of thoughtful earnest men, who, however laden with difficulties, are manfully struggling to adapt their practice to circumstances, and to effect such changes as bid fair to lead to improvement and profit.

Well also did he say that a most serious difficulty—a real hindrance to prosperity, or such changes as might lead to it among very many farmers—is a want of capital. He is undoubtedly correct in this, and we are convinced that now in Lady Day hirings, and again at Michaelmas, every farmer will do well to keep well within the scope of his means. We have always thought so, and have repeatedly proved the truth of this truism. We have no sympathy with the vanity which makes a man "acre proud," and which leads him on to hire more land than he can handle to the mutual advantage of himself and his landlord.

#### WORK ON THE HOME FARM.

Of the ordinary spring-sown crops, Barley, Oats, spring Tares, Cabbage and Kale, have all been got in well, in a seed-bed of super-excellence, so fine, so deep, so easily worked, as to be entirely satis-

factory. The planting of field Potatoes is in hand, and it goes somewhat more slowly than most other spring work, from the care we insist on in the handling of the seed. We proved to our satisfaction and profit long ago that the storage of the seed in single layers during winter was right, that late rather than early planting, with one or two well-developed shoots on the seed was right, and that a dressing of chemical manure in the furrows was right, more especially for the main crop, with the rows 3 feet apart.

Other root crops claiming attention now are Carrots and Mangolds. Only an acre or two of Carrots are sown at the home farm to have a supply for horses and cows. This crop is too expensive in the labour it involves to extend beyond narrow limits; Mangold, on the other hand, is easier to cultivate, and decidedly more profitable for farm live stock. We sow the entire crop of it in April, and find such early sowing tends very much to insure a full plant and early maturity, so that the crop can be got off the land in the autumn before there is much heavy rain, while carting is light and easy, and there is no risk of damage to the roots from frost. We know full well that in the eyes of many farmers these are trifling considerations, but we like to avoid the very considerable risk of hindrance from heavy rain, and a compulsory exposure of part or all of the crop to severe frost.

On an estate recently purchased we intend breaking up 20 or 30 acres of very poor and foul pasture with a steam cultivator, and after a summer fallow to plant it with Larch and other timber in the autumn. The Larch will be small, healthy plants, to go 3 feet apart, so that in due course the plantation thinnings may come in for estate repairs—rails, posts, gate and hurdle wood. We at first thought of a crop of Mangolds sown wide apart to clean the land, but it is so foul that we have decided for the bare fallow.

#### OUR LETTER BOX.

**Dairy Work (N. C.).**—"Butter and Cheese Making," an elementary course of instruction for technical classes, by John Oliver (late Principal of the Western Dairy Institute) and Margaret Barron (late teacher and lecturer of the Derby County Council), with numerous illustrations, price 1s. London: Bemrose & Sons, 23, Old Bailey. This is a practical manual, which may help you, as there can be no reason why you should not apply its teaching to the manipulation of the cream of your two cows. The general principles apply to all dairies, large and small. We will gladly assist you in any special difficulties if you will communicate them to us.

**Smoking Bacon (Porcine).**—A smoking room for this purpose is a very simple affair. For many years we had the annual supply of bacon and hams for a large establishment smoked in two large chimneys of an old farmhouse on the home farm of an estate under our care. Care was taken to send no resinous wood to the farm for the fires—only Oak and Beech logs being used. Both bacon and hams were in pickle a month, and in smoke a month, and we always had satisfactory results, both bacon and hams being excellent, and keeping well suspended from the beams of the old parlour which we turned into a bacon room. This information should serve you as a safe point of departure in the construction and management of your bacon smoking room. A plain, rather lofty, apartment of brickwork, rafters, or beams, with hooks for suspending the bacon; a slow fire of logs, or preferably of the sawdust of odourless timber; a small vent controlled by a damper for chimney, and careful attention to maintain a slow smouldering fire.

#### REMARKS.

- 24th.—Dull, drizzly, and showery nearly all morning; frequent sun in afternoon. Strong gale all day.  
 25th.—Alternate sunshine and cloud, with very slight showers at 2 P.M., and in evening.  
 26th.—Overcast till 11 A.M., frequent sunshine after; spots of rain at 3.15 P.M.; fine evening and night.  
 27th.—Heavy rain from 4 A.M. to 8 A.M., frequent drizzle and showers in day, rain again in evening; a gleam of sun at 2.15 P.M.  
 28th.—Gale all day, with occasional showers and frequent sunshine; fine night.  
 29th.—Dull and damp morning; occasional showers in afternoon, and heavy rain and hail at 2 P.M., gleams of sun after.  
 30th.—Sunshine early; overcast from 8.30 to 10 A.M., drizzle and showers till noon sunshine and showers in afternoon, and heavy rain at 6.30 P.M.  
 A showery week of about the average temperature.—G. J. SYMONS.

**Dobbie's Violas**  
 2/6 PER DOZEN FLORISTS TO THE QUEEN  
 ROTHESAY.

Our Violas are unsurpassed. Satisfaction to everyone guaranteed. One dozen, as follows, 2s. 6d., post free; 100 in fifty varieties, 20s.; exceptional value:—A. Grant, Bullion, Blue Cloud, Countess of Hopetoun, Duchess of Sutherland, Colleen Bawn, Dorothy Tennant, Picotee, J. B. Riding, Lord Elcho, Violetta, Duchess of Fife, York and Lancaster.

**Dobbie's Pansies**  
 3/6 PER DOZEN FLORISTS TO THE QUEEN  
 ROTHESAY.

This is a sample dozen of the grand named Pansies which we send for 3s. 6d., carriage free, 25s. per 100:—Mrs. Mark, Tom Travis, A. Mabel, D. Rennie, Lord Hamilton, George Anderson, Betsy Kelly, Ellen Patterson, D. Morrison, Dr. Bostock, Crimson King, A. Ollar, Lord Rosebery.

**Dobbie's Phloxes**  
 3/6 PER DOZEN FLORISTS TO THE QUEEN  
 ROTHESAY.

Everyone can grow and everyone can enjoy Phloxes. The following dozen, 3s. 6d., post free; 100 for 21s.:—Borsig, Christina Stuart, Chanzy, Comedie, D. Syme, Evening Star, Jas. McBride, Jas. Benuett, John Forbes, Mad. Prail, Oracle, Venus.

**Dobbie's Dahlias**  
 5/- PER DOZEN FLORISTS TO THE QUEEN  
 ROTHESAY.

We offer the following splendid selection of Dahlias, carriage paid, for 5s. per dozen; the four dozen, carriage paid, for 18s.

**SHOW AND FANCY VARIETIES.**

Canary Bird, Colonist, James Cocker, John Walker, Mrs. Gladstone, Mrs. Langtry, Miss Cannell, W. H. Williams, Dandy, Matthew Campbell, Prince Henry, Rev. J. B. M. Camm.

**CACTUS.**

Apollo (1893), Bertha Mawley (1893), Cannell's Favourite, Countess of Gosford (1893), Countess of Radnor (1893), Delicata, Beauty of Eynsford, Kynrith, Robert Cannell, St. Catherine, Snowflake, Baron Schroeder.

**POMPONE.**

Admiration, E. F. Junker, Bacchus (1893), Crimson Beauty, George Brinckmann, Grace Lilian, Little Frank (1893), Revenge (1893), Ringdove (1893), Phebe, Hector.

**SINGLES.**

Willie Fyfe (1893), Amos Perry, Butterfly, Duke of York, James Cook, Kitty, Eclipse, Chilwell Beauty, Tennyson, White Queen, Marion, Mrs. Grant.

**New Single Cactus Dahlias.**

The best of all for cut flowers. Our new set for 1895 containing six most beautiful novelties, a great improvement on our former introductions, carriage paid for 10s. 6d.

12 splendid varieties of New Single Cactus, our selection, carriage paid, for 5s.

**Dahlia Cuttings.**

We can still supply Dahlia Cuttings till the 15th April. Our selection 1s. 10d. per dozen, post free. All separately named and packed in wood boxes.

**SOW NOW.**

**CARTER PAGE & Co.'s**

**ECKFORD'S SWEET PEAS.**

Per Packet, 300 Seeds, 7d.; 2 ozs., 1/2; half-pint, 2/9; Post Free.

UNSURPASSED MIXTURE OF OVER 30 FINEST VARIETIES AND COLOURS.

Twelve varieties, separate, large packets, 3/6.

COMPLETE ILLUSTRATED SPRING CATALOGUE  
 Gratis and Post Free.

52 & 53, LONDON WALL, LONDON, E.C.  
 (Firm Established 50 Years).

**ROSES! ROSES!**

THE BEST AND CHEAPEST IN THE WORLD.  
 GREAT CLEARANCE SALE.

All have been kept moved back, and will plant now with safety. 24 Choice Standards, 21s.; 25 Half-Standards 21s.; 12 Standards, 12s. 6d.; 12 Half-Standards, 10s. 6d.; 50 choice dwarfs. 21s.; 12 choice Climbing, 6s.; 12 best Hybrid Perpetuals, dwarfs, 7s.; 6 lovely yellow Roses, 4s. 6d.; 6 Gloire de Dijons, 4s.; 6 choice Moss Roses, 3s. 6d.; 6 old Cabbage Roses, 3s. 6d.; 6 old-fashioned Roses, 3s. 6d.; 6 pink Month y Roses, 2s. 6d.; 6 quick-growing Climbing Roses, 2s. 6d.; 12 Sweet Briars, 3s. My selection, cash with order. Thousands of Testimonials.

**FLORISTS' FLOWERS AND HARDY BORDER PLANTS.**

FORBES' NEW CATALOGUE for 1895 is enlarged to about 150 pages, and very materially improved, embracing everything—new and old—worth cultivating in the way of FLORISTS' FLOWERS and HARDY PLANTS, with accurate descriptions and prices. Copious notes as to their origin, how and where best to grow, a full index of the common or popular names of HARDY BORDER PLANTS, and a vast mass of other valuable information that cannot be had elsewhere, which renders this the BEST, MOST RELIABLE, and COMPLETE CATALOGUE ever issued on this popular class of plants. Free on Application.

JOHN FORBES, Nurseryman,  
 HAWICK, SCOTLAND.

**DANIELS BROS.'**

GRAND NEW POTATO,  
**DUKE OF YORK.**

The Most Prolific Early Potato ever sent out.

POTATO—DUKE OF YORK.

A superb dwarf-growing variety, producing large smooth, oval-shaped tubers of splendid cooking quality. It is wonderfully prolific, and has yielded at the rate of 20 tons per acre. A first-class variety for exhibition.

Per Peck, 3s. 6d.; per cwt., 20s. Bags included

**DANIELS BROS.,**  
 Seed Growers and Nurserymen, **NORWICH.**

**JACK FROST**

Has caused many losses that can be made good in an easy and cheap manner by purchasing the following Bulbs and Plants, which I can strongly recommend as being first class:—

**BEGONIAS, SINGLE,**

20,000 Grand Bulbs, Mixed Colours, finest ever offered at the price. 3s. per dozen.

**PELARGONIUMS, SHOW & DECORATIVE.**

Fine Plants in Best Kinds, 6s., 9s., and 12s. per dozen.

**ZONAL PELARGONIUMS,**

Best Kinds only. 6 for 2s. 6d., 12 for 4s.

**IVY-LEAF PELARGONIUMS.**

A very Choice Lot. 6 for 2s. 6d., 12 for 4s.

**DOUBLE PETUNIAS,**

Extra fine New Kinds. 6 for 3s. 6d., 12 for 6s.

Journal of Horticulture.

THURSDAY, APRIL 11, 1895.

EXPRESS GRAPE GROWING.

ON page 147, February 25th, 1892, we published an engraving, reduced from a photograph, of a house of Grapes representing what we thought a good crop obtained from Vines the second year after planting. The Vines comprised fourteen of Black Hamburg, three Gros Guillaume, and one Foster's Seedling. They were bearing up the entire length of one side of the roof of a span-roofed house and two-thirds down the side of the other. The eighteen Vines carried and finished well 400 bunches, or say an average of twenty-two bunches per Vine; the three largest of these bunches weighing 7 lbs. 4 ozs., 6 lbs. 3 ozs., and 5 lbs. 6 ozs. respectively. The Vines were raised, planted, and grown by Mr. Charles Colebrook, Royal Nurseries, Great Grimsby, Lincolnshire, and we entitled his accomplishment, "Quick Work in Grape Growing."

We thought then, and think now, that the terms of reference were merited, for the crop was photographed only three and a half years after the Vine eyes were inserted, and two and a half years after the yearling canes were planted. It is true that Mr. H. W. Ward, the accomplished gardener at Longford Castle, followed with an example of still quicker work—namely, Vines raised from eyes in 1881, and bearing a remarkable crop the following year (1882); one of them, a Gros Guillaume, bearing three bunches, excellent in shape, colour, and finish, weighing in the aggregate 30 lbs, other varieties being equally satisfactory according to their characteristics. This was quick work undoubtedly, and the term sometimes applied to the rapid production of Cucumbers would not have been inappropriate to the case, nor does it seem to be in the case we have now the pleasure to introduce of "Express" Grape growing.

This is another example of Mr. Colebrook's which is, we think, worthy of prominent attention. It shows the great productive capacity of the Grape Vine when accorded generous and appropriate treatment by the skilful cultivator. Moreover, the results achieved are somewhat in antagonism with certain preconceived notions on two points of practice—namely (1), shaking or washing all the soil from the roots when planting, and (2) employing "supernumerary" Vines for early fruiting in order that the "permanents"

may be closely shortened after the first season's growth, borne lightly the second season, and moderately the third year for laying the foundation of a strong constitution and long continued productiveness.

It must be understood that we have nothing to say against this practice, for as judiciously carried out it has given satisfaction in hundreds of gardens, and will probably do so again; but it is not the practice of many successful growers of Grapes for market, as they want the best returns in the least time for the outlay they invest in the work. From this point of view Mr. Colebrook appears to have good reason to be satisfied with the results he has achieved. In March, 1892, he planted a house with Gros Colman Vines, raised from eyes the preceding year (not cut-backs). In August, 1893, a photograph was taken of the vinery, and this is reproduced with absolute accuracy on page 315 of the present issue. The twenty-eight Vines produced and finished well 986 bunches, weighing in the aggregate 1263 lbs., the heaviest bunch 3 lbs 10 ozs. Such a crop as is represented in the illustration in nineteen months after planting the Vines is, so far as we remember, the best example of express Grape growing that has been brought to our notice, and we shall be glad to know if a greater yield has been obtained in less time.

Naturally our readers will desire to know something about the methods pursued in the production of the crop in question. On writing to Mr. Colebrook we found he had no secrets to suppress, but most readily told us the history of the Vines and the cultural routine he pursued. It is a simple narrative. There was no carting of old soil out and new turfy loam in to make a costly border. With the natural soil fish manure was incorporated freely (Grimsby is famous for fish), and oyster shells were also liberally used. The Vines, raised from eyes, as before mentioned, in 1891, were eventually transferred to and grown in 10-inch pots. The canes ripened and were cut back to about 6 feet at the end of the year. After starting into growth they were turned out of the pots, the loose soil removed, the outside roots liberated and planted with the balls of soil intact in February, the canes not further shortened. When the leader had grown about 6 feet it was topped. The leading growth resulting was allowed to extend, but all the laterals were pinched in the manner usually practised with Vines on the spur system. At the end of the season—December—the canes were shortened to one bud below where the leading growth was topped in the summer. The bearing canes were thus 11 feet long (the length of the roof) at the beginning of 1893, and produced the crop that was photographed in August of that year.

The question might be asked if the Vines were allowed to carry any fruit during the year they were planted. Three or four bunches were borne by each according to their weight and the strength of the canes, but on the strongest Vine six bunches were retained. This Vine, Mr. Colebrook says, "is the strongest in the house to-day. I have just counted the bunches now showing—sixty-six, and last year I cut 46 $\frac{3}{4}$  lbs. of Grapes from this Vine." This is nearly 4 $\frac{1}{2}$  lbs. to the lineal foot of rod, so the Vine was evidently not exhausted by its first year's crop.

Overcropping and exhaustion are, it should never be forgotten, relative terms. What may look like a much too heavy crop on some Vines may not be nearly so heavy to them as a crop only of half the weight is to others that are enfeebled by various causes, such as defective root action, a lack of appropriate food, impaired foliage—the result of crowding, scorching, or insect ravages; any, or all those contingencies render Vines unable to bear other than unsatisfactory crops of fruit, whereas when all their requirements are met in all those respects, they mature heavy crops without being materially distressed.

Mr. Colebrook's Vines planted in 1889 have not yet suffered by early and very free cropping. They have, he says, borne wonderful crops for four years, showing not the least signs of weakness, and their promise this year is as good as ever. "They afford," to quote his words, "plain proof that the old system of allowing four or five years to elapse before covering the roof with wood

capable of bearing fruit is not necessary." He is not alone in thinking that what are known as "permanent" Vines may be humoured to an unnecessary extent in resting, while "super-numeraries" are doing the useful work. There are gardeners, and of very high standing, too, who believe that when young Vines are strong enough for bearing it is wise to let them bear to what they deem a reasonable extent, and this is much greater than others admit to be safe. Bearing does them good, brings them into good habits early, is the view that is entertained, and, like Mr. Colebrook, they have something to show in support of their theory in the form of magnificent crops of Grapes that the ultra-cautious cultivator would almost shudder to see, in the full conviction that the Vines were being ruined. It is well that both sides of the question be considered, though it is not wise to be too slow in these keen competitive days.

Possibly some of our readers who are interested in modern Grape growing—perhaps even more "modern" than Mr. W. Taylor's routine—might, if convenient, find it worth while to pay Mr. Colebrook a visit in the summer and see his work. According to an illustrated account of Grimsby and Cleethorpes his offices are in the Old Market Place, and the nurseries are only a mile distant. They are said to have been started in a ploughed field in 1878, and are now of considerable dimensions, their founder rejoicing in the patronage of Royalty. He evidently does not let the grass grow under his feet, nor Vines "rest" long unproductive.

## EMPLOYERS AND GARDENERS.

In dealing with what, from a gardener's point of view, may be rather a delicate subject, I wish it to be clearly understood that my object is not to cause any bitterness of feeling between the two classes, but rather to try and point out some of the disadvantages felt at times by both in their relations with each other, with the hope that perhaps a few stray shots may hit the mark.

Gardeners, of course, are like all other mortals, and subject to the same faults and failings as the rest of mankind. Gardeners need to have, perhaps as much as any class, an even temper and good control over themselves, for as well as finding it a somewhat difficult task at times to suit our human rulers, even the very elements are often at war with us, and seem bent on destroying us in some way or other. A gardener should also possess the art of making himself agreeable in conversation, for remember our employers, especially if they should be enthusiasts, really look forward, I have no doubt after a hard day's business, with pleasure to their quiet walk through their garden and a chat with the gardener, so the more bright and intelligent he makes himself the more likely is his employer to enjoy his company.

I am afraid gardeners sometimes, in their anxiety to secure a situation, are not quite so particular as they ought to be in getting a thorough understanding at the commencement as to what is expected of them, and the means allowed for producing the same. Situations are now so difficult to obtain that there is no doubt every excuse for them; still, in their own interest, and also the interest of the employer, it is best, as things which may appear trifling, and which, if the place can only be secured, may be left to right themselves, are, after all, very often the first that cause trouble. The employer sees fit to complain, the gardener makes excuses—not enough help, houses no good, and others. The answer is this: "You saw the place before engaging, and if you had taken the trouble might have found out all these other things, so there is no excuse;" whereas if a proper understanding had been arrived at to commence with, the gardener would have been able to say, "Sir, you have broken the contract, and can hardly blame me for the result." Some gardeners on taking charge of a garden are apt to look on their predecessor and all his works as wrong; the object of the new man becomes, so to speak, a task of pulling to pieces anything and everything.

I think I am right in assuming that this is so to a great extent, for I remember one of our illustrated papers some years ago making the matter a subject for their cartoon. The new gardener was depicted in a garden, up to his waist in weeds and rubbish, coat and waistcoat off, braces down, striving with might and main to restore things to something like order. Over the fence—spick, span, and smart—stood the late gardener. "Morning, W.; seem busy this morning." "Busy, ay! and likely to be, B.; you left the place in such a precious mess." We gardeners have, to a certain extent perhaps, deserved this, but it would be much better

if we left alone what cannot be helped. The place may be in a precious mess; and if so, it is our duty to get it out as quickly as possible, and not find fault with what has very likely been an advantage to ourselves. No doubt as time goes on, when we know more of the difficulties to contend with, we shall have a better opinion of our predecessor.

An employer has a right to a just return for the money he pays in wages, and so long as that wage is what the gardener has contracted for, be it little or much, he should devote the best of his energies and abilities to do what is required of him. Perhaps at times we lay too much stress on these words—what is required of us. It is only a very poor conception of a duty, if a man only does just what he is obliged. Perhaps many men have little encouragement to do more. To such I would say, Do not forget the advantage to your own mind, in feeling that you have honestly done your part; for though you may see no present benefit, rest assured it will come sooner or later. It is an old saying, and deserves more attention than it receives—if a thing is worth doing at all, it is worth doing well. We may become dissatisfied with our present position, and fancy ourselves fit for something better; but while waiting for opportunities, or seeking them, we should do our utmost to what we are about, as the surest way to gain a better position is to do thoroughly well, be it in ever so humble a way.

Employers are not in the habit of maintaining gardens for gardeners, but gardeners for gardens. In neglecting to observe this, I fear we very often make a rod for our own backs. Gardeners, of course, like other people have hobbies, and will, if chance permit, ride them, and if allowed to do so all well and good, but those places are few and far between. We again, like other mortals, are not easily weaned from our hobbies; but depend on it, like other riders, if we persist in riding, one day we shall be thrown. The best way, then, to avoid it is to subordinate our tastes to the employer, who has to pay the piper, and should have his Gooseberry trees planted whichever way up he likes best.

To be successful in satisfying the wants of our employer, it is well to bear in mind there is no royal road to success. Close attention to small matters go a long way further than, shall I say, scientific knowledge. How often do we see the most perfect results where the appliances are very poor? For the knowledge that we are deficient in some part of our armour makes us doubly anxious; we are continually on the watch, and often success crowns our efforts through the very point we anticipated the most danger. I do not mean to imply by this that it is not best to be properly equipped in every way, for the man who has the best convenience, and gives the same attention, ought to beat his neighbour who has not these advantages; but it is not wise to place too much reliance on these things.

Perhaps it is scarcely necessary in these days to remind gardeners of the duty of being economical in the garden, for I take it there are very few gardens where the question of economy is left in the hands of the gardener. Time was, no doubt, when in some of our best places the gardener had almost a free hand. If there are any such now I know them not; yet it is the gardener's duty to his employer to use the means which he allows to their fullest capacity, and to make their gardens if possible a source both of pleasure and profit.

Just a word to head gardeners. Many a young man's future has been made or marred by the kind of man he has had the fortune or misfortune to serve under. I could quote many instances of this did time allow, but must content myself by remarking that a kind and encouraging word costs nothing, and I know from experience how gratifying it is to receive it. My experience also teaches me that kindness and encouraging words will always go a long way further than the opposite. There is, indeed, no comparison in the work done by a man who is in sympathy with his employer and the one who is otherwise.

To under gardeners I would say, Do not forget you are a plank of the ship, each one of you, and each one has a special duty to perform if the ship is to be kept floating. No doubt you at times sigh for the happy time when you will be a captain; but take my word for it, the lot of a head gardener is not in all cases a happy one. So do your level best to strengthen the hands of your chief to the best of your ability. He may seem at times irritable, unreasonable, and generally bad to do with. You see the effect, but very often have no idea of the cause.

I well recollect serving a good kind man close on three years as foreman, one of the happiest periods of my life. We had one little hitch during that time—a very simple thing, too, but I did not feel justified in giving way. A few sharp words, then for a day or two a sort of coolness. I was troubled, but not so much as he. I could stand it no longer. I apologised; and never shall I forget the change that passed over his kind and venerable face, as, with

tears glistening in his eyes, he clapped his hand on my shoulder and said, "Well done, my lad; I am not disappointed in you. I felt sure you would be brave enough to acknowledge yourself in fault." He is still living, and I am proud to say still honours me with his friendship; and I am not the only one by many of the young men who during his long career he has had to do with who look back to the happy time spent with him as a bright gleam of the past. This is how it should be, and how it will, if each study the interest and do their best for each other in every way. I must now pass on to the other part of my paper.—GEORGE WILSON, *Swanland Manor, Brough*.—(Read at the *Hessle Gardeners' Mutual Improvement Society, March 12th*).

(To be concluded.)

#### EULOPHIELLA ELIZABETHÆ.

TWO plants of this handsome Orchid are now flowering at Kew. They were obtained in the autumn of 1893, when they were newly imported from Madagascar, and they have been growing ever since in teak baskets suspended over a hot-water tank in a tropical house; they are planted in pure sphagnum moss, and they have been liberally watered always. The stronger, writes "W." in the "Garden and Forest," has made leaves 3 feet long by 1½ inch broad, four to each growth, and one bears three, the other two spikes. These are horizontal, a foot to 18 inches in length, straight, dull brown-purple, with ovate-concave bracts. There are

FIG. 53.—ODONTOGLOSSUM TRIUMPHANS LIONEL CRAWSHAY.

(See page 322.)

sixteen flowers and buds on the strongest spike, and these are like the figure in the "Botanical Magazine," t. 7387, in size, form, and colour, except that they are not tinged with rose on the inside of the segments.

#### CATTLEYA PERCIVALIANA.

THE London correspondent of an American contemporary says that this beautiful and useful Orchid deserves to be more largely grown than it is. Several plants of it at Kew are in flower now, the flowers of medium size, elegant in form, and of the richest shades of maroon-purple and mauve. It was introduced in 1882 from South-west Venezuela, where it is said to "invariably grow on rocks, not on trees, and in full exposure to the sun, generally in the vicinity of river courses, which, in the rainy season, afford abundant moisture to the plant." Under cultivation it thrives

when planted in peat and sphagnum, either in a basket or on a raft. The preference for rocks is a peculiarity of another handsome winter-flowering Orchid—namely, *Epidendrum bicornutum*—which forms thick masses on exposed rocks near the sea in the island of Trinidad. It also thrives in peat and sphagnum in baskets, requiring excessive heat and moisture while making new growth.

#### REPOTTING ORCHIDS.

THIS is a work that requires a great amount of care and judgment, as future success depends to a great extent on the manner in which this important operation is carried out. There is such a wonderful variety in this family that no general lines can be laid down for compost, time, or manner of repotting. Take the larger fleshy roots of *Vanda* or *Saccolabium*, for instance, and compare them with the small interlacing or twining roots of many species of *Dendrobium* and *Oncidium*. To place these in similar composts, or in the same sized pots relatively, would be so obviously wrong that even a novice in Orchid-growing would hardly be guilty of it. On the other hand, many growers with a certain amount of experience will not give the consideration that is essential to the less varying types and their requirements.

Take the example of perhaps the two best known types of Orchids in existence as serving the purpose of illustration best—viz., *Odontoglossum crispum* and *Dendrobium nobile*. The former of these, as pointed out by Mr. Bardney in his very practical article on page 179, are shallow or surface rooters. These do not need a large pot or a great thickness of compost, for if provided the roots could never take to it, and the moisture-holding medium about the pseudo-bulbs will be a fruitful source of decay both summer and winter. *D. nobile*, on the contrary, seems to delight in pushing strong roots in all directions, which, if not checked or broken off, frequently grow to a length of a foot or 18 inches. This may be seen on any plant of this species growing in a warm, moist house that may happen to have young shoots at or near the top of the stems. Here, then, is a clear case for a larger, deeper pot in comparison with the size of the plant, and a compost consisting of large, rough lumps of charcoal or crocks mixed with the material used for its sustenance. The larger growing *Cattleyas*, and *Lælias* too, like this rough, open rooting medium, and although the majority of the roots are usually nearer the surface than is the case with the *Dendrobium* mentioned a fairly wide root run will be found to answer best for them.

Intermediate between the types of root mentioned are those that, being small, yet take a very firm hold and grow more or less closely matted. These would include the majority of the deciduous section of *Dendrobiums*, many *Oncidiums*, *Epidendrums*, and *Miltonias* that like a rather closer and firmer root run, and pots not much larger than is necessary to take the plants easily. Among the terrestrial species so called the same variations will be found, and the grower who pots a *Cypripedium* or *Cymbidium* on similar lines to a *Thunia* or *Calanthe* has yet something to learn of the details of Orchid culture. *Phalænopsis amabilis* and *Aërides odorata* both like sphagnum moss about their roots, yet who would think of treating them to it in similar bulk? The roots of the first named would be killed if buried at a depth at which the strong and vigorous roots of the *Aërides* will thrive.

The materials required for potting the various species has been so frequently alluded to in these pages that it is hardly necessary to repeat them here; but with regard to the manner of potting a few words may not be out of place. The distichous-leaved section are easily fixed in position, that is when the roots are abundant; more than ordinary care is, however, necessary to avoid snapping these, which cannot be bent very much any way. It is unwise to disturb these plants at all unless the temperature can be well kept up afterwards, it being far better to wait even until they are well on the move than to run the risk of checking them—a serious matter with these large fleshy roots. Should not these be abundant enough to fix the plants, a strong stake ought to be placed to each, or small plants may be firmly wired to rough blocks, and then inserted in the pots or baskets and surrounded with sphagnum. All the stem roots that can be brought down to the surface may be covered with moss, as this strengthens the plants and encourages the emission of more roots in the atmosphere.

The pseudo-bulbous division of epiphytal Orchids, as represented by *Oncidiums*, *Cattleyas*, and others, require considerable care in repotting. It may almost be taken as an axiom that the larger rooted the plant is, the larger pot or basket will be required, also the rougher the compost, and *vice versa*, the exception to this rule being noted from time to time in these pages. Those that are compact in growth, as *Oncidium tigrinum* and *Miltonia vexillaria*, are easily fixed in position by elevating the plants as required, and bedding the compost firmly around them, finishing by trimming off the ragged ends to a neat cone. With *Cattleyas*, *Oncidiums flexuosum* or *mercurianum*, and others that produce

leading growths at varying heights more judgment is required, and the plants must be manipulated so that as many of these as possible are brought into contact with the compost without burying the eyes.

The plants must be staked or tied into as neat a shape as possible, and the leads disposed as equally as may be, or a straggling ill-balanced specimen will result. *Cypripediums*, *Calanthes*, *Thunias*, and certain species of *Phaius*, *Peristeria*, and many other Orchids requiring loam in the compost, are the simplest of all with regard to repotting, and as the surface of the compost is usually kept rather below the rims of the pots no more difficulty will be experienced in fixing the plants in position than in the case with an ordinary greenhouse plant of any kind.

There are three cardinal rules to be observed in repotting Orchids of any description. 1, Provide drainage that cannot possibly become choked, but will always be free and open, so that when the water is given it permeates the whole compost, and quickly passes away. 2, Remove all decaying roots and sour portions of the compost that it is possible to get at without unduly disturbing the sound ones, and (3) fix the plants in position, so that they cannot possibly rock when moved about for cleaning or examination.—H. R. R.

#### PROFITABLE CUCUMBER CULTURE.

MANY private gardeners, myself included, when commencing Cucumber growing for market, as a rule soon find out they have much to learn. This experience has to be paid for. From six to a dozen plants grown with the aid of bottom heat, consisting not unfrequently of both hot-water pipes and hotbed material, may succeed for a time, and those responsible may have good reason to be proud of their achievements. When, however, it comes to growing plants by the hundred, and cropping heavily, the case is very different. Hotbeds from 100 to 200 feet in length on each side of a house or range of houses are simply out of the question, and some growers even dispense with bottom heat altogether, though not, I believe, before February or March, these being the months when most plants are put out. Cucumbers are not always successfully grown in private gardens. The plants may keep in a fairly healthy state, and produce enough fruit and to spare, but if much strain is put on them they collapse, while many of the Cucumbers are of poor form, and not good to eat. Market growers must have heavy crops in various stages of growth from the time their plants are large enough to bear till they are cleared out; added to this, the fruit must be of good form and colour, as it does not pay if "seconds" predominate. For the former 3s. per dozen can be obtained during the greater part of the season, but second rate fruits only fetch about 1s. 6d.

What is known as the extension system—three or four plants filling a moderately large house, is not favoured by market growers. They cannot afford to run the risk of having large blank spaces through a plant failing. A distance of about 2 feet apart is more than some allow, but it is doubtful if anything is gained by excessive crowding. Then, again, bottom heat pipes may be dispensed with, especially if the start is delayed till March and the natural soil is not of a heavy clayey nature. Where the latter prevails it pays to have a bottom heat pipe immediately under where the plants are to go, and to also form a chamber over the pipes with a view to distributing this bottom heat, and also to keeping the roots from reaching the clay. Failing to keep the roots out of a cold soil has been the cause of failure in more than one attempt to grow Cucumbers.

Not only do Cucumbers collapse completely on a very bright day when the roots are in a cold rooting medium, but the same thing occurs when they have either too much over-rich soil or have free access to a mass of decayed manure. The roots require ample air, heat, and moisture, and if we exclude any one of these failure soon results. A great heap or ridge of soil ought never to be seen in connection with Cucumber culture, and what is used should be constantly overrun by a complete network of roots. This necessarily means very close attention on the part of the grower, especially with regard to watering. A few hours' neglect may mean the loss of the greater portion of the leaves in a house. The whole of the plants may take water twice in one hot day, so rapid is the evaporation from the leaves. Less than a peck of soil suffices for each plant at the outset, and from one to two pecks may be given subsequently in the form of top-dressings. The soil must be of a loose porous nature, and composed of materials that will not sour readily. Seeing that liquid manure will of necessity be freely used, well-charred soil or charcoal and old lime rubbish should be mixed with loam devoid of fibre; but if good yellow fibrous loam can be had, chop that up roughly and only add horse droppings to the extent of one part in four. Market growers, if they have the opportunity, stack turf in the autumn grass side

downwards, and mix layers of good stable manure with this, chopping all down together as required. At Bromham in Wilts a light sandy loam with no fibre in it answers well for Cucumbers, and large quantities are sent from there to the markets.

After being planted in well-warmed soil from a week to a fortnight, according to the time of year, roots should begin to show, and when they fail to form fresh fibres on or near to the surface the plant's decadence will be rapid. In order to keep the roots active frequent top-dressings of fresh compost similar to that first used, with perhaps the addition of nitrate of soda or fish manure at the rate of a 6-inch potful of the former, and an 8-inch potful of the latter to a bushel of soil. A heavy dressing should never be given at one time, but only enough to just cover the roots. Then if the watering goes on before the old soil underneath becomes dangerously dry, the new soil does not sour, and the roots are soon in possession. Soot is sometimes given as a surfacing, but that is a mistake, as it serves to clog the soil. It might be mixed with the soil or used in water very frequently. Surfacing of fish manure, kiln dust, and other manures strong in ammonia are dangerous. After they have been damped, and the house is closed, too much ammonia is given off, and the foliage suffers badly. Nitrate of soda dissolved in water at the rate of 2 ozs. to 3 gallons of water is a safe and effective stimulant, and must be used frequently when the plants are bearing freely.

I have dwelt at length on the treatment of the roots, as it is in that direction most mistakes are made, and I will, therefore, only touch briefly on other details. Cucumbers for the market are principally grown in long, narrow, span-roofed houses, a width of 12 feet being generally the widest. The central path is sunk, and the plants are arranged along each side. A sufficiency of the side shoots are laid in on each side to just cover the trellis, and a leader is extended till the ridge is reached. The side growths or laterals are stopped at the second or third joint, and allowed to fruit to their full extent at once. This early and heavy cropping of young plants does not greatly check growth of haulm, always provided they are liberally treated at the roots, and laying-in and stopping goes on, the growths running into each other, though not to the extent of undue crowding. From first to last there must be no neglect of training and stopping, and no leaving the fruits hanging a day after they are large enough to cut. The plants, beds, and walls are freely syringed in the morning before the houses are very hot, and syringing takes place again on closing.

Only a very little air is given at the top or at the high end of houses on a slope, and the night temperatures are kept at about 70°, while a thin shading is desirable on clear hot days. Directly the plants give signs of having done their best, a fresh stock is prepared. They are then cut out, the soil is changed and replanting takes place, three sets of plants being sometimes put out in one house during a single season.—W. IGGULDEN.

### OVERCROWDING PLANTS IN POTS.

I THINK there are but few, if any, gardeners who have not at various times during their career experienced uncomfortable feelings of regret when by the force of circumstances they have been compelled to arrange plants far too thinly for their well-being. Such times do occasionally occur when it is almost impossible to follow any other course, but in a great many instances I fancy the display of a little ingenuity might end in a vastly improved state of affairs.

During the winter months, when many plants are completely at rest and others are comparatively dormant, they may be placed somewhat closely together without any serious detriment to their future welfare; but as soon as signs of growth are apparent if this crowding system is still continued, disastrous results follow. Disastrous may seem a somewhat strong expression to use in this instance, seeing how seldom it is that plants are killed outright by overcrowding; but I maintain that it is nothing short of disastrous to see plants which ought to be sturdy and strong from the first rendered permanently weak and drawn by this too prevalent practice of overcrowding.

I fancy I can divine the thoughts which will pass in the minds of many when reading the foregoing sentence. They will be something like this: Yes, but what is one to do if one has so many plants to grow and only a limited amount of space to grow them in? My answer is, Consider seriously whether or not it would be to your advantage to "grow less in number so that each be greater in bulk." If we could all keep this axiom constantly in our minds I think we should invariably secure better results. If we take as an example bedding Pelargoniums; a given number conveys a very indefinite idea of the space they will cover during a certain time. One good plant will cover during the growing season as much space as

two weak ones, and provide a more satisfactory display into the bargain. Then again with plants for decorative purposes; how much easier is the task of forming groups and filling tins and jardinettes, when well developed plants in comparatively small pots are at command, than when weak and leggy ones, showing in-different culture, have perforce to be employed.

At the present season of the year, when the majority of plants are making active growth, and when the pressure on space under glass is so great, it is especially necessary to bear in mind the evils of overcrowding, as thousands of plants, which in the spring time are in a young state, are annually spoiled, from a cultural point of view, through being placed closely together for a few weeks. Much can frequently be done to avoid these mistakes by constructing temporary frames, in which bedding plants can be placed till they are secure from frosts in the open air. This will allow a general thinning and re-arrangement of plants in houses and pits to be made, so that all may have room for abundance of air to circulate between them.

All good plant growers know and act on the important fact that in order to secure a sturdy habit of growth in plants of nearly all descriptions they must not only be arranged thinly enough for the foliage to stand clear of each other, but also sufficiently wide apart for the air to play freely around them after a considerable amount of growth has taken place. A point often lost sight of is that the wider the stage or bed on which plants are stood the more thinly should they be disposed, because the volume of light which reaches them on either side when placed on a narrow stage becomes less in proportion when wide breadths are arranged. This principle is easily demonstrated by plants on shelves, or isolated ones raised on inverted pots; in either instance more uniformity and sturdiness of growth is obtained.

A severe winter and so far uncertain spring has rendered overcrowding to a certain extent most difficult to avoid. Now, however, that a slight improvement in the weather seems slowly taking place, more than usual pains should be taken to rectify past errors and steer clear of committing them in the future.—D. W. C.

### BORDER CARNATIONS.

THE winter just past has proved one of the worst in its effects for Carnations, the mild weather up to Christmas last year laying the foundation stone of the mischief. Many plants, indeed, were then growing, a condition most inimical to the well-being of Carnations, and when frost came the stems became softened and drooped.

While some varieties of French extraction have suffered, the greater number are in excellent health. These comprise English and German varieties, which, though less abundantly floriferous, are not so liable to damage. Examples of those that are perfectly firm and plump are Raby Castle, White Lady, Germania, Foxhall Beauty, Jessica, Midas, Mrs. Muir, and Alene Neumann. Last year layers rooted so slowly that not quite half the stock of flowering plants was put out in the open. Instead, they were planted in cold frames in a very sandy and light compost. No water has been given them, and on examination the plants are found to have made many roots, and all near the surface. It is now, of course, quite time that they should be planted, but the ground is not yet dry, and, indeed, nothing can be done in the garden. It is, on some accounts, preferable to bed out plants in soil in frames rather than to winter them in pots. For ease of transit, pot culture is, of course, the better, but when the plants are to be removed a few yards only, the system of dispensing with pots is, I am sure, preferable. Some that were not ready in the autumn I have lately potted, and it is impossible, from their appearance, to say which of the plants were potted now and which in autumn. There will, however, be a slight difference between the two sets in their time of flowering, the autumn plants being the earlier.

It must be pointed out with regard to spring planting that sparsely rooted plants inserted in September would succeed, while if set out now they will almost certainly fail. They may not even take a grip of the soil; but should they do so, the plants grow so weakly that they prove miserable failures. This, no doubt, is largely the reason not only for so many blanks, but also for the want of vigorous layers to carry forward the stock. Another cause of failure is to be found in the system of providing a too liberal treatment. The loss of plants from the attacks of eelworm is appalling, and this invariably follows what is called "high cultivation." If any manure is provided, it ought to be decayed, and only used lightly. However, it is better to plant in ground that has been enriched for a crop preceding Carnations than to apply it for these flowers directly. When planting I have some sandy compost mixed with the soil round each plant, and in the case of yellow and yellow ground varieties the whole surface of

the beds to a depth of 4 inches or so is mixed with sand and leaf soil. Indeed, whenever a variety is found to be "miffy" the same treatment may be given it with success. When Carnations in abundance and of good quality are required, it is necessary to feed, but this is best done by surface dressings. For this purpose soot is excellent, and is said to be also effective as a deterrent to eelworms. I also employ pigeons' manure and an occasional dressing of chemical manure.

It is well known that growers for exhibition thin out the buds to a limited number; but for ordinary cutting purposes, thinning is not much attempted. This, however, is a mistake; I thin not only the buds, but also the grass, and by these means I secure in the end not only as many flowers, but flowers of a superior quality. The way to thin is so simple that a very large number of plants may be done in an hour. The best stage is when the buds are quite small, as they may be drawn out more easily then. When the grass is thinned the result is a stronger growth in the case of those left, and consequently earlier and better layers. Seedlings have wintered without loss. These now require a dressing to strengthen them.—R. P. BROTHERSTON.

### WATER GARDENING.

FEW, perhaps, are called on to embellish by water power their sphere of work, and fewer still to do so on the larger scale; yet many may add to the interest already provided by the introduction of suitable water plants. Nevertheless, a study of the characteristics of good examples of water-designing is worthy of regard. Should one have to perform only in a minor scale there is greater difficulty, if it be in imitating Nature, to avoid the puerile; and for the best effects a skilful hand may be required to create illusions for the eye—to complete in imagination what is curtailed by reality.

Safety lays in simplicity of design with distinctiveness of purpose. On the one hand we have, in the form of fountains and ornamental basins, the severely classical harmonising with the formal outlines of buildings on geometrical garden designs; on the other, the employment of Art to aid Nature in her freehand delineation. Admirable illustrations of either type are frequently to be met with, and occasionally some examples "whose incoherent style, like sick men's dreams, varies all shapes and mixes all extremes."

Amongst the tender aquatic plants *Ouvirandra fenestralis*, the Lattice Leaf of Madagascar, takes a prominent position, for apart from its unique character the successful cultivation of this somewhat "miffy" plant amounts to a triumph of skill. Probably the quality of the water contributes largely to results, for where confervoid growth attaches to the leaves it is inimical to health. Where this occurs sponging the leaves is sometimes resorted to, a remedy which in careless hands is as bad as the disease. Prevention by using suitable water is infinitely preferable to attempting a cure. The *Ouvirandra* is well worthy of a glass receptacle placed on the stage in a shady corner of the plant stove, thus displaying its beauty to advantage.

Amongst the lesser kinds suitable to a warm or temperate house are *Limnocharis Humboldi*, *Pontedera crassipes* and other varieties, *Pistia stratiotes*, and the curious Clover-leaved *Marsilea*, the Nardoo plant of Australia; whilst the larger-growing *Nelumbium*, the sacred Lotus, with *Nymphæas Devoniensis*, *cœrulea*, and *rubra*, are beautiful additions, if not precluded from want of space. One need not mention in the same list that imperial plant the *Victoria regia*, for unfortunately all but a privileged few must worship it afar off. Doubtless there are yet many interesting plants in the tropical waters of other lands waiting for the collector's hand to introduce them to our notice, as one feels that this section is at the present somewhat limited. Yet it is a question of demand, and the utilitarian question of space and other considerations of an aquatic house proper is prejudicial to their introduction.

Not so with the hardy aquatics, and in the open. Here the fair bosom of many an ornamental lake is waiting to be decked with the soft garniture of our charming Water Lilies. Obviously for this work we shall first consider the Lilies, for they are inimitable. If space is limited beware of that yellow-buttoned vagabond *Nuphar lutea*, which will insidiously swallow up the whole surface of the water to the detriment of appearance, and of his fair cousin *Nymphæa alba*. But few plants, aquatic or otherwise, can approach the common white Water Lily in gracefulness of foliage or beauty of flower, unless it is *M. Marlia's* beautiful hybrids. These when better known will take a high place, probably the highest in water gardening.

The pretty pink-bl. ssomed *Polygonum amphibium* is a plant to be introduced with caution, and should the pond or lake be a bathing

resort, it is in deep water a veritable death-trap should the swimmer get entangled in its wiry stems. It is also of a weedy, aggressive nature. In water not exceeding 2 feet in depth, the common Arum Lily, *Richardia æthiopica*, will succeed. This may not be generally known, but I have experience of some plants thus growing for ten years, and on some occasions being frozen in a solid block of ice without injury. A group by the lake side or "river's brim" should be tried, as even under pot culture its habit and form of foliage commend it to aquatic treatment.

For marginal planting we have many bright or interesting plants adapted for this position. Some are coarse and some are common, but if not overcrowded, and kept within reasonable bounds, what might be a drawback in the higher society of plant life is an advantage here. Overcrowding is, in all cases, to be avoided, but rigorously so in water gardening. Planting, here, is rather to serve as a garnish to the dish than to form the *pièce de resistance*.

*Butomus umbellatus*, the Flowering Rush, is pretty in its dull mauve umbels of blossom; *Equisetums fluviatilis* and *Drummondii*, the Horse-tails, are distinctive in character, and suitable where space permits, as the *Equisetums* have a trick of tunnelling and sending up their plumes in unexpected places. That ubiquitous plant, *Iris pseud-acorus*, is too well known to receive more than a passing glance, unless it is for the purpose of apologising by deputy for its commonness. Yet, scamp as it is, lounging in every ditch, pond, or watercourse, and existing on sufferance out of its element, it will if it meets with something stronger than water, in the way of sewage or decomposing matter, fairly revel in—what is to it—the good things of this life. A bundle of the rich green sword-blades 7 feet high is very attractive. Add to this the summer crop of canary yellow Orchid-like blossoms, it is needless to apologise further for it; beyond that, its powers of absorption in polluted water may possibly be of hygienic value.

In sheltered situations, and where privacy insures safety, *Aponogeton distachyon*, the Water Hawthorn, might occupy some pool, and various *Sarracenas* flourish in the sphagnum cushions of a streamlet.

The subject is one which in practice entails but little labour, affords much interest, and is one of those phases of work—if work it can be called—a little aside of the ordinary routine. The exercise is recreative, the influences are soothing; being such, they may be, though infinitesimal, a foretaste of the purer pleasures of "the still waters and green pastures" beyond.—E. K., *Dublin*.

### VEGETABLES FOR EXHIBITION.

(Concluded from page 232.)

#### ONIONS.

ONIONS for exhibition require a long season of growth, and should be sown in boxes about the first week in February in a temperature of from 50° to 55°. When the seedlings have reached the height of 1½ inch they may be transplanted into other boxes 2 inches apart, and grown in the same temperature till they are about 6 inches high, when they should be hardened in cold frames ready for planting in the open about the middle of April. The ground should be thoroughly trenched in the autumn, and heavily manured, placing the manure at the bottom of the trench and between the top spits. In the early spring soot and salt should be sown over the ground to wash in by the rain. Then about a month before planting the ground must be forked over and a little more soot scattered over it. When ready for planting give a good dressing of wood ashes, then with a trowel transplant the Onions 10 inches apart and 18 inches from row to row. If the weather is dry much water will be required, and, as soon as they are thoroughly established, a little soot, nitrate of soda, or liquid manure not too strong should be given at intervals of ten days.

It is an excellent plan throughout May and June to syringe the plants with a solution of 3 ozs. of softsoap and a wineglassful of petroleum added to 3 gallons of water. This seems distasteful to the Onion fly, and prevents it from lighting on the blades and depositing its eggs. Top-dressing the ground with well-decayed manure is of much importance, and should always be done if the soil is light and likely to dry out in hot seasons. As regards varieties, the globe-shaped sorts seem to find most favour. *Ailsa Craig* and *Excelsior* are two of the best, while *Rousham Park Hero* and *Suttons' A1* are excellent flat varieties.

#### CELERY AND LEEKS.

The seed of Celery should be sown very thinly in boxes in heat about the first week in March. After the young plants are fit to handle they should be pricked off into a frame, which has been prepared by putting 3 inches of cow manure on a hard surface of ashes, then 2 inches of soil on the top. In this the young plants will grow freely, and lift with good balls with a trowel. It is most important that the young plants should not receive the slightest check by becoming dry at the root or by being crowded, or they are sure to throw up seed stems, which render all the care and cultivation useless. About the beginning of May the trenches should be prepared, 18 inches deep and 18 in width, and filled

with well decayed manure and part of the soil taken from the trench, bringing the whole level with the surface. The plants ought to be placed 1 foot apart, and thoroughly watered in.

When the plants are making free growth the ground should be mulched with long litter to prevent the moisture escaping. About once a week liquid manure should be given. About seven weeks before the show preparation should be made for blanching. After all useless leaves and side growths have been removed, take long strips of brown paper and bind this round the plant, not too tightly. This will be found an excellent substitute for soil, as no worm or slug marks will be found, and the blanching will be more effectually completed. It is a difficult matter to say which are the best varieties to grow, as I think with Celery it is more a question of good culture than variety. The varieties that I grow are Sutton's Solid White, Major Clarke's Red, and Sulham Prize Pink.

Leeks require much the same cultivation as Celery; the only difference is in the blanching. After they are planted in the trench paper collars should be put round the neck of each plant, to prevent the soil reaching the centre of the Leek when earthing up, also to help to keep the leaves in an erect position till once the blanching is completed. When the Leeks have started to grow freely, draw up these collars once a fortnight, at the same time adding more soil until the blanched parts are about 12 inches in length. They like abundance of liquid manure, and should never be dry at the root. Of varieties Sutton's Prizetaker and The Lyon are both popular.

#### CARROTS, PARSNIPS, AND BEET.

The system that I adopt to have these clean and straight and of good flavour is as follows:—In the early autumn the ground is thoroughly trenched to the depth of 3 feet, but no manure given. In the early spring the soil is forked over and rolled firm, then with a round iron bar holes are made about 3 feet deep and 6 inches wide at the top for Parsnips, and half that depth and width for Carrots and Beet. These holes are filled up with a mixture of burnt soil, wood ashes, and a little soot put through a fine sieve, with an addition for the Parsnip of a little decayed manure, and dropped into the bottom of the holes.

At the proper season for sowing four or five seeds are placed on the top of each hole, and the young plants are thinned to one when large enough to determine which is the best. By this method there are no stones or rough lumps to obstruct the tender point from going down straight, and no fresh manure to induce forking near the surface, and yet there is sufficient nourishment in the mixture to sustain the plant during its growing season. As an experiment I had some holes made 5 feet deep, and some of the Parsnips measured 4 feet 7 inches, which shows the depth they will go if they only get the opportunity.

Parsnips are best sown as early as the state of the soil will permit, Carrots not before the beginning of April, and Beet the last week in that month or first week in May. As regard varieties of Parsnip The Student is best, while for Carrots New Intermediate, and Beet Pragnell's Exhibition and Blood Red.

#### TOMATOES.

Tomato seeds should be sown in a little heat, very thinly, about the beginning of March, and when the young plants are fit to handle, potted in 3-inch pots, and immediately they are ready for another shift into 5-inch pots. For exhibition they are best grown in an intermediate or a cool house, where they can enjoy abundance of air. It is a mistake to have the soil too rich to begin with, and if they are to be planted out better have poor soil and moderately firm, as they make shorter jointed wood and set freely. They are best trained to a single stem.

When a good crop is set thin out all deformed fruit, when feeding may commence. It is a good time then to give them a top-dressing of manure, and when the crop is swelling freely, ample liquid manure should be given to encourage the fruit to swell to a good size. Very often it is found difficult to have sufficient fruit ripe at once for certain shows. Any that would be too early should be packed in tissue paper and sawdust just when beginning to colour, and stored away in a dry room. In this way they keep in sound condition for a month or more, and will be found in perfect condition when they are taken out. As to variety, none excels Perfection when in good condition.—JAMES GIBSON.  
—(Read at a meeting of the Croydon Gardeners' Mutual Improvement Society).

#### SUPERNUMERARY VINES.

WHERE new vineries are made or old ones replanted a good opportunity occurs for the employment of supernumerary canes. There is more advantage in having a double set of rods in a vinery than many persons appear to think. When extra canes are planted there is not the necessity for cropping the main Vines so heavily, and they must thus benefit by the indulgence. Presuming the border is inside the house all that is required is to add a few feet to its width for the extra Vines. Lean-to vineries of good width are the most suitable for this double cropping method.

Where the border is, say, 10 feet wide, the Vines intended for permanent occupation are, as a rule, planted within 6 inches of the front wall and the supernumeraries 5 or 6 feet from them. Instead of cutting down the latter, as is usually the custom with the former, at least 4 feet of cane is retained. If the Vines are extra strong a couple of feet more may be left, securing them to stakes up to the wires under the roof. Growth is confined strictly to the uppermost shoot on the

cane, and this after the first season's growth may be shortened to from 3 to 6 feet, according to their strength. These canes will provide at least half a dozen bunches the following year. Such a crop of fruit must be an advantage, and in the meantime the more closely shortened permanent rods are being strengthened. As these extend upwards the temporary Vines will require some of the lower spurs cut off annually to give additional light and space to the main rods. The supernumeraries are made to fruit further upwards yearly until they are finally ousted by the permanent Vines requiring the whole of the space.

In more instances than one I have fruited these extra Vines for eight years, and with such results as to justify a continuation of the practice described. Varieties that ripen heavy crops of fruit satisfactorily with a minimum of labour expended are the most suitable, such as Black Hamburgh, Madresfield Court, Alicante, and Lady Downe's, with Foster's Seedling as a white variety.—E. M.

#### AN EARWIG TRAP.

FROM Mr. J. H. Hislop I have received one of his specially designed 9-inch flower pots, which is fitted with a water-holding rim  $1\frac{1}{2}$  inch wide and 1 inch deep. By keeping this rim full of water earwigs are prevented crawling on to the plants. If these pots can be sold at a reasonable price they should be a boon to Chrysanthemum cultivators. Earwigs have wings, and sometimes use them, but the common mode of travel is by crawling. The rim around the pot would easily be kept supplied with water when applying it to the plants. During hot weather the water would evaporate, but this would obviously be advantageous to the plants rather than otherwise.

#### DECORATIVE CHRYSANTHEMUMS.

Many varieties of Chrysanthemums of great beauty are not large enough for exhibition stands, but their value ought not to be overlooked for house decoration. Among them are the following:—

*Mrs. Conway.*—Soft yellow in the centre, fading almost to white at the tips; truly a charming variety. Dwarf and free.

*Gaetano Guelfi.*—As a white flowering decorative variety this is unexcelled; the narrow, twisted, drooping florets render it quite unique.

*Meduse.*—Terra cotta and old gold colour, flowers of medium size, with drooping florets.

*Charles Blick.*—One of the best of yellow flowering varieties for decorative purposes.

*Mr. T. W. Sanders.*—A handsome variety with long drooping florets; the colour, a soft shade of canary yellow, is most pleasing.

*H. Shoesmith.*—Light buff yellow with gracefully drooping florets.

*Challenge.*—A late flowering American variety that should prove valuable; the colour, deep yellow, is most desirable.

*Marie Louise.*—Pure white, drooping florets; late flowering.

*Souvenir de Madame Bullier.*—Intensely rich crimson or wine red florets, which recurve gracefully.

*R. Everard.*—The plum coloured florets are quite distinct from any I know in the whole of the Japanese section.

*W. Firkins.*—A lemon coloured sport from Bouquet des Dames, which is in itself a serviceable variety; much better cultivated in Scotland than in England.

*George Goodson.*—A golden yellow bronze shaded sport from La Triomphante, of compact growth and free flowering. All the above belong to the Japanese section.

#### THE N.C.S. JUBILEE EXHIBITION.

I observe that the Society purpose offering most valuable prizes, to be competed for in 1896. This early notification of the course the schedule will take is commendable, and will serve to put intending exhibitors on the *qui vive* as to the behaviour of the newer introductions in the various sections. Such experience will enable them to master any peculiarity of treatment required. I am pleased the single-flowered section is given such a prominent place as this early notice suggests. If the Committee can see its way clear to issue the prize schedule early in December at the latest, it will have done a good deal toward insuring success, and clearing itself of the remark often heard, "What is the use of sending out the schedules so late as this? One does not know what to grow."

The note I have penned herewith is the more justifiable when we take into consideration the fact of the Society offering prizes for varieties in cultivation when the Society was first established. I trust the Committee will make itself perfectly clear on this point, as to how the sorts are to be included or stipulated for. It would be a pity if such a point was left to mere guess work. Of this, though, I do not doubt. From what I have heard I expect to see not only a most liberal, but a model prize schedule.—E. MOLYNEUX.

WEATHER IN LONDON.—Dull cloudy weather has chiefly prevailed in the metropolis during the past week. Rain fell heavily on Sunday morning last, but, with the exception of slight showers, none has fallen since. Tuesday was a splendid day, warm bright sunshine prevailing. At the time of going to press the sky was dull, but with every appearance of the sun breaking through, raising hopes of fine weather for the holidays.

— THE WEATHER IN THE NORTH.—Up to the 9th inst. winter had not quite departed. On three mornings of the week preceding frosts of 5° and 6° were registered, and cold weather had generally prevailed. Sunday was clear, with a sharp north wind; Monday dull and chilling. In the evening rain set in, with a high N.W. wind, which continued little abated on Tuesday morning.—B. D., *S. Perthshire*.

— THE THOMSON MEMORIAL FUND.—In consequence of the insertion of additional names at a busy moment when preparing for press last week some asterisks were omitted from the list on page 297, and consequently the members of the English Executive Committee were not correctly indicated. These are Messrs. A. F. Barron, Bruce Findlay, P. E. Kay, G. Monro, G. Norman, F. Sander, J. Smith, R. Tait, Owen Thomas, H. J. Veitch (Chairman), J. G. Veitch (Honorary Secretary), H. Williams, and G. Wythes.

— PICOTEE-EDGED CINERARIAS.—With the present extensive range in colour of the best strains of Cinerarias it would appear difficult to find anything new in colour. When looking through Messrs. Sutton's collection at Reading the other day I noticed one plant decidedly edged in true Picotee fashion. Each floret constituting the fully rounded blossoms of a rosy crimson hue was distinctly edged with white. If this type can be maintained (and I see no reason why, as the plant noticed was one obtained by careful crossing and selecting), a distinct and pleasing break will have been obtained that will add interest to an already useful as well as pleasing section of winter-flowering plants.—E. MOLYNEUX.

— HEATING BY HOT WATER.—I was glad to see Mr. W. Taylor's article on page 252 on heating, as I am particularly interested in this subject. I should especially like to see more about coating mains with asbestos and other mixtures. There must be an enormous waste of heat when the mains are not coated with something. What would be the cost of coating them per square foot or lineal foot length of pipe, and what would be the estimated saving in fuel? If we were to suppose that long lengths of mains cost, say £20 to coat them, would the outlay be covered in twelve months in the fuel saved? It was thought by some that the Liverpool boiler contest was a white elephant, but I am glad to find that the figures I compiled for the Journal have been studied by Mr. Taylor at any rate, and may after all prove useful to some. I shall at the first opportunity revert again to Mr. Taylor's article on heating, in which there are some ideas worthy of note and full consideration.—W. BARDNEY.

— THE CHARLES COLLINS' FUND.—A meeting of the Committee of the above Fund was held in the Horticultural Club Room, Hotel Windsor, Victoria Street, S.W., on Monday, April 8th, Mr. George Gordon occupying the chair. It was reported that the amount received was £66 2s. 9d., included in this sum were two subscriptions of a guinea and 5s. respectively not yet to hand. The Hon. Secretary read a letter from Mrs. Collins stating that she had an opportunity of acquiring an old-established and flourishing baby linen and fancy business for £83, this sum including cost of fixtures, goodwill, and stock. She mentioned that prior to her marriage she had been apprenticed to and had some years' experience in a similar business, and felt sure from the thorough investigation which had been made into the one offered that it would afford a comfortable livelihood. It was unanimously agreed that the sum of £66 2s. 9d. be paid to Mrs. Collins for the purpose, and the Treasurer was accordingly authorised to draw and forward a cheque for that amount. The Committee also desires to thank all who so generously responded to the appeal; and especially Mr. H. J. Jones of Lewisham, who gave a second donation of £2 18s., making £5 in all.—T. W. SANDERS, *Hon. Secretary*.

— GARDENING APPOINTMENT.—Mr. R. Leech has been appointed head gardener to Mrs. Bickham, Gorsefield, Bowdon, Cheshire.

— MR. THEODORE GROOM, late Scholar of St. John's College, Cambridge, has been appointed to the Professorship of Natural History, Royal Agricultural College, Cirencester.

— WE learn that Mr. Edward Step, the popular writer on botanical subjects, has written a pocket-guide to British wild flowers, with coloured illustrations, to be published by Messrs. F. Warne & Co. The title of the book will be "Wayside and Woodland Blossoms."

— "FINE STRAWBERRIES," "AUGUSTE NICAISE."—In the gardens at Grimston Park, on April 6th, a magnificent dish of the above Strawberry was gathered. The fruits, twelve in number, weighed 18ozs. The heaviest fruit weighed over 2ozs., and the largest measured 7½ inches in circumference, being of excellent flavour. A finer dish of fruit would be difficult to secure.—J. S.

— ROYAL METEOROLOGICAL SOCIETY.—At the ordinary meeting of the Society, to be held by permission of the Council of the Surveyors' Institution, at 12, Great George Street, Westminster, on Wednesday, the 17th inst., at 7.30 P.M., papers will be read by F. Campbell Bayard, LL.M., F.R. Met. Sec., and William Marriott, F.R. Met. Soc., on "The Frost of January and February, 1895, over the British Isles."

— AMERICAN FRUIT TRADE.—A New York contemporary says notwithstanding the fact that fresh fruits come across the continent from California by the train-load at nearly all seasons of the year, dried and canned fruits are annually exported from the same State in still greater quantities. Last year dried and canned fruits equivalent to 30,000 car-loads, or 140,000,000 lbs., were distributed throughout the world.

— ASCLEPIAS NIVEA.—This is a small but healthy and very free blooming tender species that thrives admirably out of doors in the summer and blooms abundantly after July. Its flowers are white, and although small they are numerous and useful for cutting. It likes good soil just as well as any other plant, but will also live and bloom well in ground so warm and dry in summer that most other plants would fail in it, and we like it on this account, and plant a clump of about fifty plants of it every summer.

— OBSERVATIONS ON CURRENT TOPICS.—"E. M." thinks Lady Hume Campbell Violet is not white, as inadvertently stated by a correspondent, but blue. He also thinks Ivy does produce true roots from the stems and sends a sample. He imagines there is a mistake in the date of the Batley Flower Show (November 17th), as that date falls on a Sunday. He believes April or May too late for sowing seeds for main and late crops of Broccoli as advised by Mr. Iggulden, especially if the plants have to be grown in cold heavy soil. He also thinks Tomato plants are often too small when planted in the open. His plants are now 3 inches high, and will soon be transferred to 5½-inch pots for gaining strength by the time of planting.

— WHITE VIOLETS.—I found through an error arising from the shifting of names that I referred on page 293 to Lady Hume Campbell as a double white. Not having seen the variety previously I was not aware that it was a pale blue form sent, hence I have to retract. The white in question was Swanley White, I am informed; certainly a very fine-flowered variety, and would be very highly esteemed were it also more fragrant. As Swanley White seems to be Comte Brazza's White, we have this section materially reduced; indeed, this form being much the best, it seems useless to grow any other. When complaints are made with respect to the indifferent flowering it probably results from having failed to increase stock by means of the stoutest and most robust runners, or of crowns when divided.—A. D.

— KALE THOUSAND-HEAD.—Although this is the coarsest growing of all the Kales, and in good, deeply worked soil attains huge dimensions, yet the plants seem to be exceptionally hardy when grown in less rampant form. I have recently seen on the Surrey sand, in an open exposed situation, some remarkably green uninjured breadths, and can envy the possessors that they have such promise of tender greens immediately, whilst almost everywhere all other winter greens are so destroyed. Obviously Thousand-headed Kale should not be planted too early, and the plants are preferably grown in rather firm soil, where the usual tendency to excessive leaf growth will be checked, and in the most exposed positions. A green Kale that in ordinary seasons we are disposed to regard as only fit for cattle, is this year indeed a valuable crop.—D.

— ROYAL SOVEREIGN STRAWBERRY.—Mr. E. Parry, The Gardens, Castlemans, Twyford, Berks, sends us a few very good fruits of this Strawberry, informing us that he has been gathering similar fruits for the last fortnight five to seven from each plant, the runners taken the third week in June, and the plants placed in 6-inch pots early in August.

— HERR W. SIEBE has started on a botanical exploration of Asia Minor, with the special object of making collections of the almost unknown flora of Cilicia Trachea. Setting out from Cyprus, he proposes to visit Mersina in southern Asia Minor, proceeding then to the Kalykadnos Valley and the adjacent mountains, the steppe district of Konia, the maritime district of Egerdir, and finally, in the summer, the elevated alpine region of Geigdagh.

— CASSAVA CULTURE IN AMERICA.—Mr. H. W. Wiley, the chemist to the United States Department of Agriculture, recommends the cultivation of the Cassava, *Manihot utilisima*, in the most southerly of the United States. It furnishes an excellent food for men and cattle; though, from the small proportion of nitrogen which it contains, it cannot take the place of bread-stuffs. A very good kind of tapioca may be made from it. The yield, in sandy soils, is from 4 to 5 tons per acre.

— CAPE GRAPES.—The "Goth" steamship arrived from the Cape the other day with a cargo of Grapes, amounting in all to about 1292 boxes and cases of white and red varieties, the quality ranging from indifferent to very fair, but the prices were not those of a few years since. The consignments were sold rapidly—the whites at an average of 10s. per box (equal 7d. per lb.), and the reds fetching 35s. per box, or about 8d. per lb. The lowest price (for wasters) was equal to 3d. per lb., and the highest all over was 15d. per lb.

— THE DELIGHTS OF GARDENING.—Everyone, says a transatlantic journal, who has once tasted the real delights of gardening returns to it with zest. Tranquilly pursued it gives a certain richness to life and thought, a wholesome basis for intellectual labour. It is a common bond between the wise and the ignorant, a pursuit wherein men of different station can interchange rôles and mutually impart knowledge. Rivalry is of the friendliest. The cottager's Rose may surpass that of a duke, and the interest of one in his specimen be as keen as that shown for the flower of the other.

— THE WEATHER LAST MONTH.—March was changeable and showery, but without severe frost. We had heavy gales on the 23rd and 24th which blew down several trees, and showers of snow on the 4th. The ice on the lake was then 6½ inches thick. The wind was in a westerly direction twenty-four days. The total rainfall was 2.10 inches, which fell on twenty-seven days, the greatest daily fall being 0.30 inch on the 28th. The highest reading barometer was 30.124 on the 16th at 9 A.M., and the lowest 28.462 at 1 P.M. on the 28th. Highest temperature in the shade, 59° on the 17th and 23rd; lowest, 24° on 3rd. Mean of daily maxima, 48.61°; mean of daily minima, 34.80°. Mean temperature of the month, 41.70°; lowest on the grass, 19° on the 3rd; highest in the sun, 115° on the 11th. Mean temperature of the earth at 3 feet deep, 37.80°. Total sunshine, 104 hours 45 minutes. There were two sunless days.—W. H. DIVERS, *Belvoir Castle Gardens, Grantham.*

— DEATH OF AN OLD ROYAL GARDENER.—By the deeply regretted demise of Mr. John William Thomson, which occurred on Tuesday night, March 28th, at Hayward's Heath, the only man surviving in the last decade of the nineteenth century who was connected with the Royal Gardens in the reign of George III. has been removed. Mr. Thomson, who had on March 20th completed his ninetieth year, had resided at Hayward's Heath since 1876, where he followed his profession as a horticulturist, though of late years his extensive greenhouses had been allowed to pass into a state of dilapidation. During his long life he came into contact or had correspondence with many eminent men, of which he was exceedingly proud, and was a veritable store of anecdotes and reminiscences, extending into the reigns of four monarchs. A Shropshire man, Mr. Thomson was educated at Shrewsbury, a school-fellow being Darwin the great naturalist. He commenced his gardening career in the Royal Gardens of Cumberland Lodge and Windsor in the reign of George III., and assisted in laying out and planting the famous Virginian Water Gardens. Mr. Thomson was also gardener at Syon House, and the first flower of *Vanda teres* that opened there in 1833 was presented by him to the future Sovereign. Mr. Thomson, who had survived three Dukes of Northumberland, left the ducal employ in 1835, and for several years was the proprietor of a nursery at Hammersmith.

— THE NEWCASTLE-ON-TYNE SPRING SHOW will be held in Olympia on Wednesday and Thursday, 24th and 25th inst. Last year the show was a very fine one, and a great success. This year the Committee has added classes for groups of plants and Roses. The prizes in the cut flower classes have also been increased.

— MARCH WEATHER AT DRIFFIELD.—Mean tempera'ure at 9 A.M., 40.98°; wet bulb, 39.27°. Mean maximum, 47.44°; mean minimum, 33.89°. Highest, 58.08° on the 22nd; lowest, 22.0° on the 3rd. Mean of maxima and minima, 40.66°; mean range, 13.55°. Mean radiation temperature on grass, 27.04°; lowest, 12.0° on the 3rd. Rainfall, 2.57 inches. Number of rainy days twenty-three. Greatest amount in one day 0.47 inch on the 9th. There were no sunless days.—W. E. LOVEL, *Observer, York Road, Driffield.*

— POPULARITY OF BANANAS IN AMERICA.—During the year 1894 the importations of Bananas into the United States amounted to nearly 18,000,000 bunches. Heavy cyclones throughout the West Indies last autumn destroyed much of this year's crop, and the few cargoes now coming from Jamaica and Cuba bring high prices, some Bananas of the first grade selling last week for 1 dol. 40 cents. a bunch by the truckload. Nearly one-third of all these imports usually come from Jamaica alone, so that the market has been considerably affected by the shortage.

— AZALEAS IN NEW YORK.—The most conspicuous objects in the windows of the florists' shops in spring are compact plants of Azalea in full bloom. It is rather strange that the newer varieties are mostly those which bear double flowers, since the single-flowered kinds, says the "Garden and Forest," are generally more effective. The fashion, imported from France, of swathing the plants as well as the pots with ribbons and paper and decorating them with bow-knots of various material has nothing to commend it. Much of the beauty of a well-grown plant is in its form, and when this is hidden by upholstery the plant loses half its charm.

— TORQUAY DISTRICT GARDENERS' ASSOCIATION.—The third annual meeting of the Society took place on Friday, April 5th, Dr. R. Hamilton Ramsay being in the chair. The Hon. Secretary (Mr. F. C. Smale) read the report and balance sheet, the latter showing a surplus of £4 15s. 11d. After the election of officers, the forthcoming summer outing was discussed, and it was decided that it should take the form of a trip over Dartmoor. At the close of the ordinary business a pleasing ceremony took place, Mr. F. C. Smale being presented by the members with a handsome mahogany knee-hole writing table with brass-handled drawers. On a plate affixed was inscribed, "Presented, with a pair of brass candlesticks and inkstand, to Mr. F. C. Smale, by 100 of the officials and members of the Torquay District Gardeners' Association, in recognition of his zealous and efficient services as Honorary Secretary to the Society." The President made the presentation on behalf of the members, Mr. Smale suitably replying.

— FRUIT PROSPECTS.—There is a promise of a fine bloom on most hardy fruit trees this spring. Of course, that may not mean a good fruit crop, because there are so many slips between the cup of promise and the lips of realisation. Still, nothing is more obvious than is the fact that if there be little or no bloom there is neither hope or realisation. I have remarked the curious comparatively even condition of Apples, Pears, and Plums just now, buds seemingly to be in about the same stage of development. Pears and Plums may bloom a little later than usual perhaps, and a very good thing too, but Apples can hardly be earlier, and probably will be no later. Still, when once the bloom does make a start to open we must expect to see Pears and Plums rather in advance. It is specially interesting to find such a bloom show following on such a comparatively cold wet summer and autumn as was found last year. Still, we had a good ripening late autumn, and certainly a very maturing winter, if a long spell of intense cold and a remarkably dry late winter and spring conduce to that end. Without doubt, some good warm rains would render the trees just now great service, and help to expand the bloom. Very likely we shall be able to judge of probable fertility or otherwise by examining the organs of fruition, and if pollen be abundant then we may very reasonably look for good and plenty of fruit. There can be no doubt but that a heavy fruit crop will be of exceeding service this season. It would furnish very many persons with means they now lack, and in that way stimulate trade, as the wealth of the nation is added to. It would also give a valuable stimulus to fruit culture. It is true that in a purely decorative sense we see very much of beauty in luxuriant tree blooms, but our chief aspiration, of course, is for the fruit crop, and that the hard winter leads to the hope will come in due course.—D.

— THE PEOPLE'S PALACE AND EAST LONDON HORTICULTURAL SOCIETY.—This Society recently held its first spring show. In order to place the exhibitors on an equality, the schedule of prizes was divided into two sections, one including all exhibitors, some of whom, living on the confines of the Victoria Park, cultivate under much more favourable conditions than those in thickly populated districts, and those living in the latter or congested districts, such as Mile End, Limehouse, and Stepney. These divisions were found to work well. The exhibitors were working people, and several entries were made in all of the classes.

— MANURING HOPS.—During 1894 several experiments in the manuring of Hops were carried out by Mr. Monson, F.C.S., and from the results obtained he is of the opinion that by applying 3 cwt. of kainit per acre, at a cost of 6s., an increase of 2 cwt. of Hops may be expected. He warns growers, however, that this manure should be applied quite early in the season, for it increases the colouring matter in the Hops if put on late. Another conclusion brought out by the experiments is that 10 cwt. of gypsum will take the place of a ton of lime, so that the former may be used to advantage where the more bulky fertiliser would have to be brought from a long distance. Mr. Monson also dwells on the importance of using phosphates with nitrogenous manures, as the latter, when used freely alone, deteriorate the quality of Hops.

— WOLVERHAMPTON GARDENERS' IMPROVEMENT SOCIETY.—On Tuesday, April 2nd, Mr. Varty of Moseley Court gave a lecture to the members of the above Society on British Ferns. The lecturer stated that of all plants British Ferns were perhaps the most neglected generally, though some of them were among the most beautiful plants in existence, and pleaded for a more extended interest to be taken in them. The lecturer had a magnificent collection of dried specimens, some of them almost unique, and he greatly interested and amused the members present by recounting his difficulties and adventures in search of them. He specially mentioned old Mr. Stansfield of Todmorden as a most noted collector of British Ferns, and urged young gardeners to take up the study and collection of these plants. Needless to say Mr. Varty had the hearty thanks of the meeting for his most instructive paper.

— MUSHROOM SPAWN.—It may be that "D." is right in his estimate of the spawn as supplied to the first-class garden of which he speaks. Still, I should like to point out that with different methods of treating, manure, and with soils of various staples, Mushrooms may be produced of totally distinct qualities; so much so, in fact, as to appear of more than one variety; yet all from the same box of spawn. Given a properly prepared bed of manure, surfaced with soil of good sound texture, beaten down firmly; then, if the spawn works well, as it should do, generally speaking, there will be found in due time Mushrooms large, firm, and fleshy. It is well known that too much fire heat will cause a crop of small weak Mushrooms. I cannot understand that it is necessary to bear such a disappointment as "D." speaks of in silence. My experience of "leading houses" has been such that I think no gardener need be deterred by fear of a "row" from making any just and reasonable complaint.—JOHN WRIGHT, *Kelston Knoll Gardens, Bath.*

— NEW METHOD OF PRESERVING FRUIT.—M. Petit has noticed that by preserving fruits—Grapes, for instance—in a sealed vessel, filled with the vapour of alcohol, the said fruits keep well. On October 31st, 1894, that is, at a very late season, some Chasselas Grapes were cut and placed in a cellar, closed as firmly as possibly by a wooden door; in the cellar was a jar containing 100 cubic centimetres of alcohol; the Grapes were placed on wooden frames. In two other similar cellars, one closed, the other open, but where there was no alcohol, the Grapes were similarly arranged. The temperature of the caves ranged from 8° to 10° C. (50° F.). On November 20th, in the open and in the closed cellar, where there was no alcoholic vapour the Grapes were spoilt and rotten, whilst in the cellar in which the alcohol was placed the Grapes were in perfect condition, and free from mouldiness. On December 7th the Grapes were in still finer condition; tasted by critical connoisseurs, they were found excellent and of perfect flavour. In laying these notes before the Société d'Agriculture, M. Tisserand drew attention to the simplicity of this mode of preserving fruit; it can be practised anywhere, and needs no special apparatus. In every place where a uniform low temperature can be assured, Grapes can be stored in closed compartments, adding alcohol either in a jar, or even, according to M. Tisserand, saturating with it the wooden framework which support the Grapes. The cost of the alcohol is, it appears, very small.—("Revue Scientifique.")

— PINE CONES.—Occasionally vessels from the south of Europe bring over small numbers of what are called nut cones. They are really the cones of *Pinus pinea*, in shape and general colour resembling somewhat a small Pine Apple. When brought into some warm place, as, for example, near a steam radiator, the scales quickly begin to reflex, commencing at the base, and turning back release the pinons or edible seeds. The motion of the scales as they open is so rapid as to be plainly visible, and is quite interesting to people who have never seen the spectacle, and this exhibition gives a value to the cone apart from the nuts which it contains.—("Garden and Forest.")

— MUSEUM D'HISTOIRE NATURELLE, PARIS.—A meeting of the professors and assistants has been held, under the presidency of Mr. Milne Edwards, whereat it was decided that periodic meetings of a similar kind should be held, and a bulletin published. The object of these meetings is to promote co-operation between the several departments, and to multiply the points of contact between specialists who each in their department contribute to the advancement of science. The relations between the correspondents, collectors, and travellers for the museum, and the officials will, it is hoped, be cemented. At the meeting an account of the work done in each department will be given, and collectors will thus be enabled to appreciate the value of their collections, become witnesses of the use made of them, and better enabled to judge of the requirements of science. At the same time they will contribute information as to the localities and the conditions under which the collections were made. Six Secretaries were nominated, Mons. Poisson undertaking the duties on the part of the Botanical Department.

— POLYEMBRYONY.—The phenomenon of polyembryony, or the development of two or more embryos in a single seed, has been the subject of several investigations. It has been shown that it may be due to the division of the nucellus, or to the fusion of two ovules, or to the presence of several embryo-sacs in one ovule. Further, Strasburger has found that it is often to be accounted for by the ingrowth of some cells of the nucellus into the embryo-sac, which there develop into adventitious embryos; in other cases he ascertained that two egg-cells are normally present in the embryo-sac, which on fertilisation give rise to two embryos. Finally, Dodel and Overton showed that it was possible for the synergidæ to develop into embryos. More recently, M. Tretjakow, in a short but interesting paper (*Ber. d. Deutsch. Bot. Gesell.*, February, 1895), describes yet another cause of polyembryony. In *Allium odorum*, in addition to the normal embryo formed from the egg-cell, not infrequently the antipodal cells also give origin to embryos. Sometimes only one of these develops, but M. Tretjakow has observed all three antipodal cells start into growth and give rise to three embryos. These antipodal embryos commence their development immediately after the fertilisation of the egg-cell, and the cell divisions, at least in the earlier stages, correspond exactly with those in the embryo formed from that cell. The Russian author, accepting the view that the antipodal cells are homologous to the vegetative cells of the prothallia of Ferns, compares these antipodal embryos with those arising by apogamy on Fern prothallia.—("Nature.")

— SCILLY FLOWERS.—If the man who makes a blade of grass grow where none grew before deserves well of his country, the late Mr. Augustus Smith and his nephew, Captain Dorrien Smith, should be held in immemorial regard by the Scilly islanders. Between them they have, as Lords of Scilly, established an industry whose profits fully make up for the loss consequent on the suppression of smuggling and wrecking, and the ruin of the local shipbuilding trade. When "King Augustus" became autocrat of all the Scillies, he found the inhabitants in a most deplorable condition; so acute was the general poverty that the Imperial Government abandoned the collection of taxes, and even granted subsidies to keep the population alive. The happy idea then occurred to Mr. Smith to try the experiment of raising early flowers for the London market. Having imported a cargo of good bulbs from Holland, he established a garden at Tresco, the island where he had built a lordly mansion, and the venture proving profitable, the Scillonians in St. Mary, the biggest island, abandoned agriculture for the cultivation of the beautiful Narcissi. From that date to this the industry has thriven wonderfully, in spite of Continental competition. But the late terrible frost extended to Scilly, and not only delayed the flower harvest, but largely diminished the yield. We learn, however, that on two days last week the exportation of Narcissi from St. Mary's amounted to 26 tons, all being intended for the London market. It says much for the Smith dynasty that although the land is many hundred per cent. more profitable to its cultivators than before the introduction of flower farming, rents have not been raised.—("Globe.")

## ALPINE FLOWERS.

## MAKING AND PLANTING ROCKERIES.

*(Concluded from page 247.)*

FOR the accommodation of plants which require a greater supply of moisture than is needed by the majority the base of the rock-work will provide suitable positions. Here some provision can be made by keeping the places to be occupied by the flowers a little below the ordinary level. For some of these plants the writer has the base of his rockeries on the level of the walks, several pockets sunk below this, and separated by a stone edging from the walks.

Some very effective rockeries are made of a mound of earth almost oblong in form, with stones disposed irregularly about them, but the evil of these, as generally made, is that the stones are not arranged to conduct the rain which falls to, but from the plants. This is indeed a fault to be found in most rockeries, and the terrace system will, taking everything into consideration, be found the most

In preparing stations for many plants it will be found advantageous to place two stones of good size in the form of the letter V, the point downwards, but leaving a small open space about an inch in width. If the plants are to be turned out of pots with the ball of earth attached, a little soil should be placed at the bottom of the V, and well pressed down so that the ball of earth may rest solidly on it. Any crevices left between the ball and the stones should be carefully filled with earth made firm, care being taken that this operation is not performed when the soil is too damp. In planting Primulas, and a very large number of Alpines, this plan of fixing the plants between the stones will be found very valuable. Plants received without earth attached should be planted in a very careful way. It will generally be found profitable to be at the trouble of placing these in small pots, and allowing them to remain in a frame or cool greenhouse for a short time, then turning them out of the pot with the ball of earth intact. The trouble involved in this will be well repaid by the plants becoming more quickly

FIG. 54.—EXPRESS GRAPE GROWING—VINES PLANTED MARCH, 1892. (See page 305.)

(Photographed by H. Jancowski, August, 1893.)

satisfactory for the well-being of the plants. It may, however, be well to say that for some time a terraced rockery will present a very artificial appearance, but this will disappear with the growth of the plants, and as the mellowing influences of time act on the stones.

In preparing the "pockets" for the plants the question of a suitable compost will present itself. Plants with long tap roots which penetrate into the main body of soil of which the rockery is composed, are not so particular, as a rule, in the quality of their food, but for all choice plants suitable soil should be provided. For general purposes a sandy peat is very useful, but as this is not always obtainable a good loam with a liberal addition of leaf mould, well decayed, will suit the requirements of the large majority of plants. Those that are well known to be lime lovers, such as the Encrusted Saxifragas, Sedums, Houseleeks, and others, should have old lime rubbish or broken pieces of limestone added to the soil, and many plants are much benefited by a considerable admixture of grit. The hollows intended for plants requiring a large supply of moisture should have a light peaty soil, and before placing this in the drainage must be made good, or at least a few inches of stones and gravel put at the bottom to prevent the earth from becoming soured.

established, and the greater vigour they will display after being planted out.

In the selection of positions for the plants there is room not only for considerable exercise of taste, but also of judgment in selecting the most suitable positions for the welfare of the plants. Thus, such sun-loving flowers as the Stonecrops should have warm and sunny situations. The Primulas should generally have partial shade, and such flowers as the Mossy Saxifragas will do well enough in shady spots, with the exception of some few such as Wallacei. For plants requiring a little shade the divisions of the pockets can be so placed as to give them what they require, if provision for the requisite shelter from the bright sun is not afforded by the general construction of the rockery.

Where trailing plants are grown provision should be made in the way of higher terraces or elevated portions of the rockery. In order that these trailing plants may completely fill the "pocket" they occupy, it is found, as a rule, preferable to plant them well back and to place flat stones between the plants and the front of the terrace, so that the stems may not decay from the damp earth. Where the crevices between the stones are numerous or unsightly

and cannot be covered by trailing plants, they may be not only concealed but frequently made ornamental by placing in them various plants, such as Encrusted Saxifrages, Houseleeks, Stonecrops, dwarf Campanulas, and others which will readily occur to the reader. Even if the plants are carefully tended so that one does not outgrow another above ground, it is unavoidable that those which make large roots should in time encroach on the feeding ground of others. This weakens the latter, and it will be found necessary to re-make the rockery at occasional intervals. This need only be done after a considerable time, but annually some plants should be lifted and replanted, fresh soil being placed in the pockets.

For many Alpines an annual top-dressing of soil is required, and this may well be done in the spring, but should these plants have become too high above the soil some fresh earth should be added in the autumn. The frequent top-dressings eventually raise the level of the pockets above that of the stones which support the terrace, so that heavy rains or heavy watering will wash away the soil. This must be prevented by the addition of stones to retain the earth in position.

The mention of watering induces me to say a little on this head. While the differing conditions under which Alpines are grown in gardens as compared with those which prevail in their native habitats make it impossible to lay down any hard and fast rule on this question, one is warranted in saying that Alpines do not receive enough of moisture in the summer. Too often they have only mere dribbles applied instead of the copious supplies they require. There is no need for pouring the whole of this on the plant itself, but a good supply should be poured beside it. On warm evenings, after the sun has gone off them, I frequently water not only the rockeries, but also the gravel walks adjoining. This raises a genial moisture, which I am convinced is very beneficial to the plants.

There are many little details connected with the erection and planting of rockeries and the successful cultivation of the Alpine flowers which cannot be fully treated of at the present time. Many of these are the outcome of experience, and will generally be discovered by anyone possessed of a fair amount of knowledge of plant life. In growing Alpines we require to adopt Opie's advice as to how to mix colours—"With brains;" indeed, it may well be given to those who wish to grow flowers of any kind.—S. ARNOTT.

## MODERN GRAPE GROWING.

(Continued from page 294.)

### INSIDE OR OUTSIDE BORDERS.

THE question is often asked, Which are the best—inside or outside borders? That all depends on the knowledge, skill, and attention likely to be at command.

I believe it is possible with borders confined entirely to the inside to grow Grapes of better quality and handsomer appearance than it is with outside borders only, but there is a considerable increase of labour, and they must have the most skilful management. Where quality and appearance are the first consideration, and sufficient skill and time to use it are likely to be given them, I say make the borders inside, but if the necessary operations are at any time likely to be put off for even a day or two after they require attention, or if the aim is only to grow such fruit as shall be worth about a shilling a pound, I advise the borders to be outside, for these can, to a very great extent, take care of themselves. Not only do they catch the rain and the sweetening, pulverising action of the natural atmosphere, but also require less feeding, because the water from the clouds, as well as bringing fertilising matter with it, is distributed much better than we can do it artificially; it consequently takes less of it to moisten a certain quantity of earth, and it follows that comparatively little artificial watering is needed, and therefore less of the manurial substances are washed out. Also suitable soils when exposed to the atmosphere have the power of absorbing from it a considerable amount of moisture during nights and cool days.

I know some amateurs who have their borders entirely inside, and succeed well, but they devote a great deal of time to them personally, and some of the work is rather laborious, therefore it should only be undertaken by those amateurs who have a real love for the occupation and abundance of time on their hands, and by those gardeners who can afford to put a reliable man in charge, and hold him responsible for the vinery before all other work. A great difficulty, especially in large establishments where the duties are so varied and numerous, is that there is always more work than can be got through, consequently much of it has to be put off perhaps five minutes later than it ought to be, and it is astonishing how these minutes tell on the life and health of the occupants of our houses.

Besides the border which is confined to the inside, and that which is entirely outside, there is the one which is most general, and I think least desirable—part outside and part in. That Vines often do well and produce good Grapes by this arrangement I admit, but in ninety-nine cases out of a hundred it will be found that it is the outside border which does the work, and that all the attention bestowed on the inside portion is thrown away, for there are few or no roots there.

I see no objection when the wall is built with arches, or pillars with spaces between, to having just sufficient width inside, say 18 inches, for planting the Vines and allowing the roots free scope to the outside border; the stems of the Vines are thus protected, and the planting can be done at any time of the year. The narrow space should be securely walled off to confine the few roots that may be produced there, and allow all the rest of the floor to be used for other purposes.

If the Vines are planted outside there is another way of protecting the stems—viz., by having small holes cut obliquely through the wall just below where the surface of the border will come to, so that all the outside portion of the stem can be covered by the soil.

I prefer either of the last two systems to the "go where you like" plan of having borders both inside and out. I like to know where the roots are, although it must be owned that one sometimes gets deceived, for it is not always that bricks and mortar will prevent them getting outside when we think we have made them prisoners.

The first thing to do in connection with border-making is to secure

### GOOD DRAINAGE.

We must decide where the surface line is to be, then reckon not less than 2 feet or more than 2½ for soil, 6 to 10 inches for rubble, and then a 3-inch drain pipe should be laid in a trench not less than 6 inches lower still.

In finishing the necessary excavating we make the bottom slope slightly towards where the drain pipe is to be; 1 inch in 2 feet is sufficient. We next make the trench and lay the pipe, giving it a slight fall to the outlet. A layer of rubble, or whatever is used for drainage, is placed over the part intended for border, and including the drain pipe, using something small on the top, say cinders, small stones, crocks, or whatever is handy, to prevent the soil running amongst the drainage.

Although I do not find it necessary now to take all this trouble in providing drainage for any new Vine border or a portion that may be added to an old one here, the first was made in this way, and I should advise anyone commencing to follow the same plan, for it is better to do too much than too little for the first portion of the border, especially when the soil is of such a nature that it does not provide a quick passage through it for the water; and no one, however skilful in this respect, can be quite sure of the behaviour of a soil till he has actually practised on it. In my former treatise is given another reason for using so much rubble, which I cannot do better than quote.

"A Vine border is made to last a century, and it is well to make doubly sure that a stoppage cannot possibly take place under anything like fair management. But this is not by any means the only or the principal reason for placing 8 or 10 inches of rubble under it. The subject of aëration is a very important one, and possibly not fully understood; but this much we know, that the roots of plants cannot live without air; that air follows each supply of water given to the border, and that a system of drainage which allows a great amount of water to be applied necessarily secures abundant aëration. Brickbats and similar material also have some effect on the temperature of the soil above them, not only from the warmth contained in themselves, but from the body of air stored in the interstices, and which, being cut off from direct contact with the atmosphere of the house and that outside, must vary but very slowly. I consider that those who insert drain pipes vertically through their borders to connect the air of the drainage with that of the ordinary atmosphere make a mistake, and neutralise to some extent the good offices of the rubble, because they make it possible for a circulation of air to take place otherwise than through the soil."

If a layer of turf can be obtained for placing over the drainage it will keep all secure for a generation. If no turf is forthcoming then something else must be used as a substitute—say a little litter or a few leaves. If the soil is prevented from falling amongst the drainage at first it will keep all right afterwards unless disturbed.

We will now assume that a suitable soil is at hand agreeing with the conditions I have named, and that it is neither too wet nor too dry. If any of it is in the form of turf that does not break up easily with shifting about it is advisable to chop some of it into pieces not larger than half a brick. First place a layer about a foot thick for the lower portion of the border, and with the upper portion mix some bone dust and half-inch bones, about equal parts of each, say 1 cwt. in all to about 6 cubic yards of soil. The bones should be simply ground, not chemically treated in any way, and should be freed from fleshy matter before grinding, either by boiling or drying.

The soil should be allowed to settle naturally. If the border is outside it must not be allowed to become too wet before planting. The surface is best kept nearly level, or there may be a difficulty in watering. In some situations where the drainage and soil are both good, and only ordinary fruit is required, no elaborate preparation of border is necessary. Simply digging in some bones and bone dust, and giving an occasional top-dressing of manure may be all that is necessary, but it has never been my fortune to have to do with such a soil.—WM. TAYLOR.

(To be continued.)

## DOUBLE PRIMULAS.

THE beauty and utility of double and semi-double Primulas for cutting purposes cannot be over-estimated. For those who have to supply flowers during the winter and spring they are invaluable, but I cannot help thinking that their merits are often ignored, the single varieties taking up too much attention. Even for decorative purposes,

such varieties as Earl Beaconsfield, Marchioness of Exeter, Sutton's Double Scarlet, and Improved Carmine are equal to any of the singles.

The best way to increase the true double varieties is by division or cuttings. After the old plants have flowered they may be taken out of the pots and split up into single crowns, each with a few roots. Crock some 4½-inch pots, using loam, leaf mould, sand, and charcoal. Insert the cuttings level with the bottom leaves, plunging the pots either in a propagating case or standing them in a shady position in a warm house, using water sparingly until rooted. Another way is to remove some of the lower leaves from the old plants and cover the surface of the soil with sphagnum moss, which if kept moist will soon induce roots to form. They may then be severed, placed in small pots, and kept growing. As the pots become filled with roots remove to larger sizes until a limit of 6 or 7 inches is reached. The soil for the later pottings should have more loam, with a fair proportion of bonemeal or decayed horse manure added. About the end of May or June remove to a cool frame, watering thrice a week with weak liquid manure. Here the growth becomes solidified, and the plants readily respond to the warmth in the autumn.

The semi-doubles may be raised from seeds sown now and grown quickly, treating the young plants as advised for cuttings. The object of early sowing is to have them well established in their flowering pots before the hot weather comes. The varieties which have done good service for us during the severe weather lately experienced are Earl Beaconsfield, Marchioness of Exeter, Sutton's Double White, Improved Carmine, Rose and Scarlet.—R. P. R.

#### PRIMULAS PLANTED OUT.

THE system of planting Chinese Primulas is one that is not usually carried out in many gardens, but where extra large plants are required, either for exhibition, home decoration, or other purposes, I can strongly recommend it. During the present season we have had superb specimen plants 2 feet through, and from 15 to 18 inches above the pots. Perhaps a few details concerning the treatment given may be of interest and use to readers.

The seeds were sown in the usual manner during the latter part of February, and the plants when large enough were pricked off into pans, allowing room to place a piece of glass over them, and removed to a shelf in the intermediate house. As soon as they were large enough they were transferred to 3-inch pots, and kept at this period in a cold frame. Instead of placing them in their flowering pots in the usual manner early in June, they were planted out in cool pits, the soil used consisting of rough turfy loam, leaf soil, and decayed cow manure, with a liberal addition of mortar rubble and road grit.

The plants were ready for lifting by the second week in September, an operation that requires to be carefully done in order to insure the least possible check being given. For this potting 7½-inch pots were used, taking care to have them well drained. After potting they were placed in cold pits, kept close and shaded from the sun until they had recovered, and were then given the usual treatment to Primulas grown in the ordinary way. By November they were of the dimensions given above, well-flowered with blooms that more than covered a 5s. piece. We have some double varieties in flower at the present time in pots of the size given above one mass of bloom, treated in the same manner, and anyone who has not tried planting out will, I am sure, be amply satisfied with the results that will be achieved after giving this method a fair trial.—FOREMAN.

#### AMARYLLISES AT CHELSEA.

AMONGST the many pleasures that come to horticulturists with the spring, one of the most highly appreciated is that afforded by a visit to the Amaryllis house of the celebrated Chelsea Nursery of Messrs. J. Veitch & Sons. Here, arranged in the central bed of a large span-roof structure, one may see a sight not likely to be quickly forgotten. There are hundreds of plants varying in age from two to ten years, all carrying blooms, some of the oldest having two spikes each of three or four blooms; while the juniors have mainly but one flower spike, and with seldom more than two or three flowers. Though one may visit the collection year after year it ever comes with freshness, and is viewed with never diminishing interest and pleasure. Each year one concludes that perfection has been arrived at, only at the succeeding to see a variety such as has not before been observed. It may be the improvement is in colouration, or again it may be in form; but there it is, to be seen and admired by any who like to go.

This season is in no respect inferior to its forerunners. There are the novelties, each with some good point and some with many, and also the old varieties that we have seen in the past, and which are so good that we can but hope that we shall see them again in the future. It is impossible to predict what another year may bring us, but we may rest assured that Mr. Heal, the clever grower and hybridist, will do his utmost to place something on show that will worthily uphold the credit of the house he so well represents. His energy is extraordinary, and he has probably done as much or more than any other man for the advancement of Amaryllis, not alone in quality, but also in popular favour. It is not many years since it was the exception to find any of the better forms of these plants in private gardens, whereas now it is the rule, as but few establishments are without, at any rate, a few. This is as it should be, for the vast majority of the sorts now cultivated are exceedingly handsome, and are undoubtedly worthy of being even more extended

than is the case at present. Their beauty is of the stately order, and finds many admirers. Another point in the favour of Amaryllis is that they are fairly easy to grow. Of course prices vary considerably, ranging from a few shillings the dozen up to several pounds the bulb, but in this respect varieties may be had to meet most purses.

Let us walk round the house and name a few of the most striking forms that are at present in bloom, taking form and colouration as standards and ignoring the question of price entirely. The first to claim attention is one that received a first-class certificate at a recent meeting of the Royal Horticultural Society: it is called Gorgeous, and is certainly well named, for the rich crimson-scarlet, handsomely formed blooms are very bright and showy. The recognition accorded by the Society was well merited, as it is one of the best of the current year's novelties. This is the first time it has flowered, and the exceptionally rich colour should insure it a place in good collections for some years to come. In direct contrast as regards colour is a variety named Cupid. It is quite distinct from any other, and is certain to receive a goodly share of admiration, as it is so chastely beautiful. The ground colour is white, veined and netted bright rose, while down the centre of each segment there is a band of white, very faintly tinged with green at the base. Not only is the colour good, but the form and substance leaves little to be desired. Another variety somewhat in the same style is Iham, which is pure white striped with rose. The flowers, though perhaps somewhat small, are very charming, and as the bulb is a young one may be considerably better next season.

One of the largest is Guthrie, with singularly bright crimson flowers, which if not perfect in form are still very handsome. Paulina has a delicate beauty such as usually proves attractive, more especially perhaps to the ladies. The upper segments of the flower, which is of medium size, are bright rose, and the lower, salmon rose centred with white. A flower of great substance and beauty has been designated Bandon. The shade is bright rose markings on a white ground, also the same colours being observable in Chèmere, but the latter is of distinctly better form. Cawdor, a deep orange-scarlet-hued kind, of splendid shape and substance, is likely to secure a number of admirers, as also is the more chaste but not more charming Armoire, which is white beautifully flushed bright rose. Amongst the older varieties Perle is one of the most popular, the flowers being of a peculiarly attractive colour. Size, too, is found in this variety, which has white as a ground colour, with crimson markings. One of the most beautiful of the deeper hue forms is Dulas, which is rich velvety-crimson suffused with purple, forming a most pleasing combination.

From a decorative point of view Marlay is one of the best, for it combines floriferousness with a good habit and showy bright scarlet-coloured blooms. The hue of Finedon is orange-red, the segment being of great size and substance, the upper one on being measured showing a width of 4 inches. Philomel is singularly beautiful, though the individual flowers are somewhat small, but as the bulb is only two years old there is every likelihood of marked improvement in this respect next season. This colouration of the flower is peculiar, inasmuch as the upper part is bright rose, while the lower is clear salmon-rose, the base of the flower being white, this shade also being perceptible throughout the whole of the bloom.

Many other varieties of equal merit could be mentioned did space permit, but these must suffice. Let those who are interested in this handsome class of plants pay a visit to Chelsea, and judge for themselves which are the best, and which appeal most forcibly to their individual tastes.—SCRUTATOR.

#### HERBACEOUS PLANTS.

AMONGST herbaceous plants we find many that will supply us with flowers for cutting, this being a great consideration, for in most establishments cut flowers are in great demand. Another point in their favour is, the greater number being hardy, they require no house room during the winter months. Where summer bedding is practised on a large scale much labour and care is required to keep the plants alive through the winter, and as soon as the new year comes in many must be propagated to secure the required number. Much space that cannot well be spared is consequently requisite to protect these tender bedding plants until the time arrives for transferring them to their summer quarters.

Herbaceous plants are generally grown in gardens in some form or another. One sometimes sees them planted in odd corners; but the better plan is to have them arranged in a systematic manner, so that they may be ornamental as well as useful. Perhaps I ought to say here that in writing these notes I wish to advocate the cultivation of these plants in the kitchen garden, though my remarks may apply equally to the flower garden proper. A well arranged border on each side of a walk running through the centre of the garden is a great improvement in its appearance and one that is often met with. If many tall plants are used the shelter of a west wall is of great service by protecting them from the strong autumnal winds. A convenient arrangement, if somewhat formal, is to plant in lines, having the tallest at the back, and a border 7 or 8 feet wide will require three rows of plants.

A list of suitable plants may be a guide to some, and will include Lilies and other bulbous plants, these giving a brilliancy of colouring not found amongst herbaceous plants proper. For the back row plants of not less than 3 feet in height should be used. These are Spiræa

Aruncus, *Bocconia cordata*, *Harpalum rigidum*, *Delphiniums* in variety, *Helianthus multiflorus* and its double variety, *Lilium pardalinum*, *Campanula pyramidalis*, and *Kniphofia Uvaria*. The taller growing Asters, such as *Novæ-Angliæ* and *Purity*, blue and white Lupins, *Pyrethrum uliginosum*, *Papaver orientale*, *Thalictrum flavum*, *Lythrum Salicaria roseum*, *Spiræa palmata*, *Fuchsia coccinea*, *F. Riccartoni*, and Foxgloves.

Suitable plants for the second row will be found in *Aster longifolius*, *A. amellus*, *A. a. bessarubicus*, the two latter are amongst the most useful of Asters; *Dicentra spectabilis*, *Campanula persicifolia*, blue and white forms, *C. grandis*, *C. glomerata*, *Anemone japonica*, and its white variety *Honorine Jobert*, *Agrostemma Flos Jovis*, *Achillea Ptarmica fl.-pl.*, *Eryngium amethystinum*, *Galega officinalis*. The latter is a capital plant for cutting, especially the white form, as it lasts such a long time in the cut state if the old blooms are picked off and the water changed every few days. *Hemerocallis flava*, *H. fulva*, *Lychnis chalconica*, *L. Haageana*, *Monarda didyma*, *M. purpurea*, *Malva moschata*, *M. m. alba*, *Thalictrum adiantifolium*, *Ranunculus aconitifolius*, *Pyrethrum lacustre*, *Papaver orientale*, *Funkia ovata*, *Gypsophila paniculata*, *Fritillaria imperialis*, *Phlox* and *Pæonies* of sorts. Both the early and late flowering kinds of *Phlox* should be grown, as this will prolong the show of bloom. The English and Spanish *Iris* may be used for this row, also the following Lilies—*L. elegans*, *L. candidum*, *L. chalconicum*, *L. Martagon*.

For the front row, *Geum montanum*, *G. coccineum*, *Iberis corifolia*, *Funkia lanceolata marginata*, *Epimedium alpinum*, *E. macranthum*, *Dicentra formosa*, *Doronicum austriacum*, *Campanula carpatica*, *Adonis vernalis*, *Alyssum saxatile compacta*, *Aster alpinus*, *Anemone apennina*, *A. coronaria* of sorts, *Papaver nudicaule*, *Spiræa filipendula fl.-pl.*, *Trollius europæus* and varieties (some of these have much larger and darker flowers), *Plumbago Larpentæ*, *Fritillaria meleagris*, *Auriculas*, *Pinks*, *Giant Thrift*, *Pyrethrum roseum*. *Hyacinths*, *Narcissi*, and *Tulips* may be associated with the plants in this row. The dwarf kinds should be planted alternately with those of taller growth.

This list by no means exhausts the number of plants available for a border of this kind, but it will be found to contain some of the best. They will give a variety of colours; their mode of growth is compact, and a greater part will be found useful for cutting. There is also a number of plants of straggling habit, such as *Centaurea montana*, *Potentillas*, *Geraniums*, *Mertensia paniculata* which it would not do to include in the above list; nevertheless, they will be found useful for other positions. Dwarf-growing plants that would soon be overgrown on a border of this kind should have one to themselves, or find a place in the rock garden.

To make the border more gay during the summer months all vacant places should be filled with annuals or other plants. A good selection of the former are *Centaurea cyanus minor*, *Clarkia elegans*, *Marvel of Peru*, *Perilla nankinensis*, *African Marigolds*, *Chrysanthemums* of sorts, *Calliopsis tinctoria*, *Shirley Poppies*, *Sweet Sultan*, and *Zinnias*. These will grow from 18 inches to nearly 3 feet high. Those growing about 1 foot high are *Eschscholtzia*, *Dianthus*, *Bartonia aurea*, *Asters*, *Godetias*, *Linum grandiflorum*, *Phlox Drummondii*, *Mignonette*, *French Marigolds*, *Stocks*, and *Verbenas*. The majority of these being hardy annuals they may be sown where they are to flower.

Another, and a less formal arrangement, may be had by having breaks in the border. Instead of planting in unbroken lines, according to the height of the plants, large clumps of one kind of such plants as *Papaver orientale*, *Galega officinalis*, *Phlox* or *Japanese Anemones* may be planted at intervals along the borders extending the whole width, from front to back, unless the border is wider than the above, in which case the back line should not be broken. These bold clumps produce a fine effect when in bloom.

When planting a herbaceous border vacant places may be left in the back row to be filled during the summer with tall-growing plants and creepers. *Maize*, *Hemp*, *Castor Oil plants*, *Dahlias*, *Canary Creeper*, *Convulvulus*, *Sweet Peas*, and other plants of this class will be found suitable for the purpose. Instead of appropriating the rest of the border to herbaceous plants space may be left in front for planting two or three rows of summer bedding plants. In this arrangement we have a combination of two forms of flower gardening.

It is advisable to have a reserve border where a number of the most useful flowers for cutting may be grown, so that the principal borders may be kept gay. The present is a good time to renovate the borders, and to divide any plants that it may be found necessary to increase. A little manure should be spread over the surface and lightly dug in, this being done in such a way as not to injure the roots of the plants. Strong-rooting kinds, however, and those that quickly spread, may have their roots cut away at a given distance from the stems without injury. This will also prevent them encroaching on their weaker neighbours.

An important point with these plants, and one that is sometimes neglected, is to have them properly staked. This should be done in as informal a manner as possible, and at the right time. When it is delayed until the plants have been broken down by the wind it is impossible to make them look well. What should be aimed at is to stake them in as natural a way as circumstances will allow. Three stakes for each plant of a bushy habit will be required, these being fixed in such a way as to be out of sight as much as possible when the plant has attained its full height.—J. S. UPEX.

#### ROSES AND THE FROST.

I THINK it would be of general interest to rosarians if you published reports as to the effects of the late winter on Rose plants; and as regards Teas whether half-standards or dwarfs have stood best. We might then be able to form an opinion as to which are the best stocks, not only to yield good flowers, but to withstand the arctic winters with which we are now favoured.

In my (walled-in) garden I have lost nearly all my half-standard Teas, though they were extra well protected with dried fern all the winter; while the dwarfs on Briar cuttings, which were partially earthed up, as well as protected with fern, have taken little harm.

Of maiden Teas on half-standards nearly three-fourths have been killed by frost, notwithstanding each bud having been separately protected.

H.P.'s in the open were so severely cut up by the late spring frost of May last that they are, with few exceptions, all destroyed. I should be glad to learn the experience of others.—ERNEST WILKINS, *Hants*

#### NOTES ON ROSES.

IT is pleasant to find that Roses have not suffered nearly so much from the winter as the intensity of the cold had led one to expect. The susceptibility of Roses to cold varies considerably, even in the case of varieties belonging to the same section. For example, the common *China* is seldom killed down, while even on a wall *Cramoisie Supérieure* has often to be cut back. *Aimée Vibert*, again, is not nearly so hardy as *Céline Forestier*, and among Teas and Hybrid Perpetuals there is a marked difference. Hybrid *Chinas* are very hardy, and even more so are *Alba* and *Provence* Roses, while *Moss* Roses, again, are rarely frost-bitten.

Among climbing Roses *Félicité Perpetuée*, and *Dundee Rambler* are almost frost-proof. A peculiarity that I have often noticed is that two-year-old shoots are more liable to be frosted than growths of the past year. I have seen these damaged stems left, but it is a policy that cannot be recommended, as they may die during the summer months, and in any case do not flower well. My own plan with these is to cut them clean out and leave nothing but healthy wood.

I had a small rosery to plant last autumn. Most of the plants were in their places early in November, but more were required than had been ordered, and it was quite a month later when the work was completed. Without exception, every one of these late-planted Roses have been killed to the ground, thus emphasising the benefit of early planting.

"The Book of the Rose" came out about the time we were busy finishing the new Rose beds. It was read at once for something new. The only striking matter was that referring to manuring, the force of which, however, I did not quite see; in fact the Roses were planted in beds of pure turfy loam without any addition whatever; but after they had been tied securely to sticks, a thick coating of fresh horse droppings was spread over the whole surface of the ground. The Roses have just been pruned; the top 4 inches of soil has been pointed over and the manure buried to that depth, and I am hopeful these means will give the plants a good start.

The new *Crimson Rambler* as to hardiness has been somewhat disappointing. One plant of 1893 is quite dead, while of several planted last November all are much damaged. *L'Idéal*, again, is not nearly so hardy as *W. A. Richardson*, nor are the *Waltham Climbers* so hardy as *Gloire de Dijon*. Climbing *Victor Verdier* appears to be absolutely hardy. *Cheshunt Hybrid* has also come safely through the winter. That pretty novelty, *Janet's Pride*, is already well budded, and seems as hardy as the common *Briar*. Numbers of *Rosa rugosa* in different positions have all escaped damage, though *Madame G. Bruant* is slightly frost-bitten.—B.

#### APRIL NOTES.

IT has been frequently stated of late years that it is a mistake to suppose that Tea Roses are tender; as they are, in fact, if grown in the open, as hardy as Hybrid Perpetuals. But I confess it was a surprise to see this statement repeated in April, 1895, as it has been by Mr. Williamson (page 290) on his own and Messrs. Cocker and Prince's authority. The two latter are now no doubt having a good time, for standard Teas must be very much in demand, and, indeed, I have been unable to advise anyone as to where they are to be procured. I think we should like to know how much frost and also how much snow Messrs. Cocker had in February before we take it for granted that their Teas escaped injury from their own inherent virtue and hardiness.

The weather in Scotland is often very different to that in England, and our great trouble was that we had hardly any snow with the exceptional frost. Of the seven Roses named by Mr. Williamson, who, I suppose, had abundance of snow, only two are Teas, and I think but few of us have had H.P.'s seriously injured. A contemporary, which often alludes to the folly of protecting and coddling up such hardy plants as Tea Roses, has dropped that subject for the present; and, with admirable consistency, has been pointing out to its readers the folly of

growing such a half-hardy thing as the common Laurel, when really hardy and prettier shrubs (granted) are to be had.

Standard Teas are the trouble; mine, in all stages, cut-back, maiden, and dormant buds, are "a thing of the past." I have not one left, though they had the best position and all the protection I could give. On the other hand, I do not know that I have lost a single dwarf Tea, on much lower ground, though the protection of dead leaves was, when consolidated, certainly not more than 6 inches deep. Let inventors set their wits to work. Wanted, a scheme for protecting standard Teas from frost, that will not involve a roof, digging them up, or bending them down. I may mention that my *Maréchal Niels*, pegged down and clamped, are unhurt, though they were quite green and still growing when thus protected.

"Practice" (page 290) is "greatly in favour of spring mulching." We naturally read further to see why he recommends it, and find instead true and useful reasons for condemning it, in that it hinders the most important surface cultivation of the hoe. I am at a loss to understand what can be said in favour of spring mulching from "Practice's" point of view; but an exhibitor of Teas, who finds his blooms are too early for the shows, may sometimes find it useful, as of course it keeps the ground cold, and thus somewhat retards the blooming season.

There is no doubt that "Entomologist" (page 294) is right, and that we shall not find insect pests diminished by the severity of the winter. These things understand the art of winter protection even if we do not, and are well up in the value of earth and dead leaves as protectors. Nay, I fully expect Rose pests to be above the average in numbers. Last year we swept away a great number of the eggs at pruning time on the developed buds at the end of the shoots; but I am afraid that this season the parent moths will find no other buds on which to deposit their eggs save those on which we are depending, and eyes will have to be sharp and finger and thumb busy and industrious if our Roses are to be saved.—W. R. RAILLEM.

#### NEW ROSES.

(Continued from page 255.)

THE section of Hybrid Tea Roses has not received the numerical addition that we were led by some rosarians in this country to expect. We were told that they were coming in with a rush; that they were in fact "the coming race," and that although the Teas and H.P.'s would not be quite shut out, they would have to take a back seat. Well, there are nine new ones belonging to this section advertised, but even then we have to wait until they have flowered to ascertain whether after all they are not Hybrid Perpetuals sailing under false colours, for such Roses as *Caroline Testout* might be placed without any difficulty among the Hybrid Perpetuals. A curious comment on the supposed preponderance of this class comes for us from the National Rose Society's schedule for 1895; for there we find that the number of blooms required to be exhibited in a special class of Hybrid Teas is reduced from twelve to nine. Thus, the record since it was attempted to push this class into prominence resulted in 1893 in not one box of blooms being exhibited, and in 1894 one stand; and in 1895, in the hope of inducing more exhibitors, the number of blooms in the stand was reduced. This does not look like the run for popular favour which we were led to anticipate, and from one grower I gather the not very assuring statement with regard to the condition of his Roses, that the Hybrid Teas were the worst hit of all, and he is a favourer of this section. Here, then, is the list.

**CHARLOTTE GILLEMOT** (Guillot Fils).—A variety remarkable both for shape and odour; in form it is like the *Camellia alba plena* and *alba fimbriata*, with stout petals of a beautiful ivory white, shading off to milk white, one of the finest white Roses in the Hybrid Tea section. Considering the limited number of Roses in this section altogether this addition to description seems somewhat superfluous.

**EMIN PACHA** (Diögemüller).—A large full flower, similar to *Van Houtte* in shape, carmine rose in colour. Very free flowering in the autumn.

**JOSEPHINE MARAT** (Bonnaire).—A large full white flower, the buds lightly striped with rose colour—a good flower for cutting—has obtained two first-class prizes.

**MADAME ABEL CHATENAY** (Pernet Ducher).—A medium-sized full flower with pointed bud; carmine-rose shaded with deeper rose, and dark at base of petals; a splendid variety, cross between *Dr. Grill* and *Victor Verdier*. Obtained a first prize at the Lyons Exhibition of 1894.

**ROSOMANE ALIX HUGNIER** (Bonnair).—A very large flower perfectly imbricated: a beautiful mother of pearl white colour, salmon shade inside with light rose on the reverse of the petals; obtained two prizes.

**SOUVENIR DE MADAME EUGÈNE VERDIER** (Pernet Ducher).—A large full globular flower on a firm stalk of a beautiful milk white colour, saffron yellow at the base, other part shaded with darker yellow. Cross between *Lady Mary Fitzwilliam* and *Madame Chélane Guinnoisseau*.

**SOUVENIR DU PRESIDENT CARNOT** (Pernet Ducher).—A large full flower, with a long bud like that of *Niphotos*; the guard petals large and of a light rose colour, very light in the centre, and shaded with flesh-white at the end of the petals, very free flowering, and perfectly hardy. Obtained a first prize of the Lyons Exhibition of 1894. I am very much surprised at the varieties chosen by these French raisers for hybridising purposes, and almost think there must have been some mistake. I cannot fancy, for instance, selecting as a parent *Dr. Grill* or *Madame Chédane*, while the crossing them with

such Roses as *Victor Verdier* would seem to have been a very doubtful experiment; but they seem to have achieved success at least in the raiser's estimation, and we must only wait for ocular demonstration as to the correctness of their views.—D., Deal.

(To be concluded.)

#### FRITILLARIA SEWERZOWI.

THIS is an exceedingly interesting plant that is but rarely seen except in really good collections of bulbous plants. When first described it was said to be very small, but now great improvement may be seen in it. *F. Sewerzowi* (fig. 55) is a pleasant relief from the tessellated forms so prevalent in collections. The habit also is most distinct, the

FIG. 55.—FRITILLARIA SEWERZOWI.

bold glaucous foliage and yellowish-green flowers being attractive in groups. It is quite hardy in English gardens, but usually flowers rather too early. The bulbs should be planted in a dryish position in light sandy soil.

#### ROYAL GARDENERS' ORPHAN FUND.

ON Friday evening, April 5th, the Hotel Metropole was the scene of the seventh annual dinner of the above Society, and we have great pleasure in announcing that it proved to be one of the most successful ever held by this excellent Institution. The amount of benefit conferred on those engaged in horticulture by the above and other societies is very great, and best known to those who have reasons for feeling thankful that such were instituted.

It was in 1887 that the Royal Gardeners' Orphan Fund was established by a handful of horticulturists, who had thought not only for themselves but also for the welfare of their fellow men. The rapidity with which the Society has grown and expanded in so short a time is amazing; to such an extent, in fact that it now takes a place amongst the foremost of those of its kind. The thought of this must be gratifying to its pioneers, and we hope that gardeners all over the kingdom will rally still closer round the banner of these noble institutions, and thus assist them in conferring greater benefits on a deserving class. The chair was taken by H. J. Veitch, Esq., who is always willing to render assistance in the furtherance of good work, and it is superfluous to say that he fulfilled the duties appertaining to the office in a highly creditable manner.

Amongst those present were Sir Trevor Lawrence, Bart., N. N. Sherwood, Esq., and Messrs. J. Baldwin, T. Manning, Owen Thomas, J. H. Veitch, J. G. Veitch, F. C. Ward, G. Reynolds, J. Willard, R. Cannell, J. M. Pollett, H. Hicks, C. Penny, F. Moore, J. Hudson, G. Wythes, G. Featherby, P. Garcia, E. Rochford, J. Kinnell, J. Assbee, P. Kay, W. Poupert, A. G. Weeks, H. B. May, S. W. Segar, H. Turner, W. G. Nutting, J. Alderman, G. May, G. Gordon, W. Gregory, J. Sweet, J. Walker, W. G. Baker, W. H. Bohn, H. Williams, F. Q. Lane,

W. Ireton, G. J. Ingram, J. H. Laing F. A. Laing, W. J. Brewer, W. Barr, H. Herbst, B. Wynne, D. Gorton, A. G. Baker, E. Hill, W. G. Head, J. Wimsett, A. F. Barron, H. J. Jones, J. Fraser and W. Bates.

After the usual toasts for the Queen and Royal Family had been given, the Chairman arose, amidst applause, to propose that of "The Royal Gardeners' Orphan Fund," and, amidst other well-chosen remarks, said the Fund was originated to aid in the maintenance of the orphans of gardeners, foremen in public, private, and market gardens, and nursery and seed establishments, while rules are provided which enable the Committee to give a certain sum to start the children in the world. The Society was started in 1887 by Mr. Charles Penny, who he was pleased to see there, this being the first annual dinner he had attended since its origin. He (Mr. Penny) was now enjoying honourable retirement, and whenever thoughts of the Gardeners' Orphan Fund crossed his mind, he must feel thankful that he ever started it. In 1888 there were eleven candidates who have received an allowance of nearly £10 per annum since. This speaks wonders for the way in which it has been supported, and it was gratifying to know that at the last meeting the highest aggregate of votes was polled.

That such a fund was necessary was proved by the fact that £832 were annually paid in benefits, and since the commencement the sum of £3237 had been so paid. A pleasing feature in the last balance-sheet showed an investment of £7570, with £825 at the bankers. An average of £1500 per annum had been paid since the Fund was started, which was a wonderful fact, and one that no other institution of so short a duration could boast.

Many people thought a reserve fund was not necessary, but he thought otherwise, as they were virtually pledged to find payments for children until they attained to the age of fourteen, and should the income at any time become less they would have the reserve fund to fall back on. He hoped the reserve fund would increase, and in doing so be a help to those coming forward. As the Secretary and Committee were all honorary the expenses had been less than in any previous year. These by their energy were not only assisting sixty-four children, but the mothers as well.

Many people, he thought, did not realise the meaning of the words widow and orphans. In the case of a gardener being taken ill and dying, his poor widow is left perhaps penniless, heartbroken, and health gone; the Gardeners' Orphan Fund then steps in and says, "We will help you to bring up your family." This Fund helps those who are unable to help themselves, and by doing so obeys the Divine command which tells us to "Comfort the fatherless and widow."

In conclusion, he would remind all present that mercy always brings a double reward, and that the greatest happiness is derived from making others happy, and he would entreat them in the fulness of their hearts to give all they could, through which many could be benefited who at the last election had to be refused owing to lack of funds.

Mr. N. N. Sherwood, in replying to the Chairman, said he had received letters from Sir J. T. D. Llewelyn, Bart., Drs. Masters and Morriss, also Messrs. Dickson, Wright, Dyer, Marshall, Finch, and Sander, regretting their inability to attend. Proceeding, he said all knew the interest taken by Mr. Veitch in all charitable works, especially those connected with gardening, and he trusted the Chairman's excellent speech would be the means of drawing a goodly sum. It must be a great pleasure, he said, to Mr. Penny to see the prosperous condition in which the Gardeners' Orphan Fund is now in, and by energetic working and keeping it before the public it will doubtless develop into as great a Society as the Gardeners' Royal Benevolent Institution. He had learnt that one gentleman had collected the sum of £50 in half-crowns, and he would like to suggest some arrangement be made similar to that in hospitals, by which a person after subscribing a certain sum has a cot set apart for the use of anyone he likes to recommend. If something like this could be instituted in this Society he would be happy to be the first to make a presentation. The Chairman, he said, had graphically described instances in which the Gardeners' Orphan Fund was spreading its good work, and he trusted it would have the support of all interested in gardening, and so grow and become one of the greatest societies in the kingdom.

Mr. J. Assbee, in giving the toast of "Gardeners and Gardening," remarked that it was one which embraced a very wide area. There were amateur gardeners, gentlemen's gardeners, and market and nursery gardeners. In speaking more particularly of the three latter, he said that gardeners, as a rule, are a body of men who have great interest in their work, besides being men of many ideas and wide knowledge, intelligent and deserving. The remuneration, he said, received by gardeners in many instances is not sufficient for them to make provision for their wives and families, and it was to help such that the Fund had been established, and with wider spread of feeling he hoped it would prosper still more. With respect to the second part of the toast—viz., "Gardening," almost everyone loves gardening, whether it is on an elaborate scale, or even on a much smaller in a London window, and the keen love which is held for flowers may be seen in the way in which even a small child will run the risk of being run over in the street in order to become the possessor of some fallen blossom. He felt the toast of "Gardeners and Gardening" was one much too wide for him to thoroughly grapple with; but in giving it he would couple with it the name of Mr. Owen Thomas, the accomplished gardener of Her Majesty the Queen.

Mr. Owen Thomas in reply, said nothing had made more progress during recent years than horticulture, and in looking over a period of thirty years one could not fail to notice the extent to which methods and

systems had changed. Flowers in those days were not grown to be cut so much as they are now, not that he had anything to say against this, as it gave employment to a great many. In speaking of gardeners he regretted the recent death of several worthy horticulturists. There was Mr. William Thomson, who had revolutionised the system of Grape-growing for market, and Mr. Thos. Baines, verily a king amongst gardeners; and lastly, Mr. Wm. Dean, one of the most kind and amiable of men, and one of the best florists who ever lived. In speaking of the future of gardening, he said young gardeners of the present day were a class of men worthy of the highest praise. With respect to the Gardeners' Orphan Fund he said the chief power of the Society was centered in London, and he thought it would be a good idea to form centres in different parts of the country by which the Fund might be much encouraged.

At this point the result of subscriptions given at the table was read by Mr. Brian Wynne, and amounted to a substantial sum, particulars of which are appended. Per Harry J. Veitch, Chairman.—Harry J. Veitch, £52 10s.; J. Veitch & Sons, £26 5s.; Mrs. Harry J. Veitch, £10 10s.; J. H. Veitch, £10 10s.; J. Gould Veitch, £10 10s.—£110 5s. H. J. Jones, Lewisham, £55 1s. 6d.; Covent Garden Table, per J. Assbee, £52 10s.; Wills & Segar, £40; J. Reynolds (including Leopold de Rothschild, £20, and Alfred de Rothschild, £10 10s.), £37 11s.; The Hortus Lodge, £35 9s.; N. N. Sherwood, £35 10s.; Baron Schiöler, £30; Sir Julian Goldsmid, Bart., M.P., £21; Lord Rothschild, £25; N. M. Rothschild, £25; E. Hill, Tring, £20; W. Robinson ("The Garden"), £15 15s.; Arnold Moss (Wrench & Sons), £15 15s.; Ferdinand de Rothschild, M.P., £10; Sir Trevor Lawrence, Bart., M.P., £10 10s.; T. B. Haywood, £10 10s.; M. B. Head, £10; J. R. Stirling, £8 16s. 6d.; T. C. Ward, £7 2s. 6d.; J. Willard, £6 13s. 6d.; R. P. Glendinning, £5 15s. 6d.; John Laing & Sons, £5 10s.; Martin J. Sutton, £5 5s.; Anthony Waterer, junr., £5 5s.; A. W. Sutton, £5; Sir Donald Currie, £5; T. Statter, £5; Proprietors of "Amateur Gardening" and "Gardeners' Magazine," £5; G. A. Dickson, £5; W. G. Head, £5 5s.; H. Hartley, £5 5s.; A. W. G. Weeks, £5 5s.; H. J. Wimsett, £5 5s.; H. Hicks, £5 5s.; A. H. Smee, £5 5s.; E. Gilbert, £5 14s.; T. Turton, £3 15s. 6d.; H. J. Clayton, £3 10s.; W. J. Nutting, £3 3s.; W. Icceton, £3 3s.; J. F. McLeod, £3 0s. 6d.; H. J. Cutbush, £2 7s.; — Page, £2 2s.; H. Herbst, £2 2s.; P. Crowley, £2 2s.; R. & G. Cuthbert, £2 2s.; C. E. Osman, £2 2s.; T. Manning, £2 2s.; W. J. Brewer, £2 17s.; J. T. Bennett Poë, £2; P. E. Kay, £2 2s.; G. May, £2 2s.; Laundry, Son, & Kedge, £2 2s.; W. Bates, £2 1s.; W. Roupell, £1 14s. 6d.; J. Phillips (Edinburgh), £1 4s.; W. Smyth (Basing), £1 7s.; and further sums of £1 1s. and under, making a total of upwards of £800.

Mr. W. G. Weeks, in proposing the health of the Chairman, said it was to him a pleasure, marred to a certain extent, as he could not do full justice to the toast, and what he said was no mere figure of speech but the outpouring of heartfelt thanks. The name of H. J. Veitch, Esq., said he, carried with it a glow of goodness to anyone to whom it was mentioned, for in spite of the many duties connected with the firm he always found time to attend to the wants of the aged and suffering in the gardening world, which may be seen by his munificence and generosity in regard to the Gardeners' Orphan Fund and other societies, and anything further that he might say would, he thought, be quite superfluous.

The Chairman, in thanking those present for the kind manner in which they had drunk his health, said he felt he was a friend amongst friends, and he should like to thank Mr. Barron for the excellent manner in which he conducted the duties of Secretary, and also the Stewards for the good list of subscriptions they had succeeded in obtaining, coupling with the latter the name of Mr. Chas. Penny.

Mr. Penny, in reply, said he could not tell them what he felt. He was so pleased and gratified at the success of the Society, which, from being a cutting a few years ago, had now developed into a fine plant. He regretted the fact that more gardeners did not subscribe to the Society, as he thought every gardener might do so. He also trusted the horticultural press would do all they could to further the interests of the Society. He would also like to tender especial thanks to Mr. Barron for his services, and in conclusion said his early expectations had been more than accomplished.

Mr. A. F. Barron, in a few words, expressed his thanks, and said he should always do his best for the Society.

Mr. Harry Turner gave the toast of "The Horticultural Press," and said the Society had derived much benefit through the reports of meetings and events that appeared in the pages. Mr. George Gordon replied, and thanked all present for the generous manner in which the toast had been received; and, amongst other well chosen remarks, said members of the Press would always endeavour to do what they could for the gardening fraternity.

Selections of music, vocal and instrumental, were supplied by Mr. Herbert Schartau and others.

## ROYAL HORTICULTURAL SOCIETY.

APRIL 9TH.

THIS meeting at the Drill Hall was the best that has been held this year. The display of flowers was an exceptionally brilliant one, and was comprised of a more extended selection than has been the case at previous meetings. Orchids were not quite so numerous, but as a rule the quality was excellent. The exhibits for the Floral Committee made by far the greatest show, and in this section some plants of *Streptosolon*

(*Browallia*) *Jamesoni*, staged by J. T. Bennett Poë, Esq., of remarkable excellence.

**FRUIT COMMITTEE.**—Present: P. Crowley, Esq. (in the chair); with Rev. W. Wilks, and Messrs. T. F. Rivers, H. J. Pearson, G. W. Cummins, J. Cheal, T. J. Saltmarsh, J. Smith, G. Norman, H. Balderson, G. Wythes, J. Hudson, T. Glen, G. Goldsmith, R. W. Farr, G. Reynolds, G. T. Miles, Robert Fyfe, A. Dean, and J. Wright.

The season of the year has not arrived for other than small consignments of either fruit or vegetables to be sent for examination by the Committee, and on the present occasion Mr. G. Wythes, the energetic gardener at Syon, was the chief contributor of both. The collection of vegetables that he staged, and for which a silver Knightian medal was unanimously accorded, was, both as regards variety and suitability for the purpose for which the different kinds were grown, well worthy of the recognition bestowed during the present season of comparative scarcity of garden produce. Included in the collection were Sharpe's Victor Potatoes, Ne Plus Ultra Beans, Asparagus, Seakale, Mushrooms, Cucumbers, Cauliflowers, young Turnips, various Kales, Coleworts, Spinach, Leeks, and Chicory—not bulky samples, but just such as are welcomed both in the kitchen and dining room. Special attention was drawn to several plants of the *Victoria* Spinach, which has been found to stand the winter well. The plants were very sturdy with stout leaves, and the variety was recommended to be grown with the *Viroflay* and others at Chiswick.

Mr. Wythes also sent a box of *La Grosse Sucrée* Strawberries, fine fruits, splendidly coloured, and a cultural commendation was awarded; he also sent a very good sample of *Royal Sovereign*.

Mr. G. Goldsmith, The Gardens, Leonardslee, Horsham, sent a dish of Apples named *Burfield*—medium-sized, symmetrical fruits, prevailing colour dull red, heavily streaked with darker red—a showy fruit, but had lost its crispness. No award was made; but one of the members thought it might make a good "shop" Apple, which is not altogether a bad recommendation in these commercial days.

**FLORAL COMMITTEE.**—Present: J. Fraser, Esq. (in the chair); with Messrs. J. Laing, S. A. de Graaff, C. T. Drury, H. Herbst, R. Dean, R. Owen, G. Stevens, R. B. Lowe, J. Jennings, W. Bain, J. D. Pawle, J. W. Barr, C. E. Pearson, E. Beckett, C. Noble, C. T. Bennett Poë, J. Walker, C. E. Shea, E. Mawley, G. Paul, and C. J. Salter.

Messrs. Barr & Son, Covent Garden, were again in evidence with a collection of bulbous and hardy herbaceous flowers, consisting mainly of cut blooms of *Narcissus Horsefieldi*, *Emperor*, *obvallaris*, *princeps*, *Thomas Moore*, *Queen Bess*, *Henry Irving*, *Golden Spur*, *Ard Righ* and *rugilobus*; *Anemone pulsatilla* and *fulgens*, *Primula cashmeriana*, *Chionodoxa sardensis*, *Scilla sibirica*, *Helleborus punctatus* and *Dr. Hogg*, *Chionodoxa Luciliae*, *Megasea ligulata rosea*, *Sisyrinchium grandiflorum album*, and *Fritillaria amena rubra*, together with many others (silver Banksian medal). A collection of mixed flower and foliage plants was staged by Messrs. John Laing & Sons, Forest Hill, and amongst others were noticed *Clivias Vesuvius* and *Duchess of York*, *Caladiums Mrs. Harry Veitch* and *Comtesse de Maille*, *Calla Little Gem*, *Epiphyllum Makoyanum*, *Begonias floribunda compacta* and *Bruanti*, together with *Azaleas*, *Anthuriums*, *Ferns*, *Palms*, *Crotons*, *Dracanas*, *Isolepis gracilis*, and hardy herbaceous plants (silver Flora medal). Mr. Fitt, gardener to Earl Cowper, Panshanger, exhibited magnificent trusses of *Beaumontia grandiflora superba*, together with flowers of *Habrothamnus scabra* and *Gloneria jasminiflora*, and also a large flower spike of *Cordyline australis*, for which a vote of thanks was given.

Messrs. John Peck & Sons, Norwood, staged a compact group of foliage plants, containing sturdy examples of *Dracanas Elizabethæ*, *Madame F. Bergmann*, *Barroni*, *Lord Wolseley*, *Jamesi*, *pendula*, *terminalis alba*, *Rossi*, *Lindeni*, *Spinksi*, *superba*, *Vicomtesse de Belevale*, and *Frederica*, and others, all tastefully arranged with *Palms*, *Ferns*, and *Isolepis gracilis* (silver Banksian medal). A large and varied group of hardy herbaceous plants and cut flowers exhibited by Messrs. Thomas S. Ware, Hale Farm Nurseries, Tottenham, attracted much attention. Amongst others were noticed *Draba elongata*, *Megasea crassifolia*, *Primula viscosa nivalis*, *denticulata lilacina*, *Clusiana*, *denticulata alba*, *cashmeriana*, and *rosea*; *Saxifragas oppositifolia*, *Boydii*, *apiculata*, *Burseriana*, and *sancta*; *Narcissus reflexus* and *Bulbocodium*; *Hepatica triloba cœrulea*; *Trillium grandiflorum*, *Chionodoxa gigantea*, *Iberis saxatilis*, *Cypripedium calceolus*, *Androsace carnea*, *Puschkinia libanotica*, *Fritillaria meleagris alba*, and *Gaultheria procumbens* (silver Flora medal).

*Clivias* were staged in fine form by Messrs. B. S. Williams & Son, Upper Holloway, amongst other varieties being *Holloway Beauty*, *Surprise*, *Baroness Schröder*, *Prince of Orange*, *Madame Van Houtte*, and *Aurantiaca*. A varied group of *Amaryllis* was also staged by the same firm, containing fine flowers of *Emperor William*, *Dr. Masters*, *Curiosity*, *Ophelia*, *Distinction*, *Lord Salisbury*, *Marshalli*, *Lady Wimborne*, *Lothair*, and others (silver Banksian medal). A small but superb group of *Amaryllis* was staged by Messrs. Jas. Veitch & Sons, Chelsea, consisting of excellent flowers of *Doris*, *Chimère*, *Latona*, *Cytherea*, *Fresca*, and *Czarina*. The same firm also staged *Loripetalum chinense*, *Stachyurus præcox*, and well flowered plants of *Rhododendron Early Gem*, dug from the open ground.

Mr. Bain, gardener to Sir Trevor Lawrence, Burford Lodge, exhibited a pan of the elegant *Primula Forbesi*, and also plants of *Scutellaria Mocciniana*, together with a fine and varied collection of *Anthuriums*, amongst other varieties being *compactum*, *Rothschildianum superbum*, *Rothschildianum maximum*, *Maria Theresa*,

*album maximum*, *Archduc Joseph*, *Lawrenceanum*, *Andreanum*, *burfordiense*, and *sanguineum*, together with many fine seedlings. A large well-bloomed specimen of that peculiar plant *Ataccia cristata* was also included—the finest ever exhibited (silver Flora medal). Messrs. Sander and Co., St. Albans, staged plants of *Hippeastrum splendens*, also of *Spathoglottis plicata* and *aurea*. Mr. A. J. Reid, gardener to F. C. Carr, Esq., Farnham Chase, Slough, staged fine *Arum Lily* blooms. Plants of *Tree Carnation Mrs. Hamlet Riley* were sent by Mr. Chas. Turner, Royal Nurseries, Slough. Mr. Wm. Slogrove, gardener to Mrs. Crawford, sent a group of *Violet* plants thickly covered with bloom, of varieties *Swanley White*, *Marie Louise*, and *Neapolitan*.

*Cannas* were shown in excellent form by Messrs. Paul & Son, Cheshunt, the group containing varieties *Mrs. Tasker*, *Cheshunt Yellow*, *Comet*, *Antoine Barton*, and *Alphonse Bouvier*. *Amaryllises* were also included in the firm's exhibit, *Mrs. H. Wood*, *Venosa*, and *Sunlight* being especially prominent. A choice selection of hardy flowers are worthy of mention, and consisted mainly of well flowered plants of *Daphne Mezereum*, *Paul's Snow White*, *Pulmonaria saccharata*, *Saxifragas oppositifolia alba*, *luteo-purpurea*, *hypnoides variegata*, *Boydii alba*, *luteo-purpurea Mayli* and *sancta*, *Hepatica triloba*, *Erica herbacea carnea*, *Megasea Stracheyi*, *Anemone pulsatilla*, and *Primulas nivalis*, and *Forbesi*. The same firm also sent a fine plant of *Araucaria imbricata platifolia* in a pot (silver Banksian medal). Mr. Frank Cant, Colchester, staged an exceedingly fine collection of *Roses*, the flowers being large and of excellent form. Amongst others were noticed *Catherine Mermet*, *Maréchal Niel*, *Anna Ollivier*, *Jules Finger*, *Madame Hoste*, *Bridesmaid*, *Ernest Metz*, *May Rivers*, *Niphetos*, *Marie Van Houtte*, *Caroline Kuster*, and *Souvenir d'un Ami* (silver-gilt Flora medal). An excellent group of cut *Roses* came from Mr. George Mount, Rose Nurseries, Canterbury, containing, among others, fine blooms of *Catherine Mermet*, *Maréchal Niel*, *Niphetos*, *The Bride*, *Anna Ollivier*, and *Souvenir d'Elise* (silver Flora medal).

In a group of plants exhibited by J. T. Bennett Poë, Esq., Holmwood, Cheshunt, were large well-bloomed plants of *Streptosolon Jamesoni*. These are deserving of a special word of praise, and were said to be the finest ever produced—3 feet high and nearly as much in diameter, covered with brilliant trusses (silver Flora medal). A small group of seedling *Daffodil* flowers was staged by Rev. G. H. Engleheart, Andover.

**ORCHID COMMITTEE.**—Present: H. J. Veitch, Esq. (in the chair); Dr. Masters, with Messrs. J. O'Brien, De B. Crawshay, H. M. Pollett, H. Ballantine, W. H. White, H. J. Chapman, J. Jaques, E. Hill, S. Courtauld, J. Douglas, W. Cobb, T. W. Bond, W. B. Latham, A. H. Smee, and Fred Hardy.

A charming exhibit of Orchids was arranged by Messrs. J. Veitch and Sons, Chelsea, and comprised some bright and beautiful forms. Amongst the most noticeable were *Cattleya Lawrenceana*, *C. Schröderæ*, forms of *C. Trianae*, *Odontoglossum Ruckerianum*, *O. Pescatorei*, *O. Wilckeanum*, *Dendrobium Farmeri roseum*, *D. crassinode*, *Cymbidium Lowianum*, and *Cypripediums* in variety (silver Banksian medal).

Messrs. F. Sander & Co., St. Albans, staged a beautiful collection of Orchids, in which numerous excellent kinds were perceptible. *Phaius Sanderianus*, *Odontoglossum triumphans*, *O. crispum*, *Cattleya Schröderæ*, *Dendrobium Auguste Victoria*, *Cœlogyne lentiginosa*, *Angræcum Sanderianum*, and *Eulophiella Elisabethæ* were some of the best (silver Banksian medal).

F. Hardy, Esq., Tyntesfield, Ashton-on-Mersey, staged a fine example of *Odontoglossum polyxanthum*, Hardy's variety, and De B. Crawshay, Esq., Sevenoaks, a plant of *Odontoglossum triumphans Lionel Crawshay*, which was accorded a first-class certificate and will be found described below and figured on page 307. Mr. R. Johnson, gardener to T. Statter, Esq., Stand Hall, Manchester, showed plants of *Cattleya Mendeli Alexandra*, *C. Schröderæ splendens*, a very beautiful form, and *Lælio-Cattleya Pallis superba*, an exceptionally handsome bigeneric hybrid.

A group of Orchids was arranged by Mr. Aldous, gardener to H. J. Pitt, Esq., Stamford Hill. Very prominent were *Cattleya Trianae*, *Dendrobium thyrsoiflorum*, *Angræcum sequepedale*, *Vanda suavis*, and forms of *Miltonia Roezli* (silver Banksian medal). Mr. G. W. Cummins, gardener to A. H. Smee, Esq., The Grange, Wallington, staged a plant of *Cymbidium Lowianum viride*, carrying a handsome spike of pale green coloured flowers.

A magnificent plant of *Cattleya Lawrenceana* came from Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, as also did *Cypripedium Lawrenceanum*, *Epidendrum Endresio-Wallisii*, *Eulophiella Elisabethæ*, *Odontoglossum aspersum violaceum*, *Masdevallia leontoglossa*, and *Miltonia Bleuana nobilior*, all in excellent form (silver Banksian medal). Messrs. W. L. Lewis & Co, Southgate, showed a small collection of Orchids, composed of *Cattleyas*, *Odontoglossums*, *Cypripediums*, and others in variety (silver Banksian medal).

Two forms of *Cattleya Trianae* were staged by Mr. G. Downs, Farnham, and a cultural commendation was awarded to Mr. H. Adams, gardener to C. J. Raphael, Esq., Castle Hill, Englefield Green, for a splendidly flowered spike of *Eulophiella Elisabethæ*. From the Royal Botanic Gardens, Glasnevin, came specimens of *Cœlogyne lactea*, *Phaius assamicus*, and *Masdevallia ludipunda*. Baron Schröder, The Dell, Egham, showed a very small collection of Orchids, comprising *Dendrobium Cybele* and two forms of *Cattleyas*. J. T. Bennett-Poë, Esq., Holmwood, Cheshunt, showed fine plants of *Cymbidium eburneum* and *Lowianum*, and *Dendrobium Jamesianum*.

Mr. E. Hill, gardener to the Right Hon. Lord de Rothschild, staged a few Orchids, comprising *Cattleya guttata Prinzi*, *Lælia flava* var. *aurantiaca* (award of merit), and others.

## CERTIFICATES AND AWARDS OF MERIT.

*Amaryllis Chimere* (J. Veitch & Sons).—The segments of this superb *Amaryllis* are of great size, the colour being whitish green with bright rose marking on the upper portion of the bloom (award of merit).

*Amaryllis Doris* (J. Veitch & Sons).—The flowers of this variety are of handsome form and substance, though somewhat small. The colour is a very rich deep velvety crimson (award of merit).

*Anthurium compactum* (W. Bain).—This is a very charming form of dwarf habit. The spathe is white, spotted and patched with bright scarlet (award of merit).

*Ataccia cristata* (W. Bain).—This is a very old but still rare plant of botanical interest. The flowers are chocolate brown in colour, borne in umbels, and are of very curious formation (first-class certificate).

*Lælia flava aurantiaca* (E. Hill).—The blooms of this Orchid are of a very rich orange shade, the throat being sparsely striped crimson (award of merit).

*Odontoglossum triumphans*, *Lionel Crawshay* (D. B. Crawshay).—This is an exceedingly handsome form of the type. The blooms are large and very rich in colour. The sepals are clear yellow with bright brown patches and a yellow margin, the petals, which are broad and of great substance, being of the same rich colour. The lip is a fine feature. It has a yellow fimbriated margin, with a broad reddish brown patch and a canary yellow throat. This variety, which received the only first-class certificate awarded to an Orchid on the occasion, was promptly sketched by our artist for the illustration (fig. 53, page 307).

*Saxifraga Boydi alba* (Paul & Son).—This beautiful little alpine Saxifrage has pure white blooms of good size (award of merit).

## LIVERPOOL SPRING SHOW.

AFTER a discontinuance for a season, the spring show was again revived in St. George's Hall. The show, for beauty and quality, was pronounced by competent judges a long way ahead of either Preston or the Crystal Palace. Professional gardeners contributed handsome specimens, the majority of classes being well contested, whilst the trade assisted in every possible way, the greatest feature amongst the latter being the gorgeous *Amaryllis* staged by Messrs. R. P. Ker & Sons, Aigburth Nursery, which secured a special gold medal.

The Orchids were splendid, showing great progress, most noticeable being a handsome *Dendrobium Ainsworthi*, carrying 2400 flowers, staged by Mr. J. Bracegirdle, gardener to the Lord Mayor of Liverpool. Hyacinths and Tulips were admirably grown, the Judges having the greatest difficulty in awarding the prizes. The only weak feature in the show was the Azaleas, although a few grand specimens were brought. Boxes of Roses arranged for effect were also a great feature, more particularly the first one, put up by Mr. J. Carling, gardener to Mrs. Cope, Dove Park, Woolton.

For a table of miscellaneous plants arranged for effect Mr. J. Bracegirdle was the only exhibitor, but a most pleasing arrangement resulted. The centre contained a small Cocos, and the four corners being small Crotons. These were banked with Maidenhair Ferns, Tulips and Orchids being used as dot plants. Three competed for ten pots of hardy, herbaceous, and bulbous plants Mr. J. Grant, gardener to W. S. Gladstone, Esq., Thornlea, Aigburth, being an easy first, Mr. T. Hitchman, gardener to Arthur Earle, Esq., Childwall Lodge, being second. Mr. Grant also won with six pots of Daffodils, certainly amongst the best ever staged in the Hall, *Empress*, *Horsefieldi*, *Henry Irving*, and *Princeps* being conspicuous, Mr. W. Kneale, gardener to Lieut.-Col. Gaskell, Woolton, being a fine second. For eighteen Hyacinths Mr. T. Wilson, gardener to O. H. Williams, Esq., succeeded in winning with a very even stand. The best were *Vuurbaak*, *Lord Percy*, *Grand Maître*, *The Sultan*, *Lady Derby*, and *La Deuil*. Mr. C. Waring, gardener to Mrs. Jno. Aiken, Grassendale, was a good second, with Mr. T. Hitchman a close third. For twelve the first and second as in the preceding class won, Mr. Jas. Agnew, gardener to Mrs. Watts, Grassendale, winning for six.

It would be idle to criticise the Tulips, so even were they, Mr. James Grant winning with a good twelve; Mr. Holford, gardener to C. MacIver, Esq., Heswall, being second. For six doubles and six singles, Mr. J. Williams, gardener to C. J. Procter, Esq., Boscobel, Cheshire, secured the prizes with very fresh examples. *Amaryllis* were most handsomely shown by Mr. T. Johnson, gardener to G. W. Moss, Esq., who staged massive and shapely flowers. Considering the adverse season, stove and greenhouse plants were in good condition, Mr. B. Cromwell, gardener to J. Sutton Timmins, Esq., Cleveley, Allerton, being first with a capital *Anthurium Scherzerianum*, well-flowered *Dendrobium nobile*, and a charming white Azalea, two fine Palms, and a well-coloured Croton completing the six: Mr. R. Pinnington, gardener to Mrs. Banner, being second. Mr. Cromwell was also first for the most beautiful six forced hardy plants ever seen at Liverpool. Two charming Clematis, Mrs. Quilter and Sir Garnet Wolseley, a fine Tree Pæony, Charles Dickens Rhododendron, and Grace Darling Rose.

In addition to the fine *Dendrobium Ainsworthi* previously mentioned Mr. Bracegirdle had a very healthy *Angræcum sesquipedale* carrying four spikes and ten massive flowers for first prize in the class for three Orchids; Mr. E. Taylor, gardener to E. Pryor, Esq., Aigburth, having a good *Dendrobium Wardianum* in the second prize stand. The special cool Orchid prize kindly given by Messrs. Jas. Cowan & Co., Garston, was won by Mr. T. Wilson with capital plants of *Lycaste Skinneri* and *Odontoglossum triumphans*. Azalea prizes for three and

one, four and one Azalea mollis, and six pots of Freesias were all taken by Mr. J. Kelly, gardener to R. Singlehurst, Esq., Aigburth; Mr. Bounds, gardener to C. L. Jones, Esq., Aigburth, won with table plants, four Azaleas in 8-inch pots, and one greenhouse Rhododendron; Mr. T. Aikers, gardener to W. B. Bowring, Esq., was first with three Callas, two pots Mignonette, and one Rhododendron; whilst Mr. Lewis, gardener to S. Neal, Esq., Aigburth, again showed his superior skill by taking the first prizes for Cyclamen, Cinerarias, and Primulas; Mr. Heaton winning with two forced hardy plants.

Certificates were granted to Dicksons, Limited, for a grand display of Narcissi, the admiration of all visitors; Messrs. Cowan & Co., Garston; and Charlesworth & Co., Bradford, for a varied and choice display of Orchids; Messrs. T. Davies & Co., Wavertree, for a handsome contribution of miscellaneous plants and bulbs; Mr. H. Middlehurst, Manchester Street, Liverpool, for Narcissi in variety and compact Mignonette; Messrs. R. P. Ker & Sons for Azalea mollis (Kostar's variety) and Clivias; Mr. W. Mason, Birkenhead, for plants and Edwardian ware; Messrs. W. J. Robertson & Co. for Palms; Mr. W. Kipps for fruits of La Grosse Sucrée Strawberries; and last, but not least, a special prize for four bunches Black Alicante Grapes in splendid preservation, and an excellent basket of La Grosse Sucrée Strawberries, exhibited by Mr. T. Elsworthy, gardener to A. R. Gladstone, Esq., Court Hey, Broad Green.—R. P. R.

## FRUIT FORCING.

**Pines.**—*Early-started Fruiting Plants.*—The Queen, Enville, and Providence plants started early in the year are fast approaching the flowering period, and will be benefited by an occasional syringing at the time of closing the house, but it must be very light, and when the flowers open should not be practised. As the foliage is as yet tender it will be desirable in the case of houses with large panes of glass to afford a slight shading for an hour or two in the hottest part of the day until the foliage becomes inured to the sun's influence. When the flowering is over the fruit will advance rapidly if the roots are in good condition, and ample supplies of weak tepid liquid manure given as required. Attend to ventilating early in the morning, commencing when the temperature is at 80° and closing at 85° with sun heat. Keep the atmosphere moist by damping whenever the paths and other surfaces become dry, especially at closing time or early in the afternoon. The bottom heat should be kept steady at 80° to 90°, and the night temperature 70°, with 75° by day artificially. As soon as the suckers appear remove all except one to each plant.

**Vines.**—*For Early Work.*—Vines in pots afford creditable crops of early Grapes. The Vines for this purpose should now be in the pots they are required to fruit in, and have the growths trained as near to the glass as possible without touching, so as to secure thoroughly ripened wood. Better results, however, are had by planting the Vines in beds or borders after the method adopted with Cucumbers or Melons. A lean-to or three-quarters span-roof house, facing due south, answers perfectly if it has a border about 3 feet wide along the front, and 18 inches in depth, with hot-water pipes below for affording bottom heat. These may be disposed in a chamber or so as to allow of 6 inches depth of rubble over them. The Vines intended for fruiting next year should be strong cut-backs, which have been forwarded in another structure, and attained the growth such as that of those transferred to the largest size of pots for fruiting. If they have made considerable progress, as they will by this time, they should be turned out with the ball entire, firming the soil well about them. Turfy loam with an admixture of about one-sixth of old mortar rubbish forms a suitable compost, which need not be more than 15 inches in depth, and only sufficient used to form a hillock for planting in and breadth enough for watering. Fresh soil must be added to the sides as the roots protrude, the object being to keep the Vines perfectly under control. The canes being trained near the glass will make short-jointed wood. Stop the laterals at the first leaf, and the sub-laterals at one joint, and to every subsequent joint as made. Under this treatment the growths will be sturdy, food largely stored in the canes, also in the well-developed buds, and the wood ripen early and thoroughly. If well managed they will make canes like walking-sticks with eyes like nuts, and being as much under control as Vines in pots they can be matured early and given a rest, so as to be ready for a start by the early part of November. By this plan the root action is considerably extended, and this admits of correspondingly large feeding, the crops finishing better than those of Vines in pots.

**Grapes Ripening.**—Vines in pots that have the Grapes ripe or advanced in ripening require very moderate supplies of water at the roots. To insure a full swelling on planted-out Vines inside borders should have a thorough supply of water, ventilating early on fine days to allow excessive moisture to escape. A full crop of early Grapes is a great strain on the energies of the Vine, and through it in early forcing perfection in colour is not always attainable. Much may, however, be done by a liberal and constant supply of warm, rather dry air, combined with a comparatively low (60° to 65°) night temperature, but that in

the daytime must be well maintained at 70° to 75° from fire heat, and 80° to 85° with sun heat. Red spider usually makes its appearance on early forced Vines about the time of the Grapes commencing colouring and the small colonies on the under side of the leaves must be removed with a sponge moistened with a solution of soft soap, 2 ozs. to a gallon of water. As a preventive measure the pipes may be coated with a mixture of sulphur and skim milk. Care, however, must be taken not to overdo it or the fumes will act injuriously on the skin of the berries and spoil their appearance, the sulphur vapour being more injurious to the skin of the white than black Grapes, Frontiguans and Muscat of Alexandria suffering most.

**Succession Houses.**—Stop and regulate laterals so as to secure an even spread of foliage without crowding. Where there is not room for extension it is unwise to allow them to grow considerably, so as to necessitate a large reduction of foliage at one time, as this results in a check, which often induces shanking at a later period. Attend to thinning the bunches and berries, under rather than over-cropping the Vines. Make sure that the borders have abundance of water. Vines swelling their fruit should have a moist atmosphere, securing this by damping the paths two or three times a day, and if liquid manure be used at the latest sprinkling it will improve the Vines and act as a check to red spider. Stable and cowhouse draining diluted down to the colour of mild ale, or an ounce of guano to a gallon of water is sufficiently strong for damping with, not using more than a 4-gallon watering-canful to 30¼ square yards.

**Late Vines.**—Disbud and tie out these as they require it. Close the houses early in the afternoon with sun heat and ample atmospheric moisture by frequently damping available surfaces. Vines that were started early in March are making rapid progress, and must receive every encouragement, but avoid hurrying their growth by a close atmosphere and high temperature, especially at night, ventilating judiciously early in the day so as to secure well formed, thick, leathery leaves.

**Young Vines.**—Last year's planted canes will now be breaking naturally, and when the growths are fairly on the move a little fire heat will prove beneficial, especially on cold days. When the growths are about half an inch long, gradually remove those not required, leaving the shoots for bearing or forming the side growths or spurs not closer than 15 to 18 inches on each side of the cane. If fruit is taken crop lightly. One, or at most two bunches is as much as Vines in the first year of fruiting should be allowed to bear, but supernumeraries may be weighted with as much fruit as there is a prospect of their bringing to maturity.

**Strawberries in Pots.**—The season of forced Strawberries is, or soon will be, at its height, and the labour of watering at its maximum. Examine the plants at least three times a day in bright weather, and whenever a plant needs water give a thorough supply. East winds are usually very prevalent in spring time, and air must be cautiously admitted, as the fruit is liable to become brown and cease swelling when exposed in its early stages to currents of cold, dry air. The plants should be at a greater distance from the roof than earlier in the season, so as to allow of a free circulation of air between the leaves of the plants and the glass. Plants that are to give very fine fruits should not only be those showing the largest flowers, but these must be thinned to about a dozen or so on each plant before they expand. Bring them forward in a gentle heat in the first stages of swelling, affording an abundance of atmospheric moisture so long as the fruit remains green. When it becomes whitish-green increase the temperature gradually to 80°, 85°, or 90° on sunny days, keeping through the night at 60°, to 65° or 70°, with 5° more on dull days or from artificial heat. Continue this until the fruit becomes red all over, when the temperature should be lowered to a minimum of 60°, in which they will increase considerably in size after they are apparently ripe, and to secure high flavour a free circulation of rather dry air must be maintained, watering only at the roots to keep the foliage fresh.

#### THE KITCHEN GARDEN.

**Tomatoes.**—The season hitherto has been most unfavourable to the production of early crops; what is particularly wanted is more sunshine. Strong old plants that gave good late crops ought now to be again well set with fruit, this time produced by side shoots duly thinned and stopped at the first or second joint beyond a cluster of fruit. It is those trained thinly up the roofs that give the best results. Keep them in a moist, well-fed state at the roots, and do not cut the foliage away recklessly. Autumn-raised plants placed in their fruiting quarters early in the year made such poor progress, or else became so drawn and weakly during the frosty weather, that it would have paid better in many instances to have destroyed them and started afresh with newly raised plants. The latter would have given much better crops; but the former, where both plans are being tried, will give the earliest gatherings of ripe fruit. Strong young plants form side shoots too freely, and unless there is good room for laying in an extra growth or two all these should be removed with a view to concentrating the plant's energies in the building up of stout, hard stems and the production of heavy crops of fruit. The primary leaves are fully equal to all that is required in the way of sap elaboration. Remove any large and unshapely central flowers that may form, as these produce deformed fruit. During the flowering period the plant should be gone over daily towards noon, and the flower stems smartly tapped with a padded stick, this distributing the pollen and effecting a good set. If large handsome fruits are desired it is especially necessary to effect perfect fertilisation. Commence top-dressing plants in pots and boxes with rich compost by

the time the first fruits are set, and give liquid manure or light surfacings of special manures soon afterwards.

**Tomato Diseases.**—Several diseases have to be reckoned with by all who grow Tomatoes under glass, and in particular where fire heat is freely used. Cladosporium and the Potato disease are not the worst maladies that have to be contended with. Maintaining a good circulation of warm dry air principally by means of heat in the hot-water pipes and top air according to external conditions, also building up the plants strongly, are the best preventive measures, while if the disease blotches put in appearance in spite of these precautions anti-hlight powder should be dusted over all the older leaves. Full strength Bordeaux mixture, as advised in books, is often more injurious than the disease itself. Directly black stripe appears destroy the infested plants. Varieties that form extra large sappy stems are the most liable to infection. Nothing applied outwardly will arrest the spread of this disease, and on no account should seed be saved and sown from a tainted stock. It is possible this malady and also that known as the "sleepy" disease, will eventually be traced to an attack at the roots. A free use of soot might prove advantageous. The anti-hlight powder washed down to the underground portion of the stems would probably act beneficially as a preventive without injuring the roots, and Lysol, the new remedy for mildew and kindred diseases, might also be tried. One pint of this Lysol (an alkaline liquid) can be bought for about 1s. 9d., and this would be sufficient for mixing with thirty gallons of water for either spraying or watering purposes.

**Tomato Plants for the Open Air.**—It is a mistake to raise these long before they are wanted for the open air. Sturdy, late-raised plants are the first to become established in their fruiting quarters and seldom lose their first bunches of flower. This means, therefore, both an early and heavy crop of fruit. If seeds are sown at once in heat the seedlings when in rough leaf are placed singly in 4-inch pots, and kept near the roof glass and still in heat, they will quickly be large enough for hardening off and planting out. In the case of those planted against sunny walls head room is usually limited, and dwarf plants are the most desirable accordingly. Raise abundance of plants with a view to planting some quite in the open as well as against walls, fences, and temporary screens. Conference, Earliest of All, Laxton's Open Air, Sutton's Al, Dedham Favourite, Large Red, Mikado, Webb's Sensation, and Ham Green Favourite are all suitable for open air culture, and a trial ought certainly to be given the new Frogmore Selected.

#### PLANT HOUSES.

**Crotons.**—These are now on the move, and cuttings may be rooted where healthy young plants are needed. The cuttings should not be taken off where the wood is firm, or the lower leaves fall and roots are formed very slowly. After inserting the cuttings in sandy soil, water them and place in the propagating frame or under hand-lights until they are rooted. The hand-lights should be kept as air-tight as possible, the cuttings dewed over daily and shaded from the sun. Plants that have good heads and bold foliage may be notched, and a little sand and moss tied round the notched portion. In brisk heat where the syringe can be used freely roots will soon be emitted, and the head can be established in 4 or 5-inch pots without losing a single leaf. Plants that are needed for some time longer for table decoration and have been in the same pots for a good length of time should have a little chemical manure applied to the surface, which will assist wonderfully in retaining the lower foliage. Where numbers of small plants are needed the stems should be allowed to break after the head has been removed, and these side growths rooted when large enough. Small plants that have become stunted should have the head removed and rooted and the lower portion thrown away.

**Gardenias.**—Young plants that have been wintered in 3-inch pots should be transferred to 6-inch pots without delay. If they can be placed in brisk bottom heat they will soon start freely into growth. The shoots that the plants have made may be tied outwards towards the rim of the pots, and others from the base will soon be produced. Pinch any shoots that are taking the lead, or display signs of doing so. Water these plants carefully, as it is a mistake to keep them too wet. If plunged and the material kept moist they will not need much water beyond the daily syringings. Where the plants cannot be plunged syringe freely amongst the pots and maintain a brisk moist heat. Capital flowering plants can be produced in 5-inch pots from cuttings of young wood rooted at the present time. These cuttings root very freely, and should be inserted singly in thumb pots.

**Vincas.**—Where stoves and intermediate houses are kept gay *V. alba* and *rosea* are useful plants, and even in a cut state they last fairly well. Old plants that have enjoyed a good rest may be cut hard back, and started into growth in brisk moist heat. When started the plants may be turned out of their pots and the halls reduced by one-half, placing the plants again in the same size pots. For furnishing purposes those in 5-inch pots are often the most useful. Cuttings of soft wood root freely, and capital plants can soon be produced.

**Anthurium Scherzerianum.**—This is a very useful plant, and deserves to be grown more extensively. For associating with *Cattleyas* the effect is all that can be desired, and the spathes when cut are useful, lasting a long time in water. The plants are easy to grow, providing a good temperature can be maintained and abundance of moisture given. They do not appear to be very particular about soil as long as the pots are well drained and an open compost is used. They thrive in fibrous loam and fairly coarse gravel if good peat cannot be had. The material

used should not be raised above the rim of the pot; on the contrary, sufficient room must be left for water, and then 2 or 3 inches depth of common wood moss placed on the surface. They grow freely if potted in this material alone. A rest in a lower temperature, then ample heat and moisture while growing, are chief points to be attended to by the cultivator. If the syringe is used freely they will form a mass of roots in the surface moss.

**Anthurium Andreanum.**—This is also valuable for winter-flowering, and plants can be more effectively used in 6 and 7-inch pots than in those of a larger size. Large plants may be cut up and the stock increased without much trouble or risk of loss, or the stem of a good specimen can be notched and mossed round, and when roots have formed be taken off and placed in a 6-inch pot. The remaining portion of the stem should be cut into lengths of one or two joints—an eye to each piece is all that is needed. These quickly form roots, and by the end of the season make capital plants. If the old plant is cut over near the surface three or four shoots will soon start, and a better plant than ever will be produced. The cuttings root freely in sand and moss. Established plants will grow well in any coarse open material.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### THE APIARY.

THE weather still continues cold, bleak, and sunless, with from 7° to 10° of frost on several mornings. It was the 2nd of April before a bee was observed with natural pollen, and the weather is so unfavourable to bees outside that I have deemed it advisable not to give peameal. Such adverse weather, so fatal to bees, is the reason I have so long advocated not to feed in the spring, unless in cases of absolute necessity, nor to make any alteration whatever of the hive wrappings. Let the temperature and the increase of bees be the factor to regulate these matters.

#### YOUTHFUL QUEENS.

It is only within the past year or two that the modern school relinquished the idea that queens were at their best when three years old, and this in spite of the fact that for perhaps centuries Scottish bee-keepers have kept no other queens for stocks than those of the current year, always destroying those bred in June and July of the previous year the following season. I have had four years old, and on one occasion had one (an Italian) which bred seven seasons, but that does not induce me to keep queens longer than twelve months. After that age, if the bee-keeper has managed them aright previously, they are practically worthless.

I scarcely, if ever, lost a queen under a year old, but have at least to the extent of 50 per cent. of those two years old, while at three few survived. Queens kept in hives too small for their capacity in egg-laying may do equally as well the second year of their life as in the first year; but that need not raise the contention that queens are as good the second as the first year, because if a queen is hampered in her laying the first year she will naturally be the better able to continue as good for another year.

But this is the great point of my argument. A hive of bees only half, or less than the size it should be, cannot possibly gather half the quantity of honey a full-sized hive with a youthful queen will yield. The foregoing has been written in answer to several queries, "C. R.'s" being one, but will be useful to others who still cling to antiquated ideas.—A LANARKSHIRE BEE-KEEPER.

#### SEASONABLE NOTES.

THE present is a very trying time for bees, as during the past fortnight the weather has been dull and cold. High winds, chiefly from the north, have been very prevalent; only once during that time, and then only for a few hours, was the wind in the south. Heavy showers of hail, sleet, and rain have been of almost daily occurrence, a great change from the bright, spring-like weather experienced in the early days of March. Bees were then flying in great numbers. Pollen was being collected freely from the early spring flowers. Chief among these were the Winter Aconite, Snowdrop, and Crocus, and later from the Palm Willow. This is one of the best early pollen-producing trees I am acquainted with, and, like all the Salix tribe, delights in ample moisture.

Bees will travel a long distance to collect the pollen from this variety, and it is really surprising the quantity they will secure even from a few small trees. If they can be planted within a few hundred yards of the apiary it is better, as during the early spring when cold showers are so prevalent, and bees when heavily laden with pollen are caught in a heavy shower before they can reach their hives, are beaten to the ground never to rise again. A great

number of bees are lost in this manner, which shows the advantage of having the flowers for providing the pollen planted within reasonable distance of their hives.

In the summer, after a heavy thunder shower, when the bees are working probably a mile or more from home and are overtaken by the storm, they are beaten down by the thousand; but at that time of the year the sun comes out bright and warm, the bees soon dry themselves, and are not much the worse for the mishap. Bees I have noticed are often weatherwise, as on the appearance of a storm they take wing homewards, and I have seen the sky quite darkened for a few minutes by the number of bees returning to their hives.

Great care should now be taken that none of the stocks suffer for the want of supplies, as all will depend on the spring treatment whether the bees are strong and in good condition to gather a surplus when the honey flow comes. The warm weather experienced in the early part of last month started the majority of stocks breeding freely, and unless they are kept warm and supplied with ample food they must eventually perish.

It is a great advantage to have a few frames of sealed stores on hand, and if any doubt exist as to a particular stock, turn the cover back for a few inches and take out the first frame or two, and then quickly draw the other frames back until reaching the cluster, insert the full frame, having previously uncapped a few inches of the sealed stores. This will keep them in good condition, and is much better than feeding with syrup or candy, as the less the bees are handled, particularly at this time of the year, the better. The next best plan is to insert a cake of soft candy under the quilt directly over the cluster, or if this is not available feed from the top of hive with thin syrup, which should be supplied warm in a bottle feeder. Any wide-mouthed bottle will answer the purpose. Tie a piece of muslin over the mouth. Cut a hole through the quilt large enough to admit the bottle, putting a piece of perforated zinc over the hole underneath the quilt on top of the frames, as this will prevent the bees escaping when removing the feeder, invert the bottle directly on the top of the quilt; the muslin will prevent the syrup escaping, and will allow the bees to satisfy all their requirements without any loss of heat.—AN ENGLISH BEE-KEEPER.

#### TRADE CATALOGUES RECEIVED.

Charlesworth & Co., Heaton, Bradford.—*Orchid List.*  
J. Veitch & Sons, Royal Exotic Nursery, Chelsea.—*General Plant Catalogue.*

\* \* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Rat Poison (R. B.).**—This may be procured from Messrs. Sanford and Son, Sandy, Beds.

**Sulphate of Iron (W. E.).**—The sample is what you suggest, and is similar to that which is used to some extent for agricultural and horticultural purposes.

**Chrysanthemum L. Canning (J. H.).**—This variety was raised by a Mr. Craig, and placed in commerce in 1888. In the National Chrysanthemum Society's official catalogue the name is given as at the head of this paragraph.

**Cucumber Disease and Various Remedies (T. J. G.).**—You will find instructions for using soluble phenyle on page 241, March 14th. It was again referred to on page 283, March 29th, in reply to "J. W." who promptly used it with satisfactory results. Sulphate of iron and kainit will be found advised to "F. W." in the present issue. Corrosive sublimate solution is referred to, and methods of using it described on

page 303, last issue. First try the phenyle. If you send your full name and address, repeating your other question, it will be answered by post.

Zonal Pelargonium Spotted (J. H. S.)—The leaf is infested by the spot fungus, a species of Glæosporium, which thrives in a confined and cold atmosphere and is retarded in a somewhat dry and comparatively warmer one. The plant should be carefully watered and not highly fed at the roots. This, with brighter weather and a freely ventilated atmosphere, will enable the plant to make new growths free from the malady, but those affected will retain the malformation.

Manures for Tomatoes (R. J. D.)—Steamed bone flour and muriate of potash are undoubtedly good manures for Tomatoes. Most strong soils contain potash; but there are exceptions, and where Clover grows freely there is potash in the soil. If you wish to grow Tomatoes in the same soil that produced a good crop last year you will not err in applying the manures named at the rate of a quarter of a pound to each square yard of surface, pointing it in not very deeply, but we should place a little fresh soil round the roots when planting.

Hardy Climbers for Trellis (C. W. H.)—If the soil and climate are suitable for Roses we think the Ayrshire varieties, Bennett's Seedling, Dundee Rambler, Queen of the Belgians, and Ruga would be sufficiently hardy. Clematises would also answer. C. Flammula is one of the rambling growers, but the flowers are not gay, and we see no reason why such effective varieties as Jackmanni, Rubella, and Star of India should fail. The Wistaria would grow no doubt, but it is a question if it would ripen sufficiently for flowering. Laburnums are good for covering arches, and beautiful when flowering freely.

Fungus on Pear Tree Roots (Constant Reader).—The Pear tree roots are badly infested by the clustered mycelium of a fungus, which is undeterminable from there being no "fruits," but it is probably Agaricus melleus, the form of it known as Rhizomopha subcorticalis. The fungus has probably been introduced in portions of wood, such as twigs, in manure, or by other means, for no treatment whatever will produce a living organism, for such is the perpetuation of pre-existent parents either by spores or mycelium. You may use the following for the destruction of the mycelium—Jeyes' fluid, one ordinary wineglassful to 4 gallons of water, or soluble phenyle at the same rate, both of which may be procured from any chemist, or through him at a few days' notice.

Grapes Scalded (J. S, North Wales).—The berries are badly scalded—a very unusual occurrence for so early a period of the season, and is probably the result of bright days following on the severe and dull cold weather. There is no disease otherwise, and it is likely that a little air constantly, with a rather warmer atmosphere than usual, would have prevented the scalding of the Grapes. It is a great pity, as the berries have stoned, and in the course of a few days would have commenced colouring, when they are quite safe from danger as regards scalding. After a period of dull weather great care is necessary in ventilating, this being done early and judiciously, so as to have the Grapes perfectly dry before the sun acts powerfully on the house, then the berries become heated equally with that of the surrounding air, and they cannot then be injuriously affected.

Spraying Muscat Grapes (Novice).—Some professional gardeners have found the syringe of assistance to them in setting Muscat Grapes, but we do not advise amateurs, or gardeners either, who have had no experience in the practice, to adopt it. They may try it, if they wish, on a few bunches, and note the results, but the overwhelming majority of the most accomplished Grape growers set their Muscats without syringing the bunches when flowering. Those who find the plan answer drive the water directly on the bunches about the middle of the forenoon, forcing off the liquid globules, we presume, that sometimes prevent the pollen from reaching the stigmas for the purpose of fertilisation. We know that some have succeeded with the syringing process, but others have failed, and therefore we advise the inexperienced to proceed cautiously and experimentally in the matter.

Tomato Plant Roots (N. W.).—The Tomato plant roots did not show any signs of attack from eelworm, nor were we able to detect any micro-organism on the underground stem—indeed, that part and the fibres appeared quite normal, and there is nothing to be alarmed about, so far as the roots are concerned. We should not use any disinfectant now, but follow on with the sulphate of iron and kainit, as advised in these columns on March 28, page 283, and as there is a deficiency of colour in the leafage, employ nitrate of soda occasionally, using ¼ oz. to a gallon of water, taking care not to overdo the plants with any of these solutions, nor make the soil sodden by unnecessary waterings. Indeed, it is better to use the chemicals as top-dressings, and for your plants you should employ a mixture of 5 parts superphosphate, 2 parts kainit, 1 part nitrate of soda, and ½ part sulphate of iron, crushing the nitrate of soda, mixing thoroughly, and using from 4 to 6 ozs. per square yard every fortnight or three weeks; or, if quite vigorous enough, at more distant intervals, say every month or six weeks, whilst increasing the amount of nitrate of soda if more vigour is required.

Black Hamburg Vine Leaves Deformed (J. H. S.).—The Vine leaves are suffering from "browning," a disease caused by a so-called fungus, but really a myxomycetes—namely, Plasmodiophora vitis, which by some means (inexplicable without illustrations of a very intricate character) passes from the roots to the leaves when these are about the size of a crown piece. It arises from the spores of the

myxomycetes, which, as zoospores, form a plasmodium, and with amœba-like movements, passing from place to place in quest of food—from the roots to the leaves. The object is to prevent it, and that may generally be effected by dressings of lime to the border, which we advise to be given with as little delay as possible, employing about half bushel per square rod, and pointing in lightly. The Plasmodiophora has an abhorrence of active lime, also of corrosive sublimate, a terrible poison, and should not be used upon the foliage, but it may be used at the roots at the rate of 1 oz. to 30 gallons of water. We advise the lime as the safest and most desirable application. Admit air carefully and early, as a close atmosphere encourages the parasite, also a rich and wet condition of the border.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (R. T. B.)—1, Streptosolon Jamesoni; 2, Clivia (Imantophyllum) miniata, good variety; 3, An Amaryllis, varietal name undeterminable, except by comparison in a large collection. (C. C.)—1, Saxifraga Boydi; 2, Primula rosea; 3, Daphne Mezereum album; 4, Primula cashmeriana; 5, Cypripedium calceolus; 6, Dielytra spectabilis. (G. H. A.)—1, Lycaste Skinneri; 2, Cattleya Trianae delicata; 3, Phaius grandifolius; 4, Angraecum sesquipedale; 5, Dendrobium nobile nobilius. (Oaks).—The specimen is an Iris, but too withered for us to say what variety or species. Send fresh specimen.

GARDENERS' CHARITABLE AND PROVIDENT INSTITUTIONS.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—Secretary, Mr. G. J. Ingram, 50, Parliament Street, London, W.C.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—Secretary, Mr. W. Collins, 9, Martindale Road, Balham, London, S.W.

ROYAL GARDENERS' ORPHAN FUND.—Secretary, Mr. A. F. Barron, Royal Horticultural Society's Gardens, Chiswick, London, W.

COVENT GARDEN MARKET.—APRIL 10TH.

MARKET very quiet, with prices practically unaltered.

Table with columns for FRUIT and prices in s. d. for items like Apples, Lemons, St. Michael Pines, and Strawberries.

Table with columns for VEGETABLES and prices in s. d. for items like Beans, Beet, Carrots, Cauliflowers, Celery, etc.

Table with columns for AVERAGE WHOLESALE PRICES.—OUT FLOWERS.—Orchid Blooms in variety and prices in s. d. for items like Arum Lilies, Azalea, Asparagus Fern, etc.

Table with columns for PLANTS IN POTS and prices in s. d. for items like Arbor Vitæ, Aspidistra, Azaleas, Cinerarias, etc.

## MANGOLDS.

ABOUT the middle of April being the best time for sowing this useful crop, which is now known under the designation of Mangels, we desire to call attention to its cultivation, use, and true place in the economy of farm management. Many a time have we been asked whether it is better to sow it on ridges or on the flat. We have answered, with a full knowledge of the common opinion, that there should be ridges for a humid climate, and no ridges for a dry climate; that where enough farmyard manure can be had there should be ridges; without it, and with only chemical manures, ridges are not required. Now as to climate. In this matter we are bound to say that in the dry climate of East Anglia, at half a dozen farms in different localities wide apart, we have invariably sown on ridges, for the simple but important reason that we always use enough farmyard manure in the furrows to hold and supply the young plant with moisture. We regard this point of culture as so important that enough of such manure is always held in reserve for this, the best, most useful, and most profitable of all root crops.

The furrows are opened with double-breasted ploughs, on clean land, 20 inches apart, our aim being to have a full crop of medium-sized roots in preference to large or very large roots. Keeping this well in view, we never allow the maximum distance of 30 inches apart except on foul land in process of being got clean or free from perennial weeds. Then, and only then, is it desirable to have the extra 10 inches of space between the rows for a longer use of the horse hoes than is possible at 20 inches. We may explain that with the wider spaces between the rows, however vigorous the growth may be, the leaves are much longer in meeting across the space, and hoeing is possible, and in point of fact is done for a proportionately longer time. The furrows in either case are made deep enough to contain a layer of farmyard manure 6 inches in depth, and for the manure to be well covered when the ridges are split and the furrows closed in readiness for the sowing of the seed.

Before splitting the ridges a dressing of 3 or 4 cwt. of common salt is given broadcast, and with the seeds some chemical manure is drilled. Recipes for this differ widely; 2 cwt. of mineral superphosphate, 2 cwt. nitrate of soda, and 1 cwt. muriate of potash is an excellent mixture for the seed drill; later on after the plants are singled, have been hoed once, and are growing freely, another cwt. or even 2 cwt. of nitrate of soda may be profitably applied as a top dressing. The expenditure may appear extravagant, but it is entirely justified by results. Be it understood, however, that an excellent crop of Mangolds can be had without a top dressing of nitrate of soda; its use points to super-excellence—an extraordinary weight of crop per acre.

Very puzzling would our advice to drill manure with the seeds be to farmers whose knowledge of drills is confined to heavy seed drills pure and simple. We use a light American drill having separate seed and manure boxes, so contrived that the manure and seed pass to and through the coulters together, and so enter the soil in the groove or drill made by the coulter. We have so drilled manure with this and other seeds and all kinds of corn for many years with safety and success. The common fear that salt brought in contact with the seeds involves risk of harm during germination, being evidently groundless. It is obvious that in the process of drilling, seeds and manure become

mixed with the soil and separated sufficiently to prevent harm. The soil is thus so stored with fertility that the roots have abundance of sustenance from the very outset. The growth is free and robust after the speedy seed germination which early sowing makes certain.

The soil has ample moisture, is rich in fertility, and as the roots strike downwards they lay hold of the farmyard manure, and thenceforward have a practical immunity from drought. More than this—much more—there is no check to the growth, which goes so briskly on from seed germination to the clearance of the matured crop from the land that the storing of the roots can always be done early, while the surface is so firm that carting is light, and there is no risk of harm from frost. For every reason then let the sowing be done early; if it is done well too, in the manner we have indicated, there will be a full plant and a profitable crop.

## WORK ON THE HOME FARM.

March went out with a last week of stormy weather, its rough winds being greeted by April showers, which did much good to the young plant of spring corn. But growth was checked by cold dry wind and sharp frost during the first week of April. In the north midlands the house tops were white with snow on the morning of April 4th, and on the following morning 7° of frost were registered. Though growth has been checked in cornfields and pastures, work on the land has gone briskly. We have seen some delightful seed beds, with the tilth so fine and deep that success was a certainty in the earliest stages of crop growth.

Mangold sowing is being pushed on with more than ordinary expedition, and we shall soon be ready for sowing the first crop of Swedes and white Turnips. A field of arable land which has fallen in hand this Lady Day will be at once sown with Oats and a full dressing of chemical manure. The American Excelsior drill is a most handy implement at all times, and is especially so at this busy season of the year, for sowing corn and manure together, or for sowing light seeds alone, such as Clover, mixed grass and Clover, Lucerne, Sainfoin, and similar seeds.

Vegetable and fruit farmers are now very busy. Potato planting is being pushed briskly on, hand and horse hoes are going daily in the Strawberry fields, Raspberry pruning has only recently been finished, and the moulding plough passed between the rows on many a farm, owing to the hindrance to such work by the very late and severe winter weather in February. The manner in which Broccoli in open fields has recovered from the effects of 20° of frost is simply marvellous. No doubt the excellent plan of earthing the stems right up to the leaves in autumn is an excellent preservative. This is done admirably by one turn of the double-breasted plough between the rows, and then though the outer leaves become so browned by frost that the plants appear to be dead, stem and centre are unaffected, the crop is safe, and it is then certain to prove remunerative. The aim appears to have sturdy plants of moderate size, so well protected by soil and a dense growth of leaves as to be practically safe from frost.

## REMARKS.

- 31st.—Heavy rain at 1 A.M., sunshine all day.  
 1st.—Generally sunny till 3.30 P.M., then rain till 4.45 P.M., and large soft hail at 4.15 P.M.; fine after.  
 2nd.—Overcast morning, with frequent spots of rain early; occasional gleams of sun in afternoon.  
 3rd.—Overcast morning; sunny afternoon.  
 4th.—Slight rain and flakes of snow early; sunny at times in morning; overcast afternoon.  
 5th.—Fine, with occasional sunshine.  
 6th.—Overcast day with a shower at 1.30 P.M.  
 Temperature has fallen a little, but is in no way remarkable.—G. J. SYMONS.

**STRAWBERRIES.** Special low quotations for quantities for market growing. In small pots for fruiting first year. Open-air runners very cheap. All the leading varieties, new or old.

**FRUIT TREES**  
OF ALL KINDS. SEND FOR LIST.

**JOHN WATKINS,**  
Pomona Farm Nurseries,  
WITHINGTON, HEREFORD.

**2/6 LOOK! LOOK! 15/-**  
per doz. **100,000 HARDY PLANTS** must be cleared, per 100.  
viz:—*Achillea mongolica*, *Armeria bracteata rubra*, *Anthericum illiastrum*, *Campanula grandis*, *Centaurea montana alba*, *Delphinium grandiflorum* in var., *Dianthus deltoides*, *Doronicum Harper Crewe*, *Geum coccleum*, *Hemerocallis flava*, *Heleium omnillum*, *Potentilla* in var., *Phlox* in var., *Saxifraga ouncea*, *Trollius europæus*, *Thalictrum adiantifolium*; six for 1s. 6d.; twelve, 2s. 6d.; 100, 15s., free.

**LOGAN & CO., CHAD VALLEY, BIRMINGHAM.**

**ECKFORD'S SWEET PEAS**  
(58 Varieties). The greatest triumph in the floral world of to-day. "Lovely colours," "exquisite shades," "delightful fragrance," immense size. Don't miss the new giant white "Blanche Burpée," sealed packets, 1s., post free.

"ECKFORD'S CULINARY PEAS" are undoubtedly the finest quality in the market.

Send for Descriptive Catalogue and Cultural Notes, free from  
**HENRY ECKFORD, WEM, SHROPSHIRE.**

**FERNS** A SPECIALITY.

We have an immense stock of all kinds of Ferns, Stove, Greenhouse, Filmy, Hardy Exotic, and British, including many very beautiful varieties, rarely seen but which ought to be more generally grown. Catalogue free on application.

**W. & J. BIRKENHEAD, F.R.H.S.,**  
FERN NURSERIES, SALE, near MANCHESTER.

**FLORISTS' FLOWERS**  
AND  
**HARDY BORDER PLANTS.**

FORBES' NEW CATALOGUE for 1895 is enlarged to about 150 pages, and very materially improved, embracing everything—new and old—worth cultivating in the way of **FLORISTS' FLOWERS** and **HARDY PLANTS**, with accurate descriptions and prices. Copious notes as to their origin, how and where best to grow, a full index of the common or popular names of **HARDY BORDER PLANTS**, and a vast mass of other valuable information that cannot be had elsewhere, which renders this the **BEST, MOST RELIABLE**, and **COMPLETE CATALOGUE** ever issued on this popular class of plants. Free on Application.

**JOHN FORBES, Nurseryman,**  
HAWICK, SCOTLAND.

**JACK FROST**

Has caused many losses that can be made good in an easy and cheap manner by purchasing the following Bulbs and Plants, which I can strongly recommend as being first class:—

**BEGONIAS, SINGLE,**  
20,000 Grand Bulbs, Mixed Colours, finest ever offered at the price. 3s. per dozen.

**PELARGONIUMS, SHOW & DECORATIVE.**  
Fine Plants in Best Kinds, 6s., 9s., and 12s. per dozen.

**ZONAL PELARGONIUMS,**  
Best Kinds only. 6 for 2s. 6d., 12 for 4s.

**IVY-LEAF PELARGONIUMS.**  
A very Choice Lot. 6 for 2s. 6d., 12 for 4s.

**DOUBLE PETUNIAS,**  
Extra fine New Kinds. 6 for 3s. 6d., 12 for 6s.

Send for Catalogue, Free.

**H. J. JONES,** Ryecroft Nursery,  
HITHER GREEN, LEWISHAM.

**DANIELS BROS.**  
TOWN CLOSE NURSERIES,  
NORWICH.

**TUBEROUS-ROOTED BEGONIAS**  
(CARRIAGE FREE).  
We have much pleasure in offering fine Flowering Tubers from our grand strains as below:—

**DOUBLE-FLOWERED.** Per doz.  
Choice named varieties, including some magnificent flowers .. 35s., 40s. & 50s  
Extra Choice varieties for Exhibition, carefully selected, a grand mixture .. 24s. & 30s.  
For Pot Culture, splendid varieties of the most beautiful form and colours .. 12s. & 19s.  
Mixed Doubles for Bedding, a capital variety of good double flowers. Per 100, 40s. .. 6s.

**SINGLE-FLOWERED.**  
Extra Choice Exhibition varieties, immense blooms of the most beautiful colours and perfect form .. 18s.  
For Greenhouse and Conservatory, a very choice mixture of carefully selected flowers .. 9s. & 12s.  
For Pot culture, beautiful selected varieties. Per 100, 40s. 6s.  
Choice mixed Seedlings, all selected and approved flowers, splendid for bedding. Per 100, 25s. .. 3s. 6d.  
From Mr. R. G. MILNE, Gardener to the Earl of Minto, Aug. 2.  
"I am glad to say the BEGONIAS have done splendidly; they are by far the best strain we have. They were greatly admired by all that saw them."  
From Sir R. DICK CUNYNGHAM, Bart., Cheltenham, Oct. 6th.  
"On my return home, after a long absence, I am much pleased to find the bed of nearly four hundred BEGONIAS still full of flowers. The double ones in the house are a show for colour, size and beauty of shape."

**CHEALS' Celebrated DAHLIAS**

WORLD-WIDE RENOWN · STRIKING NOVELTIES  
NEW CATALOGUE POST FREE

*J. Cheals & Sons, SUSSEX*

**THE NEW STRAWBERRY, STEVENS' WONDER.**  
The most Prolific and Finest Strawberry grown. Solid Fruit. Good Flavour. High Perfume.  
Awarded First-class Certificates Royal Horticultural Society and Royal Botanic Society, 1895. See *Gardeners' Chronicle*, March 2; *Journal of Horticulture*, March 14; and *The Garden*, March 16.  
Good Rooted Runners, £3 100; Established in 3-in. pots, £5 100. Plants ready early in August. Orders in rotation; stock limited. Terms—Cash with Order.

**J. R. STEVENS, Clayton Nursery, HASSOCKS.**

**CHRYSANTHEMUMS**  
FOR EXHIBITORS.

Thousands of sturdy plants in 3-inch pots just ready for moving. Struck cool in single pots. The plants may be depended upon for best results, which can never be done with those struck in heat.

CATALOGUE FREE ON APPLICATION.

**J. R. PEARSON & SONS,**  
CHILWELL NURSERIES, NOTTS.

**ROSES! ROSES!**  
THE BEST AND CHEAPEST IN THE WORLD.  
GREAT CLEARANCE SALE.

All have been kept moved back, and will plant now with safety. 24 Choice Standards, 21s.; 26 Half-Standards 21s.; 12 Standard, 12s. 6d.; 12 Half-Standards, 10s. 6d.; 50 choice dwarfs, 21s.; 12 choice Climbing, 6s.; 12 best Hybrid Perpetuals, dwarfs, 7s.; 6 lovely yellow Roses, 4s. 6d.; 6 Gloire de Dijons, 4s.; 6 choice Moss Roses, 3s. 6d.; 6 old Cabbage Roses, 3s. 6d.; 6 old-fashioned Roses, 3s. 6d.; 6 pink Monthly Roses, 2s. 6d.; 6 quick-growing Climbing Roses, 2s. 6d.; 12 Sweet Briars, 3s. My selection, cash with order. Thousands of Testimonials.

**PREPARING FOR OLD AGE.**

"OLD age pensions," and how to provide them, is what may be termed a popular problem of the day. A puzzling problem, too, to many, for not a few are laudably engaged in its solution, but yet little real progress is made. Nor is it likely to be made until the great mass of the people rely less on what others may do for them and more on their own endeavours, in conjunction with some great organisation yet to be devised, based perhaps on small, or not too heavily felt, deductions from wages after the manner of the new scheme of the London County Council, which has just come into operation. It is entitled a "Superannuation and Provident Fund," and some 700 men of various grades employed in the parks and open spaces became participators in it; indeed it is a condition of their employment that they do so except in the case of any of them being already entitled to pensions under arrangements made prior to the parks coming under the control of the Council, or who can prove to its satisfaction that they have otherwise insured themselves to meet the adverse contingencies of life to an extent that will secure to themselves substantially the same benefits as they would be entitled to as contributing members of the newly established fund. This is not a mere pension fund, but may be something a good deal better, as under the pension system a man may struggle on under physical infirmity to the requisite age for retiring, "enjoy" his pension for a few months or a year, then die, leaving, it may be, a widow penniless on the world.

The arrangement now completed under Parliamentary powers consists in every member having 3l. deducted from every 10s. of salary or wages, or part of 10s. Thus, a man earning between 20s. and 30s. a week will leave 6d. behind; between 30s. and 40s. will leave 9d.; a man having £2 and less than £2 10s. a week, 1s.; and so on. Whatever the sum may be the County Council adds an equal amount; for instance, if a man's deductions amount to £2 12s. a year, the sum of £5 4s. will be invested for him, and he will be entitled to 3 per cent. interest on it and all amounts similarly contributed and added from year to

year and on the interest accruing, or, in Sir John Hutton's words, "for every sovereign contributed in the form of wage deductions the Council adds another sovereign and allows compound interest on both."

Each member has a separate account, and is entitled to have a copy of it annually in order that he may know the exact amount standing to his credit; but this amount is divided into two parts, one showing the member's contributions and interest thereon, and the other the Council's equal additions and interest accruing. This was rendered necessary on Parliament declining to agree to the Council's proposition to exempt the whole of the fund from the hands of a creditor. The public (added) money was thus not unnaturally protected, but not the members' contributions. This division of the fund, however, affords a means of differentiating in the repayment of monies to members under specified conditions, and which do not appear to be otherwise than reasonable and fair.

The prime object of the scheme is to provide a superannuation fund for workmen (and women) who have spent the best years of their life in the service of the Council and then retire, or who have to do so through illness at any time. In these circumstances the whole amount of the accumulations of both parts of the fund is to be paid to the member by cheque, or in the form of an annuity, as he may prefer; but if a member only works for the Council till he finds a better position, and retires on finding one, then only the amount of his own contributions, with interest, is paid to him—not any public money; and similarly, any member leaving the service of the Council through reductions or alterations in the establishment receives his own money with interest only. There is still another very important, and also a very proper proviso, to the effect that if any member is discharged through fraud, dishonesty, or misconduct, involving pecuniary loss to the County Council, or who retires to avoid conviction of such misdeeds, he loses his right to anything; but the Council may, in its discretion, make such repayments as it thinks fit, according to the circumstances of the case.

On the death of a member who is entitled to the benefits of the fund the full amount of his contributions and the Council's additions, with interest on both, will be paid to his representatives, and members have absolute power to dispose by will of all monies payable under the scheme. The County Council defrays all the expenses of management, and guarantees the full amount of all payments due to retiring members or their representatives under the rules provided for the management of the fund.

In the parks department, with which our readers are more particularly interested (and it is doubtless the same in others), there is an evident desire to raise the status of the men employed. Only men who have had good training in gardens, and who can present testimonials of competency and unblemished character can now obtain positions on the permanent staff. This is entirely as it should be, but is not as it always has been. The loose methods of the past led to the employment of men who were not gardeners, and to some who were neither useful nor ornamental, and it is a matter of surprise that the superintendents have done so well as they have in rendering the parks so enjoyable, considering the many crude and careless helpers which have found their way into positions which they were never qualified to fill. A change is being gradually effected, and it would seem as if the policy of the authorities was to obtain the services of the best men available, and to make their positions worth keeping. To this the just and generous scheme, which came into operation on the first day of the present month, will directly tend, and London will be eventually the gainer.

How glad would many gardeners be in various parts of the country if they could feel themselves firmly settled in their positions, and contributors to a fund so safe and so certain to be beneficial as the one in question is sure to be to those who are members in virtue of the positions they occupy. The nearest

approach to it of anything in the gardening world is the splendid Society much overnamed, and by far too many underrated, the "United Horticultural Benefit and Provident Society." It is a pity its name cannot be shortened, and its members increased a thousandfold, for it is one of the safest, soundest, and best of provident societies open to gardeners in all parts of the kingdom. If a thousand proprietors of gardens could see their way to deduct say 6d. a week from the wages of their gardeners, and add another 6d. or even a guinea a year of their own, they would set the ball rolling in a good direction, and obtain and retain the services of good, steady, prudent men, who would work the more cheerfully through the provision thus made for the demands of the future.

### EXPRESS GRAPE GROWING.

YOUR article in last week's issue of the *Journal of Horticulture* on page 305, and the accompanying photograph on page 315, under the above heading, must prove an interesting subject to many who still hold adverse views on the early cropping of Vines, and which certainly ought to convince many gardeners of great ability who still cling to the old theory, that a Vine must of necessity have a few years to become sufficiently established before it is capable of producing a crop of first class Grapes. From my own experience I have proved that Vines are capable of producing enormous crops of Grapes at an early stage of their existence under good management.

It may sound somewhat egotistical on my part to give you my own practice and experience, but I trust that it may be the means of encouraging some at least to leave the old beaten track, and try the newer method, which I and many others have proved to be sound. I have planted Vines in nearly every month in the year with most satisfactory results, but to enter into details would be impossible without trespassing too much on your valuable space, and I will therefore in the meantime confine myself to one particular case.

In the month of July, 1887, we erected a lean-to house, 72 feet by 16 feet, and planted it the following month (August 11th and 12th) with Vines raised from eyes in the month of March of the same year, and it may surprise some to know that the Vines were allowed to remain in the 3-inch pots in which they were rooted; many of them were not more than 18 inches in length, and certainly not stronger than a good straw. Many will condemn this as bad practice (so do I), as the Vines should have received better treatment. Well, the fact of the matter was simply this. We did not contemplate building this house until the following season, but after the Grape-thinning was completed a stable and other outbuildings had to be erected, and the vinery was run up at the same time, and planted with twenty-eight permanent Vines (Muscat of Alexandria), along the front. A row of supernumeraries was planted 6 feet from the front and carried up to the wires, and the same number on the back wall, and by the end of the season the whole house was completely covered with abundance of splendid well-ripened wood.

The permanent Vines were cut back, leaving about 7 feet of cane, and the supernumeraries were in some instances left nearly the whole length of the rafter according to the strength of the canes, and the Vines on the back wall treated in a similar manner.

The Vines were allowed to start into growth in the month of March. The following year, 1888, the whole broke strongly with the exception of three or four of the Gros Colman, which did not break so evenly at the base. The permanent Vines were allowed to carry seven bunches each, the Colmans (supernumerary) ten and twelve bunches each. Muscats were all cut in the month of September for market and exhibition, and averaged 2½ lbs. per bunch. The Colmans, requiring a little longer time to finish, were allowed to hang another month, and weighed 1½ lb. on an average. These Muscat Vines have borne heavy crops of Grapes every year since, and to-day they are in splendid form and as promising as ever. Thus in thirteen months from the time of planting, and nineteen months from the time the eyes were rooted, these Vines carried and finished well a heavy crop of fruit.—W. INNES, *Derby*.

### EMPLOYERS AND GARDENERS.

(Concluded from page 307.)

EMPLOYERS, of course, are subject to the same natural variations of temperament and natures as gardeners, and I am aware there are many cases in which the gardener has nothing to complain of. Still, there are others where the lot of the gardener might be much

happier if the employer would only try to do what is just and right. In some instances no doubt it occurs more from want of giving the case attention than from any desire to act unfairly, but it should be a very important matter to an employer whether his servants are happy or not. Some employers have a rather queer conception of what a gardener should be; even in what we call good places this peculiarity is often evident. For instance, a glance through the columns of our papers will reveal the fact that a gardener should never exceed forty years of age; he should always be married, but seldom is he allowed the privilege of having a family. Now, it has been my good fortune to meet some excellent gardeners over forty, and also married men with families, whom the most particular person might venture to live within a few hundred yards of. Then, again, there are those who want men thoroughly well up in their calling to make themselves generally useful—not object to a cow. I have no objection to gentlemen trying to secure the services of such men; it is no doubt necessary that they should have all this work done by one pair of hands, but I do object to all sorts and conditions of general men servants being called the gardener. The term gardener in this case covers a very wide area, and at the same time I know there are many good gardeners who are through no fault of their own compelled to fill these kind of places. Yet in many instances the title is altogether misleading, for amongst their many duties the garden is often the very last to gain their attention. Did you ever hear of a butler being wanted who could milk, a gamekeeper who could drive a pair, a coachman to do his own shoeing, or a farm bailiff who could wait at table? I have not, and it seems to me rather hard lines on the avocation, to give men (excellent men they are no doubt, and I have nothing but good to say of them in the manner which they manage to get through their difficult tasks), whenever at a loss for a name, the title of gardener.

Perhaps gardeners are, to some extent, answerable for this state of things, for I know of no class of men so willing to give away to the first applicant what has cost them years of study to obtain. They are anxious to circulate their knowledge, and no one hesitates to ask a gardener how he grows such a plant, feeling aggrieved if not told. It is not so in other walks of life. Who would be brave enough to ask his doctor to tell him, after an illness, what medicine he used, so that in future he could doctor himself? No doubt in many cases this freedom of giving information has done good to gardeners, but still I think it has also been the means of overstocking the market with a certain class of men who pass as gardeners.

Another duty of an employer is to provide his gardener with the necessary convenience for producing what is required. It may be said, Surely he will have the common sense to see for himself that unless he does so he cannot expect it? Yet I am afraid there are but few gardeners who are quite satisfied on this point. The employer sees exposed for sale, at all seasons, and in the greatest profusion, fruit, flowers, and vegetables, and often goes home dissatisfied with his own gardener. But if he would visit the places where this produce comes from, in most cases each particular kind being grown by a specialist, and who has the very best appliances for producing the same, he would probably consider his own man cleverer than he had any idea of.

A garden is looked on by many persons as a luxury, and must be endured if they are to be considered fashionable. No doubt it is a luxury; in fact, there are few things that are not. Gardeners are expected to produce these luxuries, and so long as they do so to the satisfaction of their employers, the cost of so doing ought to be credited to them as in any other business. The plants grown for decorating the house and grounds, all requiring special care, the demands of the household down to the cook, mean an amount of time and trouble that would astonish many an employer, could the gardener charge for it at the same rate as the general furnisher.

In these advanced times the question of shorter hours of labour has had the consideration of many of our leading men, and even of our law makers, but although most trades have to some extent benefited by it, gardeners have had few concessions. Why it should never have been thought necessary for them to have a few hours in the week to indulge in recreation as well as the tradesman I do not know, for I think of the two the gardener is more deserving. If a tradesman works overtime he is paid for it, and surely the gardener, as some set-off against the extra time he puts in—Sunday duty and fires, for instance—might be allowed a half-holiday once a week. For want of combination gardeners are not in the same condition to press their wants as other classes, and employers would in most cases be amply rewarded if they were to grant some small concessions on this point without being asked for them.

An employer should also satisfy himself that the dwelling places on his estate are what they ought to be. I am well aware

great improvements have been made in this respect, but much yet remains to be done. There are many cottages and bothies which to live in may mean to the occupant anything but comfort, and which, if not owned by influential persons, would soon be condemned by the authorities as an abomination.

The employer should also pay his gardener a wage he is satisfied will keep him and his family in comfort and respectability, for he is expected to have a respectable appearance, which is often a very difficult task. The supply will, no doubt, always regulate to a great extent the wage question. But I would ask, Is it just to pay a man the very lowest wage he can be had for? Before a man can expect to secure a fairly good situation he is expected to know a great deal. He should be blessed with a good education, be well conversant with all the latest ideas connected with his calling—a calling so deep and complicated, that although the oldest on record, not the most clever and scientific man who has ever lived has been thoroughly able to bottom—and what is his recompense? Why in many instances he is offered a wage at which many a bricklayer's labourer would turn up his nose.

In conclusion, I would remark that employers should also remember that servants are, like themselves, human beings, not mere machines. I am afraid in some instances the machine is taken the most care of, for of course the man's place can be filled at a less cost than a new machine, the greatest care being taken that the machine is not taxed beyond its power. The human being, on the other hand, has no dial whereby to see the amount of pressure going on in its workings, except his appearance, which unless very closely observed is not noticed. The pressure is kept increasing as necessity demands, until it is suddenly discovered that there is a limit to even man's endurance, often too late. Then comes, "Poor fellow! I had no idea he was so bad." Why? Because they had not taken the trouble to watch the indicator.

It would have been much better had the employer taken a kindly interest in the welfare of his servant. To thaw, as it were, some of those icy appearances which cause a sort of keep-your-distance feeling to creep over the servant, to make him look forward with pleasure to your approach, and not with dread, as though something was going to happen to him.

I may perhaps have said a few hard things in this paper, but I can assure you that to those to whom they may apply had I the power I would hit still harder. To those who are not offenders under any one of my indictments I feel confident that my humble efforts to bring others to their way of thinking cannot help being appreciated.

To the well doing of both classes I would say, All honour to them, and may their good example be copied by the remainder, to the mutual benefit of all, and to remember that the world, and the good and beautiful it contains, was made for all.—GEORGE WILSON, *Svanland Manor, Brough*.—(Read at the *Hessle Gardeners' Mutual Improvement Society, March 12th.*)

## SOWING AND HOEING.

DAYS of bright sunshine have come at last; the trees are bursting quickly into leaf, lawns have again assumed the rich green verdure of the spring, and the upturned soil once more dries and crumbles ready for the sower's work. During the last week or ten days I fancy more seeds have been sown in the kitchen gardens and allotments of Britain than the same class of cultivators have sown during a corresponding period for at least a quarter of a century. Since the great frost broke up there has been so few opportunities for seed-sowing in the open air, that in some districts nothing in that way has been attempted. Our experience this year will perhaps give us some idea of the "rush" of work during a Canadian spring, where the ground has to be prepared and the bulk of seeds sown within the compass of a few weeks.

Next in importance to the work of seed-sowing during the spring months is that of doing all in our power to forward advancing crops by frequently stirring the soil. After the long winter and cold early spring the ground is still wet and cold beneath the surface, and every advantage ought to be taken of sunny days to improve matters in this direction, and at the same time to impart more abundantly to the soil that active agent of fertility—the nitrogen of the atmosphere.

The immense benefit which growing crops derive from the practice of frequently stirring the soil has been amply demonstrated by both practical and scientific horticulturists. The prentice hand of an extensive garden, or the town worker who for the first time has taken up the task of allotment culture, each quickly find out how rapidly plant life grows where this continual stirring of the soil is persistently followed up; but all of them do not perhaps know the reason why this is so.

Here the scientist steps in, and tells them that this desire

state of affairs arises from two causes. In the first place because when the soil is loosened it is penetrated and warmed by the sun-heated atmosphere. Not only does this take place on the immediate surface, but the air forces itself to a considerable depth, carrying with it that necessary element for the promotion of quick growth—nitrogen, which is ever present in the atmosphere, and made available in the soil in the form of nitrates, through the agency of Bacteria, for the use of plants. The worker who is acquainted with these established facts must, I think, carry out his work with greater zest, because he knows how great is the sum total of good he is doing with the outlay only of pleasant labour.

With these thoughts (which may prove food for further reflection) passing through our minds, let us during the prevalence of the welcome sunshine ply our hoes in earnest among all growing crops in the kitchen garden; let there not remain an inch of ground unstirred, except it be in the seed beds, where we might stir up our crops as well. Here we must wait till the young seedlings appear: but, when they can be clearly discerned, the sooner the hoe is run between the rows the better. We have lately been plying the hoe frequently between our Cabbage plants (which have fortunately come through the winter well), and the way in which they show their approval of the timely attention by the rapidity of their growth, gives birth to feelings of satisfaction; indeed, the daily survey of a good Cabbage bed during warm spring weather may be reckoned as one of the "delights" of gardening. Our labours, however, have not been confined to the kitchen garden. Rose beds have been forked up, and the dry crumbling soil is being sweetened and enriched ready for the time when the strain comes by-and-by.

The occupants of herbaceous borders and flower beds are also springing into life with a rapidity by no means anticipated a few weeks ago. Hyacinths and Tulips in exposed positions are just unfolding their beauty, while those in more sheltered places are already beginning to fade. Beds of Silene and Violas have the surface soil stirred once each week, so as to bring them into flower simultaneously (or as nearly as possible so) with Aubrietias and Myosotis. I find much can be done in this way to regulate the time of flowering of the various plants used for spring bedding. The great aim of course is to have as many beds as possible in full flower at the same time. Whenever any particular bed is backward in growth the soil is stirred more frequently, often twice a week; on the other hand, in beds in which the plants are far in advance of the majority the soil gets but little stirring.

Then again after severe winters there is great irregularity in the growth of plants of the same species and varieties, and unless special attention is given this means a want of uniformity in the plants when in flower. In such instances I make a practice of watering weakly grown plants, then stirring the soil next day. By persisting in this simple practice so much may be done towards securing well-balanced growth.—BRASSICA.

## BOTHIANA.

"The youth who hopes the Olympic prize to gain  
All arts must try and every toil sustain."

PRACTICAL experience of bothy life and those who dwell in bothydom, with the important bearing this phase of a young gardener's life has on his career, induces me to think that an article upon it may prove of interest to him now, and of service hereafter. The bothy oft makes or mars a man. The youth freed from home ties, anxious to do well, equipped by thoughtful friends with some good books and much good counsel, may, with these and other advantages, still look back in after years and sigh for those opportunities which this period of life affords, and which have failed to impress their importance on him at the time. In this paper—or series of papers—I shall endeavour to supply a want felt by me years ago when treading the same critical stage of life's journey, a want which is not quite met by the best existing garden literature, nor by those valuable aids written for the students of other professions. We elders may have much or little to thank our mentors for, but it is our duty to save the younger generation some vain regrets when in the fulness of time are heard those

"Voices of the past, links of a broken chain,  
Wings that can bear them back to times  
Which cannot come again."

At the starting point of our journey, on which I hope we may travel together for some distance pleasantly and profitably, I need scarcely ask, Have you duly considered this path of life leading to the "Olympic prize?" Trusting that you have; that it has been to you a matter of that serious consideration it deserves; that your

heart is in the work undertaken by your hands, which cannot otherwise but be one of drudgery to end in disappointments, you have now some reason to ask when taking but a cursory glance at the present position of gardeners, with the concomitant evils resultant from overcrowding, what is this prize you are striving for, and for which so many are competing? You will probably substitute for the laurel crown of the youthful athlete the position of head gardener in a first-class establishment. Such you may at least hope for, and for such you must qualify. Yet the thought cannot but force itself on your mind that there is more than a slight danger of failure; so many good men apparently miss the prize. Apparently I say, for there is another and a higher interpretation of this prize of life which is your prerogative if you so will it. It is within your reach, and once grasped no man can take it from you. At the conclusion of these papers I hope to have thrown sufficient light to dispel the mists which may at present obscure it from view.

Too often do we hear of "lucky" men or *vice versâ*. Beware! This luck is the illusive offspring of fraud. Do not believe in it. It is a "will o' the wisp" luring to apathy. Banish it out of your theory of life, and substitute for it energy and perseverance.

## THE START.

You are now the new comer in the bothy. School days are gone for ever—possibly have for some time been a thing of the past. The despised school books, much dog's eared, a little tear-stained, are, I trust, in your box. It is for you to discover voluntarily that they are old friends with new faces, whereas compulsory attention previously has resulted in some enmity towards them, mingled with a little contempt which still lingers. With us, who must perforce make an early start in the battle of life, school days too often end where (figuratively) they should begin. The mind is now able to grasp, to analyse, and to perceive various truths, hitherto but partly revealed to the boy of tender years. One hour of quiet study in the bothy is worth more than a weary day dragged out on the school form. As a preliminary course of self-tuition these partly forgotten, imperfectly understood lessons, will serve to refresh and invigorate your mind. We are too apt to accord but the intrinsic value attached to such lessons, and overlook their worth as mental tonics. Moreover, "Do not pull down the scaffold poles till the building is complete."

Doubtless you have brought to your new home many good intentions and some vague ideas of profitably employing this spare time the bothy life affords. But you think it best to keep these in abeyance till a better acquaintance is made with your new comrades. If they happen to be studiously inclined, well and good, but should the reverse obtain some courage is required to overcome the diffidence ensuing. "It is the first step which costs." Here is the first, and perhaps the most serious obstacle you will have to encounter, and one too on which many good intentions are wrecked. Without waiting to see how the land lies, sail into the new port with your colours nailed to the mast. Fear not some little opposition. "Smooth water never made good sailors," nor will it on the sea of life. Enter on your new duties quietly, unassumingly, patiently observant of all that is going on around you, anxious to give of your best to those who by right expect it, nor less conscious of the responsibility attached to the time which is more or less your own, according to circumstances.

It may be thought that undue prominence is here given to this phase of bothy life, whilst its chief end and aim—viz., the working part—is ignored. But I think it may be readily granted that there is but little, if any, danger of one clashing with the other; indeed, but a little reflection will serve to show that the youth, self-controlled, contented to spend his leisure in the garden lodging, is the one most amenable to the control of those in authority and attentive to the minor duties required of him in non-working hours.

The bothy of to-day is in many places worthy of this age of progress in the gardening world, and as a bright and cheerful home for the young gardener forms an agreeable contrast to the dark, damp abode of yore, situated on the shady side of the garden wall—an aspect better suited to the culture of the Mushroom or cool Orchid than to the development of the gardener of the future. In one establishment, where I spent three years in the new bothy, almost luxurious in its spacious library, dining room, bath room, and bedrooms, nothing could more forcibly illustrate the difference between the new and old system than the new bothy we lived in and the old bothy we looked at, then converted into store rooms, with its semi-subterranean kitchens below the level of the Vine borders on the other side of the wall, the watering of which used to soak through and put the kitchen fires out. It was to us a matter of surprise that men could have lived in them, but they did, and some at least lived to make their mark in the field of horticulture.

This digression may serve to point the moral, that adverse surroundings form no barrier to mental energy, though they may present an excuse to those who are but too ready to avail themselves of one. If the will exists the way will be found. Let your journey through bothydom be such that in after years the retrospect of it will be of "the happy, the bright, the unforgotten."  
—AN OLD BOY.

(To be continued.)

PHAIOS-CALANTHE IRRORATA ROSEA.

ONE of the latest results of the hybridist's skill with distinct genera was staged at a recent meeting of the Royal Horticultural Society at the Drill Hall, and received an award of merit. *Calanthe vestita gigantea* and *Phaios grandifolius* were utilised, the former being the pollen parent. Evidences of both were readily perceptible in this interesting exhibit, which was staged by Messrs. J. Veitch & Sons, Royal Exotic Nursery, Chelsea. The colour of the flower, the form of which is portrayed in the engraving (fig. 56), is rose shading to white at the edges of the sepals, petals, and lip.

#### THE SELWOOD COLLECTION OF ORCHIDS.

AS will be seen by advertisement the extensive and choice collection of Orchids, which was formed by the late G. D. Owen, Esq., at Selwood, near Rotherham, is to be sold by Messrs. Protheroe & Morris on the 24th, 25th, and 26th inst. The first day's sale includes 370 lots, the second day 375, the third day's list nearly 300 lots of Orchids, besides greenhouse plants. Several of the Selwood Orchids have been honoured by the Royal Horticultural Society, and the whole of the plants are to be sold without reserve by order of the executors of the late proprietor.

#### BURLINGTONIA FRAGRANS.

TO many connoisseurs this charming Brazilian Orchid is insignificant, but the delightfully fragrant flowers, the sepals and petals of which are white with a yellow tinged lip, entitle it to be grown in almost every collection. This short note is prompted by the Hawthorn scent which is emitted from the opening spikes on a small plant growing in a basket in the fernery, the compost used consisting of good peat, potsherds, and living sphagnum. During the growing season we give it abundance of water, reducing the supply as winter approaches. The plant takes little room, the leaves being only 6 to 9 inches in length, and does not require much heat during the winter, the fernery temperature often falling as low as 38°.—R. P. R.

#### ODONTOGLOSSUM TRIUMPHANS LIONEL CRAWSHAY.

THE appearance of the figure of this variety in your issue of April 11th, 1895, is, I think, a remarkably quick piece of work, the time occupied from the sketching of the flower by your artist to the time I received the paper at Sevenoaks by post being only forty-six hours. He had completed the sketch on Tuesday, 9th, at 2 P.M.; I received the paper at mid-day on Thursday, the 11th. I think this worth recording, and for those of your readers who "think," they will see the extremely perfect organisation with which the *Journal of Horticulture* is managed.—DE B. CRAWSHAY, *Rosefield, Sevenoaks.*

#### BRASSIA LAWRENCEANA.

MR. H. J. CHAPMAN writes:—"On page 287 you request my opinion on the *Brassia Lawrenceana* figured on page 275. The plant exhibited was hought some years ago, with four others, as *Brassia Lawrenceana*, and has flowered regularly under this name. It was considered by all who saw it a very fine variety, and much superior to any of the others we flowered from the same importation. The plant you figure is certainly the plant I have known for years under the name, and is at the present time in commerce as *Brassia Lawrenceana*.

"At the time it was exhibited before the Orchid Committee I did not hear any question as to its correct nomenclature. Sir T. Lawrence, Bart., was in the chair, Mr. O'Brien and other experts being present. I left the Committee while the plants I had an interest in were under consideration, so I am not in position to give you any information how the F.C.C. was awarded. Mr. Kent did not see the plant until the afternoon, when he expressed a

doubt about the plant being true, and took a flower to determine the matter, subsequently writing to Mr. Measures to say it was not the true *B. Lawrenceana* but a form of *Brassia brachiata*. I have no doubt this is correct, and the plant is now labelled accordingly; but I have sent a flower to Mr. Rolfe at Kew for final decision, and will let you know what he decides."

#### EPIDENDRUM FRAGRANS.

AS the specific name implies, this is a very fragrant Orchid, and on this account should be grown. The habit is that of a small growing *Cattleya*, the pseudo-bulbs being similar, and each bearing a single leaf. Pot culture in peat and moss suits it best, and it is easily grown in the *Cattleya* house. The blossoms are produced in short racemes from the top of the pseudo-bulbs. They are peculiar in having the lip uppermost, or upside down as it appears. The sepals and petals are creamy white, and the lip is streaked with purplish crimson. It is a common plant in the West Indies, and lasts a very long time in perfection.

#### CATTELEYA INTERMEDIA.

THIS handsome Orchid is an old species in cultivation, having been brought from Brazil as early as 1824. It belongs to the tall growing section, bearing two leaves on the top of the pseudo-bulbs, as *C. bicolor* or *C. guttata*, and when in good condition attains to a height of nearly 2 feet. It is, moreover, a free-flowering, easily

FIG. 56.—PHAIOS-CALANTHE IRRORATA ROSEA.

cultivated species, which is worthy of a place in the most select collections. The flower spikes issue from the apices of the pseudo-bulbs, and often bear from six to nine flowers each 4 inches across. The sepals and petals are narrow, soft purplish rose, the lip enfolding the column similar in colour, but with a deep violet purple blotch in front. *C. intermedia* should be repotted immediately the flowers are past in a compost consisting of good peat and sphagnum moss with abundance of rough pieces of charcoal and potsherds. Good drainage must be given, and the plants grown in the usual *Cattleya* house temperature. There are several varieties of this species, *C. i. alba* bearing pure white flowers, while those of *C. i. punctatissima* have blossoms spotted with crimson purple. *C. i. superba* is slightly different in habit to the type, and usually flowers somewhat later in the season.

#### CATTELEYA LAWRENCEANA.

THIS was a very valuable addition to the spring-flowering *Cattleyas*, and quite distinct from any other. The pseudo-bulbs grow nearly a foot high, and are usually of a bronzy reddish appearance with a similarly coloured leaf. The flowers are 5 inches across, and borne on strong erect spikes which spring from the previous year's sheaths at the top of the pseudo-bulbs. In its best forms these are very deep rose in colour with a purplish shade, having a deeper blotch on the lip, the throat white. This fine *Cattleya* will not usually be satisfactory in the temperature advised for the *labiata* group generally, but delights in a strong moist heat and plenty of sunlight while making its growth. The compost may be similar to that usually recommended for *Cattleyas*, and in other respects the treatment may be identical. Although discovered many years ago, it was not in general cultivation until 1884, when, thanks to the exertions of Messrs. Sander & Co., it was introduced in large numbers. It is a native of the mountainous regions of British Guiana, and was named in honour of Sir Trevor Lawrence.—H. R. R.

## PLANT-FORMING ELEMENTS.

THE plant-forming elements have been divided by agri-horticultural chemists in two classes: (1) The organic elements, or those which appear destructible by fire; (2) Inorganic elements, or those which after combustion remain as a residue or ash. These are but general terms, for chemists recognise an element as organic or inorganic according as it is or is not a part of an organised body. Nevertheless, the plant-forming elements naturally fall into two groups, and are marked by clearly defined and widely different characteristics. The first of these elements is derived exclusively from the air, and the second furnished wholly by the soil. These two distinctive classes of elementary substances enter into the composition of plants, and both are equally essential to their life and growth.

The elements derived from the air are carbon, hydrogen, oxygen, argon, and nitrogen. These are the chief constituents of plants, forming from 95 to 99 per cent. of their entire weight, and in process of burning pass off into the atmosphere in the form of gases. It is clear, therefore, that plants must derive the organic elements directly from the atmosphere in gaseous form, but it must not be supposed that the air-derived elements are always obtained directly from the air, for the amount of organic substances present in the soil, especially when highly cultivated, is considerable, as the air-derived elements there combine with inorganic substances to form chemical compounds, and as such are imbibed by the roots of plants.

The organic elements enter plants by the roots in combination with the inorganic in the form of sulphates, phosphates, nitrates, and chlorides of potassium (potash), calcium (lime), magnesium (magnesia), and iron. These salts enter plants by the absorbent surfaces of the roots, pass upwards through the stems to the leaves and new-forming buds, and the leaves gather carbon dioxide gas from the air, which is decomposed under the action of the sun's light; its carbon remains in the plant, and the oxygen, or very nearly an equivalent quantity, is given off into the air again. By means of the carbon so acquired, and the elements derived with water from the soil, the plant is able to organise the carbohydrates, their formation proceeding in the chlorophyll cells, and the first product detected by the microscope is the starch granules; but chemically the glucoses are the first products of the synthesis.

The albuminoids cannot be produced without nitrogen, and very little of that is derived directly from the atmosphere; indeed, it is practically unassimilable by plants. Even the atmospheric nitrogen largely collected by leguminous plants is inappropriable by them until converted by a micro-organism of the bacterial class into assimilable matter; therefore, plants derive their supplies of nitrogen from the soil in the form of nitrates or salts of nitric acids. Fats, alkaloids, and acids are built up from the same food elements. The steps in the construction of organic matters are, in most cases, unknown or of uncertain conjecture. All we know for certain is that the carbohydrates and albuminoids are organised in the leaf, transformed into its substance, and thence transmitted to every living cell of the plant, which has, within certain limits, a power of selecting its food, preference being given by most to potash before soda. Even seaweed contains more potash than soda, yet sea water contains twenty-five to thirty times more of the latter than the former. Notwithstanding, plants cannot wholly reject substances that are of no use or even poisonous to them. Plants, however, are seldom poisoned by rejected matter, as cultivated soils, by the influences of aëration, chemical and physical qualities, render such more or less insoluble, consequently proportionately innocuous.

The atmosphere is practically invariable in its composition, hence its functions are essentially the same towards plants. The soil, on the other hand, is variable in composition, and has offices peculiar to itself. Thus it can be improved and enriched, and in consequence of a certain plant appropriating a given element larger than another it may be deteriorated or exhausted.

Crops cannot derive appreciable amounts of the elements found in their ash from the atmosphere, but the soil may accumulate the air elements by the waste of crops and animals, such as carbon dioxide and nitrogen, the last being chiefly supplied to plants by the soil, which is formed therein as nitrates from various sources, while the ammonia salts supply nitrogen to vegetation. Hydrogen and oxygen are supplied in the water which the roots of plants imbibe; indeed, it is from the soil that the plant gathers all the water it requires, and is the vehicle by which it receives the soil-derived elements, being the fluid medium of its chemical and structural transformations.

The elements furnished to plants exclusively from the soil are: Non-metals—sulphur, phosphorus, silicon, and chlorine; metals—

potassium, sodium, calcium, magnesium, iron, and manganese. These soil-derived elements all occur in plants in small proportions, and vary in amount from a fractional part of 1 per cent. to 10 or 12 per cent., but though the proportions are small, they, or some of them, are as important as the more abundant organic elements; indeed, both are equally essential in the formation of plant tissue. The inorganic substances of plants are ascertained by an analysis of the ash of the respective species or variety, the mineral matter remaining as residue when plants are burned. But the combustion is always more or less incomplete, so that in the ash there remains minute amounts of carbon, oxygen and nitrogen, and slight traces of chlorine, phosphorus, and sulphur are known to be given or dried off in the heating, yet the amounts are very small in either case. An analysis of the ashes of a plant therefore affords a safe guide as to its requirements of soil and manure, and that of the whole elements known to chemists not more than one-fifth are needed by plants for the building up of their structures. Four—carbon, oxygen, hydrogen, and nitrogen—of the fourteen elements are derived directly or indirectly from the air, and constitute over 90 per cent. of all vegetation, consequently the atmosphere is a sort of aëriiform food-supplying medium, which plants imbibe as gases, yet these air-derived elements are not more important factors in vegetable nutrition than the soil-derived substances that occur in much smaller amounts, for both are essential to the healthy development of plants, and of equal importance in plant economy.

Over the air-derived elements the cultivator has practically no control in outdoor culture, and it is doubtful if ammonia in glass structures has any more than a fancied beneficial effect upon vegetation. Of course, all growers know that decomposing matter, such as leaves, cocoa-nut fibre refuse, mulchings of manure, and even sprinklings of liquid manure, produce atmospheric conditions more or less beneficial to vegetation, but whether this is due to the gases evolved or the uniform hygrometrical state of the atmosphere is not determined beyond uncertain conjecture. Free nitrogen is of no use whatever to plants, not even to leguminous, but vegetation assuredly profits by the ammonia and nitric acid in rain water, yet who can tell how these in fluid form can enter plants other than through the roots? Epiphytes certainly appropriate the ammonia and nitric acid of the atmosphere, but it is by their aërial roots, not the leaf surfaces.

Nitrogen in the soil, or in a fertiliser, is never present in the form of nitrogen gas, but exists in combination with some other element or elements, yet chemists in their analyses determine, without regard to the form, how much this combined nitrogen would amount to if it were present in the form of pure nitrogen gas. It may be in the form of ammonia, as sulphate; in the form of organic nitrogen, as in animal or vegetable substances; or in the form of nitrate, as nitrate of lime, potash, or soda. Ammonia is a compound formed by the chemical union of nitrogen with hydrogen, fourteen parts of nitrogen uniting with three parts of hydrogen to make seventeen parts of the element called ammonia, consequently 1 lb. of nitrogen will make 1.214 lbs. of ammonia. Each pound of ammonia contains a little less than two-tenths of a pound of hydrogen, and this has value only in that its combination with nitrogen forms a compound more readily assimilable by plants. Hydrogen is present in all animal and vegetable substances, and forms an essential constituent of acids. It combines with oxygen to form water, of which it forms one-ninth by weight, being the lightest of all known substances. Atmospheric air is about fourteen and a half times heavier than hydrogen, but by its combination with oxygen it enters the plant in the soil waters, and its property is to make plant food more easily assimilable.

Nitrogen constitutes about four-fifths of the bulk of the earth's atmosphere, and in its free condition manifests no positive or active properties. Plants cannot live if confined in an atmosphere of nitrogen gas. The nitrogen and oxygen of the air are a mere mechanical, not a chemical, mixture, the nitrogen assumedly modifying the action of the energetic oxygen. Although nitrogen is an essential and constant constituent of plants, and the atmosphere a great reservoir of this element, there are few plants that can appropriate it from the atmosphere, and it would not be of any use to them without the intervention, within the tissues, of certain micro-organisms, which convert it from free into assimilable nitrogen. This element is also present in soils, but it exists in these in a comparatively inert and useless state. The humus of soils is a source of nitrogen, peat often containing 2 or 3 per cent. Of this nitrogen, as gas, plants can make no use, for it is only the nitrogen, combined with other elements or their compounds, that is assimilable by vegetation. As such nitrogen exists in soils and in the form of nitrates, compounds of ammonia, or combined with organic matter, and of these the chief source of immediately available nitrogen is the nitrates, then the ammonia, and very slowly that of organic matter.

\* Silica and sodium salts are omitted as unessential, from a manurial point of view, to the growth of plants.

But chemists neglect nothing in air or soil, and physiologists turn their researches to effective purposes. Thus the outcome is of material advantage to cultivators, who are able to comprehend that plants appropriate nitrogen (1) as the free nitrogen gas of the atmosphere, (2) in the form of ammonia, and (3) in the form of nitrates. Free nitrogen gas costs nothing, and the stores are practically inexhaustible. The cultivator gathers it from the atmosphere by means of leguminous crop—Beans, Clover, Peas, Tares, and others, gets it into the soil, where it is converted by the action of the nitrifying micro-organisms, in presence of certain bases, into nitrates. These bases are essential for the activity of the micro-organisms within the plants or their root tubercles that convert free into assimilable nitrogen, so as to render it available for use; and they are equally important for stimulating those in the soil for effectively producing nitrates equal to the crop requirements. Such bases are present in most soils and in nearly all plants for the normal growths of the micro-organisms; but they are unquestionably deficient in some soils, and, of course, plants for the requirements of cultivated crops. The chief of the elements needed by the micro-organisms in the soil or plants are lime and potash. Leguminous plant and soil micro-organisms cannot act to the fullest profit to crops without the essential lime or potash, hence potassic manures accelerate the growth of leguminous crops, not by simple chemical process, but by the compounds formed by the action of the micro-organism duly supplied with food or material for manufacture into nitrates.—G. ABBEY.

(To be continued.)

### THE ROYAL HORTICULTURAL SOCIETY'S EXAMINATIONS.

THIS annual function is fixed for May 1st next, hence intending candidates have to make the most of their time, as the date is very near. As notice of intention to sit for this examination had to be sent in by the 16th inst., it is obvious that any purposing to sit, and not having given notice, are too late. It is very evident that stimulus towards securing country candidates for the examination cannot be largely applied from London, and only where there exist bodies that have affinity to the object can any material interest in the examination be looked for. Naturally, seeing how many thousands of gardeners there are in the United Kingdom, and how many other persons there are outside of the profession greatly interested in horticulture, no difficulty should be experienced in securing fully 1000 candidates, yet no such number is looked for. Possibly they may not exceed 250 or 300.

Then it is natural to ask why so few relatively. There is no lack of knowledge or of literary capacity, as ample evidence is furnished in other directions. Probably the comparative lack of candidates is due to innate modesty, lack of interest, or to inappreciation of the honour that passing in such an examination furnishes. But I think the chief cause is found in that first named, and of that we have evidence in the county of Surrey, because whilst that county does, as a rule, furnish the largest number of candidates, that result is almost entirely due to the County Council Technical Education Committee and the strenuous efforts put forth by its horticultural instructors, not only to diffuse gardening knowledge but also to arouse interest in the R.H.S. examinations.

During the past winter lectures on flower, fruit, and vegetable culture have been delivered in various parts of the county, to persons of all classes. With a view to encourage members of the classes to practise the art of committing their knowledge to paper, in the form of answers to questions—practice most helpful to any purposing to sit on May 1st—a series of twelve printed questions, arising out of each lecture, was handed to each person present at a class; members then took the questions home, and were invited to furnish replies to the best of their ability during the week, and hand them in at the following lecture, or send them by post. It was expressly desired that each answer have against it the corresponding number attached to the question, and that all writing be on foolscap paper, and on one side only—name, address, and occupation of the writer being also furnished. Some persons boldly took all the six lectures in a course, others took fewer, but out of the entire number of classes some 380 papers were sent in, about one-half coming before Christmas, and the others afterwards.

It need hardly be said that going through all these papers—for not even the poorest, some coming from lads, some from labourers, some from ladies, some amateurs, schoolmasters, and some from gardeners, was ignored—proved to be a very onerous task. Every answer, and there were several thousands, was fairly and impartially appraised at its proper worth. A tabulated statement of the results was made, and then the whole of the papers were returned to the numerous writers, every one of whom who showed fair merit—a good percentage—being afforded an opportunity of entering for the R.H.S. examination. More it was very difficult to do, but it is evident that were as much done in every county in the kingdom the result might be remarkable.

Of course it is not concluded that attendance at a course of lectures on one section of horticultural work only qualifies to sit for the R.H.S. examination. That would be too absurd. But it is easy for any intelligent person going through the answers sent to the lecture questions to

find that many of the writers had both wide and sound practical knowledge, and if they sit must come out with honours. But then it is found, as a rule, that the greatest disinclination to enter is evinced by the most competent, while others, who have the smallest capacity for answering questions intelligently, have not the slightest hesitation in giving their names as candidates. Another instance of the sometimes too close alliance of modesty with ability, and the reverse. In some cases the replies were excellent, could hardly have been better, but then these were from gardeners. Most interest attached to the work of amateur members of the classes, and especially to that of ladies and lads, some of them showing remarkable capacity and knowledge.

It need hardly be said that the Surrey C.C. lecturers realise the very great difference existing between the examinations they conduct and those of the R.H.S. In the local case every question is of a practical nature, and arises absolutely out of the lecture. There is no catch question, no botany except of the most elementary kind, and nothing abstruse. Nor is there anything which has the least semblance of cramming for exams. The subjects chosen are those likely to be the most useful to the audiences, the syllabus differing entirely from that of the R.H.S., which would not meet the local requirements, though naturally much of the teaching is generally applicable. The R.H.S. exams practically demand much study of expensive text-books, such as very few can afford to purchase, and test the very widest knowledge of horticulture, theoretical and practical. In the other the exercise is a test of what lecturers teach, and that only. All the same, as a preparation for the national examination, no course can well be more serviceable than is that taken in Surrey.

It is very probable that even greater interest would be taken in these county examinations were there added to them the stimulus of some prizes or certificates. A suggestion has been made that the Technical Education Committee may be induced to offer for the best papers another winter some prizes in the form of good gardening books. It need hardly be said that such course would be hailed with great satisfaction by both lecturers and members of the classes. Of course, it would then be needful to submit the papers of answers to lecture questions sent in to some independent examiner, and also so far to divide the classes, that gardeners and amateurs should not in a sense compete with each other. That the effect would be largely to stimulate interest in the lectures, and in encouraging replies to the questions arising out of them, there can be no doubt. But all the same, the examination that would carry the greatest weight, and have for successful candidates the highest honour, certainly is that of the Royal Horticultural Society.—A. R.

I HAVE read with much pleasure and interest the remarks of "H. O. H." (page 290, April 4th) in the Journal respecting the above subject, and can fully endorse his views of what should constitute the principal abilities of a good gardener—viz., a thorough practical knowledge, gained not by theory, but by a life spent in putting his hands to all the details of his vocation with a desire to attain knowledge—not building his hopes of success on what he knows theoretically, but ever bearing in mind that proficiency is the result of studious perseverance in observing with a keen interest all that comes under his notice relating to the occupation in a practical way.

Anyone with a literary turn of mind may collect books that will furnish particulars enough to enable him to pass an examination on all branches of gardening; but all the same, that is no test of his abilities as a thoroughly practical man. Book learning is really necessary, and who is complete without it? yet it cannot take the place of sound practice. The present day needs men who have made gardening a deep study in every way from their earliest time, who have brought themselves up in all the smallest details, who have done the work and who know when those under them are doing the same in a practical way, to be able to economise and arrange matters to make up for inadequate labour power to meet the requirements of the case.

I would heartily commend to the notice of every young gardener the last paragraph of "H. O. H.'s" article, and ask everyone to peruse it carefully and intelligently, as it is much to the point.—A. KEMP, *Coalhurst, Horsham.*

### SPINACH.

I WAS very glad to see "A. D.'s" remarks respecting this vegetable on page 298. The past winter, as most gardeners know, has been a severe test for vegetables, but the Spinach has come through the ordeal as well as any. The cause, no doubt, is that being a low-growing plant, the snow covering it during the greatest severity protected it well.

I find that one sowing in the autumn is not sufficient. I therefore have for some years now found it advisable to make two. The first is early in August, generally in the open quarters from whence early Potatoes have been cleared. This gives a crop from the middle of September to Christmas and onward through the winter, should the weather prove open and mild. The second sowing is made the last week in August or not later than the early days of September. This will be of no use to pick from till the spring, but often withstands frost better than the plants from the first sowing, and comes in very useful from April to June, when the spring-sown follows on.

The seeds are sown very thinly in drills, and as soon as the young plants are through the ground they are thinned to 6 inches apart, for it is of no use leaving the plants packed together if fine sweet leaves are required. When grown in this manner a basketful can be picked in

much less time, and will give much more satisfaction than a number of thin, small leaves.

For many years now I have only grown the round-seeded, and have never been without Spinach either in the autumn and early spring. The prickly-seeded is no doubt as hardy, but I prefer the former, as I have generally found it to produce larger and broader leaves.—A. HARDING.

**EVENTS OF THE WEEK.**—Two meetings will claim the attention of London horticulturists during the coming week. At the Drill Hall, Westminster, on Tuesday, the Committees of the Royal Horticultural Society will meet, and a good show is expected; while on the Wednesday the Royal Botanic Society holds its second spring show. In the provinces there are at least three shows of interest, each opening on the Wednesday—namely, the Birmingham Daffodil and Horticultural Society's Daffodil Show, in the Edgbaston Botanic Gardens; the Newcastle-on-Tyne Spring Show, in Olympia, Northumberland Street; and the Chesterfield Spring Show, at Tapton Grove.

— **THE WEATHER IN LONDON.**—Fine weather, with bright sunshine, has prevailed in the metropolis during the past week. Thursday and Friday last were warm and genial, but a cold easterly wind which afterwards set in has marred to some extent the pleasure of holiday makers, also checking the growth of vegetation which former favourable conditions had encouraged.

— **WEATHER IN THE NORTH.**—Since Wednesday, the 10th inst., which was cold, gusty, and showery, there has been a great improvement in the weather. Although the wind has generally been easterly and sharp, there has been abundant sunshine. On a few mornings frosts of 4° and 6° have occurred. Farm and garden work is being vigorously pushed on.—B. D., *S. Perthshire*.

— **ROYAL HORTICULTURAL SOCIETY.**—The next meeting of this Society will be held in the Drill Hall, James Street, Westminster, on Tuesday, April 23rd. In addition to the Society's ordinary show the National Auricula and Primula Society will hold its annual show. At 2.30 P.M. a Conference on Primulas and Auriculas will be held in the Hall. Prof. Michael Foster, F.R.S., has promised to preside, and the following papers will be read:—"New Primulas," by Mr. J. G. Baker, F.R.S.; "Culture and Classification of Primulas," by Mr. Selfe-Leonard; and "The Auricula," by Mr. J. Douglas. By way of illustrating the Conference the Council will be glad of exhibits of as many different natural species of Primula as possible.

— **PRIZE ESSAY ON HARDY FRUIT GROWING.**—We are requested to publish the following announcement:—"The Council of the Royal Horticultural Society of Great Britain offer a prize of £10 for the best essay on 'The Commercial Aspect of Hardy Fruit Growing in the United Kingdom.' The essay is not to exceed 10,000 words, to be sent under seal to the Secretary of the Society, 117, Victoria Street, Westminster, on or before August 1st, 1895, each essay to be signed with a motto, and the writer's real name and address enclosed in a sealed envelope bearing the same motto outside, the prize essay to become the sole property of the Council of the Society to deal with in any way they may think fit. Unsuccessful essays will be returned after October 1st, 1895, on application, enclosing the necessary postage, and the motto of the writer."

— **BEAUTIFUL VIOLETS.**—When we think of the beauty, the fragrance, and hardiness of the Violet, the wonder is that it is not grown far more abundantly. I am sending a few blooms, for your inspection, of a variety that has recently originated in my garden. One shoot came on a plant of Comte Brazza's White Neapolitan, although the foliage on the plants from whence the flowers were gathered was very much scorched with the severe frosts in January and February. Still you will be able to see from the size and colour of the blooms what a fine variety it is. It seems to be the very counterpart of the old Neapolitan, but a much stronger grower and larger flower.—NORTH NORTHUMBRIAN. [The variety is excellent, the flowers being large, of good substance, and deliciously fragrant.]

— **RODMERSHAM AMATEUR AND COTTAGE GARDENERS' ASSOCIATION.**—We are favoured with a schedule of this Society, giving details of classes and prizes offered at the eighth annual show. The exhibition will be held in the grounds of Rodmersham House on August 28th and 29th. Schedules and further particulars may be had from the Secretary, Mr. T. H. Busbridge, Rodmersham, Sittingbourne.

— **LONDON'S LATEST LUNG.**—Telegraph Hill, the new open space which has been laid out by the Parks Committee of the London County Council, was recently dedicated to the public. Mr. Arthur Arnold, Chairman of the Council, said it was his privilege to plant the standard of public possession and public freedom—and on behalf of the Council of the County of London, he declared these gardens to be open for ever for the health and recreation of the people.

— **ALMOND TREES.**—The geniality of the weather we experienced some days since is shown on the several Almond trees now flowering so profusely in many parts of the metropolis, and form a pleasant spectacle. It is a tree that might well be planted far more extensively in the gardens of many new houses that are being erected round London, as it cannot be denied that they tend, perhaps more than any other tree, to brighten our murky town in the spring.—LONDONER.

— **THE WILLIAM THOMSON MEMORIAL FUND.**—We are informed that it has been proposed to close this Fund on May 1st, and therefore all intending subscribers, which we trust will be many, should forthwith send their contributions to any of the following members of the English Executive Committee, of which Mr. H. J. Veitch is Chairman:—Messrs. A. F. Barron, Chiswick; Bruce Findlay, Manchester; J. George, Putney; P. E. Kay, Finchley; G. Monro, Covent Garden; G. Norman, Hatfield; F. Sander, St. Albans; J. Smith, Mentmore; R. Tait, Manchester; O. Thomas, Frogmore; H. Williams, Holloway; G. Wythes, Syon House; or J. G. Veitch, Honorary Secretary, Royal Exotic Nursery, King's Road, Chelsea, S.W. We may remind our readers that the object of the Fund is to honour the memory of one of the most accomplished of gardeners and best and most respected of men, and at the same time aid afflicted gardeners and orphan children through the agency of the Gardeners' Benevolent Institution and the Royal Gardeners' Orphan Fund, in which charities the amount subscribed will be invested.

— **FUMIGATING—THE LATEST.**—Soon the worry and anxiety that insects have hitherto caused us in our plant houses will be a thing of the past. The XL All vapourising fumigator is certainly far in advance of anything I have used. Two dressings of the highly concentrated nicotine that is thrown off as vapour will kill mealy bug. I do not say two fumigations are ample to clear a house of bug altogether, but it will destroy all the active insects. I consider this a distinct step onwards. Those who have mealy bug in their vineries have now within easy reach material by which it can be eradicated. I have hopes that while it will destroy mealy bug it will also exterminate the small scale that infests Palms. The time spent in removing this pest from Palms has always been a source of trouble to me, day after day being used in sponging, and to little or no purpose. If nicotine vapourised in our houses will accomplish this we need not hope for greater progress in this direction. I may add that tender young fronds of *Adiantum cuneatum* in the house were not injured by the applications which killed the mealy bug.—W.M. PARDNEY, *Osmaston Manor*.

— **VIOLA CONFERENCE.**—As the "master hand" who planned and guided the Viola Conference at Birmingham last August has been called away by death the duty devolves on me of arranging what is to be done this year. I am afraid that the loss of Mr. Dean is one which is almost irreparable. Who will be so willing, so capable, so enthusiastic, and so disinterested? I know not. Mr. William Sydenham has written to me urging the arrangement of a Conference for Tamworth or Birmingham. Mr. Rowberry thinks that Mr. Dean's death will mean the removal of the Conference meeting to London, and I know this opinion is shared by several others. On the other hand, I think Professor Hillhouse, from what passed last year, will be expecting the Conference to assemble at the Birmingham Botanical Gardens on the occasion of the Pansy and Viola show there. I know this was also Mr. Dean's expectation. My object in writing to the Journal now is to ask those who are interested in the matter to write me briefly, expressing their views as to where this year's Conference should be held and when. An effort will then be made to arrange it to suit the majority of those interested. If sufficient interest is not manifested it may become a question if there should be a meeting at all.—WILLIAM CUTHBERTON, *Springfield, Rothsay*.

— SCOTTISH HORTICULTURAL ASSOCIATION.—A meeting of the Scottish Horticultural Association was held on Tuesday, April 2nd, at Edinburgh, Mr. R. W. E. Murray, President, in the chair. An interesting and instructive paper on "Eucharis and Pancratiums" was read by Mr. D. L. McIntosh, Kingsmeadows, Peebles.

— "THE AMERICAN FLORIST."—We have recently received a copy of the special spring number of this excellent American publication. It contains articles on the arrangement of flowers and other practical and useful subjects, almost all of which are admirably illustrated. The printing and the paper leave little to be desired, while the outer page of the cover representing a floral arrangement is a real work of art.

— NEPHROLEPIS DAVALLOIDES FURCANS.—This is one of the most beautiful of all Ferns when used as a pot or vase plant, having broad, furcated, glossy leaves, and a massive, full, arching head. When cut the fronds last well, look handsome, and are much appreciated for table and vase decoration when large fronds are required; for small vases, hand bouquets, and the like, of course they are far too large. When cut they may be immersed in a tub or tank of water for two or three hours before using.

— METROPOLITAN PUBLIC GARDENS ASSOCIATION.—At a recent meeting of this Association it was decided to open to the public, towards the end of May, the disused burial grounds of St. Peter's, Walworth, and St. Mary's, Woolwich, lately laid out by the Association. Attention was drawn to cases of building operations on disused burial grounds in apparent contravention of the Disused Burial Grounds Act, 1884, and it was decided to take steps to insure a full inquiry into each case. It was decided to prepare plans for the laying-out of Bromley Churchyard and St. Stephen's school ground, Bow.

— THE HESSLE GARDENERS' MUTUAL IMPROVEMENT SOCIETY.—The annual dinner of the above Society was held on Tuesday, April 9th, when the President of the Society (W. J. Wharwick, Esq.) took the chair, about sixty members and friends being present. After the dinner Mr. Wharwick gave a short address, expressing the pleasure it was to him to be amongst the Hessle gardeners, where, he said, he always felt thoroughly at home. The usual toasts were proposed, and duly responded to. An excellent programme of songs, provided by "The Kingston Quartett Party," contributed largely to the evening's enjoyment.—F. L. T.

— AMERICAN APPLES.—The exports to date of Apples during the season of 1894-95 aggregate 1,443,592 barrels, against only 168,706 barrels during the previous season of 1893-94. The record season in the export Apple trade was that of 1891-92, when, as was the case this season, the English Apple crop also failed. In that season 1,450,336 barrels of Apples were shipped abroad as follows:—From New York, 537,247; Boston, 339,964; Montreal, 320,427; Portland, 163,145; Halifax, 87,379; Philadelphia, 550; Baltimore, 72; Newport News, 1337; Norfolk, 215. The export season usually begins about August 15th and ends about April 15th. The total quantity of Apples shipped in the season of 1891-92 is now only 3738 barrels more than have been shipped thus far this season. When all the returns are in for this season it will probably beat all previous records.

— THE SLEEP OF PLANTS.—The sleep of plants is so conspicuous a phenomenon that it excited discussion and speculation as early as the time of Pliny, and many explanations were given, which science has since disproved. The drooping of the leaves was attributed by some botanists to an aversion to moisture, a theory which had to be abandoned when such movements were made on cloudy days and dewless nights. The Clover tribe, which always close their leaves at night, revel in rain, and Nasturtiums will go through a day of tempestuous weather without showing any inclination to change their position. Linnæus was the first to give to the subject special study and scientific research. While watching the progress of some plants of Lotus, he began that series of observations on which his great work "Sleep of Plants" is based. He found that nocturnal changes are determined by temperature and the daily alternations of light and darkness. Movement is not actually caused by darkness, but by the difference in the amount of light the plant receives during the night and day. Many plants, notably the Nasturtium, unless brilliantly illumined in the day, will not sleep at night. If two plants, says the "Rural World," were brought into the centre of a room, one from the open air and the other from a dark corner, the neutral light which would cause the former to droop its leaves would act as a stimulant on the latter.

— DEATH OF MRS. M. I. WATSON.—It is with deep regret that we learn the death of the wife of the well-known Assistant Curator, Royal Gardens, Kew, which took place April 6th, at the age of thirty-six years.

— "THE NATURAL HISTORY OF PLANTS."—We have received from Messrs. Blackie & Son the twelfth number of this highly interesting publication. The question of fertilisation has now given place to the discussion of the fruit, and the infinite variety of aspect assumed by the fruits of various plants is presented realistically in a large number of illustrations. The volume has prefixed to it, as usual, a coloured plate, the subject in this case being a group of West Indian Orchids.

— A BOTANICAL GARDEN FOR NEW YORK.—It begins now to look, says a transatlantic contemporary, as if the great city of New York is at last to have a botanical garden—it only remains to raise 45,000 dols. more, when the work will actually begin. Broux Park has been wisely selected as the place for its location. Too much cannot be said in favour of this addition to the attractions of New York. Its educational value would be inestimable, and it would constantly become more and more interesting and valuable as the years go by.

— CLIANTHUS DAMPIERI.—As a greenhouse climber no one can speak too highly of this plant. The flowers are not only curious in shape (resembling that of a lobster's claw) but are exceedingly attractive when the growths are allowed to hang down from the pillars or the roof to which it is trained. When planted in a cool shady corner it is astonishing what an amount of growth this plant will make in a season. It is even easier to cultivate than the Lapageria, but where the two can be grown the roof of a conservatory may be kept ablaze all the winter months, and when once established the plants are little trouble. They require abundance of water in the growing season, and also syringing twice a day. If the north side cannot be devoted to them it is advisable to shade them rather heavily in the summer, or red spider is sure to attack them. We have a huge plant of Clianthus here now in full flower, and it would be useless to attempt to count the clusters.—GEO. BURROWS, *Warwick School*.

— CYCLAMENS, PRIMULAS, AND CINERARIAS AT ALTRINCHAM.—It may perhaps not be generally known that something like 5000 Cyclamens are grown and flowered annually in the establishment of the enterprising firm of Messrs. Clibran & Sons. The strain is excellent, the result of careful hybridising. The plants are very dwarf, and furnished with handsome foliage and flowers in great diversity of colour. The Pure White is a giant flowered variety, very free and a great acquisition. Primulas are equally imposing in two very large houses. Amongst the singles Clibran's Red, Crimson, White, Rose, and Ruby Red, have flowers of the first size and quality, some measuring over 2½ inches across. King of Crimson, raised by the firm, is not yet in commerce, but has a glowing future before it. Oldfield Blue, Rose Beauty, Princess of Wales, and Avalanche are also grand varieties. In the doubles, Firefly, deep crimson; Mrs. Clibran, rosy peach; and Snowflake, the largest pure white in the collection, are all superior. Other well tried sorts, such as Candidissima, Alba grandiflora, Earl of Beaconsfield, Marchioness of Exeter, Stewarti, and Princess of Wales are largely grown, their value for affording flowers being well known by many cultivators for cutting. Cinerarias are just coming into flower, the growth is sturdy and dwarf, with flowers of superb form and colour.—A VISITOR.

— THE FLOWERING OF BULBS.—In spite of the many predictions that such bulbous plants as Snowdrops, Crocus, and Narcissi would not give such a full crop of blossom this year, I find the results are in contradiction to this theory. The excessively wet and cold summer and autumn perhaps justified the prophecy, but these prophets appear to have forgotten that the weather during April, May, and June—just the season when the embryo flowering state of the bulbs is prepared for next season's display—was quite favourable to a full flower crop. During the three months named we had an average rainfall of a little over 2.00 inches, which certainly could not be unfavourable to the harvesting of the bulbs. Throughout the period named high temperatures were recorded. These are circumstances, I take it, favourable to the flowering of bulbs the following season, irrespective of what the late summer or autumn may be. I do not think I ever remember seeing the ordinary Snowdrop in its wild state in the woods and hedge-rows blossoming so strongly as at the present time. In the poultry yard here some thousands are growing, and wonderfully fine are the flowers and leaves. Crocuses, too, growing in many thousands on a grassy plot, in spite of the thick covering of moss, are wonderfully fine this year.—E. MOLYNEUX, *Swanmore Park*.

— TONS OF CATERPILLARS.—According to a contemporary 36 tons of caterpillars and a large number of cocoons were destroyed in the effort to drive the pest from the young plantations of trees on Hongkong Island. They appeared on the Pine trees with which the Government is trying to reforest the island, and lasted for two months. Stations were established where the caterpillars were received and paid for by weight; this method seems to have been successful. It is estimated that 35,000,000 insects were killed.

— WAKEFIELD PAXTON SOCIETY.—At the weekly meeting of this Society, held on April 6th, Mr. W. Tunnicliffe presided, Mr. B. Whiteley was in the vice-chair, and there was a good attendance. After the election of new members, Mr. J. W. D. McPherson, B.A., one of the assistant masters at the Wakefield Grammar School, delivered a very lengthy and most interesting lecture on "Trees." Mr. McPherson spoke for an hour and twenty minutes without note or memoranda, and his excellent and instructive lecture was most attentively listened to and very warmly applauded. He dealt with his subject in a most exhaustive and thorough manner. After pointing out the absolute necessity of fresh air and sunlight in order that trees may flourish and be properly built up, the lecturer dwelt on the importance and value of trees from a sanitary point of view. The superstition which prevails with regard to the Ash, Oak, Maple, Sycamore, Hawthorn, Mountain Ash, and other forest trees, was dilated on in humorous terms, the lecturer remarking that many persons believe that a sprig of Mountain Ash will keep witches away. At the close the lecturer was heartily thanked.

— MEDICAL ACTION OF VEGETABLES.—The "Family Doctor," in the course of an article on the medical value of vegetables, says, "Asparagus is a strong diuretic, and forms part of the cure for rheumatic patients at such health resorts as Aix-les-Bains. Sorrel is cooling and forms the staple of that *soupe aux herbes* which a French lady will order for herself after a long and tiring journey. Carrots, as containing sugar, are avoided by some people, while others complain of them as indigestible. With regard to the latter accusation, it may be remarked in passing that it is the yellow core of the Carrot that is difficult of digestion—the outer, a red layer, is tender enough. In Savoy the peasants have recourse to an infusion of Carrots as a specific for jaundice. The large sweet Onion is very rich in those alkaline elements which counteract the poison of rheumatic gout. If stewed slowly in weak broth and eaten with a little Nepaul pepper, it will be found to be an admirable article of diet for patients of studious and sedentary habits. The stalks of Cauliflower have the same sort of value, only too often the stalk of a Cauliflower is so ill-boiled and unpalatable that few persons would thank you for proposing to them to make part of their meal consist of so uninviting an article. Turnips, in the same way, are often thought to be indigestible and better suited to cows and sheep than for delicate people; but here the fault lies with the cook quite as much as with the root. The cook boils the Turnip badly, and then pours some butter over it, and the eater of such a dish is sure to be the worse for it. Try a better way. What shall be said about our Lettuces? The plant has a slight narcotic action, of which a French old woman, like a French doctor, knows the value, and when properly cooked is really very easy of digestion."

— THE BIRMINGHAM GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—The last of the fortnightly meetings for the spring session of this Society was held on the 8th inst., when the essays on "Hardy Fruit Culture," and for which prizes in the shape of books on horticulture had been offered, were read by the competing young gardeners. The essays, of which there were eight, had been previously perused by the Committee to adjudicate on for the award of the four prizes offered. As on the last occasion, it was decided that each competitor should read out his own paper at the meeting, in preference to the whole being read by one of the Committee, an arrangement obviously preferable to the latter mode, and which had been adopted on one or two prior occasions. The first and second prize papers especially evidenced considerable ability on the part of their compilers, as in addition to a suitable preface, followed by thoroughly practical cultural details, including a selection of varieties of from six to eight kinds of fruit, and the gathering and the storing of the crops, they were further characterised by the very good composition and distinct sentential arrangement duly notified by the adjudicators. A word of praise must also be awarded to non-successful competitors for their fairly good compositions, excepting perhaps one or two who evinced a certain lack of scholastic tuition, which marred their otherwise fairly good efforts. The successful competitors were respectively Messrs. F. Milaxis, H. Wilson, F. Cox, and "Fragaria," the *nom de plume* of the fourth prize man, and whose

name could not be ascertained at the time. At the same meeting it was decided that the annual summer excursion of the members, with their wives or other lady friends, should be to Penrhyn Castle and the Penrhyn Slate Quarries in North Wales.—G.

— VEGETABLES FOR NEW YORK.—New York is supplied with vegetables from many sources outside of that produced by the local gardeners. Thus about 300 crates of Tomatoes arrived by steamer from Nassau in March, also 105 barrels Cabbage from Rotterdam. Bermuda Potatoes are arriving in small parcels, but the crop is of poor quality, lacking in size and colour. Florida Lettuces and String Beans sell fairly well. Virginia truck gardeners recently sent by one steamer 5000 packages vegetables, mostly Spinach and Kale.

— HEATING VINERIES.—In Mr. Taylor's admirable article on the subject of heating vineries there is one point to which I take exception. He says, "If there are five pipes two should be flows and three returns, or *vice versa*." I do not take exception to this part merely on supposition, but from actual practice. In two of our vineries we have six rows of 4-inch pipes, five being flows and one a return. Nothing could possibly be better than the easy way in which the water circulates through all the pipes. The five flows are taken at a right angle from the main. Having such a number of outlets for the water is all in favour of a quick circulation, the one return pipe being continually and regularly fed in carrying the water back to the boiler. In our case the water has only to travel once through the house before being conveyed back again to the boiler. As Mr. Taylor rightly remarks, all flow and return pipes should be fitted with valves. In many instances that I am acquainted with valves are not put on the return pipes. The consequence is that during the winter, when heat in a particular house is not required, the water "backs up" through the return pipe, and is a source of trouble. In addition to this, if both flow and return are fitted with water-tight valves the water is easily maintained in the pipes in the case of a breakdown to any part of the apparatus.—E.

— ROYAL COMMISSION ON AGRICULTURE.—The following evidence was given by Mr. J. K. Woodward, market gardener at Evesham, at the last meeting of this Commission:—He stated that until September, 1894, he occupied 106 acres as a tenant farmer, but he now occupied a market garden of 6 acres, and employed two men. The market gardens of Evesham and district extended to nearly 8000 acres, and were mainly cultivated as spade industry, all land planted with fruit trees and bushes and Asparagus. Most classes of land in his district were suitable for market gardening, and there was a great demand for small holdings for the purpose. The success of a market garden, like that of a farm, depended in a measure on the industry of the occupier; the return from a well-cultivated garden was very remunerative. Market gardens were usually held on yearly tenancies subject to a twelve-months notice to quit by either party. A few leases existed for short terms of years—five to seven. There were exceptions where they extended to twenty-one years. Owners were very loth to grant leases; they invariably asked a higher rental than the yearly tenant pays, and in some cases refuse them altogether. He had never seen any clause in an agreement enabling a tenant to claim compensation for improvements—*i.e.*, for planting fruit trees, fruit bushes, Asparagus, and other crops. Artisan gardeners were not generally informed on their taking a farm that if they planted fruit trees, they would do so at their own risk; but they were protected to some extent by the custom of the country. The rents of market gardens had not been reduced, and there was no depression amongst market gardeners. Very little market garden land was let at less than £3 per acre, rents of £5 to £7 per acre were not uncommon, and some land let even higher. The universal feeling of gardeners in his district was that an Act should be passed to secure their tenant right, be it great or small, and providing compensation for disturbance. Evesham and district was favoured by having two large systems of railway service, placing it in direct communication with most of the large manufacturing districts both in Wales and the North, but a great hardship was felt in a preference rate being given to foreign produce. Another grievance was that the rate for small lots of 2 or 3 cwt. was in many instances nearly double that of a 2 ton lot *pro rata*. A custom prevailed in the district, and on some estates particularly, whereby a free sale of all tenant right is permitted, the landlord requiring that the incoming tenant should be sufficiently substantial. Where a tenant wished to leave he caused it to be known, fixing his own valuation of tenant right, and on finding a purchaser they both went to the landlord or his agent, and the name of the incoming tenant was substituted on the rent roll. Valuers were very seldom called in such cases.

— PETROLEUM FOR APPLE SCAB. — A writer in "American Gardening" says that "some years ago to kill what was thought to be a worthless Apple tree before cutting it down I washed it all over with petroleum (crude oil as it is taken from the ground) in the month of February. I then left home, and when I returned the next autumn that scraggy Apple tree which I expected to find dead was as bright as a silver dollar, and the twigs had made a growth of 12 inches to 18 inches, and a few as good King of Tompkins Co. Apples as ever hung on a tree greeted me, and to-day it is a handsome bearing tree, twenty years old. Since then I have used petroleum on my Apple trees to free them from scab and noxious insects that collect and breed on the trunks of old trees. I apply it with an old whitewash brush at any time before the buds begin to swell in the spring, applying it freely on all large branches and body. Perhaps it could be applied with a sprayer more effectually." [We have recently seen a Peach tree under glass killed by a petroleum dressing.]

— MONEY IN THE GREENHOUSE. — Many people are imbued with the idea that there is a great deal of money in the greenhouse business, and amateurs sometimes plunge into it for profit. The florists' business has increased immensely during the last ten years; more flowers than ever before are grown, and more sold. There is an impression that it is a clean easy business, and a safe and profitable investment. American Beauty Roses bring 50 dols. a 100, Helen Kellar Carnations 8 dols. a 100, and Violets 2 dols.; and all that we have to do is to build some greenhouses, set out the plants, give them some water, and keep them warm; then cut the flowers, send them to the city, and get the money for them, and in a little while our pocket-book will become as big as our hat. But, alas! the facts are different. They are these: With a fair knowledge of the business, the strictest economy, and the closest application to the work, it will take an outlay of 20,000 dols. to realise a profit of 2000 dols. a year; in fact, as business now is, we are (says an American contemporary) placing the profits too high. There is considerable difference between gross receipts and net profits. The high prices received for flowers are mostly imaginary. Amateurs who have gone into the business know all about this; those who are contemplating entering should consider well before sinking their money in it.

— THE WEATHER IN GUERNSEY. — Last week was beautifully fine, after some warm rain on the preceding Saturday and Sunday. I am sorry, however, to say that the wind has again changed to N.E. with redoubled vigour, and is blanching the fresh green grass. Unless the wind changes again very quickly, the second Radish crop, now coming on, will have a severe check. Nearly the whole of the first crop of Radishes were killed by the frost, and this, coupled with the damage done to Broccoli, has been a source of very serious loss. We can now realise the woful effects of the late frosts on the shrubs. Nearly every kind has been damaged, and present a very weather-beaten appearance. Myrtles are almost past recovery, whilst Magnolias and Camellias have suffered equally. Until the Tomato season commences there is but little produce to export except flowers. The growers of produce in cold houses have had a rather rude awakening during the past six months to the risk involved in this class of house. The long spell of wet weather in the autumn causing the Tomatoes to damp off, then afterwards losing the Potato crop by the frost, has taught them a severe lesson. Yet, notwithstanding all drawbacks, the erection of glass houses in all parts of the Island is going on at a great rate—not exactly by the foot, but rather by the mile.—X., *Guernsey*.

— HEDGE PLANTS. — Mr. P. B. Christian, engineer of plantations at Tondern, North Germany, writes:—"Now, as before, people almost exclusively choose the White Thorn for laying out hedges. In fertile, well-cultivated ground, in a qualified situation, fine hedges of White Thorns may be raised if they are attentively cared for and regularly topped. But it is very often impossible to offer the necessary requisites before mentioned, even if we do not spare either cost or labour. Neither in a dry ground, in grey sand, gravel, heath country, nor in boggy, cold, flat land, in the bright sunbeams on steep slopes, can a good hedge of White Thorn be accomplished; and much less in the open acres of northern regions, where some storms, or the persistent coldness of winter, very much hinder the progress of vegetation. The Swedish upright-growing Box Thorn, however, is tougher and much more unassuming. In three to four years that plant, being content with every ground, even if it be the most barren, forms dense and durable hedges. The home of the Box Thorn is the northern part of Denmark, Sweden, and Norway, where we find the farms surrounded by it, even in parts where the climate is rough and unfavourable. The inhabitants of those countries set, therefore, a great value on the Box Thorn, which is most advantageously raised by layering in the months of March and April."

— CAMELLIA RETICULATA. — It is unfortunate that this fine Camellia is not more plentiful, for although it was introduced about 1820, it is only to be found in a few places in England. We have a fine healthy plant of it on the conservatory wall, covering a large space. For some time it has been in flower, and will be for a considerable time to come; the flowers are semi-double, of large size and frilled (over 7 inches across with us) of a glowing pinky crimson; these combined with its partially variegated foliage make a very effective show. A large plant of this Camellia would be most effective in bush form planted out in a large house mixed with others of an effective character, such as Donckelaari, the old Double White, and others of note. Although not now so much thought of as they were in former years, these Camellias, mixed with Palms, Tree Ferns, and greenhouse Rhododendrons, would when in bloom make such a house a place of special interest and attraction during the dull winter months.—A. KEMP, *Coolhurst, Horsham*.

#### WINTER-FLOWERING BEGONIAS.

WERE I to indite column after column setting forth the merits of this beautiful class of plants it would still be impossible for anyone to form adequate conception of the charming effect which is produced where winter-flowering Begonias are extensively and successfully cultivated. I need, therefore, make no apology for briefly referring to a few of the principal and most useful varieties for general purposes.

The first to claim attention is John Heal, which is one of the first to flower. It is of a dwarf and compact habit, and is exceedingly floriferous. The flowers, which are of a bright rose carmine colour, are thrown well up above the foliage, and cannot fail to please. To grow this Begonia successfully more than the ordinary care will be necessary, or the result will be the opposite of satisfactory. On no account must the plants be coddled, the better plan being to give them an intermediate temperature, and allow Nature to take its course. As soon as they are fairly started repotting should take place, removing about one-third of the old soil and placing them in a size larger pot. Watering must be very judiciously practised after repotting, for if once the soil is allowed to become sodden disastrous results will surely accrue. A suitable compost for this variety will be found in a mixture of good peaty loam, leaf mould and sharp sand. Green fly and mealy bug are particularly troublesome, and immediately signs of either are detected means must be taken to secure their eradication. I should recommend syringing the plants with a little weak tobacco water for green fly, and for mealy bug the best and safest plan is to pick it off with a fine-pointed stick. Adonis is a capital companion to the above with rather larger flowers.

In Gloire de Sceaux we have one of the most beautiful winter-flowering varieties in cultivation, and no collection should be without it. It is of an upright habit of growth, and the large flat flowers are of a beautiful soft pink, making a splendid contrast to the rich bronze foliage beneath. The best results may be obtained by raising young plants every year, as such bloom earlier and for a longer period than old specimens.

Manicata and hydrocotifolia I place together simply because they require similar treatment. The first named, although not of such a compact habit as the latter, is the better of the two. Its foliage, which is large and bold, is of a beautiful dark green colour, while the flowers of a pale pink colour are produced on large branching cymes of from 12 to 18 inches in height. Hydrocotifolia, or the Pennywort-leaved Begonia, is of a dwarf creeping nature. The flowers are produced very similarly to manicata, in large cymose heads of a beautiful rose colour, the pedicels and footstalks being of the same hue. Associated in a cut state with sprays of Asparagus plumosus they are practically unsurpassed, presenting a very light and graceful appearance. Young plants are useful for placing in epergnes in the drawing-room, two-years-old plants supplying capital ornaments for the entrance hall. Young plants should be propagated annually, as it is not advisable to grow them more than two years.

Nitida is rather a tall growing variety and delights in abundance of root room. It produces its flowers in large drooping clusters, and for grouping purposes is indispensable, while as a companion *semperflorens gigantea rosea* is very striking. *Knowsleyana* is one of the most free and vigorous of the whole section, and is of great value where cut flowers are in request during the winter and spring.

Many other varieties might be mentioned, but I shall confine myself to two others only, viz., *fuchsoides* and *weltoniensis*. The former has very much the appearance of a Fuchsia both in the manner of flowering and the shape of the bright red flowers which are produced in pendent clusters. To be successful in the cultivation of this Begonia it is essential that ample root space be afforded. The best plant I have seen was planted out in a large conservatory and clothed a large portion of the wall, the effect in the flowering season presenting a sight not easily to be forgotten. *Weltoniensis* for freedom of flowering cannot be eclipsed, and as a house plant or for window decoration is most useful, as it lasts a long time in perfection. Where the above varieties are given a fair trial, the results achieved will amply repay any trouble or labour expended on them.—GEORGE PARRANT, *Ashby Lodge Gardens, Rugby*.

#### AN OLD ROSE WANTED.

CAN any of your rosarian readers tell me the botanical name of a Rose that years ago was much grown by cottagers against their walls? It was about the height of the old China Blush Rose, but I think of more slender habit. It produced large clusters of small crimson flowers, and was called by the old women the Damask Rose. I have been trying to get these Roses from various nurserymen for years, but they always send me the old York and Lancaster, or a similar Rose, except in colour, which is crimson, and I have no doubt but what it is really the old crimson Damask, although not of the cottagers. My mistress often says, "You will get me a Damask Rose, won't you, when you are getting anything else?" I used to say, "Yes, my lady, I will;" but now I am obliged to say, "I will try."—SOMERSET.

#### EFFECTS OF THE FROST.

"W. R. RAILLEM" is correct in his conjectures (page 318) to a certain extent. During the latter and more exacting portion of the winter, we had, indeed, in this region abundance of snow; but for six weeks previously we had not this providential element during the prevalence of the frost. I presume that the experience of the Aberdeen rosarians, who have escaped so miraculously, would be the same.

In my last communication on this special subject certain words were unconsciously omitted, not by the printer, but by myself. What I intended to indicate by that somewhat fragmentary passage was this: that, though I had at least 150 distinct varieties of the Rose, and in many instances a considerable number of each, not one of these had been absolutely destroyed. Of these, not more than a score received any protection during the winter. I may also state that a large proportion of these were either Teas or Hybrid Teas.

I venture to think that if "W. R. Raillem," and many other extensive Rose cultivators would substitute dwarf for standard Teas, they would hereafter have greater satisfaction. I do not think the latter are much cultivated in Scotland.—DAVID R. WILLIAMSON.

#### IRON SUPPORTS FOR ROSES.

A LARGE number of growers have from time to time expressed their opinion that these are conducive of increased injury during severe frost. Having seen many cases where both practices prevailed, I am bound to say I find little, if any, difference. To my mind, especially in the case of Roses, it is more a question of increased exposure than any evil effects from association with iron in any form. Not only are the plants fully exposed to the whole of any severe weather that may prevail, but they are subjected to sudden and extreme changes. Bright sun for a brief period, followed by a very keen and frost-laden wind, are in my opinion far more injurious than any cause that can be clearly traced to iron supports alone. If this is not so, why do we find Roses not so situated, but still on iron supports, comparatively untouched?

#### WORK UNDER GLASS.

Mildew and aphid will soon be very troublesome unless we take early means to check as well as prevent. In a house devoted entirely to Roses I have little fear of mildew, experience having shown that a little care in the avoidance of causes is not only easy, but a safe prevention of this distressing enemy to Rose growth. Extremes of any kind are wrong, and never more so than when dealing with mildew. A free use of the syringe and a weak solution of any of the many proved insecticides will keep down all insect enemies of the Rose. But it is most essential to commence early, both as a preventive of injury and the establishment of the pests.

Mildew is the result of drought, draught, and undue changes of temperature. Good management will avoid these, and at the same time steer clear of mildew. Be generous in quantity if not in strength of liquid manures now that Rose growth is so active. A little may be afforded to young plants grafted this season, and the ammonia arising will help to keep the foliage sound and healthy. Colour and substance of leafage are imparted thus. Should the weather be warm and bright it is a good plan to slightly shade the Rose house now, or the temperature is apt to rise too high for the good of the plants, and necessitate more or less ventilation, with risk of a keen air which frequently prevails at this season.

#### ROSES OUT OF DOORS.

Our work outdoors is also coming on apace. There are both dwarf and standard stocks that were budded last season to attend to. These should be cut back close to the Rose bud, and a careful look-out kept for all suckers. Dwarf budded stocks present the most pleasing promise among all our Roses. The same cannot be said of standards, either plants or dormant buds; for, while the Briar itself is unharmed in many cases, sound buds are scarce. Spring mulching and surface stirring will soon be necessary; so, too, will the staking and tying of maidens, both dwarf and standard; therefore, opportunity should be taken to have sticks of suitable lengths ready sharpened. When maiden Roses com-

mence growth they make rapid progress, and a few days' delay in supporting, is courting failure from wind and rain at a time when the young Rose is exceedingly tender.—PRACTICE.

#### NEW ROSES.—HYBRID PERPETUALS.

(Concluded from page 319.)

THIS class, which in former years used to take the pre-eminence, has latterly fallen very much into the background; nor is this to be wondered at when we consider the magnificent varieties which have been sent out in former years; nor can there be any hope of rivalling the richness of their colouring, fragrance, or, in fact, everything—the beauty of the Rose! Does it not seem hopeless to get beyond such grand flowers as Marie Baumann, Horace Vernet, A. K. Williams, and Charles Lefevre? However, foreign raisers seem little deterred by the difficulties, and from year to year send us some, though not perhaps with such brilliant expectations as they have done in former years. The following is their description:—

**BARON DE ST. ALBE (Schwartz).**—A large imbricated flower of a fine velvety crimson red colour shaded with purple and currant red, very sweet scented.

**BARONNE GUSTAVE DE ST. PAUL (Glautenel).**—A very large flower with a firm stalk of a pale rose colour, with the reverse of the petals silvery; very free flowering and good for forcing.

**COLONEL MIGNOT (Chauvry).**—A very full large flower of a globular shape, rosy lilac colour, the reverse of the petals silvery rose, very sweet scented; offspring of Carl Coery.

**GÉNÉRAL AUNENHOFF (Lévêque).**—A well made large full flower, dark vermilion red in colour shaded with brown and puce; very free flowering.

**MADAME ANTOINE RIVOIRE (Liabaud).**—A large cup-shaped flower, very light rose colour, with the reverse of the petals of a carmine shade.

**MADAME DE LA BASTIE (Liabaud).**—A very large, full, round-shaped Rose, opening very well; of a light salmon rose colour, white on the edge of the petals, with the reverse of the petals of a duller red shade.

**MADAME LA DUCHESSE DE LORGE.**—A very large cup-shaped flower, opening very well, and of a carmine rose colour; very free flowering and sweet scented. Offspring of Elisabeth Vigneron.

**MADAME MARGUERITE MARSAULT (Cortœuf Marsault).**—A large, round full flower of a good shape, of a bright red colour, the reverse of the petals violet; very free flowering.

**MARIE HARTMANN (Hartmann).**—A large, full, imbricated flower, very good shape; colour blood red shaded with vermilion, free flowering, with the perfume of the Cabbage Rose.

**MERVEILLES DES BLANCHES (Pernet Père).**—A large full flower of a pure white colour, lightly shaded with rose colour in the centre; sport of Baronne Adolphe de Rothschild.

**MONSIEUR DE SYRAS (Schwartz).**—A large single flower, well formed, of a bright carmine rose colour, shaded with mother-of-pearl; flowering very well in the autumn.

**MONSIEUR GUILLAUME POPIE (Corbœuf Marsault).**—A large, well made, full flower of a pure bright red colour, without the slightest tinge of purple; very free flowering.

**SOUVENIR DE CHARLES VERDIER (Verdier).**—Medium sized flowers, united in a bunch of five to eight blooms of purple-violet colour, brightened with crimson-red, and darkly shaded with slaty purple; very sweet.

**SOUVENIR DE MADAME EUGÈNE VERDIER (Jobert).**—An exceptionally large flower of a fine round shape; bright rose colour, with the reverse of the petals silvery; excessively fresh delicate colour, very free flowering, and sweet scented. Offspring of Baronne Adolphe de Rothschild.

I have omitted some of the minor and more fanciful classes, for I do not find in them anything very promising or likely to captivate us much on this side of the channel; we have our own Sweet Briar Roses of Lord Penzance's raising, and I may mention here that Messrs. Keynes, Williams & Co. say we have not propagated these in anything like sufficient numbers, and the demand has considerably outrun the supply.—D., Deal.

#### MOUNT MERRION.

MOUNT MERRION, Co. Dublin, the Irish seat of the Earl of Pembroke, is situated on the gently rising ground of the southern side of "sweet Dublin Bay." From the more elevated parts of the demesne, the panorama disclosed is singularly striking. Looking seawards the bold headland of Howth on the opposite shore of the bay forms a fine background to the seascape, whilst on a clear day the blue outline of the Mourne Mountains in the Co. Down stands out sharp and clear in the far distance.

Mount Merrion is situated four miles from the "car drivingest city," and about a mile from either the Booterstown or Blackrock stations of the Dublin, Wicklow, and Wexford Railway. Merrion Avenue, a straight road from the sea, one mile in length, immediately faces the principal entrance to the demesne, entering which a noble avenue of trees forms a continuation of the line, broken only by the entrance gates. A broad margin of greensward each side of the road gives due proportions to this avenue leading to the mansion.

The quaint old pile, dating from Elizabethan times, has escaped

the improving hand which too often sacrifices historic associations to modern art. Looking through nineteenth century spectacles, this building appears somewhat undersized in relation to the broad acreage of the park and commanding aspect, an effect doubtless partly attributable to the massive trees. These are chiefly deciduous, the Elm predominating.

Inside the gardens a wide border of hardy plants comprising many good things shows that Mr. Crawford is in touch with the times. Other borders are devoted to summer bedding of annuals for cutting purposes. Asters are largely grown, and the Comet variety, especially the white one, receives due regard. This and the lovely white Princess Alice stock

FIG. 57.—MOUNT MERRION.

Situated between the mansion and the gardens is a densely timbered plateau with an underplanting of Laurels and intersected by drives. These afford some delightful peeps, one of which constitutes the view (here given) taken by Miss Armstrong. Before entering the extensive gardens some interesting—apparently natural—rockwork planted with Heaths and other suitable plants claims attention.

are of high merit when the zenith of the season has passed. A large patch of an old fringed Carnation, compact in habit, floriferous, of a dazzling crimson shade, is not to be forgotten.

In due season the extensive collection of Chrysanthemums arrayed—during their growth—in a sheltered square is, needless to say, the chief point of attraction with the fever-smitten ones, and as the immediate

neighbourhood is the very stronghold of mum growers, and Mr. Crawford literally and figuratively a giant of the tribe, love (perhaps fear) prompts due homage. Of what our portly conductor has done is a matter of recent history, carrying off at the last Dublin show a 20-guinea cup, a 10-guinea cup, and several first prizes. Of what he is going to do it is not for me to betray confidence, not forgetting "there's many a slip;" but if he does not retain his trophies in the next battle it will not be his fault, but rather that of some mountain-born breeze, which so often swoops down from the near inland hills.

In the glass department two serviceable span-roofed houses are filled with miscellaneous plants, among which is a fair sprinkling of Orchids—the ruling passion for some years of the late Mr. Welsh, Mr. Crawford's predecessor. Lean-to vineries and Peach houses, built at a somewhat sharp angle, have for many years done good duty, and do so still. In no part of the garden is the expert hand more in evidence than in the vegetable quarters, and considering how much the soil in this old garden has been taxed for generations, naught but good culture and judicious management by rotation of crops could produce results so highly satisfactory. One advantage, not always possessed by similar places, is that but few old fruit trees are allowed to cumber the ground. Well-cared-for pyramid Apples and Pears have taken their places, and prudence restricts the planting to such varieties as are likely to succeed where the soil and situation is not the most favourable.

Due respect is paid to two old Mulberry trees, favourites of the Earl and Countess. Near these trees, on a stretch of lawn "all shaven and shorn," are two massive rectangular beds, capable of swallowing up some thousands of bedding plants. These give a distinct feature to the garden, and render tribute sufficient to the fashion of bedding, for beyond a few beds which brighten up the vicinity of the mansion, the old love of hardy flowers is not jilted by the new.

Order and neatness is noticeable in all departments, bearing evidence of good generalship over the staff, each member of which appears to know what to do and how to do it.

#### OLD-FASHIONED FLOWERS.

SURELY a plea for some of these is justifiable. In these days of so much enterprise and keen competition, many and rapid are the changes constantly taking place in all phases of horticulture. The demand for something new, especially in the floral world, daily becomes more apparent, and to meet this all the skill and industry of enterprising nurserymen are called into requisition. To see the force of this fact we have only to scan the groups of plants and flowers at any large horticultural show, or wander through the Drill Hall, London, on the occasion of one of the periodical meetings of the Royal Horticultural Society. There may be seen new and rare plants of almost every species, exhibited by energetic growers, with the fond hope that the much-coveted certificate may be granted, by which the position of new additions in the world of horticulture becomes assured.

"Forward" is the watchword of the present age, and to keep pace with the times it becomes necessary that no stone be left unturned in swelling still further the vast number of beautiful flowers which now adorn English gardens. Therefore all honour is due to the indefatigable energy of raisers and growers who have done so much by their labours to raise the standard of horticulture to the condition we now see it.

There is also another side to the question; while we are so highly interested in the constant clamour for something new, do we not sometimes pause and think with feelings of regret of many old-timed favourites once so popular in our gardens, and now, alas! forced to take a place far in the background, or perhaps dropping out of the ranks entirely?

It is for such as these I would put forth a plea, and, happily, there are still many gardens in the kingdom where they are considered worthy of the place which in others is taken by something more modern and up to date. There seems to me to be a touch of pathos about old-fashioned flowers; a kind of connecting link between the past and present which cannot fail to appeal to the mind of a thoughtful man.

To illustrate this, fancy some weary wayfarer returning to the home of his childhood after perhaps a long sojourn in a foreign land. Kindred and friends are gone over to the great majority, the old house is pulled down or renovated beyond recognition, there appears to be nothing left to remind him of the old days; but, stay! there is surely something? Yes, the old garden flowers are still there, as if to welcome him home again. They spring up before him, and in their familiar forms he sees once more and lives over again his youthful days. There is the climbing Honeysuckle and Wistaria, trained in their early life by his own hands, flowering as profusely as of yore; the old Cabbage Rose bush in the corner nods him a welcome; tall Delphiniums, Snapdragons, Sweet Williams, Foxgloves, Lilacs, Laburnums, and hosts of others still occupy their old places, blooming on quite oblivious of the changing world all round. He is no longer lonely, as betwixt him and these there is a bond of friendship which long years of absence have failed to sever. No new species, however beautiful, could appeal to him like these simple flowers as he stoops to pluck a blossom ere he passes on, satisfied that all things have not changed. The tenacity in which some garden flowers stick to life is admirably portrayed by Goldsmith in his "Deserted Village," where he says:—

"Near yonder copse, where once a garden smiled,  
And still where many a garden flower grows wild,  
Where a few torn shrubs the place disclose,  
The village preacher's modest mansion rose."

Some may perhaps say, What has all this sentiment to do with the theories of modern gardening? The answer comes, Little or nothing. Perhaps, though, if I mistake not, all true lovers of horticulture are disposed sometimes to linger with thoughts of admiration and regard for flowers which adorned our gardens ages ago.

At this period of the year it will not be out of place to mention one section which it is gratifying to know never grow old-fashioned—viz, wild flowers. Soon the hedgerows and woodlands will be clothed with these gems of the spring. Beyond the pale of cultivation, they come and go undisturbed, and each season are accorded a hearty welcome: Unchanged by fleeting time, the modest Primrose and sweet Violet are held as sacred to-day as in the time when they adorned the festive ceremonies of the Druids in ancient Britain. No caprice of changing fashion ever comes to steal away the affection for wild flowers, and oftentimes may be seen the simple Forget-me-not, sweet Honeysuckle, and wild Rose mingled in decorations with costly Orchids and other delicate specimens.

No one will venture to say that the wild yellow Broom of the moorlands is not as popular to-day as when it adorned the helmet of the first of the Plantagenet kings prior to going to battle, and from which plant that line of monarchs received its name. All these worthies are now only figures in history, but the flowers are still with us, blooming on, regardless of the swift passage of time, occupying perhaps the same places from which they were plucked ages ago to crown the Queen of the May on the village green. So as they come and go we may read in their simple forms an unwritten history of the early and middle ages. There is yet another difference between wild and cultivated flowers. On seeing one of the latter the first thought of an enthusiastic gardener is, whether he cannot by his superior art improve on it and obtain something still more attractive. With the former no such idea enters his head, he is satisfied with its simple beauty, and knows that no effort on his part can add to it. Apart from gardening proper, the same love of wild flowers is displayed by all and everyone. To see this we have only to notice the crowds of boisterous excursionists returning to some crowded city after a day in the country laden with these treasures of the fields, which doubtless carry with them a gleam of sunshine into many a court and alley.

To all who are engrossed in the productions of new additions I would say, that commendable as your efforts are, let them not be the means of stealing away attention from many which were the pioneers of floriculture in England.—G. H. H.

#### MODERN GRAPE GROWING.

(Continued from page 316.)

##### THE TRELLIS.

I HAVE no reason for altering the line of trellis adopted twenty-five years ago—viz., not less than 2 feet from the glass anywhere and 8½ feet above the centre path. This brings it away from the ridge between 4 and 5 feet, one of the objects being to keep the bunches out of the reach of hats and bonnets and yet to have the foliage as far as possible from the ventilators. It is also a great advantage to have the bunches sufficiently low that as many as possible of them can be seen and attended to without steps. True, we lose a little in the length of rod, but it only amounts to about 18 inches in a wide house, and the advantages more than counterbalance this.

There is no need in our modern light houses to "keep close to the glass" for the sake of light, because it is light everywhere except it be shaded by the plants, and where a span-roofed house does not run due north and south, as often happens unavoidably, the side which is most inclined to the north will be under a disadvantage, therefore the lower the trellis can be kept in the centre of the house the longer will the sunshine reach the upper surface of the Vines growing on the colder side.

It is of the greatest importance that the upper surface of every leaf should be exposed to the action of light and air; indeed, the leaves themselves are teaching us this lesson every day in our lives, for no sooner do we tie a branch down and alter the position of the leaves than they instantly commence re-arranging themselves, and cause the stems to alter their angles and assist them in doing so. When we allow the leaves to press against the glass they are helpless and probably useless, for their upper surface is for the greater part of the time covered with water, sometimes boiling, sometimes freezing, and transpiration cannot go on properly. In addition to this they are preventing the light and air reaching other leaves. Where a practical gardener is called on to give his advice of course all these matters will be taken into consideration and well thought out at the time of fitting up the houses, but unfortunately so many proprietors, though they are willing to give their gardeners all due credit for their cultural abilities, yet seem to think that everybody else knows better about the fittings necessary for successful cultivation.

I have always been fortunate in having reasonable people to deal with in this respect, but I have seen many of my brethren of the craft who possess great abilities, and yet are severely handicapped. I know of one large establishment just lately entirely renewed. The houses are handsome, and are built of iron and glass; but the ventilating gear is so arranged that you cannot open the south side without opening the northern one at the same time. The gardener is a clever man, but if he succeeds in growing Peaches and Grapes to his own satisfaction in these structures as they are, he is far more clever than I take him to be.

In the Longleat vinery, the wires forming the trellis are stretched

lengthwise of the house, and where the Vines are to be planted at a less distance apart than ours are perhaps this is the best plan, but as none of ours are much less than 5 feet apart we have a simpler, more convenient, and less expensive arrangement. Half-inch gas pipe is fastened at the proper height by screws to the wall or mullions, as the case may be. Another pipe of the same size is suspended from the T iron, which forms a purline about 9 feet up the rafters, and small galvanised wires are stretched between these two pipes, and continued to the T iron on the opposite side of the span. Three of these wires are used for each rod—one for the rod itself, and one on each side, 16 or 18 inches from the centre wire, to tie the branches to. I find this is all that is necessary, and it makes it an easy matter to get up between the Vines, and look over them in any part of the house. As the wires are merely twisted at the ends on to the gas pipe, we find it very convenient to be able to shift one a little one way or the other, when it happens to be in the way of a favourite bunch.

THE WATER SUPPLY.

It is a cruel thing to build costly vinerias and expect a man to grow Grapes without giving him an adequate supply and means for using water. Making bricks without straw is, I believe, not an impossibility, but attempt to grow Grapes with an insufficiency of the commonest yet most precious of all liquids and you will fail. At Longleat provision was made for catching and storing a large quantity of rain water. This I now consider was not necessary, for spring water is probably the best for fruit trees, only it should not be applied too cold. Mr. Chaffin has fixed two large brewer's tubs capable of holding upwards of 7000 gallons at an elevation of perhaps 200 feet above the vinerias. These tubs are supplied by a never-failing spring of ample volume, and they are connected by pipes and taps with all the houses, where a supply of 960 gallons an hour can be had, so that with a hose watering in the summer becomes a very simple matter.

For use during the spring months we have a separate and smaller supply, which can be drawn at the requisite temperature in any one of the houses. This is used till such time as the water in the large tubs reaches a temperature of about 55°, which it generally does at the end of May or beginning of June, by which time the wants of the Vines are greater.

Where the requirements are not large a cistern supplied by a tap inside each compartment would be sufficient to afford water during the early growth of the Vines, if care was taken to keep it filled and water a portion of the border each day, or whenever the water had become sufficiently warm that it would not lower the temperature of the soil when applied to it. Some writers, I know, have said in the Journal that it is not necessary to use warm water at all; but I do not intend to take their advice. On the other hand, I do not like to use it too warm, as it takes too much out of the soil.—WM. TAYLOR.

(To be continued.)

check rapidity when falling—serving as a parachute as it were. When an earwig drops it would seem as if it must have fallen to the ground, but on a close examination, as all mummies know who tenderly watch their plants, the insect will be found to have clung to the edge of an underneath leaf or stem, and as a somewhat curious fact I may mention that I have invariably observed that if when using a bull's-eye lantern and tweezers I have failed to seize an earwig on the first occasion, the next night the insect will fall immediately the light is cast on to the plant.—HENRY BRISCOE-IRONSIDE.

[We are obliged to Mr. Briscoe-Ironside, and have returned his enclosure. His patent differs, as he intimates, from the rim barrier, which appears similar in character to that forming part of a seed pan

FIG. 58.—AN EARWIG BAFFLER.

of Mr. Wm. Moody Bell, of Cheltenham, and which we figured in 1891. It is shown as plunged in the engraving (fig. 58), and protected by a hand-light. The channel is an excellent barrier against slugs and woodlice.]

CULTURE OF DELPHINIUMS.

AS seen in many gardens in which a few of these plants are represented, the Delphinium would appear to count for little, giving no true estimate of these easily cultivated and perhaps the most noble of our hardy border flowers. Would that I could fully describe the effect produced on my mind by some 300 to 400 plants in flower, grown so admirably by Mr. Robertson, gardener to W. S. McMillan, Esq., Ardenholm, Maghull, near Liverpool, not feeble little plants, but giants of strength, from 4 feet to 8 feet high, clothed with foliage down to the ground.

In dealing with their cultivation it will perhaps be more to the point if the preparation of the ground is first dealt with. If there is no stint of good cow manure so much the better, as the bed can be properly made in the first instance; and with good feeding and top-dressing will give the most satisfactory results for some years. The site determined, remove the old soil to a depth of about 3 feet, placing at the bottom 9 inches or a foot of good cow manure, filling in the remainder with a mixture of old turves, decayed manure, and lime rubbish, levelling all ready to receive the plants.

A stock can be easily raised from seeds which may be sown at once in pans or boxes filled with good sandy soil, covering them slightly, and remove to a warm house, where the seedlings will soon appear. When large enough to handle prick into small pots or boxes, using good loam, leaf mould, and silver sand for a compost. Keep them growing steadily and harden the young plants previous to planting, which may be done when danger from frost is over. If raised from seeds they may be planted somewhat closely for the first season, as a vigorous weeding out is certain to take place if only the best are to be retained. The following season a distance of from 3 feet to 4 feet apart should be given. They may also be propagated by division, the latter being recommended where good varieties are to be increased.

Before staking it is well to determine how many spikes are to be left consistent with the strength of the plants. The inside shoots may be secured, first giving sufficient room to show the spikes to advantage. By a little judicious management foliage disfigured by cold winds in the early part of the season may be almost covered.

When the plants are about a foot high feeding may commence, with rather weak supplies of diluted liquid manure given twice a week, increasing the strength as the spikes appear. Soot and lime act as fertilisers, and are great preventives against slugs. After flowering, a good sprinkling of bonemeal round each plant will be found beneficial; continue the watering until the plants show signs of rest, when a

BAFFLING EARWIGS.

ON page 311 of last week's *Journal of Horticulture* I see an account of an earwig "trap" in the form of a 9-inch pot with a water-holding rim 1½ inch wide by 1 inch deep. I should like to say that several years ago I had a few similar pots made, but found there were several drawbacks to the same, such for instance as price, clumsiness, absorption of water in dry weather, and thus not serving their object, stagnation at the base of the pot during wet weather, also holding water when the plants are housed, another strong objection. I therefore invented a stand to hold water, which I patented some years ago (as per enclosed). A good substitute, however, at a trifling cost, is a saucer or seed pan without holes, placing a smaller one inside inverted, then filling with water. The plant when stood on the inverted pan is thus surrounded with water. My experience of the results of this protector I mentioned at the Centenary Conference of the National Chrysanthemum Society.

I am now residing in a pottery district and use bowls glazed inside, and place therein 48-size pots inverted. To secure the plants in case of wind wire tightly drawn back and front is fixed to the posts to come just under the rim of the flowering pots. The original idea is seen in the old Dahlia ring, but now other systems are followed, and in some cases trenches filled with water.

I can thoroughly recommend the two-pan system or the bowl and inverted pot, and would add that it is desirable to attach rag soaked in petroleum at the bottom of the posts, or adopt some means to prevent earwigs crawling along the wires and so reaching the plants. To those who have limited means, space, or time a considerable saving is made, and much trouble, annoyance, and disappointment spared when adopting some arrangement after the principle I have mentioned.

Perhaps I may take this opportunity to say that in regard to the movements of the earwig I think there need be little fear of its flying upwards, as after having watched this insect very closely for some years the only object of its wings, so far as my experience tells me, is to

moderately thick coating of ashes placed over the crowns will preserve them from harm during the winter. I append a list of named varieties sufficiently good to satisfy the most exacting—Britannia, Beatrice Kelway, Ben Davies, Evelyn, James Kelway, Lord Charles Beresford, Miss Macintyre, Miss Salway, Mr. Edgar Wild, Nuphar, Robin Adair, and Sea Spray.—R. P. R.

### PRUNINGS.

MR. ARNOTT'S sectional diagram (page 247) of rockwork for hardy plants was not as satisfying as his inimitable papers on that subject are. In fact, t'was pondered over till I found myself humming a few bars of that stirring old tune, "Such getting upstairs I never did see!" Yet, as he explains, the outline is not a hard and fast one; it has, too, the merit of simplicity, and a simple plan is often the safest.

If the only reason in substituting Rape for Mustard (*vide* cutting from the "Globe," page 249) is that it can be cut in a week, as against a fortnight for the Mustard, then it is no reason at all, for I find it easy to sow and reap the genuine article inside of a week. This is the gist of the matter *in globo*. I use shallow wooden trays, 1 inch in depth, half filled with rough leaf mould, on which the Mustard or Cress is sown without covering; watered with warm water, then piling the trays muffin fashion. Germination is rapid. This effected, they are removed to the light, and further watering is done by running a little water through the trays without wetting the leaves.

*Eucharis Stevensi*, judging by fig. 44, page 253, appears to be more recurved than the type, in addition to the merits claimed for it. I welcome an old friend appearing by proxy through the haze of a score of years, coupled with some kindly thoughts of him and his hospitable "missus."

"D., Deal," deals trumps in his notes on new Roses (page 254), and very reasonably asks what an English gardener would make of the name Grande Duchesse Héritière Anna Maria de Luxembourg? It is a question not easily answered. I could have recommended for the purpose an old gardener who loved his "Glory de Johns," but he has long since "shuffled off this mortal coil." Anyway, I venture to say that its own parent—the raiser—would not have known it.

All holders of (Dahlia) stock are indebted to Mr. Mawley for his comprehensive balance sheet (pages 265-267). In the Cactus section I venture to predict that Juarezi will always take high rank. In fact, they are all very beautiful, and the exhaustive analysis will keep old growers up to date, may bring new investors to take up some shares, and there is but little danger of love's labour—by "E. M., Berkhamsted"—being lost.

Mr. Dunkin ably pleads and prescribes for the sick and wounded (page 268). A hot (hospital) bed would indeed be a boon in many gardens, for many who have not this convenience are prone to sacrifice their maimed and mutilated on the altar of appearance by throwing them out. On one occasion when noting the super-luxuriance of some large Palms, in very small pots, just imported from the Continent, I was told by one who knew, that they had been grown in strong bottom heat standing thickly together. And—tell it not in Gath—where the roots had come through they had been trimmed off! Would that Mr. Dunkin could be the universal provider of the wants he so well depicts.

I am quite of the same opinion as "E. K., Dublin," on the advisability of moving with the times (abnormal seasons) in the matter of flower shows, but must confess that, while he exposes an evil, the remedy is not clear, so all concerned are as they were, and likely to remain so, unless the verdant imagination of our Hibernian friend can suggest a way out of the bog.

Glad to see you, Mr. Molyneux, among your beloved 'mums (page 277). The border section needed a little stimulus. They have it now. You had but to say "I recognise the merits of this section," when "so say all of us." I must now seek the whetstone.—SAYNOR.

### A SPRING DAY AT FULMER.

As a rule when one goes visiting in the country during the early spring months it is with the hope of seeing something special, something out of the ordinary run. A little later in the season the trees and hedges are bursting into leaf, the birds into song, and everything wears an air of tranquil peace that is peculiarly soothing to the nerves of the townsman provided he is a lover of Nature. A Londoner recently in quest of a restful pilgrimage found himself at Slough, with a four-miles drive before him, "coached" by Mr. J. G. Mowbray. The route was picturesque, the time shortened by anecdote till reaching the gates of Fulmer, and we were soon in the skilful young gardener's pleasant home. Here, "far from the madding crowd," is no haste, no bustle, no smoke—nothing but sweet surroundings and a quiet peaceful calm. Under their soothing influence we discuss congenial topics deliberately—lazily—till darkness steals silently on, rendering it impossible for us to examine what we had come in part to see—the Cyclamens—the

home display, from which plants were drawn that swept up the chief prizes at the Crystal Palace show last month.

As is befitting on the part of gardeners, we were out in good time in the morning. At no time do flowers look so fresh and so bright as under the gleams of the early sun. Refreshed by the rest of night, their substance seems increased and their charms intensified. Is it not thus with most flowers? It appears to be distinctly so with Cyclamens, which are apt to look a little jaded some hours later on sunny spring days.

The sight on entering the structure is indeed a glorious one. Each side is a mass of blooms—sheets of white, rose, red, and crimson—while on a shelf above is another bright and beautiful display. No sign of the staging is perceptible, the plants having to be placed in direct contact one with the other to permit of space being found for them. A single pot is placed on the floor, and then the individual dimensions of the plant are first recognised, being almost 2 feet across. The habit is perfect, foliage stout, strong, and beautifully marbled, and the exquisite blooms stand boldly above the leafage. That single plant in a 6-inch pot is worth travelling a very long way to see. Dozens of plants are grown, some in 4½ and others in 6-inch pots, as Mr. Mowbray is not a believer in growing plants year after year, the majority of his being two and three years of age. The strain of seeds is an excellent one, as the flowers combine so admirably clear colouration with perfection of form.

The question as to the mode of culture followed is approached with diffidence, as we fear the grower may be reluctant to give himself away, so to speak. Such, however, is very far from the truth, for he is only anxious to give the world the benefit of his experience, in the hope that it may be of assistance to some less successful slave to the Persian beauty. Its name is Simplicity. The seeds are sown in pots or pans at any time during the months of October or November, the whole, after moistening the soil, should this be dry, being covered first with a sheet of glass, and then with a piece of brown paper. The receptacles are then plunged in boxes of moss, these being stood on the hot-water pipes, the moss never being allowed to become very dry. Immediately the young plants appear the glass is gradually tilted to admit air, more and more being given until the seedlings are fully exposed. Directly this stage is reached the pots are stood on a shelf close to the roof glass of an intermediate house, and as the plants attain to sufficient size are pricked out into pans, and again placed on the shelf, where they remain until they are ready for placing singly in small pots.

The operation of potting, which commences directly the plants have two or three leaves, is carried out with the utmost care, the first shift from the pans being into small 60-sized pots. This with the next transfer, which is to large 60's, is what may be termed a light potting, the soil not being pressed at all firmly round the roots; the next move brings the plants to 48-sized pots, and the final into, as was previously mentioned, 32's or 6-inch pots, each of the latter pottings being comparatively firm. At the earliest potting the corms are buried in the soil, and at the last are right on the surface. During the whole of the period covered by the growth to this stage the plants are kept on the shelf, and freely syringed, the temperature ranging between 65° and 70°. In the month of July the plants are removed to a span-roofed pit, and there left until October, when they are brought indoors to commence flowering. From the time the seeds are sown until the plants are in flower the attention is unremitting, and as such deserves success.

The compost for Cyclamens is a matter of some importance, and varies with the different stages of growth—becoming gradually stronger. At the first it consists of about three parts leaf mould to one of loam; while at the last the positions are exactly reversed. These proportions are, it may be well to point out, approximate, as Mr. Mowbray simply goes by the feel and appearance of the soil, not measuring anything. At each of the stages a good admixture of road sidings, or in the absence of these coarse sand, is thoroughly incorporated with the soil. As with the mixing of the soil and potting the utmost care is taken to insure good drainage, the advantage of looking after such details being fully recognised.

Though Cyclamens are grown so well it must not be imagined that other plants are neglected, for such is not the case. Attention is given to all plants grown to such extent as to bring them as near perfection as possible. The Freesias may be adduced as an example of this, for though of the variety *F. refracta alba*, they have become, by extraordinary cultivation, almost unrecognisable. They are superior to those usually seen in all ways. The growth is stronger and dwarfer, the flower spikes are more numerous and more profusely bloomed, while the colour is purer and clearer and the scent even more fragrant than customary. Compared with many so-called varieties of florists' flowers, and between which there is so little difference, this is undoubtedly worthy of a distinctive name. Were it an Orchid we might dub it *F. refracta alba*, Mowbray's variety, but as it does not come beneath this magic category we must perforce leave it as it is. If the grower would favour the readers of the *Journal of Horticulture* with his method of treatment there can be no doubt that the notes would be read with interest, and be of great assistance to many persons who are desirous of improving these beautiful and deliciously fragrant flowers.

At Fulmer fragrance, combined with beauty, is the desideratum, hence we see large numbers of Freesias; handsome plants of Gardenias grown as they are rarely seen, so pure is the colour, so perfect the form and so powerful the scent, and of which details of culture would be welcomed; Violets, Hyacinths, and many others all showing the influence of watchful care. Foliage plants are also admirably grown

here, Crotons being especially rich in colour. Scent of foliage is also taken into account, for scented Pelargoniums, Lemon-scented Verbena, Eucalyptus citriodora and *E. globulus* are each well represented. A few of the many plants grown are mentioned, but these must be sufficient for the present, as we would like now to glance hurriedly at the fruit.

Both outdoor and under glass fruits are grown, many kinds being represented in varying numbers. Of the hardy fruits, nothing could be seen but bare stems at the time of our visit, though now, no doubt, with the warm sunshine rapid advances have been made. Under glass a very different aspect of affairs is seen, for here the fruit on many trees is well set, and others are in full bloom. Most of the Peaches and Nectarines are old trees that have seen their best days, but still Mr. Mowbray hopes to secure some more good fruits from them. The Vines though also rather old, are still promising a good return for labour, and if the crops of any fruits are not good, it will not be the fault of the grower, who evidently does his best to grow everything well.

Fulmer, though not an old place, has many splendid trees, Conifers being especially fine, but of these, with the Rhododendrons, more may perhaps be said later in the year. The place was "made" by Mr. J. Mowbray, sen., and under the superintendence of his son will be a lasting memorial of his untiring energy and indomitable perseverance in overcoming all obstacles. In the early days of Mr. Mowbray, sen., there was no mansion on the estate, but the present owner, Major the Hon. H. C. Legge (who, with Mrs. Legge, is very fond of gardening) has caused one to be erected. There are several good points about the place, such as the vinery, the mansion, the trees, the gardens, the gardener, and others; but these will be sufficient to show that here is comfort and unity, and such an air of tranquil peace, as is mentioned above, pervades o'er all. At last we turned our faces homeward, and soon the train whirls us into London and smoke.—NOMAD.

#### ANEMONE PATENS OCHROLEUCA.

IN complying with the request of a correspondent the illustration (fig. 59) will furnish him with an idea of this pretty variety of Anemone. It has cream white flowers, somewhat larger than those of the normal species, which are very attractive. The plant is perfectly hardy, being a native of Siberia, and is rarely seen in cultivation. *Anemone patens*, or the Spreading Windflower, is a variety little more common and easily grown. The flowers, which are about the size of those of the common Wood Anemone, are of a pleasing light yellow colour. It grows to a height of about a foot, and soon forms large clump in rich soil. Both varieties flower during May and June, but not very profusely.

#### MARKET PLANTS AND FLOWERS.

SKILFUL cultivators of plants for market purposes wisely act on the principle that it is the better plan to grow a few well than a more varied stock indifferently. Thus it is that Covent Garden Flower Market is so well supplied all the year round with plants and cut flowers, whose cultivation leaves nothing further to be desired in the ideal of excellence. How that result is obtained is most important, and is no simple question that can be answered in an off-hand manner. There are several important items to be considered and formulated previous to the propagation of stock and future development.

The principal feature of such items may be enumerated under the heads of capital, brains, energy, and last, though not least, situation. Skilful gardeners cannot grow good Grapes where the vineries are overshadowed by tall trees, nor can they in an atmosphere overcharged with carbon grow some of our common plants to perfection and fit to be admired. It may also be observed that it is to the evil influence which is ever present in the atmosphere of the metropolis that some of those nurseries, which used to be the glory and pride of young gardeners, have altogether disappeared. Situation may not be everything, but it certainly is nine points in a grower's favour. Some localities may do very well for the cultivation of Palms and Ferns, but to attempt to grow common Zonal Pelargoniums, Genistas, Calceolarias, Hydrangeas, or Roses, with a view for Covent Garden Flower Market, courts nothing but failure. Let anyone try his utmost, his Zonals lack the vigour of country grown plants; the foliage is thin and pale, the flower stalks weak, and the blooms feeble in tone; and of all places in the world where such a contrast is perceived it is in Covent Garden Flower Market.

The buyers can tell in a moment. The Genistas are weakly wooded, straggly, and the flowers a dullish yellow, and are altogether scarcely fit for the coster's barrow. It is the same with all other flowering plants he may attempt to grow, and the consequence is that they hang on his hand, and go at last for an "old song." Even if the cultivator should go in for Palms, the extra labour entailed in keeping them clean and fit for market is a great drawback. No one but those who have experienced the disadvantage of plant culture, where they are surrounded by myriads of chimneys continually on the go, knows that excellence is an impossible result.

Those who wish to make a start on their own account in the paths of the divine profession must beware a soot-laden atmosphere as they would the fabled locality of the "Upas tree." Also let them beware those glowing enticements of a good going concern of so many thousand feet of glass at moderate rental. Remember the old adage, No one likes to part with a good horse. Possibly the extensive range of houses

may not be adapted for the successful cultivation of plants for market, which is altogether a different thing than the growing of plants in private establishments. The structures may be lofty and too heavily timbered, which may do for vineries or tall Palms for furnishing, but are altogether unsuitable for growing the ordinary run of market produce. The heating apparatus may be defective in quantity and quality, the ventilation may be insufficient and unworkable, the staging may be in last stage of decay; take out your knife and give the wood a tap or two, much in the same manner as a second-hand carriage dealer raps the panels and spokes to arrive at a sense of their soundness. Then again the water cisterns may be leaky, and out of place by being situated at

FIG. 59.—ANEMONE PATENS OCHROLEUCA.

one end of the house instead of at the middle; and if a span-roofed house such cistern should extend to both pathways, so that the watering pot can be dipped in readily—no filling cans at taps will do for market growers. Then the drainage of stokeholes may be defective, causing the fires to be damped out at a most dangerous moment.

The most favoured localities, where the best market growers are to be found, and who attend Covent Garden Flower Market all the year round, are chiefly established in the sunny valleys of Kent, where there is abundance of that fine yellow loam which is the most suitable for the growth of softwooded plants. The natural soil produces first-class crops of Grapes, and when it can do that we know the value in a horticultural sense; and no doubt it is the circumstance of an abundant supply of good material that favours Kent in the eyes of market growers.

The horticulturist who pays a visit to some of those establishments may be rather disappointed to find them more useful than beautiful.

Range after range of light span-roofs from 5 to 10 yards in length, and from 7 to 12 feet in width, some sloping to the ground, others resting on brick walls about 3 feet high, and ranging from 20 to 60 yards in length, and void of all outside ornamentation, and some of them without a fence or tree to block the sight; such is a market-growing establishment; but when we look inside the houses we see how well they are constructed, how well they are heated, and how instantaneously perfect in ventilation; that the plants themselves seem to know what is required, and are matchless only with themselves. It may be a houseful of Genistas, Ferns, Cyclamens, scarlet Pelargoniums, Fuchsias, Marguerites, or splendid Mignonette grown in long narrow pits, heated of course, but so that the lights can be taken off on all favourable opportunities. The culture of all and sundry leave nothing further to be desired.

When we come to consider that the number of such growers may be counted by the hundred, for they are not only in Kent, but located round and round the outer zone of the metropolis, we can well believe the business transactions to be of no little magnitude; indeed, it may be said that the business done in plants and cut flowers shows the healthiest increase of any other profession that can be mentioned; and if the love of flowers as beautiful adornments to civil life be any criterion to go by we may certainly say that the cultivation of plants need have no fear for the future.

Though some of the best market growers may be found located in many parts of Kent, yet excellent produce comes from Clapton, Edmonton, Tottenham, Southgate, and Finchley, but the smoke fiend is fast finding them out. The Londoner himself has to encompass a distance of fifteen miles before he can be sure of beholding the sun in all its brilliancy. Botanists, as they ascend some of the mountains of the world, pass through belts or zones of vegetation, and the higher they travel members of the vegetable kingdom become more dwarf and hardy, and are lost sight of, giving place to mere lichens. Such we may compare the metropolis of the British Empire to one of those mountains, the City being the apex. We find vegetation extremely vacant, yet on examination we find on buildings, such as sacred edifices, the Liverworts, but so covered over with carbon that they might well be termed Sootworts. In moving out from the heart of the City the horticulturist recognises a cosmopolitan in the *Aucuba japonica*, but in a weakly state. Then he comes to the zone of Plane trees struggling to get to the tops of the houses, but never will. A little further come the Limes, Lilacs, and Laburnums, and the under shrubs, such as the *Aucuba*, the *Euonymus*, looking terribly sickly and dilapidated, while for a covering to the walls the Virginian Creeper seems to be the only plant to thrive, and it is not until we get to Acton or Ealing that a zone can be found where vegetation may be said to be fairly healthy and vigorous, and a type of what it ought to be.

Nevertheless, for all the drawbacks against plant life in towns a certain amount of good springs out of the black evil in the atmosphere. Innumerable plants of the commoner kinds, such as red and white Daisies, Arabis, Pinks, and a host of others not annual by nature are made so by the vitiated atmosphere, and thus a great number of small growers who propagate and cultivate such plants for market find a comfortable living.—A. M.

(To be continued.)

### VIOLETS IN WINTER.

I WAS quite pleased to read the article by your very able and energetic correspondent, Mr. E. Molyneux, on page 289, and I heartily endorse every word he writes in the praise of sweet Violets. As to their being neglected, I am pleased to say such is not the case in this neighbourhood, for there are Violet frames in most good gardens, and in a few they are quite a speciality. One young lady boasts of never appearing in public without her bunch of Violets when it is possible to procure them, and in the garden here we are expected to have Violets from October to May in a small but continuous supply—a task more formidable than your correspondent would have us believe, especially if a little artificial heat is not at command. Let us consider the very severe winter through which we have just passed. We had six weeks continuous hard frost, many times the thermometer registering over 30°, and on two occasions 37° of frost. Our Violet frames were never opened during this spell of severe weather, and if we had not had a frame which we could enter, with hot-water pipes sufficient to keep out King Frost, where would have been our continuous supply of Violets? I do not wish to imply by these remarks that Mr. Molyneux was not able to keep up the supply of flowers without fire heat, for I know he is one of those men who are difficult to be beaten by anything; but I do wish it to be understood that it is much easier of accomplishment when fire heat can be employed if required, and I maintain that fire heat is an advantage in winter Violet culture if properly applied.

The frame I mention above is really a three-quarter span pit, about 60 feet by 10, in three divisions, with a path along the back, where we root and winter our Chrysanthemums. One of these divisions was filled with Violet plants—Comte de Brazza and Marie Louise, both of which flowered splendidly just when most wanted. One hint is necessary here—do not fumigate Violets if you can avoid it, as they do not like tobacco smoke. We had some Pelargoniums on shelves in the same division which required smoking. The Violets were covered with newspapers during the operation, but it did not save them. Almost every tender leaf was marked more or less, while the Pelargoniums were injured. With the experience of last winter fresh in our minds we have

decided to erect new frames for our Violets, into one section of which we hope to arrange pipes according to the sketch enclosed.—A. HAGGART, Ludlow.

[The sketch represents a three-quarter span brick pit, 9 inches above ground on one side, and about 2 feet on the other. The upper part of the walls are 4½ inch (no doubt to be set in cement), for affording a ledge for a flow and return 2 or 3 inch pipe. The pit is 6 feet wide, there is a depth of 2 feet for fermenting materials, and a flow and return pipe for bottom heat is also provided. The desire is to afford ladies an opportunity of gathering Violets in the winter, where litter for covering frames is objectionable. The "American Florist" gives an illustration of a span-roofed Violet house with a central sunk path and side beds, heated by a pipe at the base of the rafters. In such a structure ladies could gather Violets with ease and comfort in winter.]

### FUNGOID DISEASES OF PLANTS.\*

THE importance of devoting more searching and systematic attention to the diseases of plants has been gaining ground in late years. This is evidenced abroad by the establishment of experimental stations and the publication of detailed and explicit reports, but, unfortunately, in this country very little has been done, and that solely by individual effort. It is true that we have a Government Department, which corresponds to a Department of Agriculture, but the very meagre reports are only additional evidence of the indifference which characterises the "higher powers" in all which concerns the diseases of plants. How disastrous these diseases may be has been exemplified by the damage done to corn crops in Australia, Apple crops in parts of the United States, to Coffee in Ceylon and Mysore, to the Opium Poppy in India, the Cocoa-nut Palm in the West Indies, the Tobacco crops in Australia, the Vine industry in parts of Europe, and now to the Sugar-cane in the West Indies. In nearly all these cases it was not until the diseases became established and a vast amount of injury was done, that any effort was made to combat the disease. There is no reason to doubt that it is possible to check the spread of these diseases if effort is made in time, but the great desideratum is a more extended knowledge of the nature of the parasites, and the methods of remedy which have been applied in similar cases when any one of these inflictions becomes a disaster and a large industry is threatened with ruin, and not till then, do we hear the cry for scientific investigation, and suggestions of remedies.

Those who are practically conversant with horticulture will be ready to admit that diseases in plants may have several causes. They may result from the attacks of insects of various kinds; they may be consequent on the incursions of parasitic fungi; they may result from external injuries; in some cases disease may be as hereditary as in the animal subject; and in a great many cases we venture to think that they are the result of bad or mistaken cultivation. It is not flattering to the culturist to be informed that any failure is due to bad culture, and very few would believe it if they were told; but undoubtedly, speaking from a large experience, we are bound to confess that it is not uncommon to meet with cases in which plants in a diseased condition have been supposed to be infested with fungi, and treated as such, in which no trace of fungi could be found, and the diseased condition could only be attributed to bad cultivation.

It is not our intention to occupy your time with allusion to any other of the diseases of plants than those produced by the attacks of fungi; but before making those observations to which we desire chiefly to direct your attention, we might offer a suggestion or two on a closely related subject. We will suppose for a moment that microbes and ferments are not fungi, but very close relations; yet there cannot be the slightest doubt that they are intimately associated with diseases in animals, and possibly, more than we think, with the diseases of plants. It is not so many years since the discoveries in connection with anthrax determined the question of the presence of bacteria in certain diseases of animals, whilst every year adds further knowledge, which leads to the conclusion that bacteria are not only present, but are the primary cause of many forms of animal disease.

In past times we spoke of zoology and of botany in terms which led to the inference that life in animals and life in plants were quite different things, whereas nowadays we are in the habit of speaking of biology, and thus tacitly confess that, in all essentials, life is the same in plants and in animals. Such being the case, and there are more analogies than we commonly admit, then there may be great similarities between the diseases of animals and those of plants. This was pointed out, on a memorable occasion, by Sir James Paget, and experience strengthens the views he then enunciated. There have been of late years some startling revelations as to the presence and infectious character of microbes in plant diseases; some of these have been, and others are waiting to be confirmed. Only to mention two or three we may instance the Californian Vine disease, that prevalent North American disease, "Peach yellows," another disease called the "Pear blight," and a rotting disease in Melons and Cucumbers. In the last instance experiments proved that the disease could be communicated to healthy plants by inoculation with the juice of diseased Cucumbers. Admitting all this to be substantial, we are face to face with a new aspect of plant disease corresponding to diphtheria, scarlatina, typhoid, and other zymotic diseases of animals, and a question to which horticulturists would do well to keep open ears and observant eyes.

In the case of diseases in the human subject, we know how much

\* Lecture by Dr. M. C. COOKE at the Horticultural Club.

depends on an accurate diagnosis of the disease. The symptoms must be studied and compared, and when the true nature of the disease has been ascertained the proper remedies can be applied; but it is useless to think of remedies so long as the true nature of the disease has not been ascertained. Precisely the same course has to be adopted with plants suffering from disease, and it is our first duty to avail ourselves of every facility for determining the nature of the disease. Even if we suppose that any and every man who is engaged in the cultivation of plants has the primary knowledge which would enable him to decide at once whether the disease in question was caused by insects or by fungi, or whether it resulted from some error in cultivation, this would be the farthest step that the majority would take towards an accurate diagnosis. What more would be required may be gathered from some further remarks with which we will venture to trouble you.

Diseases of fungoid origin may be classed in two primary groups, which we may call respectively endophytal, and epiphytal. The former are developed from within—outwards, analogous to small-pox; the latter commence externally and establish themselves on the surface before they penetrate the tissues, analogous to some forms of skin disease. Most important, and most fatal are the forms of endophytal disease which, as we have said, are present, unseen, in the tissues of the plant, before they present any external appearance of their presence. The two most prevalent types of this kind of disease are the rotting moulds, such as the Potato murrain, and the smut and rust fungi, such as bunt and mildew in corn crops, with such diseases of ornamental plants as the Hollyhock disease and the brand which affects the foliage of Sweet Williams, and others of the Pink family. There are some features in common, but there are other considerable divergencies in the life history and reproduction in these two types of moulds and rusts. In order to illustrate the importance which some knowledge of the life history should hold in the estimation of the cultivator we shall advert briefly to some of the phases in that of the rotting moulds, to which the general name of *Peronospora* is usually applied.

Commencing with its simplest initial form, we find that the spore or conidium, produced in great numbers on every fertile thread when mature, is an elliptical, colourless minute body, having a thin outer coating of membrane, with fluid contents. These contents soon become granular, and at length collect at three or four centres, which condense and ultimately are distinctly separated from each other by the growth of a special envelope. Ultimately the membrane of the mother cell is ruptured, and the three or four smaller bodies which have been differentiated in its interior escape, each one furnished at one extremity with a pair of delicate moveable hairs, by means of which these little bodies, now termed *zoospores*, can swim actively in any thin film of moisture on which they may fall. Possibly this film may be on the leaf of a foster-plant. In a short time all motion ceases and the zoospores come to rest, the pair of delicate cilia are absorbed and a germinating thread is produced, the point of which seeks out and enters at one of the stomata of the sustaining plant.

Having once obtained an entrance the thread grows vigorously, and a little mass of threads, called a mycelium, is soon developed within the tissues, capable of spreading itself through the plant which it has infected. In the next stage we discover that this mycelium has developed erect branched threads, which pass out through the stomata again into the external air—sometimes singly, sometimes in tufts. These are the fertile threads of the mould, which soon produce a single conidium at the tip of each of the branchlets, just like the original conidium whence the zoospores were developed. When fully matured each fertile thread produces a score or more of these conidia, which fall away when ripe, and then undergo transformation into zoospores, ready and active, prepared to pass through the same stages again, and indefinitely multiply the pest.

This history represents the ordinary conidial fructification of the mould, by means of which it is passed from leaf to leaf, and from plant to plant, until the whole area is affected. How many of the minute conidia may be transported to a considerable distance by a breath of wind it is impossible to say, but it is known that they are capable of suspension in the air, and that they may be carried to any spot where there is sufficient moisture for the conidia to be differentiated into zoospores, and afterwards come to rest and germinate. This process takes place in the summer and autumn, but there is yet another means by which the pest is disseminated in the spring.

The mycelium which flourishes within the substance of the plant infested is capable of producing larger globose bodies, chiefly within the stems, concealed from external view. These globose bodies secrete a thick envelope, mostly of brownish colour, and after development they remain in a state of rest within the stems during the winter. So that old stems of plants which are infested with the mould during the autumn conceal within themselves during the winter a large number of these "resting spores." As the old stems rot and decay the resting spores are set free in the spring, and then a period of activity commences. The contents of these globose bodies become differentiated into a considerable number of zoospores, which ultimately escape by a rupture of the thick envelope, armed with vibratile cilia, and in all respects like the zoospores which are developed from the conidia. These active zoospores swarm over the damp soil, and are carried by the spring rains into proximity with the young seedling leaves of the new crop of most plants, then the cilia are absorbed, germination commences, the delicate threads of mycelium enter the nearest stomata, and infection results. In this way, in addition to the spread of the infection from the conidia in the summer and autumn provision is made for an attack on seedlings in the spring. It will be inferred that in order to check the spread of these diseases

the conidia must be destroyed in the autumn to prevent their extension to healthy plants, and the destruction of all rotten *débris* must be carried out during the winter so as to extirpate all the concealed resting spores, and thus prevent the infection of seedlings in the spring. Thus it will be seen that a knowledge of the life-history of these parasites will suggest the best methods to be employed in their destruction.

Time forbids any illustration of the growth and development of the rust and smut fungi, so that we must rest content with the intimation that in a large number of these also winter spores, or resting spores, are produced, which remain in quietude through the winter and awaken to life and vigour in the spring. Perhaps the agriculturist rather than the horticulturist is most interested in this group of diseases, which are greatly addicted to the cereal grasses, although some of them attack garden plants.

The other primary group of fungoid diseases, which we have called *epiphytal*, are those in which the fungus makes its appearance superficially on the leaves and other green parts before the internal tissues are affected, and attain their purpose by choking up the stomata, preventing transpiration, and killing the plant by suffocation. The mycelium of delicate vegetative threads spreads over the surface like a white film, or a cottony felting, which in some cases cause the leaves to appear as if they had been dusted with flour or chalk. This appearance is very familiar to you in the hedge Maple, the cultivated Pea, the Hop, cultivated Roses, and the well-known *oidium* of the Vine. In such cases there is no constitutional disease to be dealt with, or rather, we should say, no affection of the tissues. If we are successful in getting rid of the external pest the plant is left comparatively healthy. The natural inference would be that this form of disease is more amenable to the action of fungicides than the endophytal, and its presence may be detected in its earliest stages before much mischief has been done. Hence it is a matter of considerable importance to the cultivator that he should be able at once to decide for himself whether he has to deal with an endophytal or an epiphytal parasite. Having this knowledge he will be able to apply such remedies as experience has taught him are most successful with each of these forms of disease.

It is hardly necessary to remind practical men that there are numerous forms of fungi which establish themselves on tissues in which the vitality is exhausted; on spots which have been caused by other agents, with which fungi have had nothing to do; and that such fungi are not true parasites, but merely saprophytes. They at least offer no occasion for alarm.

The conclusion to be arrived at from these desultory remarks is, the importance of acquiring knowledge, not so much of the names of species as of the life history, and especially of the methods of reproduction, in certain important groups. No empirical methods of plant treatment will be more successful than empiricism with animal disease. There is no panacea which will cure all sorts and conditions of plant disease. The only universal remedy lies in the acquisition of practical knowledge, and to this end we have often felt the great need of some authoritative manual of all the more prominent of plant diseases which could be in the hand of all who are interested in horticulture. Such book would give the descriptions of the diseases, with indications of such remedies as had been found effective, or might be tried with some hopes of success. You are well aware that the Germans, for instance, are far ahead of us in this respect, and possess elaborate and exhaustive treatises on vegetable pathology, whilst the British horticulturist, unless he is fortunate enough to be able to read German, is compelled to flounder along in ignorance with no other guide than his own experience.

If you will permit the suggestion, it seems to us that the whole subject of plant disease is one of increasing interest and importance. That it is intimately associated with profit and loss, as you cannot forget that it has been with the Potato disease and the Vine mildew, and may be yet, not only with the growth of Grapes, if the American Vine mould becomes established with us, or even with the Peach, Apple, and Pear, should you still consider them to be worthy of cultivation. The only advice that we can tender is an increased acquaintance with the life history of some of the most important and typical diseases. The acquisition of all possible information as to the antidotes or remedies which have been tried and found to be successful. And lastly, an untiring effort to discover the tendencies and predisposing causes of diseases, remembering that "prevention is better than cure," for if there is any science in horticulture it should possess some power to struggle against adverse circumstances and devise means to circumvent the most insidious of foes.

#### HARDY FRUIT GARDEN.

**Outdoor Figs.**—Figs can only be cultivated in favourable situations, chiefly against warm south walls where abundant sunshine is available to develop the fruit and ripen the growths each year. The next most important points in cultivation are a firm, restricted, not over-rich root run, and a thin disposal of the branches on the space available

for training the trees. The best soil is a calcareous loam, that overlying chalk being suitable, and sufficiently fertile in character, warm, well drained, and not too deep. When the roots are allowed to descend into uncongenial subsoil or even deeply into rich soil, strong succulent growths are developed, which are invariably unfruitful. These tend also, by encouraging others of like nature, to overcrowd the trees. A hard impervious bottom does this the most effectively. Lime rubbish mixed with the soil improves it for Fig cultivation where not otherwise suitable. It is seldom necessary to add manure.

*Planting.*—April is a suitable month for planting young trees from pots. If the roots are numerous and matted together the soil should be shaken away and the fibres disentangled, spreading them out evenly in their new position between layers of soil, which may be pressed firmly about them.

*Pruning.*—Newly planted examples if not already furnished with several branches ought to be pruned back to several buds in order to establish such, training these fan shape over the space and originating others from them for fully furnishing the trees.

*Pruning Established Trees.*—With due attention to judicious training in the first instance, and so to avoid overcrowding at any period, little annual pruning is required. Under such conditions the wood made is short-jointed and fruitful owing to continuous exposure to the influences of light, air, and sun. Thinning out rather than shortening back acts best, because the Fig bears at the points of the previous year's shoots, and to prune these away would entail loss of crop. There is, however, a system of pruning the Fig which admits of one half the shoots being pruned closely to one or two buds and the other half retained at full length for bearing. Pruning of this kind may be done in the autumn, efficient protection being afforded the trees in severe weather to prevent injury to the bearing wood. Injured shoots or any not wanted may either be cut out or shortened back to low buds. In the latter case shoots will, during the season, be produced for the following year.

*Mulching Strawberries.*—This is the best season to give a general mulching of manure to the oldest established fruitful beds which need the most assistance. A mixture of cow and horse manure is suitable. On heavy soils let horse manure predominate, fresh cow manure being too compact and cold for mulching such soil. It is best in any case to use it sparingly now on Strawberry beds without abundance of straw or other light material with it. The solid parts of the manure used serve as nutriment for the roots, the rain washing the beneficial qualities gradually into the soil among the surface roots. The light and strawy portions become blanched and clean by the time the fruit is ripe, forming an excellent bed for the fruit to rest on.

Mulching serves other purposes besides feeding. It maintains the soil in an equable condition of moisture throughout the season and attracts roots to the surface, where they multiply rapidly. Previous to applying manure unsightly old foliage should be trimmed off and strong weeds growing in the beds uprooted. Hard and trampled spaces between the plants ought to be forked over, only disturbing the parts unoccupied with roots. Small and seedling weeds may be covered with the mulching where they cannot be buried in forking over the ground.

*Young Strawberry Beds.*—If recently planted beds are lightly hoed this serves to promote growth and at the same time kill weeds. Several hoeings may be carried out before mulching these plants, as the soil being rich enough for their requirements at present does not need additional food. Later in the season a light mulching will act beneficially in conserving the moisture then present in the soil and prevent rapid evaporation, which prior to that period may be counteracted by the frequent hoeings.

*Mulching Gooseberries and Currants.*—If these are likely to need assistance at the roots during the summer a thick mulching of rich manure may be afforded now before the foliage becomes dense. Both Gooseberries and Currants root abundantly near the surface, and if the fibres cannot find due sustenance when they need it the fruit will be small and deficient in quality, the bushes also being more liable to attacks from insects. Spread the manure under the branches as far as the latter extend.

#### FRUIT FORCING.

*Peaches and Nectarines—Earliest House.*—The stoning process being over with the earliest varieties, they may be given a temperature of 70° to 75° by artificial means, but it is not good practice to maintain that constantly. Therefore allow the temperature to fall to 65° or even 60° on cold nights, raising the heat to the figures before named early in the day, keeping through this at 80° to 85° from sun heat, ventilating by the top at 70° to 75°, and opening the front at 80°, so as to secure a circulation of air and prevent the temperature rising too high. A stagnant atmosphere will be avoided by admitting a little air constantly. Close the house at 80°, and sufficiently early to allow of an advance to 85° or 90°, the trees being well syringed and good atmospheric moisture secured, which will insure the fruit swelling to a large size, but the fruit and foliage must become fairly dry before night, and clear water be used, as spring water is liable to leave a stain on the fruit.

Remove the leaves over or in front of the fruit, and turn this to the light, as it adds greatly to the value of the fruit when it is well coloured from the apex, besides improving the flavour. Syringing must cease when the fruit commences to soften for ripening, otherwise the skin may become cracked, and it then is spoiled in appearance and acquires an unpleasant, musty flavour; but a genial condition of the atmosphere should be maintained for the benefit of the foliage by damping the paths and borders twice a day. Keep the roots properly supplied

with water or liquid manure, using the latter in an available form, such as nitrates of potash and soda, when growth in either shoots or fruit is desired, as crude material in the late stages of swelling may impart an unpleasant flavour to the fruit through its not being converted into assimilable matter. Soot has this singular characteristic, and, in less degree, blood and other animal manures. A mulching of some partially decayed lumpy manure, about an inch thick, will help to keep the soil uniformly moist and encourage surface roots, whilst the nutrient matter will be in such available form as not to prejudice the quality of the fruit.

Regulate the flow of the sap by stopping all gross shoots before they have time to draw supplies from the weakest parts of the trees. Allow the leading shoots, particularly of young trees, to extend over uncovered parts of the trellis, and pinch out the successional bearing growths when about 14 inches long. In houses that contain such varieties as Hale's Early, A Bec (one of the finest second early Peaches), with Royal George, Stirling Castle, and Grosse Mignonne, and the Nectarines Lord Napier, Elruge or Stanwick Elruge, which were started about the middle of December to afford ripe fruit at the end of May or early in June, the night temperature must not be more than 60° to 65° until the stoning is completed, and 70° to 75° by day with gleams of sunshine, with 5° to 10° advance on bright days, and a free circulation of air between 70° and 75°, increasing with the advancing temperature. The prolonged cold weather had retarded forcing considerably, but no attempt at accelerating the ripening of the fruit may safely be indulged in until the stoning is completed, then they will bear a considerable advance in temperature. Pay particular attention to syringing the trees, using clear tepid rain water twice a day, and see that every part is thoroughly washed, as it is very important to have the trees free from red spider before the fruit commences ripening, otherwise it will flourish amazingly when the syringing is discontinued, and prejudice the trees in the present and next year's crops.

*Second House.*—The trees in this structure started at the new year are making satisfactory progress in growth, the disbudding being completed, the fruit thinned to few more than required for the crop, and the shoots that are to follow those now fruiting being laid in. Always allow abundance of room in the ties, as throttling the shoots has a tendency to induce gummings as well as being disastrous to the growths. Allow no more growths to remain than are necessary for next year's bearing or for the extension of the trees. Stop gross growths or remove them where practicable, as it is highly important the sap be equally distributed and an uniformity of vigour maintained through the branches of each tree. Shoots retained to attract the sap to the fruit should only be allowed moderate extension, stopping them in the first instance at three or four joints of growth. Pinch laterals at the first joint and at every subsequent one as made. Strive to so distribute the growths that the foliage will shade and protect the main branches from the direct rays of the sun as the season advances. Avoid overcrowding the trees with more foliage or growth than can have full exposure to light and air. Ventilate freely and carefully, avoiding cold currents of air and sudden depressions of temperature. As the fruits are swelling fast thin them if too thick, for with the trees in good health the fruit will stone satisfactorily and the size be correspondingly enhanced, as every fruit not required for the crop and left until the final thinning after stoning takes from the size of those allowed to ripen. Water the inside borders copiously, and afford nourishing rather than stimulating food. Dissolved bones three parts, muriate of potash two parts, and basic slag or gypsum 1 part, mixed, and 4 ozs. applied per square yard, is a good dressing for stone fruits, supplying it every three or four weeks and washing in moderately.

*Third House.*—Trees started early in February must be frequently examined for disbudding, this being best done gradually, and commencing with the strongest parts of the tree, retaining a shoot at the base of the current year's bearing wood, and leaving no more shoots on the extension than will be required for furnishing the trees with bearing wood at 15 inches apart, pinching the others on these to two or three leaves to form spurs. A shoot on a level with or above the fruit must be retained to attract the sap, pinching it at the third leaf. As the fruit is swelling freely remove those worst situated, leaving only a few more of the most promising than will be required for the crop, one to every square foot of trellis covered by the trees being ample for the large-fruited varieties of Peaches, and the medium-sized sorts and Nectarines should not be left closer than every 9 inches square to secure large, well-finished specimens. Syringe early on fine mornings, give a little air shortly afterwards, gradually increase it, and close about 3 P.M.; but if the weather be warm and bright later closing must be practised, as soft growths are induced by closeness.

*Fourth House.*—The trees started early in March are out of bloom, having set the fruit well, and having trace of aphides should be syringed with some approved insecticide or an infusion of quassia chips, 3 ozs. to a gallon of water, boiling about a quarter of an hour, then straining, and adding 2 ozs. of soft soap, dissolving and making up to 1 gallon, as there is some reduction on boiling. This mixture is good against brown as well as green fly, also effective in preventing red spider. If fumigation or vapourising be had recourse to it must be done very carefully, as an overdose injures the foliage and causes the fruit to fall. Syringe moderately in the morning and on fine afternoons, always early enough to allow the foliage to become dry before night. Disbud gradually, and rub off all small and badly placed fruits as soon as the most promising take and retain the lead in swelling. Ventilate freely on all favourable occasions, and close early with a view to husband the sun heat, but avoid a close atmosphere, admitting a little air constantly at the top of the structure to prevent a vitiated condition.

**Late Houses.**—The trees are a sight with flower buds expanding and opened blossoms. Ventilation must be freely given consistent with safety from frost, it being a good practice to turn the heat on in the morning so as to raise the temperature to 50°, and keep it at that with a gentle circulation of air, turning off the heat early in the afternoon so as to allow of the pipes cooling before night, and the temperature falling to 45° or 40°, which is quite safe, and these conditions ought to be secured after the blossoms expand, with a little air to prevent the deposition of moisture through the night on the flowers. If bees do not visit the flowers recourse should be had to artificial fertilisation, either by shaking the trees or dusting the flowers when the pollen is ripe with a bunch of feathers, Pampas Grass plume, rabbit's tail mounted on a small stick, or camel's hair brush, but the best aids to setting are perfectly developed blossoms and a genial, well-aërated atmosphere.

**Figs.**—*Earliest Forced Trees in Pots*—Early Violet and St. John's are now being succeeded by White Marseilles and Brown Turkey. To secure perfect ripening and high quality, watering must be gradually reduced and syringing over the trees cease, but trees swelling their fruit should be assisted with weak liquid manure twice a week and the foliage kept clean by syringing at closing time, this being discontinued directly the fruit gives indications of ripening. A temperature of 60° to 65° at night, 70° to 75° by day, advancing to 80° or 85° from sun heat, is suitable, closing so as to increase to 90°, but air must be afterwards admitted so as to allow the pent-up moisture to escape and prevent the deposition of moisture on the fruit, which settling on the apex is apt to cause its decay. This should be avoided by a circulation of rather warm and moderately dry air.

**Early Forced Planted-out Trees.**—A mulching of sweet, decayed manure about an inch thick is of essential service in encouraging surface roots and supplying nourishment not likely to induce grossness. Such mulching, if kept in a moist state and added to from time to time as reduced, will be full of active feeders by the time the trees need most assistance in order to perfect their crops, and substantial food, such as superphosphate 5 parts, nitrate of potash 2 parts, and gypsum 1 part, mixed, using 4 ozs. per square yard every three or four weeks or more distantly according to requirements, will secure sturdy growth (other conditions being favourable), and good results in the first and second crops. Trees in borders of limited extent and those of short-jointed fruitful habit will require copious supplies of water or liquid manure. Syringe twice a day in bright weather, occasionally in dull, and maintain a genial atmosphere by damping. Ventilate freely in favourable weather, with the object of securing stout growth and leathery, healthy foliage. Any kind of shading is injurious and must be guarded against by thorough cleanliness, pinching out the young growths and thinning out all the overcrowded shoots. Maintain the temperature at 60° to 65° at night, 70° to 75° by day, advancing to 80° or 85° from sun heat, closing so as to run up to 90° on fine afternoons.

**Succession Houses.**—Disbudding or thinning the growths, regulating the terminal and successional shoots, and stopping the spurs at the fifth leaf must have timely attention. Afford a light mulching and feed as advised in the preceding paragraph. Maintain the night temperature at 55° to 60°, 65° by day artificially, 70° to 75° from sun heat, which ought not to be exceeded without full ventilation, as it is very important the growth be stout and the foliage have good clean substance. When the trees are in full leaf the night temperature should be maintained at 60° to 65°, 70° by day, allowing to rise to 80° or 85° from sun heat, closing early with abundance of moisture.

**Late or Unheated Houses.**—The trees must have attention in pruning, thinning the least fruitful growths and the old and bare so as to afford space for the successional, avoiding overcrowding, as it is necessary the growths have abundance of light and air. Allow the shoots for bearing to grow somewhat loosely with their points to the light. Stopping must play an important part in cool houses. Pinch at the fourth or fifth joint on the young wood, which will assist the swelling of the fruit and induce the trees to break and produce short-jointed wood from the base of those in bearing. Ventilate freely at and above 50°, advancing to 65° from sun heat. The border should have a thorough watering if dry, repeating as necessary to bring it into a thoroughly moist state, afterwards mulch lightly with short manure. Figs in unheated houses do not require nearly so much moisture as those in heated structures, but an occasional damping will be necessary to maintain a genial condition of the atmosphere, ventilating freely on all favourable occasions, especially in the early part of fine days so as to secure sturdy, short-jointed wood and well developed leathery foliage.

#### THE FLOWER GARDEN.

**Alternantheras.**—Where large numbers of these are used, now is the time to insert cuttings. Pits or frames just cleared of Violets are handy for the work. Turn out some of the soil, form a shallow mild hotbed, and cover with 4 inches of fine light soil, facing this with sharp sand. Keep the frames close till the soil is well warmed, then if there is no likelihood of overheating, put in the cuttings. Every little piece will grow, and they may be dibbled in 3 inches apart each way. Kept close, shaded from bright sunshine, uniformly moist and matted over during cold nights, all will root in a week and develop into good plants. They ought to be duly hardened and moved direct to the beds. Smaller numbers may be rooted in shallow boxes, placing these in a warm house or frame.

**Iresines and Coleuses.**—There is yet time for raising these richly coloured summer bedding plants. The tops may be rooted in pits and frames much as advised in the case of Alternantheras, or they may

be rooted in pots or pans in propagating frames, transferring them to small pots or boxes after they are rooted. Not till the middle of May should there be any hardening, the second week in June being early enough for planting.

**Perilla nankinensis.**—This annual still finds favour with many as a bedding plant, and succeeds well in the back rows of ribbon borders, affording a good foil to variegated Pelargoniums and shrubby Calceolarias. It grows rapidly, and if seeds are thinly sown at once in pans or boxes, and placed in a warm frame or other heated structure and shaded from bright sunshine, germination will soon take place. They may be planted direct from the seed pans or boxes.

**Bedding Beet.**—When not grown too strongly the bronze purple leaves of Beet prove very effective either in masses, patches, or lines. Dell's Crimson is a suitable variety, and in poor soil may be sown in front of lines or as an edging to Calceolarias and tall-growing Zonal Pelargoniums. Late in April or early in May is a good time to sow the seeds where the plants are to grow, or the seeds may be sown in boxes under glass, and transplanting be resorted to. The stronger growing Chilian or Brazilian Beet is more fit for new shrubberies or for grouping in large beds. It is the richly coloured midribs and stalks that make these ornamental, and the colours are most pronounced when the plants are grown in rather poor soil.

**Ricinus.**—Seeds of these germinate in less than a week, and when raised very early the plants are almost certain to become leggy and starved. R. cambodgensis and R. Gibsoni are of a sturdy habit of growth, seldom exceeding a height of 4 feet, in colour are of a deep purple, and are the best for the centre of a large bed or for growing singly among flowering plants. Sow the seeds singly in 4-inch pots, and place in brisk heat. Directly the plants are up set them on a shelf near to the roof glass. By the middle of May they will be ready for cooler quarters, and hardening will be complete by the second week in June.

**Amaranthuses.**—A. melancholicus ruber is sometimes used as a substitute for Iresine Herbsti, while the more elegant, taller-growing A. nobilis pyramidalis, A. salicifolius, and A. tricolor are very effective as "dot" plants in mixed beds. Unfortunately all are very tender. Seeds may be sown now, and will germinate quickly in a brisk heat. They may, where at all crowded, be pricked out in other boxes of light soil, or in the case of the taller growers be placed singly in 3-inch or rather larger pots, keeping them in a light warm position till well established in their fresh quarters.

**Marigolds.**—African and French Marigolds are very effective in mixed borders, and the Tagetes, or miniature forms of the latter, are very good substitutes for shrubby Calceolarias. Sow the seeds now thinly in boxes, and place in gentle heat to germinate. Transfer to cooler quarters before the plants become leggy, and if the latter are not crowded there will be no necessity to prick them out in other boxes or frames, as they transplant readily without much soil being preserved about the roots.

**Zinnia Haageana imbricata flore-pleno.**—This is a capital substitute for yellow Calceolarias, and is particularly effective in ribbon borders. Late in April is quite soon enough to sow seeds. Pans or boxes of good light soil should be used and the seeds be sown thinly, giving the benefit of a little heat. Sometimes they are planted out direct from the pans or boxes, but if at all crowded should be first pricked out in other boxes or beds of soil.

**Miniature Sunflowers.**—What is known as the New Miniature ought to be grown everywhere, and in particular where cut flowers are in demand. The plant is of a very branching habit of growth, attaining to a height of 3 feet or thereabouts. The flowers are small, single, yellow in colour with a dark centre, and borne on long slender foot-stalks. Sow the seeds thinly in pans or boxes in gentle heat, harden in good time, and plant where they are to flower. Any of the taller growing varieties may be similarly treated.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### THE SEASON IN PROSPECTIVE.

ARE we to have a good honey season? is a question more easily asked than answered. Generally speaking, flowers and bees come simultaneously. In one sense the present year may not be an exceptional one, but the fact cannot be disguised that hives, as a rule, are not more than one-third the strength they were two months ago. Since Christmas north-westerly and north-easterly winds have prevailed, consequently we have not as yet had a single genial spring day. The bees have not obtained more than a few minutes at a time to fly, and many which went out never returned, the ground everywhere within range of the flight being thickly strewn with chilled bees. This is the story of every bee-keeper I hear from.

There is this hope; all hives well provisioned are furnished with much brood and many young bees, and the loss of adult bees

daily is less than the supply of young additions creeping out of the cells. They very soon gain strength, and when genial weather comes, may be as strong as if the spring had been mild. The great strain on the queens, owing to many eggs being eaten when hives are so much depopulated, renders it imperative for the bee-keeper to commence raising young queens to take the place of older ones at the earliest opportunity. When queens are sorely taxed and hives weaker at this season than we might expect, drones are brought forward in such hives as early as if they were normally strong.

Taking my data from former and long experience, that with good weather and a profusion of bloom on the respective honey-yielding flowers, nothing serious has occurred to damp the hopes of the ardent bee-keeper. It is now the middle of April, and buds of many fruit and other trees which I have in some seasons witnessed in blossom on the first of this month are scarcely showing green, favouring bee-keepers greatly, especially those situated in late districts.

It depends much on the course bee-keepers pursue and their management generally whether they will reap their full yield of honey. There never was a season in my time so disastrous to hives as the present one; it is therefore necessary, if the maximum profit is expected, to keep the bees breeding; this may be done if hives do not lack anything necessary, but neglect of any one thing will assuredly tell against both bees and bee-keepers. Feeding judiciously, keeping the interior of the hives free from damp and draughts, and superseding all old with youthful fertile queens, will work wonders, which to many not accustomed to introducing young blood appear miraculous. By proper attention to weak hives they may become before the close of the honey season the best. In spite of the drawbacks of the untoward season, with fine summer and autumn weather it may be the best honey season we have experienced; this being the wish of many besides—  
A LANARKSHIRE BEE-KEEPER.

#### BEES UNSATISFACTORY.

"I HAD three stocks of bees in frame hives, and during last summer, although not a favourable season, two of them filled a crate of twenty-one sections each, and in the autumn had sufficient sealed stores in brood combs to carry them over the winter without any feeding. The other stored no surplus, but appeared to have sufficient sealed stores to winter on. Being anxious to see if all was right I have lately examined them, and found the two former strong in bees with ample stores, but the bees in the latter hive were all dead, and not a particle of food remained in the hive. Can you tell me the cause, as when covered up for the winter they appeared to be quite as well off for stores as the others? Is it owing to the severe winter, or do you think it a case of foul brood?"

The queen in all probability was old, and would not commence her maternal duties till late in the season, consequently when the honey flow came, and it was of short duration, the adult bees would have dwindled down very much, and would not be strong enough to gather but little more honey than was required for their daily consumption. I have often noticed when a colony is not headed by a prolific queen the workers appear to lose heart. When this is the case they do not work freely, and it is much better to unite them to another stock or introduce a young fertile queen from a strong colony.

In this instance I do not think the severe winter can be blamed for the loss, but the bees from the strong stocks would probably rob them, as robbing is often very prevalent in early spring and autumn when the outside supplies are falling short. I always reduce the entrance of all my hives when robbing is likely to take place, as should a stock by chance be weak the inmates have a much better chance of repelling the invaders than if the entrance was left open its full length, as when food is getting scarce a strong colony can always be depended on to protect its stores. It is the weak that suffer, and when attacked, unless steps are at once taken to prevent it, a hive is soon cleared of its stores and the bees die of starvation.

In a very bad case of robbing it is sometimes necessary to remove the stock attacked some distance from its original stand, but in ordinary cases, if the entrance is reduced so that only sufficient space is left to allow one bee to pass at a time, and a little carbolic acid is sprinkled on the alighting board or elsewhere, if the robbers are likely to gain admittance, this will soon have the desired effect. When once a serious case of robbing takes place in an apiary it sets the whole in commotion, and unless checked in its early stages much mischief may be done, resulting in the loss of several good stocks of bees which, under careful management, would in time have paid a handsome profit for the trouble bestowed on them. Should the stock be short of stores feed at night with warm syrup.—AN ENGLISH BEE-KEEPER.

## TO CORRESPONDENTS

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Split Walnut Tree (Somerset).**—The stem has been split by the frost, and we do not know that you can do better than plaster the fissure well over with a thick coating of cement.

**Lily of the Valley Failing (Nemo).**—When Dutch crowns have to be relied on for early forcing failures such as yours frequently occur. The variety is evidently not suitable for the purpose. We do not suggest there are no varieties grown in Holland that will not force, but it is well known that, as a rule, Dutch are inferior to Berlin crowns, also to many grown in England, for the production of early flowers with the aid of brisk artificial heat.

**Agathæa coelestis (C. F.).**—This plant, commonly known as the Blue Marguerite, grows and flowers freely in loamy soil in a very light position in a greenhouse, also when planted out in good soil in an open position in the garden at the same time that Heliotropes and other tender plants are "bedded out." Cuttings of the young shoots root readily in moist sandy soil in a close heated frame, or under a bell-glass in a warm greenhouse.

**Camellia Leaves Spotted (E. G.).**—The brown spots are caused by the sun acting powerfully on the parts whilst wet, or excessive evaporation from their surface when covered with water. It may be caused by drip or condensed moisture falling on the leaves. Washing them will not prevent the spotting, but a freer circulation of air would be beneficial, especially in the early part of the day. A solution of 2 ozs. of Gishurst compound to a gallon of water is quite strong enough for washing the leaves, and is suitable for the purpose.

**Cockroaches (A. B. C.).**—The specimens represent the largest of our native cockroaches, the *Blatta germanica*. It is not a very common species, seldom occurring in houses, but being found in fields amongst heaps of rubbish, dead leaves, and sometimes in hollow trees. If introduced to a garden it might soon increase and become troublesome if circumstances were in its favour. For the familiar *B. orientalis* sometimes quits the kitchen and makes excursions to gardens and frames where, owing to its nocturnal habits, it may do mischief frequently and escape detection.

**Iris from Seeds (X. Y. Z.).**—Seed may be sown in sandy soil, preferably as soon as ripe, in pans or boxes, placed in a cold frame, keeping the soil moist. Sow thinly to prevent disturbing the seedlings, but they may be gently raised when large enough and pricked off a few inches apart. After June they should have full exposure, and for safety may be wintered in a frame, planting them out the following spring, or preferably assigning them their flowering quarters in autumn, protecting the roots with a mulch of cocoa-nut fibre refuse. Efficient drainage must be given, and the less the roots are dried the better. The situation should be fully exposed to the sun, yet protected from easterly or strong winds. Roots sufficiently strong for flowering may be expected after three years' growth.

**Crop Constituents (Exam.).**—You ask for something concise. We know of nothing more compact yet comprehensive on the subject than the following, which we take from an excellent chapter on the Chemistry of Garden Crops, in Sutton's "Culture of Vegetables and Flowers."\* The principal garden crops are grouped in two classes:—  
"In Class 1 phosphates and potash predominate. This class includes the following: the Pea, containing phosphates 36, potash 40; Bean, phosphates 30, potash 44; Potato (tubers only), phosphates 19, potash 59, soda 2, lime 2, sulphuric acid 6; Parsnip, phosphates 18, potash 36, lime 11, salt 5; Carrot, phosphates 12, potash 36, soda 13, sulphuric acid 6; Jerusalem Artichoke, phosphates 16, potash 65. In Class 2, sulphur, soda, and salt predominate. This class includes the following: Cabbage, phosphates 16, potash 48, soda 4, lime 15, sulphuric acid 8; Turnip, phosphates 13, potash 39, salt 10, lime 10, sulphuric acid 14; Beet, phosphates 14, potash 49, soda 9, salt 20, lime 6, sulphuric acid 5. You had better procure the work and read the whole chapter. You will also find an enormous amount of useful information packed in over 400 pages. The sixth edition of the work has recently been issued. It is in every way creditable to the great firm that has produced it, and more need not be said.

\* Sutton & Sons, Reading; Simpkin, Marshall, Hamilton & Co., London.

**Mentzellas (T. P.).**—These plants are hardy, annual, biennial, or perennial herbaceous plants, the flowers being orange or white, solitary, racemose or cymose, opening only during sunshine. They grow 1 to 2 feet high or more in rich soil. The species are showy and well worth growing. Any ordinary garden soil suits them, and the seed may be sown early in April where it is to remain; but in dealing with doubtful species it is desirable to raise the plants in gentle heat in spring, and when the seedlings are sufficiently large they should be placed singly into small, well drained pots, keeping them near to the light, not too close and not giving too much water. Some of the seedlings could be planted out, others kept in pots and wintered, if not annuals, on a dry shelf in a cool greenhouse or protected frame, planting out the following spring after well hardened.

**Grubs in Turf for Potting Purposes (T. J. M. Dyke).**—The "caterpillars" are the grubs known as leather-jackets, the larvæ of the daddy longlegs or crane fly (*Tipula oleracea*). They feed on the roots of grasses and many other plants, gnawing the stems just below the surface of the ground, and thereby totally, or according to the damage, destroying the crop. The grubs are extremely difficult to kill by means of chemicals, the safest being nitrate of soda, the soil being spread about 1 foot thick and an ounce per square yard sprinkled on it, letting lie a few days and then turning. Another plan is to use traps of pieces of Carrot, Mangold Wurtzel, Potato, or Turnip affixed to sticks and sunk a few inches within the heap. These baits must be examined every day for a few days, and then every other day, the grubs found attached to them being removed and destroyed. By continuing this process, renewing the baits as required, the heap may be freed of the grubs, as they will make for the surface of the stack in quest of food.

**Tuberous-rooted Begonias (J. P. K.).**—We expect to see thousands of Begonia plants raised from seed sown a month or two ago flowering beautifully this season, both in pots and planted out in flower beds. Grown well, under suitable conditions, the plants cannot help flowering the first season. Stout short-jointed cuttings, neither too soft nor too firm, root readily in a mixture of sand and leaf soil or cocoa-nut fibre refuse, with the pots plunged in a gentle hotbed of 80° or 85°, in a frame or other suitable place having a temperature of 60° or 65°, not overwatering, yet affording adequate moisture. Daily sprinklings are fatal to success if the soil is dry below. Cuttings root freely in the summer inserted in light soil under hand-lights in a shaded position in the garden; indeed, many are rooted without the aid of glass. The less the plants are shaded the better, a little tiffany usually sufficing. In some houses they grow fairly well under light permanent shade, such as that from summer cloud. The most luxuriant and floriferous plants in open air beds are not artificially shaded, but have abundance of roots working freely in rich moist soil.

**Sowing Rhododendron Seeds (V. W.).**—For the sowing of these seeds peat should be broken up and placed in a cold frame to the depth of about 2 inches, that placed on the top being very fine. The surface must be pressed down and made as level and even as possible, and the seed sown towards the end of this month. It must not be covered, but after sowing give a good watering with a fine-rose can. Great care must be taken that the surface never approaches dryness, not even after the seedlings appear. The lights of the frame in which the seed is sown should be whitewashed and kept close to prevent evaporation, and even when this is done it will be necessary to lay mats over the frame during very bright weather. As soon as the surface of the soil is green a little air must be admitted to prevent the seedlings damping off. They must be gradually exposed to light and air until the lights can be drawn off. This should be done at first during dull or showery weather, but care must be taken that the soil in which the plants are growing does not become saturated. When the seedlings are large enough, say during the early part of July, they should be pricked off into other frames or boxes, where they can be shaded until established, and protected with lights during the winter. It is not necessary to prick off the seedlings singly; on the contrary, they may be transplanted in little patches, leaving an inch or a little more clear space between each patch of plants. The next season they will fill up this space. They should remain undisturbed during the winter, giving them the protection of mats or fern during severe weather. In spring, when all fear of frost is passed, the young plants may be transplanted 6 inches apart, so that a small hoe can be used amongst them.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*J. D.*)—1, *Celsia arcturus*; 2, *Dendrobium Devonianum*; 3, *Fabiana imbricata*; 4, *Grevillea robusta*. (*G. M.*)—*Polygala Dalmaisiana*. (*Oxon.*)—1, *Cœlogyne ocellata*; 2, *Oxalis rosea*; 3, *Cœlogyne barbata*; 4, A very good form of *Lycaste Skinneri alba*. (*Amateur*)—Through inefficient packing all your specimens were dead when they reached us; send fresh examples, packing as directed in the above rules, and we shall be glad to assist you. (*Nemo*)—1, *Schomburgkia crispa*; 2, *Oncidium flexuosum*; 3, *Dendrobium Farmeri*. (*E. B.*)—*Vanda suavis*. (*P. F. W.*)—1, *Cibotium princeps*; 2, *Cyathea Smithi*; 3, *Polypodium*, possibly *verucosum*; 4, *Athyrium Filix-fœmina orbiculare*; 5 and 6, varieties of *Dendrobium nobile*. (*Oaks*)—A sub-species of *Moræa*, called *Homeria*, and very nearly allied to the *Iris*.

MANGOLDS.

VARIETIES of Mangolds are steadily increasing, and the choice of sorts, which once lay between the Yellow Globe and Long Red, now ranges over nearly a score of sorts enumerated by some of the great seed firms. Though this multiplicity of sorts is somewhat of a nuisance, and may not point to any material improvement in the root itself, it is undoubtedly a sign of its popularity and increasing usefulness. For general practice it is considered that Long Red answers best for deep rich loams, Yellow Globe having preference for more shallow soils. In our practice we pay no heed to this, as we have invariably had full crops of both types by the process of ridging described last week. To select one kind as worthy of preference for general cultivation we may take Sutton's Golden Tankard as excelling in bulk of crop, quality of roots, and early maturity, such points being remarkable only under really sound cultivation, and we must not be understood to recommend this safe and excellent sort to the exclusion of all others.

So important do we know early sowing to be, that we must again call particular attention to it. If, as we strongly recommend, the seeds are sown by the third week of April, the soil then retains sufficient moisture to insure quick

germination, followed by unchecked growth. Then, once get the roots established in the farmyard manure, and the young plant is practically protected against harm from drought. We have striven to make it quite clear that in Mangold culture we value farmyard manure much more for its retention of moisture than for the modicum of plant food which the plant can obtain from it.

It is to the rich store of fertility imparted to the soil by the chemical manure that we look for the promotion of rapid and robust growth. To turn this to full account let the singling of the plants be done as soon as they are large enough to handle. The distance apart is anything from 12 up to 20 inches, according to sort and soil. It is probable that more nutritious roots are obtained when they are 14 or 16 inches apart than at the greater distance. Frequently annual weeds appear so thickly around the Mangold plants, that without prompt attention to singling and hand-hoeing they would either be smothered or so much drawn up into slender growth as to be worthless.

Marvellous is the rapidity of growth after the singling and first hoeing. This is owing mainly to the quick action of the nitrate of soda, and also to the solvent power of the common salt. With full exposure to light and air the growth is also sturdy and robust. It is important when singling to know if there are to be one or more surface dressings of nitrates subsequently. If so, then the plants will require more space than they would do without it. The weeds are never suffered to become large, hoeing by horse and hand being done often enough to destroy them as they appear. There is then practically no waste of soil fertility, and by the time the spreading leafage puts a stop to hoeing there is a clean surface, and our work of cultivation is ended. We like to have this done before "haysel," every available hand being required to save the hay; but the growth of the Mangold plant is not always sufficiently advanced to admit of this, and though the haymaking is important, it must not be allowed to absorb labour to the detriment of the Mangolds. We require both roots and fodder for winter provision, and by a little judicious management both can have due attention.

Early sowing points to early maturity, and a clearance of the crop before there is any serious risk of harm to it from frost. In warm, late autumns the temptation to leave out the Mangolds on the land for weeks after they ought to be in clamp proves irresistible to many worthy farmers, who, when a sudden change comes to cold and wet, find themselves in difficulties which, by the exercise of a little decision and prudence, might have been avoided. Let our aim be, then, to obtain a big crop of small roots, which, weight for weight, are altogether more useful and more nutritious than large roots. To get them off the land early in the autumn before there is much risk of severe frost, to store them so well for winter and spring use as to feel confident that frost of exceptional severity can never reach them, and if clamps are made to place them close by a hard road, or where the roots are to be used.

WORK ON THE HOME FARM.

Is it a sign and token of inferior workmanship, of deterioration in skill of farm labourers of the present day, that so many ricks have been stripped of thatch by equinoctial gales? Never before have we seen such damage of this sort from wind, and we are convinced that very much of the damage might have been avoided had the workmanship been less superficial in character. The custom of using short wooden pins and rope yarn in rick-thatching is decidedly wrong; we require much longer pins, and the thatch so secured that, though high wind may ruffle, it cannot blow it off. Let this and kindred matters be taken into schemes for technical education, and let certificates be granted for the best workmanship, and thus form an incentive to workmen, such as wages never can do.

Recent alterations at a homestead, which we were asked to inspect and report on, gave us something to commend and something to blame. The dairy was excellent, the fittings being simple and efficient, the ventilation good, the walls faced with white glazed tiles, the whey and separated milk passed by a pipe to a cistern near the piggery, and water laid on. The cheese room was equally good, being com-

modious, having ample shelving, proper ventilators, and a stove for ripening cheese. The faults were in the outbuildings, where, with plenty of space roofed in, no provision had been made for calf rearing, there was no poultry house, and no cart hovel. All these things are indispensable, and yet had been overlooked, simply because the repairs had been entrusted to a builder who knew nothing of farming.

Let poultry and pigs have the special attention which they require in the spring. In both of these important matters we can venture on a surplus of stock over possible requirements, so as to be able to select the best of each, and to discard for sale all that are not wanted. The fact of so much lean poultry being imported from Ireland for fattening should act as an incentive to every farmer to raise very considerable numbers of chickens as an article of farm produce, for which there is always a profitable sale, and as an outlet for some of the cheap corn.

EXPERIMENTAL FARMS.

AN interesting report has just been published by the Federal Government of Canada, giving an exhaustive description of the various experimental farms which have recently been established within this vast territory. The primary object of this movement is the improvement of agricultural methods and the education of immigrating farmers in the proper equipments and the instruments necessary for the cultivation of the land.

It appears that the central experimental farm is situated near Ottawa, comprising over 500 acres of land and a complete outfit of buildings and the necessary machinery. The buildings are beautifully fitted for cattle, horses, pigs, and poultry, and all of these are well stocked. There is also a dairy, equipped with the modern appliances for carrying on experimental work; and a seed testing and propagating house, as well as a conservatory. In addition to this central station there are eleven experimental farms situated in different parts of Canada, and these carry on experiments in agriculture, horticulture, and arboriculture with much profit.

The Government has arranged that these farms should be so situated as to render them as helpful as possible to the most thickly populated districts, and in their equipments and general methods they resemble closely the central station. The staff of workers at the central experimental farm includes a director, an agriculturist, a horticulturist, a botanist, an entomologist, and a chemist. There is also a poultry manager, a "foreman of forestry," and several assistants to assist the members of the staff. The work is varied in nature, and has to do with practically everything which relates to farming in Canada. Experiments are also carried on to determine the vitality and purity of various agricultural seeds, and to investigate the nature of the diseases of plants and trees, and the cure for the ravages of insects. Various kinds of fertilisers are tested to determine their comparative value with different soils and crops.

The study of the care of animals is also a very important interest, and the value of different breeds of stock, and their adaptability to various climates and other conditions, are carefully investigated. These stations also examine the scientific and economic sides of butter and cheese making. Experiments are also carried on to determine the best methods of planting and pruning trees for fruit raising or for shelter or timber.—("Echo.")

THURSDAY, APRIL 25, 1895.

### BRITISH CENTRAL AFRICA: CLIMATE AND PRODUCTIONS.

THE Shire Highlands is that part of British Central Africa which lies a little to the east, but within the northern basin of the Zambesi River. For the last three years it has been under the administration of the British Government. The Highlands, taken as a whole and comparing it with the other great divisions of Africa, is fairly healthy for Europeans if they take the greatest care of themselves. Here, practically, we have no scarlet, typhoid, enteric, or yellow fevers, no cholera, nor any of the diseases which cause so much mortality in other countries, but to a very great extent this immunity from disease is counterbalanced by the serious mortality resulting from African malarial fevers, the most deadly form of which is hæmaturic fever. Statistics are not yet to hand, but I believe I am correct in saying that the Europeans at present in the country number over 300, a large majority of them being settled around Blantyre. It is noteworthy to mention that nearly 200 of them hail from the land of Burns and Scott.

The altitude of the Shire Highlands' plateaux, roughly speaking, is from 1500 to nearly 3500 feet above the sea level. From these elevations again rise some magnificent mountain masses, the chief amongst them being Mount Mlanje, which has only recently been ascended to the summit, and found to be 9680 feet in height. All round Blantyre are some very picturesque mountains, notably Mount Ndirende 4500, and Mount Gochi 5000 feet, while near the Blantyre the flat-topped mountain of Chiradzulo rises to a height of 5500 feet above the sea level.

Needless to remark, the presence of these hills and mountains influences the climate to a marked degree. The Shire Highlands is both well watered and wooded. Large forest trees are conspicuous by their absence, except along the banks of streams, and hidden away in the fertile valleys, where are to be found some handsome specimens, comprising *Khaya senegalensis*, *Erythrophleum guineensis*, *Parkia filicordia*, and several others.

The rainy season generally commences in November, and lasts until April, and with the

**OLDFIELD NURSERIES, ALTRINCHAM,** ALSO AT MANCHESTER AND LLANOUJNO JUNCTION.

advent of the rains usually sets in the "seedy season," when native and European alike may expect to be down with that "scourge of the country," malaria. The average yearly rainfall, recorded at Blantyre and surrounding district, is from 50 to 55 inches, and the average temperature about 55° Fahr. The highest reading yet recorded by the writer (at the hill station) was 96° and the lowest 37° in the shade.

Like our friends in South Africa, we have for months past been subject to the plague of locusts, which have done an enormous amount of damage, the first planted crops of the natives having been devoured. The locust is a very dainty feeder; he disdains the hard tough grass of the bush, but has a decided preference to the sweet tops of the green Maize, and he does not object to the fresh green shoots of the Coffee plant, especially the young seedling Coffee. He seems to take a special delight in eating them through, and leaving them lying on the ground. I have myself lost, on an average, this planting season nearly 20 per cent. of young seedlings, and several other planters have fared much worse.

It would be amusing, if it were not so pathetic, to watch the native efforts in frightening the locusts from their gardens. They are constantly on the watch, and all day long is heard the noise of shouting and beating on empty tins and pots in their efforts to drive away the pest; but notwithstanding such constant exertions, their Maize crop for the year is nil, and from reports which reach us from other districts it is an entire failure. However, during the past month the locusts around here seem to have entirely disappeared. No doubt the everyday constant rains we have had has either killed or driven them away, and the natives are once more—in some cases for the fourth time—sowing their gardens. Let us hope that their efforts this time will be successful, for their own sakes, as the occurrence of a famine in the country would not only strike a very severe blow at the native labour supply, but would be a fatal thing for the poor native, as he has yet to learn the meaning of "saving up for a rainy day."

Perhaps a few words regarding the progress that is being made in Central Africa may be of interest. It is noteworthy to remark, and we have every reason to hope, that in the matter of a few months Blantyre will be in direct telegraphic communication with London *via* the Cape. It is even now possible—I am told it has been already done—to transmit telegrams from Blantyre to Cape Town and thence on to London. The Blantyre section of the line has been completed, and extends for some distance beyond the Zambesi; the South African section reaching to near Mount Darwin, the gap between the Zambesi and Mount Darwin being covered by runners. The Chief Constructor and his men may possibly reach Blantyre about the month of July, when they will continue the construction of the line from that point on to Lake Nyasa, and no doubt if we only give them time they will yet reach to Cairo. We also hear whispers of a railway; but up to the present it has only reached the dignity of a whisper. However, we should all welcome it. Several railway schemes have been in the field, but Messrs. Sharrer's (the great trading and planting concern) seems to be the only one able to hold its own. Very possibly some day we shall all be agreeably surprised by tidings of his success bursting on us.

It is very satisfactory to be able to report that prices realised on the sales of the past year's Coffee—from this part—have been very favourable. From price lists just to hand from London brokers, we note that they range from 95s. to 106s. per cwt., while the crop at present on the trees is a very heavy one, and the export for this year should more than double that of 1894. It is interesting to note that the export of Coffee has risen from little over 5 tons in 1889 to 74 tons in 1894. The soil and climate of the Shire Highlands are admirably adapted for the cultivation of Coffee. It seems to have found in these uplands just exactly what it requires—a sufficient rain supply, a climate suited to its growth, and an enormous extent of virgin forest land. We have no disease here, the dreaded Coffee leaf fungus, *Hemileia vastatrix*, has not yet put

in appearance, and needless to remark, every precaution is taken to keep it out of the country. Long may it be conspicuous by its absence.

The Rubber Vine, *Landolphia*, of which there are at least four distinct kinds, is found growing in the valleys and along the river banks. It has very slender stems and glossy evergreen leaves. Very little is done by the natives in collecting the Rubber, although they are well aware that a good price for it is always obtainable from Europeans. I believe the total amount exported last year did not exceed 600 lbs. The Rubber trade could be largely increased and be made very remunerative. A very much brisker trade is done in oilseeds (a kind of *Sesamum*, allied to the family *Pedaliaceæ*) and *Strophanthus*. Several hundred pounds worth were exported last year, but for the most part the trade in these articles is confined to the lower river. Of *Strophanthus* there are three varieties found growing in the south portion of the Shire Highlands.

In the woods are to be found many native fruits, but not one of them, as far as I have seen, is worth the trouble to pick from the tree. However, at higher altitudes is to be found the Bramble, the fruit of which is just as good as the home Blackberry. The Pine Apple, which has been introduced from the coast, is found in nearly every native village, and grows to great advantage. It is called by the natives its proper name, *Ananas*. The Banana also forms a picturesque feature in every garden. Strange to say the natives do not seem to care for the fruit, they prefer rather to sell than eat it.

We have tried many experiments with the Grape Vine, but up to the present our efforts have not been crowned with success; in fact, one is almost safe in saying its cultivation in the Shire Highlands is an utter failure. Peaches grow and fruit very well, as has already been proved, both in the mission garden at Blantyre and also at Mandala, and I have no hesitation in saying, based on the success of the Peach, that all other stone fruits, Plums, Apricots, and others, would do equally well if they were introduced. Tobacco one finds growing around every native hut, for, bear in mind, the native is a confirmed snuffer; women and men, and even very young children, all take their "bit pinch," and seem to enjoy it too. Guavas, Figs, Loquats, and the Cape Gooseberry are all distinct successes, whilst the English Potato may be said to have found a new and congenial home in Central Africa.

In travelling through the country, especially just previous to the rains, what strikes one most (especially if he be of a botanical turn of mind) is the immense variety of beautiful wild flowers, and ground and tree Orchids. Some peeping out from the roots of trees, others hanging down from the stems; whilst in the sheltered fissures of the rocks are to be seen graceful masses of Maidenhair Ferns. Clothing the mountain side there appears to be flowers in bloom all the year round, while in the valleys grow majestic Tree Ferns, bearing their fronds on stems 10 to 30 feet in height. Regarding tree Orchids I only know of two varieties, one a *Dendrobium*, the other a *Vanda*, that are really worthy of cultivation. At present I have growing in my verandah a *Vanda*, which, when in flower, was the admiration of all who saw it. It had no less than sixteen spikes of bloom, with from ten to twelve flowers—milk white in colour, and each 2 inches across—on each spike. In the evenings it emitted a most pleasing scent.

It would be very interesting, botanically, to know the number and names of species of wild flowers growing in the Shire Highlands. Wild flowers, did I say? Why there are very many far superior in many ways to numbers which are tended with such care and attention in greenhouses at home. Mr. John Buchanan, F.L.S., has done much in collecting specimens, which from time to time have been forwarded for classification to Kew Gardens. Nearly 2000 distinct species, "including all kinds," have been already sent to Kew. Their botanical names could be given, but a bald enumeration of the same would, I fear, prove somewhat uninteresting, and would take up too much of the valuable space

of the *Journal*; and I have not the faintest doubt would, from the compositors, bring down on our heads a few "anathemas," which we can very well do without.—G. A., *Blantyre, Brit. Central Africa, March 8th, 1895.*

#### BRASSIA LAWRENCEANA.

THE plant figured at page 275 under the above name, and subsequently referred to at pages 287 and 331, is unquestionably *Brassia brachiata*, *Lindl.*, as proved by a flower sent by Mr. Chapman. I immediately saw that the figure did not represent *B. Lawrenceana*, *Lindl.*, which is cultivated in various collections under its correct name, for I have several times seen it during the last few years. How the error came to pass the Orchid Committee I cannot imagine. How distinct the two plants are may be seen by comparing the two plates, "Botanical Register," xxvii., t. 18 (*B. Lawrenceana*), and xxxiii., t. 29 (*B. brachiata*).—R. A. ROLFE, *Kew.*

#### LYCASTE ROSSIANA.

THIS is an Orchid which from its distinctiveness and its beauty should be grown far more extensively. I saw a plant of it recently in one of Messrs. J. Veitch & Sons' Orchid houses at Chelsea, and was much taken with its charming appearance. The flowers are of medium size, the sepals being greenish yellow, petals bright clear yellow, and a lip of the same colour with a rich crimson band crossing the throat. *L. Rossiana* first flowered with Mr. H. J. Ross at Florence, in whose honour it was named.—H.

#### MONOGRAPH OF ODONTOGLOSSUM CRISPUM.

THIS species having become eminently the queen of Orchids, it is now high time that a monograph should be devoted to it and its correctly named varieties, that we may know where we are amongst them and the many grand new kinds that bloom out of the importations.

With this object in view I have decided to compile from all sources the needed matter, and to figure the fine varieties already known. If your readers will all kindly send me their good *Odontoglossums* (for in time I hope to treat the genus to the same thing) and photographs, for some may not like to send their treasured spikes, I shall have the support I need. Then comes the financial aspect. The more subscribers the cheaper it will be. The announcement will appear in due time.—DE B. CRAWSHAY, *Rosefield, Sevenoaks.*

#### ORCHIDS AT WARWICK.

DURING a recent visit to the Rev. Mr. Way's interesting garden at the King's School, Warwick, I was much struck with a particularly fine group of Orchids. *Dendrobium Wardianum* was in strong force, every plant being vigorous, healthy, and splendidly flowered. A great feature in the collection was the wonderful variation to be found in the markings of the flowers in various plants, the lip spots being in many instances extremely rich in colour, varying from a crimson-magenta to true crimson. The plants were not large, but displayed something better than mere size—viz., the unmistakable stamp of high culture.

*Cattleya citrina*, *Odontoglossum Rossi majus*, and *O. crispum* were also represented by many well-grown plants in full beauty. The whole collection, whether in or out of flower, reflects great credit on Mr. Geo. Burrows, Mr. Way's head gardener.

Attractive as Orchids are at all times, it is only when skilfully grown and tastefully arranged, as in the present instance, that the singular beauty of their quaint forms elicits the fullest admiration.—W.

[A photograph of the Orchids referred to shows that they are excellently grown by Mr. Burrows.]

#### DENDROBIUM PULCHELLUM.

THIS singular but very attractive little Orchid seems to be by no means popular in collections, orchidists apparently not caring much for these small-growing species. It is, nevertheless, extremely pretty and very free flowering, the blooms being large

in comparison with the growth, which is of a rambling nature, the tiny cylindrical pseudo-bulbs or stems growing in all directions when in congenial quarters.

The plant is deciduous, and the flowers are produced from the nodes in early spring after the leaves have fallen. The sepals and petals are rosy lilac, the lip similar in colour, rounded in front with a deep yellow blotch in the centre, margined with white, and elegantly fringed with purple. *D. pulchellum* does not thrive in a pot in the ordinary way, as it produces its roots all up the stems, and needs something for these to cling to as they are evolved.

A cork block dressed with sphagnum, or wide shallow baskets with the same material, are the best receptacles for the plants, and they must be grown in a warm moist house during the summer. When the growth is complete remove the plants to a light sunny place in a cooler house, as although a small growing kind it requires a good season of rest, or but few flowers will be produced.

FIG. 60.—*LÆLIO-CATTLEYA EPICASTA*. (See page 364.)

During the resting period no water will be required unless the plants shrivel. If this occurs give them a thorough soaking, and give no more until perfectly dry. They should have a little new material every season after flowering, and as the bulbs are spent they should be cut out to make room for the new ones, pegging these down with small wire pegs. This species is also known as *D. Loddigesii*, and is a native of China and Northern India, whence it was introduced in 1833.—H. R. R.

#### DENDROBIUM NOBILE IN BASKETS.

THIS is one of the best Orchids for the grower with limited accommodation. No more economical way of cultivating this *Dendrobium* is known than growing it in baskets. In a well-filled plant stove, or even in a vinery, space can generally be found for suspending a basket or two from the rafters under the roof. In such a position they obtain a sufficiency of light and abundant moisture supplies. Now is a good time to set about making up new baskets or renovating old. As the plants pass out of flower new growth commences to push, and this is a good time for increasing the stock. Every bit with a root attached will grow if

reasonable treatment is afforded afterwards. Baskets are easily made, teak wood being the best, but it is advisable to purchase them ready made from dealers. The size of the baskets is a matter of taste, and must depend to a large extent on their proposed occupants. I have seen fine blooms produced on plants growing in baskets but 6 inches square. The baskets should be lined with moss to prevent the soil falling through, and for appearance sake.

A suitable compost for this *Dendrobium* is composed of equal parts of fibrous peat and loam. Charcoal, broken in Walnut-sized lumps, help to retain porosity. A handful of finely ground bones stimulates the growth, increasing its luxuriance and length of stem, accompanied by a larger number of blossoms. The tallest and strongest plants should be placed in the middle of the basket, finishing off in one corner, surfacing the whole with moss. A thorough soaking with tepid water should be given to settle the soil about the roots. For a week or so all the moisture required can be given by the aid of the syringe, this being brought into use two or three times daily.

When in full growth abundant supplies of water should be given, and occasionally doses of liquid manure will be an advantage, at all times using it in a tepid condition.—B. W.

### SUNSHINE AND SHADE.

THE past year of 1894 with its predecessor of 1893, whilst affording practical examples of sunshine and shade, do not for the purposes of this subject yield data so strongly bearing on it as the ordinary type of weather in the British Isles, which may be termed mixed. But little if any trouble in the matter of shading our plant houses occurred during that glorious and prolonged Italian summer of 1893. The maximum amount of shading which was then required to veil our plants from the solar rays, entailed but the minimum amount of labour in the performance. Indeed, were similar seasons the rule instead of the exception, this subject need hardly have been broached. The same, perhaps, though in a less degree, with the sunless summer of more recent date; although, in this case, anxiety ensued in watching for those rays, which long delayed bringing additional danger to delicate subjects under glass.

We are not, however, ruled by exceptions. The ordinary course is looked for, and for such must preparations be made. April, the month of smiles and tears, sees all the paraphernalia of blinds and rollers, pullies and cords, in active running for the season. Personal experience and observation of things past and present lead to the inference that there are but few places in which this important means to an end has attained to perfection. Many places there are, certainly, where the subject is indeed a shady one. In some large gardening establishments a crop of trouble is annually raised by this means. Neither time nor place need be particularised here, for what is common in one is common to many, and those who have joined in a general stampede when some passing cloud peremptorily ordered the bothy hands to quit their meals, know how welcome was the perfectly fine day or the thoroughly wet one.

I have some lively recollections of a comrade on a lofty house savagely ripping off the caudal appendages of a new Glengarry bonnet as the breeze fluttered them in his eyes whilst trying to free the offending blind. Such experiences are of the long ago; yet with all the evident marks of progress in horticulture, things pertaining to this subject appear to have made but slight advance. Warped rollers, kinking cords, sticking pullies, and the tattered and torn stage of a blind's life are still as much to the front as they are in the background of bothy life. One need not plead the cause of our embryo gardeners and fail to recognise the bearing such matters have on those in authority over them. In those well conducted establishments where all but martial law prevails, any portion of the machinery of working when not running smoothly affects the whole.

Horticultural builders, many of whom by their practical knowledge of our requirements give such results in glazing, heating, and ventilation as to leave nothing on that head to be desired, have not, I think, given to this question the consideration it deserves. There are good all-round reasons why it should receive that attention, and be thought as necessary by them as it is known to be by us for the perfection of plant culture. In many instances proper fixtures for shading should be made a part and parcel of the structure, thus avoiding temporary makeshifts too often seen. Indeed, in some cases where this matter has been altogether lost sight of in the original design, difficulties which have to be met are never entirely overcome. There is, I think, sufficient scope in this subject to engage the attention of a specialist.

Equally important is the material for the blinds and the machinery for making them available with the least possible

amount of friction, figurative or literal. Among the various materials used for the purpose, I would ask, Have manufacturers given us the best possible to have, and of the highest possible durability? If it is allowed that in some or any of the shadings to be had, this has been attained to—which is a matter for doubt—I would again ask whether the chemist cannot assist with some solution which will as a preservative yet add to their lasting powers. As there yet remains to be produced a special cord—horticultural cord—to match the good qualities we look for in the shading material, probably the best thing yet obtainable is patent sashline, and for ordinary purposes No. 5 is suitable.

Difficulty is often encountered in the pullies, by their not being adapted to the angle of a roof, thus wearing out the cords by friction and causing frequent blocks. Those who are conversant with the subject cannot fail to notice the weak points in the apparatus in ordinary use, one of which is to be found in the rollers with the method of attaching the blinds to them. In the present day, when steel is in various instances replacing wood, tubular steel rollers appear to me to commend themselves for the purpose, nor should there be any difficulty in attaching the material to them. Anything other than wood may suggest breakage of the glass, yet there should be considerably less risk than with a warped, wobbling wooden roller on which the blind is seldom rolled up as compact as it should be.

Although we require the best weather-resisting material which fully answers the purpose of a perfect shade without unduly darkening the interior, there is no reason why this should not have the protection of a coping when not in use; that is, where the style of building and method of ventilation admits of it being fixed. Truly this is nothing new, for as a junior—some thirty years since—it was my duty to run the blinds up snugly under the coping, where during the winter season they were available, and of great service on an exceptionally severe night.

Of the manifold methods employed in shading plant houses details need not be entered on here. If there are any systems unknown to me affording a happier experience than mine has been with this subject, it would, I venture to think, be worth making known for the benefit of bothered ones. And if there is any perfect plan which would bring peace after thirty years' war with a subject more shady than sunshiny, details of such illustrated by diagrams would prove more helpful than any suggestions here advanced, for a theory undemonstrated by practice is but a mirage.—E. K., *Dublin*.

### PLANT-FORMING ELEMENTS.

(Concluded from page 333.)

#### NITROGEN AND POTASH.

IN contradistinction to plants using the uncombined nitrogen of the air for their own or a succeeding crop's benefit, there are some that are considered to obtain nitrogen by the leaves absorbing ammonia directly from the air. This rests upon no solid foundation, and the deductions from practice are uncertain conjectures. An ammonia-charged atmosphere certainly favours the growth and health of plants in glass structures when present in small amount, and rain water fresh from the clouds accelerating plant growth more than the water long kept in tanks; also, pond water is better for plants than that from deep wells, and ammoniated water employed for syringing is more beneficial to the growth than if used ordinarily. Is not this conclusive? Do chemists find more nitrogen in such ammonia-fed plants, or is there not rather a larger appropriation of the inorganic elements than is the case without the so-called ammonia vapour? Any attempts at feeding plants with ammonia by the leaves is as uncertain as dangerous, for any excess—more than is contained in ordinary atmospheric air during moist weather—has a prejudicial effect upon vegetation in variable measure. That this moist atmosphere, with its ammonia and nitric acid, favours plant growth is manifested on every hand, and the much larger amounts of atmospheric moisture and minute quantities of ammonia arising from decaying substances in glass structures accounts for plants under artificial treatment surpassing in vigour those grown under natural conditions. Thus plants under glass have the best natural circumstances accorded to them without the disadvantages, and they flourish correspondingly by the uniformity of the moist growing atmosphere.

It is, however, through the roots that plants chiefly take up ammonia compounds, and the main source of the nitrogen obtained by vegetation is from the soil, being taken up by the roots of plants in the form of nitrates. A nitrate is a salt formed by the chemical union of nitric acid with a metal, such as potassium or sodium, and by the process of nitrification ammonium compounds and organic substances in the soil are converted into nitrates, which are the most available form of nitrogen for taking up by the roots

of plants. Both ammonia compounds and nitrates readily dissolve in water; the first are largely retained by the soil, but the nitrates are liable to be carried away and lost in the drainage waters. Even nitrogen itself is lost to the soil by the decay of organic matter, the nitrogen escaping in the free state into the atmosphere, but the amount is small in most cases; yet with a large percentage of lime in the soil there is a great waste of nitrogen from the use of ammoniacal manures, as the ammonia volatilises rapidly into the air, and, even in glass structures, is practically lost, for to deepen the colour of foliage of plants and promote the growth of their stems, leaves, and useful products, it must be got into the living tissues and active cells, where only it can profit in combination with the inorganic elements, and without this nitrogen there can be no economic utilisation of potash.

Potassium is a bluish white metal, first obtained by Sir H. Davy in 1807. Salts of potassium, however, only concern cultivators, unless it be that they may know the term potash in analyses applies to the potassium compounds as present in the form of potassium oxide. The potash of plant-ash and fertilisers is generally in the form of carbonate, sulphate, or chloride, compounds readily soluble in water, and only the amount which is available is considered in analyses.

Potash compounds or salts exist in the ocean, and silicates of potassium occur almost everywhere in the earth's crust, their disintegration being the direct or indirect source of the soluble potassium salts found in all fertile soils. Clay soils usually contain an abundance of potash combined with silica and alumina, but only weathering or cultivation renders such stores available as food for plants. Burning clay does this more effectively than the action of air, water, and frost. Such earth is much prized by horticulturists for dressing land and mixing with composts for fruit trees or plants in pots or borders. The burning releases the potash locked up in the silica and alumina, while the staple is changed from a compact impervious mass into an open and permeable medium. Liming and good culture also assists in releasing and transforming the treasures of potash in clay soils; indeed, these operations are essential for rendering the stores of potash available as plant food:

Potash is always present in the ash that remains when dried plants are burned. New stems and twigs of plants, such as hedge trimmings, prunings of fruit trees, leaves, and stems of herbaceous plants are, as a rule, richest in potash. A ton of new stems and twigs contains about 80 lbs.; leguminous plants, the straw of Peas or Beans, 40 lbs.; and of hay or cereal straw 35 lbs. of potash. Such material is therefore well worth saving either for the compost heap or burning. Burning destroys the organic matter, hence the finer parts should be reserved for compost, and the rougher only burned, then the two mixed together form an admirable dressing for land, especially grass or lawns, and light soils, which usually stand more in need of both humus and potash than heavy soils. There is little danger of loss of potash in drainage waters, as moist soils absorb potash from its solutions and convert it into insoluble forms, thus storing it away for future use.

Wood ashes are one of the chief sources of commercial potash, and the product is called pearlash, an impure carbonate, with the formula, when normal,  $K_2CO_3$ . It is largely used in commerce, but chiefly in gardens for destroying scale insects on fruit trees. In addition to the carbonate of potash wood ashes contain carbonate and phosphate of lime and magnesia, all essential plant foods. A bushel of wood ashes of the best quality contains about 4 lbs. of potash and 1 lb. of phosphoric acid. They are valuable as manure for light soils, as solutions of the alkalies make the soil more plastic and adhesive than pure water. Wood ashes are singularly effective on leguminous crops, and as top-dressings for grass land and lawns, encourage the growth of Clover and best grasses, destroy moss and worthless vegetation. With the special object of encouraging leguminous plants one-fourth of gypsum should be added to the wood ashes. Half a bushel of wood ashes per rod is an excellent dressing for Wheat, Rye, or Oats, also for Strawberries and Onions, applying in the autumn or early in the spring, harrowing or pointing in lightly. A peck of wood ashes per rod in the early spring is usually sufficient for lawns. If very mossy use double or even treble the amount in the autumn, also employ the last-named quantities on grass land in the autumn or early in the spring or after haytime. For Cabbage, Cauliflower, and all Brassicas half to one bushel per rod may be used with great advantage early in the spring, harrowing or pointing in, or apply at the time of planting. Composts for Cucumbers, Melons, Strawberries in pots, and Tomatoes may have a pint of wood ashes added to each bushel of soil, or that quantity may be employed for top-dressing each plant of Cucumber, Melon, or Tomato.

Wood ashes are not commandable everywhere, hence chemical mixtures have been substituted, such as calcined oyster-shells,

14 lbs.; bonemeal, 7 lbs.; kainit,  $3\frac{1}{2}$  lbs.; mixed, and used in the autumn or early in the spring, from half to full quantity of mixture per rod. Prof. S. W. Johnson suggests a mixture of fresh burned shell lime, 30 lbs.; bonemeal, 10 lbs.; kainit, 8 lbs.; using 10 lbs. of the mixture per rod in the autumn or early in the spring.

Kainit is the most frequently used of mineral salts, containing potash, and is found in vast deposits near Stassfurt, in Northern Germany. It is a mixture of the chlorides and sulphates of potassium, sodium, and magnesium, and a good sample contains 12 to 14 per cent. of potash. Kainit is a good fertiliser for Cabbage and Brassica crops generally, cereals; leguminous—Beans, Clover, Peas, Potatoes, and other root crops. A minimum dressing is 2 lbs., and a maximum 5 lbs. per rod, the mean  $3\frac{1}{2}$  lbs. being a full one for most horticultural crops, and half for agricultural, or  $2\frac{1}{2}$  to 5 cwt. per acre. Instead of this better results are had from equal portions of superphosphate and kainit, and using  $3\frac{1}{2}$  lbs. per rod, 5 cwt. per acre in the autumn or early in the spring for fruit trees, not forgetting that nitrogen giveth the increase, or full value of the phosphatic and potassic elements, therefore employ  $1\frac{3}{4}$  lb. of nitrate of soda when growth fairly commences in the bushes or trees in the spring. Remember also that kainit and all potash salts can only profit when in full conjunction with phosphatic and nitrogenous manures.

Carnallite, kieserite, krugite, and sylvanite are names of German potash salts, similar in composition to kainit, but as a rule inferior, being hardly safe to use for horticultural purposes, for the chlorides of the substances are positively injurious to certain useful crops, carnallite being a double chloride of potassium and magnesia. But the chloride is mollified by nitrogenous matter; therefore carnallite may be usefully employed on peaty soils.

Sulphate of potash is also chiefly obtained from the Stassfurt mines, and the commercial article contains from 28 to 35 per cent. of potash, while the pure sulphate contains 50 per cent. Sulphate of potash benefits leguminous crops, also those of roots, as the chlorides of the other potash salts sometimes injure these crops to a certain extent. It is considered a good manure for plants requiring potash, such as Vines and fruit trees generally, also Beets and Potatoes, from 1 to 2 lbs. being used per rod, but the sulphates of potash are less effective in promoting growth than nitrate, for the leaves of plants to which it is applied become filled with starch grains, and instead of being transferred to where this substance is to be stored or made use of they remain in the leaf tissue, causing it to become fleshy and sickly looking, but with nitrogenous matter in corresponding proportion the transference goes on in due course and with mutual benefit. Sulphate of potash should be supplied in the autumn or early in the spring, and when the plant starts into growth afford nitrogenous matter so as to derive full benefit from the potash.

Chloride or muriate of potash is the richest and most soluble of all the German potash salts, containing about 50 per cent. of actual potash. Used alone it is apt to injure certain plants by the deleterious nature of the chloride on plants in active growth, which, however, is counteracted by admixture with phosphatic and nitrogenous substances, as is the case in the commercial fertilisers. If applied alone it should be in the autumn or early in the spring, and phosphoric acid and nitrogen being present in proper form and due amounts, it will give a good account of itself, with decided profit to the cultivator, on almost all crops. From 1 lb. to 2 lbs. per rod is a suitable dressing, always keeping it from growing foliage or even tender young roots. It is well adapted for fruit trees in mixture with superphosphate and nitrate of soda, say mineral superphosphate seven parts, dissolved bone four parts, muriate of potash six parts, nitrate of soda three parts, crushed fine, mixed, and applied just before growth commences, and afterwards at intervals of four to six weeks up to the fruit changing colour for ripening, using 4 ozs. per square yard at the first dressing, and 2 ozs. at subsequent, the mixture being always best given in light mulching, never more than an inch thick of short, decayed, lumpy manure, otherwise there is some danger of injuring tender surface roots.

Fish guano is essentially a potash manure, the fish refuse being mixed with the German potash salts. A complete fish manure contains 15 per cent. of sulphate of potash, 7 per cent. of nitrogen (equal to ammonia), 10 per cent. of magnesia, and 8 to 20 per cent. of phosphates, though some kinds contain much lower per-centages of potash, nitrogen, and phosphates. From  $1\frac{3}{4}$  lb. to  $3\frac{1}{2}$  lbs. per rod or  $2\frac{1}{2}$  to 5 cwt. per acre are full dressings, supplying early in the spring and as required during growth for subjects that depend on artificial supplies from time to time, such as plants in pots or borders of limited area.

Nitrate of potash or saltpetre is both a nitrogenous and a potassic manure, hence a valuable but a dear fertiliser. It, however, is very little use by itself, for it is not enough to supply nitrogen and potash; but phosphates also are absolutely essential

for the profitable cultivation of crops, and without due proportions of all a full measure of success cannot be attained. To render the nitrogen and potash thoroughly efficacious for plant growth and perfection of its crops, especially of fruit or seeds, also of flowers or buds for producing them, phosphates must be added and in maximum amount relatively to the other ingredients, say five parts superphosphate, three parts nitrate of potash, and one and a half part gypsum, mixed, employing 4 ozs. per square yard, always with or slightly in advance of growth in the plant, and as needed during that to sustain it and bring its crops to perfection.—G. ABBEY.

### FLORAL FACTS AND FANCIES.—9.

THERE are some questions floating about in the world which people never seem to be tired of, and to which they keep on returning with new interest, such as "Who wrote Junius's letters?" or "Who was the man in the iron mask?" Another of these that reappears now and then is, "Why should the Cowslip have been thus named?" As to the Oxlip we may consider that name an afterthought, given to the scarcer species because the feminine epithet had been attached previously to the Cowslip. Cowslips grow wild, certainly, along meadows grazed by cattle, but so do many other plants that come into contact with the lips of these animals. Of course, some folk want to make out that the Anglo-Saxon "Cuzlippe" might have had another meaning entirely; but of all the suppositions relating to the cow the likeliest seems to be that the velvety petals were fancied to resemble that quadruped's under lip. There is another puzzle, the plant is also called the Paigle, Pagil, or Peggle, a name apparently not limited to this species, but sometimes given to other native flowers. A leading philologist states its origin is most uncertain, though, as applied to the Cowslip, it may allude to a belief that a liquor made from the flowers cured palsy. Even yet it is thought the plant has remedial powers in chest diseases. One of the old notions concerning it is that the nightingale haunts places where it grows freely, and in some parts of East Kent it is oddly called the "Horse-buckle." Milton spoke of the flower as being wan and pensive, fitting for a funeral wreath; but more usually it is considered a symbol of "winning grace." Gibbs, one of the Old Brompton florists, produced a large number of variations about sixty years ago, which were deemed curious, especially the hose-in-hose form. To that plant which some have styled the American Cowslip has been assigned the character of "divine beauty," probably from its having been linked by Linnæus with gods and goddesses. He gave it the name of Dodecatheon Meadia, in honour of one of England's greatest physicians, also after a classical plant, now unrecognisable, upon which, it was said, each of the twelve celestial deities conferred some virtue. It was not inappropriate to this American species, for it bears upon the stem a cluster of reddish or lilac flowers of that number.

Some misapprehension has arisen from our common name of the allied Primrose, because it has been thought our ancestors called this a Rose. Really it was *Primerolle*, in reference to the early appearance of the flower along sheltered spots, so it came to be a symbol of "youth," but Shakespeare uses it as a figure for gaiety and pleasantness (the "Primrose path"). After all, the two meanings are not far apart. It is in one way a pity that the Primrose should have been taken as a party emblem, for this has led not only to the extensive gathering of the flower in its native haunts, but to the uprooting of the plants, so that the species has disappeared from places where it grew freely years ago. Yet, popular as the Primrose is, the repute of the spring salve made from its leaves seems to have vanished. The kindred Polyanthus, a flower which decorates so many borders in April, though it likes not the air of large towns, from its showiness became generally a symbol of "pride." Yet a crimson one is said to be significant of "mystery," and to present a lilac flower to a friend is to express "confidence" in him or her. Some early devotee of the Auricula, noticing its variations in colour and markings, called the flower a reminder of the "art of painting," but the scarlet varieties are said to suggest "avarice." When the plant first reached England people called it the Mountain Cowslip or Bear's Ear; this is, in fact, the meaning of the Latin name. The time of its greatest popularity was about 150 years ago, when it was the special favourite of flower growers amongst the artisans. Maddock, florist at Walworth in 1792, catalogued upwards of 500 varieties. The Evening Primrose claims a passing word here from the popular name it bears, though the *Oenothera* belongs to a family unconnected with the Primulas, but it tells us of "inconstancy," perhaps because the petals fade off rapidly, or that, in some kinds, they undergo a singular change of colour a little while after the flower has opened.

Pass we now to the *Ranunculus*, of which the above-named

Maddock, so renowned for Auriculas, remarked that we could produce, if need be, more varieties of it than of any other garden flower, though in 1628 Parkinson knew only eight double sorts, but then the plant had not long been introduced. The old gardeners were slow to discover that this *R. asiaticus* from the Levant was related to the Buttercups familiar along our English fields and lanes. From the original red type, by seedlings and division, were afterwards produced such showy and many-coloured flowers that, in floral language, the *Ranunculus* came to mean "resplendent charms." Some gardens in the old-fashioned style will yield specimens of the Aconite-leaved *Ranunculus*, or Crow-foot, grown under the name of Bachelor's Buttons. Why it is specially bacheloric we know not; also we are informed that the plant represents "lustre," possibly a compliment to the unmarried individuals of either sex. Indeed, one white variety gives us the other side, as it has been styled the "Fair Maids of France." One friend, however, tells me that he has heard a garden species of Catchfly, or *Silene*, called the Bachelor's Button too.

Amongst the cultivated Crowfoots there are several plants that have a double character. As part of the army of Buttercups in spring they tell of "cheerfulness," but as Crowfoots they remind us of "ingratitude," because under cultivation they do not improve in quality; their acrid nature is rather intensified than otherwise. One species, indeed, is actually called *R. sceleratus*! Some London gardens used to have another species, then occasionally found wild about small copses near the metropolis, grown under the name of Goldylocks, the *R. auricomus*, one innocuous member of a poisonous group. This appellation, however, has also been given to a shrub of the Composite order, a *Chrysocoma*, rare on our western coasts, and of which we have more showy species from South Africa. Another Crowfoot, the small Celandine, dear to the poets, is said to tell us of "joys to come." The name also associates its flowering season with the arrival of the Swallow from afar; but we must remember that the Greater Celandine in the Poppy family received its name for a different reason, because it was supposed the bird gave the plant to its young as a sight strengthener, and villagers have applied its thick juice to their eyes, not without risk.

In the Adonis or Pheasant's Eye we see a border flower that few recognise as a native plant. Token of "sorrowful remembrance" this, since it is linked to the classic legend of Adonis. Our own Shakespeare has told the tale again, how the weeping Queen of Love, as she lamented the death of Adonis, caused the earth to produce a plant the flowers of which resembled the blood flowing from the wounds he had received. Country folks say that the wild Anemones cannot bloom till they have been blown upon by the winds of March. They may have been called "Wind-flowers" from the fragility of the petals, or because the tails by which the fruits of some are adorned carry them rapidly through the air. The pale species of our woods suggests "sickness," the plant being regarded as an almost universal cure for the maladies of spring. A portion of it was worn round the neck, not taken by the sufferer. Under cultivation, as in exotic species, the stamens become petals, and a pretty double flower is formed, the Pasque Anemone.

*A. pulsatilla* was so named by Gerard because he found it flowering at Easter. The story that its juice was used to colour Easter eggs seems to be a mistake; for some reason or other it is a symbol of "unpretentiousness." The scarlet Anemone of Italy tells, they say, of one that is "forsaken," and the blue variety speaks of "hope." It is found wild, apparently, in a few places, but authorities consider it was introduced by the Dutch gardeners. Another species of the *Ranunculus* order is the showy double Pæony, the flowers of which indicate "shame," and to the garden Larkspur has been assigned the meaning of "fickleness."—J. R. S. C.

### CARNATION NOTES.

I WAS sorry to see Mr. Martin R. Smith, page 287, give an account of such bad results from his experience with Carnation seedlings. I am glad to say we have been more fortunate. We have one small border of ninety-five plants, seedlings from two pods of seed saved in 1893. The seeds were sown as soon as ripe, and the young plants pricked in boxes, wintered in a cold frame, and planted out in May last year. All of them grew well, three flowering in the autumn. At the first sharp spell of frost I gave them a mulching of 3 inches of decayed leaves, with the result that we have not lost one. Now they are beginning to grow again, and I shall be anxious to see them flower.

Raising seedlings is very interesting, especially when you "cross" them yourself. As mentioned above three seedlings flowered in the autumn of last year from seeds saved from a pod of a white "self" border Carnation—a large-flowered crimson and yellow "fancy"—and the three that flowered were all purple "selfs." This, to me, seems rather curious. We have had another, to me, real curiosity. It is a seedling from a crimson self, crimson and yellow fancy. Fifteen plants

came up from the pod of seed sown in 1893, and up to now nine of them have flowered in 7-inch pots in the greenhouse.

This particular one, I thought, when expanding its flower, would have a "blind" centre. But first of all it opened one set of petals, and then from the centre of this appeared another flower, perfect in every way, forming a kind of "hose-in-hose" Carnation, the bottom part being about 4 inches in diameter, and the centre 2 inches. Another rather curious thing was one side of the "hose-in-hose" was a very deep crimson ground shaded lake, the other being buff ground shaded scarlet. Several other flowering shoots are spindling up now; is it probable that the blooms from them will be the same as the first?

We have only just commenced raising our own seedlings, and perhaps some of our "big growers" will say how far seedlings are likely to follow their parents, and if they often break away to entirely different colours. Of the above mentioned plants that have flowered two are crimson selfs, the remainder being all fancies of different shades.—*JOHN ETTLE, Glais House Gardens, Swansea Valley, S. Wales.*

**WEATHER IN LONDON.**—A decided improvement has taken place in the weather during the past week, and in consequence vegetation of all kinds in metropolitan districts is now growing rapidly. Bright spring-like days have for the most part prevailed, with warm sunshine interspersed by genial showers. Yesterday (Wednesday) was particularly agreeable.

— **THE WEATHER IN THE NORTH.**—With less sunshine than in the preceding week the weather has notwithstanding been pleasant enough for the season during that ending the 23rd. Somewhat cold easterly winds prevailed in the earlier part, but Friday and Saturday were fine and mild. Monday was drizzly, and rain fell copiously during the night and again on Monday evening. Tuesday morning was dull, with the thermometer at 53°. Vegetation has progressed rapidly during the last few days.—*B. D., S. Perthshire.*

— **SHIRLEY AND DISTRICTS GARDENERS' AND AMATEURS' MUTUAL IMPROVEMENT ASSOCIATION.**—A meeting was held at the Parish Rooms, Shirley, Southampton, on Monday, the 22nd inst., when the President (Mr. W. F. G. Spranger) presided over a fair attendance of the members. Mr. W. Frank Perkins gave an interesting and instructive lecture on "Seeds: Their Composition, Growth, Structure, and Germination." "Curiosities of Seed Life" was also dealt with in an instructive manner, showing how winged and hooked seeds are adapted for distribution. A large collection of seed was shown by Mr. Perkins and Messrs. Toogood & Sons in illustration, and a very curious and unknown pod of seed was contributed by Mr. W. H. Rogers, containing hundreds of flat winged seeds, each an inch square. A vote of thanks to the lecturer and the exhibitors, and a resolution to pay a visit to Kew Gardens as an outing early in July, terminated the proceedings.

— **GARDENERS' ROYAL BENEVOLENT INSTITUTION—THE WOLVERHAMPTON AND STAFFORDSHIRE AUXILIARY.**—It has been decided to hold a floral fair and promenade concert in the Wolverhampton Drill Hall on April 30th and May 1st. All the artists have been engaged, and many florists have promised to assist in the decorations. Exhibits are also expected from Shrewsbury, Sheffield, and other parts. The promoter, Mr. G. A. Bishop, is very anxious that gardeners and others in the county and friends outside should render all the assistance they can by sending cut flowers, buttonholes, sprays, bouquets, or any exhibits, which will be considered a gift to the Institution. Gardeners could greatly help the Floral Fair by sending, at a very small cost, boxes of cut flowers for the ladies to sell. The principal gardeners in the county will act as Stewards of the Auxiliary. A working Committee has been appointed, and the Chairman has already collected nearly £30, and anticipates, with the co-operation he hopes for, to raise treble that amount. Friends wishing to take part in the undertaking should write G. A. Bishop, Netherton Farm, Wightwick, Wolverhampton, or send flowers and other things to the Drill Hall, not later than April 30th. We are asked to commend this co-operative effort on behalf of a splendid charity to the attention of our readers, but think it will commend itself, and trust the result will be in the highest degree satisfactory.

— **THE TEMPLE SHOW.**—Her Royal Highness the Princess of Wales has graciously consented to attend the Society's Great Flower Show in the Inner Temple Gardens on May 21st, and the show will be open for three days.

— **MR. H. SHOESMITH**, who is well known as a Chrysanthemum grower, has taken a business—the Claremont Nursery, Woking, an improving town in Mid-Surrey, and the home of some ardent amateurs in horticulture. The nursery contains good ranges of glass, Mr. Shoesmith intending to turn them to the best account, and to be heard of again.

— **TRUFFLES.**—Of all the delicious species of the Fungus family the Truffle probably heads the list. They are found chiefly in Oak forests. Growing wholly underground they can only be found by the aid of dogs carefully trained to scent them. The dogs indicate where they are, and the hunter digs them up. There is no reason why they might not be introduced into America, says a contemporary; but it is said to be difficult to get the dogs.

— **SEAKALE.**—When at Dropmore recently Mr. Herrin showed me a large breadth of ground prepared and set apart for the reception of Seakale root cuttings. He mentioned that he planted some 5000 yearly, because the demand for this excellent vegetable was so great. "We can practically put it on the dinner-table every day of the winter," he said. "It is only needful to have good roots, not necessarily large ones, in abundance, and the rest is easy." A large stock of roots has been of great value to any gardener during the past winter. How much better is it to grow Seakale in this way, practically treating it an annual, than by the old, untidy method, still seen in many gardens, and which gives such poor control over the roots during the dead of winter. Those who grow on the old bed system seem now rather out of date.—*D.*

— **THE CONSTRUCTION OF ROCKERIES.**—I fear I must plead guilty to having sent an unsatisfactory diagram with my articles on the construction of rockeries for Alpines. Your very able contributor, "Saynor" (page 342), is too complimentary to me in other respects, but I confess that the diagram is not what it should have been. Unfortunately, the art of drawing is one of the many accomplishments which the lack of the natural talent prevented me acquiring. The diagram was made a little more obscure by the omission from it of the letter F, which in the key pointed to the body of soil which had not been put into terrace form. As your contributor says, the outline is not a hard and fast one, but is merely to give a general idea of how to proceed. Alpines have to be grown in our gardens under purely artificial conditions, but it is wonderful to see how soon they modify the appearance of the rockeries on which they are placed. Prune away, Mr. "Saynor!" We are all delighted to read your "Prunings," and shall all be benefited thereby. May the whetstone be always at hand, so that the edge of the knife may be sharp enough to cut out all the useless growth to the great advantage of what is left.—*S. ARNOTT.*

— **LIVERPOOL HORTICULTURAL ASSOCIATION.**—The sixth and last meeting of the session was recently held in the Free Library, William Brown Street, the Chairman being Mr. T. White. Mr. Jno. Cowan of The Vineyard, Garston, read a paper on "How the Usefulness of Horticultural Societies and Associations might be Extended." At the outset he spoke of the great advance of education, in which horticulture played a prominent part. For one exhibition held twenty years ago we had now ten or twelve, and he was in favour of having more still. To make associations more useful he advocated the foundation of properly constituted committees in popular centres, who could grant certificates or awards to new and meritorious plants and products, which would carry the same weight as those of the R.H.S. Such committees should also be able to conduct horticultural examinations. In concluding, Mr. Cowan spoke of the stereotyped way in which our exhibitions are arranged, with scarcely any departure from year to year. Mr. White agreed that exhibitions were too monotonous. Mr. R. G. Waterman in the main coincided with what Mr. Cowan had said, saying that there ought to be something done so as not to let northern gardeners, who were quite as capable as any in the kingdom, have to be always a year behind in new and rare plants. Mr. R. Pinnington said he would for the present like to see each large association in a position to send at least two of its members to London twice in the year to report on new and noteworthy plants and other products. Mr. Stoney, Mr. Massey, and Mr. Foster also added interesting remarks. A hearty vote of thanks was proposed to Mr. Cowan for his admirable paper.—*R. P. R.*

— WE are informed that the Reigate Rose Show, in connection with the Cottage Garden Show, is fixed for July 10th.

— GARDENING APPOINTMENT.—Mr. H. R. Richards, lately head gardener to Colonel H. Trafford Rawson at Roche Court, Salisbury, has been appointed head gardener to the same gentleman at Coldton Hall, Bury St. Edmunds, Suffolk.

— WATERLOW PARK.—Under the direction of Mr. J. Pallett, the Superintendent, many improvements have recently been carried out in Waterlow Park, Highgate. All the paths have been remade, and large patches of the lawns turfed. The flower borders are stocked with Hyacinths, Daffodils, and Polyanthus, and there is every prospect that the herbaceous plants, which made such a splendid show last year, will again be a credit to the place.

— PRIMROSES AT COVENT GARDEN.—On Primrose Day Covent Garden Market presented an unusually busy appearance by reason of the enormous quantities of Primroses which had been imported into the metropolis. The majority of these were in root form and not obtained before the previous day in order that their beauty might be longer retained. It is stated that the plants were not so numerous as last year, and that buyers had some difficulty in procuring large supplies.

— GOLD-LACED POLYANTHUSES.—I saw a number of seedlings raised from the late Barlow strain growing the other day at Farnham Royal, and assisted in the selection and marking of many of the best. Mr. W. James, who inherits his father's excellent judgment, is taking great pains to preserve the strain pure. All who grow this section of Polyanthus know how readily they retrograde if other than the best forms are retained. Now is the time to sow Polyanthus seeds to secure good plants to bloom next year, and if some of special excellence result then it may be with a few wisest to lift carefully and establish in pots, standing them in a frame or cool greenhouse for seeding, or to keep for division, and thus increase those worthy of that course.—A. D.

— WAKEFIELD PAXTON SOCIETY.—At the meeting of this Society on April 13th Mr. George Parkin gave a valuable and interesting lecture on "The Rearing and Preservation of Insects." After describing the most prominent order of insects, and the special varieties which make themselves manifest either injuriously or beneficially on crops, garden or agricultural, Mr. Parkin pointed out that in order to meet the attacks of the one and to encourage the visits of the other a correct knowledge of their life history was an essential preliminary. He urged that this was best obtained by rearing and watching specimens of the various kinds through their several stages, and a great part of the lecture was devoted to describing how this could be done, and the apparatus required. The lecturer illustrated his observations by showing a choice and beautifully mounted collection of lepidopterous and coleopterous insects, drawings, and materials. A number of questions were answered, and in conclusion Mr. Parkin was most heartily thanked for his lecture, and for the very valuable services as an entomologist which he has for a long period rendered to the Society. Mr. J. S. Brown presided, and Mr. H. S. Goodyear occupied the vice chair.

— CAMELLIA RETICULATA.—Relative to Mr. A. Kemp's remarks (page 337) regarding this, the grandest species of Camellias, it may be additionally interesting to note that (somewhere I have read) some twenty-five years ago there was a fine specimen at Bank Grove, Kingston-on-Thames, the residence of Mr. Byam Martin, and stated to be 20 feet high by 50 feet in circumference. In one year it produced 4000 flowers! There is also a large specimen of it growing in a pot at the Botanical Gardens, Edgbaston, Birmingham, and which annually blossoms profusely, forming as it does a most attractive object in the large conservatory there. As a good companion to the former plant a remarkable specimen of the old Double White was recorded thirty-three years ago at growing at Sundridge Park, Kent, whilst at the present time there is also a fine and healthy plant of the same variety growing in an immense rectangular wooden tub, and the plant itself similar in size to the Bank Grove specimen. It was presented to the Society by a gentleman in the neighbourhood about two years since. I have a vivid recollection of having intimate relations with, upwards of forty years ago, a large tree of *Camellia reticulata* planted out in the unique ridge-and-furrow roofed conservatory at Trentham Hall Gardens, and which specimen, I believe, is still in existence there, consequently must now have attained to a gigantic size. In comparison with other species of the genus *C. reticulata* possesses one fault—if fault it be—and that is an inherent tendency to sparseness of foliage and leggy branches, unless attention is paid to frequent stopping of the young shoots during the plant's early youth.—WILLIAM GARDINER, *Birmingham*.

— CAPE FRUIT.—Fairly large consignments of fruit recently arrived by the "Norman." These, the bulk of which were Grapes, were offered for sale at Covent Garden Market. This importation showed a marked improvement on those previously received, the use of wood wool being largely responsible for the improvement.

— CYTISUS ELEGANS.—This is a shrub resembling *C. racemosus*, but superior in every way, the flowers of a deeper yellow colour, being larger, and borne more profusely. After flowering the plants should be cut back, and stood outside all the summer. It will be found necessary to trim the plants to keep them in good shape. The plant in question is hardier than *C. racemosus*, and is one of the very best for greenhouse decoration.—J. T.

— NEW YORK FRUIT STANDS.—For a week or two past the sidewalk fruit stands have been decorated with branches of *Kalmia latifolia*, its glossy green leaves being very effective in setting off the colours of Oranges, Bananas, and Apples. Leafy twigs of Wild Cherry are largely used during the summer for the same purpose, but these Laurel leaves have only lately come into such general use. The supply comes from the coast counties of New Jersey.

— RHODODENDRON FORSTERIANUM.—This was raised by Mr. Otto Forster in Austria, and is a hybrid between *R. Veitchi* and *R. Edgeworthi*. It has large white flowers, tinged with lemon on the uppermost side of the corolla tube. The corolla is divided into five spreading lobes, being crisped or wavy at the edges, measuring 5 inches across. The flowers are borne three to four in a head, and are very fragrant. This plant is now in flower in the temperate house, Kew.—J. T.

— VIOLETS.—I am sending you a few flowers of Lady Hume Campbell and Comte de Brazza White Neapolitan Violets. During the very severe weather in January and February last the plants were closely covered up for fifty-eight consecutive days, having neither light nor air all that time. When opened out they were as fresh and healthy as if they had only been shut up for a few hours. Lady Hume Campbell is not nearly so well known as its merits deserve.—NORTH-NORTHUMBRIAN. [The Violets are very fine indeed, some of them exceeding  $1\frac{1}{2}$  inch in diameter, and the leaves are extremely robust.]

— ANECDOTE OF THE MISSEL THRUSH.—During the severe weather of February, one of these birds suddenly made its appearance in the shrubbery attached to a Gravesend residence, the species not being often noticed in that district of Kent. His relations with the other birds that haunted the shrubbery (the owner being one of those kindly folks who dispensed crumbs and meat to "hard-up" birds at that time), were anything but of a friendly character. He chased them about at every opportunity, so they raised warning cries whenever he approached, but possibly he had been offended at the reception he received on his arrival. This bird fed voraciously on the berries of the Privet, and at last was found dead one morning, showing evident signs that these had disagreed with him. Whether it was excess after abstinence which caused this I do not know, or whether they were unsuitable food. Many birds that eat berries in the winter will not touch those of the Privet.—J. R. S. C.

— ROYAL METEOROLOGICAL SOCIETY.—At the meeting of this Society on the 17th inst., which was held at the Surveyors' Institution, Westminster, Messrs. F. C. Bayard and W. Marriott communicated a paper on "The Frost of January and February, 1895, over the British Isles." The cold period, which commenced on December 30th and terminated on March 5th, was broken by a week's mild weather, from January 14th to 21st, otherwise there would have been continuous frost for sixty-six days. Temperatures below 10° Fahrenheit, and in some cases below zero, were recorded in parts of England and Scotland between January 8th and 13th, while from the 26th to the 31st, and from February 5th to 20th, temperatures below 10° occurred on every day in some parts of the British Isles. The coldest days were February 8th to the 10th. The lowest temperatures recorded were 17° at Braemar, and 11° at Buxton and Drumlanrig. The mean temperature of the British Isles for January was about 7°, and for February from 11° to 14° below the average, while the mean temperature for the period from January 26th to February 19th was from 14° to 20° below the average. The distribution of atmospheric pressure was almost entirely the reverse of the normal, the barometer being highest in the north and lowest in the south, the result being a continuance of strong northerly and easterly winds. From a comparison of previous records the authors are of opinion that the recent frost was more severe than any since 1814.

— **SOLDANELLA ALPINA.**—We have at the present time this rare alpine plant in flower in the rockery here. It is an event, I believe, that seldom occurs in this country, its native home being that of the summit of the Alps on the snow level. To grow the plant well it requires to be planted in peat at the foot of a large stone with a north aspect.—GEO. BURROWS, *Warwick School*.

— **CEPHALANTHUS OCCIDENTALIS.**—This plant is commonly known as the Dwarf Button-ball. It is usually found in swamps and other damp places; but like swamp plants of every kind, with almost no exception, it thrives much better in dry ground than in its native place. There is quite a demand for it, says "Meehan's Monthly," by ornamental planters, many thousands having been sold by leading nurserymen during the past ten or twenty years. They grow much larger in cultivation than in nature, and plants may frequently be seen 7 or 8 feet in height, covered with many hundreds of its sweet-scented white heads of flowers. It is quite a favourite with insects; but for all their visits, it is adapted to self-fertilisation.

— **TASMANIAN APPLES.**—Tasmanian Apples are arriving in excellent condition this year, and a portion of the cargo of the s.s. "Cuzco," which brought 12,000 cases, was recently sold by auction at Covent Garden Market, realising prices which are said to be remunerative to the Colonial growers, whilst they are decidedly satisfactory to the London consumers. The excellent quality of the Tasmanian, Ribston, Cox's Orange, New York and Sturmer Pippins, and of the Scarlet Pearmain, Alfriston, and Prince Alfred are widely recognised. They fetched from 9s. to 16s. per case, coming into competition with the last of the Nova Scotia and Canadian Apples, which are selling at from 16s. to 20s. per case.

— **SEEDS WITHOUT FERTILISATION.**—Some years ago Mr. J. Smith of Kew had a plant of the Euphorbia family which was wholly pistillate; not another plant was known in Europe, and yet it produced perfect seeds. On this account, the plant being of a new genus, he named it *Cælebogyne*, a Greek term representing this curious behaviour. Peculiarities of this kind seem incomprehensible, and yet they are generally believed in by scientific men. Mr. David H. Day of Buffalo Fendleri produces seeds without being pollenised, and the writer of this paragraph one year cut off all the pollen-bearing flowers of the Castor Oil plant, so that not a particle of pollen perfected, and yet the plant produced its complement of seeds. The whole experiment, however, can be so easily repeated that it is much better to consider this result as only a possibility until further experiments have been made.—("Meehan's Monthly.")

— **THE WORLD'S GREAT FORESTS.**—At a recent meeting of the American Association for the Advancement of Science reports were read by several members giving the results of their investigations as to where the greatest forests in the world are situated. The object of these investigations was principally to ascertain the exact influence of forests for equalising the climate and the rainfall of the globe. In the provinces of Quebec and Ontario, north of the St. Lawrence river, there is one great continuous tract of forest, which extends northwards to Hudson and Labrador, and which measures altogether about 1700 miles in length, and 1000 miles in width. There is also another large area of timber lands in South America, which occupies the valley of the Amazon, embracing large portions of Northern Brazil and Eastern Peru. This forest is estimated to measure about 2100 miles in length by 1300 in width. Recent explorations have shown that Central Africa possesses a tremendous forest. This forest is situated in the valley of the Congo, bounded on the north-east by the waters of the Nile, and by the Zambesi on the south. Its width has not yet been surveyed, but its length is estimated to measure at least 3000 miles from north to south. Again, there is another in Siberia, ranging from the plain of the Obi River, on the west, to the valley of the Indighinka, on the east, and embracing the great river valleys of the rivers Olenek, Lena, and Jana. The average breadth of this great forest region is 1700 miles, and the average breadth from east to west about 3000 miles. The principal trees in that vast and extensive taigas and urmans are the Conifers, comprising Pines of several varieties, Firs, and Larches. The central parts contain thousands of square miles, which have never been explored, and to which not even the most experienced trappers have ventured to enter. It is stated that the beautiful semblance of the lofty Conifers, which exclude the pale Arctic sunshine, is extremely bewildering to the eye—so bewildering that all sense of direction is lost. Their height averages about 150 feet, and they stand so closely together that walking among them is difficult.

— **THE FROST AND LAVENDER.**—So great are the depredations caused by the severe frost in the Lavender fields in the neighbourhood of Wallington, that a great majority of the plants have been totally destroyed, and in large fields, comprising several acres, the whole have been pulled up and burnt. As Lavender is extensively grown in the district, the loss of this season's crop will prove a serious item to the cultivators.

— **VALLISNERIA SPIRALIS.**—According to the "New Zealand Herald" this aquatic plant has lately been found in Lake Takapuna, and some of the residents on the shores were apprehensive that it might become inconvenient by blocking the entrances to their boat-houses. The leaves of this plant are sometimes as much as 15 or 16 feet long. It is a well-known tropical and subtropical water plant, but has hitherto been unknown in New Zealand. The news of the presence of this terrible weed in New Zealand is a most serious item. In Canada it has choked many rivers, and stopped the traffic on them, until the way has been reopened at great cost. Fortunately the Vallisneria can exist only in water. When brought to land and partially rotted it makes a capital manure, and is often ploughed in. It is also used for top-dressing meadows. The plant is at present unknown in Australia.

— **THE XL ALL FUMIGATOR.**—This aphid destructor is employed by Mr. James, of Farnham Royal, for fumigating both Cinerarias and Calceolarias. For the latter especially the strong nicotine fumes emitted by the vapour, with which the house is filled, are found to penetrate to the aphides, which infest the under sides of the leaves, much more effectually than smoke does, and even bloom is found, after repeated fumigations, to be quite unharmed. The process is a very simple as well as a clean one. The spirit which is dissipated in the house is poured into small metal dishes, a very small amount being ample. These dishes stand on a perforated metal cone, that encloses a glass spirit lamp. It is therefore but needful to have some three or four of these things in an ordinary house, light the lamps, the house is soon full of the powerful vapour, and every aphid is destroyed.—D.

— **TAPPING MAPLES.**—Professor Wood, while he was a member of the staff of the New Hampshire Agricultural Experiment Station, made some tests with regard to the flow of Maple sap which are of interest. Maples are usually tapped to the depth of about an inch, and this practice is based on the belief that the sap comes chiefly from the wood of recent growth, so that any tapping deeper than the layers made during the last six or eight years is useless labour and an unnecessary injury to the tree. Professor Wood's experiment, however, seems to show clearly that the flow of the sap is largely dependent on the depth of the tap, and that sugar makers may with great profit tap their trees to a depth of 4 or 5 inches. The additional injury to the tree is slight, says the "Garden and Forest," especially if the hole is small, and when a three-eighths of an inch bit is used and the bark is left uninjured the holes will be grown over the first summer after tapping. It seems that twice the amount of sap can be obtained by tapping 4 inches deep instead of 2, while the sap from deep boring is almost as rich as the other. The exposure of trees to the sun has much to do with the result from tapping on different sides, and there is little doubt as to the correctness of the popular view that the trees should be tapped on the south side wherever practicable.

— **PRESERVING SPECIMENS.**—Since the best teachers of science in these times insist that their pupils shall study objects before they receive much instruction from books, instructors of botany find it difficult to procure at any given season of the year enough fresh material to fully illustrate different subjects. In following any textbook, for example, enough specimens to illustrate the different sections of the book as they are taken up at different dates can rarely be found. To obviate this difficulty, Professor Beal writes to "Science" that he has collected quantities of stamens of different plants, say the Berberry, Lobelia, Cypripedium, and others, and preserved each kind by itself in a solution of 25 per cent. alcohol, or of 1 of formalin to 100 of water. These specimens are all ready when the subject of stamens comes to be studied, and the preserved objects can be placed in a small dish before the pupils when fresh specimens cannot be procured. If they are not allowed to dry they can be used for successive classes. In the same way Professor Beal has preserved forms of pistils, the torus and other parts of plants, including fruits of various kinds, such as half-grown Plums or Cherries, fruits of the Mandrake, Bloodroot, and Mulberry at different stages of growth, and in this way lessons in morphology can be made more impressive than they would be if one illustration was used at one time, and the others a week or a month later.

## THE "DROOPING" DISEASE IN TOMATOES.

I AM sending shrivelled Tomato plants. They were looking fresh and well early in the week, then they commenced flagging, never to freshen up again. It is the same with pot plants, as those planted out, and it makes no difference whether chemical or animal manure only is used. Only a very few are stricken at present. I can see nothing wrong with the roots or stems, but suspect eelworms are the cause. Anyway, we have ordered a good supply of phenyle, and it will be used extensively directly it arrives. Some few Cucumbers are behaving very similarly. I should like to know what Mr. Abbey thinks about this case. We want to know something positive. No conjectures will meet the difficulty.—W. IGGULDEN.

[The Tomato plants are singularly healthy at the roots, and pushing a number from the stems, the soil being specially favourable for root formation and supplying nourishment. The leaves are attacked by what is known as the "drooping" disease, the tips becoming blackened, shrivelling, and dying as if destroyed by a corrosive substance, such as sulphate of copper, which is sometimes used as ammoniacal sulphate of copper solution for plant diseases, and is often as disastrous as the maladies it is intended to prevent or remedy. The disease, however, is not caused by ammonia, though it may induce a certain condition of plant favourable to the development of the micro-organism, which is the whole and sole cause of the affectation.

This is produced by a slime fungus, a myxomycetes, which, however, does not produce slime, as in the finger-and-toe or clubbing of Turnips and Brassicas generally, but is a near ally of the "browning" or "brownure" of the Vine, caused by the so-called slime fungus (*Plasmodiophora vitis*, *Masse*). The Tomato slime fungus, *Plasmodiophora tomati*, *Abbey*, blackens the leaves of Tomato plants, always commencing at the extremities, destroying the young tissues, so that they wither or suddenly collapse as if for want of water, whilst the older parts of the leaves become spotted with yellowish brown, turning to dark brown (hence the term "browning") and finally decay.

The tissue is somewhat thickened in the first instance, which is due to the growth of the micro-organisms within the cells, the substance or juice of the plant being converted into jelly-like matter, which ultimately splits up into myriads of cells, it being in its active state a mere mass (plasmodium) of naked protoplasm, each cell surrounding itself with a wall and forming a spore, the resting stage of the myxomycetes, when the danger ceases, as these bodies cannot vegetate until certain conditions are available, as they often are in the spring, but more frequently towards the end of summer. These are but generalities, for the spores only lie until favouring conditions cause their bursting and the appearance of the zoospores to form a plasmodium, the union of two or more such zoospores being the only known means of fertilisation. Such plasmodia then creep about in quest of food, but how they get into Vine or Tomato leaves, or even those of Orchids on blocks or in baskets suspended from roofs, is not known. The Orchid spot slime fungus (*Plasmodiophora Orchidi*, *Masse*) cares nothing for the verdigris (acetate of copper) of the copper wire nor for sulphate, it having a remarkable rejective power—a sort of animal-like instinct, as well as power of movement. This is mentioned because sulphates have been advised for Tomato diseases, especially sulphate of iron and potash, and it is certain that myxomycetes thrive on sulphur, hence superphosphate is the worst known manure for Turnips, as regards attacks of finger-and-toe or clubbing. Perhaps it is necessary that the sulphur combine with ammonia; indeed, such is the case, for the majority of myxomycetes are always found thriving on substances rich in nitrogen, both as saprophytes on fungi proper, or as parasites on these, as well as some of the higher plants.

Evidence of the peculiarities and modes of life of the myxomycetes are essential for grappling with the mischief, and gardeners were the first to contend successfully with these lowest forms of vegetation. The "flowers" of tan (*Æthaliium vaporarium*, *Fr.*) is a slime fungus, so called; it is not a fungus at all, but a lower form of vegetation even than "bacteria"—a myxomycetes, and half a century ago I was told to sprinkle such patches of the yellow spume with quicklime. The old gardener had practised this over fifty years, and from whom he had it I know not; all the same, it is the best remedy for slime fungus, whether as a saprophyte on tanner's bark in stoves or as a parasite in Turnips, Vines, Tomatoes, or Orchids—that is, rub the spots with quicklime until dry, as for canker in Cucumber and Melon stems. When we come to look into these things it is astounding to find how scientific many practical gardeners are, only they do not know it. Lime was known to the Romans as one of the best dressings for land, and it is certain that British farmers once believed in it, as is attested

by the numerous old chalk pits existing in various parts of the country, especially in Hertfordshire.

For "browning" in Tomatoes there are three things that may be of use—1, The preventive or remedy—a good dressing (1 peck to half bushel per rod) of quicklime to the soil. This will kill the plasmodia of the slime fungus, provide lime for forming nitrate of lime, either by nitrification or equivalent compounds by chemical agency; this will disfavour the myxomycetes, and benefit the plants against other parasites. 2, Cut off the affected parts and burn them, dusting the plants from base to summit with air-slaked, but very floury, lime. 3, Earth-up the plants with good soil, such as turves subjected to a temperature of over 212° previously, so as prevent any danger of eelworm, mites, or other parasites, and sprinkle a good handful of basic slag phosphate on every square yard of such top-dressing.

The cells of the Tomato leaves where thickened and yellowish brown are destroyed by the myxomycetes, being crammed with spores, which appear about the size of small Cabbage seeds when enlarged 1040 diameters. This hint may be of use to persons who wish to see the spores, but the plasmodium in the tissues appears as a jelly-like mass of naked protoplasm, and is only detectable by those conversant with normal cell structure and myxomycetes conformation.—G. ABBEY.]

## HARDENBERGIA COMPTONIANA.

THIS beautiful plant was for many years known as *Kennedy* *Comptoniana*, and is not by any means a new plant, as a "Gardener" surmises, who sends a specimen and desires our opinion of the plant. When trained to the roof of a greenhouse or a conservatory, and bearing its long pendulous dense racemes of brilliant blue flowers, the beauty of this Leguminous plant can be fully appreciated, especially if it be associated with climbers bearing lighter or distinctly coloured flowers, as the contrast shows it to better advantage.

If planted in a border the soil must be specially prepared, a compost of peat, light turfy loam, and sand being suitable, providing good drainage, whether it be grown in a pot or border, as, like many of its relatives, it cannot endure stagnant moisture about the roots. Some care, too, is needed to keep the plant free from insects, particularly mealy bug, which has a great liking for it. Little pruning is requisite, except to remove the old bare or weakly shoots. The flowers, though small, are borne in such dense racemes (see fig. 61) that their size individually is scarcely noticeable. The petals, keel, and standard are bright rich blue, the last-mentioned portion of the flower having a ring of white at the base, which renders by contrast the blue colour even more intense.

## VEGETABLE NOTES.

THE present is the third year in succession that Broccolis have succumbed to the severities of winter. Last year I decided, and as it proved, fortunately, to limit the amount of space occupied by ordinary kinds, and to increase that set apart for sprouting sorts, with the result that not a single plant of the former outlived the frost, while the outside leaves only of the latter were destroyed. Ever since the break up of winter we have been able to gather sprouts, first off the purple-sprouting, and latterly off the white. Than the last named there is no more delicious vegetable. I have also a good breadth of Carter's Universal Broccoli. Of this every plant is alive and healthy. Those who have not sown any of these ought to do so at once.

For very many years I have acted on a conviction that Spinach for winter and spring use is almost always sown too late in the season. The past season has again proved this to be correct, as I have had nothing off sowings made later than the end of August. It would appear that sowings of "winter" Spinach have generally failed this year, though Spinach is one of the hardiest of vegetables. For many weeks the quarter on which our crop is growing was covered with a sheet of ice, and yet the plants came out practically unscathed, and with a thaw the gathering of the crop was resumed. The sorts grown are Giant Viroflay and Parasseux de Catillon, the latter a capital round-leaved variety. Of the Lettuce-leaved I intend to sow a large space next autumn. Of those sown in September the one sort likely to be of any value is the "Slow Seeding," a dwarf-growing variety of Continental introduction. All the large round-leaved forms are much superior to the ordinary "winter" Spinach, a variety that might very well be dispensed with.

Lettuces, in frames as well as in the open, were all destroyed. Being somewhat short of full-grown plants, I filled several boxes in October with small plants, and sowed seeds at the same time. Kept in a cool house the former were ready to use by the end of January. October seedlings, which are not numerous on account of vermin having eaten the seeds and young plants, are now useful; and another sowing, made in the beginning of January, is almost fit for using. Of a few sorts tried, All the Year Round has proved the best.

Being somewhat hopeless of getting the earliest sowing of Peas into the ground at a reasonable time, I sowed seeds in boxes, and after

germination kept the plants standing in a cool structure until the ground was fit for planting. These plants have done so well that, notwithstanding the little extra labour involved, it may in future years be worth while to continue the practice. I sowed four sorts, but the one I am referring to was Chelsea Gem for the earliest crop. Leaf mould was employed for two reasons—first, because in it the seedlings would root freely; and next, because the roots could be lifted without breaking, and could be easily shaken free of soil.

The seeds were evenly distributed, at a distance of one-half to three-quarters of an inch apart. As soon in March as the ground was fit to work, the seedlings were laid in shallow trenches; two lines were planted together 9 inches apart, and the space between each plant was about 3 inches; the rows were 2 feet apart; a little free soil was placed

something to work for, and one not only works harder at the subject, but finds a greater pleasure in doing so.

We, as gardeners, must not look on theory as useless (it is to those who study theory alone), but as a valuable help; for, combined with good sound practice, it is a boon which only those who know it can appreciate. How many plants are killed annually by diseases which are preventable? How much manure is wasted by those not knowing the plant's requirements, besides the losses due to overfeeding? Many other instances could be given of the value of a theoretical knowledge of our work, but the above will suffice.

Readers, your attention was called last week by A. Kemp to the following paragraph written by "H. O. H.," page 290:—"Let a man by perseverance and study obtain a first-class certificate for the superior

FIG. 61.—HARDENBERGIA COMPTONIANA.

over the roots, and the rows were staked at once with short Spruce branches. It is only by contrasting these with the earliest sowing in the open ground that the full extent of the benefit is seen, and that not alone on account of the advanced growth, but also the greater vigour of the plants.—R. P. BROTHERSTON.

#### EXAMINATION IN HORTICULTURE.

I HAVE read the remarks on page 290 by "H. O. H.," also those by Mr. A. Kemp, page 333, on the above subject, and I think there is a certain amount of indiscretion in clinging as they do so tenaciously to the practical part of gardening alone; for the man who understands the science and practice of gardening has a much better chance of doing his work successfully than one who is only practical. It is well known that men could gain from books full particulars to enable them to pass an examination, but if they do so, what do they gain by it if they are not gardeners? If they are, they must naturally be better for their book learning; and what is more natural and encouraging than to test such knowledge by an examination? With such an object in view there is

cultivation of fruits, flowers, and vegetables at some of the leading horticultural exhibitions held at various places throughout the country, with a first-class testimonial from his employer for proficiency in the various branches of his calling, and I venture to say that will have more weight with the majority of employers than any first-class certificate granted by the R.H.S." To point out how very weak such an argument is only requires the answers to the following questions:— 1, Have we all the same privilege in showing our products? 2, Are all the flowers, fruit, and vegetables grown by the successful exhibitor or the men under him? 3, Have we all the same advantages gained by good soil and manure? 4, Are the glass houses as efficient in some gardens as they are in others? 5, Is the district, its surroundings, and atmospheric conditions equal in all parts of the country?

Many good gardeners are not allowed to show. Many of the under gardeners grow the flowers, fruits, and vegetables, which others get the credit for. The soils differ so much in various parts of the country, consequently some gardeners have better advantages than others. In some gardens there are only old glass houses; could gardeners with these be expected to compete with those who have houses built specially for their requirements? Some again have advantages in being in a district

where there is nothing but pure fresh air, while others are in the vicinity of large towns. Looking at the disadvantages which debar some of us from gaining certificates for showing our fruits, flowers, and vegetables, would it not be an advantage when applying for a situation to have one of the R.H.S. certificates besides the usual references we get from past employers? No one would think of applying for employment with one of these certificates alone, but they would show an employer that we knew something more than the practice alone. Because men gain prizes at horticultural shows I do not consider they are the best gardeners on that account, for probably we might find as good if not better men amongst those who are not allowed to show.

I would advise young gardeners not to be led away by any kind of argument either way, but to think for themselves, and they will see that theory alone is perfectly useless; but combined with practice it is one of the best things a gardener can have to help him to understand the lifelong work in which he is engaged.—W. D., *Turnford*.

MARÉCHAL NIEL.

Of all Roses this is perhaps the most popular, and so well known and appreciated that nothing need be said by way of description or praise. It is a question if all private gardeners are aware how easily a good forcing stock of this fine Rose may be worked up by grafting, provided there is a good stock of plants in a sheltered position out of doors or under glass, the latter preferably, as scions may then be taken at any time during the winter. The best stock for the purpose is the Briar, seedlings or cuttings being suitable.

This Rose does not thrive long on the Manetti, and although on the Gifferae it makes a wonderful growth, it is questionable if the plants will thrive for any length of time, excepting on a light soil. According to my experience the latter stock is more suitable for budding on in the open than for grafting. Presuming that a sufficient number of stocks are potted during the autumn in 60-sized pots, a start may be made—say, at the new year. A propagating case in a greenhouse or stove should be set apart for the purpose, large enough to hold about 100 plants, as if this is not enough a succession may be worked.

The stocks should be placed inside three or four weeks previous to working, in order to have them well on the move. The scions must be taken from wood of the previous year, not pithy, and as near the same size as the stock as may be. At the season mentioned they should be taken from an indoor plant, as most of the outdoor growths would be rendered unfit for the purpose by frost. If, however, these are taken off in the autumn, laid in a sheltered place and carefully protected, they are quite as good as indoor growths. Each joint will make a scion, but if wood is plentiful they may with advantage be left a little longer. Head off the stocks as low as possible, about 1½ inch being ample height for working. This in order that the union may be buried at subsequent potting.

It is a good plan to thoroughly rinse the pots and lower parts of the stocks before commencing, as this prevents the possibility of grit being introduced into the point of union. The ordinary whip graft is eminently suitable, and as it is the easiest system, should be practised. See that the outer hooks unite at the point of the scion and on one side; if on both so much the better. This requires a little manipulation if the stock and scion differ in size, but is conducive of a firm union. Tie the grafts firmly with raffia previously moistened, no wax or moss being required if the work is performed expeditiously, and plunge them at once in the propagating case. Syringe lightly twice or thrice daily, and keep quite close and shaded until the union is complete and the plants are beginning to grow. After this admit air very gradually, and never allow the leaves to flag. If carefully inured to the light and air of the house the frames or glasses may generally be taken off when the growths are about 2½ inches in length. It is better to leave the plants in the case for a few days for fear of their flagging, when it will be advisable to again cover them for a short time in the middle of the day.

After removing them from the plunging material they may be stood on a moist stage and kept far enough apart to allow of syring between the pots, also sprinkling the plants freely on bright days. Thought must now be given to where the plants are to be grown, and they are so accommodating that a place may be found for them in most gardens. A good place for the first few months is a midseason vinery, allowing them to grow straight up, tying the growth loosely to stakes as it develops. If the plant breaks naturally, two or even more shoots may be allowed to grow, or if this style of plant is preferred they may be stopped at the required height and the necessary number of shoots encouraged. The first shift should be given as soon as possible, as the plants quickly become stunted in the small pots. Four-inch pots will be large enough at first, using a compost of clean fibrous loam and a little leaf mould pressed rather firmly, and if the loam is very heavy a little road grit or sharp sand may be used.

As soon as these pots are filled with roots place the plants in the 9 or 10-inch size, a few half-inch bones being used with one large crock for drainage, and pure fresh loam for potting. This must now be

rammed very firmly, as a short-jointed solid growth is desirable. If a light position under glass is now unavailable owing to the foliage of the Vines or other occupants causing too dense a shade, the plants may be stood out of doors in a warm sheltered spot, not exposing them to the sun immediately after repotting, or the foliage will suffer, but gradually inuring them to the altered conditions. If care is taken that the plants are not checked in this or any other way, they will by the end of September have made fine growths of from 10 to 15 feet in length, and this should be hard and well ripened to within a couple of feet of the top at most. If the plants are intended for forcing they must on the approach of severe frost be placed in a cool airy house or shed where they can be protected and taken inside as required. In any case they will need some protection, as such plants are naturally more tender than those grown in the open air.

In order to induce the free production of lateral shoots for flowering, the stems must be trained round stakes placed in the pots, trained over an arching trellis or depressed in any way according to convenience or fancy; and after flowering should be at once cut down to within a few eyes of the bottom, when strong vigorous shoots will be produced to be grown on in a similar way the ensuing year. Where a large number of plants are required, grafting may go on all through the spring, summer, and early autumn—at any time in fact, though the last three months of the year are the least suitable.—H. R. R.

### ANEMONE BLANDA.

THE flowers of this species which expand in the earliest days of the year are ever welcome. Sometimes the last days of the year give us a few of its blue blossoms, but generally it waits until the end of January or the beginning of February before opening its enticing flowers. Although it is welcome before most of the Snowdrops or the Winter Aconites flower, it is doubly so when it gives us a blue to harmonise with the white and yellow of the others. Thus, when the Snowdrops and Aconites are in bloom, and a few hours of sunshine come to brighten the garden, this "Fair Windflower" forms a fitting companion, and the trio give us something to gaze on with the highest appreciation. It seems invidious, among the many beautiful Anemones, to single out this one as especially worthy of the English name of "Fair Windflower;" but all the same, *A. blanda* is worthy of a pleasing name, and is so beautiful that every garden of hardy flowers should include it among its choicest occupants.

It appears to be closely allied to the beautiful *A. apennina*, but presents a few features by which it may be distinguished from that species. In its best forms the flowers are of a deeper blue, and more finely rayed, besides being of a larger size. The styles are also black and pointed, and the leaves smoother, but harder and more dwarf, than those of *A. apennina*. The leaves are what are known as triternate, with the segments deeply cut and acute, and the involucral leaves stalked, trifid, and deeply cut. The flowers are said to have from nine to fourteen sepals, and vary in size, some of the best forms being over 2 inches across. The height is also variable, but it generally grows to about 6 inches high. It is believed that it came originally from Greece, but it is also found wild in many parts of the Mediterranean region. In the course of last year the writer heard of a very fine variety, which had been sent to this country by Mr. Edward Whittall of Smyrna, and which that gentleman believes came from Samos. Some good forms are also included among the tubers from Cyprus and Bithynia.

The variation in colour has already been alluded to. This ranges from deep to pale blue, some having a slightly rosy tinge; and there are also white varieties, differing considerably in purity of colour. A good deep blue variety is sometimes offered for sale under the name of *Ingrami*.

In order to enjoy to the full the beauty of *Anemone blanda* it should have a sheltered and sunny position, its flowers only opening properly when the sun is shining upon them. A little shelter from cold winds is an inestimable advantage to such early blooming plants as this Windflower. In my garden it has done well in the soil generally recommended—sandy peat or light loam—but recently one of my correspondents informed me that it was much finer if grown in a clayey soil. He has had great experience in the cultivation of hardy border flowers, alpine, bulbous and tuberous rooted plants, so that one feels disposed to experiment in the way of treating *Anemone blanda* with a heavier soil than formerly.

With a plant which naturally blooms so early it is desirable to have it planted in the autumn, but it is probable that some bulb dealers may still have dry roots in stock which could still be planted. In placing them in the earth much difficulty is generally experienced in distinguishing which portion of the rough-looking tuber should be placed downwards. Generally a few fibrous-looking roots are attached to it, and when this is the case these denote that that side of the tuber should be placed downwards. When these roots are absent it is sometimes possible to discover the knob-like points from which the leaves and flowers afterwards emerge, and which should be placed upwards. At times, however, careful examination fails to point out either roots or crowns, and one has to have recourse to planting them sideways, although it is sometimes difficult to do even this, so unshapely are some of the collected tubers when received. When large enough *Anemone blanda* may be increased by division of the tubers, and a convenient mode of increase to many is by means of seeds which germinate with more certainty if sown as soon as ripe.

This Windflower is subject to a fungoid disease which causes much

loss, and for which there appears as yet to be no satisfactory remedy. Anti-blight powder may be tried, and it is possible that in some gardens the tubers may require to be lifted annually, dried, and replanted. So charming a flower well deserves any care which is required to make it succeed, and its bright flowers will make it a universal favourite.—S. ARNOTT.

#### EXPRESS GRAPE GROWING.

MR. INNES' article in the *Journal of Horticulture*, page 328, on the above subject, is interesting in these commercial days. His success as there detailed is remarkable, and no doubt many of your readers, including myself, would like to know in what sort of compost these Vines were planted to make such headway in the time stated. If Mr. Innes can find the time to impart further information it will be instructive and appreciated. I have seen samples of the fine Grapes grown at Derby, and heard excellent accounts of the same; I therefore await with interest his reply to my request, if convenient to him to do so.—J. J. CRAVEN.

THE extraordinary case of express Grape, or more particularly Vine growing, by Mr. Innes, which he records on page 328, has set me, and doubtless many others also, longing to know more of the methods which bring about such very satisfactory results; and if Mr. Innes will kindly tell us I feel sure space will be found to do so in your columns, which he seems to fear.

It would be more than interesting to learn how to produce such crops as described from Vines no stronger than straws when planted out of 3-inch pots in the middle of August, and thus having only the tail end of the summer to "cover the house with splendid, well-ripened wood." According to Mr. Innes' figures the young canes were cropped at the rate of, for temporary Vines—Gros Colmans—14 lbs. per rod; and as if to prove how groundless our fears are of overcropping young Vines, Mr. Innes tells us he cropped the permanent Muscats at an average of 15½ lbs. per rod of 7 feet, or nearly 2 lbs. heavier than the temporary Colmans.

It is especially noteworthy that these Vines are "still in splendid condition;" had they been planted early in April instead of the middle of August the results, though still excellent, would not have been quite so surprising.—W. H. L.

#### THE EARWIG BAFFLER.

ON page 341 a drawing is given of one of these. I may state I have made these in different forms since 1864, and sold one to Messrs. G. Neighbour & Sons in that year. The principle, as shown at page 341, differs in no respect from what mine were, unless it was the hollow centre which admitted a pot or the leg of a bee hive.—W. T.

[We have received letters on this subject from two other correspondents, in substance identical, but as neither of them has sent his name and address the letters are not inserted.]

#### CHRYSANTHEMUM NOMENCLATURE.

THE American Chrysanthemum Society, when it resolved to register no new seedlings that bore names already in use and appearing in the English N.C.S. catalogue, acted in a manner that is deserving of our highest commendation. The rule has resulted in the greatest possible benefit to cultivators on both sides of the Atlantic by preventing much confusion that would certainly otherwise have ensued from florists of different nationalities whose language was the same.

In perusing the lists of American novelties there is always much pleasure to be derived in noticing the distinctive, if sometimes a little inelegant, style of nomenclature that the transatlantic growers adopt. Prominent examples for 1895 are as follows:—Latest Fad, Brigand, Diavola, Experiment, Bronze Giant, Octoroon, Parting Guest, Oakland, Millbrook, Philadelphia, Nemesis, Sunrisc, and Radiance.

What a contrast to some of those from the Continent; we are to have another Etincelant, Vesta, Hebe, D'Artagnan, Tendresse, Ganymède, Boule d'Or, L'Echevelé, Surprise, Mignonne, and others which have been used two or three times over.—P.

#### SHORT NOTES FROM AMERICA.

MR. SPAULDING'S catalogue of new Chrysanthemums contains about sixteen pretty little photo engravings of American seedlings set up in the prevailing fashion there—viz., in vases.

Mr. Hugh Graham, the raiser of Philadelphia, and the only American who has ever been awarded a medal of our English National Chrysanthemum Society, is sending out three other new seedlings this year called Mrs. Wm. Hurley, Mrs. Thomas E. Wiedersheim (both of them certificated by the American Chrysanthemum Society), and Katherine Leech.

Messrs. Pitcher & Manda's catalogue for 1895 is a very artistic production, and contains, among numerous other illustrations, phototype

pictures of Chrysanthemum J. H. Troy, the much-talked-of Pitcher and Manda, and a pretty chromo-lithograph of four or five hardy Pompons from a painting by Paul de Longpré.

Special Chrysanthemum seeds fertilised in Japan are now being offered for sale in the States, and are said to have been crossed and fertilised by secret methods unknown outside the land of the rising sun.

Messrs. Nathan Smith & Son in their new list give the names of the best varieties for market plants. Most of them are, of course, of American origin, but in whites they mention Mdme. F. Bergman and *Enfant des deux Mondes*; in pinks, Mrs. Bruce Findlay; in crimsons, Wm. Seward and John Shrimpton, which are all from this side.

Hitherto Pompons have not been much in vogue with the American Chrysanthemum fancier, but one well-known firm announce that they have secured from various sources a magnificent collection of about 100 distinct varieties.

Large numbers of the best American Chrysanthemums are now in the hands of the French raisers, who will, no doubt, be able to turn them to good account for seedling purposes, and by this means help to improve the quality of the Continental stock, which a year or two ago began to show signs of exhaustion.—P.

#### ROYAL HORTICULTURAL SOCIETY.

APRIL 23RD.

THE meeting at the Drill Hall on Tuesday last was a very successful one in every way. Both for the Orchid and Floral Committees the exhibits were many numerous and of splendid quality, while the display as a whole was greatly improved by the presence of the Auriculas and Primulas staged in conjunction with the National Auricula and Primula Society, and a report of which will be found elsewhere.

FRUIT COMMITTEE.—Present: T. Francis Rivers, Esq. (in the chair); with Dr. Hogg, Rev. W. Wilks, and Messrs. G. Bunyard, G. Reynolds, H. Balderson, F. Q. Lane, G. Wythes, J. Hudson, C. Herrin, W. Farr, J. Cheal, A. Dean, and J. Wright.

With the advance of the season we naturally find an increase in the variety of subjects placed before the Committee, and on the present occasion both fruits and vegetables were creditably represented.

Mr. W. Meads, gardener to A. Henderson Esq., Buscot Park, Faringdon, sent very handsome fruits of the Countess Melon, for which a cultural commendation was awarded. Seldom are finer examples seen at this early period of the year, and hence the award in question.

Excellent fruits of the Royal Sovereign Strawberry came from the Horticultural College, Swanley. They were of good size and superior flavour, the best, in the latter respect, up to date; also fine fruits of Sir Joseph Paxton. A cultural commendation was accorded for both samples, and the Royal Sovereign was highly commended as a forcing variety.

Andrew Pears, Esq., Spring Grove House, Isleworth (Mr. W. Farr, gardener), sent bunches of ripe fruit of *All the Year Round Tomato*, and also fruiting plants, for showing the productiveness of the variety. The fruits are below medium size, but borne in long racemes, after the manner of Horsford's Prelude, the shape of the fruits resembling Chiswick Red. They are very firm and of excellent quality, and a first-class certificate was unanimously awarded.

Messrs. B. S. Williams & Son, Holloway, sent a plant and excellent pods of a forcing Kidney Bean. As it was not named, it was proposed to be sent to Chiswick for trial. Mr. G. Wythes sent a dish of very fine Seakale, grown and blanched with soil in the open air, also a splendid sample of Sharpe's Victor Potatoes. Mr. Wythes sent as well several bunches of Foster's Seedling Grapes, from Vines in pots—very good, but not quite ripe. A cultural commendation was unanimously awarded for Mr. Wythes' highly creditable contribution. This unforced Seakale is most valuable, but only provided in comparatively few gardens.

Mr. T. Goldsmith again sent the Burfield Apple from Leonardslee. It is undoubtedly a showy Apple, and would sell freely in shops; but as the fruits were not of sufficiently high quality for dessert, the Committee desired to test the cooking quality of the fruit prior to venturing an opinion on the merits of the variety.

Messrs. Sutton & Sons, Reading, sent a number of plants of *Suttons' Hearting Curled Kale*—evidently a very hardy, distinct, and excellent variety, and an award of merit was voted with unanimity. The firm also sent twenty-one varieties of Radishes—all good, the majority representing varieties for growing in the open air, but some recommended for forcing. Of these the most distinct was *Suttons' Earliest Frame*, that may be described in the French way as having crimson roots, or an oval shaped Radish drawn out to thrice the usual dimensions; it was crisp and excellent, and an award of merit was granted forthwith. The other varieties were also as good of their kinds as could be desired, both as regards crispness and colour. An attractive assortment of Variegated Kale was also staged. In addition to the awards mentioned, a cultural commendation was awarded for the entire collection.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. John Fraser, Owen Thomas, C. T. Drury, H. Herbst, H. B. May, E. Molyneux, G. Stevens, J. H. Fitt, J. Jennings, R. B. Lowe, Chas. Jeffries, J. D. Pawle, W. Bain, Geo. Gordon, E. Beckett,

Chas. E. Shea, C. Blick, Chas. E. Pearson, H. J. Jones, G. Paul, H. Turner, Jas. Walker, G. Nicholson, H. S. Leonard, and W. J. Grant.

Mr. P. Perry, gardener to J. C. Tasker, Esq., Middleton Hall, Brentwood, showed a charming group of pot Roses, for which a silver Banksian medal was awarded. The varieties included Her Majesty, Innocente Pirola, Mrs. John Laing, Madame Lacharme, and Merveille de Lyon, all the plants being admirably grown.

Pot and cut Roses were extensively and well shown by Mr. W. Rumsey, Joynings Nurseries, Waltham Cross. The plants in pots were splendidly grown, while the cut blooms left little to be desired. Niphotos, Maréchal Niel, and The Bride were amongst the very best (silver-gilt Flora medal).

Cannas in good variety were arranged by Messrs. Paul & Son, The Old Nurseries, Cheshunt, who also staged Roses in pots. Amongst the most noticeable were Carmine Pillar, Madame Hoste, Elise Finger, Magna Charta, and Gustave Piganeau (silver Flora medal). Amaryllis in variety and splendid condition were staged by Messrs. B. S. Williams and Son, Upper Holloway, and a basket of *Leschenaultia biloba* major from the same source was very charming (bronze Flora medal).

Mr. G. Jackman, Woking Nurseries, arranged a handsome collection of hardy plants and a few Roses. Double and single Primulas, Violas, *Myosotis*, Poet's Narcissus, Fritillarias, and *Andromeda floribunda* were very prominent (bronze Flora medal). Foliage plants were well staged by Mr. H. B. May, Upper Edmonton. *Pteris cretica* Wimsetti received an award of merit, as also did *Tropæolum Coolgardie*. Many other Ferns were shown, and also *Dracenas* and Palms (silver Flora medal).

Mr. G. Reynolds, The Gardens, Gunnersbury Park, showed exceptionally well grown plants of *Primula obconica*, receiving for them a bronze Banksian medal. Mr. J. Walker, Thame, staged cut Roses in great variety, and was awarded a silver Banksian medal.

Cut Roses in superb condition came from Mr. F. Cant, Braiswick Nurseries, Colchester. The flowers were of handsome shape and superb colouration (silver Flora medal). Cannas, Carnations, and Primulas came from Messrs. H. Cannell & Sons, Swanley; Mr. Mount, Canterbury, staging cut Roses in very charming condition and variety. A silver Flora medal was recommended for this exhibit.

A handsome plant of *Cineraria cruenta* came from the Royal Gardens, Kew. The Guildford Hardy Plant Nursery sent a superb exhibit of Primulas and other hardy flowers (silver Flora medal). A cultural commendation was accorded to Mr. F. Cornish, gardener to Lady Bowman, Dorking, for a pan of *Epigea repens*. Mr. W. Bain, gardener to Sir Trevor Lawrence, Bart., Dorking, sent Primulas and Polyanthus in variety, and was adjudged a bronze Banksian medal.

Daffodils and Tulips were splendidly shown by Messrs. P. Barr and Son, King Street, Covent Garden. Amongst the most prominent were Autocrat, Horsefieldi, Exquisite, Captain Nelson, Magog, Duchess of Westminster, Barri conspicuus, Acis, Madame de Graff, and Glory of Leyden (silver Flora medal). Hardy shrubs were exhibited by Messrs. W. Paul & Son, Waltham Cross, many kinds being included.

Messrs. J. Veitch & Sons, Chelsea, exhibited baskets of new varieties of blue Primroses and *Alyssum saxatile citrinum*, also *Epiphyllums* and *Gloneria jasminiflora*. The Primulas sent from the Royal Gardens, Kew, were of exceptional beauty, and comprised many rare forms. *Amherstia nobilis* was also sent from Kew. Messrs. W. Paul & Son staged a plant of a charming new fimbriated *Camellia* named Bathazar. The Rev. G. H. Engleheart, Appleshaw, received a silver Banksian medal for a collection of Daffodils that comprised many seedlings of his own raising.

Messrs. H. Low & Son sent a box of their new Mignonette, Bush Hill White; while Mr. T. S. Ware exhibited Narcissi in grand condition. *Poeticus poetarum*, Barri conspicuus, Empress, Emperor, Sir Watkin, and Leedsi amabilis were particularly striking (silver Flora medal). G. F. Wilson, Esq., Weybridge, received an award of merit for *Polyanthus Hermand*.

Mr. C. Wright, gardener to T. McMeekin, Esq., Norwood, staged flowers of two seedling *Rhododendrons*.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); Dr. M. T. Masters; with Messrs. Jas. O'Brien, De B. Crawshay, H. M. Pollett, H. Ballantine, W. H. White, H. J. Chapman, F. Sander, J. Jaques, E. Hill, W. Cobb, Thos. Statter, G. Courtauld, T. B. Heywood, G. Shirland Ball, and W. H. Protheroe.

Mr. H. J. Chapman, gardener to R. I. Measures, Esq., Cambridge Lodge, staged a number of cut Orchids, in which forms of *Vandas* largely predominated (silver Banksian medal). The Orchids, intermingled with Ferns, exhibited by Messrs. B. S. Williams & Son, Upper Holloway, were very charming, and comprised *Chysis bractescens*, *Odontoglossum Halli*, *O. triumphans*, *Coelogyne Massangeana*, *Dendrobium superbum*, *D. Wardianum*, and several fine *Cypripediums*, besides many others (silver Banksian medal).

Mr. Johnson, gardener to T. Statter, Esq., Stand Hall, Manchester, staged a plant of the superb *Cattleya Prince of Wales*, which is one of the most beautiful hybrids we have. A few Orchids were shown in good condition by Mr. G. Cragg, gardener to W. C. Walker, Esq., Winchmore Hill. Mr. White, Orchid grower to Sir Trevor Lawrence, Bart., Dorking, sent plants of *Dendrobium cretaceum*, *Masdevallia Armini*, *M. fragrans*, *Eria* species, and others, all of botanical interest. Mr. T. Stafford, gardener to F. Hardy, Esq., Cheshire, showed a few Orchids, including *Cypripedium Gowerianum magnificum*, which was accorded an award of merit.

De Barri Crawshay, Esq., Rosefield, Sevenoaks, showed a plant of *Cypripedium Mulus*, Rosefield variety. Mr. Johnson, gardener to

G. Marshall, Esq., Grimsby, arranged a small group of Orchids comprising *Cattleya Harrisii*, *Dendrobium Paxtoni superbum* (award of merit), and several others. Messrs. Veitch & Sons, Chelsea, exhibited a varied collection of Orchids composed of *Cymbidium Lowianum*, *Oncidium concolor*, *Cattleya Mendeli*, *C. Lawrenceana*, *C. Schilleriana*, *Lælio-Cattleya Epicasta* (first-class certificate, see below) *Lælia Latona*, a hybrid between *L. purpurata* and *L. cinnabarinus*, *Odontoglossum triumphans*, *Cypripedium Orion*, *Masdevallia ignea*, and numerous others (silver Flora medal).

The collection of Orchids shown by Messrs. F. Sander & Co., St. Albans, was very beautiful, and comprised many excellent forms, amongst which the following were prominent:—*Masdevallia Veitchi*, *Cypripedium macrochilum*, *Cattleya Frederick Boyle*, *C. Schroderæ*, *Dendrobium thysiflorum*, *Epidendrum nemorale*, *E. Rogersi*, and *Odontoglossum cirrhosum*, *hystrix nobilis*, *crispum roseum*, *crispum triumphans*, *Pescatorei*, and *Edwardi* (silver Flora medal).

*Cattleyas* and other Orchids were shown by W. M. Appleton, Esq., Weston-super-Mare. Messrs. W. L. Lewis & Co., Southgate, staged a bright and well-diversified collection of Orchids, of which *Lycaste trifoliata Lehmani* received an award of merit (silver Flora medal). Messrs. H. Low & Co., Clapton, also Orchids in splendid form, including *Cymbidium Lowianum*, *Cattleya Mendeli*, *C. Mossiæ*, *C. Schröderæ*, and several others (silver Banksian medal).

*Cattleya Schiöleræ* in various forms was shown by Messrs. Heath and Son, Cheltenham, who also staged *Phalænopsis* and *Odontoglossums* (silver Banksian medal). An award of merit was accorded Paron Schiöler, Egham, for *Dendrobium Hildebrandti*, which is described below.

Mr. F. J. Thorne, gardener to Major J. J. Joicey, Sunningdale Park, staged magnificent specimens of *Dendrobium atro-violaceum*, *Cypripedium Elliotianum*, both of which received cultural commendations. The same exhibitor also staged *Phaius Blumei* var. *assamicus*.

G. T. Pitt, Esq., Stamford Hill, was accorded a silver Flora medal for a handsome exhibit of Orchids in variety.

In addition to the general show there was a class for a collection of Narcissi, and many very handsome flowers resulted. The Rev. S. Eugene Bourne, Dunston Vicarage, Lincoln, was a splendid first. Mr. Downes, gardener to J. T. Bennett Pöe, Esq., Cheshunt, was second; M. Cammell, Esq., Loxwood House, Billinghamurst, third; and W. J. Grant, Esq., Bassaleg, Newport, fourth.

#### CERTIFICATED PLANTS.

*Bougainvillea speciosa superba* (G. Stanton).—This is a richly coloured form of the type (award of merit).

*Cattleya citrina* (W. Rapley).—Though keeping the old name, this is a distinct improvement on the well-known type. The colour is the same, but the flower is of better substance, while the lip has an edge of creamy white (first-class certificate).

*Cypripedium Gowerianum magnificum* (J. Stafford).—This variety is of fine form and of great substance. The flower much resembles the type, but is somewhat larger and of finer colour (award of merit).

*Dendrobium Hildebrandti* (Baron Schröder).—The sepals and petals of this *Dendrobium* are creamy white, the lip being of the same shade, with a yellow throat (award of merit).

*Dendrobium Paxtoni superbum* (J. Johnson).—This is a much improved form of the well-known type (award of merit).

*Lælio-Cattleya Epicasta* (J. Veitch & Sons).—This is one of the finest bigeneric hybrids that this (or any other) firm has introduced. It is the result of a cross between *Cattleya Warscewiczii* and *Lælia pumila*, of which the latter was the seed parent. The sepals are narrow, long, and of the most pleasing shade of purplish rose, the petals being broad, of great substance, and also of that colour but in a rather deeper shade. The lip, however, may be termed the best feature. The outer edge is deep purplish rose shading to bright maroon, then comes a band of pure white shading to yellow, the base of the throat being bright purplish rose. The illustration, fig. 60, page 353 (sketched at the Drill Hall), will convey to our readers the form of this handsome flower (first-class certificate).

*Lycaste trifoliata Lehmani* (W. L. Lewis & Co.).—This is a charming *Lycaste*. The sepals are pale green, and the petals white tinged with green. The lip is very much fimbriated and of the same colour as the petals (award of merit).

*Polyanthus Hermand* (G. F. Wilson).—This is a very beautiful variety with rich purplish blue flowers of large size (award of merit).

*Pteris cretica Wimsetti* (H. B. May).—This is a very charming crested form of the popular *P. cretica* (award of merit).

*Rose Marchioness of Londonderry* (Paul & Son).—This is a fine Hybrid Perpetual with creamy white flowers of fine form (award of merit).

*Rose Bridesmaid* (Paul & Son).—This Rose belongs to the Tea section, and is of good substance. The colour is pale salmon pink (award of merit).

*Tropæolum Coolgardie* (H. B. May).—This is a very floriferous yellow coloured kind that will doubtless be of much value for pot culture (award of merit).

#### THE PRIMULA CONFERENCE.

Under the presidency of Professor Michael Foster, F.R.S., a Conference on Primulas was held in the hall, at which a paper on "New Primulas" was read by Mr. J. G. Baker, F.R.S., and another on the

"Culture and Classification of Primulas" was given by Mr. Selfe-Leonard. The Chairman, on introducing the essayists, remarked that horticulturists derived a large amount of pleasure in cultivating and adding to the stock of plants already known, and that gardeners by their superior art can do a great deal in the way of hybridisation and other means towards bringing into existence varieties of plants which Nature under ordinary circumstances does not.

Mr. Baker then read a highly interesting and exhaustive paper, in which he portrayed the amount of work that had been done on the genus *Primula* since the last Conference was held in 1876. At that time there were between seventy and eighty varieties, and now there are 150 known, so that they have been nearly doubled during the last twenty years. The essayist then went on to give a graphic and historical view of the whole genus, stating that in 1888 Dr. Parker of Berlin wrote a monograph of the whole, in which he divides the genus into twenty groups. Another book, also from Berlin, deals with the European species. According to the "Kew Herbarium" out of the 150 species now known fifty-four of them hail from China and Japan.

Of the *Sinensis* group, of which there are fifteen varieties, seven are natives of China, one of Japan, and the remainder from the Western Himalayas. The well-known *verticillata* is a native of Arabia and Abyssinia, and *bullata*, of which there are four varieties not yet in cultivation, is a native of China; this is an interesting group, very like Primroses. *Primula vernalis*, to which Primroses and Cowslips belong, is confined solely to Europe.

By the aid of a diagram a vivid description of the different species was given, also showing in what parts of the world were their native habitats.

In a few brief remarks on the cultivation of new and as yet little known Primulas, Mr. Baker said he thought the best method was if possible to obtain all available information on the habits and positions of growth in their native climes, and failing that to try the treatment under which known members of the same group were grown.

Mr. Selfe-Leonard, in course of his paper, said that in looking at hardy Primulas from a gardener's standpoint, it was a surprising thing to notice the small extent to which they were cultivated in English gardens, considering the comparative ease with which they may be grown. This might be traced to the fact that some few had failed to give satisfaction, and so the whole class had become discredited.

At the last *Primula* Conference a list of those then known was published, since then the number of species and hybrids has been greatly augmented, which, however, are in need of a better classification, as competent botanists think that the confusion which exists amongst them is extreme. For instance, *Primula integrifolia* has been known by five different botanists under other names.

In commencing the cultivation of these plants he thought the best plan was to begin with those varieties which are most distinct and easy to grow. In exhibition, too, he thought the mode of staging was not of the best, and could be made to look much more pretty and natural than by the present system of showing them in pots. The classes, too, might be better arranged—namely (1) Greenhouse species; (2) Large habited, hardy, and of easy culture; (3) Small growing mountain varieties. The reasons for this was that the greenhouse kinds, though beautiful and interesting, were out of place with small and alpine sorts, though all at present can be accommodated under one class at shows.

In speaking of Alpine Primulas he said the culture was simple, the treatment usually applied to Auriculas being suitable, with the exception that they should not be allowed to go entirely to rest in the winter as is the case with the former. Soil was not of the first importance, as good loam with a little sand suits them well, abundance of good drainage being essential. The east and north sides of rockeries were the most suitable for them, as the partial shade is not only congenial to them but assists in prolonging the flowering.

That they delight in cool conditions is seen by the fact that Northern Europe is more suitable for them than South. He thought a chalk soil was in no way essential for them, and they may be grown in gardens to advantage without the presence of a particle of chalk or lime. In selecting a few suitable for the rockery and garden the following were given—*P. auricula* (golden yellow), *P. viscosa nivalis*, *P. rosea* in its best varieties, *P. viscosa major*, in many forms, *P. spectabilis* and its varieties, and *P. marginata*, together with *P. integrifolia*, *P. Fosteri*, *P. longiflora*, and several others.

But little discussion followed, and the Chairman, on rising to propose a vote of thanks to the essayists for their interesting papers, said he thought the Society might issue an authentic list of known Primulas that would prove of great service, and that botanists, when collecting and sending home any new ones, might also send some details regarding the character of the soil in which they were found growing, as this likewise would prove useful in their cultivation in England.

After the usual votes of thanks had been given, the Conference was brought to a close.

#### ILLICIAM FLORIDANUM.

THIS plant is commonly known as the Florida Orange tree, and "A. B." will find no difficulty in growing it. The flowers of this *Illicium* (fig. 62) have a strong aromatic odour resembling aniseed, and are composed of a great number of radiating, slightly recurving, dark reddish crimson flowers borne singly near the points of the shoots, but thrives best in a warm sheltered position. In the southern and western counties of England, and near the sea coast, it succeeds in

the open border, but in northern or cold districts it might with advantage be grown in cool conservatories or greenhouses. It requires an abundant supply of water all through the summer, and must not be allowed to become dry in the winter. A mixture of peat and light loam forms a suitable compost for it when grown in pots, though in the open air it will flourish in any ordinary garden soil, providing it is fairly rich and of a loamy or peaty nature.

#### MARKET PLANTS AND FLOWERS.

(Continued from page 344.)

THE market grower with capital has a manifest advantage over one whose capital lies, as it were, in his hands. The one can use a little more patience and manipulate his productions to perfection, while the other

FIG. 62.—ILLICIAM FLORIDANUM.

rushes off to market with more moderate stuff, and, as a matter of course, he neither finds so ready a sale nor so good a price. Yet if he be favourably situated, and not overburdened with rent, and strictly sober and industrious, there are few professions that will give him more comfort in the decline of years than that of horticulture.

Railway facilities are of vast importance to market growers; there they can obtain in a general way fuel for the furnaces, and send off light goods, such as cut flowers. Kent is fairly interlined, and the north of London is quite a network of railways. To the west of London they have been somewhat slower in developing, but now that the Metropolitan has an extended service to the Vale of Aylesbury we shall see in the near future market growers springing up in such localities as Wembley, Harrow, Pinner, Northwood, near to the famous "Moor Park," and Rickmansworth, all as yet in a state of virgin purity as far as market growers are concerned.

Growers for market, especially the flower market, should never have

their eyes closed to the emporium. Some flowers do close their petals when the sun departs, just as some servants forget to open their eyes to duty. This is a very important point. No doubt market work is extremely trying to some constitutions in the very busy season. Some cultivators, after being hard at work from early morning, have to set off a long journey to market, where they may reach late in the evening. Then the plants have to be unloaded on to what may be called double-decked trolleys, and the market porters wheel them away to the particular stand which is numbered and rented from year to year. Then when the grower has staged all his plants, his horse cannot stand in street all night, so is taken to some place of bait, while the cultivators snatch an hour or two's rest at some hostelry, and by four o'clock the following morning they must be at their stand in the market ready for the buyers—the best buyers. If by chance the grower or his deputy sleeps on, and does not arrive at the market as soon as it opens for sale, he has a great chance of missing the market, which is tantamount to missing the best prize. Beware of that circumstance, for it is not to the purpose of growing plants to perfection if they cannot be sold to the best advantage.

It is also well for the grower or his salesman to take a cursory glance round the market for the purpose of comparing notes. In March, when a great quantity of *Genistas* make their appearance in the market, unless they be first-class stuff it is no use asking too high a price and sticking to it. Take chances as they come, and endeavour to allow no would-be buyer to go away unsatisfied. In the busy market season the plant salesman has enough to do to watch all points; they have little or no trouble with the best buyers, but experience a deal of what is extremely trying to a similar temperament from the lowest class of buyers, chiefly composed of costers, who have a knack of hanging about, and often drive away good buyers, and if it were not for the important circumstance that they buy largely and chiefly what the best do not want, their presence in the market would be an intolerable nuisance.

#### THE MARKET.

Covent Garden Market for the sale of plants and cut flowers from time to time has been enlarged to meet the requirements of the trade, and the present season has seen a new market opened purposely for the convenience of the continental cut flower trade which has now become so extensive, contrasting wonderfully with the narrow limits which a few years ago it possessed, when one solitary continental representative brought into market his consignment of cut flowers in a few boxes strapped to his shoulders.

It is predicted that there awaits a bright future for British art in the twentieth century. Vouchsafed commercial prosperity there need be no fear of the decay of British art, nor yet of that which ministers to all artistic efforts, the charm of beauty combined with utility, the resources of Flora.

When we think of flowers, and the part they play in sustaining animated nature, and the pleasure they give to the sick as well as the healthy, there need be no wonder at the vast stride which Flora's universal guests have taken of late years to win popular favour; and that they found favour in the late Duke of Bedford's eye, that does not prove that he had an eye for beauty, or else His Grace would never have sanctioned the erection of such a structure for the sale of continental cut flowers. Let us hope the iron edifice may be only temporary, until such time as a further extension of the present Flower Market may be taken in hand, and so have room under the one roof for foreign as well as home produce in the way of plants and cut flowers. Covent Garden Flower Market opens every Monday, Wednesday, and Friday evening at eight o'clock for the convenience of growers and others who may choose to bring their produce overnight, so as to be ready for market the following morning, when sale begins by five o'clock. But in the busy season, from the beginning of April to the end of June, the Market is open every week day evening, and opens an hour earlier the following morning, and always closes by 9 A.M. Unsold produce may be left without any extra charge beyond the usual Market fee. The Market is open every week day morning for the sale of cut flowers, independent of the busy season.

The market porters are most obliging, and carefully help the growers to stage their plants, and in the busy season the task is far from an easy one. Some hundreds of thousands of plants, in what is technically known as 48's, have to be wheeled in and staged every evening, besides innumerable boxes of seedlings and cuttings of the finer sorts of bedding plants, as well as the commoner varieties of plants, such as Daisies, Pansies, Creeping Jenny, Wallflowers, Sweetwilliams, Gardener's Garters, Old Man, &c., &c., too numerous to mention. Covent Garden Flower Market is a rare sight indeed when all the foregoing plants are present smiling beneath long banks of Roses, Marguerites, Lilies, Geraniums of every hue, with any quantity of Ferns and Palms, dwarf and tall. May is the month to see the wealth of flowers, though a visit to Covent Garden Flower Market at any season of the year, a lover of flowers will be rewarded by excellence of culture and always a good variety of subjects.—A. M.

(To be continued.)

#### ROUND ABOUT SEVENOAKS.

A DAY in the country; what attraction it has for the jaded Londoner! At the prospect of it a thrill of pleasure runs through his frame similar to that of a weather-beaten sailor at the first sight of his native land. Only to be away from the din and bustle of the City and free to roam

through green fields and shaded woodlands is all that many weary workers desire.

It was with such thoughts as the above that a City scribe wended his way (in spite of the cold east wind) to one of the great railway centres on Bank Holiday with the intention of enjoying a quiet day away from London smoke. Dwellers in the country do not realise what Bank Holiday means to the Londoner, and to see the force of it no better place could be chosen than any of the large railway stations on such a morning.

The eager boisterous crowds jostled pellmell into the carriages, those who could find room sitting and others standing, but all anxious to get away, the stylishly attired City clerk side by side with the coster in the orthodox get-up peculiar to his calling. Bustling railway officials, tired of answering the same repeated questions, are likewise anxious that the crowd should be gone.

Amid lively jokes and peals of laughter, this was at last effected, and in course of time Sevenoaks was reached, on which, with a true horticulturist's nature, thoughts at once turned towards a garden.

To satisfy the ruling passion of most gardeners—viz., visiting gardens and talking over the cultivation of such, Chevening Park, the ancestral home of the Earl of Stanhope was decided on. The mansion is beautifully situated in a vast tract of land from which it takes its name, and surrounded by magnificent specimens of forest timber, with undulating woodland glades forming a charming background to the landscape, and giving the whole a calm and sequestered appearance. Frost has here, like everywhere else, played havoc amongst Conifer, ornamental shrubs and Roses, Laurels and Evergreen Oaks having suffered terribly. In the glass department a high standard of cultivation is everywhere maintained. In the early vinery good bunches of Black Hamburgh, Madresfield Court, and Foster's Seedling were noticed in an early stage of swelling, while a succession house devoted to Muscats showed prospects of a fine crop, the bunches being large and to all appearance setting satisfactorily.

Summer bedding is extensively practised, for which purpose large numbers of Pelargoniums, Begonias, Lobelias, and such-like are annually propagated. Melons, Cucumbers, Tomatoes, Figs, and Strawberries in pots are grown to some extent, and all in good condition, together with decorative flower and foliage plants. Neatness and order prevail in the pleasure grounds and kitchen garden, the latter being large and surrounded by a high wall, against which have been planted young fruit trees, such as Peaches, Nectarines, Plums, Pears, and Cherries, since Mr. Chas. Sutton took charge of the gardens six years ago, in place of worn-out specimens which formerly grew there.

A pleasant feature in the grounds are clumps of Daffodils of the common and more choice varieties, dotted about and flowering profusely on the turf banks, a system of planting which might with advantage be adopted and practised in many gardens. A curious freak of Nature was noticed in the shape of a large clump of giant Horse Chestnut trees, all of which had arisen from one parent by means of the lower branches coming into contact with the earth and naturally layering themselves, rooting and forming a separate tree, which process is still going on, and proving that in time a whole forest might be so formed.

Amid such surroundings a pleasant day passed too quickly away, and as evening advanced steps were again directed towards the station to once more encounter the same crowd, but with what a different aspect! The boisterous laughter of the morning is superseded by tired and weary expressions as the city dwellers journeyed homeward laden with Primroses and other wild flowers to brighten their dwellings, and to be kept as long as possible as a memento of Bank Holiday in the country.—WANDERER.

#### ROYAL BOTANIC SOCIETY.

APRIL 24TH.

THE second spring show in connection with the above Society was held at Regent's Park on Wednesday. Though the classes in many instances were not well filled, a bright and varied display of bloom was given, many of the exhibits being of high order. The miscellaneous groups, as usual, were large and good, and formed a bright and pleasing feature. We append a list of the prizewinners in the principal classes.

Messrs. Paul & Son, Cheshunt, was a good first for collection of Roses in pots, the plants being large and well clothed with bloom. Amongst other varieties were Céline Forestier, Caroline d'Arden, Mrs. John Laing, Beauty of Waltham, Madame de St. Joseph, Jeannie Dickson, Madame Victor Verdier, Gustave Piganeau, Paul's Carmine Pillar, and Souvenir de S. A. Prince. Mr. W. Rumsey, Waltham Cross, was second with plants not so large as the former, conspicuous amongst them being Chas. Lefebvre, Beauty of Waltham, Magna Charta, and Niphotos.

Mr. T. S. Ware, Tottenham, gained first prize for a collection of hardy herbaceous plants, several of which were very striking. Amongst others were noticed *Arabis alba*, Pink Mrs. Sinkins, *Adonis vernalis*, *Saxifraga Wallichi*, *Dielytra spectabilis alba*, *Anemone fulgens*, *Spiræa japonica multiflora compacta*, and *Orchis fusca*.

Mr. T. S. Ware was also first for group of Begonias. The plants were sturdy and well grown, the blooms being varied in colour, compact, and of good substance, the chief varieties being Brilliant, Novelty, Perfection, Duke of Teck, Picotee, Murillo, Miss Dora Richardson, Regina, Bexley White, Mrs. F. Fell, Champion, Snowdrift, Princess May, and Arthur Pitts.

Messrs. Paul & Son were first for a group of Amaryllis, the flowers being bright and effective. The second prize fell to Mr. James Douglas, gardener to Mrs. Whitbourn, Great Gearies, Ilford.

Mr. James Douglas claimed first honours for group of Cinerarias, the plants being large and well clothed with flowers. Amongst others were noticed Purity, C. J. Dowling, Novelty, and Conquest. Mr. J. Douglas was also first for collection of hardy Primulas, amongst which *P. verticillata*, *japonica*, *amœna*, *Auricula*, and *Forbesi*, were all well represented.

The first prize for a group of Pelargoniums fell to Mr. C. Turner, Slough, for well-flowered plants of Spotted Beauty, Rosetta, Kingston Beauty, Buffalo Bill, Mrs. Coombs, Ed. Perkins, Purity, Magpie, Fireball, Prince Henry, Fanny Gair, Empress of India, and others. Mr. Scott was also first for a group of Imantophyllums the plants being large and well flowered.

The first prize for a group of greenhouse Azaleas fell to Mr. W. Barrett, gardener to Mrs. Thompson, The Hoo, Sydenham Hill, the plants being remarkably well bloomed and containing, amongst others, Roi d'Hollande, Dr. Livingstone, Meltoni magnificens, and Model. Mr. R. Scott was second with plants neither so fine or well bloomed as the above.

Mr. Jas. Douglas claimed first honours for group of Auriculas, the plants being compact in form, with flowers of good substance; amongst others were noticed Dean Hole, Rev. Chas. Kingsley, Peri, Frank, Chastity, Chas. Turner, and Dr. Hardy, together with several excellent seedlings. Mr. Chas. Turner was a close second, conspicuous in the group being Charles Perry, Blue Peter, Heroine, Fred. Knighton, Florrie, Elegance, Roland, and others.

Among the miscellaneous exhibits was a fine stand of Roses from Mr. Frank Cant of Colchester, many of the flowers being fine and well formed, the varieties being Catherine Mermet, Général Jacqueminot, The Bride, Niphetos, Ethel Brownlow, and others. Stands were also exhibited by Mr. Geo. Mount, Canterbury, in which The Bride, Catherine Mermet, Niphetos, and Maréchal Niel predominated. Another collection came from Mr. J. Walker, Thame, Oxon, in which Maréchal Niel and Niphetos were conspicuous. Messrs. J. Veitch, Chelsea, sent a small miscellaneous group, amongst others being *Gloneria jasminiflora*, *Epiphyllum Gærtneri*, and *Alyssum saxatile citrinum*.

Mr. W. Barrett staged fine examples of Mignonette in pots. A large and exceedingly diversified collection of cut flowers of Narcissi and Anemones was tastefully arranged by Messrs. Barr & Son, King Street, Covent Garden.

Messrs. Hugh Low & Co., Clapton, staged a fine group of greenhouse plants, amongst which were *Boronia heterophylla*, *Rose Crimson Rambler*, and *Acacias cordata* and *armata*. A group of Orchids and Cannas was also staged by the same firm, and produced a showy effect, amongst the former being *Cattleyas*, *Cymbidiums*, *Dendrobiums*, and *Odontoglossums*.

A fine group of mixed flowers and foliage plants came from Messrs. J. Laing, Forest Hill, comprised chiefly of *Begonias*, *Carnations*, *Imantophylliums*, *Crotons*, *Caladiums*, and *Palms*.

Messrs. John Peed & Sons, Norwood, staged a bright collection of mixed plants composed chiefly of *Anthuriums*, *Imantophyllams*, *Draœnas*, *Caladiums*, and *Palms*. A group of *Roses* and *Azaleas* was staged by Mr. P. Perry, gardener to J. C. Tasker, Esq., Middleton Hall, Brentwood.

An excellent group of *Cannas* was staged by Messrs. Paul & Son, Cheshunt, comprised of *Cheshunt Yellow*, *Progression*, *Phœbus*, and others. Messrs. B. S. Williams & Son, Holloway, staged a group of *Dielytras*, a good collection of *Orchids* such as *Cattleyas*, *Dendrobiums*, *Cypripediums*, and *Odontoglossums*, together with a number of well-flowered *Amaryllis*. An effective collection of *Narcissi* and *Gladioli* was shown by Mr. T. S. Ware, Tottenham, making a very creditable display.

Two excellent fruits of *Countess Melon*, cut April 16th, were staged by Mr. W. Meads, gardener to A. Henderson, Esq., Buscot Park, Faringdon, Berks.

## NATIONAL PRIMULA AND AURICULA SHOW.

### SOUTHERN SECTION.

THE annual show of this Society was held at the Drill Hall, Westminster, on the 23rd inst. Taking into consideration the late season the show was in every way a creditable one. The Alpine section of the *Auricula* was very sparsely filled, but *Primulas* and *Show Auriculas* were both good, though the flowers lacked the sparkling lustrousness that is apparent when grown and shown under the most favourable conditions. Mr. T. E. Henwood deserves a word of praise for the admirable manner in which the show was managed.

In the class for twelve distinct *Show Auriculas* Mr. T. E. Henwood, Reading, was a capital first with well-grown plants of *Lancashire Hero*, *John Simonite*, *Rev. F. D. Horner*, *Black Bess* (very fine), *Acme* (good), *Prince of Greens*, *Mrs. Potts* (very fine), *James Hannaford*, *Geo. Rudd*, *Heroine* (good), *Richard Headley*, and *Abbé Lizst*. The second prize fell to Mr. Sanders, gardener to Viscountess Chewton, Cobham, the varieties being *Heroine*, *George Rudd*, *Engineer*, *Abbé Lizst*, *Acme*, *George Lightbody*, *Heatherbell* (very good), *Black Bess*, *Lancashire Hero*, *Mrs. A. Potts*, *Mrs. Dodwell*, and *Rev. F. D. Horner*. Mr. Patterson, Sunderland was third, and Philip J. Worsley, Esq., Clifton, fourth, amongst whose collection were several pretty seedlings—namely, *Little John*, *Turk's Cap*, *Merry Monarch*, and others.

Mr. Sanders gained first honours for six *Auriculas*, distinct, the

flowers being good, and the varieties *Acme*, *George Rudd*, *George Lightbody*, *Heroine*, *Mrs. A. Potts*, and *Rev. F. D. Horner*. Mr. Henwood came second, with plants not quite so fine in flower and substance. The third prize was awarded to Mr. Patterson, Sunderland; fourth to J. T. Bennett Poë, Esq., Holmewood, Cheshunt; and the fifth to Philip J. Worsley, Esq., Clifton.

For four distinct *Auriculas* Mr. J. Sargent was a decided first, with fine plants of *Rachel*, *Acme*, *Rev. F. D. Horner*, and *Heroine*. Mr. Smith, Bishop's Stortford, was a good second. Mr. Collier, gardener to Miss Kyrke Penson, Durham, third; Mr. Phillips, Bracknell, fourth; Mr. Keen, Southampton, fifth; Mr. Gilbert, Guildford, sixth. For two *Auriculas*, distinct, the first prize was gained by Mr. Sargent for good plants of *L. Hero* and *Rachel*; the second fell to Mr. Smith for *Rev. F. D. Horner* and *Mrs. Potts*; third to Mr. Walker, Reading; fourth to Mr. Phillips, Bracknell; fifth, Mr. Collier; and sixth to Mr. Gilbert.

For a single specimen of green-edged *Auriculas* Mr. James Douglas was first with *Abbé Lizst*, Mr. Sanders second, Mr. T. E. Henwood third and fourth, Mr. Phillips fifth, Mr. Smith sixth, Mr. Sanders seventh, and Mr. Collier eighth. For one grey-edged specimen Mr. Collier was first with *G. Lightbody*, J. T. Bennett Poë, Esq., second, Mr. T. E. Henwood third, J. T. Bennett Poë, Esq., fourth, Mr. Patterson, Sunderland, fifth, Mr. Collier sixth, and Mr. Smith seventh and eighth. For the single plants of white-edged varieties, second Mr. James Douglas, third Mr. Walker, fourth Mr. J. Douglas, fifth Mr. Sanders, sixth Mr. Collier, and seventh Mr. Patterson.

Mr. C. Phillips, Bracknell, Berks, was first for single plant of *Selfs* with *Miss Barnett*, Mr. Jas. Douglas second, Mr. W. Smith third, Mr. Patterson fourth, Mr. J. Douglas fifth, Mr. T. E. Henwood sixth, Mr. Sanders seventh, and Mr. R. Dean eighth. For seedling *Alpine Auricula*, with white or cream centre, the first prize was gained by Mr. Sanders, and second by Mr. C. Phillips. For *Alpine*, with gold centre, Mr. Phillips was granted first and second prizes.

The first prize for fifty *Auriculas* fell to Mr. Jas. Douglas, the group being composed of well-grown plants of excellent varieties, amongst which were *Ariel*, *Rachel*, *Elaine*, *Dr. Hardy*, *George Rudd*, *Abbé Lizst*, *Acme*, *Fanny Glass*, *Unique*, *Sir W. Hewitt*, *Lancashire Hero*, *Heatherbell*, *Rev. Chas. Kingsley* (very fine), *Sapphire* (good), *Apollo*, *Mrs. Moore*, *Dr. Kidd*, *Mrs. Potts*, *Frank*, and others. There were also several excellent seedlings included in the group. Mr. Sanders was a good second, conspicuous in the exhibit being *Sapphire* (very good), *Walker*, *Frank Simonite*, *Black Bess*, *William Brockbank*, *Clipper*, and *Miss Prim*. The third prize fell to the Guildford Hardy Plant Company, Guildford, for a collection of plants not so fine, though containing many good varieties.

*Alpine Auriculas* were well represented, and in the class for twelve, distinct, Mr. Phillips, Bracknell, was a capital first, his plants being good in substance and of excellent varieties—namely, *A. R. Brown Phillips* (a very fine variety), *Mrs. Martin Smith*, *Clara*, *Dragon Fly*, *Dot*, *Mrs. Gorton*, *Little Gem*, and *Sophie*, the remainder being seedlings of fine form and distinct colours. The second prize fell to Mr. James Douglas, whose plants were well grown and the varieties distinct, being comprised of *Dean Hole*, *Chastity*, *Miss Moon*, and *Novelty*, together with several fine seedlings. Mr. Patterson was third, Mr. Chas. Turner, Slough, fourth, and Mr. Sanders fifth.

Mr. Jas. Douglas was a decided first for six *Alpine Auriculas*, distinct, the plants being substantial and the flowers large and varied, and comprised of varieties *Dean Hole*, *Novelty*, *Chas. Turner*, *Miss Mollie*, *Miss Moon*, and a fine seedling. Mr. Phillips was second, Mr. Chas. Turner third, Mr. Walker fourth, and Mr. Patterson fifth.

For four *Alpine Auriculas* the first prize was awarded to Mr. Walker, Reading, for good plants of *Freda*, *Mrs. Lawrence*, *John Lawrence*, and *John Keen*. J. T. Bennett Poë, Esq., was second with plants not so compact as the former; Mr. Keen, Southampton, third; Mr. Fish, Broxbourne, fourth, and Mr. Collier fifth.

For a single *Alpine Auricula* with gold centre Mr. C. Phillips was first with *Dreadnought* (a fine variety), and also second with *Evelyn Phillips*, Mr. Walker being third and fourth. Mr. Chas. Turner was first with single plant of *Alpine Auricula* with white or cream centre with *Winifred*, a very distinct variety. Mr. Phillips was second and third, Mr. Walker fourth, and Mr. Collier fifth. In the class for six gold-laced *Polyanthus* Mr. Weston, Balham, was first; Mr. R. Dean, Ealing, second, and Mr. Jas. Douglas third. For three of the above Mr. Douglas was first, Mr. R. Dean second, Mr. Weston third, and Mr. Sanders fourth.

For twelve *Fancy Auriculas* the first prize fell to The Guildford Hardy Plant Company, amongst other varieties being *Belle*, *Old Gold*, *Rolts Green*, *Khartoum*, *Innonence*, *Bronze*, and *Lalla Rookh*. Mr. Jas. Douglas was second, with colours not so great in variety as the former; while Mr. R. Dean claimed third. Mr. R. Dean gained first honours for twelve *Fancy Polyanthus*, the plants being well bloomed, and of distinct and pleasing colours. Mr. Sanders was second, his plants, though larger, not being so compactly grown as the former. The third prize fell to Mr. Jas. Douglas, and the fourth to Mr. Gilbert.

For twelve single *Primroses* Mr. R. Dean was again a good first, Mr. Jas. Douglas second, Mr. Sanders third, and Miss Hopkins, Mere, fourth. For six double *Primroses* in pots the first prize fell to Mr. Jas. Douglas. For twelve hardy *Primulas* Mr. Douglas was first with well flowered plants of *Primula floribunda*, *verticillata*, *P. Auricula Linnaeus*, *viscosa*, *intermedia*, *rosea*, *cortusoides*, *amœna*, *obconica*, *japonica*, and others. In the class for a group of *Primulas* and *Auriculas* arranged in box, the first prize fell to Mr. Jas. Douglas, his exhibit being extremely varied and arranged with charming effect.

## FRUIT FORCING.

**Vines.**—*Early Forced.*—Red spider usually makes its appearance in the earliest house about the time the Grapes ripen, and increases rapidly during the time they are hanging, which is a serious matter to the foliage and succeeding crop. Painting the hot-water pipes with a thin paste of sulphur and skim milk has a deterring effect on the insects, the fumes given off by the sulphur when heated to 170° being fatal to them, and there is no danger to the Grapes providing the coating be thin and the pipes not highly heated. When, however, the hot-water pipes are heated so as to surcharge the atmosphere of the house with sulphurous fumes the skins of the Grapes are more or less prematurely hardened, and in the case of Frontignans and Muscats discoloured and injured. Due supplies of water at the roots and a genial condition of the atmosphere are essential conditions of Vine growth, and as the preservation of the foliage of early forced Vines is an important factor in respect of next year's crop no pains should be spared to keep it healthy. Whatever watering is necessary after the Grapes commence ripening should be supplied in the early part of fine days, so that surplus moisture may pass off before closing time. A light mulch of partially decayed sweet manure will tend to promote root action and the health of the foliage whilst preventing undue evaporation.

Early Grapes do not always colour well, the defect arising from continued hard forcing or overcropping. It is avoided by careful management and judicious apportioning of the crop to the capabilities of the Vines. In cases of overcropping much may be done towards colouring by a supply of dry warm air and a comparatively low night temperature. Where Grapes are fully ripe a reduction in temperature is advisable, but it must not fall below 60° at night, and need not exceed 65° in the daytime by artificial means. Moderate moisture should be maintained for the benefit of the foliage, and will not do any harm to the Grapes provided the air is changed by free ventilation.

*Succession Houses.*—The work now will be of a routine order, and of this stopping and regulating the growths are important. Where the space is restricted stop the shoots two joints beyond the fruit, and as increase of foliage is desirable, leave the laterals above the bunch, also below when the spurs are a good distance apart, but when close remove the laterals from below the bunch except from the two lowest joints. Pinch the laterals at the first joint, especially those from the basal leaves, also those above the bunch, unless there is space for extending the laterals, when they may be allowed to make two or three leaves, but no more growth should be encouraged than can have exposure to light and air. After the space is fairly furnished keep the growths closely pinched to one joint as made. Where there is more space stopping will not take place until growth has extended four or more joints beyond the fruit. The great evil is overcrowding, which deprives the foliage of light and air, and restricting the growth is intended to avoid that.

*Tying the Shoots.*—Securing the shoots in the places they are to occupy during the summer demands careful attention. It is a common practice to commence tying down the growths as soon as they are long enough to bend. This is not advisable except as a precaution against injury from frost, as the shoots at this stage are so tender that the slightest twist the wrong way breaks them. It is a better plan to defer tying down until the shoots are less sappy, which may be when the fruit is formed, but a good method is to so dispose the rod that the shoots, instead of being brought down to a nearly horizontal position, will have a good incline upward, yet sufficiently outward or oblique to admit light to the basal leaves of the bearing or spur growths. Always allow sufficient space in the ligatures for the proper development of the shoots.

*Vines in Flower.*—Midseason Vines, such as Hamburgs, set freely in a comparatively low temperature; but it is advisable to maintain a moderate amount of heat, say 65° to 70°, by artificial means, so as to insure a fairly dry atmosphere with a change of air constantly, as this aids the flowers in throwing off the caps and liberating the pollen. Muscats and other shy-setting varieties should have a circulation of rather dry air, and a temperature of 65° to 70° at night, advancing to 80°, 85°, or 90° from sun heat, raising the points of the bunches to the light, and liberating the pollen at midday by gently rapping the foot-stalks of the bunches. If there be a deficiency of pollen, take it from those varieties that afford it abundantly, such as Black Hamburg and Alicante, and apply it with a camel's-hair brush to the shy-setting kinds, previously removing the caps by lightly brushing over the bunches.

*Thinning.*—Commence thinning the berries of the free-setting varieties, such as Black Hamburg, directly the setting is effected, as then the fertilised can be distinguished from the small imperfectly impregnated. Some varieties, as Gros Colman, Gros Guillaume, and Trabbiano may be thinned whilst they are flowering, and this is the way to get berries an inch in diameter in the finest possible clusters of even-sized and best berries. Follow up the thinning early and late, and on dull days, never handling the bunches with heated hands nor rubbing them, heedless of the consequences, for every slight injury to the

skin at this time develops into a large blemish later on. Remove surplus bunches unflinchingly, as it is better to under rather than over-crop, and every bunch or berry removed early is to the advantage of those left on the Vine.

*Young Vines.*—Those planted last year are breaking naturally, and may be assisted with gentle fire heat in cold weather. The canes being depressed to cause them to break regularly down to the basal buds, should be tied in position after the growths have started fairly, otherwise they will acquire a position unsuited for tying down without danger of breakage. If more than one shoot start from a joint remove the smallest, leaving one only, and when the most promising can be decided upon disbud, leaving the best shoots about 18 inches apart on both sides of the canes. Crop permanent Vines lightly, one or two bunches being the maximum, as the better the Vines are established the more satisfactory they will prove in the end. Any extra Vines planted to fruit early and afterwards cut out may each carry six or eight bunches, or even more, according to the vigour of the Vines; but overcropping will certainly prove disastrous to both colour and quality.

*Planting Vines.*—When Vines are starting into growth naturally is a good time for planting, though some gardeners prefer the late summer after the wood is mature, but whilst the leaves are on the Vines. For very early forcing inside borders are the best, and heated ones desirable for the tender varieties, such as Black Muscat (Muscat Hamburg), Muscat of Alexandria, and Canon Hall, also for Madresfield Court. These splendid Grapes may then be ripened by the end of May or early in June, when they bring good returns. For ordinary purposes the border may be partly within and partly outside, planting the Vines inside the house. The Vines, it is assumed, were cut back in early winter and have been kept in a cool house, the buds now having grown an inch or two long. Turn them out of the pots, remove every particle of soil, carefully preserving the fibres. Spread the roots out straight and flat, the soil of the border having been brought to the required level, covering the roots to a depth of 3 inches, working the soil well amongst them with the hand, and giving a good supply of tepid water, mulching with about an inch thickness of short litter.

If the canes have not been shortened do not cut them now, but pinch the growths at the first leaf from the upper portion down to where fresh growth is desired to issue, and cut away the pinched part when the Vines have made several inches of growth in the desired shoot or shoots, as then there is no danger of bleeding, and the extra leafage will favour root formation. Sprinkle the house and Vines twice a day, and if the weather be bright and the panes of glass large, shade lightly from 10 A.M. to 2 P.M., when the house should be closed, damping all available surfaces. Temperature 55° at night, 65° by day artificially, and 70° to 75° with sun, running up to 85°. When the Vines start into growth give every encouragement, increasing the temperature to from 60° to 65° at night, 70° to 75° by day, and 80° to 85° or 90° from sun heat. Avoid forcing treatment at the beginning, it only causing growth at the expense of stored matter, and induces thin foliage, incapable of full elaboratory functions.

**Cherry House.**—When the stoning is completed the fruit commences colouring and swelling for ripening. The temperature may then be raised, but not exceeding 65° by artificial means in the daytime and 55° to 60° at night, with a little ventilation, increasing it at 70°; but the temperature must not be allowed to exceed that degree in the early part of the day without full ventilation. From the commencement of colouring until the trees are cleared of their fruit syringing must cease, or the fruit will crack, but a good moisture should be maintained in the house by keeping the surface of the borders moist, or if the trees are in pots damping the floor two or three times a day, avoiding, however, a stagnant atmosphere. The border should not lack moisture, trees in pots being well watered. Aphides must be kept under, fumigation or vapouring being the only safe process after the fruit commences ripening.

**Cucumbers.**—Fruit is now abundant and cheap, the plants despite the severe weather having made good progress. Attend to tying the shoots, stopping at one or two joints beyond the fruit, removing bad leaves and exhausted growths so as to maintain a succession of bearing wood. Water plants in houses abundantly, and with weak liquid manure about twice a week, syringing the foliage and walls daily about 3.30 P.M., when the house can be closed. Preserve a night temperature of 65° to 70°, 70° to 75° by day artificially, 80° to 85° or 90° from sun heat, ventilating from 75°, being careful to avoid cold currents, and close sufficiently early to run up to 90°, 95°, or even 100°, with abundance of atmospheric moisture in the house. Sprinkle available surfaces occasionally in the evening with liquid manure, or a little sweetened horse dung on the surface of the bed will supply ammonia to the atmosphere, nutriment to the soil, and encourage surface roots.

*Pits and Frames.*—Plant in these will hardly need shading as yet, but the foliage must not be allowed to flag. Use tepid water through a fine-rose watering-pot at about 3 P.M. over the foliage, a light sprinkling sufficing, closing the lights at the same time, but as the nights are as yet cold be careful that the foliage becomes dry before night. Close early and employ a thick night covering. Maintain a good bottom heat by linings, renewing them as necessary. Pot or sow ridge varieties if not already done, keeping these and other young plants near the glass.

**Melons.**—As the fruits of the earliest plants increase in size the supports must be lowered or otherwise adjusted. Stop the laterals frequently, or thin them where they are crowded. Supply water or liquid manure liberally to plants on which the fruits are growing rapidly, but avoid excess of either, especially liquid manure, which may

injure the roots, and the fruit in consequence will not finish satisfactorily. Plants coming into flower should only have sufficient water to prevent flagging, and a drier condition of the atmosphere is essential to a good set, especially in the case of very vigorous plants. Attend regularly to the setting of the blossoms, and stop the shoots one joint beyond the fruit when impregnated, removing all superfluous growths after the fruit is set. Avoid giving stimulants to plants until the fruit is swelling, when liquid manure may be applied liberally, especially to plants carrying heavy crops, continuing the supplies until they are well advanced towards ripening. Maintain a night temperature of 70°, 70° to 75° by day, and 80° to 90° with sun heat, closing early, when the plants may be syringed, except when in flower and the fruit ripening. If canker appears rub quicklime into the affected parts.

#### THE KITCHEN GARDEN.

**Kidney Beans.**—There will be no falling off in the demand for these during the next two months. Deep narrow boxes holding a single row of plants are preferable to pots at this time of the year, the plants remaining in a healthy productive state far the longest in the former. In any case they must be kept well supplied with water and liquid manure. Those planted out between rows of Tomato plants will soon be yielding heavy crops, and newly planted vineries might be similarly utilised. According as pits or frames are cleared of early Potatoes, plant with Kidney Beans, having these in small pots in readiness for the positions. All the preparation needed is the removal of rubbish, a levelling over, and a thorough soaking of water if at all dry. Put the plants out 4 inches apart in rows not less than 15 inches asunder. Stake at once and mulch with short manure. Keep well supplied with moisture, and shade lightly during the hottest part of the day, especially if fire heat is used and a high temperature maintained.

**Kidney Beans in the Open.**—If raised in the open somewhat early, protection of some kind should be provided. Hand-lights will not be liberated from Cauliflowers so early as usual, but directly they are available their destination ought to be a warm border where they can be filled with Kidney Beans out of small pots. Sion House and Ne Plus Ultra are good early varieties, and these may now be sown on a warm border thinly in drills 15 to 18 inches apart. Canadian Wonder is good for affording a succession.

**Beet.**—The improved form of Turnip-rooted is the best for an early crop, medium-sized roots proving tender and well coloured. Moderately firm ground favours early "bulbing." Seeing that they will not be long on the ground they may be planted 5 inches asunder in rows 1 foot or rather less apart. Seeds of the Turnip-rooted may be sown on a warm border or with the main crop quite in the open. The main crop of the long-rooted varieties should now be sown, and on ground manured for a previous crop. The rows of the neat growing Dell's Crimson or forms of the latter may be 12 inches apart, stronger growers being allowed another 3 inches.

**Carrots.**—Coarseness is also objectionable in the case of Carrots. If the main crop varieties are sown much before the end of April the roots are liable to become too large, also splitting and keeping badly. This crop, again, should be grown without the aid of fresh or solid manure. The cleanest and best roots are produced in free working, sandy soils, but very good ones can also be had from comparatively heavy ground. Nantes Horn and The Guerande are suitable for present sowing. The rows of these may be arranged 9 inches apart, but the Intermediate and Long Surrey should have more space. Dust wood ashes lightly along the drills prior to covering the seeds, by way of a preventive of grub attack.

**Chicory.**—Not nearly enough of this is grown for winter use. It should be remembered that the blanched tops are not only good in a salad, but also cooked and served as a vegetable. Either Improved Large-rooted or Large Brussels (Witloef) or both may be sown now thinly in drills 12 inches apart. Large straight roots are most desirable, therefore sow on ground prepared as for Carrots, and let the thinning be well attended to.

**Salsafy and Scorzonera.**—Owing to a lack of variety during the past winter these vegetables have been used up more closely than is often the case. Long, straight, moderately stout roots are most desirable, and the seeds should, therefore, be sown on ground free of strong, solid manure, and in a finely divided state. Early raised plants are apt to run to seed, but there will be but few "bolters" if the seeds are sown now. The drills may be drawn 12 inches apart, and the seeds sown thinly.

**Borecole.**—Most of the species require a rather long period of growth, or otherwise they fail to attain their most productive hardy state. If the plants are large enough for pricking out they will be none too early, providing the ground is ready for their reception. Owners, or those in charge of small gardens, may yet plant Ashleaf or other early maturing short-topped Potatoes in rows 3 feet apart, planting Borecole and Brussels Sprouts in the furrows after moulding-up the Potatoes. Read's Hearting and Tall Green Curled are good, but scarcely so hardy as Sutton's Arctic Kales (purple and green), and these, with the very hardy Cottager's and Asparagus Kale, may yet be sown in the open with every likelihood of good results.

**Broccoli.**—Only Veitch's Autumn Protecting should be raised early, especially if the ground cannot be reserved for these crops. By sowing now thinly in the open the plants will be ready as soon as crops that are preceding them can be cleared off. Snow's Winter White ought never to be sown earlier than this. Veitch's Early White forms a good succession to the latter. Leamington, Knight's Protecting, Carter's Universal, Model, and Late Queen are all excellent and reliable. The

white and purple sprouting forms ought to be treated similarly to Borecole.

**Chou de Burghley.**—Now is the best time to sow this form of Cabbage. Raised earlier and planted on strong ground objectionable coarseness is unavoidable.

**Savoy Cabbage.**—These, again, are of little value when either very early or coarse. If Tom Thumb, Early Dwarf Ulm, Dwarf Green Curled, and Drumhead are sown now thinly and quite in the open, abundance of plants ought to be available for succeeding early vegetables.

**Birds versus Seeds.**—In some gardens seeds are much preyed on by chaffinches and other small birds. If they cannot be kept off by means of lines of black thread crossing and recrossing each other, or benders and doubled fish nets, or pea stakes laid thickly over the beds, the plan of red-leading the seeds should be adopted. Not many seeds will be drawn out of the ground when it is seen they are coated with red lead. Seeds moistened in a damp cloth will not clog together, and well rolled in red lead the latter will adhere freely to it. Red lead will not affect the germinating power of the seeds.

## THE BEE-KEEPER.

### APIARIAN NOTES.

SINCE the 17th inst. the frost has disappeared, and more genial weather reigns in the north. It is not, however, strictly speaking, bee weather, as many busy workers are chilled when out foraging. The bee-keeper must, therefore, keep a watch over his stocks to maintain them in a breeding state, as stoppage to that at this season means no profit. Embrace the first opportunity as circumstances arise to raise young queens to supersede effete ones.

#### VARIETIES OF BEES.

Are we advancing or retrograding? The above question is put with the view of encouraging inexperienced bee-keepers to put to test amongst other things the varieties of bees, and prove for themselves which are the best for their positions and surroundings. I am one of those old apiarians who believe the old black or British bee is no longer to be found pure in the British Isles, consequently a fair trial with the different breeds cannot be made. It is true that some persons think they have the original natives; at least, as one writer says, "they are as near blacks as need be." Crosses are always good honey gatherers, and but for foreign bees there would have been no crosses.

When I started in 1863 with the pure Italian Alp bee, I soon learned if honey was to be expected from them much larger hives must be used, and this applies to every foreign breed imported. The autumn months of 1863 and 1864 were exceptionally fine, as well as the aftermath of red Clover, which both Italians and blacks frequented, but while the Italians made weight from it and other autumn flowers, the blacks made no weight. As years advanced, we had evidence, both at home and at the moors, that the introduction of the Italian Alp bee was a happy hit.—A LANARKSHIRE BEE-KEEPER.

#### SEASONABLE NOTES.

THE favourable change in the weather that has taken place during the past fortnight has been beneficial to the bees, and it is interesting to bee-keepers to note the many varieties of flowers that are now in bloom. Although this is a backward spring there is no lack of pollen-producing flowers, and doubtless a little honey is also obtained. The only fruit trees at present in bloom are the Apricot and Gooseberry. The former, thanks in a great measure to the bees, are setting their fruit freely, and as they are much later than usual in opening there is every prospect of a heavy crop of fruit, although the trees are not protected in any way.

Previous to keeping bees somewhat extensively we were in the habit of covering the trees with canvas blinds every night, and on more than one occasion failed to obtain a crop of fruit. Assuming that spring frost was the cause, but since discarding the covers and leaving the trees fully exposed to all weathers, there has been only one partial failure, and that was last year, when the severe frost on the 21st of May blackened all the fruit on the projecting spurs, although they were as large as horse beans. Those on the young growths that were laid in close to the wall escaped, and we were eventually rewarded with upwards of 100 dozen of superior fruit.

Every gardener should keep a stock or two of bees, if only for the fertilisation of fruit. I do not say in that case he would always command good crops, as it is well known to all observers that trees when exposed without some protection will always suffer from late spring frosts. But is not the frost sometimes blamed

instead of the true cause, defective fertilisation? I am, after many years' experience, convinced in my own mind that such is the case, as by observing fruit trees only a few miles away that were quite barren of fruit, and noting that no bees were kept in the immediate neighbourhood, whereas in another district not far distant where bees were plentiful there were good crops of fruit.

At this time of the year tens of thousands of bees are on the wing, not a flower will escape the busy worker. To illustrate how industrious bees are, I have only to mention a field of Beans; no matter how large, every flower will be found on examination to be fertilised, either by the humble bee or the hive or honey bee; and as their proboscis is not long enough to reach to the bottom of the tube of flower if they attempted to reach it from the entrance to the open flower, instead of wasting their time in a fruitless occupation they bore a hole from the outside at the bottom of the flower. By this means they obtain the nectar, and the bloom is fertilised.

The humble bee used to have the credit of boring the hole, and the honey bee followed after and extracted the honey. I think, however, the honey bee is quite capable of doing the whole of the work, and on examining a large field of Beans not a flower will be found to have escaped. Were they not fertilised in this manner the crop would result in failure, as the Beans would not set. Bees will travel a long distance to a field of Beans, as they come into bloom just before the white Clover, and when flowers are rather scarce one comes to the conclusion that if there were more gardener bee-keepers no harm would be done, but probably a great amount of good.

This must be my apology for approaching the subject in these notes. The majority of employers would allow bees to be kept in their gardens, and by using the modern frame hive they are ornamental as well as useful, and are easy to manipulate. No one need have any fear of handling bees. I recommend our native black or brown bee in preference to all others, as hybrids are vindictive. Anyone who is at all nervous should, until experience is gained in handling them, be protected with gloves as well as a veil, but after a little practice the gloves in the majority of cases will be discarded, and much pleasure be derived from the busy workers, and as bee-keeping can be commenced with a small outlay the majority of gardeners may indulge in it.—AN ENGLISH BEE-KEEPER.

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Vine Growths Deformed** (*D. and W. B.*).—The laterals appear as if, in part at least, affected with the "browning" disease; but they need careful microscopical examination, which they shall receive, and the results will be published in a future issue.

**Inarching Vines** (*S. W.*).—In all probability the Black Ham-burgh will grow and fruit well on the Trebbiano stock under the usual good cultural attention. We do not anticipate that the stock will materially influence either the colour or quality of the Grapes, but this can only be determined by experience, as sometimes the unexpected happens in such cases.

**Freesias from Seeds** (*Freesia*).—Thin the seedlings to about five in a 4-inch pot. Avoid putting the seedlings in a draughty frame or house, as that is most injurious. Keep the young plants in a cool temperature and close to the glass. If the seedlings thrive and become sturdy plants with the pots full of roots, give them a little weak liquid manure, which will help them on, and they should bloom in July or August. Seedling Freesias will not always bloom the first year, but will make good flowering bulbs for the following season. Had you given particulars as to where the seeds were sown and the treatment they had received we could, perhaps, have given a more explicit and useful reply.

**Chickweed** (*Sympathy*).—What you send is a good sample of the plant you desire to try medicinally. We hope it will do good, and it is at least harmless; indeed, it is stated by a good authority that the young shoots and leaves when boiled can scarcely be distinguished from Spinach, and are equally wholesome. The botanical name of the Chickweed is *Stellaria media*.

**Mildew on Roses** (*Nemo*).—For mildew on Roses a good plan is to syringe with a solution of sulphur and water, a 3-inch potful of the former to three gallons of the latter. The sulphur should be first mixed with a little water into a paste, and then the remainder added. The sulphur may remain on the Roses three or four days and then be washed off. Cold draughts and dryness at the root will cause mildew, and nothing will keep the plants free for long if these important matters are not carefully attended to.

**Weevils on Ferns** (*B. W.*).—The enemy which is making such havoc with your Ferns is the very destructive weevil, *Curculio*, or *Otiorynchus sulcatus*. These beetle-like pests will eat almost anything, and are by no means easy to eradicate. In the grub state they feed on the roots of plants, and when developed devour the leaves and flowers. Search for them sedulously, especially at night, catching all you can, and so prevent a further increase. Shaking the plants violently over a white cloth at night will dislodge many, and they will be visible on the white surface, and can be the more readily secured. A bitter decoction of aloes, quassia, and tobacco is said to render plants distasteful to the weevils. Early in the spring as much of the old soil should be removed from the Ferns and other plants as can be safely done, and probably many small white grubs, the larvæ of the weevils, will be destroyed. Keep the soil moist, and a solution of hellebore, made by pouring boiling water on 2 ozs. of the powder, then increasing to a gallon of water before using, might do good. It will not injure foliage or roots.

**Gladioli Diseased** (*A Gladiolus Lover*).—The "grass" certainly presented the appearance of injury from a noxious atmosphere, but on a close examination it was manifest that the epidermis and underlying tissues were not damaged by such means, they being quite normal, yet dry and robbed of nourishment. The stems also were quite healthy—that is, normal, but impoverished and dried as grass is from the tips of the blades downwards during droughty weather. On examining the corms we came across the cause of the mischief—mites, invisible to the unaided eye, and just discernible by the ordinary pocket magnifier with a power of from three to six diameters as a moving roundish, semi-transparent yellowish white body. This insect (so called) swarmed on the old corm, literally eating it away, and preventing the ascent of the nutriment imbibed by the roots, and thus the "grass" became brown, dried, and withered, the sap being intercepted and appropriated by the mites. It is a very common British species, a near ally of the more common cheese and flour mite (*Tyroglyphus siro*, *Linn.*, *Latr.*). It, however, belongs to a different genus—namely, *Rhizoglyphus echinopus* (*Hypopus dujardini*, *Clap.*). It is very common on Hyacinth bulbs, and a very nasty creature to get on the person, causing much irritation and even suppuration from the skin being rubbed where it has been, as we know from personal experience, and are loth to examine such specimens microscopically, as it means much discomfort. The best thing to do is to burn the plants and soil, turning them out of the pots and placing all in the fire, then steep the pots in hot water. The plants are too far gone to admit of recuperation; but if you wish to preserve them water with a solution of corrosive sublimate (a terrible poison, so corrosive that it must not be handled in the pure state),  $\frac{1}{4}$  oz. to a 4-gallon bucketful of water, using so that the soil and, of course, the corms of the Gladioli, be thoroughly wetted. We ask you to be very careful with this solution, as it will kill all forms of animal life, from worms up to man, that partake of it, even low forms of vegetation, such as fungi; but at the strength named it is not injurious to the higher plants, from Ferns (inclusive) upwards, when applied to the roots, whilst many will bear it on the foliage at half strength. But whilst it will kill insects it is fatal to all birds and animals that partake of such insects; hence it is a very undesirable remedy.

**Tomato Leaves Diseased** (*Cross*).—The Tomato leaves are infested by the drooping disease-producing parasite (*Plasmodiophora tomati*), a so-called slime-fungus, which is frequently accompanied, or rather followed, by *Bacterium Halstedii*, especially when the stems of the plants are attacked, then the whole plant suddenly collapses; but when the leaves, which are marked by yellow spots turn brown, the ends or tips turn black and droop, hence the term "drooping" disease. There are also sometimes, and the mycelium appears in your case, presence of a fungus proper—namely, *Macrosporium Solani*—which alone or in conjunction with the *Plasmodiophora* may cause the foliage to wilt and hang down in a discoloured mass, whilst the fungus produces its spores from the stouter parts, which turn brown in large blotches. All the parasites are introduced with the soil, and the only remedy so far as known is corrosive sublimate solution, 1 oz. to 15 gallons of water, giving the soil an ordinary watering so as to moisten it evenly. This will not injure the plants in the least, whilst it will destroy all animal life, including eelworms and low forms of vegetation. Unfortunately it is a virulent poison, but after many experiments we have found it the only certain preventive. Lime is nearly as effective as the corrosive sublimate, and being perfectly safe under any and all circumstances, we strongly advise its use in preference to the mercurial chloride solution. A peck to half a bushel of quicklime may be used per rod, and with it top-dressings of farmyard or other solid manure may be given with

perfect safety, provided a little quicklime is mixed with it, say one-tenth. This will act so that nitrate of lime will be formed, and few, if any, parasites can withstand this combination, whilst the plants profit to the fullest extent. We should use the proposed mulch, sprinkling a good handful of basic slag phosphate on the manure per square yard, which will give the lime (50 per cent.) and essential phosphoric acid and iron. Besides this, you may cut off the infested leaves and burn them, then dust the plants from the soil to the tips of the growths (every part) with air-slaked lime, passing through a hair sieve, then add 1 per cent. of carbonate of copper (precipitated), mixing thoroughly and passing through the hair sieve a time or two to insure thorough mixture. The 1 per cent. means 1 oz. carbonate of copper, perfectly dry, to 100 ozs. of air-slaked lime, quite dry and floury. Apply with a bellows. With this at the tops and corrosive sublimate solution in the soil Tomato growers may largely protect their plants from animal and vegetable parasites, conditional on the practice of sound cultural management.

**Potato Set Diseased (R. H. K.).**—The discolouration in the set is caused by the action of the mycelium of the Potato curl fungus, which was first discovered in England in 1764, and soon afterwards was noticed in Rhenish Germany and elsewhere. It was very hurtful to Potato crops in this country at the beginning of the present century, but has been less so since 1820. Hollier and Reinke found the mycelium in the tissues, not of the tubers, but of affected plants, and agreed that the disease is hereditary, or that diseased tubers produced diseased plants. Without entering on a description of the fungus, we may say that it is, as seen in the tuber before us, a stage in the development of the Potato curl fungus (*Pleospora polytricha*) which may or may not develop on Potato plants, but it is common enough on many others in the mature form as *Pleospora herbarum*. The diseased tuber first gives rise to the fungus that caused the sudden collapse of Potato tops in many places in this country in 1894, and was noticed and figured in this Journal, the first indication being a curled plant here and there about earthing-up time, and later by the collapse of the tops generally, without any manifest infection of the tubers; but some afterwards become affected, no doubt by spores washed into the soil. Infected sets such as the one before us seldom produce tubers, or if any form they remain very small, for the vitality of the plant is used up in producing the fungus. The spores are spread far and wide, giving rise to the Potato top disease—the *Macrosporium Solani* again—which is carried over from year to year in the tubers. Steeping the sets in corrosive sublimate solution is the only known preventive of curl, only the Potatoes being dressed that are required for setting, as the tubers so treated are poisonous to animals and man. The sets should be steeped in the corrosive sublimate solution about an hour and a half. This may be conveniently done by placing them in coarse sacks. The corrosive sublimate (Mercuric bichloride) should be prepared in an old wooden tub, but sound, not using metal vessels, first dissolving the chemical, which should be finely powdered, using 1 oz. to 1 gallon of hot water, allowing this to stand overnight, then place in the tub intended for dipping the Potatoes 6½ gallons of water, and pour in the 1 gallon solution. Allow this to stand in the tub four to six hours, agitating frequently during that time to insure equality of solution before using. This solution is equally efficacious in preventing the scab fungus (*Oospora scabies*).

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*W. P. B.*)—1, Either *Abies Albertiana* or a very fine growth of *A. canadensis*, probably the latter; 2, *Diplopapus myrsophylla*; 3, Possibly a *Rhamnus*, species undeterminable. (*M. A. R.*)—1, *Omphalodes verna*; 2, *Hepatica angulosa*; 3, *Scilla bifolia*; 4, *Saxifraga (Megasea) crassifolia*; 5, *Primula rosea*. (*Amateur Orchidist*).—1, *Dendrobium Wardianum*; 2, *Lycaste Skinneri*; 3, Poor form of *Odontoglossum Pescatorei*; 4, *Cattleya Percivaliana*; 5, *Sophronis grandiflora*; 6, *Angræcum sesquipedale*. (*B. W.*)—*Cattleya Trianae delicata*. (*O. N. C.*)—1, *Dendrobium fimbriatum oculatum*; 2, *Odontoglossum Rossi majus*. (*Daffodil*).—Narcissi are florists' flowers that can only be named by comparison. (*Caterham*).—2, *Maxillaria tenuifolia*; 3, *Dendrobium moschatum*. (*J. B.*)—1, *Scutellaria Mociniana*; 2, *Saxifraga (Megasea) crassifolia*; 3, a *Doronicum*, possibly *caucasicum*. (*J. W.*)—1, Send particulars as to where found, and we may be able to identify, though the specimen is in such a bad state; 2, *Fuchsia procumbens*. (*East Grinstead*).—1, *Cœlogyne pandurata*; 2, *Vanda suavis*.

COVENT GARDEN MARKET.—APRIL 24TH.

OLD Grapes are now finished, new ones taking their place. Heavy supplies of Cucumbers and Strawberries, prices seriously affected by the holidays.

MANGOLDS.

REPEATEDLY in our Home Farm articles have we called attention to the exceptional value of a few acres of arable land to dairy farmers, as affording them the means of providing themselves with roots and certain other crops, but roots especially for their live stock in the winter and early spring. We know some farmers who appear to have just the right proportion of their holding in plough for this purpose, and who manage it to perfection; but, then, these are men of mark—intelligent, thoughtful, energetic, and so sensible that there is no hesitation in asking for advice in any new departure, any point of practice not quite clear to them, or in which they think improvement possible.

In the main they are invariably successful—are prosperous men, and their prosperity is owing in no small degree to a liberal but judicious expenditure on manure, seeds, and labour. On the other hand, by far the greater number of dairy farmers will have nothing to do with arable land, on the plea that they have neither implements or horses to work it, and that they should have to rob the pastures of manure, for which they have not half enough as it is. They admit that Mangolds are so useful that they buy some most winters, often having to cart them from farms a considerable distance away, to say nothing of Oat straw obtained in the same costly manner. As to chemical manure, that is too expensive! This is no fanciful statement, but is well within both our past and present experience. We are just—as we write—sowing some late Lent corn on arable land, which has been on offer to several grass farmers whose holdings

lie near to it, and to whom it ought to have been a boon most precious, a rare chance to have been seized with avidity.

As a crop for cleaning land Mangold has a special value. It can be sown successfully either in April or May, the manure is kept close to the plant, and by having the rows 30 inches apart, or even more for very foul land, if frequent and prolonged horse hoeing is possible. We thus obtain a useful crop of roots for the winter, get the land clean and ready for a corn crop, or for laying down to temporary pasture with a crop of winter Oats. If this be our aim, then a special effort must be made to get the Mangolds off the land early in the autumn, and also to sow as early as possible in April. Quick growth and early maturity being then of more than usual importance, there should be at least one dressing of nitrate of soda immediately after the singling of the plants.

We mention winter Oats in connection with this root crop because wherever it is possible to grow Mangolds winter Oats ought to answer. It is quite possible winter Oats may be an unknown quantity in the farming economy of localities where our readers may wish to try them. Any mention of such Oats to local farmers will probably induce them to say they never heard of them, and do not believe they will answer. A few years ago this actually happened to a gentleman who, acting under our advice, introduced them as a novelty on his home farm. He was rewarded by a fine crop, which we saw, and with which he was much pleased, as he found both corn and straw had a special value.

In storing Mangolds make and keep a firm resolution that the storing shall be so thorough that one may be certain the roots are safe from frost, however severe. Having regard to the value of straw and litter of all kinds, a frost-proof root hovel should be regarded as an indispensable adjunct to the home-stead. To anyone doubtful of the necessity of this we commend a fair calculation of the annual cost of ordinary clamping in litter and labour. With one or more suitable hovels it is a mere matter of carting, which has to be done in any case.

Mangolds are richer in sugar, starch, and albuminous compounds than Swedes, but rather more care is required in using them, because when lifted they are pungent and relaxing. It is for this reason that they do not come into use much before Christmas. Often has this holding over till the New Year of a big store of Mangolds proved of immense benefit to the live stock, affording it a grand addition to the dietary at midwinter onwards till May day. Passed through a mincing machine and mixed with straw chaff it is then palatable, nutritious, and safe food. This is the East Anglian method for all stock except sheep. Whole roots may safely be given to young or full-mouthed sheep, but for older sheep with broken teeth they should always be minced so as to avoid risk of loss from choking.

WORK ON THE HOME FARM.

Spring chickens are backward and scarce owing to the long late winter, early broods having suffered severely where the ordinary rough and ready practice prevails. When the cold weather did go, the only thing to do was to set as many hens as possible; this proved a slow affair, so few hens being "broody." Incubators and foster mothers have consequently proved of exceptional value in the preparation of numbers of chicks for the milder weather. Happy is the home farmer having such modern appliances; without them there must be difficulties about early chicks.

See that now and onwards abundance of chickens are reared for the selection of pullets for autumn and winter eggs. It is entirely a question of numbers, successional broods, healthy birds, and eventually winter management. Given birds of the right age this is easy enough; and, remember, the home farmer must keep up a full supply of new laid eggs the year round, simply because it is known to be possible. In this matter look to breeds. Place no reliance upon so-called everlasting layers for winter eggs, or they will fail you. Dorkings, Orpingtons, Leghorns, Anconas, Minorcas, and Andalusians are all good layers. We rather cling to the first mentioned, because of its excellence for table poultry when crossed with the old Game.

When to sow the first Swedes is often a debateable matter. We keep to the Norfolk custom of sowing early in May, because we have found

that the risk of mildew is not of serious moment. A first sowing of white Turnips can also be made now, to be followed by other sowings in June and July. The drilling of early Cabbage, Drumheads, and Thousand-head Kale is also in hand for autumn and early winter use. It is good practice to have these green crops drilled early, singled, and well established before there is much risk of hot dry weather.

Spring corn sowing should now be finished without the loss of a day, or the crop will be light and so late in ripening that harvesting may be difficult. It is only in emergencies that very late corn sowing should be done at all, and then we prefer Oats as about the only safe late crop.

SORTING POTATOES.

A LONG bitter winter, with frosts so keen as to be almost unknown in these latitudes, then early spring days, with saturated fields and leaden skies, whose downpour only ceased for a few hours at a time, are circumstances which have led to great backwardness in all work appertaining to the farm. Now all is hurry and bustle, so much to do, so little time in which to do it. Dry winds have made the land workable, and the work on a mixed farm is something to see to believe. If the work of three months is to be crowded into one, either there must be a large importation of outside labour or means must be found for facilitating operations. The most tedious work here is Potato sorting, and hands are few. It was therefore with great interest this week the trial of a Potato sorter was watched. The variety was "Garton," the destination Covent Garden; the sample therefore must be first rate. Also the fact that Garton seeds are of value this year, made it desirable to take as much out as possible. Like all great inventions the scheme seems simple enough when seen. Three riddles, one above the other, with three separate exits. An old man and boy fill what for want of a better term may be called the hopper. A very old man turns a handle, which gently shakes the three riddles from side to side. At the principal output stand three women, who watch and remove any diseased or large ugly growths (you see the machine is but a machine, and cannot discriminate between quantity and quality). Another woman is carrying off seeds, and the third opening shoots out small rubbish. The action is so gentle that there is no unnecessary bruising or rubbing, and the turn-out is a ton per hour. Of course the work could be much quicker, but then possibly Potatoes would escape the eyes of the watchers, and spoil a first-rate sample. Then, too, a hindrance at this time of year is the excessive growth. The riddles must be removed, and the mass of shoots and rootlets cleared off. Unmistakeably this will be of great assistance to Potato growers, and has only to be known to be appreciated.

A remote village on the Trent is the home of this invention, and doubtless the name of that village will become a "household word." Talking of "pies," this Garton pie made north and south has entirely escaped all ill effects from frost. Possibly, some on-lookers might wonder at the immense heap of straw and earth which has been removed, and might with reason calculate the expense had been great; but the vexation would have been greater still had the uncovering revealed a mass of decayed, putrefying tubers. The Swede pies here, which were only treated to ordinary coverings, have had a pitiful tale to tell. Labour there had indeed been expended in vain, for the pied roots were far worse than those in the open field.—THE MISSUS.

REMARKS.

- 14th.—Bright sunshine with cold breeze; clear cold night.
  - 15th.—Generally overcast till 11 A.M., bright sunshine after.
  - 16th.—Overcast morning; bright sunshine from noon.
  - 17th.—Showers about 4 A.M., and overcast till 9 A.M.; sunny from 10 A.M. to 3.30 P.M., but hazy and close after noon. Frequent distant thunder from 3.40 to 5 P.M. with slight rain; dull evening and rain at night.
  - 18th.—Dull and overcast throughout the day; clear night.
  - 19th.—Rain between 6 and 7 A.M., and overcast till about 10 A.M., alternate sunshine and cloud after; clear night.
  - 20th.—Fine and generally sunny.
- A fine mild week.—G. J. SYMONS.

# DICKSONS' NEW IRISH ROSES.

ALEX. DICKSON & SONS

Have pleasure in announcing for distribution in May a further series of their

## CELEBRATED PEDIGREE ROSES,

HELEN KELLER (H.P.), Rosy Cerise, superb .. 10/6 each  
 MAVOURNEEN (H.P.), Silvery Flesh, first rate 10/6 ..  
 MARJORIE (H.T.), White, Pink centre, very pretty 7/6 ..

ALSO  
 The Best of the NEW FRENCH & BRITISH ROSES.  
 Descriptive Catalogue Post Free on application,

## NEW (H.T.) ROSE

BELLE SIEBRECHT (Mrs. W. J. Grant).

Raised by ALEX. DICKSON & SONS, distributed by SIEBRECHT and WADLEY, New York.

The most valuable introduction of the past ten years. This superb variety has gained the highest awards wherever exhibited in Great Britain and America, chief among these being the National Rose Society's Gold Medal.

Valuable alike for exhibition, decorative, and forcing purposes. No collection, however small, complete without it.

PLANTS IN POTS IN MAY, 10/6 EACH.

## THE NEW EARLY STRAWBERRY 1895, STEVENS' WONDER.

The earliest variety in cultivation and very prolific; solid fruit, good flavour, high perfume.

Awarded First-class Certificates, Royal Horticultural Society, and Royal Botanic Society, 1895. See *Gardeners' Chronicle*, March 2; *Journal of Horticulture*, March 14; and *The Garden*, March 16.

Having purchased the whole of the stock of this grand new early Strawberry from the raiser, we have pleasure in offering it as follows:—

STRONG PLANTS, in Pots, £5 per 100, 15/- per doz.

RUNNERS .. .. £3 .. .. 9/- .. ..

Ready for delivery early in July. Early Orders requested as stock is limited. Further particulars upon application.

WM. CUTBUSH & SON,  
 HIGHGATE NURSERIES, LONDON, N., AND BARNET, Herts.

## FORBES' SPECIALITIES

The undernoted low offer is made for Cash with Order. All are selected from my WORLD-RENOWNED Collections. Correctly named and Carriage Paid; 12 varieties to the dozen, and from 25 to 50 varieties to the 100; all my selections.

ANTIRRHINUMS—6s. per dozen; 30s. per 100.  
 BEGONIAS—Seedlings, 4s. per dozen; 20s. per 100.  
 CARNATIONS—6s. per dozen; 35s. per 100.  
 DAHLIAS—All sections, 6s. per dozen; 30s. per 100.  
 DELPHINIUMS—6s. per dozen; 30s. per 100.  
 HARDY BORDER PLANTS—£s. per dozen; 30s. per 100.  
 PANSIES—8s. 6d. per dozen; 20s. per 100.  
 VIOLAS—2s. 6d. per dozen; 17s. 6d. per 100.  
 PENTSTEMONS—6s. per dozen; 30s. per 100.  
 PHLOXES—6s. per dozen; 30s. per 100

CATALOGUE (150 pages) Free on Application.

JOHN FORBES, Nurseryman, HAWICK, N.B.

## BEGONIAS,

DOUBLE AND SINGLE, FOR BEDDING.

Extra superb in quality, and Large Tubers by the dozen, 100, or 1000. Also for Conservatory or Exhibition.

Illustrated and Descriptive Catalogue Free.

B. R. DAVIS, YEOVIL NURSERIES

## JACK FROST

Has caused many losses that can be made good in an easy and cheap manner by purchasing the following Bulbs and Plants, which I can strongly recommend as being first class:—

### BEGONIAS, SINGLE,

20,000 Grand Bulbs, Mixed Colours, finest ever offered at the price. 3s. per dozen.

### PELARGONIUMS, SHOW & DECORATIVE.

Fine Plants in Best Kinds, 6s., 9s., and 12s. per dozen.

### ZONAL PELARGONIUMS,

Best Kinds only. 6 for 2s. 6d., 12 for 4s.

### IVY-LEAF PELARGONIUMS.

A very Choice Lot. 6 for 2s. 6d., 12 for 4s.

### DOUBLE PETUNIAS,

Extra fine New Kinds. 6 for 3s. 6d., 12 for 6s.

Send for Catalogue, Free.

### SPRING PRUNING.

"SURELY this is all done," some readers may not unnaturally say to themselves, as thoughts are converted into words in an involuntary sort of way (which is very much the way of the world) when they see the above short heading. No doubt the pruning of fruit trees in general ought to have been completed, as a rule, some time ago, and it is not very unlikely that a goodly number were too much pruned; but then, again, there are probably many thousands which have not been touched with the knife that would have benefited by its use; and, what is more to the point, may be benefited yet. This applies to trees that were planted last autumn or quite recently during the present spring. The writer planted some last week, and expects every one of them to make good growth during the ensuing season.

These remarks have been incited by the condition of several trees in a garden, which may be, and almost certainly is, typical of other gardens in various parts of the country. This garden contains fruit trees of various ages, chiefly Apples, Pears, and Plums, as well as Currant and Gooseberry "bushes" between them. The owner of the garden must be a fruit enthusiast, or he would not continue planting trees year after year, seeing how little fruit he has obtained, or is likely to obtain, from them. He is not unlike many another—an enthusiast without knowledge, but perhaps has a larger share of the virtue of patience than is enjoyed by the majority, and makes his quiet life happy by living on hope.

It is wonderful—no, perhaps only natural—to see in many an example how easy it is to do exactly what is wrong in the absence of guidance pointing out what is right. Were it not for the teaching of the young—training them intellectually and morally—one shudders to think what the result would be. Untaught and unrestrained the child would grow in years and in mischief, doing wrong by nature and right by accident. It seems to be very much the same on the part of a host of persons, who may be expected to have arrived at years of discretion, in the "management" of their fruit trees and bushes. Discreet the owners of them may be

## NEW PLANT CATALOGUE (No. 133) FOR 1895

WM. CLIBRAN & SON

152 Pages with full descriptions of all the FINEST NOVELTIES and the BEST OLD VARIETIES of the above-named plants.

OLDFIELD NURSERIES, ALTRINCHAM,

ALSO AT MANCHESTER AND LLANUDNO JUNCTION.

in their habits of life, and, in fact, worthy men and excellent neighbours; but regarded in connection with the fruit trees they think they are growing, they are mere children, untaught and untrained, either doing nothing or doing mischief. That this is so, any observer who has been trained as a grower of fruit may see for himself if he drives through sundry villages, and looks over the hedges into the gardens of amateurs and tradesmen as he passes along. It is a pity that it should be so, but so it is, and it is evident that the teaching of practical horticulture in schools, and among the community generally, has been delayed too long.

In the particular garden in question excellent young trees had been planted, as could be clearly seen, some three, some two years, with others about as many weeks. Also a number had grown old enough to be "trained" into bushes and pyramids, and ought to be now in excellent bearing condition. We pause to look at them. Bushes and pyramids! This is what they were some feet above the ground, but by no means down to it, for a good reason, showing very bad management. They had been very much let alone in their early years, and then, when they were "getting too tall, cut into shape." They are now weak, much too weak, at the base, and strong, a deal too strong, at the top. But the owner seems determined to keep them down, or rather cut them back in the winter, for they rush up in spite of him in the summer, but are practically blossomless, and obviously therefore can bear no fruit. Nor will they produce any if they are similarly treated for a generation. They simply represent the mischief of a child who cuts and slashes, and is perhaps proud of his skill with the knife.

It is butchery, undisguised glaring butchery; the outcome of ignorance, and fruit trees similarly mutilated may be seen over the length and breadth of the land. Their root force predominates so powerfully that the annual grossness is but the natural result, and the annual mutilation, miscalled pruning, increases the evil it is vainly hoped to prevent—barrenness. Shorten those strong roots instead of the branches, but removing entirely a number of these so that those which remain are 18 inches asunder, permitting no others to grow between them, and the trees would soon bear more pecks of fruit than they now bear pounds. Digging round them, and severing some of the strong roots now would be going veritably to the root of the evil; and preventing the thicket of summer growths by rubbing out nine out of ten of the shoots now pushing to produce them, would be a change from common mischief to common sense.

Now let us look at the young trees. Just as the older with their powerful roots have been pruned ten times too severely, so with remarkable perversity the recently planted trees with weak roots—the majority of the food imbibers having been left behind in the process of digging up—have not been pruned or had their long young branches cut back at all. Some of these were 3 feet long, about three of these with one or two shorter formed the "head." There they remain now, just the same in number and very little more in length than they were three years ago, some of them studded with blossom, especially towards the tips. The two-years-planted are in much the same state, and if all the blossoms set and fruit remains the trees will be exhausted—ruined. In that way thousands of trees are brought into a stunted condition, and are to all intents and purposes useless during the rest of their miserable lives.

The trees now making their first start into growth after planting are pushing into leaf from the tips of the 2 to 3 feet long branches to a third of the way down, and over the lower half or more of each stem the buds will remain dormant. The Willow-like branches will be the same in number next year as this, but hard, thin, and hide-bound, because it is impossible that the comparatively few roots can do much more than keep them alive. They should be cut back now, and the sap having been summoned into activity, would have its force concentrated on a third of the length of the stem and buds, these latter be forced, and an increased number of

branches issue for forming the framework of a good tree in each case during the coming summer. Of that there can be no reasonable doubt, for the trees are clean, healthy standards which had grown with great freedom last season. They are capable of being made valuable in a very few years, but are in danger of being spoiled, in this case through the want of timely pruning, as certainly as the established trees before mentioned are rendered profitless each year by the excessive and irrational use of the knife. Exactly what is wrong is being done in these two cases in entirely opposite directions, and it is very unfortunate that so many persons, and some even who call themselves gardeners, do not appear able to differentiate between the nature and capacity of trees which on the one hand have roots out of all proportion in strength to the branches, and the other where the branch growth to the same extent preponderates over the power of the roots.

It does not follow that every tree which has been recently transplanted must of necessity have its branches shortened for insuring its growth. It is a fact that unsold trees in nurseries are commonly planted late in the spring—brought together in a quarter, and not cut back; but just because these trees were not sold they were far less vigorous than those that were, and the roots are equal to the support of the naturally shorter and weaker branches—weaker because the best trees go first, and so the selecting continues till the worst only are left behind. These are kept alive the first season and shortened the next, by which time they have made sufficient roots to produce free growth the second summer, and make thrifty saleable "stuff" in the autumn.

As in the case with Apples and such-like trees in the amateur's collection above referred to, so in the case of the so-called bushes. Gooseberries and Currants, with three or four long branches, have not been cut back after planting, and there they have stood for two and three years, gaunt and ungainly, miserable apologies for what fruit bushes should be, instead of occupying vacant air space all around them and forming profitable examples through shortening the long young branches after planting, and thus producing more. This shortening may be done now—at once—with great advantage to young trees innumerable that are pushing growths from the extremities of the long summer shoots of last year; but if last season's shoots of removed trees are weak they may remain unshortened, not forgetting to cut them back in the autumn.—  
A TRAVELLER.

### TO-MORROW.

"It will do to-morrow" is the kind of insanity that makes aphides laugh, rusts Carnations, mildews Roses, freezes houses, and brings the sheriff right in across your threshold." So says "The American Florist," and although this habit of procrastination may not with us put the man in possession, nor enable us to see the smile of an aphid, not less does it emphasise the proverb, "Prevention is better than cure." Even farther does it go, and provide explanations of things which cannot otherwise be argued away. There are in the field of horticulture abundant pegs which serve to hang on an excuse for that putting off to a more convenient season, and by no means unjustifiable excuse either. The past year of unhappy memory provided a plethora of them. It also furnished some happy examples of prompt action which were at the time duly recorded for our benefit.

A practical illustration was that afforded by the Queen's gardener (Mr. Thomas) and all his men turning out on the eve of that cruel May night, fighting the elements and obtaining a right royal victory. To borrow another trite phrase from our friends across the water, he "licked Creation," and it may be added the proverb, for without preventive measures there would have been no cure—to-morrow.

With the text pure and simple but little dissertation is necessary. Positively, it points with no uncertain hand to the evils of procrastination; negatively, to the benefits of the stitch in time. There is no phase of a gardener's duties nor place in the sphere of his work to which it is not applicable. It is a golden rule, the observance of which will, by the timely use of the hoe, save endless labour in handweeding. The stormy wind which springs up suddenly in the night will be baffled of its prey amongst the Chrysanthemums tops, and the hundred and one things for which

the time is ripe will be done to-day, which may be too late to-morrow.

True, it often means working at high pressure to cope with all a day brings in its train; but it is a duty we owe to others, to ourselves, and to the dignity of the art in avoiding the hurry and bustle of being always a little behind. Now and again we may notice some writer giving really sound practical information on the same principle. We are advised to-morrow as to what we should have done to-day. In addition to the evils exposed in the text I would say this phase of the subject makes readers sorry and editors vexed, for to be advised when too late is "like the wrong medicine, nasty to take and sure to disagree."

Besides these sins of omission, many of which entail a long penance for a small error, obviously the text is capable of further extension. We may at the right time wrestle with and overcome mildew and rust, and make the aphides laugh on the wrong side of their faces, yet stave off the meeting of some disagreeable facts of the same insidiousness of growth. Keeness of competition for places or prices in private establishments or the open market is so patent to all and so acutely felt by many at the present day that we may take the question in the broadest sense, and ask ourselves what are we doing for to-morrow to palliate the disorder which will then have reached a more acute stage, whilst the climax is yet remote.

At first sight the question, which here resolves itself under two heads, appears to be neither amenable to prevention or cure. But is it not just possible that the very magnitude of the evil is a means to the end? Taking gardeners first, we see luxuries of one generation becoming necessities of the next. Now, luxuries may be dispensed with, as they are only controlled by sentiment, whereas necessities stand on a very different basis. The gardener, as the producer, does not generally come under the head of luxuries; yet, too often I fear, has he been considered to be one, and felt his position dependent on the fortunes of his employer. A turn of the wheel inimical to the welfare of the one has brought disaster to the other. In the process of retrenchment the gardener has been weighed in the balance and found wanting, possibly and probably through no fault of his own, but rather of a long-established system he or his employers have been diffident to change. Yet men duly impressed with their responsibility cannot ignore the power they possess nor the urgency of making it known. The practical spirit of the age pervading all sorts and conditions of men resolves itself into the question of counting the cost—will it pay? And when the gardener shows that his work can and does pay—of which there are many practical examples to-day—then his position, as a class, is fixed on the firmest possible basis, for a paying concern needs no props.

On the other head of this question, as to what pays to grow from a business point of view, and that is the most practical of all, some prominence has of late been given to it in these pages. It is to be hoped that the prize medal essay when it comes will settle the matter, at least for to-day. Granted that such desirable results are arrived at, it would not be safe to assert, "It will do to-morrow." Our transatlantic cousins, with their proverbial smartness, anticipate what the world is likely to want to-morrow, and by the exercise of their creative faculties furnish the article and the necessity for it contemporaneously; reaping the benefits of being first in the field. Necessity is not invariably the mother of invention, rather is it at times the offspring of it. The world was neither clamorous for sewing machines nor bicycles until they were invented, now each goodwife's needle flies by mechanism, and all the world (and his wife) go on two wheels. Can we not, with glutted markets and falling prices work on parallel lines; off the beaten track where follow my leader is so much in vogue; let the world wake up to-morrow with a new want already supplied from some hitherto obscure source? The public at large are very much like children; do not ask them their wants to-day, but judiciously place a supply before them to-morrow.

A whole nation wants Tomatoes when acres of glass erected for their production pour tons of the fruit into the market. "Mushrooms for the Million" are provided all the year round, and growers rush in at this game of "follow my leader" until but the narrowest margin of profit rewards their efforts. Men who have made their mark (and their dollars) in these or similar phases of culture, see the dangers ahead, and honestly warn intending competitors. From the broad and liberal lines of political economy we may look beyond the market area and note the enormous advantages conferred on the people by a cheap food supply of high quality. Armies and navies may wax and wane, but in spite of present depression there are great natural laws protecting our food producers, for a nation must eat, whether it fights or not. War is a luxury, food a necessity; and the progress of education raises the standard of living so that a fresh dish is looked for in the menu to-morrow.

The recent article in the *Journal of Horticulture* on "Express

Grape Growing" must have created a deep impression on thinking men. With some it should be a lasting impression. Already I (figuratively) see this literary seed thus sown springing up through the length and breadth of the kingdom, producing such fruit at such prices that the artisan will share in the dish hitherto confined to the tables of the wealthy. Express Grape growing will of course yield quick returns and correspondingly smaller profits, but the day of small profits is at hand, and to ensure them will demand all the considerations expressed in our text.

"It will do to-morrow" has, I fear, to answer for many shortcomings. That day in the distance dimly seen enveloped in its nimbus of possibilities, which some find to be but the blight of privation, of poverty when revealed at the last stage of life's journey. To all the pleadings for, and expoundings of the objects of our benevolent and benefit societies are disregarded, and another wrinkle is eventually added to the brow of care. This is unsatisfactory, yet must we hope to see it overcome. Happily we are imbued with the thirst for perfection. It is an innate attribute of man. Progress is progress though by easy stages, and "We are a stage too, not the end, others will come our work to mend."—NEMO.

## AURICULAS.

THOSE who knew anything of this beautiful spring flower anticipated that after the very severe weather through which we have passed that neither in quantity nor quality would the exhibition be up to the mark of former years. It is quite true that frost will not kill the Auricula, and indeed in many cases during the past winter the pots have been frozen completely hard, but notwithstanding this the plants do not come out of the battle uninjured. The blooms even though they may not have risen above the foliage become crumpled and never open flat and smooth, while the long continuance of the severe weather so retarded their expansion that one felt that unless where heat had been applied it would be well nigh impossible to place an exhibit on the table; nor were these anticipations falsified.

In the chief class of twelve show Auriculas there were only four competitors, and consequently only four out of the six prizes were awarded, and when it is remembered that last year Messrs. Horner, Douglas, and Simonite were amongst the exhibitors, and that this year not one of them put in an appearance, it will be at once seen what a falling off there was; nor was this all, as some of the collections bore unmistakable marks of having been forced into bloom. Now, although the Auricula will stand a certain amount of heat judiciously applied, it will not endure forcing. Where heat is used simply to prevent the inroads of frost, and so preserve the flowers from injury, the Auricula will not only stand it, but rather rejoice in it; but where something more than this is done, the exhibitor, finding that his flowers are late and will not be ready for the exhibition, applies heat to force them on, then the plant rebels, and refuses to submit patiently to a proceeding so entirely at variance with its requirements. The flowers then become drawn and weakened, and the blooms themselves are quite out of character. It is curious, for instance, to see how the body colour of the flower is affected. From all these observations must be exempted the collection shown by Mr. T. E. Henwood of Reading, for this I consider to be the perfection of Auricula growing. I know Mr. Henwood's little Auricula house, and can only say that it is nothing but intelligent skill and constant attention that could produce such results.

There is another error into which Auricula growers have fallen. In order to produce larger flowers they have stimulated their plants by the application of a quantity of manure, the result of which is coarseness and loss of character in the flower. There is no doubt that many persons, even amongst those who ought to know better, attach a good deal of importance to size. It is so in all flowers; big Roses, Pansies, and Carnations are regarded with more favour than more moderate sized ones. Now, of course, where size can be combined with refinement there can be no objection to it, but too frequently size implies loss of refinement, and yet a large Paul Neyron Rose or Carnation of the Souvenir de Malmaison type, oftentimes finds more favour than the smaller and more refined varieties. I have often stated, and am more than ever convinced of its truthfulness, that rejecting not only the filthiness which older generations of florists used to put into their composts, but also the applications of simpler manures, those growers will do best who would confine themselves in the main to good fibrous loam. I believe that a compost composed of three parts of this with one part of leaf mould and a little sand, will be just such a mixture as the Auricula will rejoice in.

This love of size is nothing new, although the rigid florist sets his face against it; but on looking back to some fifty-five years

ago I well remember exhibiting a plant of Fletcher's Ne Plus Ultra (then a new flower), but coarse to a degree, and which would not be tolerated now in any first-rate collection. I showed it in, I think, a stand of six against one of the best Auricula growers I ever knew—Dr. Plant of Monkstown, near Dublin. It threw the balance in my favour, and the judges, who could not have been, I think, very exacting florists, placed me above him. The pips were nearly the size of a crown piece, and, of course, out of proportion with those of the other varieties in the stand.

I have already mentioned the excellence of Mr. Henwood's plants. Some of them were especially fine. There was a splendid truss of Richard Headly, of which I had almost said it was the best I had ever seen; but then came back to my mind that magnificent plant of it which my late friend (the Rev. F. Tymons) brought once some years ago to one of the Society's exhibitions in South Kensington. I have never seen its equal either before or since. Mr. Henwood grows it exceedingly well, and manages to have it always in flower at the time of the show, which is somewhat remarkable, as it is with most people a very late bloomer. Then he had a good truss of that most beautiful white-edged Ben Simonite, which few can grow on account of its delicacy, and no one can grow as Mr. Henwood does. There was a fine truss of Prince of Greens, with the usual excellencies and defects in that flower, its splendid edge and its sickly looking tube. Abbé Lizst, a flower of Mr. Douglas' raising, promises to be a welcome addition to our list of green edges. The edge is a particularly bright green, and the constitution of the plant is said to be good. James Hanford, another of Ben Simonite's seedlings, also promises well; in fact, green edges, which have hitherto been a very restricted class, have considerably increased in numbers.

The older flowers, such as Emperor, are going out of cultivation, and Colonel Taylor, which was long regarded as the best of its class, is not very often exhibited. Dr. Hardy, another of Simonite's raising, was shown by Mr. Douglas in his stand of fifty; it is likely to be a valuable flower, although the bloom alluded to was somewhat defective both in the eye and paste, probably owing more to the season than to anything else. Of course Mr. Henwood had Geo. Lightbody, for what stand would ever be complete without it? although the truss was surpassed in excellence by one exhibited by Mr. Collier, gardener to Miss Kirke Penson, which gained the premier prize as the best Auricula in the show. In Mr. Sanders', the second, collection was a very fine bloom of Mrs. Dodwell, one of the Auriculas raised by the late Mr. Woodhead, which in this instance had a very clear white edge. There was also a very fine truss of Simonite's Heatherbell, and Lancashire Hero, which somehow or other one does not see so often as formerly, was very good.

In self Heroine, Mrs. Potts, and Black Bess were frequently shown, and with the exception of two new flowers Miss Barnett and Cherub held their own in their class. Mrs. Potts, beautiful as it is in colour, has the defect of a weak stem and rather sprawly truss, but its colour is exquisite, and shape perfect. One great charm of this show is that it brings together those whom we can meet on no other occasion, especially such northern growers as the Rev. F. D. Horner, for many years the champion grower, and Mr. Ben Simonite, who has done so much to add to our choicest collections. Then there was Mr. Collier, gardener to Miss Kirke Penson of Dinham House, Ludlow, whom I had not met for some years, and about one of the best growers of George Lightbody I ever met with, and whom probably we may not see there again, as owing to death the place is broken up.

Before I close these rambling notes there are one or two thoughts which suggest themselves to me. I notice the great advance made by the south in the cultivation of this flower; indeed, it is mainly confined to Reading, and as I remember for many years there were but two exhibitors near the metropolis, the change is a very pleasing one, and then one cannot but remark how the older flowers still hold their sway. George Lightbody was raised between forty and fifty years ago, and although growers have tried they have not been able as yet to raise another grey edge comparable to it. Curiously enough it was the only one Mr. Headly ever raised which was worthy of him. So, again, amongst white edged, Acme that I recollect seeing forty years ago with Mr. Read is still difficult to beat when at its best. Then, again, it is remarkable how indispensable seem to be the four varieties—Mrs. Dodwell, Rachel, George Rudd, and Black Bess—raised by the late Mr. Woodhead, and which every year make us more regret the loss of so intelligent and skilful a florist, who, had he been spared, would, I have no doubt, have added many fine varieties to our collections. Thus, once more have I have been permitted to say something of a flower which captivated me some sixty years ago, and amongst the many claimants to one's attention still maintains the position which a first love ought to hold. So, my brother

Auricula growers, especially you who are young and vigorous, spare no efforts to cultivate and improve a flower which will never fail to maintain its interest for you, and which will afford you many an hour of unalloyed pleasure and gratification.—D., Deal.

## BOTHIANA.

(Continued from page 331.)

BEING practically your own master inside the bothy, free to think, to act, to fill up the spare time as you will—whereas, during the working hours as a servant you have no choice but to obey—you are now leading the dual life of master and servant, an intimate relationship which is not always conducive of the best results, unless your mind, as the master, exacts and obtains that implicit obedience as necessary here to success as in the garden. That this master (yourself) is inexperienced you will admit, hence advantages are apt to be taken in a form of internal argument, in which reason is sacrificed to fancy.

It is imperative that you should work on a clearly defined system. Desultory work seldom accomplishes much. Let your plan of study be the ground plan, judiciously designed to meet the requirements of the future. Then, when duly considered and wisely arranged, abide by it. Apart from this, note all details of daily work in the different departments, and let your first moments of leisure after working hours be devoted to recording them in a diary. For this purpose an office diary for the current year, three days on a page, costing from 6d. to 1s., will suit admirably, and form a ready mode of reference in the future. You can also on a blank page, generally provided, neatly write out a plan of study. Each night when all duties, physical, mental, and moral are ended, fail not to take a momentary survey of the day that has gone, and conscience will infallibly tell you whether it is a sound thread you have woven into the web of your life.

In a choice of subjects avoid the error of attempting too much. Do not spread your interest over too wide a field, but it is essential that variety should be introduced; thus will your self-tuition be, not only a recreation to the daily toil, but each section of it will form an antidote to monotony in another. You may consider it somewhat of a slight to your intelligence in mentioning the three R's, previously hinted at in connection with the school books. Do not take it as a disparagement of your mental attainments, yet, if so be that you can happily afford to despise them, let their place be taken by similar ones of higher grade.

## READING.

"Some books I'd have, and some acquaintance too;  
But very good, and very few."

This, first of the three R's, is alone a subject worthy to fill a volume. The old-time counsel bidding the boys mind their books may now be construed into, Mind what books you read, and how you read them. To consume the fleeting hours in the perusal of attractive but unprofitable literature is not only useless, but worse than useless, for by its means the mind is sown with weedy thoughts detrimental to the culture of the useful, the good, the noble. It may serve the murderous intention of killing time, too often openly avowed in the bothy, but invariably defeated by the scythe-armed conqueror. Nor is it of advantage to meander aimlessly through the best fields of literature. Accompany the author, grasp the subject, and form a mental analysis as you proceed.

Cultivate the art of reading in a critical spirit. Compare familiar ideas with your own experience, and let each new truth as it is revealed to you be indelibly impressed on the memory. Once the impression is properly conveyed to the mental cylinder it can never be lost; hence the greater reason that it should be matter worth retaining. In the preface to a book, which is too often "skipped," is given what is necessary to know; it is the credentials of a stranger, with his reasons for claiming your attention. Frequently is a book borrowed or bought with the sole end of amusement; but if you select your books as you would, or ought to, your friends, there is no reason why pleasure and profit should not go hand in hand. As a gardener, how delightful it is to accompany Humboldt through the virgin forests of the tropics, or trip with Burbidge through Borneo! Yet even with these and similar books of travel, they are rather to be regarded by us as relaxation than to have the prior claim on our time.

Current garden literature will receive a weekly welcome in the bothy. It is the medium of touch amongst men of the profession distributed over the area of the gardening world, and forms a chronicle of progress in all departments. A standard work on gardening is indispensable. Thompson's "Gardener's Assistant" in its comprehensive treatment of so broad a subject is—to the present—unexcelled. As your limited means will allow, the various valuable

works specially treating on the different phases of fruit or plant culture are worthy additions to your small library.

WRITING.

"In graceful curve, and every flowing line,  
Untutored pens by practice learn to shine."

Apart from the value of writing a good hand—and in this practice is the high road to perfection—as an aid to the memory, it is of the first importance. Those subjects which deserve and require more attention than obtains from the most careful reading, may by transcription form with the reading a system of double entry on the mental ledger. Yet much of the value of these writing lessons may be lost, unless that scrupulous attention is paid to it that it deserves. Do not lose sight of the dual object here presented.

Keep all your transcript books, and mark progress periodically. Compare your latest performance with its predecessor. Let the criticism be conscientious and impartial, and each improvement, however slight, be the incentive to further endeavour. As writing is worthy of occupying a considerable portion of spare time, some consideration should be paid to the selection of books or articles for transcription, choosing such as are models of excellence from a literary point of view. In this matter, as indeed in all others, let quality more than quantity be the object aimed at. Sentence by sentence, with careful attention to punctuation, will not only accomplish the ends alluded to, but be the means of the art of composition entering into your studies. The school grammar may, too, be of service here, and needless to add the dictionary is requisite.

Many gardeners are by reason of the isolated position they occupy compelled to live in a little world of their own, thus prohibiting that social intercourse with kindred spirits which is as profitable as it is enjoyable. In the vicinity of some large cities mutual improvement societies have been formed. Should such be within your reach you will not, I am sure, ignore the advantages to be derived from this union of hearts and hands.

"Through mutual intercourse and mutual aid  
Great deeds are done and great discoveries made;  
The wise new wisdom on the wise bestow,  
Whilst the lone thinker's thoughts come weak and slow."

My experience of these societies has unfortunately been limited to reports of them in the gardening press, as in my journey through bothydom I was not so happily situated as to be in touch with any of them. Judging by their works, including some admirable essays which now and again find their way into print, I think any young gardener is wise, if circumstances permit, in linking himself to this chain of brotherhood.

Gardens, like gardeners, are stamped with an individuality. Half a dozen establishments within a limited area, and under the same local influences of soil and temperature, will yield a variety of effects. One place will be noted for its Orchids, or Chrysanthemums; another for its Vines, Pines, or what not, and the whole form a nucleus of practical information, which if disseminated through the channel of periodical meetings must result in mutual benefit. The friendly spirit of rivalry will also spur on the young traveller to measure his paces with his fellow competitors, and by the exercise of his pen he too can contribute his quota to this exchange of thought and practice. The pages of our gardening journals are open to those workers and thinkers able to jot down their experience in presentable form, yet how much greater must be the mass of valuable information locked up by diffidence arising from the want of early training of this faculty. Endeavour by all and every means to acquire the pen of a ready writer, to the end that your ideas may be "moulded and clothed in the soft garments of their native tongue."—AN OLD BOY.

(To be continued.)

CÆLOGYNE PANDURATA.

GREEN flowers are rare, and when they do occur they are usually monstrosities, and devoid of any pretensions to beauty. Black is also exceedingly rare in flowers, and this renders the above-named Orchid all the more remarkable, for it contains a combination of the two colours very strongly marked. The sepals and petals are a

pure bright green, the lip also is green at the margin, but it has a black centre and veins of black in the lateral lobes also. The plant is of stout growth, and produces a long raceme bearing six or eight large flowers in well grown specimens. It is a native of Borneo, and has been repeatedly found flourishing on trees in damp situations. The plant requires the temperature of a Cattleya house, and a shaded position, succeeding well in a basket suspended from the roof. The woodcut (fig. 63) represents a flower of this remarkable Orchid.

DENDROBIUM CAMBRIDGEANUM.

A GOOD basketful of this pretty species makes a fine display at this season, the drooping habit of growth showing the flowers to great advantage when grown this way. The species is deciduous, but unlike the majority of this section flowers upon the newly formed leafy stems. The blossoms are produced in twin-flowered peduncles chiefly towards the top of the stems. They are each fully 2 inches across, bright golden yellow, with a deep maroon blotch on the rounded downy lip.

This plant usually commences to grow early in the winter,

FIG. 63.—CÆLOGYNE PANDURATA.

and from then until it flowers should have the lightest position available in the warmest house, the atmosphere being kept well charged with moisture. The leaves must be kept on as long as possible, their function being to help swell up the pseudo-bulbs. As soon, however, as all are fallen the plants must be kept drier at the roots, and in the atmosphere. I usually place this Dendrobium out of doors in the summer time, not fully exposed to the sun, but hung in a tree, this treatment causing the plants to bloom freely. At the end of August they are taken to the Cattleya house and kept dry until signs of growth appear, when they are again introduced to more heat.

D. Cambridgeanum may be grown in three parts of sphagnum moss to one of peat, and given good drainage in small suspended pots or baskets. It roots and grows freely, and if care is taken to thoroughly ripen the growth in the autumn, at the same time avoiding shrivelling, it will also produce a fair complement of flowers. It is also known as D. ochreatum, and was introduced from the Khasia Hills in 1837.

PROPAGATING DENDROBIUMS.

The season having again arrived for cutting away the old stems of D. nobile, when this is practised it may not be out of place to remind growers of the ease with which this and a few other Dendrobiums may be propagated by laying the old pseudo-bulbs on boxes or pans of suitable moisture-holding substance. When there are good forms that it is wished to propagate no better way can be found, and the plants raised are infinitely better than old plants

divided up. The growth is green, and one is not so liable to propagate insects with the plants.

The stems may be laid on entire or cut in lengths, the latter being preferable, as the eyes break more freely. If the old plants have been infested with insects, the stems must be well sponged. Usually fill the pans to within an inch or so of the top with crocks, laying a little live sphagnum below and above the stems. They are then placed in the East Indian house, and damped over daily with the syringe. When the growths are well advanced they may be separated by cutting through the old stem between each with a sharp knife. They may eventually be either potted singly or grouped to form small neat specimens, and if kept through the growing season in a brisk moist heat they will by the end of the ensuing year have formed strong well-furnished plants.—H. R. R.

### FUNKIAS.

THESE handsome deciduous herbaceous plants are worthy of being largely employed in extensive gardens, as there are so many positions in which they thrive, where other plants do not. The appearance of the strong growing varieties is bold and striking, and those of less vigorous growth have such beautifully marked and showy leaves, which vary considerably in the different stages of growth, that they are thoroughly adapted for pot culture; indeed, I think those cultivators who commence growing them in this way are not likely to relinquish the practice, especially if they happen to have much house decoration to do, and who has not in these days of artistic development?

All the species are readily propagated by division, which may be effected during the winter and spring months. All that is required is to cut the clumps through with a sharp spade. Each portion ought to comprise several crowns, except in those cases where a particular variety requires to be propagated as quickly as possible, then each crown may be planted separately, and especial care should be taken when the division is made to secure a few young roots to every crown. The present is a good time to divide strong plants in the open air, as they are now commencing their growth. I strongly advise those who have not hitherto grown Funkias in pots to give them a trial at once. Sieboldiana and Fortunei are two of the most vigorous growing varieties, and well adapted for planting in masses in the foreground of shrubberies, indeed they will succeed fairly well in any odd corner under the shade of trees, where few other things except Ivy will grow.

It is, however, necessary to prepare a good sized hole before planting, so that they may start with a foot or so of soil around them quite clear of tree roots; when established they will take care of themselves. A little decayed manure may with advantage be placed at the bottom of the hole. I have several fine clumps (which have been treated in this way) growing under the dense shade of Lilac bushes where few other plants will thrive. The flowers of the first named variety are a delicate mixture of white and pale lilac in colour, and those of Fortunei lilac of two distinct shades. When cut the flowers do not last long, but being borne on stems 18 inches in length often prove useful for arranging in trumpet-shaped glasses. The beautiful glaucous leaves, having conspicuous ribs, are attractive in appearance throughout the summer.

*F. japonica aurea* is one of the best of the species, the bright variegation of the leaves, in which there is a gradual blending of green with the golden markings, gives them an unique appearance. Unfortunately, however, as the summer advances the leaves become dull in appearance. Notwithstanding this undesirable freak it is a great favourite wherever grown, and is invaluable when grown in pots for decorative purposes. *F. ovata alba marginata* is also another form of attractive appearance, the leaves having a broad margin of white, and on that account is of great value when grown in pots. *F. subcordata* is a green-leaved kind less vigorous in growth than many of the varieties having plain green leaves. The flowers, which are white, are borne only slightly above the foliage, which rarely attains a height of more than 9 inches. The variety is on that account suitable for planting on rockwork or near the front of herbaceous borders.

In gardens where pleasure grounds are extensive a fine feature may be made of Funkias by planting large masses of them in various positions. For instance, when traversing the numerous walks which one always finds in such grounds, it is not unusual to come upon naturally formed recesses with overhanging trees and surrounding shrubs. Here a large mass of *F. Sieboldiana*, encircled by variegated Periwinkle or dwarf growing British Ferns, would come upon any garden wanderer as a pleasant surprise. Undulating banks, having a background of trees or shrubs, might with advantage be converted into a Funkia quarter.

In such a position it would be interesting to plant every species and variety known to be worth cultivating, arranging each in irregular masses, so that the pleasing shades of colour which their leaves possess might be carefully blended rather than contrasted. The habit of growth of each particular variety should also be carefully considered at planting time. In doing this some would plant the strong growing ones on the top of the bank, arranging the others according to their height, so as to form a graduated surface from front to back. A much better plan, I think, is to place a good clump of the tallest growers in prominent positions here and there, and then plant patches of the dwarf varieties between, allowing each ample room to develop, so that the natural surface of an undulating bank, in which swells and depressions of outline merge into each other in easy grace, is distinctly maintained. A feature like this well carried out is, I opine, a not unworthy adjunct to the most pleasing scenes to be found in the best of British gardens, and Funkias are a genus of plants deserving of a greater amount of attention from gardeners in the United Kingdom.—H. D.

### DISINFECTING SOIL.

DISINFECTING soil for Cucumbers and Tomatoes as a preventive of diseases caused by eelworm, mites, and fungi, including bacteria and myxomycetes, or so-called slime fungus, is a very important subject. Whenever there is a suspicion of the soil intended for these, or indeed any kind of plant, harbouring parasitic micro-organisms it should be disinfected before use. This may be effected in various ways, the more drastic being that of fire and poison.

1, *Fire*.—Procure a large iron plate and place it on an improvised furnace formed of loose bricks about four tiers high, leaving a slight space here and there as draught holes. Make what is termed a hearth fire, and when the plate becomes hot place the turves thereon, grass side downwards, and leave them until heated, so that the hand cannot be borne a minute on the top or soil side. Remove the sods so heated and stack them. Follow with another lot of turves on the hot plate, and from thence to the stack, and so on until the whole stock of compost has been treated. When such a stack of loam is cool enough it is fit for use, and in no way prejudiced as compost, provided it is not surcharged with coal tar, as would be the case if exposed to a "green" coal fire. This can be avoided by using charcoal or coke, but there is no danger from coal if the hot plate is used.

2, *Poison*.—Procure an ordinary paraffin cask, cut it in two, so as to form two tubs, and burn out any petroleum therein by a wisp of dry straw lighted, not burning the wood, but merely the oil. Put into the base of one of these a wooden faucet or tap. Wash both out clean, and place in one 14 gallons of water. Then place in the other tub 1 oz. of finely pulverised corrosive sublimate (mercuric chloride,  $HgCl_2$ ), and pour on this 2 gallons of hot water, and allow it to stand overnight, after well stirring. Pour the solution into the barrel containing the 14 gallons of water, and let it stand six hours, agitating at least once an hour to insure a thorough mixture, and it is then fit for use. Spread out the soil 1 foot thick and sprinkle it with the preparation, using about a gallon per square yard. If the soil, as should be the case, is in a moist state previously, the corrosive sublimate solution will pass through about the thickness of soil named. Let it lie twenty-four hours, then chop up and mix thoroughly, but not placing the heap thicker than the 1 foot for at least another twenty-four hours. The soil may be used, say on the third day, and if thoroughly impregnated with the poison all parasites will be destroyed. In the case of ordinary soils, it is only necessary to water with the corrosive sublimate solution in the usual way, giving the quantity named per square yard.

It may be applied after the plants are put out, and it will not injure them, but, of course, it is not then a disinfectant, but a curative agent, and if eelworms are present it will kill them; but it will not repair the damage they have done. The strength recommended is one part in two thousand (half that used in surgery), and will not injure the plants, but as a virulent poison must be used with extreme caution.

3, *Non-poisons*.—Preparations of carbolic acid, such as soluble phenyle and creolin (the former Little's and the latter Jeyes'), not only kill the parasites, but actually benefit the plants, using twenty-five drops per gallon of rain water, or an ordinary wineglassful may be used with every 3 gallons of water for disinfecting soil, and moistening it evenly through, as in watering plants generally. It is not desirable to use it on dry soil, but on that moderately moist, or in such condition as when plants are usually watered. These substances in no way sterilise the micro-organisms beneficial to vegetation, and if mineral manures are given—especially lime,

potash, and other inorganic elements—nitrates must form, or nitric acid and ammonia chemically unite with their bases, and the plants will make good use of them under the essential surrounding conditions.—G. ABBEY.

### MODERN GRAPE GROWING.

(Continued from page 341.)

#### RAISING THE VINES.

MOST people who only require a few Vines will buy their plants ready grown, and unless they are adepts at raising them, and have the convenience to do so, this is the better plan; but for those who wish to raise their own, I will describe the method of doing it.

The usual and best method is to insert single eyes or buds from ripe wood of one year's growth. The wood should be cut straight across on the upper side of the eye, and almost close to it; then take the piece of wood in the left hand, with the eye downwards, and, commencing just below the part opposite to the eye, make a slanting cut from 1 to 1½ inch in length, and after cutting a very small piece off the thin wedge-shaped portion at the bottom, to prevent any raggedness, the eye is ready for insertion. Small pots, 3 to 4 inches in diameter, are used for the purpose, and a single eye is placed in each. The soil used should be mostly loam, but if a little good leaf mould is mixed with it the rooting process will be facilitated.

The soil should be placed loosely in the pots without any pressing, heaping it up above the rims; then take each cutting, and insert it straight down the centre of a pot, and with the two thumbs placed one on either side of the cutting press the soil firmly down, adding more if necessary, and leaving the eye covered to the depth of half an inch, and also leaving half an inch space in the top of the pot for watering. The soil, of course, should be in good working condition, neither too wet nor too dry, and rather erring on the side of dryness. The time for this operation is as soon as the leaves have fallen, or between the middle of December and the middle of January.

A temperature of 55° to 60° by fire heat is sufficient, and though they may be plunged as long as they remain in these small pots to prevent too rapid changes in the way of moisture and temperature, they should not be subjected to a great amount of bottom heat. The leaves will generally commence to grow first, and then there will be a stop in the upper portion till the roots have started. When they show signs of making a second start at the top the roots will probably have reached the sides of the pots, and the young plants will be in the best possible condition for removing into pots of a larger size, say 6 or 7-inch. It is very important to have the soil in good condition for this shift, and it should be in the house for several days before the operation takes place.

A good substantial loam, with a little admixture of bone dust is all that is required. Care should be taken not to break the balls, but after securing the drainage and placing a handful of soil at the bottom of the pot the ball containing the young plant should be placed in the centre with its surface an inch below the rim. The new soil is then pressed rather firmly with a potting stick in the space between the ball and the side of the pot, finishing by leaving about three-quarters of an inch space at the top for watering. The upper half inch of soil should not be pressed but left loose, and do not be too particular about making it very fine and level. The whole process is but the work of a minute, and any longer time spent about it is only mischievous.

There is no reason why the young plants should be injured in the least by this repotting, but there must be no taking them to the potting-shed and no cold soil used, and, what is of equal importance, there must be no coddling or nursing as if they were so many invalids who had undergone the amputation of some of their limbs. The plants as they are potted should be arranged on a bed of ashes, sand, or gravel, not boards or slate, and be kept continually in a light position. As regards air and temperatures, they should be treated exactly the same as I shall recommend for permanent Vines. In a few weeks they will be ready for their final shift into 11 or 12-inch pots, and this is done in much the same way as the former shift, but adding a few half-inch bones as well as the bone-dust to the loam.

The best plan of training is on wires, fixed to the roof of a small house or pit, with not less than an 8-foot rafter. About Midsummer Day they should be stopped, and any growth made at the end after this should be kept checked, leaving a leaf at a time if this is found necessary, and keeping the laterals pinched in to one leaf. The stems will now thicken, and the buds become plump. It is of no consequence if one or two buds burst near the top, as that portion will be cut off; but if too many are inclined to burst, then a little lengthening must be allowed to take place to prevent this happening.

Now these directions are of no use to anyone who will not follow them thoroughly. This hard stopping will not answer if you are growing the young Vines on the stewing system, as so many people do. Treat them, as I have said before, the same way as I recommend for permanent Vines, never syringe them, and never shut them up with a high temperature or a saturated atmosphere. By September, or as soon as the wood begins turning a little brown, the laterals may be entirely removed as far as the partial ripening condition extends, following it up as it is seen there is no danger of the eyes bursting, finally cutting off the unripe portion of stem at the top, and you will be rewarded with plump brown eyes while the principal leaves are still green.

Some will say, Why take all this trouble with Vines that are to be cut down? Well, if you wish your plants to flourish in after years you must grow abundance of good, hardy, medium-sized roots, and ripen them

well. This can only be done by attending well to the upper portion of the plants. The best growers for sale take particular care about all this, but since the demand has sprung up for a low-priced article a great many Vines are now sold which are necessarily grown in a cheaper manner. These may look very well, and satisfy the purchasers at the time, but after results are not quite the same.—WM. TAYLOR.

(To be continued.)

### RADISHES.

IT seems at the outset about as difficult to write an intelligent paragraph concerning Radishes as to make an epic from the proceedings of a police court. Still Radishes have a good deal of interest, and most certainly they have about them a great deal of beauty. I am now referring to small spring Radishes chiefly, although there are some of giant form that are very useful in the winter when sliced with salads, and merit much wider cultivation than they usually obtain. The long white and rose-coloured forms have almost huge roots, whilst the older Black Spanish Turnip, as well as tapering rooted varieties, are most acceptable salad elements.

Of all early salading none seems more welcome, nor are more sweet and crisp, than the small coloured and early sorts. They are from a salad point the barbingers of spring. To many of us there has not been great variety, even in Radishes. We have ordered seeds from year to year of the mixed Turnip forms chiefly, the long tapering forms having got somewhat out of date. Then we have more recently added to our orders the pretty French Breakfast varieties, and there have stopped. But to Messrs. Sutton & Sons, of Reading, are we indebted for the eye opener as to Radish varieties they have, and of which such a very interesting as well as charming exhibit was made at the recent Drill Hall meeting. Few who saw these very pretty and varied samples could but feel their mouths to water, as mentally they crushed the delicate flesh between their teeth, as the roots were so soft and crisp that the most tender of molars could eat and enjoy. Here were some twenty-two distinct varieties, but they were not all in commerce. Most of them were new, and some of them had in a marked degree that desirable quality for forcing varieties—very short tops.

Of the number nine were shown specially as forcing kinds, not only because their tops are so diminutive, but also because extra precocious. Then there were thirteen others having stronger leafage, seeds of which had been sown at the same time as the short-topped sorts, but the latter had beaten them by several days. All were raised from seeds sown on a warm manure bed out in the open, and in six weeks were pulled in perfect condition. No one can say that such quick maturing does not indicate precocity. Here is a wrinkle also worth noting, that seeds thus sown on a hotbed not only germinate far more evenly, but also much more quickly than when sown in the open ground, so that even a bed for Radishes for specially early use soon repays for itself. These short-top varieties are so suitable for that form of culture that the bulbs may be set as thickly as they can stand on the ground and all will mature. A mat or two thrown over the bed at night is very helpful in retaining warmth and protecting from frost, and for that purpose a few stout sticks bent over the bed, or a light framework of wood, standing a few inches above the plants will suffice. Such a bed would do admirably to bring on Marrow plants after the Radishes were pulled if hand-lights were used to protect them for a few weeks.

The special short-topped or forcing varieties were Earliest Frame, about 1½ inch long, of the Olive form, though thinner, bright red colour, very handsome and crisp; a very beautiful variety this. Also Crimson Forcing, about 1 inch long, Olive shaped, deep rich red; Sutton's Carmine, rather shorter, of a beautiful bright carmine hue; Red Turnip, round, bright, and pretty. There was also a similar form having white tips. The French Breakfast form is also red with white tips, but rather more pointed in shape. Earliest of All has a pretty cerise coloured skin with a very tiny top; there is also a white form of it. The general collection included, of stronger leafage, Wood's Frame, Long White, and Long Violet, all very distinct; also the Scarlet Olive and White Olive; Scarlet Globe, rich colour, a fine variety. The Fern or lacinated-leaved Radish is distinct and novel, and has pretty red Turnip roots. Other forms were the ordinary French Breakfast, these white-topped, and Ruby Turnip. All serve to show that of forcing or early Radishes we have now a very liberal choice.—A. D.

### OLD ORCHARDS.

IN the western counties there are far too many worn-out orchards in evidence, and I find they are nearly as plentiful in some parts of the midlands. Curiously enough, one of the worst I know forms part of what is supposed to be a model farm. It is also observable the owners or those in charge are beginning to wake up to the fact that something ought to be done towards "mending or ending" such a discreditable state of affairs. As might be expected, renovating measures, or what are expected to be such, vary considerably. In some instances the hand-saw and bill-hook are principally relied on to effect an alteration for the better, a goodly supply of firewood being the first outcome of these rather drastic proceedings. Some few operators are not content with this; but, in addition to letting much light and air into previously badly crowded trees, they also dress the stems and principal limbs with limewash. It occurs to some few that the roots also stand in need of assistance, and these either apply liquid manure, of which there is

usually large quantities literally running to waste during the winter on some farms, or else give a liberal dressing of farmyard manure, while the American method of folding and fattening sheep in orchards is tried by the more enlightened farmers and growers. Already an improvement has been effected in many instances in the quality of the fruit produced, but the unfortunate part of the case is that more than half the trees operated on are of comparatively worthless varieties.

Fine old trees of Blenheim Pippin, Warner's King, Reinette de Canada, Wellington, Norfolk Beefing, Colonel Vaughan, Beauty of Kent, Cox's Pomona, and a few other valuable varieties are well worthy of every attention, and the first-named in particular should never be cut down before it is seen what can be done towards restoring the trees to a more healthy, profitable state. Now that good samples of superior varieties are fast becoming more plentiful there will be no demand for rubbishy or worthless Apples, and the trees that produce these are not worth retaining, unless for the purpose of cider making. Re-grafting with superior varieties is one good way out of the difficulty, especially if the roots also be attended to, grubbing up and replacing with young trees being another.

Judging from the number of young trees to be seen in old orchards this form of renovation has been adopted by a majority of owners, though in many cases with very indifferent results. Farmers are too fond of buying what they want in the open market, taking their purchases home with them. This may answer well enough when they obtain their trees from a reliable local nurseryman, though even in this case a few hours' exposure to cold drying winds have done great harm to the roots. More often than not the trees are brought from a distance and sold by auction. They are large, are sold cheaply, and are dear at any price. It does not occur to the purchasers that these trees or bushes are mostly of varieties for which there is little or no demand, and are cleared out cheaply from large nurseries accordingly. Sometimes speculative individuals buy up long rows at clearance sales of nursery stock trees, probably not having been transplanted for several years, and these tall trees are dragged out of the ground and hawked about the country. In any case no reliance can be placed on the nomenclature, and long exposure of the roots gives a check from which the trees recover but slowly if at all.

At least one-half of those wretched, stunted young trees to be seen in old orchards are varieties that no experienced fruit grower would recommend or plant, though the cause of their unhappy plight may have yet to be given. Where the mistake is made in so many instances is the preparation of the site. These trees are not planted exactly where the old ones stood, but if they are in the same orchard and are given no fresh soil they might just as well occupy the old sites. How can the ground generally, in an old orchard, be otherwise than completely impoverished of all the elements required to build up and sustain young trees?

If my advice is taken only well proven varieties of fruit will in the future be ordered, a fair price being given to a reliable nurseryman for the trees. Select sites as near as possible midway between the old stations, taking out a cartload of the old, reserving the turfy top spit, and bringing in a similar quantity of fresh soil for each tree. Then all young orchard trees must be properly staked, or crooked stems will become the order of the day. They ought also to have their stems effectively railed or bushed round as a protection against calves, sheep, hares, and rabbits. Full grown cattle, horses, and colts I would keep out of an orchard.—W. IGGULDEN.

## MARKET PLANTS AND FLOWERS.

(Continued from page 366.)

### PREPARING PLANTS FOR MARKET.

It cannot be too forcibly expressed that the grower who takes the greatest care to make what plants he may choose to send into market as attractive as possible, to command the taste of the buyers, is in a fair way to success. His plants must be showy, healthy, neatly grown, and tolerably hardy, which last feature should not be lost sight of. If the growers would only but give some of their plants a week in a cool house prior to sending them to market, the florists who supply the public would not have so many complaints to answer about the undurability of what they now supply.

Plants in pots are generally sold by the dozen, though some growers are not above selling single specimens. Spring plants, such as Hyacinths, are made more effective if planted three bulbs in a 48-pot, a mixture of colours, or all whites, Tulips, five bulbs; Van Sion Narcissus, four bulbs; Lilies of the Valley, twelve to fifteen crowns, as they do not all grow with the same vigour. These are first grown in boxes or beds where a proper temperature can be maintained, and as each become ready are transplanted into pots or boxes and prepared for market. It may be remarked that some growers of spring bulbs, as soon as the plants are ready for decorative purposes, send them to market in small shallow boxes, each holding about four dozen, which not only saves weight and pot room, but they are also more handy for the florist for furnishing purposes, such as making up baskets and other floral devices with Palms and Ferns. Tulips are made up in the same way, six dozen in each box; smaller boxes with two dozen.

The spring flowers such as the foregoing are extremely pretty and most pleasing, adapting themselves to what may be termed indifferent treatment. They all seem to possess abundance of nutriment stored up to carry them on successfully, whereas the plants that come afterwards have to be more carefully handled by the florist in making up the different objects of floral beauty.

Those who wish to grow Hyacinths for market must procure the best kinds and as early as possible. The first supply should be planted by the end of September, so as to meet Christmas demands, and onwards to March, which generally brings a brisk demand for all spring flowers, and a greater variety of plants begin to find ready sale; such as Genistas, a most useful and popular plant for window decoration; Spiræas, Mignonette, Lilies of the Valley, Primulas, Cinerarias, Cyclamens, Azaleas, Deutzias, Marguerites, and all ornamental plants, such as Ferns in pots, from thumbs up to 32's, and Palms of all sizes, also hardy shrubs, such as green and golden Euonymus, Aucubas, Rhododendrons, all newly potted and made to look fresh and green.

Palm growers are most careful to have their produce properly cleaned and staked if need be. Indiarubbers, Aspidistras, Crotons, and Dracænas must all be in a shining condition, and flower pots washed, for nothing adds to the beauty of the plant more than a clean flower pot.

A good trade is also done in the finer climbing plants for conservatories, such as the showy Clematis, which some growers produce as early as March nearly in flower. The beautiful white Mrs. Bateman, lilac Lady Londesborough and Albert Victor, are made all the more showy and attractive by being placed six plants in a small box, thus forming quite a picture. We may soon expect to see a great novelty, no less than a scarlet Clematis, which is said to have all the free blooming qualities of Jackmanni, with flowers of greater substance.

Climbing plants for covering walls, balconies, and verandahs, such as the common Virginian Creeper, also Veitchi, one of the very best; Clematis Jackmanni, very popular; the common Irish Ivy, also small-leaved varieties, are extensively sold, all neatly staked or tied-up compactly.

### THE FLOWER ROOT SEASON.

March may be said to be the commencement of the root period, and according to the character of the weather so the season may be late or early.

Amongst the various flower roots which find the readiest sale Pansies are without doubt the most popular, but they must be good, large, solid flowers, with blooms fairly expanded, and sent to market in small boxes containing two dozen plants. Violas are treated in the same way, and also find ready sale. Red and white Daisies are in good demand; Polyanthus, Wallflowers, dark and yellow Sweet Williams, Canterbury Bells, Forget-me-nots, Antirrhinums, Creeping Jenny without limit all find purchasers through the months of March, April, May, and part of June, then the sales begin to flag, and the root season soon comes to an end.

### THE BEDDING SEASON.

With the bedding season commences the busiest market period of the whole year. No one need wonder where all the plants go to. Let them but take a walk through the streets and squares, fashionable or unfashionable quarters of the metropolis, in the month of June, and see the windows and balconies and "hanging gardens" replete with double pink Ivy Geranium, Marguerites, Fuchsias, Mignonette, Musk, Lobelia, Creeping Jenny, Pelargoniums, and others without end. Even business premises have now begun to take the flowers in hand, and above the entrances and windows the flowers now surmount and give to such places quite a gala appearance. And the bedding out of suburban gardens is a question of millions.

Of such plants as Pyrethrum (Golden Feather) pricked into shallow boxes, six or seven dozen in each box, Lobelia ditto, and Coleus, Petunias, Verbenas, Calceolarias, Echeverias, Amaranthus, Perilla, single Dahlias, Fuchsias, Musk; in fact, all plants that are used for bedding purposes, are chiefly grown in handy shallow boxes. The cultivator who goes in for the above should aim at evenness of quality and full boxes, and have a good supply to meet the market from the beginning of April right away to the middle of June, and he will have no cause to complain.

The bedding season, running conjointly with the season for the furnishing of the multitudinous windows and balconies throughout the metropolis, is the grower's harvest, and he must be prepared with good forward stuff, "showy" is the word. Whether it be boxes of common red or white Daisies, or Zonals, Fuchsias, Heliotropes, and others, let them be showy and shapely, they will command the market.—A. M.

(To be continued.)

## EXAMINATION IN HORTICULTURE.

I HAVE read the remarks of "W. D., Turnford," page 361, on the above subject, and noticed how careful he was to evade the main point in question. Why did he omit the last few words of the paragraph commended by Mr. Kemp, page 333, when his advice to young gardeners is to think for themselves and they will see that theory alone is perfectly useless? Then why give a certificate for a thing which of itself is perfectly useless?

I hope twenty-five years' experience has taught me not to condemn the theory of gardening. Nay, I commend it, for what gardener is perfect without it? I thoroughly agree with the remark, that combined with sound practice it is a boon, and I am pleased to say that the practical man knows how to appreciate it.

Through fear of trespassing farther on your space I will only add that I still adhere to what I have written on page 290. To my mind a certificate gained under present conditions is misleading as a test of a man's abilities as a gardener, and leave readers of the *Journal of Horticulture* to judge for themselves.—H. O. H.

**THE WEATHER IN LONDON.**—The weather in London during the past week has been very variable. At the end of last week heavy showers fell, and on Saturday thunder accompanied downpours of rain. Sunday was dull and cold, but since then the weather has been bright and genial.

— **WEATHER IN THE NORTH.**—For the past week the days have mostly been dull, and a good deal of rain has fallen, especially during the nights. The minimum temperature has never been 40°, and rapid progress has been made in vegetation. Tuesday morning was bright with a coldish west wind, and a high and rising barometer.—B. D., *S. Perthshire*.

— **ROYAL NATIONAL TULIP SOCIETY.**—This Society, in order to encourage the cultivation of the Tulip, is prepared to hold its annual exhibition this year about the end of May in a fresh locality. If any horticultural society within 100 miles of Manchester entertains the idea of having the exhibition in its district, full particulars can be had on application to the Hon. Secretary, Mr. James W. Bentley, Stakebill House, Castleton, Manchester. The southern Tulip show will this year be held in the Temple Gardens on the opening day (May 21st) of the Temple show.

— **JOURNAL OF THE ROYAL HORTICULTURAL SOCIETY.**—This publication has just come to hand, and contains, besides general matters of interest, the papers that have been read at the Drill Hall, which are as follows:—"Cactaceous Plants," by Mr. John W. Singer. "Filmy Ferns," by Mr. J. Backhouse. "Relations Between Gardeners and their Employers," by Mr. Malcolm Dunn, F.R.H.S. "Lord Bute's Vineyards," by Mr. A. Pettigrew, F.R.H.S. "How to Popularise Orchid Growing," by Mr. E. H. Woodall, F.R.H.S. "Origin of Common Vegetables, and their Value as Food," by Professor G. Henslow, M.A., F.L.S., &c. "Chrysanthemums," Mr. C. E. Shea, F.R.H.S. "Principles of Judging at Flower Shows," by Mr. Jas. Douglas, F.R.H.S.

— **THE FRUIT PROSPECTS IN NORTH STAFFORDSHIRE**—These are, so far, very cheering. The Apple trees are very full of fruit buds. The recent copious showers are greatly helping them to burst. Plums and Damsons (for which this part is famous) will soon be a splendid sight, and should mild weather continue there will undoubtedly be heavy crops of fruit; there are good signs of healthy foliage, which will prove a great protection. Gooseberries and Currants are very promising, considering the damage done by the birds. Raspberries and Strawberries leave nothing to be desired in appearance, especially where the latter have been well protected with abundance of litter.—F. WARD, *Denstone*.

— **GUIDE TO THE KEW ECONOMIC MUSEUM.**—We have received No. 2 of this publication, which deals with Monocotyledons and Cryptogams. The preface says that "the botanical character of the plants represented by the specimens and products in this museum are chiefly these:—1, The embryo plant in the ripe seed has but one seed-leaf, or cotyledon (hence called Monocotyledons) and the first leaves alternate. 2, The species having woody stems, form isolated bundles of wood, which usually do not increase in thickness year by year; once formed they remain unaltered in diameter, scattered through the pith-like substance of the stem. 3, The parts of the flowers are usually in threes. 4, The veins of the leaves, excepting in a few orders, are parallel, or if diverging, not irregularly netted. The collection occupies two floors, commencing in room No. 1, on the left-hand side of the passage on entering by the north door. The number of each room is affixed above or by the side of the doorway leading into it. The cases and objects specified in this guide are each numbered consecutively from room No. 1. In all there are 147 cases, and the contents of each are described." Case 147 contains Myxomycetes, which have been more than once mentioned as injurious to vegetation by Mr. G. Abbey. The note on this case in the Guide is as follows:—"A small, but widely distributed group of organisms, remarkable for the power of voluntary movement during the earliest stage of their development. For this reason the group is considered by some authorities as belonging to the animal kingdom."

— **GARDENING APPOINTMENTS.**—Mr. J. Bennett, for some time gardener to Jas. Hornsby, Esq., Stapleford Park, Melton Mowbray, accompanies this gentleman to Laxton Hall, Wansford, Mr. Ellis succeeding as gardener at Stapleford, which has been purchased by John Gretton, Esq.

— **INJURY TO LAVENDER BY FROST.**—I was not at all surprised to see the note of reference to the quantity of Lavender plants killed by the recent frost about Wallington. Several acres have been under cultivation here for the last few years. I am sorry to say much of it is killed outright, especially the plants raised from slips inserted during the autumn of 1893, and finally planted last autumn.—E. MOLYNEUX, *Swanmore Park*.

— **BEES FERTILISING BEANS.**—On page 370 "English Bee-keeper" mentions Beans being fertilised through the agency of bees puncturing the blossoms at their base. This is done by other insects besides wild bees and *Apis mellifica*. Are the flowers fertilised in this manner? When the bees puncture the blossoms they are after honey, and do not come into contact with the anthers or stigmas of the flowers. I have perhaps not given the matter the attention to warrant a contradiction, but think so long as bees do not enter the mouth of the blossom they are of no service, but would like to hear what others have to say.—OBSERVER.

— **NATIONAL HORTICULTURAL SOCIETY OF FRANCE.**—The international horticultural exhibition to be held in the beautiful Tuileries Gardens, Paris, in connection with the above Society promises to be a great success. Applications for entries are very numerous, but considering that upwards of 30,000 francs are offered in prizes this cannot be wondered at. Special arrangements have been made with the Customs for the facilitating of the entry of exhibits from abroad. The show opens on May the 22nd, and continues until May 28th. Full particulars may be had from the General Secretary, Mons. Abel Chatenay, 84, Rue de Grenelle, Paris.

— **HORTICULTURAL LECTURES AT GRASSENDALE.**—The second course of horticultural lectures under the auspices of the Garston Technical Instruction Committee has just come to a most successful conclusion. In no other part of the Liverpool district can we point to such good results, every meeting being well attended. The following lectures have been given:—"Orchids," Mr. R. Todd; "Primulas, &c.," Mr. J. Glover; "Hardy Fruit," Mr. T. White; "Chrysanthemums," Mr. G. Haigh; "Herbaceous Plants," Mr. John Moir; "Cultivation of the Vine," Mr. J. J. Craven. In concluding, I may remark that Mr. Blomley has for a second time ably fulfilled the office of Chairman, and Mr. D. H. Browning, the courteous Secretary to the Instruction Committee, has worked with a zeal which has commended itself to all in the neighbourhood. The next course of lectures commences in October.—R. P. R.

— **DEATH OF MRS. A. H. SMEE.**—A large number of our readers will learn, as we do, with extreme regret of the death of this kind and estimable lady, which occurred on Wednesday in last week, after a long and painful illness, borne with great patience and fortitude. Mrs. Smeed shared with her husband the love bestowed on the garden, and took great interest in the varied contents in it and the well-being of the workers. A local paper, the "Carshalton Herald," publishes the following just and appreciative tribute to the memory of the deceased lady. "Mrs. Smeed had resided at The Grange for something like sixteen years, and during the whole of that time had taken an exceptionally active interest in the doings of the locality. She did not believe that her duty towards her neighbour had been done when she had forwarded a cheque to the local clergy or a subscription to some charitable society. She knew that sometimes a sympathetic word is of more value than silver or gold, and no inconsiderable portion of her time—which might perhaps have been more pleasantly spent in the social amenities open to her—was devoted to visiting and relieving the sick and distressed. Her character, kindly and sympathetic heart, always felt for those in trouble. The extent of her charity will never be known, and still less the number of personal services she rendered to her poorer neighbours in times of difficulty or trial. As an evidence of her kindly disposition and thoughtfulness for others it may be mentioned that at Christmas last, when she was weak and ill from pain almost past bearing, she herself took measures to insure that none of her pensioners and none of those she had been accustomed to help at Christmas time were without their customary remembrances, and her bereaved husband is not alone in his sorrow at her decease." Not alone, we may add, by a very long way, and many persons beyond the locality in which he resides will extend heartfelt sympathy towards the great amateur horticulturist.

— THE TIMBER SUPPLY OF THE UNITED STATES is being exhausted at twice the rate of its recuperation from tree growth.

— WE regret to announce the death of Mr. Andrew Kerr, Nursery Manager for nearly twenty years to Messrs. Stuart, Mein, Kelso, which occurred on the 14th inst., after a long and painful illness.

— TROPÆOLUM TRIOMPHE DE GAND.—This plant is grown to the best advantage at The Priory, Warwick. Some two or three dozen pots of it were placed at the foot of the iron rods that support the roof of the flowering house in the early winter, and after the plants had been trained to the glass they were continued until they met each other. The effect now produced is very charming and picturesque. Mr. Smith, the gardener, told me that some thousands of blooms had been gathered for winter decoration.—G. BURROWS.

— GROWING ASPARAGUS IN AUSTRIA.—A Belgian horticultural journal describes certain means employed in Austria to obtain enormous sticks of Asparagus. One consists in placing over the head of the Asparagus, as soon as it appears above ground, a wooden case pierced in its upper portion with holes to allow of the circulation of air. A more rough and ready method is the fixing of an inverted bottle over the plant, which grows through the neck. Asparagus grown in this way is not coarse and insipid like much giant Asparagus that is forced, but delicate and tender as the thin green wild variety, or the ordinary garden Asparagus.

— LILIUM HARRISI.—The growth of this plant has become an important industry in Bermuda, as indicated by the fact that the annual exportation of bulbs from the island to the United States for the past five years has, according to an American contemporary, been from 2,500,000 to 3,000,000. As the average production of every bulb is six flowers, from 15,000,000 to 18,000,000 blooms are used in America in decorations yearly. Of course this entire crop is not used for the Easter festival, as the Easter Lily has been popular for the past ten years for interior decorations, weddings, receptions, or other similar ceremonies. But American growers insist that fully 60 per cent. of the entire crop is used during Easter week.

— THE PLUM BLOOM.—This is everywhere just now a mass of snowy whiteness. What a promise does it offer of a Plum crop. The recent rains softened the air, the bloom buds, and leafage, therefore the burst of bloom was, almost irrespective of sort, simultaneous. We could just now do with rather more of sunshine to help set the flowers, but at least there is no frost, and the nights are not cold. If only one-fifth of the bloom produces fruit there will still be an enormous crop, and these immense crops are hardly desirable in the interests of the trees or of cultivators. It is not easy, however, to thin Plums on myriads of standard trees, as they are too big and too much out of reach. On bush and wall trees that can be done easily. In view of so great a Plum produce it will be well for fruit preservers to make the most of it, as we may have to wait a couple or three years before the trees can fully recuperate. The great profusion of bloom on the wild Blackthorn shows that it is a natural Plum season. We can now fairly hope to see a great and a profitable crop.—A. D.

— FUNGUS ON QUINCE.—The fungus which spots the leaves of the Quince and produces the black spot on the fruit is nearly always present, and this is especially true when the trees are standing in sod. It is from the effect of this disease that the leaves of the Quince often begin to fall in August and early September, while, of course, the foliage ought to persist until the fruit has ripened, for the loss of the leaves deprives the fruits of nourishment at the time when they are completing their growth. This defoliation also prevents the tree from storing up energy for the next year's crop. But not only is the fruit stunted before it is fully grown, but the fungus also attacks the fruit itself, causing cracks and lop-sided growth, as in the case of Pears when attacked by the same fungus, *Entomosporium maculatum*. In a late bulletin on the Quince in western New York, Professor Bailey shows that this fungus can be held at bay by spraying with the useful Bordeaux mixture. Half of the foliage fell from the unsprayed trees, and the remaining leaves were small and yellow. The foliage on the sprayed trees was large and dark green, and plainly helping the growth of the fruit. Experience seems to show that the spread of the spot may be wholly checked, even after the leaves are conspicuously marked by it. Of course, it is unwise to wait until the disease appears, and the first application ought to be made soon after the blossoms fall.—("Garden and Forest.")

— IT is stated that there are 82,222 ACRES OF RAISIN VINEYARDS IN CALIFORNIA, producing 80,000,000 lbs.

— THE FERN VEGETATION OF JAMAICA is said to be the richest in the world, comprising between 400 and 500 species.

— PEACHES IN MICHIGAN.—Michigan is entering the list as a Peach-growing State. Orchards are being formed of 500, 1000, and even 10,000 trees. The promoters of the enterprise anticipate a good return on their outlay, as the conditions are said to be favourable for the culture of Peaches.

— A LEXICON OF ORCHID HYBRIDS.—This is a little work of some 140 pages published by M. Octave Doin of Paris, and compiled by Herr E. Bohnhof. It is divided into two parts, the first containing a list of the artificial and natural hybrids known up to January 1st, 1895, the second consisting of tables to facilitate finding the parentage and synonyms of the hybrids, as well as those hybrids obtained reciprocally. What prefatory and explanatory matter there is apart from the tables has been expressed in English, French, and German, and will serve materially to extend the usefulness and popularity of the publication.

— CHISLEHURST GARDENERS' ASSOCIATION.—The members and friends of this Association celebrated the close of the fourth session by a dinner, on Wednesday, April 24th, the President, Mr. J. Lyne, occupying the chair, and thanked the members for the loyal manner they had supported him since he had filled that office. The Secretary, Mr. R. Filkins, in proposing "Continued Success to the Chislehurst Gardeners' Association," gave a résumé of the work done by the Association during the past year, and also presented a financial report, which was very satisfactory. Mr. McKirchor, from Messrs. B. S. Williams, replied to the toast of "The Visitors," and a most enjoyable evening was spent.

— THE PEOPLE'S PALACE AND EAST LONDON HORTICULTURAL SOCIETY.—We have just received the balance-sheet and report of this Society, and are glad to note the finances are in a prosperous state. The report, too, shows that good work has been done, and that flower culture in the East of London is being materially increased. We trust the Society will continue to flourish, and that the two shows arranged for the coming seasons will be great successes. Praiseworthy encouragement has been given by Messrs. B. S. Williams & Son of Holloway by the presentation to the People's Palace Winter Garden of nearly 300 plants, including Camellias, Azaleas, and Palms. The Honorary Secretaries are Messrs. H. E. Boulton, E. Flower, and C. E. Osborn.

— THE EASTBOURNE BATTLE OF FLOWERS.—The weather conditions were unfavourable at Eastbourne on the 24th inst., when the central feature of Carnival Week, the Battle of Flowers, took place. Up to the commencement of the proceedings the outlook was bright and promising, but heavy clouds then overspread the town, and for about an hour rain fell in copious showers, causing no little discomfort, and marring to some extent the spectacular effect of the fête. It, nevertheless, was a great success, alike in regard to the dimensions and brilliancy of the pageant, the crowds which gathered to witness it, the beauty and variety of the individual "exhibits," and the character of the arrangements. Decorations had been carried out on an extensive scale, especially on the Grand Parade and other thoroughfares traversed by the procession, the householders and shopkeepers having united loyally with the Fête Committee in beautifying the streets and buildings, and producing effects of colour and design that commanded general admiration. The abnormal assemblage of visitors was greatly swollen by the excursionists who arrived during the morning in thousands from London and all parts of Sussex, and such dense masses of holiday-makers have, perhaps, never before gathered in the town at any one time. There was inevitable crowding and excitement during the progress of the "battle," but excellent order was preserved. The procession, which was hailed with continued rounds of cheering, consisted of between sixty and seventy gorgeously decorated carriages, including four-horse coaches, pair-horse and single-horse vehicles, children's and village carts, and allegorical cars. In the decoration of the vehicles and horses drawing them, neither money nor trouble had been spared. At a given signal, after the judging was over, the flower-throwing between the spectators and processionists commenced, and this was kept up vigorously along the whole length of the Parade, some thousands of bouquets being utilised for this purpose. The fusillade occasioned much merriment, and the spectacle presented from the tribunes was extremely pretty.—("Standard.")

— THE presence in the sick room of FLOWERS WITH DELICATE FRAGRANCE is generally beneficial. Certain colours are said to act favourably on the nervous system. Red blossoms are stimulating, while delicate blue flowers are soothing.

— PROTECTING SEEDS FROM BIRDS.—In "Work for the Week," page 369, we are reminded of protecting seeds by means of red lead. The writer has overlooked what he probably knows, that brickdust is very often sold as red lead, and does not act as a deterrent to birds as genuine leads, red or white, do.—T.

— WEATHER IN THE ISLE OF WIGHT.—Mr. C. Orchard writes:—"We are having genial weather—mild bright days and showers at night, which is making everything that has survived the frost grow like magic. There is promise of a good bloom on all hardy fruits, and Strawberries are coming round, although they were apparently killed. We shall soon be able to see to what extent the more tender plants and half-hardy shrubs have suffered. Our usual summer visitors of the feathered tribe arrived not quite a week later than last year. Swallows were seen on the 9th, the nightingale heard on the 10th, and the cuckoo on the 11th of this month. I cut a dish of 100 Asparagus on Friday April 17th, whereas I cut last year on March 31st. If we are fortunate enough not to have any late spring frost everything looks promising for a good season of vegetables and fruits. The spring seeds are germinating far better than one could have expected after the bad harvesting season last year."

— COATING HOT-WATER MAINS.—In reply to Mr. W. Bardney's inquiry in "Notes and Gleanings" (*Journal of Horticulture*, April 11th) respecting the cost of coating hot-water mains with asbestos and other compounds. This can be done at a cost of 6d. per foot superficial measurement, and undoubtedly under any circumstances would effect a great saving in the cost of fuel. I regret I am not in a position to give Mr. Bardney an estimate of the amount of fuel that would be saved, as so much depends on the distance the mains have to be conveyed. As a matter of course, the greater the distance the greater would be the saving. In the case of a steam boiler the difference between an unprotected and a coated one would be about 10 to 15 per cent. in fuel, and I presume the saving would be much greater in that of greenhouse boiler and mains, as it frequently happens that great lengths of the latter are often exposed. This is a subject which deserves more attention than it has hitherto received.—W. I. D.

— EASTER DECORATIONS.—The tendency to use plants in flower for house and church decoration at Easter was, says an American contemporary, stronger this year than ever, and was conspicuously manifested in the increased size of the specimens offered. Of course, there was a great array of Lilies, and plants were valued according to the number of flowers they carried, each flower being valued at 25 cents. There were Dutch bulbous plants, Hyacinths, Tulips, and Daffodils in abundance; Violets and Cyclamens in pots, and Spiræas in great quantities, including some of the newer varieties under various names. Among many other shrubs forced into bloom Hydrangeas, Cytisus, and Azaleas were far the most numerous. Singularly beautiful plants of *Acacia paradoxa* commanded a ready sale. Among the other flowering shrubs specimens of the Tree Pæony *Reine Elizabeth* were very effective. Our native Laurel, *Kalmia latifolia*, *Andromeda speciosa* and *A. japonica*, Lilacs, Snowballs, *Boronias*, *Metrosideros* were more rarely seen, and the price for these varied according to their quality and size.

— VIOLETS IN THE WINTER.—Such a structure as that suggested by Mr. Haggart on page 344 cannot but have its advantages over an ordinary two-light garden frame if we are to reckon upon having such severe weather as that passed through during the past winter. I fear, though, in ordinary cultivators' hands much red spider would be the result with such a quantity of piping and such a small volume of air above the soil. If Mr. Haggart were to confine himself to a single row of 3-inch pipes around the pit, and not a flow and return both back and front, I think then the suggestion has much to recommend it. I do not agree with having a hotbed under the plants, no matter how slight. This is quite unnecessary. A space, however, for giving efficient drainage is necessary. With the aid of hot-water pipes the difficulty of opening the lights during 30° frost is much minimised of course, but some care will be necessary not to employ the heat too freely. In the hands of such an able cultivator, however, as Mr. Haggart I have no doubt about the results. Growing extra plants in boxes on a shelf in a vinery or Peach house is a good plan to save the opening of the frame during exceptionally sharp weather.—E. MOLYNEUX.

— ELECTRIC HEAT has been successfully applied to the thawing of frozen water pipes. A wire is run into the pipe until it meets the obstruction, and the current is then turned on.

— KEW GARDENS.—Orchids at Kew, says a contemporary, always exert a fascinating influence over the numerous visitors to the Gardens, and at the present time the display is large enough to be of considerable interest to orchidologists. A few days ago there were about 120 distinct species of Orchids in flower in the two houses devoted to Orchid culture, and besides these there were a few hybrids and several varieties flowering.

— VEGETABLE AND ANIMAL PARASITES.—These are now known to be the immediate cause of many of the diseases of plants and animals, but we do not yet know what are the direct causes which set these low organisms in motion. The germs of these little organisms seem to be continuously existent in localities where they have been once known. But they are not active, and consequently not observed, except when some peculiar combination of conditions occur. There is no difference in this respect between them and the common Mushroom. Spores, or reproductive organs of the Mushroom, will lie in the ground for many years in a perfectly torpid state. It is only when the exact temperature, the same degree of humidity, and quality of food, all meet together in conjunction, says "Meehans' Monthly," that the spores develop, and a full-blown Mushroom, with its cobwebby mycelium underground, rapidly grows. The millions of dollars spent by municipal corporations in "stamping out diseases" by various contrivances to destroy germs or spores are usually wasted, and though millions of germs may be destroyed, millions can never be reached, and these will make matters lively when the conjunctive conditions meet. Fortunately, Nature does not permit this often. The true effort lies in preventing the meeting of these conditions for germination, but until science tells us just what they are we are powerless. But it will come in time.

— WAKEFIELD PAXTON SOCIETY.—At the usual weekly meeting of the members of the Paxton Society held on the 20th inst., Mr. J. G. Brown of Cutwood was in the chair, and Mr. Herbert Chapman occupied the vice-chair. There was about an average attendance. A very useful, seasonable, and practical paper on "Rhubarb" was read by Mr. W. Hudson, head gardener to Mr. W. T. Marriott, J.P., of Sandal Grange, one of the oldest and most active members of the Society. Mr. Hudson dealt with his subject in a thorough and most interesting manner, and his lecture was attentively listened to and warmly applauded. The essayist not only dealt with the question of the general cultivation of Rhubarb, showing how to grow it in the open garden and how to force it, but he referred to some of the many uses to which Rhubarb may be put, and also alluded to some of its medicinal properties: Mr. Hudson commenced his lecture by describing the best mode of planting with Rhubarb in early spring a plot of ground which had previously been well and deeply dug or trenched, and liberally manured. If the new plantation was to be made from old roots these must be divided with a spade into separate parts, no matter how small if only a plump and healthy crown was retained to each portion. The divided portions should be planted singly, 3 feet apart every way, and during the summer they should be encouraged to grow by waterings of liquid manure. Where plants from seeds were used no division of the roots was necessary, and such plants might be placed 18 inches apart each way, and at the end of the second year's growth every other plant might be taken out for forcing. It was not wise to pull too freely the second year, but after that, if it was well attended to, they could scarcely hurt it by pulling. If they adopted annual planting, on however small a scale, it would be advantageous both in productiveness and flavour, and also in earliness and size of stalks. He recommended the following three varieties to follow each other in succession:—Prince Albert, Linnæus, and Victoria. Of course, artificial means had to be resorted to in order that early productiveness and the desired colour might be obtained. There were many ways in forcing Rhubarb. One was to place large pots over the roots as they were planted in the open ground, and then to cover the pots with a quantity of hot manure; but the practice most generally adopted was to dig up any number of roots and plant them in ranges of pits or frames heated by hot manure, hot-water pipes, or flues. Rhubarb made excellent wine, and he would not be surprised to hear that Rhubarb was responsible for a great deal of what is sold as champagne, and he would rather have good Rhubarb wine than bad champagne. A long and most interesting discussion ensued, in which several of the members took part, and then a very hearty vote of thanks was accorded to Mr. Hudson for his excellent paper.

## ROSE SHOW FIXTURES FOR 1895.

- June 19th (Wednesday).—York.\*  
 „ 20th (Thursday).—Colchester.  
 „ 25th (Tuesday).—Isle of Wight (Cowes).  
 „ 26th (Wednesday).—Richmond.  
 „ 27th (Thursday).—Gloucester (N.R.S.) and Canterbury.  
 „ 28th (Friday).—Exeter.  
 „ 29th (Saturday).—Windsor.  
 July 2nd (Tuesday).—Diss and Sutton.  
 „ 3rd (Wednesday).—Brockham, Croydon, Ealing, Farningham, Lee,† and Sittingbourne  
 „ 4th (Thursday).—Eltham and Norwich.  
 „ 6th (Saturday).—Crystal Palace (N.R.S.).  
 „ 9th (Tuesday).—Westminster (R.H.S.), and Wolverhampton.\*  
 „ 10th (Wednesday).—Chelmsford, Hitchin, and Redhill (Reigate).  
 „ 11th (Thursday).—Helensburgh, Woodbridge, and Worksop.  
 „ 17th (Wednesday).—Derby (N.R.S.).  
 „ 18th (Thursday).—Halifax.  
 „ 20th (Saturday).—Manchester.  
 „ 23rd (Tuesday).—Tibshelf.  
 „ 24th (Wednesday).—Chesterfield and Newcastle-on-Tyne.\*  
 „ 25th (Thursday).—Trentham.

\* A show lasting three days. † A show lasting two days.

I shall be glad to receive the dates of other Rose shows than those named above for publication in future lists.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

## PERPETUAL CLUSTER ROSE.

ON his return from the battle of Waterloo a soldier brought with him to Blantyre a blush Monthly Rose, which bloomed in clusters during the winter. I remember seeing the Rose as it grew near the window where the old soldier lived, and near my house. I saw it in bloom about Christmas, but a gardener, who grew and propagated it, says it bloomed in the severest winters. Is this Rose known in England or to the trade?—W. T.

## ROSES AND THE FROST.

Mr. WILKINS' suggestion on page 318 might be followed with advantage. At the same time, one should give a word or two on the situation, soil, and state of their Roses before the hard winter arrived. In connection with this subject I find a few curious records on page 318. For example, "B." states that Aimée Vibert is not nearly so hardy as Céline Forestier, nor L'Ideale so frost-withstanding as W. A. Richardson. Now, I have both of these, in many forms and all sorts of positions. L'Ideale, Aimée Vibert, and Kaiserin Frederich are three of the hardiest Roses I grow.

I can fully sympathise with Mr. Wilkins and "W. R. Raillem," for almost all of my standards and half-standards are gone. Not more than 10 per cent. of the buds worked last year on these stocks, and which were full of promise in the early part of the winter, are now alive. Mr. Wilkins and "W. R. Raillem" protected, and, nevertheless, seem to have suffered equally as bad. In one bed of Teas on the Briar I find only three varieties that are not killed outright; and, singular to say, all of these are Hybrid Teas—Viscountess Folkestone, Caroline Testout, and Triomphe de Pernet père.

"B." apparently did not protect, and he certainly gives a more hopeful account than the others. So often have I seen those protected suffer worse, if any difference, that to my mind it is waste of time. Dwarfs may be earthed up to advantage, and are then safe as regards the most valuable bottom eyes.

I was glad to see a further comment on the Messrs. Cocker's plan of non-protection. When "B." mentions his loss with Roses planted in December, may we not also take a further hint, and never plant in the dead of the winter? I would rather wait until spring than plant after the ground has got cold. Even during an ordinary winter, December and January planted Roses have frequently failed to turn out so satisfactorily as those moved at a time when new growth would be soon commencing. I can confirm "B." as regards the great hardiness of Rosa rugosa, also Mosses, the Scotch, and other Briars; I have not a single loss among Hybrid Sweet Briars, both in plant and bud. Another exceptionally hardy Rose is the old York and Lancaster.

As a commencement of Mr. Wilkins' suggestion, I may say our soil is an ordinary loam with a little lime, the main positions two open fields on the summit of a hill, facing due north and south. Both in the open and in sheltered beds on the southern sides of hedges our standards and half-standards are a failure. Old and young plants, as well as dormant buds, have been terribly hit on this stock, and once more do we see the great advantage of dwarfs over standards in any form.—A. PIPER, *Uckfield.*

## THE PROMISE OF HARDY FRUIT.

TAKING all kinds of fruit into consideration I think the promise of a crop is most favourable. Apples generally are well set with fruit buds, though there are exceptions. The trees exhibit a scarcity of promise. I allude more particularly to those which have been planted from three to five years. Trees of Warner's King of the age indicated are almost blossomless, whereas established trees are thickly clustered with plump flower buds. Other varieties might be named that are behaving in a similar way, notably King of the Pippins and Lady Henniker. The reverse is the case with Ecklinville and Cox's Orange Pippin; while Keswick Codlin, Lord Suffield, Worcester Pearmain, Lane's Prince Albert, Golden Spire, Hawthornden, and Alfriston are covered with blossom buds. Of the newer kinds Bismarck, Grenadier, and Lord Grosvenor promise well. Although it is a pleasing sight to see the trees wreathed in bloom, I do not always find that such trees yield the best crops of fruit.

Pears are not so abundant in their promise of fruit as last year, still taking them on the whole a fairly good Pear year may be expected. Plums, in spite of the heavy crops borne last year, bid fair to give satisfactory results. The trees are now expanding their flowers, and fine weather only is required to insure a full yield of fruit. Cherries in this neighbourhood never fail to give abundance of fruit, and this year is not expected to prove an exception to the rule. Peaches have flowered freely, and are setting well; but the continuance of rain, with the absence of sun, is making itself felt in the paleness in colour of the leaves. Trees growing in heavy, retentive soil quickly exhibit traces of this defect.

Gooseberries and Currants promise well, the trees of the former as yet showing no signs of red spider attacks. Raspberries have suffered very much from the severe frost. Many of last year's canes are injured and some killed down to within a few inches of the ground. It is surprising to see how well the Strawberry fields look in such a short time after the severe winter. A month ago many of the Strawberry plantations looked as though they were killed outright. Where the plants were neglected in trimming off the old leaves for some months after the fruit was gathered they appear to have suffered the most. Such an occurrence should answer as a guide in future. Early trimming of the leaves not required has much to recommend it, especially when followed by such weather as that experienced.—E. MOLYNEUX, *Hants.*

## TROPÆOLUM TUBEROSUM.

I SEND you tubers of this Tropæolum thinking you might like to plant them. The plants are well adapted for trailing over trellises or archways in any sunny position. The bright orange and scarlet flowers are very conspicuous in the autumn. What the Flame Plant, Tropæolum speciosum, is to the north this species is in the south, only the former requires a cool aspect and the latter an open sunny position. They do best in light rich soil, and grow very rapidly, reaching a height of 8 or 10 feet, or they look well trained over some Pea boughs, when they will interlace and form a dense bush. The tubers should be taken up in the autumn and stored in sand secured from frost. Although in the island here they remain in the soil as a rule, yet they are not safe in such a severe winter as the past one has been.—C. ORCHARD, *Bembridge, Isle of Wight.*

[We are obliged by the tubers, which are in themselves attractive, as will be seen by the engraving of one of them, associated with a flowering spray. We have often answered inquiries in reference to this old plant, which seems to be worth trying in suitable positions as suggested by Mr. Orchard. According to the "Gardeners' Dictionary" Tropæolum tuberosum was introduced from Peru in 1836. It seems to have been first grown in a spindling manner in pots in greenhouses, though it may have been a year or two sooner, as we find recorded in "Paxton's Magazine of Botany" that "in the early part of the summer of 1837, Mr. Young of Epsom, from a laudable desire of ascertaining the true habits and disposition of this plant, caused a number of tubers to be placed out in a bed in the open ground. As soon as they began to grow a few bushes were placed in the ground round each plant, and in the course of the summer they grew so vigorously and luxuriantly as completely to cover the bushes which had been placed for their support, and each plant formed a dense mass of verdure, 4 feet high, and full 6 feet in diameter. This, compared with the weak and stunted manner in which they had grown while kept in pots, was considered perfectly astonishing; still not the slightest disposition to produce flowers was discovered. However, about the latter end of September the flowers began to exhibit themselves from the axil of each leaf, and in the month of October each plant was most profusely studded with its elegant blossoms. It is worthy of remark that Nature seems to have furnished this plant with long flower stalks for the purpose of displaying the flowers, for every flower protruded itself beyond the leaves and branches, and stood out boldly and advantageously to

view. It is needless to add that the effect produced was beautiful beyond description.

"Some slight frosts occurring in the latter end of October, without injuring this plant, it was considered that it would prove quite impervious to the influence of cold; but a more severe one coming in November, the stems and foliage were completely destroyed, just as the flowers had attained to the highest degree of perfection, and it was

In reference to the last remark, Dr. Hogg records in the "Vegetable Kingdom" that the tubers of *T. tuberosum*, when cooked, are eaten by the natives of Peru. They have also been tried in this country, and been considered by some to form an agreeable dish. When boiled they are of a soft, pulpy substance, and in flavour resemble Seakale, mixed with the hot taste of garden Cress. Some who have thus used them state that they have a very delicate flavour, like the richest Asparagus,

FIG. 64.—TROPÆOLUM TUBEROSUM.

then deemed prudent to remove the tubers from the soil, and preserve them through the winter in a dry and dormant state. This should teach us that, to insure an abundant display of flowers without subjecting the plants to injury from frost, they should be planted out early in the spring, in which case they would doubtless form a most brilliant and attractive feature in the flower garden during the summer and autumnal months. These tubers are also edible, and Mr. Young informs us that they are, when boiled, superior in flavour to any Potato, though they are disposed to be watery, and do not boil firm."

and superior to the Potato, but they are disposed to be watery and not to boil firm. It has been found that, when used immediately after being taken up, the tubers have a disagreeable taste, and to remedy this, in Bolivia, where the plant is called *Ysano*, they freeze them after they are cooked, and eat them when frozen. The ladies of La Paz are very fond of them, and in the season of the *taichas* large quantities are sopped in molasses and taken as refreshments during the heat of the day.

The tubers sent by Mr. Orchard are the finest we have seen. They have not been cooked, but planted.]

## EXPRESS GRAPE GROWING.

ARTICLES in the last three *Journals* have proved very interesting to old Grape growers; how much more so then must they have been to the coming heroes in exhibiting campaigns?

Before saying a word or two on my success in rapidly fruiting Vines, I cannot help speaking of what I have seen respecting the statements of Mr. Wm. Innes. I think they only give a faint idea of the work he carried out. His vineries were well built on a field of good turf; his practical skill in erecting a powerful engine for raising water and warming the same with steam, with a knowledge of chemistry, and combining a healthy Vine manure for his own use, were great accessories to the success attending his labour. I think the last house erected by him the greatest marvel of skill in cultivating the Grape. He turned the first year of the house to good advantage in the form of an extraordinary crop of Tomatoes, grown on perpendicular wires while the Vines were growing, and took medals at London and Manchester. Perhaps Mr. Innes may kindly give us the history of cropping and planting this house.

Just a few words, though nothing new, on the quick cropping of Muscats, and having splendid ripe Grapes five months after planting. I selected extra strong canes from Mr. Pearson's stock in the autumn, started them early in the pots, made the border ready, having the house moist and warm, and planted early in March (now fifteen years back). They broke regularly, every eye showing fruit. The Vines were allowed to grow their full length as purchased, carrying four bunches to a rod, ripening grand finished fruit; with an extra row of supernumeraries in pots, fruiting well, the new house had a full crop. I was induced to cut back two rods to 3 feet the following year; they never came up to the mark again, but with the rods left intact a heavy crop resulted, many bunches weighing 6 lbs., and admirably coloured. The Vines are doing well to this day. So much for the non-cutting back method.

To replenish Vines take down a rod when started and showing the bunches; layer as many spurs as convenient in pots, with the bunch of Grapes attached. In a month's time you have rods 6 to 9 feet getting well established in the pots; after two months the rods are ready for severing from the parent, and planting in permanent quarters for a full crop the following year. I have a Black Hamburgh with four good rods so raised now, and fruit for thinning, that will soon be put in permanent places.

With all our express Grape growing we cannot cope with our veterans. Mr. Hill, Keele Hall Gardens, had in April, 1864, an early house of Grapes which sold for 21s. per lb., and in April, 1863, early house of Grapes which sold for 25s. per lb.

Statistics taken for Mr. Hill when I was with him in these good days, 1853 to 1863, are as follows:—

*Grapes*.—Royal Horticultural Society.—Twenty-two first prizes, eleven seconds, six thirds, large silver medal, silver Knightian medal, two first-class certificates.

*Grapes*.—Royal Botanic, Regent's Park, 1853 to 1863.—Twenty-three firsts, eight seconds, thirteen third prizes, and Mr. Ivery's prize.

Crystal Palace Company, 1855 to 1863.—Fourteen firsts, seven seconds, two thirds, extra, Lady Downe's. He had also first prizes at the shows of the British Pomological Society in 1859 and 1860 for collections of Grapes.—GEO. BOLAS.

ONE of your correspondents, Mr. Innes of Derby, referring to the article and photograph of one of my vineries in the *Journal of Horticulture*, pages 305 and 315, on the above subject, states that he planted a vinery August 11th and 12th with Vines raised from eyes in the month of March of the same year, and the Vines allowed to remain in the 3-inch pots they were rooted in until they were planted, and many of them were not more than 18 inches in length, and not stronger than a good straw, and yet they carried a very heavy crop, ten to twelve bunches on each Vine, the following year, averaging 2½ lbs., and that they were good enough for exhibition. I should like to say that I have had twenty-five years' experience with Vines, and I have not yet been able to get to the above standard, although I have had sixteen years of "Express Grape Growing," as you term it, and have been well satisfied with my results. But my experience is that to succeed we must keep the young Vines "going" early in the season, and have their growth finished about the time Mr. Innes planted his house, and then they have plenty of time to ripen the wood and plump the buds for the following year. I cannot see how Mr. Innes could possibly have a crop of first-class Grapes the following year after planting, for the Vines were allowed to be in 3-inch pots five months longer than they should have been, and being planted August 11th or 12th it seems to me that it would take them until the 1st of September to start into growth, and then we must allow them at least three months to fill the house with wood suitable to produce first-class Grapes. This lands us into the end of November or December. I should like to know how Mr. Innes ripened the supernumerary Vines at all when the roof must have been covered with the permanent Vines, which he states were cut back the following year. Has there been no mistake—an accidental mixing of years? Was it not 1889, instead of 1888, that the Vines did so well?—CHARLES COLEBROOK, *Grimsby*.

MUCH has been written in the *Journal* of late anent the wonderful results obtained in such short periods by various cultivators. It will be interesting to know how long the same Vines continue to give such results. For my part I must say I am sceptical about the life of such

Vines. I have noted more than one instance where wonderful crops were produced for a couple of years or so by extremely youthful Vines. Personally, I would rather see a continuation of a yearly good crop from what I call rationally managed Vines, and with a promise of certainty for the next fifteen or twenty years, than these mere "flashes in the pan" style of Grape-growing.

I have waited to see if any record would be published of Vines treated on the express system of culture and production that had given these wonderful results continuously for the last fifteen or twenty years. As yet I have not been gratified by such news. In the majority of cases the quotations have come from market growers. I wonder how many gardeners, with a limit of perhaps three vineries, there are who would like to risk the prospect of years of steady, regular crops for a few extraordinary results obtained by the system not in vogue when the likes of myself served our apprenticeships?

When I planted the three vineries under my charge sixteen years since last April I was bold enough to say I thought the Vines would last thirty years without renewing. Half that time has passed, and the Vines exhibit no diminution of crops; in fact, the house devoted to Muscats was better furnished with fruit last year than it had been in any previous season. The Vines were not allowed to cover their allotted space in an almost incredibly short space of time; but an abundant supply of fruit was maintained from the first by the aid of supernumeraries.

More than one vinery of my acquaintance that was planted in the same year as these have been replanted already, the result of attempting to obtain extra heavy crops. The cultivators of Grapes on the express system have much in favour of argument on their side as long as the same results continue. By our new fraternity I expect to be classed as one of the old fogies for penning this article. I, too, have some reason for argument—namely, results of the past as against prospective expectations.—E. M.

It is with pleasure that I comply with the courteous request of your correspondents, Messrs. J. J. Craven and "W. H. L.," in your last week's *Journal of Horticulture* (page 363). I will endeavour to relate my *modus operandi* as briefly as possible.

The Vine border in the house referred to was made up entirely of a strong clayey loam, cut from an old pasture, with the addition of six loads of river sand and one ton of our Fertilitas, all being well incorporated with the loam, and with this compost alone the inside border was completed before planting, and made up to the depth of 2½ feet. The garden roller was brought into use between the hot-water pipes, and where the roller could not be used the soil was thoroughly trodden, until the whole border was as solid as we could possibly make it.

When all was ready the Vines were turned out of their pots, partially shaken out, and the roots disentangled as well as we could under the circumstances, and laid in the soil to the depth of 4 or 5 inches, each Vine receiving in its turn (as the planting proceeded) a good soaking of tepid water. The planting being completed, which was all done in the cool of the evening, the Vines were shaded for several days during bright weather, and the house kept moderately close. The Vines were syringed three or four times a day until they began to show signs of moving, when the shading was gradually removed and the midday bath discontinued. An increased temperature was allowed both night and day, maintaining a night temperature of 70°, and from 85° to 90° during the day, closing the house early in the afternoon, raising the temperature 10° or 15°, using the syringe freely, and damping every particle of surface, and the vapour troughs were kept full of water.

The permanent Vines were stopped at the point where the supernumeraries reached the trellis. The latter were allowed to travel to the top of the house without interruption and were then stopped. In a few days the terminal buds were again on the move, and were allowed to grow unrestrictedly until the end of November, when these growths were gradually shortened. A brisk heat was maintained in the pipes and increased ventilation both day and night, with copious supplies of water and the free use of the syringe two or three times a week to preserve the foliage as long as possible until the wood was hard and brown. As soon as the Vines shed their foliage they were shortened as described in my last letter, and the house thrown open for about a month before starting it again.—W. INNES, *Derby*.

## THE GLOXINIA.

Now that seedlings, owing to careful hybridising and selection, are superior to what they formerly were, we do not find so much time and labour spent on the propagation of named varieties. The seedlings from a good strain are far more healthy and vigorous in growth than any propagated from a special kind.

Do not waste time in sowing seeds from an indifferent strain; far better have a much less quantity for the same cost. Many plants are already raised, yet sowing may still be done. Obtain some good leaf mould and bake it, so as to kill all vermin. Fill some pots or pans about three parts up with coarse compost of any kind, free from worms and other pests. Surface this with the baked leaf soil, peat, and sand in about equal parts. Make the whole level and firm, then thoroughly water through a fine rose. We do not want to use water sooner than can be avoided after the seeds are sown. Sow very carefully, and never cover the seeds with soil—simply lay a sheet of shaded glass over the whole, and place in a light position away from direct sunshine.

Keep the pans dark until the seeds commence to germinate, gradually

admitting more light by moving away the shading. The seedlings must be grown robustly from the first, and are apt to damp if kept too wet or shaded. Directly they are large enough to handle prick them into other pots or pans containing similar soil. They will then be ready for placing in thumb pots, which operation should be performed so as to avoid any check to growth, and stand the pots on a shelf close to the glass and in full light. Turfy loam, leaf soil, peat, well-decayed manure from an old Melon bed, and sand in about equal parts is a good compost at this stage. I stand the pots in this stage in shallow trays. It is easy to have a little cocoa-nut fibre refuse in these, and it not only avoids any risk of sudden drought, but they are easily removed when needed.

Always pot fairly firm and keep the corms or crowns a little above the soil. As they fill these pots shift them into their flowering size at once. If this stage is arrived at by intermediate shifts it is next to impossible to avoid serious injury to the leaves, and however handsome the flowers may be, they are of little value without good foliage. A little bonemeal mixed with the same compost as before will be suitable for the final potting. Place one good crock over the hole, and then with a few cinders sufficient drainage is secured for so porous a compost as this. Moisture, but absolutely fresh, is a great item with the Gloxinia. As they progress a warm, and finally an ordinary greenhouse temperature, will suit them well. Weak liquid manure is a great help, but it must be clean and applied with care. Any stain on the foliage is disfiguring, and it is very difficult indeed to remove.

Now a word upon propagation in other ways. Select a few of the best of the seedlings—which will be in bloom from July to September—and remove a well-matured leaf from each. Cut through the midrib and chief lateral ribs of these in several spots, and then lay the leaf on a compost of sand and cocoa-nut fibre refuse, placing a little dry sand on the surface of each cut. Keep the fibre and sand only moderately moist, and young corms will soon appear at each severance. Generally the leaf decays away safely; if not, cut away the decaying part. After the whole of the leaf has ripened or decayed the corms may either be taken out of the fibre and put in sand, or left as they are until the next season. I choose the latter plan, and fill a pot with leaves from one plant and insert a small label with a brief description of the flower. Stand the dormant corms in a greenhouse temperature; any odd corner will do so long as they are kept sufficiently moist to avoid shrivelling. At the time when more seeds are sown let these corms be potted up into thumb pots and treated exactly as described for the seedlings in the same stage. They will afford an earlier supply than the latter of the same season, after which I would cast them on one side, except in the case of an extra good variety, which may be retained for leaf propagation again. They do not come so robust and free-growing after continued propagation as seedlings, and we can each season choose from the cream of the latter, while by this selection we are sure of some good kinds in the first supply.—CULTIVATOR.

## ROYAL HORTICULTURAL SOCIETY.

APRIL 23RD.

SCIENTIFIC COMMITTEE.—Present: Professor Michael Foster, F.R.S. (in the chair), the Rev. W. Wilks, Drs. Hugo Müller, F.R.S., and M. T. Masters, F.R.S., with Messrs. McLachlan, F.R.S., Arthur Sutton, and G. F. Wilson, F.R.S.

*Fasciated Lily*.—From Baron Sir Ferdinand von Mueller came a photograph of a fasciated specimen of *Lilium auratum*, which bore 208, more or less, developed flowers.

*Superposed Bulb in Leucoium*.—Dr. Lowe, Wimbledon, sent a specimen of *Leucoium* with one bulb superposed on another. The older of the two bulbs had produced a cylindrical stem or rootstock about 1 inch in length, which bore at its extremity the new bulb, so that the two bulbs resembled beads strung on a necklace.

*Cuscuta on Pelargonium*.—Dr. Masters exhibited a plant of *Pelargonium* densely covered with a mass of long fine threads, which had been taken for aerial roots, but which were clearly the thread-like stems of a species of *Dodder*, probably introduced with the peat made use of in potting.

*Androgynous Willow*.—The same gentleman showed specimens of Willow catkins, the lower portions of which bore female flowers, the upper male flowers. Between the two were several flowers in which one stamen was perfect, whilst its neighbour in the same flower was half anther, half carpel. In some cases three catkins, one terminal, two lateral, merged from the same node. The catkins and the branches in the vicinity in some, but not in all cases, were marked by irregular swellings. These, when cut open, were each found to contain the larva probably of some beetle. It is thus a matter for speculation whether the irritation set up by the puncture of the insect had anything to do with the morphological changes observed.

*Saintpaulia ionantha*.—Dr. Masters showed flowers received from Mr. Ernst Benary of Erfurt, showing a considerable range of variation in size and in colour. With reference to this matter, the proposal to refer this East African genus to the Chinese *Petrocosmea* was mentioned, and the opinion of Mr. C. B. Clarke, the monographer of the order, was cited to the effect that until the ripe fruit of *Saintpaulia* was examined, and the numerous new forms of this order lately introduced, carefully investigated, it was considered better to retain for the present the genus *Saintpaulia*—though, in all probability, it would eventually have to be merged into some other genus.

*Cattleya Lawrenceana*.—Sir Trevor Lawrence, President Royal Horticultural Society, sent a raceme of this species bearing six flowers,

all of which presented the same peculiarity. The two lateral petals were joined at their inner edges, and adherent also to the back of the column.

*Lindley Library*.—Mr. Arthur Sutton obligingly presented to the Lindley Library a fine copy of L. Plukenet's "Opera Omnia," six volumes in two. Plukenet's volumes have an historical interest, as they serve to fix the date of introduction of many garden plants. Plukenet was botanist to Mary, Queen of William III., was Superintendent of the Gardens at Hampton Court, and at one time had a botanic garden of his own not far from the present site of the offices of the Royal Horticultural Society.

### LATE-FLOWERING CHRYSANTHEMUMS.

THESE, for many purposes other than show, have a special value. For the table, conservatory, and Christmas decorations late Chrysanthemums will always be in demand. M. Délaux is sending out two new varieties of this description, which he says begin to flower in December, and are fully out by January 1st. They are called *Heliotrope* and *L'Hiver fleuri*. He has some others under trial, and it is to be hoped that before putting them into commerce they will be thoroughly proved. Another French grower, M. Sautel, promises some similar additions from his seed bed.

### HAIRY CHRYSANTHEMUMS.

Notwithstanding the "boom" a few years ago for hairy Chrysanthemums, there does not seem to have been sufficient encouragement offered to induce the raisers to produce new varieties in any great numbers. I notice, however, that the N.C.S. has a class for six varieties distinct, in which the following prizes are offered: Silver cup, presented by Mr. A. Pooley, for the first prize; silver medal, second prize, and a bronze medal third. Out of the novelties for this season the Americans do not offer any new seedlings of the hirsute section, and the French announce about eighteen. Most of the latter, however, are from an obscure grower, and will probably not reach this country at all.

### NEW CHRYSANTHEMUMS FOR 1895.

The number of new French seedlings announced for distribution this spring is simply bewildering, and what is a noticeable feature in connection with the subject, is the increasing number of new seedling raisers. Tempted, perhaps, by the success of some of the older raisers, new ones are now coming forward every year to offer their productions to the Chrysanthemum importers and growers. I notice the names this year of seventeen different raisers, which is unusually large, and their contributions, consisting of early, late, hairy, and ordinary November flowering varieties, amount to 345 supposed new sorts. It is too tedious to calculate how much money is required to purchase the whole of these novelties, and I have no doubt it will not be attempted by any of the English trade, although we may expect to find the seedlings of such well-known growers as Messrs. Delaux, Calvat, Boucharlat, De Reydellet, and several others at the trade displays next autumn.

The Americans do not seem to be quite so prolific. Eight distributors in America announced the more modest number of sixty-seven varieties between them, with about a score of others which are stated to have been introduced from Japan. Mr. Spaulding takes the lead with twenty-five, but nearly all the other American raisers are content to put into commerce only about half a dozen each.—C.

### THE CHRYSANTHEMUM IN ART.

AT the Centenary Conference of the N.C.S. which was held in 1890, Mr. Haité, the well-known artist, read a paper under the above heading which will be found reported *in extenso* in the Journal for Dec. 4th of that year. Reviewing the various types of Chrysanthemums from an artistic standpoint, Mr. Haité specially draws attention to the Japanese form, which, both in England and Japan, is regarded by art workers as the kind of flower most suitable as a decorative subject.

I think, however, that the Japanese artist can have but very few examples of the true incurved Chrysanthemum, as we know it, at hand, because this type is essentially a European production. But even supposing they had, there is every probability they would not select it with the freedom with which they do the looser and less formal Japanese flowers. These certainly seem to appeal to the artistic temperament, and to the taste of the ladies much more forcibly than their stiff and formal rivals.

Japanese pottery, fans, textile fabrics, pictures, metal work and carvings, almost without exception, depict only blooms of the Japanese type. Sometimes, but very rarely, an Anemone may be found, but in any case where an incurving flower is represented the variety chosen is of the Comte de Germiny or Mrs. C. W. Wheeler build.

During the past few years the European artists, ever ready to seize new ideas, have borrowed very largely from their Japanese *confrères*, and anyone interested in the flower whose walks have taken them in the West End, and other busy places in London, cannot have

failed to remark how largely the popular Oriental flower has been used in what may be termed commercial art work in England. Wall papers, cretonnes, tapestry, China, pottery, and many other domestic and decorative articles have been the subjects of *Chrysanthemum* ornamentation by English designers, and in corroboration of Mr. Haité's remarks almost without exception has the subject been some form or other of the Japanese type.—P.

### THROUGH THE PARKS.

WHAT the green oasis is to the weary traveller over the Saharan Desert, so are the parks and open spaces to the dwellers in this vast city, and fortunate it is that so many of them have been kept intact from the encroachment of the speculative builder. There, within easy distance of the busiest street or most crowded slum, are to be found sylvan scenes and rustic nooks, where the eye may rest on Nature in her most pleasing garb, or the mind be so enraptured with the quietness of the scene that it is possible almost for one to forget for the moment that one is in the midst of the metropolis.

London dwellers may well feel proud of the spacious parks, for it is in this respect that the metropolis has such an advantage over any other large city in England. A pleasing aspect about such as Hyde and Regent's Parks is that there is little of that stiff, artificial look which so characterises many such places. Nature seems to have special thought for the dwellers in the crowded city, for once within the gates may be seen huge forest trees growing in magnificent splendour, flowers blooming profusely, and birds singing, whilst the rich verdure of the grass on every side show that in spite of the smoky surroundings, that each and all are doing their share towards making the scene pleasant to all who see it.

Great is the credit due to the authorities for their commendable efforts in producing at the several seasons of the year brilliant and varied displays of flowers, which add so much to the brightness of the scene. A special feature in Hyde Park at the present time is the refulgent beauty of the bulbous flowers, a sight which has only to be seen to be appreciated. On entering at the Stanhope Gate a whole sheet of bloom presents itself, all discriminated with excellent taste, there being no erroneous mixing of colours, but all harmonising in pleasing unison.

Several of the beds are mixed, one with the fine *Narcissus* Sir Watkin and the rose-coloured Queen of the Hyacinths; another with *Narcissus* princeps and blue Hyacinth Couronne de Celle; and another with *Narcissus* Golden Spur and fancy coloured Pansies.

A pleasing effect is caused by a mass of white Hyacinth *alba maxima* surrounded by Pansies, and followed by a bed of *H. King of the Blues* and *N. Horsefieldi* mixed. White Hyacinth *La Grandesse* planted alone looks charming, as also does a bed of the yellow *N. maxima* mixed with the light blue Hyacinth *Regulus*. A special feature is a group of blue Hyacinth *Grand Maître*, the spikes and flowers being especially fine, and encircled by the rose coloured variety *Lord Macaulay*.

Again may be seen Hyacinth *L'Incomparable* in mass and surrounded by *H. alba maxima*. Especially worthy of mention are large beds, centered with light rose Hyacinth *Fabiola*, the white *La Grandesse* forming a band round. Many beds are devoted entirely to *Narcissi*; amongst others being *N. maximus* Emperor, *Sir Watkin*, and princeps. Hyacinths *La Grandesse*, *Lord Derby*, *General Havelock*, *Mont Blanc*, *Charles Dickens*, *Lord Wellington*, and the graceful habited *Mina*, may also be seen to great advantage.

Tulips, single and double, are strongly in evidence, their bright and varied colours rendering them especially noticeable. Amongst the doubles are beds of *Tournesol*, *Murillo*, *Gloria Solis*, and others; while the singles are represented by *Proserpine*, *Queen of the Violets*, *Chrysolora*, *Cottage Maid*, *La Belle Alliance*, *Queen Victoria*, *Duchesse de Parme*, *Joost Van Vondel*, and *Yellow Prince*, the last named emitting a pleasant scent.

A striking feature is several beds of single Tulips and *Doronicum plantagineum* mixed indiscriminately together, and blooming profusely.

Masses of the blue *Muscari botryoides* have a pretty effect, whilst Wallflowers, Daisies, Auriculas, Polyanthus, and Primroses are accorded prominent positions. The modest *Scilla sibirica* forms the groundwork for several beds planted with *Narcissi* *Horsefieldi* and Emperor.

The view presented in the flower garden in Regent's Park is one of equal merit; the beds are laid out with great taste, the bright and varied colours of the flowers being very effective. The beds are situated amid sweeping avenues of Horse Chestnut and Lime trees, all bursting forth in the bright verdure of the spring, and forming a bright contrast to the spread of flowers which form, as it were, a groundwork to the landscape. In spite of the ravages caused by the severe frost amongst the ornamental and other shrubs, many are now growing profusely, whilst the Flowering Currant looks very pretty amidst the dense green.

The modest *Saxifraga crassifolia* may be seen peeping from under the shrubs, whilst the grass banks, clothed with *Narcissi*, Hyacinths, and Tulips, all mixed in pleasing harmony, present a sight perhaps more charming than the more orthodox style of planting.

Other beds are formed of *Narcissi*, Auriculas, Tulips, *Sedum glaucum*, *Scilla sibirica*, *Sempervivum calcareum*, and others. Large vases, massed with single Tulips and others with yellow Wallflowers, are exceedingly pretty. Beds planted respectively with Primroses, *Doronicums*, Wallflowers, and Auriculas form a bright display, while one of the chief

features is formed by long borders planted indiscriminately with Hyacinths, Daffodils, *Dielytra spectabilis*, and Auriculas.

Beds of Hyacinth *gigantea* surrounded with white Violas are effective, as so are others with mixed Hyacinths in various colours. Especially noticeable is a large triangular bed of *N. Sir Watkin*, around which is a band of dark Wallflowers. Hyacinths *Chas. Dickens*, *Roht. Steiger*, and others are exceedingly fine, while amongst the Tulips bright displays of *Keyser's Kroon*, *Duchesse de Parme*, *Joost Van Vondel*, *Yellow Prince*, *Cottage Maid*, and *Proserpine* add much to the richness and variation of the display.

The bulbs flowering in the London parks this year were supplied by Messrs. Jas. Carter, High Holborn, London, the general excellence of which is a great credit to the firm, as the effect caused by them is one that it would be difficult to excel.

Long might one linger amid this maze of floral beauty, admiring this or comparing that; and in conclusion, it is not superfluous to add that great credit is due to those in charge for the exquisite manner in which the whole has been planned, and it is gratifying to know that without travelling outside the precincts of London everyone who is so disposed may, without any charge, feast his eyes on these charming gems of the spring.—WANDERER.

### PLANT-FORMING ELEMENTS.

I READ with considerable interest the full and instructive article on the above subject which appeared in the last two issues of the *Journal of Horticulture*. I think it is well worth the careful study of all those who are interested in horticultural work, for there is much to be learnt from it. I noticed on page 332 Mr. G. Abbey says "argon" enters into the composition of plants. "Argon," being a newly discovered element, it would be interesting to know something more about it; but I failed to find anything further about it in the articles named. Mr. G. Abbey must have had some authority for the above statement, so perhaps he can explain "how it is assimilated by plants," for it would not do to assume that because argon and nitrogen are found so intimately connected together that they must consequently be both taken up by the plant. From recent experiments carried out by Professor Ramsey to see if "argon" could be found in plants or animals, he came to the conclusion that none was present, but that probably the method of analysis was not suitable for its detection.

Further investigations are needed, but until they have been carried out we must be satisfied with what Mr. G. Abbey can tell us on the subject.—W. DYKE, *Turnford, Herts.*

### AMONGST THE DAFFODILS.

WHEN one reaches the Long Ditton Nurseries of Messrs. Barr & Son, Covent Garden, he is certainly amongst the Daffodils, for there are in all upwards of 15 acres devoted to this class of bulbous plants alone. The picture is a glorious and at the same time an impressive one, such as can only be seen at rare intervals. Great breadths of all the most popular varieties are seen, such, for instance, as a plot of *Barri* conspicuous, containing something like 20,000 bulbs. Impress this fact on the mind, and endeavour to realise what the effect will be when you stand in front of the beds, and some small idea may be formed of the display that is made. Then near at hand is a stretch of *Emperor*, with its stout foliage and handsome substantial flowers. Here, again, are about 12,000 roots, and the effect is perhaps even more striking than that of those previously named. Certainly, seen as they are at Ditton, Daffodils are well worthy of their popularity, and one might say of even more than is at present accorded to them.

The names of Barr and Daffodils may now safely be termed synonymous, and it is just possible that the compilers of the next big dictionary will so far recognise the fact as to place it on permanent record. There can be little doubt that if a letter was addressed to Messrs. Daffodil & Sons the postal authorities would promptly deliver it at 12, King Street, Covent Garden, and in doing so they would be right. If one might be allowed to coin a new word one might dub Mr. Peter Barr a daffodilist, because he has in collecting and studying them, made himself conversant with their history and with the varieties now grown to a remarkable extent. He has wandered (by no means aimlessly) over thousands of miles, ever on the look out for something new, and it is to these journeys that we are indebted for many extremely beautiful introductions. In this good work of finding new forms and studying old, Mr. Barr has found an able colleague and lieutenant in Mr. William Barr, who is at present in Cornwall investigating the flowers of the Scilly Islands. As all lovers of Daffodils thirst for novelties, and knowing that the Messrs. Barr will continue their energetic labours, they may be sure of having their wishes gratified to a good extent, and in the furthering of the popularity and increasing the cultivation of these plants the firm will doubtless secure the reward it so very richly deserves.

It is a well-known fact that if a certain variety of Potato be grown on the same land year after year it will deteriorate, and it is equally well known that if the same sort is planted on entirely new ground, providing, as it will, a change of food, it will improve sometimes to a very remarkable extent. This fact, as Messrs. Barr have proved, is just as applicable to *Narcissi*, and with admirable foresight they have taken an area of land in the southern part of Lincolnshire where Daffodils

are known to thrive with the sole object of improving their stock, not so much numerically as in point of quality. This was first done as an experiment, and it turned out most successful. The plan followed is to plant the bulbs first at Ditton and then to remove them to Lincolnshire, a system that has been found to improve them in every respect. Of course, this system entails much additional labour and expense, but it will doubtless prove remunerative in the long run. We can hope so, at any rate.

As it is no joke for the interested visitor to have to wander over some fifteen acres of ground to see his favourites, and then stand a chance of missing some of the best, provision has been made to obviate all this. What may be called sample beds have been made up, comprising examples of all the varieties grown in the nursery, and these are situated immediately on entering. This is indeed a boon, especially when a visitor is very much pushed for time, and it is important that a certain train be caught. Of some varieties there are several rows, whereas of others there will be found only one. This system may be termed unique, inasmuch as it provides very great advantages to the examiner without a single disadvantage. Of course after the visitor has gone closely over these samples he can then walk round the beds and take general glances at the whole collection. Though only so few bulbs are planted in many cases in these beds, the effect is a very pleasing one.

To name all the sorts that are grown would be a very big task, and it would not serve any useful purpose, as so many of them have been widely grown for a number of years, but perhaps a short selection may prove acceptable to those readers of the Journal who have not been, and will not be, able to see for themselves. The various sections, it is perhaps needless to add, are all largely represented, and it will not be attempted here to classify them to any particular extent, as such details may be readily procured from the very comprehensive catalogue issued by the firm.

First on the list must come the superb Weardale Perfection, which was figured in the *Journal of Horticulture* for April 19th, 1894. It is certainly one of the most massive of the large trumpet section, though it is closely followed by Glory of Leyden, which with the first named should on no account be omitted from a collection, at any rate not from one that has aspirations to perfection. Belonging to this group is Madame de Graaff, a bloom of which is represented in fig. 65. This variety is of a white or very pale sulphur colour. Such varieties as Emperor, Empress, Horsefieldi, and Her Majesty are so well known and so highly appreciated that they need no words here. P. R. Barr, a seedling from Emperor, is very beautiful, and is securing numerous admirers.

FIG. 65.—NARCISSUS MADAME DE GRAAFF.

Belonging to another section, and different in every way, is Leedsi Beatrice, one of the most chastely beautiful varieties in commerce. The flower (see woodcut, fig. 66) is almost pure white in colour, and it should receive more attention than is the case at present. Two other Leedsis of merit are Ceres and Gem, each of which might well be grown. Of the Barris probably conspicuous is the best, but another charming form is albus Sensation.

Of the incomparabilis group Sir Watkin is usually accorded the place of honour, but another equally worthy of mention is Gloria Mundi, which is not quite so large and has a much flatter cup. Other grand sorts are sulphureus Hogarth, Jas. Bateman, and Duchess of Westminster. Besides these there are the ever popular Poet's Narcissi and

the charming double forms, but sufficient have now been mentioned to give an idea of how diversified is the collection.

Tulips and Hyacinths have also made a glorious display at these nurseries, but they are now fast getting past, such being, in fact, the case with the Narcissi, all having been so severely injured by the tremendously heavy rains to which they have been subjected.—H.

#### FLOORS CASTLE GARDENS.

THROUGH the kindness of Her Grace the Duchess of Roxburghe I have twice had the privilege of visiting the famous gardens and grounds of Floors Castle, in Roxburghshire, one of the noblest and most impressive of the many grand mansion houses of which Scotland can boast. It was erected from designs of Sir John Vanbrugh, the celebrated

FIG. 66.—NARCISSUS LEEDSI BEATRICE.

architect, in 1718, receiving, however, at a comparatively modern date those elaborate and extensive additions, designed by Playfair of Edinburgh, which have made it the palatial edifice it is now. Floors Castle, as its original name of Fleurs implies, wears all its weight of majesty lightly, like a flower.

One of the finest views of this charming residence of the Duke of Roxburghe is obtained from Kelso Bridge, where the silvery Teviot unites its waters with those of the classical Tweed. The prospect from that point is exceedingly imposing, and lingers enduringly in the regions of memory. The marvellous combination there presented of rivers, woodlands, and distant mountains is one more easily remembered than described. Right in front is the town of Kelso, assuredly one of the most beautiful in Scotland, deriving much grace from its proximity to the ducal domain, with the noble fragment of its ancient Abbey, founded contemporaneously with those of Jedburgh and Melrose, towering above the houses to a height of 70 feet. The architecture of the Abbey is Saxon or early Norman, with the exception of the central arches, which are of Gothic design. To me it was more inspiring than even Melrose, so greatly glorified by the genius of Sir Walter Scott. I did not, however, contemplate the latter in the "dim moonlight," hut in the glaring blaze of day.

When first I had the gratification of visiting Floors Castle and its romantic surroundings I was conducted through the gardens by the Minister of Kelso—a college friend of mine—whom I was visiting at that time. On the second occasion I had the congenial companionship of Mr. Nicolas Barnes, now head gardener to His Grace the Duke of Westminster, who has promised to show me at some future, and I hope not far distant period, the floral glories of Eaton Hall.

The "artificial" system of garden decoration has often been condemned, but there can be no question that when the finest "Geraniums," Begonias, Lohelias, and Calceolarias are so splendidly combined and artistically contrasted as I saw them at Floors they constitute a uniquely superb effect. But, for such a combination of dazzling colours (amply relieved by surrounding foliage) the most faultless artistic intuition is necessitated, and that, as most of us know from observation, is seldom found.

What impressed me chiefly, however, during my visit to Floors Castle was the wealth of tropical flowers, several of which had conservatories to themselves. Some of the Orchids were especially attractive, among the finest of these being the *Cœlogynes*, *Cypripediums*, *Cattleyas*, and *Lælias*, including my own supreme favourite *purpurata*, *Aërides*, *Calanthes*, *Odontoglossums*, and exquisite *Oncidium*s. I did not notice that unique Orchid *Anguloa Clowesi*, of which I saw some very striking specimens last May at Mr. William Bull's establishment at Chelsea. For my first introduction to this singularly interesting variety I am indebted to another great orchidist, Mr. Chamberlain. For any

acquaintance I may possess with distinguished modern hybrids I am indebted to those consummate hybridists, Messrs. Sander of St. Albans.

I saw at Floors, on the occasion of my second visit, an immense variety of Palms, tropical Ferns of vast dimensions, Lapagerias, Camellias, and Gardenias; many of which were already past the flowering season, while others were in full bloom. The Duchess of Roxburghe, like Her Grace of Sutherland, is an ardent cultivator of Lilliums and Carnations; among the former being giganteum, auratum, chalcedonicum, longiflorum Harrissi, Martagon album, davuricum, and speciosum; these representing the following great families—viz., Archilirion, Eulirion, Martagon, and cardiocrinum. The Carnations cultivated at Floors Gardens are for the most part (with the exception of the imperial Malmaison, which luxuriates in the conservatories) border varieties, such as Germania, Gloire de Nancy, Crimson Clove, Pride of Penhurst, Raby Castle, and Mrs. Reynolds Hole. The last-mentioned variety has nothing to recommend it save its colour and dimensions, it has no fragrance, and invariably splits its calyx—a serious limitation. The Duchess of Roxburghe would do well to add to her extensive floral collections a considerable number of modern Roses of great merit for garden decoration.

The following are among the fruits which, at the period of my visit, were cultivated at Floors:—Black Hamburg, Muscat of Alexandria, Lady Downe's, Gros Colmar, and Gros Maroc Grapes; the Royal George, Gros Mignonne, and Prince of Wales Peaches; Lord Napier, Humboldt, Pine Apple, Elruge, and Victoria Nectarines; Jefferson, Green Gage, Transparent Gage (Rivers), Coe's Golden Drop, and Magnum Bonum Plums; May Duke, Morello, Frogmore, and Bigarreau Cherries; Moorpark and other Apricots; and all the leading species of Apples and Pears, among the latter being Williams' Bon Chrétien, Marie Louise, Pitmaston Duchess, Beurré Diel, Louise Bonne of Jersey, and Doyenné du Comice.

I might have spoken of the magnificent trees, many of them several centuries old, by which Floors Castle is on every side environed; of the intense historic interest of the surrounding scenes; of Kelso, and the early days of Sir Walter Scott, when his happiness was brightest, before Fame came to him with her awful penalties, and shattered his noble life; of Flodden Field and its Flowers of the Forest, and "Cheviot's Mountains Blue;" but it would require a pen more eloquent than mine to do justice to such themes, and therefore for the present I must bid Floors Castle and its classic surroundings a reluctant adieu.—DAVID R. WILLIAMSON.

#### STANSTEAD PARK NURSERIES.

CLOSELY as the name of Laing is associated with Tuberous-rooted Begonias it is almost, if not equally, as much so with Clivias and Caladiums, but these latter not having attained to such extraordinary popularity, the connection is not so widely recognised. Notwithstanding this it cannot be doubted that the ability and energy of the founder of the house of John Laing & Sons, together with the branches, have been indefatigably devoted to, as it were, popularising the two useful classes of plants named. New varieties have yearly been put in commerce, each in some respect superior to its predecessors, until to-day the collections have reached a point that could not even have been dreamed of a few years ago. The numerical advance has certainly been far more rapid with the Caladiums, but in point of quality the running has been very even.

These plants are, however, hardly comparable from a utilitarian aspect, as the Caladium is, as everyone knows, a foliage plant requiring heat and moisture to bring it to perfection, whilst the Clivia, or Imantophyllum as it used to be called, is a flowering plant that attains to the highest excellence in the greenhouse. Then, again, the points looked for in the one are entirely opposite to those in the other. The leafage of the Caladium must depend on its colour and surprising venation for its place in popular esteem; the Clivia, on the contrary, being entirely dependent on its flowers, and not on the bold, strap-like foliage which, however fine, would not of itself prove a sufficient recommendation to extensive culture. Let us then, after taking these things into consideration, go through the two collections, and see which are the most worthy of cultivation in each.

The Clivias coming first in the houses may be accepted as the whole and sole reason of putting them in the premier position in these notes. They are plants that ought certainly to be represented in every greenhouse, as they combine an exceptionally striking appearance with an unusually strong constitution, which renders them of great utility for decorative purposes where something of an imposing nature is desired. The culture, too, is of the simplest, so much so in fact as to permit of an inexperienced amateur growing them with almost an equal success as the professional gardener, who as a rule has so many more conveniences, as well as the benefits derivable from a thorough knowledge of the plants and their requirements. Not that the amateur, who perhaps has only one small house at his command, can have such large plants or maintain such an extended display of blossom as his brother, but the plants may be quite as creditable in every way, and productive of as much or perhaps more pleasure and interest. In addition to the ease of cultivation Clivias have another recommendation, and an important one—namely, freedom from insect enemies. This may well be called an important point, as there are so few greenhouse plants that are not subject to attacks in some form or another. Certainly Clivias are liable, but even if insects do establish themselves on the leaves these are of such a nature as to permit of speedy and effectual eradication by the aid of a sponge and some water.

Despite these merits Clivias cannot be said to be very largely grown. It is true we may see them in many gardens thriving remarkably well, but in some only one or two can be found, while in others again they are conspicuous by their absence, and that in places where they could be easily grown, and where they would certainly prove of great value. One might be inclined to think that the price was prohibitive, was it not known that they can be purchased at very low rates, much lower indeed than numerous other occupants of our greenhouses, that have not nearly so many good attributes to commend their culture. But we will not devote time and space to surmises, none of which may hit the nail on the head, but at once enter a protest against this neglect, and a plea for their greatly extended cultivation. We cannot expect the popularity of the Begonia or the Rose, but they might well be placed on a par with many other plants that could be mentioned, and it is highly probable that they would give quite as much satisfaction, and perhaps more than some.

As the varietal names of many may not be familiar to some readers it may be of use to mention a few of the best that were seen in Messrs. Laing's establishment a few days ago. Let it, however, be borne in mind that all are not enumerated, there being many others that might find as much favour as the undermentioned, so much naturally depending on individual taste in the matter of colouration. Bright in hue, of stout substance, with a sturdy habit of growth, the one named Firefly will probably please everyone. It is new, flowering this season for the first time, and this again will be a point in its favour to those whose thirst for novelties may be termed nothing short of insatiable. It is a grand addition, and its flowers are as near scarlet as any sort at present in commerce. Entirely distinct from the foregoing in respect to colour, age, and brightness is Sulphureum, which tells its own shade. Though old it must not be omitted, as it lends variety and thus enhances interest. The truss of Duke of Teck is very fine, the colour being a pleasing orange scarlet; while Duke of York, though of somewhat the same colour, is distinct in the shape of the flower, which is very handsome. Other noticeable varieties were Patrick Davidson, Mrs. Laing, Mrs. Joseph Broome, Beechdale, Scarlet Perfection, Lady Wolverton, Miss Ellen Terry, Ignea, Mrs. John Laing, and last, but by no means least, the Right Hon. Joseph Chamberlain, the merits of which were recognised in a practical manner at the last meeting of the Royal Horticultural Society by the assignment to it of an award of merit. Though brief this selection contains none but of good quality, and may be accepted *in toto* as worthy of close attention.

Turning now to the Caladiums, we find a class of plants providing a wider and more diversified range than those previously named, only in this case the whole of the beauty lies in the leafage. It is, perhaps, unfortunate that Caladiums must have, to grow them successfully, a good amount of artificial heat with a moist atmosphere. These essentials are obstacles to their culture by many amateurs, who may only have very limited accommodation, but if they have a warm structure it will never be complete in the foliage section until it contains a number of these very beautiful plants. The range of colouration covered by Caladiums is very wide, and the peculiar transparency of the leaf texture with the charming venation render them objects of interest and admiration. No other plants possess these attributes to such an extent, and hence no doubt their great popularity in establishments where the needful conveniences for growing them are at hand.

The Laing collection of these plants is a complete one, probably comprising all the sorts best worth growing, and it is kept up to date by the addition of any new variety of merit that may be introduced from time to time. To enumerate all the varieties would be almost an impossibility, and brief reference will therefore be made to those only that were the most conspicuous, either in respect of size or colouration of the foliage. It is difficult to know where to commence, but it is thought that general admiration will be accorded to L'Automne, which has rather long whitish-green leaves with lilac coloured spots and patches. It is very distinct, as also is Lymington, a green leaved variety with white markings. Other excellent kinds are James H. Laing, Mons. Degros, Madame Hubert Koechlin, Le Nain Rouge, Comte de Germiny, Comtesse de Maille, Golden Queen, and Ibis Rouge, and these, though few in number, must suffice in the present reference.

Though Clivias and Caladiums have received attention in these notes, there are many other plants of interest and beauty in the Stanstead Park Nurseries, and as they cannot be specified here it is recommended to readers that they pay a visit and make their own judgments, travelling either by the L.B. & S.C. Railway to Forest Hill, or the S.E. Railway to Catford Bridge, both of which are within easy walking distance.—NOMAD.

#### NEWCASTLE-ON-TYNE FLOWER SHOW.

THE Newcastle Spring Flower show was held on Wednesday and Thursday, April the 24th and 25th, at the Olympia. The entries, says a local contemporary, were fewer than usual, but the tables presented an attractive appearance, and the larger exhibits of tubed plants were in as gorgeous bloom as we are accustomed to see them on these occasions. The large plants in front of the platform in particular presented a mass of colour, consisting chiefly of white Deutzias and crimson Azaleas. There was also a very fine row of large plants under one of the galleries, the first prize, Countess of Haddington Rhododendron, being especially noteworthy. It was covered with almost perfect flowers of white and pale pink. It was sent by Mr. N. Black, gardener to Miss Pease, Darlington.

The fine lofty Palm sent by Mr. J. Kennedy, gardener to Mrs. Lange, Gateshead, attracted a lot of attention at the end of the hall nearest the doorway. It was flanked on either side by the first and second prize stands of plants exhibited respectively by Mr. J. Wood, gardener to Mr. Hopper, Morpeth, and Mr. J. McIntyre, gardener to Mrs. Pease, Darlington. Mr. Wood's stand showed a brilliant surface of variegated colours, prominent among which were those of varieties of Orchids, Crotons, and Amaryllis. Mr. McIntyre's stand was well arranged, but in less striking tones than the other.

Near the platform Messrs. Wm. Fell & Co., nurserymen, Hexham, exhibited, not for competition, a very fine collection of Ghent Azaleas and Azalea mollis, Tulips, cut Narcissi (including nearly all the varieties in cultivation), and Palms. Messrs. Robert P. Kerr & Sons, nurserymen, Liverpool, had on exhibition a striking lot of new Amaryllis seedlings in various hues of red. Other lots not for competition included a pretty stand of cut flowers by Mr. W. Handysides, Newcastle; a stand of choice Ferns by Messrs. W. Edwards & Son, Nottingham; and a stand of preserved Palms from Messrs. Carnegie & Co., Newcastle. Mr. John Forbes, nurseryman, Hawick, sent a fine collection of Polyanthus and Primulas.

There was but a moderate show of Spiræas, Cinerarias, and Dielytras, but in the same line of tables was a very numerous representation of Hyacinths, the greater part of one side of a long table being occupied by them. While they presented a very pleasing picture to the eye in those pretty and delicate tints that develop so charmingly out of the bulbs, they were not seen at quite their best. Last year's wet season has prevented them ripening properly. The display of yellow Narcissus was good. There was a small but choice selection of Orchids and a few lots of Roses of the yellow Maréchal Niel variety hardly so fully developed as usual. There was a good show of Tulips and Cyclamens.

By far the greatest attention was paid, as usual, to the bouquets and epergnes in the cut flower section. Here the display was very fine. The first prize for bridal bouquets was secured by Messrs. Perkins and Sons, Coventry, the well-known artistes in this department of floriculture, with a charming composition, in which white Orchids and Gardenias were the chief items. The same firm was first for the coloured hand bouquet, which was made up of crimson, yellow, and shades of pink in Roses and Orchids. Mr. F. Edmundson, Newcastle, took first place in the epergne competition, and obtained the Banksian medal of the Royal Horticultural Society. His epergne consisted of a base of red, yellow, and white Roses, surmounted chiefly by Orchids, Lily of the Valley, Marguerites, and sprays of feathery grass.

### BIRMINGHAM DAFFODIL SHOW.

APRIL 24TH AND 25TH.

THIS, the third annual Narcissus exhibition of the Birmingham Botanical and Horticultural Society, was pronounced to be the largest and finest of its kind ever held in Birmingham, filling, as it did, all available space in the large exhibition conservatory and the new annexe. Unfortunately, however, the unpropitious state of the weather, especially on the second day, proved inimical to a good attendance of visitors.

Mention alone of the names of several of the leading firms and amateur Narcissi growers in this country and from the Continent as contributors to the show would be sufficient to indicate the quality and extent of the productions. The Rev. G. H. Engleheart's new seedling Ajax, Ellen Willmott, was awarded the silver medal as the best flower in the show.

Accompanying this now champion of Daffodils the same exhibitor was awarded a special certificate for his new incomparabilis, Dorothy Yorke, similar to the Lulworth, but with a wider open cup of intense glowing red colour, and also for his chaste and elegant Snowdrop. Altogether his group of beautiful hybrids proved to be one of the strongest attractions in the show.

The silver medal offered for the best collection of Narcissi was strongly contested for by Messrs. J. R. Pearson & Sons, Nottingham, and the Rev. S. Eugene Bourne, Lincoln, and so nearly alike were they in the opinion of the judges that eventually they were awarded equal prizes. As worthy of notice in this collection mention may be made of the splendid Weardale Perfection, the superb Lulworth, Captain Nelson, Gloria Mundi, Duchess of Westminster, Flora Wilson, C. J. Backhouse, Queen Sophia, Madame de Graaff, the magnificent Glory of Leyden, and the beautiful cream-coloured and chaste Mary Magdalene de Graaff, whilst the cream of the Nottingham collection comprised such as Katherine Spurrell, J. B. M. Camm, Golden Spur, Glory of Leyden, Weardale Perfection (a single bloom), and the beautiful Mary Anderson. All of the above, including several other varieties in this splendid collection, were much admired. Messrs. De Graaff were represented by a collection of about thirty kinds of seedlings, including Glory of Leyden and Mrs. Pope. An exquisite "shower" bouquet, composed of a tasteful arrangement of Daffodils of the most delicate shades, was staged by Mr. Pope, and was deservedly awarded the first prize. This was closely followed in merit by a similar arrangement by Mr. Geo. Newell (gardener, W. G. H. Kenrick, Edgbaston); the third prize being awarded to the Rev. J. Jacob, Whitechurch, Salop.

Amongst local contributors, Mr. R. Sydenham was awarded a silver medal for a collection of Narcissi, Streptocarpus, and Uriah Pike Carnations in pots and in a cut state. To Professor Hillhouse a certificate of merit was awarded for a collection of Daffodils in pots. Mr. F. M. Mole, Edgbaston, exhibited an interesting collection of cut hardy

Daffodils. There was only one table decoration, a tasteful arrangement, by Miss L. Ashby Bolton, Edgbaston.

Silver medals were awarded to Messrs. P. Barr & Son, London; Messrs. James Veitch & Sons, Chelsea; and Mr. T. S. Ware, Tottenham, for large and grand stands of Narcissi. Messrs. Barr & Son also staged a showy group of Tulips and bulbous alpines. Special certificates were awarded to Messrs. J. Veitch for collections of blue Primroses and a fine plant of Alyssum saxatile citrinum. In this section Messrs. Pope & Son exhibited a group of very pretty new hybrid hardy Primroses and Auriculas.

Prizes were offered for Narcissi grown in pots, and which were fairly well shown by several exhibitors. The following is a list of prize-winners:—For a collection of Daffodils Messrs. Pearson & Son and the Rev. S. E. Bourne, equal; third prize, Mr. Wilson, South Cave, Yorkshire. In the remaining classes the chief prizewinners were the Rev. S. E. Bourne, Messrs. Pope & Son, Rev. J. Jacob, Messrs. G. M. Crawford, J. W. Wilson, W. J. Grant, Rev. S. P. Haydon, Miss Maybell, Messrs. W. G. Newell, M. Coyer, M. Scearly, Knight, Miss Lasky, and the Rev. G. H. Engleheart.

### NATIONAL AURICULA SHOW.

APRIL 27TH.

THE northern section of this Society held its annual exhibition at the Botanical Gardens, Manchester, on Saturday last. Owing to the late spring none of the exhibitors could show their usual strength, and the display, particularly in the edged classes, was a disappointing one. Many exhibitors of note were unable to stage any plants at all, and were it not for the fact that Alpines were shown in large numbers, the show would have been a failure. Polyanthuses were in better form than usual, and some seedlings of great refinement were shown by Messrs. Oldham and Thornley. Messrs. Beswick and Gorton showed seedling Alpines, showing marked improvements in this popular flower. Mr. Charles Turner, Slough, exhibited one beautiful variety, Roland, large in size, beautifully flat, good centre, and broad shaded edge of purple. Mr. Bentley exhibited some good seedling selfs, to one of which, Gerald, a deep maroon self, very circular and perfectly flat, a first-class certificate was given. The awards were as follows:—

Class A, six dissimilar Auriculas.—First, Mr. T. Lord, Todmorden, with selfs, Mrs. Potts and Brunette; grey edges, George Lightbody and Richard Headly; green edge, Rev. F. D. Horner; and white edge, Acme. Second, Miss Kirke Penson, Ludlow, with self Mrs. Douglas; grey edge, Lancashire Hero and George Lightbody; green edge, Col. Taylor; white edges, Heatherbell, and Beauty. Third, Mr. J. W. Bentley, Middleton, with selfs, Mrs. Potts, Carbuncle, and Miss Lewis (seedling); white edge, George Rudd; grey edge, Complete; green edge, Rev. F. D. Horner. Fourth, Mr. B. Simonite, Sheffield. Fifth, Mr. J. Dicken, Ashton-under-Lyne. Sixth, Mr. Stokes, Birmingham.

Class B, four dissimilar Auriculas.—First, Mr. T. Lord, with Mrs. Potts, Rev. F. D. Horner, George Lightbody, and Acme. Second, Miss Kyrke Penson, with Mrs. Potts, Rev. F. D. Horner, George Lightbody, and white edge John Simonite. Third, Mr. Bentley, with Mrs. Potts, Complete, Hibernia, green edge; and a seedling, white edge.

Class C, pair of Auriculas.—First, Mr. R. Gorton, Eccles, with Heatherbell and a seedling self. Second, Mr. W. H. Midgley, Halifax, with Rachel and Mrs. Potts. Third, Mr. G. Middleton, Prestwich, with Beauty and Mrs. Potts. Fourth, Mr. E. Shaw, Moston, with George Lightbody and Brunette. Fifth, Mr. J. Wood, Stalybridge, with Acme and Confidence. Sixth, Mr. Stelfox, Stalybridge. Seventh, Mr. Buckley, Stalybridge.

Class E, single plants, green edges.—First, Mr. Lord, with Rev. F. D. Horner. Second, Miss Kyrke Penson, with Lovely Ann. Third, Mr. Lord, with Prince of Greens. Fourth, Miss Kyrke Penson, with Colonel Taylor. Fifth, Mr. Bentley, with seedling. Sixth, Mr. Buckley, with Lancashire Hero. Seventh, Mr. Simonite, with James Hannaford. Eighth, Mr. Bentley, with Hibernia.

Class F, single plants, grey edges.—First, Miss Kyrke Penson with Dinham. Second, Miss Kyrke Penson with George Lightbody. Third, Mr. Middleton with Rachel. Fourth, Miss Kyrke Penson with Lancashire Hero. Fifth, Mr. Midgley with George Rudd. Sixth, Mr. Midgley with Alexander Meiklejohn. Seventh, Miss Kyrke Penson with C. E. Brown. Eighth, Mr. Wood with Confidence.

Class G, single plants, white edges.—First, Mr. Gorton with Heatherbell. Second, Mr. Lord with Acme. Third, Mr. Lord with Conservative. Fourth, Miss Kyrke Penson with True Briton. Fifth, Mr. Shaw with John Simonite. Sixth, Mr. Simonite with seedling. Seventh, Miss Kyrke Penson with Frank Simonite. Eighth, Mr. Lord with Beauty.

Class H, single plants, selfs.—First, Mr. Bentley with Gerald (seedling). Second, Mr. Bentley, with Sybil (seedling). Third, Mr. Lord with Mrs. Potts. Fourth, Mr. Bentley with Red Perfection (seedling). Fifth, Miss Kyrke Penson with Black Bess. Sixth, Mr. Bentley with Elsie (seedling). Seventh, Mr. Simonite with Flamingo. Eighth, Mr. Bentley with Carbuncle.

Premier Auricula of the show, George Lightbody, shown by Miss Kyrke Penson.

Class I, four dissimilar Alpines.—First, Mr. J. Beswick (Middleton) with Bright Eyes, Dr. Knott, John Allen, and another seedling. Second, Mr. R. Gorton with Emir and three seedlings. Third, Mr. Stokes with Mrs. Walker, John Allen, John Ashton, and Rev. Mr. Durnford. Fourth, Mr. Bentley with Chas. W. Needham, Mrs. Martin, John Allen,

and seedling. Fifth, Mr. C. Turner (Slough) with Mrs. Harry Turner, Countess, Roland, and Winnifred. Sixth, Mr. Clements. Seventh, Mr. Lees (Middleton).

Class J, pair of Alpines.—First, Mr. Stelfox with Diadem and seedling. Second, Mr. Wood with Diadem and seedling.

Class K, single plants, yellow centres.—First, Mr. Beswick with Rev. Mr. Darnford. Second, Mr. Beswick with John Allen. Third, Mr. Gorton with seedling. Fourth, Mr. Gorton with Emir. Fifth, Mr. Beswick with Percy. Sixth, Mr. Bentley with Chas. W. Needham.

Class L, single plants, white centres.—First, Mr. John Lees with seedling. Second, Mr. Turner with Winnifred. Third, Mr. Beswick with John Ashton. Fourth, Mr. Gorton with Stanley. Fifth, Mr. Beswick with seedling. Sixth, Mr. Gorton with Mrs. Beswick.

Premier Alpine of the show, Mr. Charles Turner with Rowland; and special prize for the best plant of John Allen, Mr. Bentley.

Class M, three dissimilar black-ground Polyantheses.—First, Mr. A. Oldham (Middleton) with Mrs. Brownhill and two seedlings. Second, Mr. Beswick with Mrs. Brownhill, Cheshire Favourite, and Lancashire Hero. Third, Mr. G. Thornley (Middleton) with Mrs. Brownhill, Exile, and Cheshire Favourite. Fourth, Mr. Middleton with Mrs. Brownhill, Exile, and Cheshire Favourite.

Class N, three dissimilar red ground Polyantheses.—First, Mr. Thornley, with Middleton Favourite, George IV., and Sidney Smith. Second, Mr. Middleton, with William IV., Lancer, and George IV. Third, Mr. Beswick, with Middleton Favourite, Exile, and William IV.

Class O, single plants, black grounds.—First, Mr. Thornley, with Mrs. Brownhill. Second, Mr. Oldham, with seedling. Third, Mr. Beswick, with Cheshire Favourite. Fourth, Mr. Thornley, with Exile. Fifth, Mr. Thornley, with Mrs. Holden.

Class P, single plants, red grounds.—First, Mr. Thornley, with seedling. Second, Mr. Thornley, with George IV. Third, Mr. Thornley, with William IV. Fourth, Mr. Thornley, with President. Fifth, Mr. Middleton, with Middleton Favourite.

#### HARDY FRUIT GARDEN.

**Disbudding.**—As soon as the fruit has set on Apricots, Peaches, and Nectarines proceed with the operation of disbudding superfluous growths, continuing it gradually until all unnecessary shoots are removed, and only those left which are essential for the continued productiveness of the trees, to provide for due extension, and to encourage the proper development of the fruit. Apples, Pears, Plums, and Cherries may have the growths thinned out immediately the latter are long enough, they having made considerable progress as a rule before the trees flower, but in this respect reference is made chiefly to Apples and Pears. It is best to take the earliest opportunities of disbudding, so that the process may be spread over short intervals without having recourse to frequent removals of large quantities at one operation. Severe disbudding disarranges the circulation of the sap to an extent which may prove an unfavourable if not a serious check. Therefore, for this reason alone, it is best to commence in time, the stronger the growths the greater is the check to the flow of sap. When the weather is cold, and growth makes no progress, cease disbudding until activity in the trees recommences. Attend first to the higher parts where the vigour is the greatest, and work downwards to the weaker, which may well be left later, not only without detriment, but with positive advantage.

**Apricots.**—As these bear fruit both on the young wood of the previous year and on spurs formed naturally disbudding should be proceeded with carefully, removing first the ill placed growths wherever situated. Those on the back and under sides may be dispensed with entirely. Any promising shoots on the front of permanent branches that appear likely to develop into natural spurs may be left, preventing other young shoots obstructing light from them. They need abundance of both light and air, that their development may be gradual, tending to fruitfulness. Leave a sufficiency of young shoots all over the trees as successional to take the place of the present bearing growths. One from the base of each of the latter is ample for this purpose, except where there are vacancies to fill, when two may be reserved. The shoot at the point of the bearing branch must be allowed to grow, so that sap is attracted to the fruit. It may, however, be pinched at the third or fourth good leaf lateral, the sub-lateral growth following being kept to one leaf.

**Peaches and Nectarines.**—As a rule with these, the bearing parts are kept confined to the young wood, natural spurs not forming so freely as with Apricots. Any that do form should be encouraged by giving them full exposure. They prove useful on the front part of branches, and at other places where it is necessary to dispense with annual growths, spurs may be developed, though crowding of these, as of other growths, must not be tolerated. The management of the young successional shoots reserved at the base of bearing wood is precisely the same as for Apricots. As the growths advance lay them in in the proper

direction. Shorten the leader of the bearing shoots when the lower leaves are large enough, reserving three of the best to assist the fruit swelling, which is of great importance. Without such aid the fruit drops prematurely, and the prospects of a crop are spoiled. Sometimes an error in shortening the bearing shoots at the winter pruning to a wrong bud may result in this, as it is impossible for wood growth to be produced from those parts containing only blossom buds. The first available wood growth may in such cases be made a leading shoot, and the part barren of wood buds shortened to where one starts, providing there is fruit below. If not, these details are unnecessary, the shoot being eligible for cutting out entirely, giving the space for the training of a successional shoot. Very strong growths issuing from dormant buds at any part may well be cut out before they assume the form of robbers, and utilise a large amount of sap, to the detriment of medium and weak wood. If well placed, however, for filling up vacancies existing reserve them, subduing their vigour somewhat by stopping, so as to cause the sending out of side growths, which will be of medium strength, and more likely to be fruitful.

**Plums.**—Wall trees require the shoots on the young wood regulating by disbudding the ill-placed and weakest, such as those on the back and under sides, reducing the front growths to fair distances apart. Any of these that do not assume the desirable characteristics of naturally developed spur growths should be induced to do so artificially by pinching to the third good leaf. Reserve a number of well placed shoots for growing full length, eventually laying them in to the wall without crowding.

**Apples and Pears.**—Growths are very freely produced from wall and restricted trees generally, a large proportion of which might be gradually reduced by disbudding. Besides growth from visible buds there is a number from quite dormant buds, both among the spurs and on the old branches, and it is these which choke the trees with useless, unfruitful growths. Their removal is extremely beneficial to those left, and simplifies the management later in the season. What will ultimately be spray in the centres of standard and half-standard trees may easily be rubbed or cut off now.

**Vines on Walls.**—If pruned on the spur system all growths beyond two must be removed from each spur, leaving one to bear fruit and the other as a successional shoot to be pruned to two buds the following winter. Where strong, well-ripened canes have been laid in some of the buds must be rubbed off. Bearing growths a foot apart are quite close enough to admit of the foliage having a proper share of light and air.

#### FRUIT FORCING.

**Peaches and Nectarines.**—*Earliest Forced House.*—In the structure containing trees of Alexander or Waterloo and Early Louise Peaches, Advance and Early Rivers Nectarines, started about the middle of December, the fruit is ripening or ripe. The foliage must be kept dry, as water will act injuriously upon the fruit, but due supplies of water should be given at the roots, also the floor and other surfaces sprinkled twice a day in bright weather and occasionally in dull, so as to secure a fair amount of atmospheric moisture. This is essential to the health of the foliage, which otherwise would be injuriously affected and the wood and buds become prematurely ripened.

Trees of the standard varieties, such as Hale's Early, Royal George, Stirling Castle, Dymond, and Grosse Mignonne Peaches; Lord Napier, Darwin, and Elruge or Stanwick Elruge Nectarines that were started early in December are now taking their last swelling, and must not suffer for lack of water at the roots; the atmosphere ought also to be kept moist by frequently sprinkling the paths during the day, syringing the trees in the morning and again when closing the house. This will keep down red spider. It is imperative that the foliage be perfectly clean when the fruit commences to ripen, as the syringing must then cease over the trees, and the red spider, if any, will then so increase as to seriously imperil the current crop and prejudice that of the following year. The night temperature will be quite safe at 65° to 70°, and 5° less, though retarding the ripening, will not tax the energies of the trees so much as the higher temperatures. Leave the ventilators slightly open constantly at the upper part of the house for effecting a change of air and preventing the deposition of moisture upon the apex of the fruit. This is sometimes provocative of "spot" in the finest specimen, as the fungus and moisture are co-relative conditions. In the daytime 70° to 75° by artificial means, and 10° to 15° more with sun heat, will be suitable temperatures. Cease syringing the trees directly the fruit commences to soften for ripening, otherwise the skin will be disfigured and the quality deteriorated, often acquiring a musty flavour, due to presence of a minute fungus or mould.

*The Stoning Period.*—When the stones are being formed hurrying the trees may bring off the greater part of the fruit, and overcropping, even if stoning be effected, has a tendency to promote premature or imperfect ripening, the fruit not swelling freely, nor attaining good flavour. A temperature of 60° to 65° at night and 70° to 75° by day is as high as is safe until the stoning is completed; therefore avoid high night temperatures and sudden fluctuations by careful attention to ventilation. A little air left on at night will prevent the deposition of moisture on the foliage to any serious extent, increasing the ventilation when the sun shines upon the house in the morning, yet without lowering the temperature. Avoid fumigation or even vaporisation at this stage, as there is danger of crippling the foliage, and this gives a check such as sometimes causes the fruit to fall. Early closing is an advantage in promoting the advancement of the fruit, but it must not be done to the extent of undue excitement, nor be continued too late,

the temperature being allowed to decline with that of the sun. A little extra latitude given the growths will aid the fruit in the last swelling, but on no account allow foliage to be made that must be removed afterwards in large quantity, as this will give a check disastrous to the crop.

**Trees Swelling their Fruits.**—When the fruit is set it swells rapidly until the commencement of the stoning process, then remains comparatively stationary for a month or six weeks, and after that takes the final swelling for ripening. The first swelling is materially accelerated by a genial condition of the atmosphere, and the means employed to secure a good root action with a steady progressive development of the growths are best effected by a judicious and gradual regulation of the shoots by the process of disbudding. Thinning the fruit early and judiciously is essential to secure a good size in the first swelling, as the matter that would otherwise be expended in the fruit removed goes to those retained for the crop. Overcrowding must be avoided by judicious thinning, leaving no more growths than can have full exposure to light, removing any surplus gradually, so as not induce very vigorous growth in the shoots retained. Avoid a confined moist atmosphere, as this favours wood growth at the expense of the fruit. Ventilation must be such as to insure the thorough elaboration of the growths as made, keeping them short-jointed and sturdy. The more vigorous the tree the greater is the danger of the fruit being cast in stoning, and the mischief is aggravated by severe disbudding. In the last swelling after stoning the shoots should be well tied down, so that the fruit may have the benefit of all the light possible, and also be exposed to the sun. Moderate lateral extension materially assists the swelling of the fruit, care being taken that the principal foliage and fruit be not interfered with. Inside borders must be thoroughly watered when necessary, and extra nourishment given to weakly trees, either in the shape of approved fertilisers as top-dressings washed in or as liquid manure.

**Figs.**—*Early Forced Trees in Pots.*—The fruit of the large varieties, such as White Marseilles and Brown Turkey, is now ripening or ripe, and the supply of water at the roots being diminished, but not so as to affect the foliage, and if the syringing is discontinued, and a free circulation of warm, dry air afforded, leaving a little ventilation by the top lights constantly, excellent dishes of wholesome and luscious Figs will be produced. These drier conditions must be relative only, for moderate soil moisture and a congenial atmosphere are necessary for good results in the second crop, and may be secured by an occasional damping of the paths and walls in bright weather, or when the surfaces become dry. As soon as the first crop is gathered examine the trees for red spider and scale, syringing them with approved insecticides. Syringe twice a day, renew the top-dressings, and water at the roots with weak liquid manure. If the second crop be very abundant thin it by removing the fruits at the upper part of the growths, leaving that for the crop nearest to the base, being careful not to overtax the trees, as this will prejudice the first crop another season.

*Early Forced Planted-out Trees.*—The fruit is advancing rapidly for ripening, and in taking the last swelling is greatly benefited by thorough moisture at the roots without undue moisture arising from the soil. Mulching the surface after a good watering prevents evaporation to a great extent, encourages surface roots, and a good result in the second crop is assured under other favouring conditions. Cease syringing the trees when the fruit commences ripening, avoiding a superabundance of moisture about the house, having a little ventilation at the top constantly and a free circulation until the fruit is all gathered. Fruit intended for packing should be gathered slightly under ripe, so as to keep a few days and travel better than thoroughly ripe; but Figs for home use should be left until they have "tears" in the eyes, the skins cracked with lusciousness, and the head drooping; then they are delicious.

**Succession Houses.**—Attend to stopping side or spur growths at the fifth joint, and subsequently to one or two, but too many side shoots must not be encouraged, as the fruit and wood require light and air for maturation. Train in extensions their full length, thinning or removing strong growths, so as to admit light to those retained and to the fruit. Syringe the trees so as to prevent attacks of red spider, supplying water as necessary to maintain thorough moisture at the roots. Renew the mulching, especially where the trees are in restricted borders, and keep it moist so as to encourage surface rooting, and feed with top-dressings of the advertised fertilisers.

**Strawberries in Pots.**—There is always danger of red spider appearing on Strawberry plants forced in vinerias and Peach houses, and it is soon transmitted to the Vines and Peach trees, becoming a source of much anxiety to the grower. Much can be done to prevent infection by removing the plants to another structure for finishing off, but there is not such convenience in many places, so that the arrangements are mainly confined to keeping up a succession of fruit. Crops ripening too fast may be retarded in a variety of ways for several days in case an extra supply is required for particular purposes. Turning the fruits from the sun, shifting the plants to a north house, or after the fruit is ripe removing the plants to an airy fruit room or even open shed, taking the usual precautions against birds, are some of the expedients, and others will suggest themselves. Plants intended for affording late supplies and grown in low houses or pits should have their flower-spikes thinned to the requisite number, and if the pots are stood on ashes, or even plunged, there will be a moist genial atmosphere highly favourable to the plants, provided the material is kept properly moist. Many excellent Strawberries are grown in frames, the plants being plunged in coal ashes well up to the glass, but leaving room for a circulation of air to play between the glass and the leaves of the plants, and the forward plants from these structures can always be selected to take the place of

those that are ripe or ripening. Duly supplied with water, and fed with liquid manure, very fine fruits are obtained in cold frames, and they come in a fortnight before outdoor supplies.

#### PLANT HOUSES.

**Mignonette.**—Plants that are flowering should not be allowed to seed or their growth will soon be brought to a standstill. When this is done the plants under good treatment continue to grow and yield fine spikes of bloom. When the pots are full of roots clear root water should be given every time the plants need water. On no account must the plants be allowed to become dry, if they do the foliage will soon turn yellow and the spikes of bloom be very poor. Plants raised from seeds sown in 5-inch pots in September, liberally thinned to four or five plants and pegged down, may be allowed to come into flower if needed. The plants not needed to bloom may have the first flowers removed, and the spikes from the next growth will be finer. The plants should occupy a cool airy place and stand on some moisture-holding base. Where standards or large pyramids are required for autumn or winter, seeds of Parsons' White and Miles' Hybrid Spiral should be sown at once in 2½-inch pots, and covered with a little soil. When large enough the young plants should be thinned to one for the former and three or four for the latter. The plants should be grown for a time in an intermediate temperature, and then be transplanted to a cooler structure, never permitting them to become root-bound; 10-inch pots are suitable for flowering the plants in.

**Rhodanthes.**—When these are needed in good condition for decoration no time should be lost in transplanting the seedlings. The pots may be filled with loam, a little leaf mould, one-seventh of decayed manure and a little sand, being well drained and filled firmly to within an inch of the rim, the remainder being filled more lightly to prick the seedlings into. Water at once, shade from the sun until established, then give air freely to insure sturdy compact growth. This is a saving of seeds, but the easiest method is to sow in the pots in which they are to flower and then thin out the plants to half an inch apart when the seed leaves have been produced. The plants are more leggy, but this is not seen when grouped amongst other plants.

**Primula obconica.**—Seedlings should be ready for transplanting from the seed pans into boxes an inch apart in a compost of equal parts of leaf mould and loam with a liberal addition of sand. They should be placed in an intermediate temperature and shaded from the sun. These are most useful plants, and flower profusely during the winter. For the conservatory or for cutting they are invaluable. *P. obconica* is so easily raised from seeds that the old plants are not worth retaining.

**Cinerarias.**—A few of the best varieties may be selected for seed-bearing. Seedlings should be placed in pans or boxes 1½ inch apart until they are large enough for small pots. To grow these plants well they should never be kept in heat or their constitution will be ruined. A few more seeds may be sown in a pan in an intermediate temperature. As soon as the seeds have germinated, harden, and place in a cool house. Give all the light possible, but shade from bright sunshine.

**Tuberous Begonias.**—Tubers started early in boxes should be well established in their first pots, and ready for larger sizes. Large tubers may have a good shift, and the plants be hardened as soon as possible. They do well after potting in frames where gentle bottom heat can be given by the aid of fermenting material, and allowed gradually to cool down. If kept too long in a close confined atmosphere they grow soft, and the foliage is very liable to rust, and once the plants are attacked they rarely do well. Later plants should be gradually hardened, so that they will bear greenhouse treatment as early as possible. Seedlings in pans and boxes may be planted out 4 inches apart on the surface of a hotbed, on which 3 or 4 inches of old potting soil and Mushroom bed refuse has been spread. They grow rapidly under these circumstances, and the best can be lifted out with good balls and potted.

**Clivias.**—As these go out of flower repotting should be done without delay. Good varieties growing in 6-inch pots may, if necessary, be placed in others 2 inches larger, while those in large pots that have become crowded may be split and potted singly in 6 and 7-inch pots, in which they are most useful. It is not necessary to secure a quantity of roots with each portion, as they may be inserted similar to Pine suckers. After potting they need the most careful watering until they are rooting freely—too much will prove detrimental to them. The plants may be placed in any structure where they can be partially shaded from the sun, and a fair amount of moisture maintained. They will under these conditions soon form roots and establish themselves. Seedlings should be kept in a warm house, or the progress is slow at first. The plants do well in good loam, one-seventh of decayed manure and sand.

**Carnation Miss Joliffe.**—Young plants raised from layers last autumn should be placed in from 3 to 5-inch pots without delay. These may occupy a cool, light, airy frame, where they will grow without drawing. Water carefully, and pinch the shoots to induce the plants to branch. Cuttings rooted in thumb pots in heat under bell-glasses should be hardened as quickly as possible, and when the pots are filled with roots be placed into 3-inch. Cuttings may still be rooted of this or any other good winter flowering variety. Plants of Miss Joliffe, Winter Cheer, and others rooted late last year, and now in 6-inch pots, will be ready for placing into others 2 inches larger.

**Pink Margaret.**—These are exceedingly useful for autumn, winter, and spring flowering. Many of the flowers are sweet, large, double, and of the most beautiful colours. Seedlings should not be kept too long in a close confined atmosphere, as they do best under cool conditions, and once they are established in 2-inch pots the points of the plants should

be removed. To secure the best results they should be potted in 7 and 8-inch pots. In these sizes they continue to grow and flower, while in those of a smaller size they are brought to a standstill. There have been many complaints this year that during the winter the flower buds were blind. This is due to too low a temperature and to root activity being brought to a standstill.

## THE BEE-KEEPER.

### APIARIAN NOTES.

I FIND from my correspondence from many quarters there is a wide difference in the state of hives in sheltered localities from those in places exposed to the piercing March and April winds. Wintering has been more uniform, deaths occurring only where solid and damp floors are still in use. We are now having seasonable and genial weather with copious showers, which is causing a rapid growth; but it is not bee weather. So far as working is concerned it has all to be done by the bees yet. The Gooseberry blossom will soon be out, and the first fine day bees in fruit districts will get ample honey and pollen. Young bees are numerous in most hives, and in some of the most advanced drones are making their appearance. With fine weather during May they may be all more forward by the middle of June than they were in years past with mild Aprils and cold Mays.

The bee-keeper should have all things in readiness for the busy time—hives, supers, sections, foundation, and all necessary appliances. Have everything at hand, so that there will be no searching for anything when wanted.

If any hive shows signs of dilatoriness smell it, and see if it is not affected with foul brood, and take the necessary and precautionary measures to eradicate the disease. It is easy to distinguish between a healthy and diseased hive; the former has a warmish and sweet smell, the latter a harsh and pungent one. Let the examination of a suspected hive be made within doors, so that no *débris* may fall from the combs to the ground, nor bees from healthy hives come to rob them. These are all mischievous sources of infection. The *débris*, which may be cleared out of an infected hive by the bees, or that which may fall to the ground from the combs when manipulating, is eagerly gathered by bees of healthy hives.

Every piece of cloth or part of infected hives should be steeped in a solution of some strong disinfectant, and the bees subjected to three changes before putting them into a permanent clean hive. By pursuing a course similar to advice given thirty-four years ago I cleared my apiary of foul brood, and by a rational method of management since have not seen a single cell of it in any of my hives.—A LANARKSHIRE BEE-KEEPER.

### FLOWERS FOR BEES.

THE change in the weather experienced during the past few days will prove beneficial to growing crops, but has not been favourable to the bees. Heavy showers of rain have fallen during the past forty-eight hours, and over 1 inch has been registered, which means 100 tons of water per acre. A great change in vegetation has taken place during the past ten days; trees that were dormant are now bursting into full leaf, and the bees will reap full benefit from the fast opening flowers in all directions.

A few notes on flowers frequented by bees at this time of the year may be of interest to bee-keepers, and may also cause them to be interested in the flowers chiefly in request for the benefit of their busy workers, and prepare them for another year. I find the majority of spring flowers are visited by bees, whereas later in the season when flowers are more numerous there are only certain kinds they work on. Even the modest Daisy growing by the roadside is frequented by the bees for the pollen obtained from its early opening flowers.

*Arabis alba* at the present time is a mass of white flowers. Bees are particularly fond of this plant, and it should be extensively planted by all bee-keepers and others who have the space at command. It looks well in large masses, and is very suitable for planting on a rockery, where it may remain undisturbed for years. It is also useful for edgings to borders or elsewhere, as it is perfectly hardy, having withstood the late severe winter with impunity. Its propagation is very simple. After the flowers are over, if an increase is desired, divide the plants and dibble them out a few inches apart in the open garden, and no more attention will be required, as they will root freely, otherwise they need not be disturbed for years, as they will go on increasing in size, and will not die off as some other similar plants will if not propagated yearly.

*Myosotis dissitiflora* is now a mass of bloom, and is one of the most beautiful of our early spring flowers. During the brief spells of sunshine bees have been very active on this variety. When planted in a mass and a few bulbs of yellow Tulips dotted between them have a very pretty effect. These may be propagated from divisions, similar to the *Arabis*, or from seed sown as soon as ripe, and the plants will bloom the following spring. Primroses, Violets, and Cowslips, common in the fields and hedgerows, but fast becoming extinct near our large towns, owing to the craze for obtaining plants. Bees may constantly be seen working on these plants. The Wood Anemone is another good bee flower. Many acres of woods are at the present time a mass of bloom, forming quite a picture, from which the bees derive great benefit.

Daffodils having flowered very freely this year, but are now nearly over, have been a great attraction to the bees for the pollen obtained from them. These may be planted in the grass, and if not disturbed will seed freely, which will in a few years bloom, forming large masses of their beautiful yellow flowers. Tulips of various colours also grow freely on the grass. The scarlet *Duc Van Thol*, when planted in conjunction with Daffodils, has a very pleasing effect. *Doronicums* are also useful for the purpose, and are very showy flowers at present in full bloom. These should be planted in masses, and are propagated by divisions of the root. The wild Cherry is abundant in the surrounding woods; large trees of these are now a mass of bloom. Bees work freely on them, obtaining a great amount of pollen and a little honey from the flowers. Several varieties of Willows are now in bloom and produce more pollen than any tree that I am acquainted with. These and the wild Cherry are a source of never-failing pleasure to the bees, and fortunate is the man who has a few trees of the different varieties planted near his apiary.—AN ENGLISH BEE-KEEPER.

### TRADE CATALOGUES RECEIVED.

J. P. Williams Bros., Heneratgoda, Ceylon.—*Tropical Seeds and Plants.*

T. S. Ware, Hale Farm Nurseries, Tottenham.—*List of Dahlias and Begonias.*

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Exhibiting Pelargoniums (*G. H.*)**.—We think the variety you name would be open to disqualification in the class to which you allude.

**Daffodil Baskets (*Gardener*)**.—We think your best method of obtaining quick information would be to write direct to Messrs. Barr and Son, King Street, Covent Garden, or other growers of these flowers for sale.

**Conservatory (*L. D.*)**.—If a glass structure employed for the conservation and agreeable association of plants is detached from a dwelling-house, such isolation does not in the least "disqualify" it, to quote your own term, from being regarded as a conservatory. Some of the finest conservatories in the kingdom are not connected with dwelling house or mansion. Conservatories, as a rule, differ from greenhouses in not being occupied with formal shelves or stages for accommodating the whole of the plants which are grown in pots; in conservatories some are usually planted out, or pleasingly grouped otherwise than on stages, though these may not be entirely absent from some of the structures.

**Disbudding Cyclamens (*Youngster*)**.—Good growers of Cyclamens never think of disbudding, as it would spoil any of the plants to do so. If you wish to grow Cyclamens well, the first thing is to procure seed from a good strain of strong and sturdy growth. Place the seeds singly an inch apart in pots of free sandy soil, to avoid crowding the seedlings. As the seeds are often long in germinating, take care that the soil does not become stale or sour. Grow the young plants without the least check in an intermediate house till June, when they should be

in 4-inch pots, then transfer to a cool frame, syringing frequently on bright days, repotting as necessary; placing them in a cool house in October for the winter, keeping the frost away, when they will begin to bloom, and should keep on till the end of March. This is Mr. Mowbray's practice in a nutshell, and if you grow the plants as well as he does you will be satisfied.

**Cyclamens Failing (Silva).**—You say your plants "were obtained from Mr. Cannell, and were dried after flowering last summer and put into heat this spring, yet have produced very little foliage and no blooms." If we are to understand that the corms were totally dried and remained so for three or four months we should say the life was all but dried out of them. We have seen plants after flowering with the pots plunged over their rims in cocoa-nut fibre refuse in the open at Swanley, and after taking a natural rest (not dried artificially), push clusters of robust leaves through the fibre in the course of a few weeks. If such plants have some of the loose soil removed from the roots when thus starting into growth, and fresh given, and have proper cultural attention in a cool frame till the autumn, continuing it afterwards in a heated pit or greenhouse having a temperature of 45° to 55°, they make fine flowering specimens, if the corms were not too old to begin with. Cyclamens enjoy a rather moist genial atmosphere, and neither succeed under very dry surroundings, nor in a very cold greenhouse in the winter. Possibly you may not have the most suitable structures for growing these plants, and those you have will never recover on a dry shelf in an airy conservatory. They would be much more likely to do so if planted out in free soil in a partially shaded position in the garden. They might possibly then commence growing in the summer, and if so, may be taken up and potted. We have not, however, much hope of their satisfactory recovery.

**Diseased Mushrooms—Springtails (A. K.).**—The "buttons" were certainly damaged by some insect which had almost, and in some cases quite, severed the connection between the clusters and the mycelium, hence they ceased swelling, and the small ones went off as fast as formed. The small insects have done the mischief, but the cause of their presence was the damp litter in which they were introduced and bred. Both the samples in the box and bottle were the same, and the insect (so-called) is one of the springtails or Thysanura, of the tribe Collembola and family Poduridæ. It is named *Achorutes purpurascens*, *Lubb.*, and is found "on a hothead and under branches of trees throughout the year"—(*Lubbock*). The insects are sometimes so common in places where fermenting materials are employed that they swarm as thick as powder, and they browse on any tender plants they can, rasping off the cuticle, so that the plants often flag and sometimes perish. While we were examining one of the creatures it sprang 2, and sometimes 3 inches high, and as it is only  $\frac{1}{8}$ -inch in length, a 6-foot person with similar power would be able to leap 144 feet high. The principal food of this animal is nitrogen, which it procures as a rule from decaying vegetable matter, but it is very fond of fungi, the saprophytic, as these are highly nitrogenous. It loves moisture, hence the moist condition of the bed would favour the increase of the pests and their depredations. Lime and soot water have little or no effect on them, but they are speedily destroyed by chloride and nitric acid, which, in the form of a solution of common salt or nitrate of soda, will not injure, but if anything, benefit the Mushrooms. One-half to 1 oz. of salt in a gallon of water may be used, or one-quarter to half an ounce of nitrate of soda, the smaller dose being the safest for forced Mushrooms, but outdoor ones will usually bear the stronger. It is well to keep both from the clusters of small Mushrooms, but moistening the surface is imperative. The insects do not go deeply into the beds.

**Amaryllis not Flowering Satisfactorily (The Boy).**—By *Amaryllis* you, of course, allude to hybrid or cross-bred varieties of *Hippeastrum*, which in some sorts are deciduous and in others evergreen, but all require a season of rest, yet water should never be entirely withheld, especially from the varieties more or less evergreen. The growing season begins usually in February, and lasts until about September, during which they should have a minimum temperature of 60° to 65°, with 5° to 10° more by day, and 10° to 15° rise from sun heat. Young bulbs and unsatisfactory plants should be potted if they require it just when starting, shaking out some or the whole of the soil, well filling in the new amongst the roots, and making it quite firm with a hand rammer. Rather heavy or good bodied loam, with a fourth of well decayed manure, a sixth of sand, and a twelfth of charcoal, form a suitable compost, a 9-inch potful of honemeal to a barrowload of loam being an advantage. Good drainage is very important. The plants require careful watering until they take well hold of the soil, then they should receive supplies corresponding to the growth and requirements, being duly syringed, so as to keep down red spider and other pests. The plants require abundance of light and sunshine, nurserymen doing them well, because they grow them in span-roofed houses, thus insuring the formation of a sturdy growth, thick leathery leaves, and abundant stored matter in the roots. They also secure uniform moisture and possibly some ammonia by the use of tan or cocoa-nut fibre refuse. Of course, slight shade is necessary during the flowering period to preserve the blossoms, but at all other times the plants cannot have too much light. When the plants are growing and have plenty of roots top-dressings of the advertised fertilisers occasionally or liquid manure should be given, the thing being to get sturdy, vigorous growth and support, so as to get flowering strength into the bulbs, which are what the growth is previously. Plenty of air must be administered in summer, so as to insure the thorough elaboration of the juices, not diminishing the supplies of water until the foliage gives indications of ripening, taking care to get the plants thoroughly ripened before or by

autumn, when the pots with their contents may be placed in a dry, cool house until starting time. With attention to these matters you ought to have few or no flowerless bulbs.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*J. H.*)—If you read the above conditions you will find that we do not undertake to name plants which have originated from seed, as such are florists' varieties, including those you send, not distinct species. (*J. H.*)—1, *Anchusa italica*; 2, *Pulmonaria officinalis*; 3, *Forsythia suspensa*; 4, *Martynia fragrans*. (*J. J.*)—*Pulmonaria officinalis*. (*J. C.*)—The Arum Lily is frequently seen with double spathes. 1, *Curculigo recurvata*; 2, specimen insufficient, possibly *Pulmonaria officinalis*; 3, *Arabis albida*; 4, *Asplenium flaccidum*; 5, *A. hulbiferum*. (*V. B.*)—1, *Ceologync cristata*; 2, *Cypripedium Elliotianum*; 3, *Dendrobium nobile*. (*Rosshire*)—The Azalea is a variety of *amœna*, the bulbous plant *Ornithogalum pyramidale*.

PASTURE CULTIVATION.

CAREFUL revision, the addition of an index, and notes on worthless grasses and poisonous plants found in pastures, are the special features of the fifth edition of Mr. Martin J. Sutton's book on "Permanent and Temporary Pastures," a copy of which has been sent to us by the publishers. We

have held this book in reserve for some weeks till we had sufficient leisure to give it the attention it deserves—something very much more than a mere passing notice. It is now lying open before us in the very heart and centre of the best grazing district of High Leicestershire—a district where it is still possible for makers of Stilton cheese to obtain from the factors a shilling a pound for cheese of the highest quality, and yet where abundance of cheese is to be had at the local cheese fairs for half that price and less. It is these facts, and an intimate knowledge of the heedless mismanagement and neglect of pastures which prevails so generally, with few exceptions, that induces us to call special attention to Mr. Sutton's book as being a safe guide in the improvement of old pasture, in the management of new, and in the laying down of land to permanent and temporary pasture.

We possess, and highly value, a copy of the edition de luxe which costs a guinea, but we prize even more highly a copy of the popular edition to be had for a shilling, which, though containing no illustrations, has the whole of the chapters, and which therefore brings this invaluable guide to pasture cultivation within the means of everyone. This is desirable for many reasons, one of the most important being given in the first chapter on the extension of pastures, wherein it is shown that there was in England alone an increase of permanent grass between 1871 and 1894 inclusive of 4,392,213 acres, and that there are now 13,127,788 acres in permanent grass, and only 11,752,329 acres under arable culture.

Advisedly do we ask, Are we to regard this vast area of upwards of thirteen million acres of permanent pasture as being land "out of cultivation?" That is the term applied to all land laid down to grass in the great corn-growing district of East Anglia, and judging from the lamentable condition of very much of the pasture in the grass country in which we are now writing, it is applicable to pasture very generally. Certainly, Mr. Sutton's book may be taken as an emphatic protest against the term and against such malpractice, both in its description of the forage plants suitable for pastures, and in the cultural chapters which include, with that already mentioned, the drainage of grass land, cultural preparations for laying land down, the selection of grasses and Clovers, spring and autumn sowing, the immediate after management of new pasture, Kidmore experiments with manures on grass land, the management and improvement of old grass land, hints on haymaking, hints on grazing, grass ensilage, and temporary pastures of from one to eight years. Thoroughly practical from beginning to end, revised and brought well up to date, the book is admirably calculated to assist in the evolution of profitable farming under an agricultural depression which has rendered farming upon old lines an impossibility.

Especially do we commend this book to the attention of landowners, as calculated to show them something of what land is still capable of, and as an indication of a standard of excellence in pasture management. So far as is possible we have always given tenants a free hand in the management of their holdings, but we have so much difficulty in getting tenants to adopt anything like the systematic cultivation of the pasture for which they pay a rent which, in comparison with that of arable land, is certainly high, that we would in their agreements certainly have a covenant binding them to a systematic use of manure. In other words we would insist upon sustained fertility of soil, and so render the seasonable growth of pasture herbage a certainty—an early growth in the spring, a full and early crop of hay, an abundant aftermath, and pastures green as an emerald all the winter. Under such a regimen the brown, bare, poverty stricken aspect of permanent pasture during the winter, now so common, would become a thing of the past, both hay crop and grazing

herbage would be more abundant, live stock would be better nourished, farmers more prosperous, rent day well met, the landlord more satisfied, and the whole matter placed entirely upon a better footing. If with such desirable, because profitable, pasture cultivation we could have equal attention to the selection and breeding of live stock, we should have real progress, improvement both thorough and lasting, and a return of really profitable farming once more.

#### WORK ON THE HOME FARM.

The change to warmer weather and April showers sufficiently abundant to induce quick seed germination and brisk plant growth has told upon all crops. Pasture is growing freely, but the herbage of poor upland pasture is still very backward. It was time that we had such a change, the tardy spring having kept growth so backward that even now some pasture will hardly be ready for the stock on May Day. Well is it when there has been no turning out from dire necessity. We know of more than one instance where through the ten long weeks of bitter late wintry weather the whole of the store cattle were kept going well with silage; dairy cows, too, had a fair quantity of it in their mixed dietary without harm to the milk, but positive good, both colour and flavour of butter being decidedly improved.

This is a word to the wise for the coming hay time. By all means make hay with abundance of bright sunshine, but if when the grass is ready for mowing the weather is seriously unsettled then turn to ensilage for part of the grass. The point is to have the grass ready for mowing early, and to get the hay or silage early, so as to have a sufficiency after grazing for the cows and cattle.

The rain has not been so heavy as to seriously interfere with work on the land; horse hoes and cultivators are going briskly. This has been of especial importance to us on some foul land which has fallen in hand in the usual bad condition, rendering the cost of clearing it a very heavy matter indeed under any condition. With favourable weather now and steady persistent effort the greater part of the twitch is got out and burnt. It is perhaps under such pressure that the value of chemical manure becomes most apparent, because it is so portable as to be easily applied, it tells so quickly, and sustains the crop so thoroughly as to afford the best possible results, and one feels that the money spent on it has proved a good investment, and the result satisfactory in every way.

#### OUR LETTER BOX.

**Tainted Butter (N. C.).**—The fact that your butter is made in strict accordance with Miss Barron's rules affords proof that the taint is owing to some outside influence, which you must set yourself to discover. Here are some hints for your guidance. If butter is kept in a room with porous woodwork, walls, ceilings, or floors, or having drains near or opening into a drain, or with the window or ventilator opening on to a yard, rubbish heap, or any other accretion of filth, it will taint quickly. Taint may also arise from food or other things being placed in the room. The butter is so well worked that we are inclined to suspect contact with some impurity—some foul odour—after it is made. Adverse influences before churning are found in the cows' food and surroundings—foul water, foul air, and dirty milkers' hands. In one case known to us the cause of taint was traced to cracks in milkpails which had become filled with filth, yet the pails to outward appearance were perfectly clean.

#### REMARKS.

- 21st.—Rain from 3 to 5 A.M.; alternate cloud and sunshine in day, threatening at times.  
 22nd.—Generally overcast, but some sunshine in the middle of the day; rain in evening and night.  
 23rd.—Overcast morning with occasional spots of rain early; bright sunshine in afternoon.  
 24th.—Overcast early; fine and sunny from 10 A.M. to 2 P.M., then overcast, and spots of rain about 3 P.M.; slight showers in evening.  
 25th.—Heavy rain from 8.30 to 9.30 and rain till 11 A.M.; overcast day, with occasional sunshine; showers in night.  
 26th.—Generally overcast, with rain at intervals; occasional gleams of sun.  
 27th.—Rain early; dull, drizzly, and showery morning; thunder at 1.30; frequently sunny in afternoon; rain again in evening and night.  
 — A rainy week, with temperature slightly above the average.—G. J. SEYMOUR.

# DICKSONS' NEW IRISH ROSES.

ALEX. DICKSON & SONS

Have pleasure in announcing for distribution in May a further series of their

## CELEBRATED PEDIGREE ROSES,

HELEN KELLER (H.P.), Rosy Cerise, superb .. 10/6 each  
 MAVOURNEEN (H.P.), Silvery Flesh, first rate 10/6 ,,  
 MARJORIE (H.T.), White, Pink centre, very pretty 7/6 ,,

ALSO  
 The Best of the NEW FRENCH & BRITISH ROSES.  
 Descriptive Catalogue Post Free on application,

## NEW (H.T.) ROSE

BELLE SIEBRECHT (Mrs. W. J. Grant).

Raised by ALEX. DICKSON & SONS, distributed by SIEBRECHT and WADLEY, New York.

The most valuable introduction of the past ten years. This superb variety has gained the highest awards wherever exhibited in Great Britain and America, chief among these being the National Rose Society's Gold Medal.

Valuable alike for exhibition, decorative, and forcing purposes. No collection, however small, complete without it.

PLANTS IN POTS IN MAY, 10/6 EACH.

### HARDY FLOWER NOTES.

SPRING has come with reluctant feet, and many flowers seem loth to expose their loveliness to the cruel mercies of the cold, harsh air. Still Nature compels them to make an effort to fulfil their destiny, and with manifest unwillingness many unfold their charms.

The Daffodil—the universal favourite—waves to and fro in unison with the music of the winds. Snowy Arabis makes sheets of white on the rockeries and borders. Alyssums show a glimmer of yellow which quickly develops into masses of brilliant gold. The early Tulips have come into bloom, and given us a foretaste of the delights the vivid colours of the later ones will yield. The “fair and frail Anemone,” as Shelley calls it, entrances us with its beauty, and Primroses and Polyanthuses seem to vie with other plants in yielding us pleasure. This running commentary, as it might well be called, could be continued long enough, but we must pass from the general to the particular, and single out some plants for more detailed notice.

Very charming are these flowers, and in their fashioning Nature has not forgotten to give us varieties which cannot be mistaken for the “snow that has stayed too long,” inasmuch as they have flowers of other colours. These coloured varieties of the Wood Anemone do not bedeck themselves with the brilliant hues of some of their congeners, such as Anemone coronaria or A. pulsatilla, but they have a softness of colour which appeals to all who love chaste shades in flowers.

We have the pretty variety of Anemone nemorosa named rosea, the equally attractive bluish variety called cœrulea, which is again surpassed by the fine one known as cœrulescens, and I have now the good fortune to possess one named purpurea, which was, I understand, raised by Mr. James Allen, to whom I am indebted for it. I am not sure that I should call it purple, although in gardening that word has to do duty for many tints. Still, the plant is a pretty one, and will be prized by those who seek to add to their collections of plants those which are “new and rare.”

Among the plants which the mention of the Wood Anemone suggests to one's thoughts is a

**OLDFIELD NURSERIES, ALTRINCHAM,** ALSO AT MANCHESTER AND LLANDUDNO JUNCTION.

charming little *Potentilla* which came into flower in the beginning of April, and which some of my visitors, even those well acquainted with flowers, at first sight take for a variety of *Anemone nemorosa*. This is *Potentilla alchemilloides*, which, besides its attractions of beauty and neatness, has also the merit of continuing in flower for a very long period. This will be apparent when I mention that it was one of the last of the rock plants to go out of flower last autumn, and that in such a late spring as this it came into flower with the opening of April. It does not seem to be generally known, nor to be in the hands of many of the nurserymen. The flowers are pure white, and are very freely produced.

The plant is aptly named *alchemilloides* from the resemblance of the leaves to those of the Alpine Lady's Mantle, and the habit is exceedingly good. On a somewhat dry rockery this little *Potentilla* only grows to about 4 inches in height. It may be increased by division, and as it has survived last winter without protection it may be considered quite hardy in dryish soils.

No one can write on hardy flowers at this season without thinking of the Daffodils, among the most graceful and beautiful of our garden flowers. While the fine forms and colours of the yellow and bicolor trumpet varieties are ever welcome, we cannot feel our garden complete without some of the white and sulphur-coloured kinds. Some years they disappoint us, but this year they are blooming with unusual freedom, and their chastely coloured flowers are much admired. Very beautiful, indeed, are such flowers as *cernuus*, *moschatus* of Haworth, if in truth it is Haworth's plant; *albicans*, *tortuosus*, Colleen Bawn, and others. *Pallidus præcox*, too, always a good bloomer in my garden, has flowered even more freely than usual, and I feel inclined to add to my stock of this early and pretty Trumpet Daffodil. It flourishes better on the rockery than on level ground, and in a position where it has a good deal of sun.

A day or two spent in other gardens than my own has made me resolve to make a fresh attempt to succeed with the *Puschkinias*, which have hitherto baffled me to establish. In the course of some three days I saw them growing well in as many gardens and under different conditions of soil and situation, so that I am hopeful that in some part of my garden I may be able to establish this pretty bulbous plant, which is also known as *Adamsia*. There seems to be some confusion regarding the specific name or names of the plant or plants to be found in gardens. I have been turning up some of my works of reference to endeavour to reconcile the various statements I had previously heard and read, and find that it seems to be now accepted that *P. scilloides*, *P. libanotica*, and *P. sicula* are the same, and that *P. s. compacta* has more numerous flowers than the type, and has also a more compact habit.

I had for some years been under the impression that *P. scilloides* and *P. libanotica* were not the same, and that the former had narrower and fainter coloured blue lines down the centre of its white flowers than *P. libanotica*. One must, however, bow to superior authority, but it will be noticed that the difference which was supposed to mark two species will be found to exist in the plants grown in gardens under either name. One can only suppose that in a wild state the *Puschkinia* will show considerable variation. *P. scilloides* is a native of Asia Minor and the Mediterranean regions, and grows from 4 to 8 inches high. The flowers, which are produced in racemes on a leafless stalk, are white with a pale blue stripe down the centre and on both sides of the perianth segments. The leaves are narrow, rather lance-shaped, and grow to 7 or 8 inches in length.

It is named in honour of M. Pouschkin, a Russian botanist. Sandy loam and leaf mould is said to be the most suitable soil, but it has not succeeded with me in this medium, while I have seen it doing well in a good loamy soil, and also in that of a stiff, clayey nature. Bulbs should be procured and planted in the autumn.

For some time the various hardy *Primulas* have received an increased share of attention from hardy flower growers. This they well deserve from the beauty of many of the species and their

hybrids, and from the fact that there is hardly any limit to the possibilities in store for these plants, when the skill of the hybridiser is devoted to their improvement. We can all admire the beauty of the *Auricula*, whether seen in the hardier alpiners or in the more refined stage varieties, and what has been done with these may be done to some extent with many species not yet taken in hand.

Not that they have been entirely neglected, for many of the fine *Primulas* generally supposed to be species, are either natural or artificial hybrids. For some time I have been gradually forming a small collection of the hardier sorts, and among these few have this spring given greater pleasure than *P. Steini*. This is said to be a hybrid, and according to Mr. D. Dewar's "Synonymic List of the Species and Forms of the Genus *Primula*," drawn up for the *Primula Conference* at South Kensington in April, 1886, its parents are *P. minima* and *P. hirsuta*. It is an exceedingly beautiful little *Primula*, with small toothed spathulate obovate leaves, and very bright purple flowers produced on short stalks, which in my garden are not more than 2 inches high.

It is grown on the east side of a terraced rockery in a "pocket" filled with sandy peat, and planted between two stones, so that its roots come in contact with them. It has stood the last two winters without covering or protection of any kind, so that its hardiness seems to be quite beyond doubt. It is to be hoped that the *Primula Conference* this year may cause still more interest to be taken in this beautiful class of plants.

Among my acquisitions in the way of bulbs last autumn was *Tulipa Kaufmanniana*, of which I had heard a great deal. My solitary bulb flowered early in April, and proves to be the variety known as *T. K. albo-variegata*, which has the inside of the perianth white, becoming yellow towards the base, the outside being also white but tinged with grey and rose. It grew about 9 inches high, and although a pretty Tulip is rather lacking in the brilliancy we look for in nearly all the plants of this ornamental genus.

It is, however, one of the flowers which improve on examination, and recalls such flowers as some of the Water Lilies, although this is only from the colouration. As may be gathered from the specific name, which indicates the advance of the Russians in Central Asia, it is a native of that region where the name of Kaufmann has become so well known. Although introduced in 1877 it is not as yet widely known in gardens. From the description of the type it should be more brilliant than the one under notice, as it has a bright yellow perianth.

Even as one writes growth is rapidly advancing, and before this appears the rockeries and borders will be bright with flowers of many hues, and so attractive that it will be only with difficulty that we are able to leave them even for the congenial task of telling their charms through the unsatisfactory medium of pen and ink.—  
S. ARNOTT, *Dumfries*.

## WALLFLOWERS.

ONE glance at the above familiar name is this year quite enough to bring to the minds of many of us thoughts of dismal failure. Spring time has, however, again arrived, and it would be unwise to allow one failure to deter us from making adequate provision for another season, when the chances are all in favour of a successful termination of our labours.

Independent of these considerations it seems to me that Wallflowers are quite indispensable spring-flowering plants, because they supply flowers with a rich perfume which at the same time can vie in brilliancy of colours with anything to be found in the open air during the early spring months. All varieties of Wallflowers are suitable for planting in large beds and borders. Hitherto the great difficulty has been to secure a variety sufficiently dwarf and compact in growth to admit of its being planted in groups of formal beds without destroying the balance of growth so necessary in such instances to secure a good effect. Fortunately, however, the right thing has come at last in the form of Sutton's dwarf bedding varieties. The intrinsic merits of these cannot be too widely known, for they are simply perfect.

In a short note published in this Journal recently I referred to

these as being the only varieties which had come through the late severe winter without injury; but I refrained from saying much about their very dwarf habit then, as I intended to wait till they were in flower, so that I might write from experience only. They are now (April 27th) unfolding their flowers rapidly, and I must say they have fully realised the high opinion I had formed of them. The height of the plants when in full flower varies from 5 to 7 inches, and the habit is thoroughly sturdy and compact.

These bedding varieties may be obtained in two distinct colours, yellow and rich brown. The first named is particularly valuable on account of the flowers being of a beautiful bright orange yellow, a shade of colour always in demand among spring flowering plants, on account of the many blue and purple shades to be found in other plants in flower at the same time. Golden Tom Thumb is another excellent dwarf Wallflower, being particularly rich in colour, and growing only slightly taller than the varieties previously mentioned. As far as my experience goes these are the three best dwarf Wallflowers in cultivation. Turning to other varieties which grow rather taller, and are suitable for large beds and borders, we have plenty of fine varieties to select from.

Primrose Dame and Fairie Queen supply quite new shades of colour, being sulphur and delicate lemon respectively; each is good in its way, and well adapted for using as "dot" plants, with a groundwork of *Myosotis dissitiflora*. Veitch's Selected Yellow is also a grand variety for that purpose, the flowers being large and wonderfully bright in colour. We have now so many shades of yellow in these charming flowers that I think a wondrously beautiful effect might be produced by planting a large bed with all the yellow varieties obtainable.

Arranging the darkest shades in the centre, and so graduating them as to have the pale lemon colours as near to the outer edge as their height will allow, finishing off with a band of dwarf bedders, or this variety might be planted as a groundwork with clumps of taller kinds arranged here and there. Eastern Queen is a most peculiar and attractive form. The marble-like intermingling of apricot with creamy white reminds one of the quaint markings of German Irises.

Harbinger and Parisian Early are each well-known early kinds, which for that reason are well worthy of being grown in pots; indeed, there are few more showy pot plants in early spring than well-grown Wallflowers of the best types. If these are brought into flower before those in the open air begin to unfold their beauty few would object to them on the score of being common. Double German varieties are not so extensively grown as the single types, and I think will never be so popular for bedding purposes. They are, however, extremely showy, and no garden should be without them. A spike from a well-grown plant is so massive as to be quite a show in itself.

I find that May is quite early enough to sow all the varieties, and I prefer sowing thinly in the open air, the seedlings then come sturdy from the start, and throw out their side shoots close to the ground. When sown in boxes the young plants often become drawn before being transplanted. Then, no matter how good the strain may be, the dwarf habit so desirable is not easily attained. When the seedlings are 2 inches in height I transplant in rows 9 inches apart, and allow 3 inches between the plants in the rows. Later on every other plant is lifted and planted 9 inches asunder.

By thus allowing abundance of room very sturdy plants are obtained by the autumn months. Those intended for flowering in beds should if possible be planted in October, so that they may become established before severe weather sets in, the risk of being killed by frost is then reduced to minimum.—H. D.

CATTLEYA CITRINA.

At the last meeting of the Royal Horticultural Society, held at the Drill Hall, on the 23rd ult., Mr. W. Rapley, gardener to H. Grinling, Esq., Harrow Weald House, Middlesex, exhibited a plant in flower of this grand old Orchid. The blooms were so fine, as well in substance and colour as in form, that the Committee accorded to it a first-class certificate. This *Cattleya* is so well known as to need no special description, but attention may be called to the lip (see illustration, fig. 67), which is a superb feature. Had this not passed the Committee we might recommend it should be named *C. citrina*, Grinling's variety, as it is well worthy of some distinctive appellation.

EPIDENDRUM STAMFORDIANUM.

It may interest readers of the Journal to know that we have an *Epidendrum Stamfordianum* which has produced thirteen beautiful spikes of bloom from five growths which it made last year. There are nine spikes from three growths, and four from the other two, giving a total of 617 single flowers. On Easter Sunday we had a *Dendrobium fimbriatum oculatum*, with twenty-four spikes fully open, and others showing colour. This plant produced thirty-three spikes, two or three spikes on a growth, averaging eleven flowers to a spike.—C. PAYNE, *Teashurst, Dorking*.

THE SELWOOD COLLECTION OF ORCHIDS.

The sale of this collection of Orchids, conducted by Messrs. Protheroe & Morris, secured some high prices, the best of which was 140 guineas given for twenty-four bulbs, four leads, of the

FIG. 67.—CATTLEYA CITRINA.

*Cattleya Hardyana* (Selwood variety). This specimen, which secured an award of merit last year, was described as "a grand plant, sepals and petals rosy mauve, veined white, lip rich maroon, with yellow blotch on each side of the throat." Seventy guineas each was the sum paid for several other varieties, and the whole collection fetched £3804.

CATTLEYA TRIANÆ PRINCESS BEATRICE.

Mr. W. Drover, F.R.H.S., of the firm of W. & G. Drover, had the honour of making the bouquet which was presented to Princess Beatrice on the opening of the fancy fair at the Town Hall, Portsmouth. Blooms of *Cattleya Trianæ* were much admired by the Princess. The colour was of soft rich mauve, with delicately fringed edge; the lip very large, rich purple. Through the permission of Prince Henry of Battenberg the firm is allowed to name it Princess Beatrice.

CATTLEYA MENDELI.

Although there has not been so many varieties of this *Cattleya* described as of *C. Trianæ* or *C. Mossiæ* there is nevertheless considerable variation in the size and colour of the flowers. Some of the best types are fit to rank with the finest of the genus, and there is not a variety that is not well worth growing. The flowering season is usually April or May, though a few of the later varieties are sometimes in flower as late as midsummer. A good typical flower would be from 6 to 7 inches across, and the sepals and petals are light rose, the lip broad, spreading in front, wavy and prettily crisped. This latter is often deeper in colour than the sepals and petals, with a deep yellow blotch in the throat, the side lobes

frequently white. The pseudo-bulbs are shorter than those of *C. Trianae*, furrowed, and each bears a single leathery leaf. The cultivation of this species presents no special difficulty, but it is not quite so free flowering as *C. Mossiae* or *C. Trianae*.

The proper season for repotting is immediately the flowers are over, and a rough open compost over good drainage is essential. *C. Mendeli* is a native of New Grenada, originally introduced in 1870. Some of the best known varieties are *C. M. bella*, a nice form with pale lilac sepals and petals, the lip having a good deal of yellow veined with lilac and white. *C. M. Blunti* is a smaller albino form, the only colour being a yellow blotch on the lip. *C. M. grandiflora* is a handsome form nearly 8 inches across, the sepals and petals broader than the type, the lip very broad, and altogether a magnificent flower. *C. M. Rothschildianum* is a deeper coloured variety than the type, the sepals, petals, and lip being bright amethyst purple. *C. M. Victoriae* is a pure white form of the type, excepting the markings on the lip. This was, I believe, introduced by Mr. W. Bull, who has a good stock of it. *C. M. superbissima* is somewhat similar to *Rothschildianum*, but rather larger. This does not by any means exhaust the list of varieties, but those named are probably the most distinct.—H. R. R.

## BOTHIANA.

(Continued from page 377.)

### DRAWING.

"The pencil oft avails—words failing to express—  
To clothe the crude idea in rational dress."

IN the order of sequence pertaining to the three R.'s, arithmetic here has its place. The art of figures is not to be contemned, and must of necessity be a part and parcel of future requirements. The slate and pencil may not unworthily be included in your educational stock in trade, and may serve as a refresher on occasion. I have found it do so on a winter's night when firing duties kept one up to the "wee sma' hours," and the eyes which dare not close found relief by it from reading and writing. This digression appears necessary to prevent exclusion of a subject which need not longer detain.

I pass on to what can hardly fail to prove to you—as it did to me—the most fascinating of studies in the bothy. On the importance of a knowledge of drawing in our profession there cannot be two opinions. The value of the art is admitted. As the shuttle of thought plys in the loom of memory, I cannot recall any pleasanter hours than those spent over the drawing board—a pleasure emphasised by the profitable investment this proved to be when bothy days were gone for ever. As an educational agent in training the hand and eye drawing is unrivalled, and considering how much its correlative objects are present in our duties it would not be easy to over-estimate the benefits a knowledge of it confers. By its means difficulties apparently insuperable vanish. Excellence takes the place of mediocrity at one-half the expense of force. Its importance is now generally admitted by members of the craft, whereas in the youth of a bygone generation such aspirations were too often crushed by some of the old school, who would rather by force of windy argument show how they had contrived to live and thrive in ignorance rather than admit its value. True, it may be granted that they could form no proper estimate of a thesis they did not possess.

Those were the days when to write a fair hand placed the performer far up in the orchestra of life's concert. Not so now. This is evident to you, and I venture to predict that in the near future employers will expect their gardener—if he is of any status, and this you aspire to—to produce a neat and correctly drawn plan to a scale where contemplated alterations of any magnitude are in view. Gardeners like to have their own way, and they should get it, if it is the best way, which it generally is. This is my experience. I want my own way to build, to alter, pull down, put up from a gardener's point of view; but the subject is well thought out before applying to the powers that be, and the thoughts of the new pit, house, walk, or what not, are interpreted on paper to be produced when the question is raised. This is more convincing than a babel of technical talk, which often ends in postponement for ever, and this simply for the want of a medium of lucid expression. Here is the medium: a ground plan, section, elevation of the new house, designs for new beds, or the laying out of a new garden and grounds with all accessories.

During the period of bothy existence the requisites for drawing need be but of the simplest description, such as will readily fit in your trunk and make but a slender demand on the pocket. The articles required are a drawing board, T-square, two set squares, set of mathematical instruments, pencil, camel's-hair pencil, stick

of Indian ink, some sheets of cartridge paper, with a few drawing pins for holding the paper on the board. The drawing board I would advise to be of such dimensions as will fit in the bottom of your trunk, about 18 inches by 24 inches. This and the T-square may be home-made; but it is essential that they should be well made and true, hence I would give the preference to bought ones. Instruments commonly known as drawing tools may be purchased from 1s. upwards. The whole outfit, including all mentioned, may be purchased for about 5s.; but as this is of the cheapest and simplest kind it may not commend itself to students of more ambitious tastes. My reason for bringing this, and all outlay pertaining to the bothy lessons, to the lowest point consistent with utility is, that not any excuse on the score of expense shall be available to the young beginner.

The outfit, as above, is amply sufficient if the patience and perseverance are forthcoming. Should these virtues be wanting the costliest tools will not avail, and better by far that I should incur some dissentient criticism from practised hands than one youth should be deterred from starting. When leaving the bothy for good and all, and a more pretentious outfit appears desirable, hand them over to some young brother of the craft with a little sympathetic counsel. In drawing do all in pencil first, acquire the habit of keeping your paper clean, ink over the pencil lines when satisfied that any errors have been corrected, clean over the whole with a piece of stale bread. Be not discouraged by the crude appearance of early attempts. The stiffness of the hand will soon give way to a free-and-easy manner. Number consecutively and date each sheet, thus marking progress, as advised in the writing lessons. A very little practice will afford the opportunity of making plans of such things as are at present around you, to be utilised in the years to come.

As a gardener's chief requirements are practically confined to the geometrical section of drawing, it is absolutely necessary to acquire the elementary principles of it. In the series of drawing books published by Vere Foster or Cassell & Co., the numbers specially treating on this subject will sufficiently introduce it to you, and lay the solid foundation for subsequent work. Devote some time to this elementary training prior to commencing more ambitious designs. Hasten slowly is an ethic of self-tuition not to be trifled with.

In the "Gardeners' Assistant" you will find plates illustrating horticultural buildings, and when commencing similar work these will furnish ideas to work on, and an idea of the results you should and can attain to by practice in this department of plan drawing. Faint washes of Indian ink will give the touch of a master hand in depicting the lights and shadows falling on the glass. Note also the scale to be found accompanying a plan you wish to model your work on. A little practice, with some thoughtful attention, will clear away those little difficulties at first experienced with it. Later on a box of water colours may be added for tinting flower garden designs. The drawing books mentioned above may be had for 1d. or 2d. each. It is quite possible some friendly hand may guide you on little points which I am precluded from doing; but failing this, it is quite possible for you to succeed if you intend to do so. Do so, and you will not regret it.

### BOTANY.

"To him who in the love of Nature holds communion with her visible forms,  
She speaks a various language."

In the pursuit of knowledge, and taking it for granted that a foretaste of those pure pleasures derived from it have been already experienced, the feeling will arise to economise the spare time of summer days, as well as winter nights. The subjects previously brought under notice are, it is obvious, pre-eminently adapted to the latter. With the lengthening days of summer the pen, the pencil, or the book are apt to lose some of that magic influence they have, I trust, woven around you. Counter attractions now present themselves, and the desire prevails to go forth into the fields, the woods, breathing the deep beauty of Nature. It could not be otherwise, nor should it be otherwise. The silent teacher has glorious lessons for her pupils. Be one of them. Read the pages of her immortal books, science holds the key, and that key is botany. You may doubtless enjoy all that young life can enjoy in admiring fresh scenes, but it is the turning over the pages for the pictures and ignoring the teaching.

The affinity of botany to gardening is evident, and the importance of a knowledge of it is illustrated by the prominence it holds in the curriculum of other professions. That a man may be an excellent gardener and not a botanist, or *vice versa*, goes without saying. One may even go farther and note some instances in which the study of this science has developed into an all-absorbent passion where the chief ends and aims of gardening find no place. With

us there is not any danger of this occurring. We may at least acquire an elementary training, and derive much benefit from it. By its means new fields of thought are opened up, additional interest given to those objects of our direct care, and the beauty of our native flora revealed. A concise analysis of the organs of plants is given in the "Gardeners' Assistant"—this, with the practical lessons on chemistry following it, cannot well be overlooked by you; add to this a manual on elementary botany as a pocket companion, your rambles will then be neither aimless nor fruitless. Opportunities will be afforded for making acquaintance with new bits of the old country, and Shanks' mare—an unrivalled means of locomotion within a radius of twenty miles—will give facilities for observation, storing up many a pleasant picture for the future when recalling memories of the past.—AN OLD BOY.

(To be continued.)

### PACKING AUSTRALIAN FRUIT.

THAT large numbers of sound antipodean Apples arrive in London at this season of the year is beyond question; but how many fail on the way we have no means of knowing. In a recent experimental consignment of fruit the failure was, in the case of Grapes, Plums, and Pears, complete (except in the case of a hard stewing Pear), while the special means taken to preserve the Apples did not in any sense answer the purpose intended. We have been requested by Mr. L. M. Hutchinson to examine samples of fruit sent by Mr. George Neilson, Curator Royal Horticultural Society's Gardens, Melbourne, Victoria, and mention the results. As we have said, the Grapes and Plums were all spoiled, also, with one exception, the Pears; we have only to refer to the Apples.

Some of these, also the other fruits, had been dipped in a preservative solution, and appeared as if varnished; while others were wrapped in soft white paper and embedded in Melaleuca or Titree bark, a colonial product.

The preservative solution, from which so much appears to have been expected, proved either useless or worse. The Apples were gathered and dipped on March 1st, shipped the next day, and examined in Fleet Street on April 26th.

Three out of four of the dipped Cox's Orange Pippins were quite spoiled, the prevention of evaporation appearing to have incited internal fermentation, blackening the fruits throughout. Those not varnished were not all decayed, but the best of them were devoid of the characteristic flavour. The fruits were excellent samples when gathered.

Fruits of *Æsopus Spitzenberg* Apple were not decayed, yet were of practically no value, being musty, sweet, and soft.

Samples of the variety named Perfection were very attractive, but too far gone and quite mealy.

All the specimens of London Pippin were sound, varnished and unvarnished, but were either devoid of flavour or unpleasant to the palate. This proved the best traveller; but not many persons would twice buy Apples so defective in quality.

Adams' Pearmain fruits were of the first size, but two out of three that had been dipped were blackened and spoiled; sound fruits, sweet, but very dry, and of practically no value.

The Melaleuca bark has proved the reverse of advantageous as packing material. As a matter of fact it was more decidedly Apple flavoured than were the fruits themselves, from which it had absorbed the virtues.

We received in May, 1883, a small consignment of Australian Apples, packed by Mr. Neilson and brought over by Mr. Hutchinson. These were exhibited at an evening meeting of the Royal Horticultural Society at Burlington House, and evoked expressions of surprise and admiration. Each fruit had been simply wrapped in white paper and closely packed. Only a few were shrivelled, most arriving in splendid condition. It is possible that if the few that were shrivelled had been wrapped in less porous paper (such as "butter paper," in which "W. R. Raillem's" Roses (page 407) came so fresh last week) that they might have been fresh too. A sample of the paper has been taken by Mr. Hutchinson, and will probably be tried in Australia.

We are inclined to think, however, that if sound fruits, gathered at the right time, and firmly packed so as to be quite immovable, without paper or anything else, except, perhaps, a surrounding lining of non-conducting material, such as hair felt, attached inside the cases, would be as likely to arrive in a sound state and of good quality, as they would under more elaborate methods; and certainly both the "preservative dipping" and Melaleuca bark led to the decay of most of the fruits and loss of flavour of others in the consignment in question. Obviously Australian Apples arriving in this country in May and June do not prejudice the sales of home-grown fruit.

### MY FIRST FLOWER SHOW.

No matter where, no matter when, sufficient to say that the importance I felt from the time it was decided who was to go, who stay at home, was out of all proportion to the subordinate position I then held as a junior in the bothy. Days, nay weeks, previous had the coming event cast its shadow before, and as the crisis approached something akin to disorder was visible in the most orderly of well kept gardens. Grave, sober-minded old labourers took surreptitious peeps at us through door or sash, and prophesied according to their views of life in general, and of flower shows in particular. Even "the Missus," whose motherly supervision made our neat little bothy homelike, at last forsook the care of our beds and board, and was engaged, spectacles on nose, peering into specimen plants for stray bugs which might mean disgrace, or sponging the foliage, so that no leaf was left unturned, whereby our efforts might be crowned with success. For were we not competing for the group—the blue riband of the Royal Stone-wallshire Horticultural Society?

It was to be a hard fight. So said those who knew, and from what I could glean, victory or defeat hung in the balance over a fine specimen Allamanda, which—that it might be in the prime of prime conditions at the appointed time—had made journeyings off from a hot house to a cool one, and back again according as blooms developed or hopes rose and fell. Our most formidable opponent possessed as good a specimen, but now, on the eve of the contest, our plant being engineered to perfection, it was a foregone conclusion that the enemy's plant would be either a little early or a little late, and who could match the matchless?

So far so good; with a sense of relief we took a last look at the beauties packed in the van; fastened the tail sheets and saw the plants curtained in comfort for the night, with our hamper of necessaries, comprising blocks, matting, moss, and sundries swung hammock fashion from the axles. So far as weather was concerned, and needless to say it did concern, a falling glass did not provide the brightest of prospects, yet even that was (prematurely) settled to our satisfaction. Older heads shook out statistics showing how at such a show it was fine, and such a one wet, so that the balance of opinion went as we wished (beforehand).

Now, as some twelve miles intervened between the sphere of our hopes and the arena of realisation, an early start to cover the distance at a walking pace was imperative. Well grown, well bloomed plants, however well packed, must not be needlessly shaken, nor whip nor spur urge our steady old horses to "rattle their bones over the stones." Having by such incontrovertible logic—as detailed—pre-arranged the weather, prejudged our plants so satisfactorily, a busy day with a prospective busier one to-morrow gave urgent reasons for rest, and the wisdom of it without further debate was impressed by the teeth of that old saw, "early to bed, early to rise." Our carter, who lived outside the garden walls, had promised to call us at half-past two—should he wake! We had promised to call him at half-past two, should we wake, hence from mutual dependence arose mutual distrust. My watch—a family heirloom of the turnip type—was not infallible, having a habit of marking time indifferently by stopping and going on again spontaneously, whilst the remaining watch in the bothy would not go at all.

Fully impressed with my responsibility I fell asleep, matches by my side and the good old timepiece under my pillow, to be awakened by one of my comrades stentoriously exclaiming he knew it was time to get up. Assuming his knowledge to be reliable, one leap brought me to the floor with the prompt attempt to misfit on my garments, when came the pertinent question, "What's o'clock by your watch?" It told me—and was endorsed by my own feelings—that we had been in bed just half an hour and five minutes. So again silence reigned, interrupted only by the striking of matches through the night. Finally some troubled dream connected with plants accompanied by a sort of spirit rapping-tapping at the window pane resolved itself into a tangible rattling, with the voice of our carter saying, "It's half-past two and pouring o' rain, be you chaps gwine to lay abed all day?" Instant activity dispelled such an impertinent insinuation, and we were soon prospecting our breakfast and the weather. A wet morning, however unpleasant, meant, of course, a fine day—it would clear, which it eventually did on the morrow.

On with top coats, off in good time in spirits the downpour could not quench, probably sustained by some cigars of the Chou d'Anglais type bought at the village shop specially by myself as an offering meet for the occasion. So on, the three of us, riding by turns, through the grey gloom and the unceasing splish splash of the rain. What matter, the plants were safe and we were sound—neither pepper nor salt.

Some anxiety was manifested by my comrades on approaching the turnpike, and the question was raised, "Will old Pikey be up?"

but "old Pikey" slept the sleep of the just and delayed us unjustifiably, considerably ruffling our tempers ere the fee was paid and the passport made out freeing us from further impositions of that kind. Nearing the place of rendezvous, tempers were again tried by observing the opposition load of plants converging towards us from a road at right angles. Our phlegmatic driver was now thoroughly aroused, and such compliments as "Yah! poonch thy yeard" were freely exchanged with the rival Jehu, accompanied by an apparent desire of the twain to race as well as fight. Valour, however gave way to discretion, in fact later on in the day to brotherly love, for the same two drivers were to be seen convivially toasting those healths which but a few short hours previously they had ardently desired to injure.

Of the events of that eventful day but one or two need be recorded here. The band of the Coldstreams (appropriate for a wet day) discoursed sweet music under the muffling canopy of a tent. One grateful recollection yet stands out clear and distinct amidst the troubles of staging, the anxiety of results, the music and the mud, that was a substantial free breakfast to which we juniors were admitted after our betters—the judges and the heads—had done justice to it. As for the blue riband, first prize for the plants which we had awarded to ourselves the day previous, the judges confirmed that decision. "Old Pikey" gave us no trouble on our return. Our "gaffer," whose confidence in us had not been misplaced by his staying at home, met the wanderers with a lantern. Drenched, tired, and satisfied, our adventures ended in a peaceful night's rest to all, especially—THE JUNIOR.

**EVENTS OF THE WEEK.**—After a lapse of three weeks the Committees of the Royal Horticultural Society meet again at the Drill Hall, Westminster, on Tuesday next, while on Wednesday the Royal Botanic Society will hold its summer exhibition in Regent's Park. These appear to be the only events of particular horticultural interest during the forthcoming week.

— **THE WEATHER IN LONDON.**—During the past week we have experienced glorious weather. The sun has shone brilliantly on each day, and is rapidly gaining considerable power. The nights, however, continue cold, frost having been registered on several mornings, notably on Thursday last, when 5° were experienced in an outlying southern suburb, and the atmosphere is very dry.

— **WEATHER IN THE NORTH.**—May opened with a drizzly morning and a cold W. wind, but the day improved towards evening. The morning of the 2nd was dull, but since then, till Tuesday, the weather has been very bright and fine, although the wind has generally been easterly, and cold evenings have occurred. Trees and hedges are rapidly advancing, and pasture is now abundant.—B. D., *S. Perthshire*.

— **DEATH OF MR. THOMAS HOGG.**—We regret to have to announce the death of Mr. Thomas Hogg, the head of the old-established seed and nursery business of Hogg & Wood of Coldstream, N.B. Mr. Hogg had been in indifferent health for some months, and notwithstanding frequent visits to the various health resorts of the Continent, and voyages to America and the Mediterranean, his constitution was unable to resist a complication of ailments. Mr. Hogg was visiting the salt baths at Droitwich when he died on the morning of 4th inst., aged seventy-four. He was a Justice of the Peace for Berwickshire for many years.

— **NATIONAL AMATEUR GARDENERS' ASSOCIATION.**—At a meeting of the above Society held on Tuesday evening at the Memorial Hall, Farringdon Street, E.C., with Mr. T W Sanders in the chair, an exhaustive and instructive paper on "Zonal Pelargoniums" was read by Mr. H. J. Jones of Lewisham. The essayist dealt lucidly with the cultivation of the above plants in all stages, and on conclusion of the paper a short but interesting discussion took place. In the exhibition room creditable displays of Zonal Pelargoniums, Azalea mollis, Violas, Fuchsias, Auriculas, Asparagus, Rhubarb, and Seakale were staged, for which points were awarded.

— **ROYAL HORTICULTURAL SOCIETY.**—The next meeting of the Society will be held in the Drill Hall, James Street, Victoria Street, Westminster, on Tuesday, May 14th, when a large show of Daffodils and other hardy flowers is anticipated. At 3 P.M. Dr. Morris of Kew will deliver a lecture on the "Plants and Gardens of the Canary Islands." The lecture will be illustrated by dissolving views from the magic lantern.

— **ROYAL METEOROLOGICAL SOCIETY.**—At the ordinary meeting of the Society, to be held by kind permission of the Council of the Surveyors' Institution, at 12, Great George Street, Westminster, on Wednesday, the 15th instant, at 7.30 P.M., the following papers will be read:—"The November Floods of 1894 in the Thames Valley," by G. J. Symons, F.R.S., and G. Chatterton, M.A., M.Inst.C.C. "Barometrical Changes Preceding and Accompanying the Heavy Rainfall of November, 1894," by F. J. Brodie, F.R.Met.Soc.

— **NEW VIOLA CHARM.**—Mr. William Cuthbertson sends us flowers of this variety, and writes:—"We have had all the best varieties of Violas in bloom in pots in a cool greenhouse for some time, and the above variety well merits its name. It is a most beautiful shade of lavender, like that of the old-fashioned Marriage-ties. The variety was raised by Mr. Samuel McKie of Belfast, and is being distributed this spring by Mr. William Sydenham of Tamworth. All Viola fanciers should make a note of it." [The colour of the flower is very delicate and pleasing.]

— **FERNS AT KEW.**—The Director of the Royal Gardens, Kew, has favoured us with a copy of a hand-list of the Fern and Fern allies cultivated in those gardens, and which has just been published. Before the list of Ferns, which is alphabetical, is an admirably written preface, giving in brief the history of the collection, from which it appears that in 1846 there were 400 species of Ferns grown, while the present hand-book contains no less than 1116 species and varieties with ninety-seven Fern allies, this being exclusive of British Ferns, which number 586 varieties. The price of the publication is only 6d., and it may be had from the Gardens.

— **SEAWEED AS A FERTILISER.**—On the sea coast this is of much importance. When wet it is two-thirds water, but when dried on the beach only about one-third its weight is water, and it is a useful absorbent in stables. The wet seaweed contains nearly 1 per cent. of nitrogen, potash 3 per cent., and phosphoric acid 1½ per cent. If the rockweed is dried until it contains only half as much water as when wet, a ton of it will have nearly twice as much of these elements. The nitrogen is lost if the seaweed is burned. Seaweed also contains considerable soda and lime, and is good for all crops if spread on the soil and lightly ploughed or harrowed in.

— **ROYAL BOTANIC SOCIETY.**—At a meeting of this Society held recently, Mr. Granville R. Ryder in the chair, among the objects of interest exhibited were a number of growing plants of *Sansevieria cylindrica*, the Bowstring Hemp, obtained by dividing one of the stick-like leaves transversely into pieces and planting them, when young shoots appear at the base, although no sign of any node or budding point can be traced on the leaf. The plant is remarkable as producing one of the strongest of known fibres. It was remarked at the meeting that the conservatories of the Society were now at their best, the Azaleas and Rhododendrons being in full beauty; one very large plant of Rhododendron Countess of Haddington being a mass of delicate pale pink flowers of enormous size and wax-like texture.

— **GLASS STRUCTURES IN WINTER—ESSAYS.**—Some time ago we offered a silver medal for the best essay on the profitable employment of such glass structures in the winter as are frequently devoted to Cucumbers and Tomatoes in the summer. The response has equalled our anticipations. Out of the number of essays sent in eight are chosen as worthy of very careful re-examination. These are sent under the mottoes (here given alphabetically) of "Excelsior," "Excelsior" (Nantwich), "Henri," "Lego," "One of the Craft," "Practice," "Semper Eadem," and "Viola." We fear that one or two of the essays may not prove of the stipulated length, others appear to have been hurriedly written, and more than one which is well written does not show clearly the results of the practice advocated. All these points will have to be considered, and as we are cognisant of the identity of one contributor (and one alone) the whole of the essays will be placed in the hands of an adjudicator, who possesses knowledge on commercial horticulture, and has had much experience in the examination of essays; his report will be awaited before a decision is arrived at, and before the envelopes containing the names of the essayists are opened.

— THE first annual show of the COVENTRY CHRYSANTHEMUM SOCIETY will be held on Wednesday and Thursday, November 6th and 7th.

— CIDER.—Can any of your readers give me full particulars (or refer me to any book or paper) for making unfermented cider that will keep good for twelve months?—R. BINNS.

— GARDENING APPOINTMENTS.—Mr. W. Whit, for the past thirteen years head gardener at Wyndham Hall, Melton Mowbray, has been appointed head gardener to H. G. James, Esq., The Chestnuts, Oadby, Leicester. Mr. W. A. Jenkins, for the past fourteen years head gardener to Brodie Cochrane, Esq., Aldin Grange, Durham, has been appointed Curator under the Corporation of Stockton of the Ropner Park and Recreation Grounds.

— MR. E. WALLIS, The Gardens, Hamels Park, Buntingford, Herts, writes:—"The weather here during the past month has been very even and genial for the growth of vegetation. The frosts during the past month have not been so severe as usual during April. Rain has fallen on eight days during the past month. Maximum in any twenty-four hours was 0.37 on the 25th. Total during the past month 1.42, against 1.42 of 1894."

— APRIL WEATHER IN SUSSEX.—"R. I." writes:—"The total rainfall at Abbot's Leigh, Haywards Heath, Sussex, for April, was 2.50 inches, being 0.82 inches above the average. The heaviest fall was 0.77 on the 25th. Rain fell on twelve days. The maximum temperature in the shade was 69° on the 17th, and the minimum 31° on the 15th. Mean maxima, 56.12; mean minima, 39.18°. Mean temperature, 47.60°, which is 6.46° above the average. A favourable month, a fair amount of sunshine and no frosts."

— APRIL WEATHER AT DRIFFIELD.—Mean temperature at 9 A.M. (corrected) 47.54°. Wet bulb 44.12°. Mean maximum 54.05°; mean minimum 36.85°. Highest, 64.2° on 21st; lowest, 27.5° on 13th. Mean of maxima and minima 45.45°. Mean range 13.2. Mean radiation temperature on grass 29.65°; lowest 15.8° on 8th. Rainfall, 1.75 inch. No. of rainy days 9. Greatest amount on one day, 0.59 on 25th. Mean amount of cloud at 9 A.M. (estimated) 5.7.—W.G. LOVEL, *York Road, Driffield, Observer.*

— WEATHER IN SOUTH WALES.—The following is a summary of the weather here for the past month:—Total rainfall, 3.30 inches; maximum 1.17 inch on the 22nd, minimum 0.02 on the 7th. Rain fell on twelve days. Total sunshine, 105 hours 10 minutes; maximum twelve hours on the 15th, minimum ten minutes on the 9th. Sunless days, six. Sunshine did not exceed four hours on twenty days, and on twelve days it was less than two hours. The wind was in the N. and N.W. on thirteen days, S.E. and E. on thirteen days, and for the remainder of the time S.W. Very cold cutting winds all the time, with sharp frosts.—W. MABBOTT, *Gwernllwyn House Dowlais, Glamorgan.*

— ABERDEENSHIRE AGRICULTURAL RESEARCH ASSOCIATION.—The work of this Society in 1894 was largely concerned with an inquiry into "degeneration of Rye Grass and possible recovery." It is argued that in permanent pasture "starvation of plants, and non-utilisation of the plants when grown, are the features to be remedied in order to secure permanent pasture of the valued Rye Grass." The supreme value of *Lolium perenne* in pastures, as demonstrated by Sir John Lawes and others a few years ago, appears to be steadily acquiring additional confirmation in different parts of the country, and the economic importance of the question is beyond all doubt. We are afraid that confusion is likely to arise from the adoption of a practice in vogue at some of the American experiment stations, where the word "legume" is used to denote "leguminous (papilionaceous) plant." In this report we read, "Legumes—i.e., Tares, Peas, Clover, Lucerne, &c." The word "legume" has already a definite meaning attached to it by English botanists, whilst in colloquial use in France it has another and a wider application. Exception should also be taken to the use of the term tubercles (or tubercles) to denote the structures on the roots of leguminous plants. Lawes and Gilbert have, with admirable consistency, adhered throughout to the word "nodules," and it is unfortunate that this example has not generally been followed. Students of agriculture are hearing more and more of tubercle in animals and of the disease termed tuberculosis, and there is a tendency, at least on the part of beginners, to think that all tubercles must be alike. The general adoption of the word "nodules," as used by Lawes and Gilbert, would lessen the possibility of confusion.—("Nature.")

— BLACK GRUB.—Can any of your readers tell me how to get rid of a black grub that I find eats off the stem of Pansies and Iceland Poppies just above the roots? I found as many as eleven of these grubs attacking the roots of an ordinary *Lilium candidum*. Is there any preparation that will kill them without injuring the plants?—L. S. G.

— THE FLOWER SEASON AT THE ISLES OF SCILLY is now about finished. Although prices at the beginning of the season ruled high the returns to the Islands will fall considerably below the average. The early Narcissus crop, the *Soleil d'Or*, was a failure throughout the Islands, and the total number sent for the year will be about 100 tons short of last year.

— A NEW BOTANICAL MAGAZINE.—With the somewhat unwieldy title, "Allgemeine Botanische Zeitschrift für Systematik, Floristik, und Pflanzengeographie," a new monthly botanical journal has been started at Carlsruhe, under the editorship of Herr A. Kneucker. Its aim is especially to deal with the study of difficult groups of plants, diagnoses of species, critical forms and hybrids, geographical botany, and the results of the travels of botanists.

— FLOORS CASTLE.—Mr. Williamson may know if he chooses that "Floors" (Floors Castle) means the floors or terraces formed by the river Tweed that flows at the foot of the Castle—that is the definition I have always understood it to mean, and not flowers or *fleurs*. As gardener at Floors during the whole of the seventies, Mr. Williamson will pardon me for the presumption I here take in the correction of his otherwise appreciative description of Floors and its gardens, and its unique natural position.—K., *Belgium.*

— CARDIFF HORTICULTURAL SOCIETY.—The seventh annual show of this Society is announced to be held in the Sophia Gardens, Cardiff, on August 14th and 15th, and the schedule shows many excellent prizes are being offered. One of the chief classes is for twelve stove and greenhouse plants, the amounts offered being, first, £12; second, £8; and third, £4. These should be provocative of keen competition. The Secretary is Mr. Harry Gillett, 66, Woodville Road, Cardiff, to whom applications of all kinds should be addressed.

— THE DEVELOPMENT OF CUCURBITA PEPO.—In the "Bulletin" No. 9 of the "Minnesota Botanical Studies" is an interesting article by Mr. A. P. Anderson on the Grand Period of Growth in the Fruit of *Cucurbita pepo*. From the time of fertilisation to that of ripening the development may be divided into three periods—a period of active and continuous increase from the time of pollination to the grand maximum; one of decline in the daily increase and rise in the daily decrease from the grand maximum to the beginning of ripening; and the ripening period. During this latter period an extended decrease, due to transpiration, lasting throughout the daily hours, was quickly followed by the maximum increase. At the time of the grand maximum the fruit gained 782 grammes in weight during twenty-four hours. The variations in length of the internodes occurred simultaneously with corresponding increase and decrease in the weight of the fruit.—("Nature.")

— BACHELOR'S BUTTONS.—In reading, as I always do with much interest, the articles of the series on "Floral Facts and Fancies," which appeared in the Journal of April 25th, I observe your contributor's remark that the "Aconite-leaved Ranunculus" is grown in some gardens as Bachelor's Button. I have heard this name applied to the double variety of *R. aconitifolius*, which, as your able correspondent says, is named the "Fair Maids of France." The true Bachelor's Button is, however, another species of *Ranunculus*, being the double form of *R. acris*. It seems that several other flowers bear the name, and among these are *Geranium Robertianum*, *Lychnis diurna*, *Scabiosa succisa*, and also in Devonshire the flowers of the Burdock, the Pennywort, a small *Chrysanthemum*, and the Feverfew—"Friend's Flowers and Flower Lore." By the way, a curious name in the S.E. of Kirkcudbrightshire for the flowers of the Burnet Rose (*R. spinosissima*) is "Sodger's Buttons," "Sodger" being the Doric for soldier. In connection with the same interesting article you will perhaps allow me to correct what appears to be a press error on page 356. "J. R. S. C.," speaking of the Wood Anemones, says, "Under cultivation as in exotic species the stamens become petals, and a pretty double flower is formed, the Pasque Anemone." I think the sentence should have ended at "formed," and that the words "the Pasque Anemone" should have formed the beginning of the next paragraph. It is perhaps not of much consequence, but one finds how easily errors of plant names are perpetuated, and the Pasque Anemone is, of course, *A. pulsatilla*.—S. ARNOTT.

— PINK ERNEST LADHAMS.—Not only as a free-flowering variety in the open, but for growing in pots to give blooms during March and April, this is valuable. In Mr. Ladhams' nursery at Shirley I lately saw several hundred plants that had been flowering under glass, and will continue for some time to come. The best of plants are obtained by inserting pipings directly the first plants have flowered in the open in an almost spent hotbed. They should be planted in well-worked not too rich soil in an open position. Here they will grow stocky, and can either be lifted for pots early in the autumn, or be left to flower where growing.—E.

— DERBYSHIRE AGRICULTURAL AND HORTICULTURAL SOCIETY.—The schedule of the Horticultural section of the show of this Society, to be held on November 11th and 12th, has just reached us. There are open classes, and also a number restricted to amateurs, the prizes in all being very encouraging. The principal class is for a group of plants to be arranged in a space of 200 superficial feet, for which five prizes of £20, £15, £10, £5, and £4 are offered. Three prizes of £10, £8, and £6 are offered in another class for twelve stove and greenhouse plants. Such offers should bring very strong competition, and insure a splendid show. Schedules and full particulars may be had from Mr. Sidney Burton, Canal Office, Derby.

— CUTTINGS, STRIKING OR ROOTING.—Since I had placed before me the other day a copy of the list of questions set for the recent horticultural examinations of the Royal Horticultural Society I have been gravely cogitating the point which is the proper expression to use in the case of root development in cuttings. Do they "strike" or do they "root?" I do not wish to refine over trifles, for to all gardeners the expression or term "striking" means rooting. But in the case of an examination paper set for students of all classes of the community there is a possibility that the word "striking" as applied to root production by a cutting may be misunderstood. The term "striking" is not an apt or really a correct one. It seems to have originated from the use of the term in another way—cuttings strike root. In the case in question it does seem as if it would have been more proper on the part of high authorities, and certainly in a horticultural as well as botanical sense fitting, to have asked how the process of "rooting" in a cutting was developed, rather than the process of striking.—STUDENT.

— ANEMONE PULSATILLA.—This native species of Anemone is at present very attractive in gardens, its finely cut, silky looking leaves and pretty purple flowers being considerably admired. It varies in shade of colour in a wild state, and in cultivation this variation is becoming more marked, a pure white variety being now offered by some nurserymen under the name of "White Swan." In another direction a change in the colour is also desired, this being to obtain red flowers. I was much pleased to receive for inspection some which were kindly sent me by Mr. Mallender of Hodsock Priory Gardens, one of the Journal contributors. These were very fine, and Mr. Mallender is to be congratulated on his success. Some were of a beautiful mahogany colour, and looked very handsome. I have a number of seedlings coming into flower from seeds gathered from a bright red variety by a friend, but regret to see very little difference from the ordinary colour among them. The Hodsock Priory strain seems, however, to be not only a good but a progressive one, and one can only hope that Mr. Mallender will persevere and eventually succeed in improving still further.—S. A.

— BEES FERTILISING BEANS.—Replying both to "English Bee-keeper" and "Observer," I beg to say that the only possible aid to fertilisation which bees can give when sucking honey through the puncture at the base of the flowers must be caused by their shaking the blooms. In no other way can they assist fertilisation, as they do not come in contact with either anthers or stigma. Müller is our best authority, and he says in the case of the Bean that "It is visited by *Apis mellifica*, sometimes collecting pollen, sometimes sucking through the holes bitten by *Bombus terrestris*, and 'when collecting pollen' effects cross-fertilisation, as well as those bees which suck in the normal manner."—"Müller's Fertilisation of Flowers," pages 206 and 207.) Darwin also speaks of this habit of some of the bees sucking through the holes bitten in the calyx of Bean flowers at page 405 of "Cross and Self Fertilisation of Plants." He also proceeds to discuss the motive which impels bees to gnaw holes through the calyx and corolla of flowers. I have often wondered if in time the Bean and other plants will develop a calyx sufficiently strong, or evolve some other means to defeat the ends of these pirates. The Bean is supposed to be a native of Eastern Europe or Northern Africa. I wonder if anyone can tell us if the flowers are punctured and operated on in a similar fashion in these parts of the world.—WILLIAM CUTHBERTSON, *Rothsay*.

— AN OLD PEAR TREE.—Passengers to Lawrence *viâ* the Essex branch of the eastern division of the Boston and Maine railroad may see, says the "Auckland Weekly News," in passing the high bridge approaching Davenport, a wonderful instance of the vitality of the Pear tree by glancing down into the little hollow on the left. It was planted by Governor Endicott, the first head of the Massachusetts Bay Colony, in 1630, and stands on the once famous colonial Orchard Farm. The old tree, a mere shell, with apparently all its inner integuments gone, nothing but the outer bark remaining, and the substance of that split in twain, still stands, and renews again its vernal beauty in a wonderful display of blossoms.

— BORONIA HETEROPHYLLA.—Beautiful and useful as is this plant when grown in bush form for the embellishment of greenhouses at this time of the year, it is perhaps even more so when grown as a standard. A few days since when walking through the houses at Messrs. J. Laing & Sons' nurseries I noticed a few specimens so grown which were exceptionally ornamental. Considering the ease with which it may be formed into such a shape it is somewhat surprising that it is not much more frequently seen in private establishments. Naturally it comes in useful for the back of an arrangement, and saves the necessity of using pots or blocks for mounting, which are very likely to prove an eyesore unless carefully covered.—H.

— WAKEFIELD PAXTON SOCIETY.—At the meeting of this Society, held on the 27th ult., Mr. B. Whiteley presided, and Mr. W. Hudson of Sandal Grange was in the vice-chair. Mr. J. G. Brown, Curator of Outwood Cemetery, and for many years gardener at Hatfield Hall, read an excellent and practical paper on "The Cultivation of Bulbs for Spring Flowers." The essayist referred to most of the varieties of bulbs for spring flowering, and, speaking from long and successful practice, described the best mode of planting and growing them both in pots and in the open garden. A long and interesting discussion ensued on the paper, and at the close a hearty vote of thanks was accorded to Mr. Brown, who said it was always a pleasure to him to do anything he could on behalf of the Paxton Society.

— GREEN APPLE APHIS.—A report has been circulated to the effect that a green insect, abundant in numbers, threatens to do much damage to the fruit buds in New York, Ohio, Michigan, Indiana, and Illinois. Through our correspondents we find, says an American contemporary, that the cause of this report is the green Apple aphid, and that it is restricted to only a few localities. Of it Professor Forbes says through the Illinois Agricultural Board:—"These insects, which have recently hatched from small shining black eggs laid on and about the bud of the Apple, rarely do any permanent mischief in the Apple orchard. The buds commonly unfold so rapidly that their development is not checked, and the insect itself begins to disappear in about three weeks from the time of hatching. It can be destroyed when thought necessary by a thorough spraying with a 5 per cent. kerosine emulsion. In most cases, however, its destruction by this means would be a waste of labour and money, since it is not likely to be undertaken until near the period of the normal disappearance of the aphid."

— THE WOOD FOR BROOMS.—There is but a small amount of wood in a broom, but so many millions of these implements are used every year that the consumption of wood for broom handles is a considerable item. "The Southern Lumberman" states that while it would have been almost impossible to sell a broom-handle made of heavy hardwood a few years ago, at present the reverse is true. The manufacturer prefers hardwood because it does not require so large a bolt, can be turned down smaller and yet retain sufficient strength, and can be ornamented more cheaply and artistically. Brooms with hardwood handles sell more readily and do not deteriorate in appearance like the soft wood handles. Any kind of inexpensive hardwood, such as Beech, Birch, Maple, or Ash, makes acceptable handles, while springy woods like the Elms are not saleable, because one essential feature of a good broom is a straight handle. The manufacture of broom handles can only be made profitable when the timber runs largely clear. In the Eastern States the timber waste in making broom handles exceeds 50 per cent., while in the south-west it is usually less than 25 per cent. There are four factories in Amsterdam, New York, one of which has a capacity of 1200 finished brooms a day. They use hardwood handles from the south and west, and get them for less than the bolts ready for the lathe can be furnished from native hardwood. The handles are turned green and dried afterward. The large end on which the brush is wired must be thoroughly dry or the broom will work loose. The drying of the upper part of the handle is of less consequence, except in the saving of freight.

— THE POISONOUS PRINCIPLE OF PRIMULA OBCONICA.—Dr. Riehl of Vienna University, says the "English Mechanic," has been experimenting with the poison of the *Primula obconica*. It was found that the tiny hairs on the leaf and stalks irritated the skin, and gave rise to swellings and inflammation. Dr. Riehl succeeded in extracting the poison, and, by means of injections with it, claims to have healed more than one obstinate skin disease. His experiments are not yet completed, but they are stated to promise good results.

— TROPÆOLUM TUBEROSUM.—In the spring of 1893 Mr. Orchard very kindly sent me two or three tubers of this *Tropæolum*, which were planted on a south border. No flowers of consequence were produced the first year. A thick mulching of leaf soil was laid over the surface in the autumn, and in spite of the 24° frost experienced on the 5th and 6th January, 1894, strong sucker-like growths came up in the following April. During the summer and early autumn the growth was exceptionally free, the bright orange and scarlet flowers being produced in abundance, continuing until the plants were cut down by frost. After the experience of the previous winter I had no thought or doubt of the hardness of this *Tropæolum*. The usual mulching was given, but, alas! not with the same or anything like similar results. I greatly fear the whole mass of tubers, which had increased so fast as to cover a space fully 2 feet in diameter, is killed. I am exceedingly sorry for this mishap, as the plant was thought highly of by all who saw it. The densely growing leafage forms such an excellent setting for the showy blossoms, which are so freely produced in September and October. It would be useless to attempt to grow this plant in any but a sunny spot, as owing to the gross growth and the lateness of flowering poor results would be obtained in a shady site.—E. MOLYNEUX.

— GRAFTING OLD TREES.—It is now past the grafting season for the year, but there can be no harm any the more in discussing the question, what are, so far as the stock tree is concerned, the best conditions for the production of a fine robust head in the earliest space of time. I was reading recently in one of the papers some rather hot comments on the practice advocated of grafting old trees rather hard back, and advising in place grafting on many branches high up. Now, I do not claim to have had so much experience in this direction as some of your readers, but all the same I have had in my life a good deal, and I invariably adopted the practice of grafting as hard back as I well could, and with the very best results. On the other hand, I have seen many trees grafted high up, but never with to me, whatever they may have been to the operators, satisfactory results. My experience, and it began some forty-five years ago, invariably was that beheading old trees back to some three or four of the stoutest branches, and within a couple of feet or so of the break from the main stem, putting on two, three, or four stout hard grafts as big as a man's finger, very tightly driven home and wedged, then tied and clayed, always gave the first year stout sturdy growths, of which in the winter the weaker could be removed, the rest partially shortened back, and thus was laid the foundation of what became in three years a splendid head. Such results have come in scores of cases. But when a tree is beheaded so sparingly that it has some twenty to thirty comparatively small branches to be grafted smaller grafts are used, and some invariably fail. Then, because of the wide disposal of the sap force in the tree, growths are at the first always weak. Again, because there is so much area of stem left on the stock, growths that are but robbers break out all over it, and unless these are carefully pulled, give immense trouble. When closely headed back such trouble is minimised, and the graft growth, because of the concentration of the sap force, is so much stronger. I have seen no reason to alter my preference for low-down grafting.—A. D.

### SPRING BUTTERFLIES.

THAT the majority of British gardeners have no very little admiration for butterflies is a fact. I believe, yet as a tribe of insects they are not markedly enemies of flowers, fruit, or vegetables. Certainly the first butterflies that emerge in spring somewhat numerous, the familiar whites of our gardens, are the parents of a brood of troublesome caterpillars, but most species that we see at flowers do no harm. Indeed, we might consider them adornments to the scene, giving an agreeable addition by their beauty and lively movements. Perhaps during the spring more than any other season butterflies attract our notice both in the open country and in gardens, because for five or six months insect life has been dormant. People have, however, said of butterflies generally that they appear to be lazy members of the insect race, mere honey sippers—quite a contrast to bees, ants, and many diligent species. A butterfly's life is short, and does not call it to active effort except for the continuance of the species, but it is, probably, a useful insect in a way that might not be supposed, that is, when wandering from flower to

flower it sometimes assists the fertilisation of plants by conveying pollen, or dislodging it from the anthers.

I have spoken of butterflies as insects that indicate the arrival of spring, but occasional specimens are visible in the early months of the year, though not in a severe season like that of 1895. These are hibernaters, whose winter residence is in wood and haystacks, hollow trees, or odd nooks, out of which a day of milder temperature draws them for a brief excursion. In January and February it is not unusual to see the brimstone butterfly, or one of the tortoiseshells. The peacock and the painted lady may come forth on a fine March day, but not till April do butterflies newly hatched from the chrysalis show themselves. The first I saw in North Kent this year was on the 17th ult., a large white. The small garden white usually precedes that species by a few days, sometimes it emerges at the beginning of the month should the season be forward. This is an insect quite at home in the heart of cities, where butterflies seldom abide, breeding yearly in the gardens and squares of London where various ornamental Cruciferous plants, *Tropæolums*, *Mignonette*, and others furnish food to the caterpillar, which, like its big relative, also devours vegetables of that order in kitchen gardens, on which eggs have been placed by the parents during the spring or summer, for both species are double-brooded.

One of our familiar writers on garden insects remarks that the butterflies appearing during April and May should be hunted down mercilessly, since it is easier to kill the mother insect than the fifty or sixty caterpillars that will be her descendants. We are not, however, yet used to the sight of a gardener improving "the shining hour" by rushing about with a green or white net in hand, but it is advisable to reduce the numbers of the spring brood as far as possible, by searching for and removing eggs and young caterpillars from their food plants. It is owing to the fact of the first hatch frequently escaping notice, because gardeners have so much to occupy them in the spring, that the succeeding summer brood is apt to be more numerous and destructive, especially to Cabbages or allied culinary species.

Where the smaller butterfly, the *Pieris rapæ*, does unsuspected mischief, is by its artful habit of working into the heart of a Cabbage while young, and lying concealed there till adult. As it happens, the detection of the egg is not easy, but if we light on one others are probably not far off; they are usually placed singly, being like tiny sugar-loaves, only with numerous ribs. The young caterpillar on emergence begins life by eating its egg-shell, an odd performance it seems to us; but the same habit prevails amongst many species. About the second week in May they are appearing on the leaves; many of them may be washed off by tobacco water, any soapy solution, and other compounds found efficacious in the removal of juvenile caterpillars. Though in colour they closely resemble the leaves, birds discover them, and reduce their numbers, the common sparrow eats them, and they are said to be sought by the thrush, also by the wren.

That the large white (*Pieris Brassicæ*) in its caterpillar stage also furnishes food to some birds is unquestionable, but some insect-eaters shun it, probably deterred by its very unpleasant odour, which is an additional cause of annoyance when it is found devouring vegetables. On the average, it is more mischievous than the smaller species, and it has this peculiarity, that there seems to be a succession of the butterflies of the summer brood, so that caterpillars are to be found quite on till autumn, even to the end of October some years. Frequently the eggs are laid in clusters of eight to twelve, each being like a miniature nine-pin. When newly hatched the caterpillars of each batch feed together awhile, which is a help to their detection. The eggs are, of course, best removed before the time of hatching, if observed.

Our crops of Cabbages, Cauliflowers, Broccoli, and also Turnips, would, however, suffer far more than they do from this butterfly were it not for the exertions of a tiny ichneumon fly, the *Microgaster glomeratus*, a four-winged insect, which, under the microscope, is seen to display a beautiful opalescence and metallic brilliancy. Dozens of its grubs live within a single caterpillar residing between the skin and muscles, they devour its fat, but do not kill the caterpillar until it has nearly, or quite, attained to its full size, and is preparing to change into a pupa. Then they issue forth, and decorate the wasted carcass with their numerous golden cocoons, common on walls and palings in winter, yielding a new spring brood of useful flies.

May brings to our gardens the showy and active butterfly, the Red Admiral, or was it at first "admirable," because of its bold colouring? yet another name for it was the "alderman," its red and black hues reminding people of the gowns that some aldermen wore. Swift and courageous is *Vanessa Atalanta*, not limited in its taste for sweets to the honey of flowers, for it often visits ripe fruit, and delights to come on an exudation of sap. Somehow, it has lately got a bad character, and has been referred to as an enemy of orchards, but it does no appreciable mischief, even when it is abundant. The caterpillar feeds on the Nettle, so do those of the small tortoiseshell and peacock butterfly in the same genus, and they have been placed on the list of useful species, being large consumers of what is a troublesome garden weed. Years ago the common butterfly was not unusual about gardens during May, the caterpillars feeding later upon the Red Currant, also upon the Hop. It has now become very scarce and local.

In the good old times we read of the fruit trees suffering from the attacks of the Hawthorn butterfly or black-veined white, its caterpillars being not unfrequent even near London. As a British species it has become comparatively rare, though on the Continent it is still complained of; and some seasons thousands of the caterpillars appear about orchards, selecting for their spring food both leaf and blossom buds.—ENTOMOLOGIST.

## MARKET PLANTS AND FLOWERS.

(Continued from page 380.)

## WHAT TO GROW.

To make a beginning, and to see the way clear to a profitable result, the commencement of the busy market season should always be borne in mind, and every preparation to meet some of the varied demands of that most important period put in hand, and kept in practice.

It has already been remarked that a grower cannot have too many good Zonal Pelargoniums, in the market commonly termed "Scarlet Geraniums," of the Vesuvius type. The grower should also have a good stock of white and pink Zonals, all autumn rooted, to make good plants by the end of March.

To make up for a deficiency of Zonals some thousands of 48's of Giant Mignonette ought to be sown early in August, another stock later on, and endeavour to keep up a successional supply from the beginning of March. Good seeds ought to be sown thinly, and when ready for market one plant of Mignonette often, but not always, makes a perfect specimen. The plants should be neatly staked, which should be done a few weeks previous to their being sent to market.

Mignonette for market purposes is best cultivated in long narrow pits, placed as near to the glass as possible, and the lights taken right off on all favourable opportunities; at no time give the plants more artificial heat than what is really necessary to keep secure from damage by frost. A single flow and return pipe will be sufficient, and if the return is diverted so as to occupy the centre of the pit after the first sowing of Mignonette has been marketed, which ought to be by the beginning of April, fill the pit with masses of "Geranium" cuttings in 60's, give plenty of heat, and they will all be ready for market just at the proper time, the beginning of May, and will be no trouble to sell. After the spring-rooted plants fill the pits with Cucumber plants, and so carry on the season until it is again time to sow the Mignonette.

Be careful to have the soil used for Mignonette perfectly free from worms, a loamy soil is the best, and one layer of crocks is sufficient. The soil should be pressed firmly in the pots, and if the seeds are good a few for each pot will do; they should be lightly covered and the surface pressed level, standing the pots where no worms can enter the soil, finally placing them in their winter quarters. Several sowings may be made, once a month. Mignonette if grown well always finds ready sale up to the month of July, when the plant season may be said to terminate. Then the grower should double his diligence, and concentrate all his energy in propagating for another season. "Geraniums" of the Vesuvius type, also Jacoby, tricolors of the Mrs. Pollock type, as also the silver variegated sort, and golden bronze, sell better in large 60's than in 48's, because they are more in request for bedding than for other decorative purposes; also the double pink Ivy. This variety, with the scarlet Vesuvius and the dark crimson Harry Jacoby, should be well established in 48's by the beginning of January, but not allowed to grow too much unless wanted for propagation. The aim of the cultivator should be to grow sturdy plants about a foot high from the pot, with three or four shoots, and by April there should be no difficulty in having them with three or four well-expanded trusses on each plant. Any of the shoots which show a tendency to grow stronger than the others may be cut off at a suitable point and made into cuttings; on no account let the least part be thrown away, for a penny saved is a penny gained.

The double Ivy "Geranium" will require a little more attention by placing a neat stake in the centre of the pot, and about 15 inches high. The plant should be induced to break into four or five shoots, which must be neatly looped to the support, and when about to bloom the flower stalk should be so trained as to have the flowers just on the top of the plant and close to the foliage; then it looks extremely pretty and is most saleable.

Should the scarlets be growing too luxuriously, say about the month of March, and short of house room, it is a good plan to shorten the shoots of every other plant, and so prevent overcrowding. The plants so cut back will soon break, and so follow the earlier ones to the market. The Fancy Pelargonium used to be largely employed by the London florist for the furnishing of windows and balconies, but since the introduction of the Marguerite this pretty class of plants are not in such request. Nevertheless, good healthy plants in 48's, well bloomed, always find ready sale in the months of May and June.

All the Pelargoniums grow luxuriantly in rich turfy loam with abundance of coarse sharp sand to keep it open and sweet. The loam and the sand should be well prepared by throwing in a heap, chopped over and over, and finally passed through a coarse sieve and placed where it may be always ready for use. The siftings are useful to place over the drainage in the bottom of the pots, and should always be preserved for that purpose.

Summer and early autumn-rooted stock make the best plants for 48's, and if each cutting be rooted in the smallest thumbs, and then transferred to 60's, no check is given to the plants, and they may be had in form by the beginning of the year. The plants should at all times be kept as near the light as possible with abundance of air on all favourable times, even in January and February if mild and no likelihood of frost. The fires should be kept low but ready, and air freely admitted to the plants. As the sun increases in brilliancy it becomes necessary to apply a little shading to the roof; a drying wind and a scorching sun is almost as harmful to the plants grown as a winter blizzard.

If the glass is good and any clay or lime in the neighbourhood, a handful or two well dissolved in a pailful of water, and syringed over the outside of the glass, is a very easy and inexpensive shading; a shower of rain may wash it off, and is welcome to do so, for the moist atmosphere with April sunshine is most conducive of healthy and robust vegetation. Should the liquid shading by any chance get through the glass and spatter the foliage, wash it off previous to sending the plants to market or to the purchaser, and so maintain the reputation of the establishment.

The White Marguerite, with its cheerful looking flowers so much like the "Gowan," leads one into a reverie, and to remember the old love song, "Meet me on the Gowan lee." Thousands of persons toss up their heads and declare that the French Daisy is nothing more than a perfected Gowan, and pity the taste of those who use it largely for floral embellishment.

The good grower pays no heed to such fancy, but endeavours to cultivate what takes the public taste, and keeps rooting and increasing what he knows will be wanted in due season. For a certainty the White Marguerite is one of those plants which take hold of public favour and will continue to do so for some time to come, for without doubt it is the most appropriate flowering plant which has ever graced the outside of a window. Though at the same time there may be too much sameness in the way the plants are displayed in the windows and balconies of the metropolis. A little more colour or greenery, such as a graceful Palm or two overtopping the flowers, is more artistic.

The White Marguerite may be had in flower all the year round, but from the middle of April to the end of June, Covent Garden Flower Market can have no glut of good plants. In season they may be found in the conservatory, in the hall, on the staircase landing, on the side table, in the fireplace, in the window boxes, on the balconies, even to the housetops, and they never seem out of place.

The Marguerites which command the best price and ready sale are those plants which are about 15 to 18 inches high and as much through. When the plants are ready for market each should be encircled and compressed with a single and almost imperceptible slip of matting, which will allow the plants to be packed more closely.

It will be found that the best plants are developed from summer-rooted cuttings, choosing healthy stock and perfectly free from the fly. The old stools should not be thrown away. If they are shaken out of their pots, cut well back, and repotted into smaller sizes, using fresh stiffish loam, they ought to make splendid plants for another year.

In the winter months keep the plants as near to the glass as possible, and when they begin to fill out and require more room every other plant may be shortened. The cuttings may be put in thumbs, three in each pot, and as soon as rooted shifted and grown in larger. They will be capital stock by June. On no account let the Marguerites be overcrowded, nor yet give them a close humid atmosphere. Give them abundance of air and supply a little stimulant as they approach inflorescence.—A. M.

(To be continued.)

LA FRANCE ROSE.

WE figure a bloom of La France Rose, not grown by a great amateur rosarian, but by the possessor of a suburban garden—Mr. R. W. Gardner, Shirley Villa, Palmer's Green, Middlesex—who was proud of it, as well he might be. It was one of the finest we have seen, and might be described as one of the most charming of Roses represented in fullest beauty. The plant was bought in January last year from Mr. Watson, florist, Bowes Park, N., placed in a pot, which was plunged in the garden, the pot resting on a tile, for preventing the ingress of worms. There it remained till the winter, when it was slightly pruned and removed to a greenhouse. The soil used in potting was turfy loam. A top-dressing of decayed manure was given before the plant started into growth, supplemented by occasional applications of liquid manure, and it goes without saying that insects were not allowed on the plant. Mr. Gardner is to be congratulated on producing this splendid bloom.

## SEASONABLE NOTES.—MARÉCHAL NIEL UNDER GLASS.

I READ with interest the remarks of "H.R.R." (page 362) on this head, and am much surprised that he recommends grafted plants for the growth of this grand Rose. I have no doubt that half-standards trained in regular upright rods under the glass, and cut clean away to the horizontal arms at the conclusion of flowering, on the system described more than once in the Journal, will produce the finest blooms, and I should think more of them per square foot of glass can be raised than in pots.

To show the faith that is in me I have forwarded half a dozen blooms to the Journal office. The plant they were cut from is an ordinary half-standard, planted some ten years ago at a cost of, say, 2s. 6d. The space it covers on the roof of my greenhouse is 17 feet by 12. I have already this year cut 251 such blooms on this space, and there remain buds for future cutting to the number of 292, total 543 to 204 square feet of glass. The blooms I have sent are a fair sample of those already cut,

and I do not hesitate to say that a large majority of them have been fit to show in any stand of Teas I have hitherto exhibited. I should be glad to know if anyone can beat this for quantity and quality with regard to space, by any other system of growth and training.

It is fair to say that this is a crop above the average in point of numbers—it has generally been between 300 and 400. Some check occurred at an early stage of growth to several of the laterals, which broke again, giving two and in some cases three blooms to one eye. I ought here to say that in speaking of 543 blooms, I mean "trusses," only one Rose being allowed to each shoot. And I must also say that some of these and the later buds, perhaps a third or a quarter of those that remain, appear to be smaller and below the average of those already cut.

#### ROSE MRS. W. J. GRANT.

It is a matter of congratulation to all rosarians that this fine variety is now to be procured in this country; but I am very sorry to see it advertised under another name, and I earnestly hope that all Rose growers will make a point of ordering it, speaking of it, and exhibiting it under its real name. In the case of those varieties declared by the N.R.S. to be duplicates, there is an unwritten law that the oldest name shall stand, and this is properly and strictly carried out in the N.R.S. catalogue.

But this is not a matter of a "too similar" variety, but the veritable same Rose, which, as named Mrs. W. J. Grant, received the gold medal as the best Rose of the year in 1892. Of course, they may call it what

FIG. 68.—ROSE LA FRANCE.

The first bloom was cut on April 11th, and to all appearance they will last longer than usual, beyond the middle of May. I have no idea of the money value of such blooms, but I should think it would make a pretty fair return per foot run of glass. The outlay is a trifle, the labour very small, and I have had practically no mildew or green fly. One of the two horizontal arms is at last weakening through canker, but I have already trained another shoot to take its place. The system of training was fully explained in "Manners and Customs" in the Journal, and "The Book of the Rose." I take no credit for it, it is not my invention. I got it from some paper, I think the Journal itself.

[The Roses received were of the first order of merit, and the leaves in their way as fine as the blooms. They arrived as fresh as when sent off, through each bloom being carefully enclosed in "butter paper," which, while being soft, prevents the escape of moisture from the blooms. It is likely to be tried in the packing of Tasmanian Apples for transit to this country. We wonder whether this packing for Roses is the invention of Mr. or Mrs. W. R. R.]

they like in America, and that is no business of ours; but I hope to find a general consensus of opinion that a Rose raised in the British Isles, named here, and under that name receiving a special mark of recognition from the N.R.S., should retain that name in this country; indeed, I should vote against any proposal that the other name should be added to the list of synonyms. It would be best to make no comparison whatever between the two names, but simply to adhere to our own as a matter of right.

[Unquestionably Mrs. W. J. Grant is the correct name of this Rose, and no other name should be recognised in the United Kingdom, whatever may be the case elsewhere.]

#### EARWIGS.

The "black grub" is already making its presence felt pretty widely, and I fear, as lately stated, that insect pests may prove rather a nuisance this season. Earwigs are a trouble to us as well as to our Chrysanthemum friends, and a rosarian may therefore perhaps be pardoned

for taking an interest in Mr. Briscoe-Ironside's "Earwig Baffler" (page 341).

I confess I was very much surprised at the whole thing. A patent for keeping away from a plant an insect possessing a splendid pair of wings, by means of a slender rim containing water level with the ground, seems to me one of the funniest things that have appeared in the Journal for a long time. It reminded me of the ancient libel against the men of my native county (Somerset), that they built a hedge to keep the cuckoos in.

It was plain there must be some explanation, and it is to be found in Mr. Briscoe-Ironside's words (p. 341), "I think there need be little fear of its flying upwards, as having watched this insect very closely for some years, the only object of its wings, so far as experience tells me, is to check rapidity when falling, serve as a parachute as it were." I would like to ask him if he has ever seen this done; if he has ever seen an earwig dropped from the hand to the ground, use its wings to break its fall. I have certainly thus dropped a good many scores, and should have been very much surprised to see it. Why, hardly any beetle or chafer can open its wings when falling a short distance, and none of them has its wings so wonderfully compacted and folded over and over as an earwig. It is probably a slow and elaborate ceremony with an earwig to commence flying, but once started there need be little doubt I think, of its power to fly "upwards." Will "Entomologist" be kind enough to say whether an earwig can fly over an inch or two of water, or as high as the leaves of a Chrysanthemum plant?—W. R. RAILLEM.

### HERBACEOUS PLANTS IN JULY.

FOR flowering during the month named the following kinds have given me satisfaction, and as it is not yet too late for planting many of them (which are plunged in pots in nurseries), a record of my experience may perhaps be useful to some readers.

*Border Carnations.*—The great improvement which has taken place in this class of late years has given us plants which greatly enrich our herbaceous border. I can never, as an old florist, disparage the beautiful flaked Carnations and delicately edged Picotees which have formed the delight of so many generations of florists, but their very delicacy of colouring deprives them of their effectiveness as border plants, and for this purpose they have been superseded by what are now called border kinds, and in the beautiful additions made by Mr. Martin R. Smith and Mr. Douglas (in yellows) and other growers we have some very charming flowers. Such varieties as Mrs. Reynolds Hole, Theodora, Kettin Rose, Niphotos, Mrs. Muir, and others come in most effectively, especially when grown in small clumps, and during this month afford a copious supply of sweet-scented flowers.

*Coreopsis grandiflora.*—This is the best of the herbaceous varieties of this genus; there has been some difficulty as to its being confounded with lanceolata, but as a free-flowering bright yellow plant it is very desirable.

*Centaurea macrocephala.*—A very large, showy, if somewhat coarse plant. Though it is more suitable for larger gardens than mine, it is so very handsome that I do not care to be without it; but here it is only suitable for the back row of a wide border.

*Aquilegia chrysantha.*—While the greater number of the Aquilegias are attractive this is one of the boldest and most beautiful, and coming later into flower than the others, remains for a long time in beauty after they are past and gone. It is, therefore, more easy to keep this true than any of the other Aquilegias. There is no class of plants which is so readily cross-fertilised, and therefore the attempt to keep any species distinct is an almost hopeless endeavour. I used various devices with such plants as Aquilegia cœrulea, and thought I had succeeded in keeping it distinct, but the seedlings have been more or less incorrect, not one of them coming perfectly true.

*Telekia speciosa.*—This is another very striking yellow-flowered plant, but like the Centaurea rather coarse, and must also be consigned to the back row. It is not so soft and tasselly in appearance as Inula glandulosa, but for all that it is a plant which one would hardly like to be without.

*Geranium pratense fl.-pl.*—One of the most beautiful forms of our native Geraniums, very free and vigorous, the flowers continuing for a long time in perfection. It is abundant as a wild flower in the North of England, but is not found down South.

*Linum perenne.*—This very beautiful blue perennial Flax continues a long time in flower, and its brightly coloured blooms, similar to those of the annual species, are very acceptable, although they have, like others of the genus, the habit of closing their flowers early in the day.

*Catananche bicolor.*—A very common Everlasting-like flower, producing its white and blue flowers on the same plant. It is very useful for cutting, and continues in bloom for several months together.

*Stenactis speciosa.*—Sometimes called Erigeron. Although this is a somewhat common flower it is one of those which no herbaceous border can very well dispense with.

*Tradescantia virginica.*—Both the blue and white varieties of this well-known plant are very showy, and easily grown, as they will thrive in almost any garden soil, and require to be kept somewhat within bounds.

*Bupthalmum salicifolium.*—One of the best of the genus, with bright yellow forms forming a succession of blooms for some weeks.

*Eryngium giganteum or niveum.*—Why called giganteum I can

hardly see, as it does not grow nearly so tall as Oliveanum or amethystinum, but both are most desirable border plants. The peculiarly metallic blue of the latter, which is common to both stalks and flowers, makes it a most desirable plant, while the character of the foliage of both keeps them a long time in perfection.

*Monarda didyma.*—This, one of the oldest flowers of our cottage gardens, where it is generally known as Bergamot, deserves a place in every herbaceous border on account of its peculiar colour and strong and pleasing perfume, but it is not nearly so often planted out as it ought to be.

*Cypripedium spectabile.*—This, the most beautiful of the North American terrestrial Orchids, delights in a cool and moist situation, being generally found in swampy places. I have had a good display of it for many years, and it is always to me one of the most attractive of my July flowers. The drought of 1893 did not at all suit so moisture-loving a plant, and although it bloomed again well this year it has not been nearly so luxuriant as previously.

*Orchis foliosa.*—This beautiful Madeira Orchid accommodates itself easily to our climate, and although I have never had it in the same perfection as I have seen it in other gardens, it forms a conspicuous object when in flower.

*Alströméria aurantiaca.*—This, which is almost a weed in many gardens, I could not for some time establish in mine, but have at last succeeded. I do not know why it did not thrive with me at first, as I had done what I could to induce it to grow, and am very glad indeed that it has asserted itself at last.

Such are some of the more noticeable plants which flower in July. I have left out many others, such as the Spiræas, Galegas, Gaillardias, Heleniums, and Potentillas, but I think I have shown that even without the use of bedding plants a garden may be full of flowers for those who trust to herbaceous plants alone, while their great variety both of form, colour, and perfume gives them advantages which bedding plants do not possess to anything like the same extent, while for cutting purposes for the house they have, I think, a very distinct advantage.—D., Deal.

### EXPRESS GRAPE GROWING.

SOME interesting details have lately been given in the Journal of cases of "Express Grape Growing," and the results chronicled are really remarkable, especially so in the case of the Vines planted out of 3-inch pots in the middle of August, when no thicker than straws!

That these Vines covered the house with splendid well-ripened wood before the end of the season is wonderful, seeing they had, as your correspondent "W. H. L." remarks, "only the tail end of the summer" in which to change from straw-like canes into splendid Vines, capable of producing heavy crops the very next season.

Had the Vines been planted earlier in the season and been even moderately good canes when planted, the results attained to would have been capital, but, of course, not so remarkable as is this case of weak Vines planted late in the year.

In 1870 we planted the bulk of our Vines here from eyes rooted in February of the same year. They were rooted and grown on in the bed of a Pine pit, on turves, with some fine soil on top. The Vines were twice root-pruned in the bed—first lengthways, then across. They were then lifted and placed in a similar bed of turf and fine soil, only wider apart. They grew rapidly, and when about 3 feet high they were again root-pruned in a similar manner to their first root-pruning, and suffered no check. The consequence was that when we lifted them for planting they were vigorous Vines, with a mass of fibrous roots peeping out at all sides of the squares into which the turves had been cut. We planted some of them in May, some in June, and some in July, and they all did splendidly, running up to the tops of span-rooted houses 18 feet high, and filling all the roof space with grand wood and foliage. When pruned the canes were hard and well ripened, and from 3 inches to 3½ inches in circumference.

Though the permanent Vines could easily have borne a good crop the next season we decided to let them have another year's unrestricted growth, not burdened with even a single bunch. The temporary Vines, however, bore a good crop that year, and finished the fruit splendidly.

The permanent Vines we planted thus in 1870 still continue to bear annually as well as could be desired, and we look on this as very good work, seeing the Vines have for so many years been producing heavy crops of the best quality Grapes, and they were not all planted in good soil.

We could not get very much good turf when they were planted, and many of them had to be content with very poor stuff indeed. We, however, found out what suited them in the fertiliser line, and continue to benefit thereby by having the pleasure of seeing the Vines so vigorous and fruitful after so many years of heavy cropping.

In our case no claim for special express Grape-growing is made. We planted the Vines in the best possible condition. They grew so well and ripened their wood so thoroughly that all of them could have borne heavy crops the next year—that is, in less than nineteen months from the time the eyes were put in we could have had them all bearing a heavy crop had we so desired. But we deemed it more profitable only to crop the temporary Vines, and let the permanent canes have another season in which to mature.

We have no reason to regret the system we adopted, and if planting Vines on a large scale again would pursue the same plan.

It will be interesting to note the future progress of Mr. Innes' Vines.

In common with "W. H. L.," and no doubt many more, I shall be glad to hear that these remarkable Vines continue to flourish and fruit as well as at present.

There can be no doubt that had they been properly grown before being planted, and had they been planted earlier in the season than they were, they would have been even more remarkable than they have proved.

Many Grape growers for market contend that it is more profitable to plant after cropping heavily every year, and replanting whenever signs of failing vigour are shown, than it is to take moderate crops and maintain the same Vines in vigour for many years.

This is a matter open to debate, and some, of course, take one opinion and some the other; but I think there is no difference of opinion regarding the desirability of having good Vines when planting. It is certainly a great advantage to have this, and when such poor Vines as Mr. Innes describes, are planted late in the season, it is almost miraculous when they do so well, and are able to produce such heavy crops the next season.

The use of Grapes—well ripened and of good variety—is most beneficial to the health of the community, and that they are now so abundant is matter of considerable moment, as they can be had by all at reasonable prices. Indeed the producer has now come to consider the prices as rather too reasonable for the consumer, and rather too unreasonable for himself.

No return to the good prices of bygone years can be looked for. Every year, doubtless, the quantity of Grapes sent to market will increase, and when we hear of such wonderful crops produced from such material in so short a time, it seems likely that the markets will be glutted in the future.

The public, however, should learn to discriminate between well grown and indifferently grown Grapes. They are as different as night from day. Get a good well-grown and ripened Black Hamburgh, Muscat of Alexandria, Duke of Buccleuch, or Madresfield Court, and you have splendid flavour and quality. Get a good Gros Colman or Lady Downe's, grown and ripened with abundance of heat combined with judicious airing, and they are vastly different from the ordinary run of Black Alicantes grown in a cool atmosphere and with the proper qualities not developed, though of course at best the Alicante is a second-rate Grape, still it can be improved by proper culture.

What we want in the future is—in addition to "Express Grape growing"—proper Grape growing, that is, such culture as will not only produce quantity but quality.

There is nothing to prevent this being done, if only the right means are used, and then we should have the British public not only consuming more Grapes, but realising what fine things they are, how health-giving, how refreshing, and how luscious.—JOHN THOMSON, *Clovenfords*.

I HASTEN to set Mr. Colebrook's mind at rest by assuring him that I have made no mistake, and that every word I have stated to be perfectly accurate. They are accomplished facts, and well known to many who saw the Vines and Grapes for themselves. I would refer Mr. Colebrook to my first letter (page 328), and respectfully request him to read it again, as he is evidently labouring under a misapprehension by stating in his article on page 386 that my Vines carried ten and twelve bunches, each averaging  $2\frac{1}{4}$  lbs. What I did state was that the permanent Vines carried seven bunches, averaging  $2\frac{1}{4}$  lbs., and the supernumeraries ten and twelve bunches, average weight  $1\frac{1}{4}$  lb.

When on a visit to Gordon Castle Gardens, Morayshire, late in the autumn of 1877, I saw there, under the able management of that grand old gardener, Mr. Webster, a house of young Vines which had been planted in the month of July, raised from eyes that season, and at the date of my visit, somewhere towards the end of November, these Vines had made a growth of upwards of 20 feet of splendid wood. I cannot say whether Mr. Webster fruited them the following season or not, but I certainly should have had no hesitation in doing so.

I quite agree with your correspondent, "E. M." (page 386), that time alone will prove whether the cropping of young Vines at so early a stage of their existence will prove injurious in the long run. I do not think for a moment that Vines judiciously cropped under good management need suffer in the least degree. A large amount of discretion is needed and must be exercised, and the general condition and strength of the Vines taken into consideration, which must be the guide in determining the amount of fruit each Vine is capable of maturing; and then so much depends on the general management, including feeding. What is a success in one man's hands frequently turns out a failure in the hands of others. I have a very grave doubt as to whether Vines at the age of fifteen, twenty, or thirty years, even under the best of management, would compare favourably with Vines of a younger growth. I know of some old Vines which are giving marvellous results in the hands of good gardeners; but I think "E. M." is too able and experienced a gardener to admit that there are many Vines at the age of twenty or thirty years worth retaining as compared with young Vines. I find there are but few market growers in the present day who care to waste time with old Vines, and depend upon it they are not the men to throw away that which is most profitable.

I think Mr. Geo. Bolas' interesting letter (page 386) goes to prove that in his case, after fifteen years' trial, the express system has been a success. Looking at this subject from a market grower's point of view, it becomes a matter of vital importance in these days of keen competition. With small profits, quick returns become more and more a necessity, and I fear the signs of the times point to a still smaller

margin of profit in the near future. It therefore behoves us to be up and doing. Grape growing in the present day to pay requires both quantity and quality and no waiting. Mr. Bolas gives us a cruel reminder of the "good old days" when Grapes realised 25s. per lb. What a contrast with the prices of to-day! "Nemo" also reminds us on page 375 of the Journal that in those days Grapes were confined to the table of the wealthy, but now they are within the reach of the poor.

I will give, in the way of information asked for by "E. M.," a brief record of Vines planted in ten years ago, and in doing so I find it raises another important point—viz., the effect heavy crops of Grapes may or may not have when allowed to hang on the Vines through the winter and well into the months of February and March. I planted upwards of 300 permanent Vines in 1885. About 250 of these were one year old, the remainder were raised from eyes the same season. The first named were planted in April and the latter towards the end of May, with about 300 supernumeraries also raised from eyes that season, and planted when about 12 inches in length. When each had made about 8 feet of growth they were stopped and again allowed to break, and long before the end of the season they had reached the top of the house.

The following year the oldest Vines carried seven bunches each, and those we raised from eyes the previous season carried five and six bunches each and finished the fruit to perfection. As a test question as to the effect the early cropping may be supposed to have on Vines I will select one particular house, which has passed through what may be considered the most trying ordeal. The vinery is a steep-pitched span-roofed house, 100 feet by 24 feet, and was planted with eighty-two permanent Vines (Gros Colman), 2 feet 4 inches apart. The entire crop was allowed to hang each year, with one exception, into the months of February and March. I regret I cannot give the exact dates when the cutting of the crop in this house commenced each year except in 1892, when a note was made of the weight of crop, but being the last house for eight consecutive years I give the following dates, taken from the day book, when the last was cut—viz., March 11th, 1887; March 7th, 1888; March 15th, 1889; February 24th, 1890; March 7th, 1891; February 15th, 1892; February 27th, 1893; and January 30th, 1894; and from the time the last of the fruit was cut until the house was started again did not exceed a fortnight, except in the years 1892-94, when they had about a month's rest, and these Vines are as vigorous and carrying and finishing as fine crops of Grapes as ever, but how long this may continue I am not going to predict.

I thank Mr. Bolas for the compliment he pays me, and I hope at some future time to give a brief account of the house he refers to.—W. INNES, *Derby*.

#### SPRING PRUNING.

THE leader, page 373, lays before readers clear facts that anyone living in the country may see for himself. It is a great pity that there are thousands of trees in exactly the condition as "A Traveller" describes. No doubt the owners and planters are very much to blame for allowing the trees to continue in such a miserable plight.

There is also another side to the question that should not be lost sight of. I allude to the state of the trees when received from the nurseryman or fruit tree vendor. Some growers of trees for sale allow them to "run up" in a far too limited space of time to enable them ever to make really good trees until they are taken in hand by persons who have not the same reason for doing so. When fruit trees are allowed to remain 4 feet and more in height after the growth from the bud or graft at the first pruning, what can we expect such trees to do the year following?

Will one tree out of twenty managed in this manner ever make a decent bush or pyramid of either Apple or Pear? I say No without hesitation. The grower of this class who points with apparent pride at his Apple trees 5 feet high for the low price of 9d. each is not the man to teach would-be fruit growers how to manage their trees. As I have scores of times told cottagers and amateurs who required a few trees for their garden, far better pay 2s. for a really good tree than the 9d. for such an one alluded to above.

When we see inexperienced persons leaving 6 inches of growth on espalier trained Apple trees that already have spurs several inches long, how can we expect mismanaged young trees to be put into a better shape? These are not simply matters of assumption, but hard facts, as I have experienced many times, and in two particular instances last month only. In one case trees had been received from a nurseryman of reputation for other goods than fruit trees evidently. They were of the class noted 5 feet high, with one or two straggling branches 1 foot from the ground. Above this a clear stem 3 feet long, and a few more branches at the top. Here was a specimen for a person void of experience to tackle. Now, "Mr. Traveller," you could hardly blame the owner if two years hence this tree had not grown into a good one, could you?

In spite of the amount of garden literature available, lectures and private tuition, it is astonishing what a mass of ignorance still exists on fruit tree cultivation. Plain horticultural teaching in schools will do much towards enlightening the future generation, certainly. The present tyros must look to their own interests somewhat, and pick up information where they can. Nurserymen have the opportunity to educate this class; some of them do right well by sending out properly managed trees. I find this class of cultivator—cottager and amateur—is quick to follow example; none is better than a young fruit tree having a well-laid foundation.

One other point in "A Traveller's" article, planting trees at this season. It is generally admitted that the best season for fruit-tree planting is directly the leaves fall. Granted that this is so, some persons think though that if circumstances do not favour this being done one year they must wait until the next year before planting. Obviously this is wrong. Surely a tree planted in April, carefully tended through the summer, mulching the surface soil, and supplying moisture as required, must be in a better condition next November than one newly planted. It is surprising what a number of roots are formed by April-planted Apple trees in five months. It is the condition in which the roots are found at all periods of their existence that insures success or otherwise.—E. MOLYNEUX.

#### CHRYSANTHEMUMS IN VASES.

FROM Mr. Pulham, the well-known rockery builder, who combines terra-cotta pottery with his business, I have received a very useful specimen of a vase for growing and flowering Chrysanthemums in. Instead of the well-known terra-cotta the vase in question is stone colour, the sides being ornamented with clearly defined Chrysanthemum leaves. In size the vase measures 13 inches in diameter, and is 18 inches high. Where vases on terraces or by the side of paths or in the conservatory are appreciated capital plants could be grown, producing a splendid effect. For open air flowering the early section like the Desgranges family, Ryecroft Glory, Comtesse Fouchier de Cariel, or Roi des Précoces would be found the most suitable. In vases of the size named there is ample space for three plants.

#### LATE-FLOWERING CHRYSANTHEMUMS.

In the face of such sterling varieties for late flowering as L. Canning, Leon Frache, Mons. E. A. Carrière, Golden Gem, W. H. Lincoln, and the newer Challenge, the varieties alluded to on page 387, which Mons. Delaux is sending out, will have to possess points in advance of those named before they will be accepted by English cultivators. Like "C.," I trust all will be thoroughly tested before being put into commerce. Much disappointment will be saved by rigid selection of seedlings in the future. None but what is really an advance on older ought to be encouraged. The public has had, in the past, too many of these so-called improvements that they are chary about speculating in novelties except the recommendations are *bona fide*.

#### HAIRY CHRYSANTHEMUMS.

Taken as a whole the craze for this section has not kept pace with its first instalment. The advent of Mrs. Alpheus Hardy created much interest, curiosity, and admiration. Undoubtedly the alpha of this section is still the finest of the whole batch when seen in its proper form. Many persons have not only discarded this variety on account of its being "miffy" in growth, but they have committed the whole race to the rubbish heap. Nowadays cultivators and visitors require that a Chrysanthemum shall not only possess novelty but some beauty as well. It cannot be said that the hirsute appendage on the florets is any gain for vase decoration in a cut state.—E. M.

#### NEW ANEMONE CHRYSANTHEMUMS.

LAST season there were several excellent exhibits of Anemone varieties at the shows. In spite of the trade protest that they do not pay, I was hopeful to see some valuable new additions announced this spring from the Continent. Out of several hundred novelties of all sections, I have only been able to discover two of the Anemone type offered for distribution. Simon and Descartes were perhaps the best of 1894, the former being particularly fine in form and delicate in colour.—P.

#### AN AMERICAN CHRYSANTHEMUM ANNUAL.

THE "Florists' Exchange" of New York, in reviewing the "N.C.S. Year Book," remarked that "The success of this venture from a literary standpoint is but another reminder of the need of a publication of a similar nature in this country."

From a private letter to hand last week I learn that a gentleman well known in American horticultural circles has been engaged for some time on such a work, and that it is in the hands of the printers, and will be ready for publication in a short space of time. To those who are interested in watching the novelties from the other side of the Atlantic such a work will no doubt be acceptable.

It would be instructive to know at the same time when the American Chrysanthemum Society contemplates issuing a new edition of its catalogue. The last and only one we know of was printed in 1892.—CHRY.

#### MORE LONDON PARKS.

THOUGH the name of Victoria Park is not such a household word as either that of Hyde or Regent, it is for natural beauty and brilliancy of the spring bedding in no way inferior to either of these. In the long

sweeping drives and pleasant walks of the former the fashionable inhabitants of the West End may ride or stroll at their leisure, while in the latter, thanks to the meritorious endeavours of the London County Council, pleasures of an equally high order are provided for the thickly populated masses of the East.

It is needless to add that these are appreciated in every sense of the word, but the full extent is only known to the crowded dwellers in these parts, who are at liberty to roam at will through a maze of verdant and floral beauty, the like of which up to recent years could only have been found in the private domains of the wealthy. The sporting element is likewise catered for, as on a wide expanse of green sward no less than thirty-six cricket pitches and a like number of tennis courts are prepared and kept in order, while for those of a gymnastic turn of mind a whole complement of apparatus is provided. The children, too, are not forgotten, and one of the most interesting corners in the Park is the space set aside for the gambols of those under twelve years of age. Swings and such like are provided, and in addition to these is a huge bed of sea sand, brought expressly from Lowestoft for the purpose, and here the little urchins sport and play to their hearts' content; that they thoroughly enjoy it may be gathered from their merry peals of laughter and the expressions of mirth that may be seen in their young faces. For older boys a capital bathing place is provided, and after four o'clock on bright afternoons it would not be exaggerating to say that the water is alive with them.

But why am I wandering from my subject? It was the flowers I went to see, and truly they were worthy of a visit, in spite of the fact that the Hyacinths and many of the Tulips were on the wane. The beds are numerous and extensive, and the number of bulbs taken in planting them must be very considerable. They are all laid out and planted with artistic taste, the colours being blended in such pleasing unison that could only call forth ejaculations of approval from the most severe critic.

One bed, producing a fine effect, was planted with the showy Tulip Keyser's Kroon and yellow *Doronicum plantagineum*, mixed; while another was rendered gay by Tulip Rose Gris de lin and Auriculas. Large beds of Proserpine were also displayed, as were also others planted with Tulips Joost Van Vondel, La Belle Alliance, and Thomas Moore respectively. In the centre of this group was a large mass of the purple Tulip Van der Neer, surrounded by the sweet scented and effective Yellow Prince. Nothing added more grace to this brilliant display than beds of that favourite old Tulip White Pottebakker, with its tall heads of flowers towering up and rippling gently in the breeze.

The Hyacinths were unfortunately past their best, but those remaining of La Grandesse, King of the Blues, Charles Dickens, Czar Peter, gigantea, and Lord Macaulay gave a good idea of what they must have been when in their beauty. Among the Daffodils were beds of Sir Watkin and Horsefieldi, while in others were noticed masses of bright Wallflowers (a rare occurrence this spring), and such old favourites as Polyanthus, Auriculas, Daisies, and Pansies.

A pleasant feature in Victoria Park is the large number of forest trees planted in avenues, and the flowering and ornamental shrubs. The showy blooms of *Magnolia conspicua* peeping out from a background of foliage were a picture in themselves, while the large trees of wild Cherry clothed with its snowy white flowers proved a pleasing contrast to the brilliancy of *Pyrus japonica*. Lilacs, Laburnums, and Thorns are all full of bloom buds, and on the verge of bursting forth.

Any notes on Victoria Park would not be complete without a mention of the glass structures and the extensive operations that are going forward for the preparation of summer bedding. Thousands of *Pelargoniums* are being hardened for this purpose, all sturdy plants and in good condition; and in addition are to be seen large numbers of Cannas, *Alternantheras*, *Coleus*, *Begonias*, *Ageratums*, Harrison's Musk, *Lobelias*, and numerous other things, giving some idea of the amount of anxiety and labour that is entailed in producing the masses of floral beauty that make London parks gay in the summer. A large conservatory recently erected, to which there are yet additional wings to be added, is kept continually gay with flowers, which doubtless are a source of pleasure to many a plant-loving worker, whose only facilities for growing his favourites may be the window of his dwelling. A promising collection of Chrysanthemums are now advancing in growth for the purpose of making gay the large exhibition house when summer beauty has passed away. A large number of subtropical plants are also in evidence, amongst which are splendid specimen plants of *Agave americana*.

In conclusion, a special word of praise is due to Mr. J. W. Moorman, the able Superintendent of this park, not only for the brilliant display of spring bedding, but for the able and enthusiastic manner with which he deals with the many complex and arduous duties connected with his charge.

Very different in outline, but no less pleasing in effect, is Greenwich Park, which perhaps for rural and undulating scenery has no superior, if any equal, in the environs of London. The long grass slopes and pleasant valleys are everywhere studded with giant Elms, Horse Chestnuts, and other forest trees, many of them old and weather beaten—truly figures in history. The extensive view to be obtained from the high eminences add much to the beauty of the landscape. There may be seen the Gordon Boys' Home, which is so closely connected with the name of the gallant hero of Khartoum, and the far-famed Greenwich Hospital, while beyond are the waters of Father Thames studded with masts, and further still rises the hazy smoke from the great metropolis. The spring bedding here is quite in character with the truly natural form of the surroundings, for in strolling along one comes suddenly on a bright bed of mixed Tulips, and a little further on

is another one gay with Polyanthus, or in another direction may be found other beds of distinct colours, amongst which White Pottebakker was particularly striking. Had time allowed much more might have been seen in this pleasant resort, but as the shades of evening were commencing to fall, steps were directed homeward, with a thorough satisfaction that the time had been well spent.—WANDERER.

### STRAWBERRY LAXTON'S LEADER.

MESSRS. LAXTON BROTHERS have sent us samples of a new Strawberry of very great promise. It is the result of a cross between Noble and Latest of All, and named Leader. The specimens certainly "lead" Noble a long way in quality, firmness, and flavour, while not being behind it in size. The plants were taken from the ground and potted in September last, and the fruits ripened just after Royal Sovereign under the same cultural conditions. We figure a typical example, but not the largest, which was  $7\frac{1}{2}$  inches in circumference, and append a description:—

Fruit large, bluntly conical, but occasionally flattened and wedge-shaped, and more or less deeply ribbed; colour glossy crimson, studded with numerous yellow seeds or achenes; flesh scarlet, with a whitish band, of good texture; flavour piquant, sweet, with a pleasant aroma. The fruits travelled well.

Since writing the foregoing we have received three fruiting plants. These are sturdy in character with very downy leafstalks and strong flower stems bearing large flowers like those of Latest of All on one plant, the other two plants carrying handsome fruits, the best weighing  $1\frac{1}{2}$  oz., and the others very little smaller, with the true Strawberry flavour as fully developed as we usually find in fruits ripened naturally. The variety cannot be shown in a forced state before the Fruit Committee of the R.H.S. this year, as the crop will be over before the next meeting, but it is in the collection at Chiswick, and there we shall look out for "Leader" in the open ground.

### PRUNINGS.

WITHOUT underrating the weight of diplomas sealed and signed by the Royal Horticultural Society, I do not think their face value is of such high importance as our young aspirants to fame are inclined to imbue them with. I would rather look on these exams and the preparation they entail as a stirring of the mental faculties in the spring-time of life, whereby the seeds of experience are afforded a well tilled medium for germination, to bear sound fruit in the summer of life. The gardener in embryo is afforded many opportunities which his forbears missed by being born too early. May many a youngster win the maximum "marks," and wear his newborn honours modestly.

Mr. Wilson's admirable paper on "Employers and Gardeners" (concluded on page 328, April 18th), expresses what many feel and think and know to be true, but which, by force of circumstances, must have remained hidden under the bushel of prudence. Yet, perhaps the man in active life with his heart in his work thinks last and least for himself. He is a man apt to rise at untimely hours, nor does he seek his couch until sundry nocturnal rambles rid his charge of some pest which chooseth darkness for its evil deeds. To rush from a heated house coatless or hatless as the first warning note of the coming hailstorm strikes the glass is thought nothing of at the time, but it may be sowing the seeds of rheumatism. Still is not the earnest, devoted, prudent gardener appreciated? I dare venture a prediction that any pruning which would sever Mr. Wilson from his employer would be painful to both. Let us hope for more and closer unity between (I like the old formula) "master and man," and it is worth striving for by all.

Truffles (page 357) ". . . delicious species . . . fungus family . . . probably heads the list." Well, that's a matter of opinion. I do not think we shall ever hear of Truffles for the million. Anyway, if our American friends want them, and cannot get the dogs, pigs for hunting purposes are, I believe, used in the South of France. I have found Truffles under Cedars of Lebanon, and thus discovered them through the squirrels, who were continually scratching away the few inches of hard, dry soil to reach them. On one occasion in planting some Laurels under the Cedars in another part we came across some fairly good specimens, which were duly presented to, and appreciated by the cook.

Green flies and all the flyers we have fumed in the old-fashioned way, and choked ourselves in the fuming. Mr. Bardney (page 334, April 18th) likes the new XL All vaporiser. He has liked many things in his time, and it is hoped will live long to like more. I have found the fumigating sheets invaluable, but not inexpensive. A few thousands of cubic feet look big on paper, but do not usually require a great deal of glass to cover them. The principle of the vaporiser appears to mark a change in the system, as doubtless the atmosphere is by this means charged with minute particles of nicotine which pass not away like the smoke.

There is yet one thing wanting—viz., we want these articles a little cheaper, for encouraging a freer use of them. Then we shall be happy. What severe trials young gardeners of a passing generation were put to when boxed up with the burning paper or rag to keep it from flaring. Some could stand the ordeal, and some were sickened for days. Well do I recollect one summer's night, when all hands were piped to the "big conservatory," each with a wire basket, and two with an infernal machine—an iron truck, in which heated bars fired the paper—how a comrade, feeling those qualms equivalent to *mal de mer*, escaped in the gathering gloom to a broken pane in the sash on the ground level. Alas for the sequel! being on his knees with his head protruding from the friendly porthole—old "Spot"—the governor's bulldog spotted him, went for him, and there was a "flare."

Clianthus Dampieri? (page 335). I quite endorse all you say about this, Mr. Burrows, as a floriferous climber, easy to grow, handsome and useful. You describe your fine plant so well that I am at it with my pruning knife. Snip! off comes Dampieri, on goes puniceus. I cannot but assume that you have mistaken C. puniceus—the Lobster-claw, for C. Dampieri, the gorgeous Glory Pea. The latter is all but of bushy habit, and seldom seen in perfection. The best example I have seen of it was planted in a compost of loam and leaf mould, and grown in a box

FIG. 69.—STRAWBERRY LAXTON'S LEADER.

standing on a coil of pipes in a temperate house, where a free circulation of air was maintained. It is easily raised from seed, but not so easily reared to perfection.

"The Old Boy," or (begging his pardon) "An Old Boy," in his first paper of "Bothiana" thinks of his bothy days. I think a good deal of individualism flows out through a pen aside of the subject it is treating upon, and when an old boy writes for young ones he recalls the past and dips in sympathetic ink. May I suggest, "Old Boy," that when stage No. 1 of a gardener's life is completed you will then supplement "Bothiana" with stage No. 2, and give us Gardeneriana? This, I take it, is of no less importance, for there are rocks ahead in the first (Head) situation, which, if they do not wreck, are as well avoided.

Royal Horticultural Society, April 23rd. Medals, certificates, and cultural commendations galore. Who was present before I prune? So-and-so. Ah! be canny then. Fruit Committee, "Countess Melon," I like that name; Strawberries, Kidney Beans, Victor Potatoes, Seakale—open air; "valuable," exactly so; "only provided in comparatively few gardens." Humph! could trundle you on a few barrowloads, gentlemen, and so could all my neighbours for miles around. Some of them grow it no other way. More shame for them. But we all cover it with fine sifted coal ashes—burnt ones from the stokehole are best. What heads! how good! but we can have too much of a good thing, and with Spinach, French Beans, Villam's Cabbage, Asparagus—now cutting, and the survivors of the fittest amongst the Broccoli, why Seakale is now a glut in the garden [and kept there!—EDS.].

"Round about Sevenoaks" went the "Jaded Londoner" (page 366, April 25th), jostled pell-mell, going and returning. I hope "the city dwellers when they journeyed homewards laden with Primroses and other wild flowers" left the roots behind them. Well, your bank (holiday) note, in spite of the weary, weary tone pervading it, shows that you enjoyed it. How circumstances alter cases! I say, Oh, for a sniff of London town, with its Embankment gardens, people's parks, Kew, Fleet Street, and the quintessence of activity! Better wear out than rust, "Wanderer."

Could "The Missus" (page 372, April 25th) be induced to procure a sketch of that Potato-sorting machine she so graphically describes on

page 372? and would our mental food-providers reproduce it on these pages? Or is it doomed to remain in that "remote village on the Trent." It should be useful. Wants a good deal of manning (2) though—and womaning (4), besides the boy = 7, with the "Miasus" looking on (total, 8), and being only a machine "cannot discriminate" and sort out the faulty tubers.

I have a friend in London who tells me that he knows a machine which *does* discriminate, for when it is corking bottles of wine in Mr. H. R. Williams' gigantic stores in Lime Street, and gets hold of a bad cork, it throws it aside in disgust, not one in a thousand passing in a faulty state. London again! But I must cut it short, or I shall be making the Editors "corky," as wine does not, I think, make glad the hearts of many gardeners, so snap goes—SAYNOR.

### ARGON.

IN reply to Mr. W. Dyke, page 388, I beg to say that I gave argon on page 333 as an air-derived element on the "authority" that there is frequently a discrepancy in the results obtained in ascertaining the density of nitrogen gas procured from the atmosphere, plants and animals, which leads to the conclusion that some unrecognised element must be present to account for the discrepancies in the calculation. To this Mr. Dyke replies—"It will not do to assume that because argon and nitrogen are found so intimately connected together that they must consequently be both taken up by the plant." This is ignoring the fact (for there is nothing assumed) that the newly discovered constituent of the atmosphere "argon" by Lord Rayleigh, and almost immediately confirmed by Prof. Ramsey, was indicated by Cavendish in the last century as a disturbing element in the nitrogen gas derived by him from the atmosphere. Cavendish discovered the peculiar properties of hydrogen, and the qualities by which it is distinguished from atmospheric air. To him we owe the important discovery of the composition of water. Scheele had already observed that when oxygen is mixed with double the quantity of hydrogen, this mixture burns with an explosion without any visible residuum. Cavendish confined both gases in dry earthen vessels to prevent the escape of the product of their combustion, and found that the residuum was water, the weight of which was equal to the sum of the weight of the two gases. Priestley observed that a quantity of atmospheric air confined in a tube through which the electric spark was transmitted, lost in volume, and formed an acid which reddened the tincture of litmus. Cavendish took up this cue, confining in the tube a solution of pure potash, which absorbed the acid, and he proved it to be nitric acid. The analysis of the air which remained in the tube after the experiment showed that the weight of the oxygen and nitrogen which had disappeared was equal to the weight of the acid thus formed. He easily determined the proportion of the nitrogen to the oxygen, which was 2 :  $\frac{3}{8}$ . It was found, also, that when both gases, sufficiently pure, were mixed in that proportion, and exposed to the electric spark, the mixture disappeared entirely, by which his discovery was completely confirmed.

Thus Cavendish\* acquired distinguished rank among those learned men who have most contributed to the progress of chemistry, and it is due to him that Lord Rayleigh and Professor Ramsey have been able to account for the discrepancies in the results obtained in ascertaining the density of nitrogen gas by the discovery of argon, the existence of which had been indicated by Cavendish in the last century. Numerous experiments were made to test the validity of Cavendish's hypothesis; in fact, all chemists acknowledge that there is some unrecognised element present in the nitrogen gas as derived from air, plant and animal analysis, and that element as regards air has been shown by Lord Rayleigh to be argon. This element is not yet proved simple, some having doubt as to whether there are not two substances in combination rather than one only. One thing only is certain, the newly discovered element (if it be one and not a compound) does not combine with any other element, which is fatal to the mixture doctrine, but there are other reducing agents in the world besides chemicals, such as the micro-organism which converts the free nitrogen of leguminous plants into assimilable, and it is a notorious fact that Clover fields in blossom produce an atmosphere largely laden with ozone, as indicated by the so-called sulphurous odour, and belongs to something developed in the atmosphere by electricity. It is a colourless gas, unknown in a pure state, but hitherto has only been obtained mixed with several times its weight of air or oxygen.

Its properties are oxidising; in fact, "ozone is nothing more or less than oxygen in a peculiar active condition"—(Johnson, "How Crops Feed," page 64). Ozone is formed by chemical action as well as by electrical disturbance, and is due to the union of oxygen with phosphorus, if indeed it is not formed by the oxidation of every oxidable substance, a portion being diffused—that is, of the oxygen in the peculiar active condition—into the atmosphere through escaping immediate oxidation. Sir J. B. Lawes, Sir J. Gilbert, and Pugh found no such evidence; but it is that conclusive that plants do not evolve ozone as well as oxygen from the foliage, and especially flowers, when acted on by sunlight? There is little or none of it in crowded cities, less in slums, and the vicinity of manure heaps, as it there finds organic matters, and combining therewith its presence cannot become manifest.

Nitrogen is a colourless, inodorous, tasteless, uncondensable gas, existing free in the air, the intercellular spaces of leguminous plant cells,

and the air bladders of fishes. In combination with other elements it constitutes many minerals and a great variety of animal and vegetable substances. Lavoisier gave this substance the name of azote (Greek, *a*, privative; *zōē*, life), because it is incapable of supporting life; but Chaptal gave it the name by which this gas is now known because of its entering into the composition of nitre (nitric acid). It is readily obtained from the atmosphere by removing the oxygen, which may be done by burning phosphorus in an enclosed space of air or by passing air over heated copper. In doing this there is a discrepancy in the weight of nitrogen, and in ascertaining to what this discrepancy was due Lord Rayleigh discovered the gas suspected by Cavendish, and to which the name of argon has been given. It is what? Anything more than inert nitrogen! Surely, Mr. Dyke has authority for his negative statement, and will be able to supply the necessary information. This is essential before we proceed to explain "how it is assimilated by plants." What evidence have we that argon is but a form of nitrogen? Professor Ramsey's experiments are based on the principle that the process which liberates nitrogen also sets free argon, which is very suspicious of there being only a technical difference between nitrogen and argon, the latter corresponding to the ozone form of oxygen. The Peas and mice subjected by Professor Ramsey to experiment for the discovery of argon in nitrogenous vegetables and animal tissues are far from conclusive; indeed, it was Dumas' method for extracting nitrogen, the powdered Peas or mice being mixed with copper oxide and lead chromate in a heated tube, whereby the hydrogen, oxygen, and carbon, are removed and the nitrogen is collected. Was there no indication in the weight of this nitrogen of another element—to wit, argon—extremely inert nitrogen? Professor Ramsey is silent about this, even doubting that the process adopted was not suitable for detecting the new element.

Surely we ought to be satisfied with Lord Rayleigh's and Professor Ramsey's statements, and not as physicists raise the question, Do plants assimilate argon? First, let chemists tell us that it has been detected in nitrogenous vegetables and animal substances, as Sir J. B. Lawes and Sir John Gilbert found there was more nitrogen in leguminous plants than could be possibly derived from the soil. Then and not till then may we set to work and prove that argon is present in plants for preventing that decay or impairment of tissue which must otherwise attend over-assimilation of the free nitrogen of leguminous plants by the microbes. Thus it would not be a matter of assimilation, but of insuring the general slowness of the fixation of free nitrogen in leguminous plants in symbiosis with microbes.

The probability is that plants do not possess the power of assimilating argon any more than the free oxygen, hydrogen, and nitrogen gases, but that is no reason why they may not absorb argon as well as the other elements, including carbon, and because free nitrogen is fixed by leguminous plants in symbiosis with microbes there is no cause to assume that argon must be assimilated, even if it does enter into the composition of plants, and of which there are certain indications. It may not, however, be possible to detect it at present through the method employed being at fault, but chemists will sooner or later make all clear in respect to this interesting discovery.

The chemical constituents of the atmosphere must enter into the composition of plants. Evolution points to a primitive atmosphere of absolutely pure nitrogen, there not being any free oxygen, and with only such carbonic acid and water as were evolved from volcanoes, which extended over the greater part of the earth's surface, the first organised beings came into existence. Only plants of the Algæ class could then exist, animals being unable to subsist in such atmosphere. In course of time enough oxygen would be evolved by vegetation for the support of animal life of a low order, and as vegetation extended there would be both nutrition and air enough for the support of higher forms of animated beings. The struggle, therefore, would be between oxygen on the one hand and nitrogen on the other. Micro-organisms acted in behalf of vegetation—the more nitrogen appropriated the more oxygen liberated, and the more of that the greater the fixation of carbon. This implies more animals subsisting directly or indirectly upon vegetation, and so on up to the present time. Up to a certain geological period there would be little or no ozone, but it would appear with the spread of vegetation on the land, for there could be no ozone evolved by marine plants. This ozone is simply a peculiarly active form of oxygen, and there is evidently a counterbalancing incombustible element—an evolution from or a primitive form of nitrogen. Will Mr. Dyke kindly tell us what he knows on this subject? It will fill up the gap between now and when further investigations are concluded in respect of argon.—G. ABBEY.

### EXAMINATION IN HORTICULTURE.

IN reply to "H. O. H." (page 380) I wish to say I omitted the last few words of the paragraph because I considered there was nothing of any importance in them. I quite agree with him that a certificate for the successful culture of some kind of fruit, flowers, or vegetables, is an advantage to its possessor; but to gain such is not practical to gardeners generally. Your correspondent on the same page asks, "Why give a certificate for a thing which of itself is perfectly useless?" And yet when he is speaking of theory lower down the article he says, "Nay, I commend it, for what gardener is perfect without it?" If "H. O. H." thinks that the questions set at the examination are all theory, he is mistaken, and for the benefit of those who have never seen them I have

\* Messrs. Blackie's "The Popular Encyclopædia," half vol. iii., page 189.

sent those which were set at the exam on May 1st, 1895, and I will leave them to judge what chance a man with theory alone would have in answering them.—W. D., *Turnford*.

### ROYAL HORTICULTURAL SOCIETY'S EXAMINATION IN HORTICULTURE.

#### QUESTIONS.

EIGHT questions only to be answered; four from Division A, including No. 5, which must be answered by every candidate, and four from Division B.

#### DIVISION A.—ELEMENTARY PRINCIPLES.

- 1 (a), What substances do plants absorb by means of their roots? Explain the process of absorption by the root.
- (b), What elements do plants obtain from the air, and by what agency do they obtain them?
- 2, Explain the effect on flowering plants of an adequate, a deficient, or of an excessive amount of heat.
- 3, How are "cuttings" made? Describe the changes that occur during the process of "striking."
- 4, What are the objects sought to be obtained in digging the soil?
- 5, Write as full and orderly a description as you can of any plant in common cultivation, through all stages of its growth, from the germination of the embryo to the formation of the seed.
- 6, What organs of the plant are represented respectively by an Onion, a Cabbage, a Potato, Beet, Turnip, and a pea-pod?
- 7, Describe the mode of growth of the common Mushroom.
- 8, What is meant by "green fly"? What is the best application to rid plants growing out of doors of this pest?

#### DIVISION B.—HORTICULTURAL PRACTICE.

- 9, Name six of the best species of hothouse flowering plants, and give some of the general details of culture. Name some of the insect pests that infest such plants, and state the best method to be adopted for their destruction.
  - 10, Give general details for growing Peas, and the method of culture, time of sowing, &c., to give a supply for as long a period as possible. What is the use of the nodules on the roots?
  - 11, What is an Alpine plant, as the name is generally understood in gardens? Describe the cultural requirements of such plants, and the best way to propagate them.
  - 12, What is the original parentage of Cauliflower and Broccoli? Give the method of culture, and the best varieties to obtain a succession all the year round.
  - 13, Give some details of the culture of Grape Vines under glass. Describe the diseases to which they are subject, and the insect pests which attack them, and their cure.
  - 14, What kind of fruit trees and bushes are best adapted for culture in small gardens? Briefly describe the best method of culture, and arrangement of the trees and bushes.
  - 15, In a walled garden, what kinds of fruit trees would you recommend to be planted on the four aspects, south, north, east and west? What distance apart should the trees be? Suggest the best width of the borders, and height of the walls.
  - 16 (a), What do you consider the best class of soil for fruit trees, and how ought it to be prepared for them?
  - (b), Is there any method of culture likely to prevent canker in Apple trees, or gumming in Apricots, Cherries, and Plums?
- [Perhaps some of our readers might like to indulge in a little home educational exercise in answering those questions.]

### TOTLEY HALL.

At Totley Hall, the residence of W. A. Milner, Esq., situated four miles from Sheffield, may at the present time be seen one of the best collections of Daffodils to be found in the north of England, numbering about 300 varieties. It was my privilege on May Day to view this magnificent show, and as Mr. Milner and his talented gardener (Mr. T. Birkenshaw) are enthusiasts in the culture of Daffodils and Orchids, a visit at this time of the year is instructive and interesting.

Two long winding borders, each 12 or 14 feet in width, are planted with Daffodils—hundreds of thousands of bulbs—of all the best and most rare varieties, each being kept together, but the whole forming a mass of colour not easily to be forgotten. The blooms are larger and the plants better grown than any I have previously seen. The foliage is of great strength and substance, showing their cultivation is well understood. The bulbs are lifted every second year, the land well trenched, a good layer of cow manure being placed at the bottom of the trench, the bulbs being at once placed back into the soil. The massive blooms show that this treatment suits them.

The various sections are well represented. Grand blooms are to be seen of Emperor, Empress, Horsefieldi, Bicolor and others. Several blooms were at their best of that magnificent new variety, Weardale Perfection, which is far ahead of all other varieties, as may be seen by comparing with a large bloom of Empress. Glory of Leyden and Madame de Graaff were showing good blooms, but were not as massive as the former. Other good varieties noted were Sir Watkin, Barri conspicuus, Shirley Hibberd, Duchess of Westminster, Barri Autocrat, Madame Magdalene de Graaff, Barri Sensation, Princess Mary, Backhousei, P. R. Barr, Maximus, and others too numerous to mention. In

the grounds there are borders containing a choice collection of herbaceous plants, also a rockery planted with alpine.

In the houses may be seen some remarkably well-grown Dendrobiums. One of *D. thysiflorum* has twenty-five fully developed racemes of bloom on it. This plant has had the same number of racemes for several years past, several being taken off to throw more substance into those that remain. This plant alone is worth going a long distance to see, as in addition to its free flowering qualities, it is one of the best varieties. *D. Paxtoni* is also well grown, and one plant was carrying thirty-eight fine racemes of bloom. A splendid collection of *D. Wardianum* is grown, and the plants now making strong growths, this being also the case with *D. nobile*. On inquiring of Mr. Birkenshaw what treatment he gave them, I found they were potted in equal parts peat and sphagnum, shutting the house up in which they are grown with plenty of sun heat and moisture, giving air at night to reduce the temperature and strengthen the young growths.

*Cattleya citrina* is also well grown on blocks, the bulbs and blooms appearing to gain in strength each year. *Disa grandiflora* is remarkably fine; they are in the best of health, and as there are upwards of ninety plants they will make a good show when in bloom. Other Orchids were doing well, as were the ordinary stove and greenhouse plants. A fine plant, growing on the back wall of one of the houses, of *Clianthus puniceus*, had flowered well, thousands of blooms being expanded at one time. Vines were carrying good crops of fruit, the whole reflecting great credit on the gardener. All interested in gardening are welcomed by Mr. Milner to enjoy the floral treat, a kindness appreciated by at least—ONE OF THE CRAFT.

### MARKETING APPLES.

#### A HINT FROM AMERICA.

SOME essential points to be considered in the marketing of fruit were given by Mr. George A. Cochrane in a paper read a few weeks ago before a meeting of the Massachusetts fruit growers in Worcester. The salient points of this were printed in the "Garden and Forest," and we reproduce them for the benefit of growers, to whom the hints will doubtless be of interest and use.

"For several reasons the barrel is too large a package for Apples, which should be marketed in boxes no larger than those used for Oranges and Lemons. Last autumn I advised the trial of such a package, and suggested that each Apple be wrapped in paper as Oranges and Lemons are. Three thousand cases were sent to me for shipment to Europe. Out of fifty growers of Apples only three understood what a close selection of fruit meant, and the Apples sent by these three growers sold in London at 2 dols. 40 cents a case, when fruit in a barrel, which held three times as much as one of the cases, brought only 4 dols. Some growers sent windfalls, in the hope that wrapping them in paper would insure their safe arrival in England. Some sent Snow Apples and Russets mixed in the same case. Of course, when barrels are used, new ones and not second-hand flour barrels should be procured, for no matter what care is taken to dust and wash them sufficient flour will remain in the seams or staves of old barrels to rattle out in transportation and dust the fruit.

"In packing a barrel select a fair sample of the contents for the bottom layer. Place the Apples, stems down, in the form of a ring, beginning at the outside, and having secured this layer firmly, place the second layer in so as to fit closely in the interstices, then fill the barrel quickly and gently, and when one-third full rock it slightly to settle the Apples. Repeat this rocking when the barrel is about three-fourths full, and when it is filled place a padded board on the top and rock it while the board is held down firmly. Then place in sufficient fruits to form a cone at least 2 inches above the chime. Now force the head down with a barrel-screw presser, nail the chime hoops, both top and bottom, securely, and have the head-lining sufficiently large to lap the presser that forms the head.

"Never pack red Apples until they are of a good colour. It is an expensive blunder to wait until the last moment and then strip the tree of all its fruit. It is also a mistake to pick the Apples faster than they can be packed. It is a good plan to go over the trees a week or a fortnight before the general picking and remove the well-developed and well-coloured fruit and market it at once. Apart from the advantage of early marketing, such pickings help the fruit which remains, increases its size, and improves its colour. Apples should be headed up at once, and if they are to be held they should be hurried into cold storage as near a temperature of 32° as possible. They should never be allowed to lie on the ground, and under no circumstances must they be exposed to sun or rain after being picked or packed. Autumn varieties decay quickly, because they are exposed to a higher temperature after leaving the tree than the winter varieties are, and more fruit is lost after being picked in the heat than from the frost.

"Growers who keep Apples in bins to market during the winter should select and sort at the time of picking. Only perfect and healthy fruit must go into such bins. Cellars should be ventilated so that advantage of any change in the temperature can be taken and the fruit kept as nearly as possible at the required coolness. When the average temperature has been above 45° from the time of sorting to December 15th Apples should be marketed as soon after the turn of the year as possible. When they are kept in the bin after this time they will not stand rough usage and will not answer to ship to Europe in barrels. One reason why autumn fruit does not pay arises from the fact that large quantities of delicate fruit is placed in one compartment,

which, because it is air-tight, becomes overheated. Such delicate fruit ought never to be placed in barrels, except for near-by markets, and then only under the most favourable conditions of weather. Were American Apples marketed in as sound condition as Oranges are, if they were graded as Oranges are as to quality and size, if they were wrapped and packed as Oranges are, they would be worth three times as much as they now command in Liverpool."

#### FRUIT FORCING.

**Vines.—Early Houses.**—Where the Grapes are ripe moderate moisture must be maintained for the benefit of the foliage, and it will not injure the fruit, provided air is admitted so as to prevent the deposition of moisture on the berries. A little ventilation constantly, and a gentle warmth in the hot-water pipes, which will be necessary to prevent the temperature falling below 60° at night, and by increasing it early on fine mornings the Grapes will heat equally with the surrounding air, and spotting thus be prevented. If Black Hamburgs, or even Madresfield Court, a slight shading, such as that from a double thickness of herring net drawn over the roof, will prevent the Grapes losing colour to a great extent under powerful sun, especially where the panes of glass are large, and do much to preserve the foliage in good condition. This must be kept as free as possible from red spider, as the retention of the principal leaves, with a moderate amount of lateral growth, is essential for the development of the buds for providing next year's crop and the prevention of their starting prematurely, as would be the case if the foliage was shed early. Where fermenting material has been used on outside borders a portion of it should be removed or it will have become cold and heavy, leaving sufficient to avoid giving a sudden check.

**Vines Started at the New Year.**—The Grapes are commencing to colour. Inside borders must have due, but not excessive, supplies of water, and a light mulching of short, sweet material, but no great means should as yet be employed to produce a dry condition of the atmosphere, as the Grapes will swell considerably in ripening. Tepid liquid manure will greatly benefit weakly or heavily cropped Vines, or a top-dressing of the advertised fertilisers applied after the soil has been duly moistened, and then washed in moderately, will tell in the current and succeeding year's crop. Sprinkle the house in the early part of the day and at closing time, a little ventilation being provided constantly to induce a change of air and prevent the deposition of moisture on the berries. Maintain the temperature at 70° to 75° by day from artificial means, and 80° to 85° through the day from sun heat, advancing in the early afternoon to 90° or 95°, falling with the declining sun to a night temperature of 60° to 65°, 5° more by day and night being necessary for Muscats. As the fruit advances in colouring the moisture should be gradually reduced and the ventilation increased, but there must not be any diminution of the temperature until the Grapes are fully ripe. Grapes that are liable to crack, such as Madresfield Court, or to "spot," as Duke of Buccleuch, may, when ripening commences, have the needful supplies of water or liquid manure, and then have the inside border mulched with a couple of inches thickness of dry material, which, with early ventilation in the morning, insure these remarkably fine Grapes arriving at perfection.

**Succession Houses.**—Thinning the berries, stopping, and tying, must be attended to as occasion requires. Especially let all superfluous bunches be removed as soon as the number to be left on a Vine is decided. This is matter requiring some judgment, having regard to the vigour of the Vine and the variety; a pound of Grapes of the large-berried sorts, such as Black Hamburg, per foot run of rod being a good crop, and usually as heavy as forced Vines will bring to perfection annually. Examine the borders of succession houses at least once a week, and when dry supply water freely. Inside borders, especially those of open material, and with thorough drainage, will take almost any quantity after the Vines are in full foliage; and with a full crop of Grapes, liquid manure, or its equivalent an approved fertiliser, should be applied at every alternate watering. Outside borders will not, as yet, require water, but where they lie high and dry, the soil being free, a light mulch of short material will prove beneficial, but avoid heavy dressings of soapy manure.

**Late Houses.**—Late Vines must be tied and stopped as soon as they have made the requisite growth, pinching always being done when the leaf at the stopping joint is the size of a halfpenny. Allow sufficient lateral growth for covering the trellis evenly with foliage without crowding. Admit air freely on all favourable occasions, as there is the greatest benefit in well-developed leaves, stout and firm in texture, as on these and their continuance in health, with due supplies of nourishment at the roots, depends entirely the swelling and maturity of the crop, particularly the colouring or finishing process. Every advantage, therefore, should be taken of sun heat to increase the ventilation early in the day, but close early, excessive fire heat being injurious, and a vitiated atmosphere baneful.

**Newly Planted Vines.**—When the roots have taken to the fresh soil and become active the Vines will show it by advancing in growth, and with due attention in watering at the roots and maintaining a genial atmosphere they will make rapid growth. Allowing all the wood to remain that can be exposed to light secures a vigorous root formation and a sturdy cane, through which the sap flows freely. This practice, however, is not so much in vogue at the present time as formerly, the number of shoots corresponding to the rods required per Vine being left on each, and the laterals on these are pinched at the first leaf and so on throughout the season, which results in thoroughly solidified canes that are allowed to bear an amount of fruit equal to about 1 lb. per rod in the following year. Whether this is a better system than the old one remains to be ascertained, not from a few years' experience, but from that extending over a prolonged series. Supernumeraries intended for heavy cropping next year should be confined to one rod or cane, and the laterals pinched at the first joint, stopping the cane when it has made 8 or 9 feet of growth up the trellis. The buds will then attain to perfect formation and matter be stored in the cane in their immediate vicinity.

**Vines in Greenhouses and Unheated Houses.**—The Vines will now require disbudding, stopping, and tying. One shoot is sufficient to each spur, unless they are wide apart, when two may be left, but there must be scrupulous attention to prevent overcrowding, every leaf having space for development. Reserve the growths that show the best bunches, rubbing the others off. Stop two joints beyond the bunches, but rather than crowd pinch one joint beyond the fruit or even level with it. Tie down the shoots carefully and gradually. Stop the laterals at the first and every subsequent joint of growth. Old Vines do not sometimes bear freely, the spurs being weak. It is best to lay in shoots from the base of the rods and train them at intervals of about 3 feet, or one to each rod, which will increase root action, the Vines attaining greater vigour, and when the canes are formed the old rods may be cut away. This will cause diminished crops for a short time, but the old Vines with fresh canes will bear excellently, or much better than from old spurs. Apply a dressing of chemical manure, 3 or 4 ozs. per square yard, and point it in very lightly. Inside borders may be treated similarly or be supplied with liquid manure, giving water as required, when dry a thorough soaking, and a light thin mulching of short sweet manure will, by keeping the surface moist, encourage active roots near the top of the border.

**Melons.—Early Plants.**—When the fruit begins ripening lessen the supply of water at the roots, but not so as to distress the plants by causing the foliage to flag, for if the growths be kept clean and the roots in good condition a second crop of fruit may be had. Atmospheric moisture should be withheld and a circulation of dry air insured, increasing the temperature to 70° or 75° artificially and 80° to 90° with sun heat. Cut the fruits before they are very ripe, keeping them in a fruit room, or place not directly exposed to the sun, yet sufficiently warm to insure ripening, for two or three days, so as to mature evenly, when only they are in proper condition to be sent to the table. Cracked fruits are produced by a close and moist atmosphere, especially at night. If any fruits show a tendency to crack cut the shoots about half way through with a knife a few inches below the fruit, and diminish the supply of water, leaving a little ventilation constantly to prevent moisture condensing on the fruit.

**Successional Plants.**—In order to effect a good set of fruit the atmosphere should be kept rather drier and warmer when the plants are coming into blossom, attending early to the ventilation, and leaving a little constantly if there is danger of moisture condensing on the flowers. Fertilise the blossoms when fully expanded, stopping the shoots one or two joints beyond the fruit at the time the fertilisation is done. To secure a full crop take care to have a number of fruits on individual plants in the same stage of growth. Earth-up the plants with some rather strong and rich loam after the fruits commence swelling, ramming it down firmly, placing a little quicklime around the collar to prevent canker. Plants swelling their fruits should be freely syringed in hot weather about 3 P.M., damping the floor in the morning and evening, or oftener if necessary. Shade only to prevent flagging. Ventilate early in favourable weather, commencing from 75° to 80°, increasing or decreasing it through the day as may be necessary, maintaining a day temperature of 80° to 85°, or 90° with sun heat, closing between 80° and 85°. If an advance is made after closing to 90° or 95°, or even 100°, it will materially assist the fruit in swelling, and lessen the necessity for fire heat at night, but it must be accompanied by plenty of atmospheric moisture. If aphides or thrips appear fumigate moderately, with tobacco or vapourise with nicotine on two or three consecutive evenings, taking care to have the foliage dry, and for red spider and white fly dress the hot-water pipes with flowers of sulphur.

**Pits and Frames.**—Train the growths evenly, avoiding crowding, adding fresh soil to the hillocks as the roots protrude. The shoots should be trained sufficiently far apart as to allow the light to reach the bed, then the growths will be sturdy and fruitful. Fertilise the flowers about midday, stopping the laterals one joint beyond the fruit. Still maintain a good bottom heat by linings, and employ thick night coverings, as the nights are yet cold. Commence ventilating early, between 70° and 75°, and keep through the day at 80° to 90° from sun heat, closing early in the afternoon, so as to secure a temperature of 90° to 95°. Sow seeds for raising plants to put out in pits or frames as they become cleared of bedding plants and early Potatoes, potting the plants as required.

## THE FLOWER GARDEN.

**Auriculas.**—The Alpine varieties at the present time are very beautiful. New seeds of the commoner forms germinate freely enough, but those of choicer strains are not so reliable, the seedlings showing very irregularly. If, therefore, only a few plants come up in the pans lift these out with the point of a label, filling up the holes with a little fine soil, as there is every likelihood of others coming up. Seeds may yet be sown in pans of fine loam, leaf soil, and sand, a cold frame proving the best place to stand these. Seedlings obtained in this way may not flower next spring, but they will develop into stocky plants for the following season. After flowering, old plants may be freely divided and placed in cooler quarters till the autumn, when they can be again returned to the beds.

**Polyanthuses and Primroses.**—In order to be certain of having seedlings strong enough to flower freely next spring they should have been raised either last summer or in March this year. The summer-raised plants are naturally the strongest. Both these and any pricked out in boxes should before dry weather sets in be planted out fully 4 inches asunder each way. Seeds may be sown from the best varieties and sown in a small bed in the open, and propagating by division can also take place during this month.

**Daisies.**—Directly flowering is over these ought to be lifted, and freely divided, every little piece with a few roots attached will grow, providing all are firmly replanted in a cool border and given water occasionally in dry weather.

**Wallflowers.**—If only a few of these are wanted sow the seeds now in a box, and later on prick out the plants 6 inches apart each way. Large numbers may be raised by sowing in the open ground. The soil should be well prepared and the seeds sown in drills 6 inches apart. Prick out the seedlings in nursery beds, as then they transplant more readily in the autumn. The large double German Wallflowers may also be sown now, and if stopped once will make bushy plants. Both single and double Wallflowers may be propagated by means of cuttings. Short but not "wiry" side shoots should be slipped, not cut, off the old wood, and the heels be lightly trimmed prior to inserting firmly in the soil.

**Violets.**—Much the finest flowers of these are obtained from young plants. The ground for a fresh bed should be lightly manured and in a good condition at the present time. It should be trampled firm as for Strawberries. Not till the young leaves are fully grown should replanting take place. When lifting and dividing give the preference to the younger divisions and newly rooted runners. One foot apart each way is not too much space to allow. In dry positions water will be required occasionally, and a mulching of short manure would benefit both new and old beds.

**Campanulas.**—*C. medium calycanthema* can be had pure white, and in pink and blue shades. Sow in pans or boxes and place in a cold frame, and prick the seedlings into boxes first, and when large enough plant a foot apart each way in beds or borders. They transplant readily in either the autumn or spring.

**Humea elegans.**—Fill a pan with fine sandy soil, moisten, and then sow nearly on the surface, placing the pan on a greenhouse shelf, covering with a square of glass and shading. The seedlings should be first pricked in pans of fine light soil, and from these shifted singly into 4-inch pots in which they are to be wintered. Those who have wintered a stock of plants in 4-inch pots ought long ere this to have shifted them into 7-inch pots, keeping them in a greenhouse. Any to be flowered in pots and plunged in the open, ought now to be given a shift into 10-inch pots, using a moderately rich, loamy soil, and potting firmly.

## THE KITCHEN GARDEN.

**Potatoes.**—Potato planting will have been completed later than usual, but if the sets were previously sprouted other cultural details may yet have to follow closely. Directly the rows are sufficiently well defined loosen the soil by means of heavy hoes and then draw up a ridge. This should be done as early in the day as possible. One day's neglect of this important work may mean blackened shoots and a light crop. Small plots of early Potatoes should be temporarily protected.

**Runner Beans.**—Seed sown early has not germinated very satisfactorily. Another sowing should be made if possible, either singly in 4-inch pots or thinly in boxes, placing in gentle heat to hasten germination. The plants ought not to be kept in heat after they are up, cold frames or rough protection of some kind being less likely to weaken them unduly. Temporary protection should be afforded when the plants are put out. Sowing in boxes is also the best plan where poultry and such like are apt to interfere, Runner Beans transplanting readily enough. The soil ought to be well manured, and if near a good water or liquid manure supply so much the better. If tall stakes can be afforded single rows should be 6 feet apart, but one long old-fashioned double row (the seed being sown in drills 1 foot apart) is sometimes enough for a family. Stakes can be dispensed with altogether by sowing thinly in drills 3 feet apart, thin to 1 foot apart and keep all running growth closely pinched back. It is not yet too late to plant two rows of early Potatoes between rows of Beans 6 feet apart, or a single row between those only 3 feet apart.

**Vegetable Marrows.**—Plants that have been kept in small pots till they have become drawn, hard-stemmed, and yellow in colour, would yet be surpassed by plants raised from seeds sown now. Great heaps of manure are neither necessary nor desirable for these crops. If sheltered corners in a frame ground are devoted to Vegetable Marrows then mix garden soil, road trimmings, and such like freely with the heap of manure and other decaying material, making all level and solid. Give

the seeds or plants a start in small mounds of good loamy compost. An early start would be made by planting soon and protecting with frames or hand-lights, and plants obtained by sowing now where they are to grow should also be roughly protected. Vegetable Marrows may either follow early Potatoes or be sown among them, the Potatoes coming away before the Vegetable Marrows require much space. Dispose the latter from 4 feet to 6 feet apart each way, and profitable crops will be had in the midland and southern counties of England at any rate without much further trouble. The Long White and Long Green are among the most reliable varieties. Always sow more seeds than plants are desired, as surplus plants can and should be removed easily enough.

**Ridge Cucumbers.**—These fail during sunless wet seasons, but in favourable summers will succeed in the warmer parts of the country in little besides common garden soil. They are not so hardy as Vegetable Marrows, and should not be sown so soon. The second week in June is the best time to plant unless protection can be afforded, and seeds may be sown where the plants are to grow a week or ten days earlier. Prepare a ridge or mound as for Vegetable Marrows, and both kinds ought to be carefully screened from strong winds.

**Gourds.**—Where there is space between fruit trees on sunny garden walls one or more Gourds could be fruited with good effect, and they might also cover temporary or permanent archways, and such like. Give each plant a spit or more of good manure for the roots to take possession of later, but avoid overdoing it, or there will be too much haulm. As far as raising or planting out is concerned, treat similarly to Vegetable Marrows. Long stout stakes are needed for the plants, both against the walls and in the open.

## APIARIAN NOTES.

## SEASONABLE NOTES.

WITH the advent of May bee-keepers should be on the alert. All stocks must be examined, and a note made of each for future reference. When each stock is numbered, and the business is conducted in a methodical manner, it is not nearly as formidable an operation as at first sight appears.

A small book that may be carried in one's pocket I have found most useful for the purpose. In this is entered the number that is marked on each hive and the age of the queen should be booked against the number corresponding with the hive. This is most important, as the strength of the colony will depend to a great extent on being headed by an active fertile queen. A note should be made as to the condition of each stock. Those that require feeding should be promptly attended to, although flowers are appearing in all directions. Bees may die of starvation during a spell of wet, sunless days, such as have been experienced very recently. A case in point came under my notice quite recently. The bees in one stock, a very strong one, were one evening found on the alighting board in great numbers; many of them were dead, others were quite feeble, and unable to crawl into their hive. On lifting the quilt the remaining bees were found between the combs in a state of stupor, and to all appearance past recovery. The cause was at once apparent, not a particle of food remained in the hive. Means were at once taken to prevent a collapse. A couple of hot bricks were placed on top of the quilt, a bottle feeder filled with warm syrup being placed on the top of frames, and the whole covered with a warm covering.

On examination of the hive next morning the bees had quite recovered, and were as lively and active as those in the other hives, the whole of the syrup having been taken by the bees. This stock has since been fed daily with a little thin syrup given warm in the evening, and is now doing well. Now is the time to make a comparison between old and young queens, but it does not always happen that queens reared a year ago are more fertile than those that are a year older. Although I am an advocate for young queens I have at the present time colonies headed by queens that are two years old, and are as strong as the best of my stocks headed by young queens. Where a number of stocks are kept there are always individual stocks that do much better than others.

At the present time I have two frame hives of the same size and manufacture, each holding fourteen standard frames, standing side by side. They were obtained a year and a half ago from a lady bee-keeper who was leaving the neighbourhood. No. 1 swarmed in the early part of last June. A young queen was reared, which in due course filled the hive with brood; they did not store any surplus, but filled their frames with honey, which was left in their brood combs for them to winter on. No. 2 did not swarm, but worked well, and filled a crate of well finished sections. The queen was very prolific, so I did not requeen this stock. The queen must be at least two years old. According to

theory, the former at the present time should be the stronger of the two, whereas quite the reverse is the case, as the latter is one of the strongest stocks in my apiary, and the former one of the weakest. Why this should be I do not know, but the fact remains that it is not necessary or advisable to requeen a stock that is doing well.

There are exceptions to every rule, and this is one to the point, still in a general way young queens are to be preferred to aged ones. I have often had queens do much better the second year, but I do not advise them to be kept longer. This, however, should not be left to chance, but a system should be carried out whereby half the stocks in an apiary should be requeened each year, and it ought to be done as early in the season as possible.—AN ENGLISH BEE-KEEPER.

#### TRADE CATALOGUES RECEIVED.

W. & J. Birkenhead, Sale, Manchester.—*Catalogue of Ferns and Selaginellas.*

G. Bunyard & Co., Maidstone.—*Herbaceous and Other Plants.*

E. P. Dixon & Sons, Hull.—*New Plants.*

W. Lovel & Son, Driffield, Yorks.—*Strawberry List.*

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Salt for Asparagus and Seakale** (*Saline*).—It is not too late to put salt on Asparagus beds, but it is best to give it earlier, both for the benefit of the "grass" and as a deterrent of slugs. A dressing of 2 or 3 ozs. per square yard should be applied just before growth commences in spring, but a little will do no harm at other times during the summer; in fact, will do good in dry soils. It is best scattered on with the hand, and a showery day selected, as it will then soon disappear. Salt is also beneficial to Seakale, applying it similarly as for Asparagus, and preferably before the plants commence growing, or, if afterwards, keeping it from the leaves, as all it falls on will be more or less damaged.

**Potato Curl** (*H. P.*).—Hallier advocated the view that the cause of this puzzling disease is *Pleospora polytricha*, but Reinke and Berthold opposed it; while Schenck, in a series of observations and the cultivation of the diseased plants, obtained from them fungi which were much like one form of conidia attributed to *Pleospora herbarum*, and which he called *Sporidesmium exitiosum* var. *Solani*. Following this up, and from Nature—the only real authority—we found that sets containing mycelium of curl fungus produced haulm on which were borne from hyphæ within the leaves the outgrowths of *Macrosporium commune* var. *Solani*, identical with Schenck's *Sporidesmium*, and later there was developed the perfect form or resting stage, known as *Pleospora herbarum*. This is frequently confounded with *Cladosporium herbarum*, simply because it is found in association with *P. herbarum*, but there is no connection whatever between the two.

**Strawberries for Forcing** (*Daniel*).—La Grosse Sucrée, Royal Sovereign, Auguste Nicaise and Sir Joseph Paxton. Stevens' Wonder, and Laxton's Leader are very promising first and second early varieties respectively, and well worth obtaining for stock. We think Stevens' Wonder will be distributed by Messrs. Cutbush & Son, and will no doubt be duly advertised. The runners should be layered either, as soon as they are ready, in small pots or in the fruiting pots, selecting those from fruiting plants only, and the earliest and strongest runners, leaving them attached to the parent plants until well rooted. For the final potting a rather strong loam is best, but the plants will do well in light fibrous loam, adding a peck of wood ashes and a 9-inch potful of some approved fertiliser to every harrowload of loam and mixing thoroughly. Your questions on hulbs are not clear. If you require a succession of both kinds from Christmas till May it cannot be effected in the most satisfactory manner by any three varieties of each kind, especially of Tulips. Please write again, there is plenty of time for ordering bulbs.

**Destroying Woodlice** (*H. A.*).—It has been repeatedly stated that woodlice have been caught in thousands by placing some partially decayed and dirty old boards face to face, and covering these with litter where the pests abound. Smooth new boards are of no use, but the older they are the better, and there should be space for the woodlice to enter between them. They should be examined every morning, taken up, held like a trough, and the contents emptied into a tank or vessel of water. It is a certain mode of riddance if properly carried out.

**Hedge Unsatisfactory** (*M. G.*).—It is extremely difficult, and sometimes impossible to induce a thin hedge to thicken at the bottom without reducing its height. Improvement may sometimes be effected by cutting down some of the growths which form the hedge without materially impairing it as a screen; and some growths may occasionally be spared for "laying"—that is, cutting them almost through at or near the base, so that they can be bent down and affixed in position where required. Hedges often get weak through poverty of soil and drought, and they invariably suffer in that respect under trees. The only remedy in such a case is to break up the ground, so that strong and copious supplies of liquid manure can be directed to the roots, afterwards top-dressing with a thick layer of good manure. Where it is convenient to do so strong young plants may be put in for forming a better base, providing enriched soil and keeping the roots moist.

**Strawberry Weevils** (*Leatherhead*).—Various weevils attack Strawberries, and most destructive they are. Those you send are, we think, small or young examples of *Otiorynchus picipes*; but other species are similarly injurious, and the habits of all are practically the same. They eat almost anything green, and often do serious damage to Vines, Roses, Ferns, Raspberries, and Strawberries. They hide in the daytime and feed at night, as a rule. Many have been caught at night under glass by shaking infested Vines or plants over white sheets, in order that the pests may be visible and secured. In Raspberry plantations thousands have been literally "secured" by shaking the plants at night over wooden troughs smeared with tar. Raspberry growers say petroleum is of no use against the weevils, as "they like it." Slates or tiles laid between the rows of Strawberries have proved tempting lurking places for weevils, and many have been caught by their aid. Gas liquor diluted with five or six volumes of water and carbolic acid have also proved useful applications. Mr. Abhey mentions preparations (No. 3) at the foot of page 378 last week, which might be tried; but weevils are proverbially difficult to deal with, and nowhere less so than in beds of Strawberries. You should make a fresh plantation distant from the old, and when this is destroyed dress the site with gas lime, half a hushel to the rod, to remain on the surface for two or three months before digging and cropping.

**Tomato Stem and Root Diseased** (*J. L.*).—The stem and root are hadly infested with eelworm, and swarm with cysts or developing eggs of the parasite, which in all the stages of the micro-organism is well represented. The long bodies are the males, the short and stout ones the females. The oblong bodies are the cysts or developing young, their form being clearly seen through the enclosing membrane or sac, and the oval bodies found on the breaking up of the pear-shaped receptacles are the eggs, which simply grow into cysts, often within the parent, and burst forth. The plants in such case are too far gone for recuperation, but you may use a solution of nitrate of soda, 1 oz. to a gallon of water, and when the plants need water again supply a solution of kainit, 1 oz. of the salt to 1 gallon of water. This is a good and safe remedy, always provided that the plants are not too far gone, and it is followed by placing turves against the stems above ground, so as to induce roots from that part for the supply of nutriment to the plants. The turves should be disinfected by the saturation of them a few days prior to use with the foregoing solutions, which will give excellent results in the crop with freedom from eelworm. The species of eelworm is *Anguillula obtusa*, a common British one, and mainly differs from *A. or Heterodesa radicola* in the males being shorter or more obtuse. The treatment advised is only for Cucumber and Tomato plants in fruit so as to enable them to perfect their crops.

**Wireworms** (*A. G. G.*).—The guano, 28 lbs. per chain, is an excellent dressing, and ought to give good results, both as regards the wireworm and the crop of Runner Beans, which, as you say, soon outgrow the pests when the Bean plants begin to make lateral roots. A dressing of quicklime fresh from the kiln is excellent for land infested with wireworm, especially that of old turf recently broken up. Half a ton per square chain, placing the quicklime in heaps convenient for spreading, sprinkling with water, and covering with a little soil till fallen. Whilst quite hot and floury the lime should be spread and pointed-in with a fork not more than 6 inches deep. Corrosive sublimate solution would kill the wireworm, but it must be very cautiously used, as there is danger of its getting into wells with the drainage water, or into other receptacles, where it may cause serious consequences to man and beast. Sprinkling the rows with it would be quite sufficient, and 1 oz. to 30 gallons of water a suitable strength. The price of corrosive sublimate is about 6d. per ounce retail. It should be procured finely pulverised, and must not be handled in the pure state. Hellebore powder sprinkled on beans with a dredger will not hurt the wireworms unless they eat it, which they are very unlikely to do. We advise the lime and nothing else, unless you like to use phenyle, which will kill or drive the wireworms away, and materially aid the plants in their growth. Wireworms are not at all fond of Tomato plants, but they will eat the roots, and the reason they did not attack yours was probably due to the guano mixed with the soil.

**Insects in Mushroom Bed (H. R.).**—The "grub" is the larva of one of the Rove or "cocktail" beetles, a smaller species than the "devil's coach horse," and though one of the Staphylinidæ belongs to another genus. It is *Staphylinus erythropterus*, and is mainly carnivorous, but feeds more or less on decayed vegetable or not healthy plants. We have no experience of its injuring Mushrooms, but it may feed on those in a state of decay. The "white worm," are not eelworms, but common in decaying wet matter, and certainly attack the roots of many plants. It is called *Euchytræus Buckholzi*. The salt or nitrate of soda solution will destroy the pests, but there is danger in making the beds too wet for the Mushrooms. The "specimens" last sent in a box without any packing were shaken and dried into dust-like particles.

**Vine Leaves Injured (Profit).**—The Muscat Vine leaves are very stout in texture, and there is no mildew, or any discernible disease on them. Their appearance suggests an overdose of ammonia vapour, accelerated by the house being kept close during the prevalence of the late dull damp weather, and on a return to bright days not giving proper care to the ventilation. The tissues are considerably thickened, especially on the upper surface, and to some extent scorched. We do not see in what way defective root action could produce the condition of the leaves, as the supply of matter from some source has been abundant, and it is hardly likely it would be wholly derived from stored material. Defective root action, however, would prove disastrous to the foliage after a spell of dull weather, for on a return of bright days the amount of evaporation would be much increased, and the demand for sap proportionate. This would produce flagging and to some extent scorching, but we consider the mischief is caused mainly by the ammonia vapour, or some such agent acting on the epidermal cells.

**A Good Pansy (T. T.).**—The points to be aimed at in a Pansy may be described as follows:—1, Each bloom should be nearly perfectly circular, flat, and very smooth at the edge; every notch or unevenness being a blemish. 2, The petals should be thick, and of a rich velvety texture. 3, Whatever may be the colours, the principal or ground colour of the three lower petals should be alike; whether it be white, yellow, or straw colour, plain, fringed, or blotched, there should not in these three petals be a shade difference in the principal colour; and the white, yellow, or straw colour should be pure. 4, Whatever may be the character of the marks or darker pencillings on the ground colour, they should be bright, dense, distinct, and retain their character, without running or flushing—that is, mixing with the ground colour. 5, The two upper petals should be perfectly uniform, whether dark or light, or fringed or blotched. The two petals immediately under them should be alike, and the lower petal, as before observed, must have the same ground colour and character as the two above it, and the pencilling or marking of the eye in the three lower petals must not break through to the edges. 6, If flowers are equal in other respects, the larger, if not the coarser, is the better; but no flower should be shown that is under 1½ inch across. 7, Ragged or notched edges, crumpled petals, indentures on the petal, indistinct markings or pencillings, and flushed or run colours, are great blemishes; but if a bloom has one ground colour to the lower petal and another colour to the side ones, or if it has two shades of ground colour at all, it is not a show flower. The yellow within the eye is not considered ground colour.

**Vine Growths Deformed (D. and W. B.).**—Although the crumpled condition and the discolouration of the leaves betokened "browning" disease, there is nothing discoverable of that nature in the internal tissues, and beyond a slight clamminess no traces outside of slime fungus (*Plasmadiophora vitis*). On looking at the cuts where the winter pruning had been effected we found a curious consortism of fungi—one the sclerotium of the fungus called *Polyactis*, or more properly *Botrytis cinerea*, and from it the *Peziza* form in grand array, with its myriads of spores which give rise to the *Botrytis* again. Associated with these was the very common glaucous mould (*Aspergillus glaucus*), and also *Penicillium glaucum*. There was likewise growths of a *Botrytis*, but an abnormal form of any figured species, if one. These were all external and sprang from the cut, except the *Peziza*, which was from a sclerotium on the bark, and not one would account for the condition of the Vine growth. On cutting through the spur transversely the wood was found discoloured, and this continued down, and passed up the young shoots as a blackish stain. This stain proceeded from the external cut surface, not by the pith, but between the bark and young wood, and not being present below the growths indicates that the parasite entered by the wound. What the parasite is we are unable to say, as there is no outgrowth directly traceable therefrom, or is the mycelium at all characteristic of any of the fungi named; but if, as we anticipate, some parts of the affected growths become decayed and mouldy, we may determine the cause of the mischief, which may be a parasite of the worst kind. If such outgrowths appear we should be pleased to examine them. In the meanwhile we advise dressing the cuts—the old wounds caused in pruning—with a solution of sulphate of iron, 1 oz. to a gallon of water, applying with a stiffish or half-worn clean painter's sash brush. It would have been better to dress the whole cane or rod, and it may yet be done, using it on the old and last year's wood only. An application of air-slaked lime, dry and floury, to the border would also be beneficial, employing from a peck to half a bushel per rod, either leaving on the surface for washing in, or slightly pointing into the soil.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds

should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (W. K.).—*Dendrobium fimbriatum oculatum*. (P. B.).—1, *Lychnis dioica rosea plena*; 2, *Muscari botryoides* (Grape Hyacinth); 3, *Fritillaria meleagris alba*; 4, *Anemone pulsatilla*. (O. G. M.).—1, *Dendrobium Wardianum*, good form; 2, *Odontoglossum triumphans*; 3, *Cattleya Trianae*, very fine variety. (B. T. R.).—1, *Anthericum variegatum*; 2, a *Tradescantia*, varietal name undeterminable from such a withered specimen; 3, *Selaginella Kraussiana*; 4, *Adiantum pubescens*; 5, *Nephrolepis exaltata*; 6, *Dicksonia antarctica*. (Sunbeam).—*Ribes aureum*. (H. M. H.).—1, *Kerria japonica flore-pleno*; 2, *Amelanchier Botryapium* (Snowy Mespilus); 3, *Pulmonaria officinalis*; 4, *Cytisus albus luteus*; 5, *Epimedium alpinum*.

BUTTER.

INQUIRIES about points of practice in butter-making which have come to us recently from several of our readers are a reminder that the circulation of the Journal is ever increasing, that facts with which its older readers are familiar are either quite unknown to new readers, or such knowledge as they possess is vague, indefinite, misleading, and that it is not only important but imperative that vital points of practice shall be repeated with sufficient frequency to help them, and we may well add, to jog the memory of old practitioners.

We are writing this article on May Day out among the dairy farms of the High Peak in North Derbyshire, and in a report of the Manchester Butter Market of this morning we are told that warmer weather and an increasing supply has brought prices down, giving buyers every opportunity of satisfying their requirements at all manner of rates, from 60s. to 90s. per cwt., according to quality, in Danish, Swedish, Irish, Hamburg, Australian, Finnish, and Russian butters. That Irish butters especially show good value, but the make of some sorts is fodder and not yet keeping, except specially fine samples. That centrifugal creameries are coming well to the front, and making good prices, fully equal to the best Danish. This statement of the progress of business in what is claimed to be the premier butter market of England is specially significant as showing the marvellous competition in the open markets of this country, the profitable growth of home competition in the produce of butter factories, and as marking the difficulty of fixing quality at this season of the year.

The "fodder" condition denotes the adverse influence of certain food on the keeping property of butter as winter merges into spring, and as a change is being made in the dietary from the "fodder" stores of winter to an addition of green food. It is precisely this bad keeping, this deterioration in quality soon after the churning, which puzzles many an inexperienced butter maker. The "fodder" condition may be owing to the cows having bad hay, or a superabundance of Swedes, Mangolds, silage, or they may have had access to foul water, or if let out on pasture they have eaten every green plant so greedily that it is quite possible some poisonous plant may have been consumed by them. All or any of such things are to be regarded as predisposing causes of bad keeping in butter. The remedy, or rather the means of prevention, is in our own hands.

It is as clearly the duty, as it is to the interest, of every dairy farmer to know thoroughly how food affects the milk, what proportion of doubtful food he may venture to include in the dietary with safety—*i.e.*, without any possibility of imparting bad flavour to milk or butter. Also the nature of the herbage of his pastures should be beyond a doubt. There are meadows in certain localities which have long been known as unsuitable for grazing dairy cows, as the butter always goes wrong when the cows are turned on to such meadows. How anyone can rest content with a mere knowledge of the fact without seriously setting themselves to ascertain the cause and to apply the remedy puzzles us.

Surely the day has gone by for dairy mysteries of any sort. Technical knowledge, and the advice and assistance of experts is now available in every country side, the day of the "wise" man or "wise" woman of the parish is ended, and the day of wondering why the butter will not "come," will not keep, or is streaky, ought to belong to the past also. Certainly all that goes to the management of dairy cows, to the manipulation of milk, cream, and butter is so simple, cause and effect in relation thereto are so clearly defined and so entirely outside the pale of so-called mysteries, that really good butter all the year round ought to be the general rule—bad butter only the result of an accident, a passing fault easily corrected.

We would have plain and simple rules of management, mastered by every cowman and dairy woman; especially would we have the term of cleanliness made clear to them in its widest and most comprehensive significance—cleanliness of food, water, air, buildings, litter, the cows' udders, the milkers' hands, dairy utensils, of everything brought in contact with the butter, all tending in the direction of the prevention of faults, of the avoidance of vexatious losses, of the exercise of especial care in spring and autumn, of that crown and finish of the work—the production of butter of the highest possible excellence always.

#### WORK ON THE HOME FARM.

All really well managed pasture had a full bite of herbage on May Day, to the quick, strong growth of which genial showers and warm nights during the last days of April materially contributed. There is always some risk of butter troubles as turn out time approaches. A little extra care in feeding and in churning soon sets matters right, or rather prevents any serious mischief, and when the cows are fairly settled down to grazing both colour and flavour in butter should be at their best.

Look closely after cows, especially delicate ones, for the first two or three weeks after they go out to grass, as it is then that cases of hoove, or distention of the stomach by gases generated by the stomach being packed with a large mass of food, which the afflicted animal appears unable to digest. In our experience such cases have not been of frequent occurrence, and one easily detected, first by the cow getting away from the herd, standing alone listless, neither grazing nor ruminating, its head hanging down, its stomach much distended, its whole appearance denoting suffering. Prompt action must be taken. It is always best to call in a veterinary surgeon, but if one cannot be had at once, and the cow by its moaning shows that it is in intense pain, it should have a strong purgative, and the gas made to escape by the insertion of a short tube through its hide.

The rough but efficient method of the old cow leech was repeated doses of Epsom salts as internal treatment. Externally, at a distance of two moderate spans from the nearside hip in the direction of the head and in a line parallel with the spinal column, the hide was pierced by the point of a sharp knife, and a wooden tube thrust in. This tube was cut from the Elder tree, planted for this purpose near the cowyard, with bark and pith removed, and a leathern flange let into a nick near the outer end of the tube, which was about 6 inches in length, and through which the gas at once escaped with such rapidity that the cow had immediate relief. Subsequently the cow was dried off and fattened, as it was thought to be unfit for breeding again, and there was much risk of a recurrence of the hooven condition.

#### HOME-RAISED CABBAGES.

A FRIEND writes the following:—"A neighbour of mine has been in the habit of getting his Cabbage plants for lamb food from South Lincolnshire at so much per 1000. Last autumn, having near home a piece of land suitable for the purpose (about 1 acre 1 rood), he bought instead 15s. worth of seed, an early variety called, I believe, Emperor. Fortunately for him the bitter frost was accompanied by a great depth of snow, and this effectually preserved the plant life beneath. He drew out 40,000 of the best plants for his own use, and then found he had a few to spare. These few brought him the comfortable little sum of £14, a sum not to be despised in these days of deep depression. Personally, I think he might have made more of them; but being new to the trade he hardly knew where to place them to the best advantage."

[In a lecture delivered at Nottingham five or six years ago Mr. J. Wright stated he had been "admiring 3 or 4 acres of Mangold Wurtzel—the finest crop he had seen, and valuable; but was startled on being told it was the second crop, and that the grower of the Mangolds had drawn £200 out of the land the same spring. This was by the sale of such plants as above named—Savoys, Cabbages, and others, from 150,000 to 200,000 being pulled daily for a month, and sold for 1s. 6d. to 3s. a thousand, sent off in truckloads to his salesmen in large markets." That example of profitable culture was in South Lincolnshire, and the thrifty farmer is not in the least likely to go to the workhouse.]

#### REMARKS.

28th.—Overcast morning, frequent sunshine in afternoon, bright night.  
29th.—Bright sunshine all day, fine night.  
30th.—Sunshine most of the day, but cloudy at times in afternoon.  
1st.—Generally sunny in morning, cloudy afternoon, with rain from 3.30 to 4.30 P.M.; fine again later, and clear night.  
2nd.—Bright sunshine throughout.  
3rd.—Bright sunny morning, cloudy at times in afternoon, and windy.  
4th.—Unbroken sunshine, with fresh breeze.  
A very fine week, with two slight radiation frosts and bright sunny days. Shade temperature, near the average.—G. J. SYMONS.

# DICKSONS' NEW IRISH ROSES.

ALEX. DICKSON & SONS

Have pleasure in announcing for distribution in May a further series of their

**CELEBRATED PEDIGREE ROSES,**  
HELEN KELLER (H.P.), Rosy Cerise, superb .. 10/6 each  
MAVOURNEEN (H.P.), Silvery Flesh, first rate 10/6 ..  
MARJORIE (H.T.), White, Pink centre, very pretty 7/6 ..

ALSO  
The Best of the NEW FRENCH & BRITISH ROSES.  
Descriptive Catalogue Post Free on application,

## NEW (H.T.) ROSE BELLE SIEBRECHT (Mrs. W. J. Grant).

Raised by ALEX. DICKSON & SONS, distributed by SIEBRECHT and WADLEY, New York.

The most valuable introduction of the past ten years. This superb variety has gained the highest awards wherever exhibited in Great Britain and America, chief among these being the National Rose Society's Gold Medal.

Valuable alike for exhibition, decorative, and forcing purposes. No collection, however small, complete without it.

PLANTS IN POTS IN MAY, 10/6 EACH.

Full Descriptive Particulars Post Free on application to

## A NOTE ABOUT VIOLAS AND PANSIES

Reduced Prices for May.

### A VERY SPECIAL HALF-CROWN LOT.

While Stock holds out during May we offer 13 strong plants of grand named VIOLAS for 2s. 6d. Customers may select the sorts they would like from the undernoted list, or we shall be happy to do so for them. The names are given just to show the value and genuineness of this offer:—

Archibald Grant	Favourite	Marchioness of Tweed-
Ardwell Gem	Goldfinch	dale
Annie King	Holyrood	Sweetheart
Blue Cloud	Iona	Sylvia
Bullion	James Cocker	True Blue
Colleen Bawn	J. B. Riding	White Duchess
Columbine	Laverock	White Flag
Countess of Hopetoun	Lord Elcho	Wm. Neil
Countess of Kintore	Mrs. H. Bellamy	York and Lancaster
Dorothy Tennant	Mrs. Kinnaird	Picotée
Duchess of Sutherland	Mrs. C. Turner	Violetta
Edina	Mary Gilhert	

100 Plants in at least 25 varieties, post free for 15s.

### FANCY PANSIES.

Grand named varieties, producing flowers 2 to 3 inches in diameter. Colours as varied as the rainbow. 3s. 6d. per doz. Just coming into bloom.

100 Fancy Pansies in at least 25 varieties, post free for 20s.

### SHOW PANSIES.

This is the class which embraces the dense purple and black selfs so much admired. Prices same as for Fancy Pansies. 1 dozen Show and 1 dozen Fancy for 6s.

HALF-DOZENS AT SAME RATES.

**DOBBIE & CO.,**  
FLORISTS TO THE QUEEN,  
**ROTHESAY.**

## JACK FROST

Has caused many losses that can be made good in an easy and cheap manner by purchasing the following Bulbs and Plants, which I can strongly recommend as being first class:—

### BEGONIAS, SINGLE,

20,000 Grand Bulbs, Mixed Colours, finest ever offered at the price. 3s. per dozen.

### PELARGONIUMS, SHOW & DECORATIVE.

Fine Plants in Best Kinds, 6s., 9s., and 12s. per dozen.

### ZONAL PELARGONIUMS,

Best Kinds only. 6 for 2s. 6d., 12 for 4s.

### IVY-LEAF PELARGONIUMS.

A very Choice Lot. 6 for 2s. 6d., 12 for 4s.

### DOUBLE PETUNIAS,

Extra fine New Kinds. 6 for 3s. 6d., 12 for 6s.

Send for Catalogue, Free.

HITHER GREEN, LEWISHAM.

## THE NEW EARLY STRAWBERRY FOR 1895, STEVENS' WONDER.

The earliest variety in cultivation and very prolific; solid fruit, good flavour, high perfume.

Awarded First-class Certificates, Royal Horticultural Society, and Royal Botanic Society, 1895. See *Gardeners' Chronicle*, March 2; *Journal of Horticulture*, March 14; and *The Garden*, March 16.

Having purchased the whole of the stock of this grand new early Strawberry from the raiser, we have pleasure in offering it as follows:—

STRONG PLANTS, in Pots, £5 per 100, 15/- per doz.

“ RUNNERS .. .. £3 .. .. 9/- .. ..

Ready for delivery early in July. Early Orders requested as stock is limited. Further particulars upon application.

### THE PROMISE OF MAY.

BEAUTIFUL indeed is our country, now in its freshest dress of tender green, and wreaths of sparkling blossom. Blossom! Was ever finer seen than that which the present month has brought in such lavish profusion on trees, in gardens, and orchards? Almost everywhere where fruit trees are grown and have arrived at the stage of productiveness, they have been or are enrobed in loveliness, especially the Apples. Just a week ago a call was made at Chiswick, and though the Plums had cast their silvery mantle and the splendid pyramid Pears were being studded with setting fruits, yet did the garden seem to be full of beauty, so bountifully were the Apple trees laden with their delicately tinted flowers. Not in their abundance alone were these myriads of blossoms imposing; but in their size, substance, and splendid development they commanded equal admiration. No finer display—no brighter promise—has ever been seen, and one shudders at the thought that a cruel frost should come and in one fatal night turn present hopes into grievous disappointment.

The blossoming time is a fortnight (more or less) later than was the case last year. But does this afford assurance that a harvest of fruit will follow? Not necessarily; for if the cold wave, that seems bound to come in May, should be of an intensity equal to that on the memorable 20th of the month last year, the lateness of the blossom and the consequent youthfulness of the tender fruit cannot prevent destruction. If security rested in lateness, then would the Apple crop of last season have exceeded in abundance that of the Pears, the fruits of which were more firmly set, older, and more hardy at the time the frost swept through the land. Therefore, the early blossoming Pears largely escaped, while the later blossoming Apples generally succumbed. Not until we have a race of Apples that flower after the 20th of May and onwards for a week can crops of fruit be regarded as absolutely certain any more than Heliotropes, Dahlias, and other tender plants can be held to be safe which are “bedded out” before that time. It is true that summer-like days and balmy nights have tempted the

exposure of such tender plants sooner, and they have sometimes prospered, but it was more by good luck than good management. It is all the same fortunate that such escapes are possible, or it would be a dreary outlook for fruit growers who cannot protect their trees.

When gardeners and others so manage fruit trees that they are wreathed with stout blossoms on firm wood, from the base to the extremities of the branches, they have done their share and their duty, and, taking one year with another, the yield of fruit, assuming the varieties are of the best, will repay for the outlay in cultivation, provided the site and soil are not inherently unfavourable for the attainment of the object in view. In this fact, for fact it is, there is hope and encouragement. The man who possesses the soundest knowledge on the subject of fruit, and who exercises the best judgment in the choice of site, soil, and varieties, at the same time following the most intelligent methods in procedure, is bound to have an advantage over his fellow worker, who, through lack of knowledge, pursues an erroneous course of routine. One of the questions asked by the Royal Horticultural Society for students to answer is whether trees can be made to resist canker and other maladies by good management and cultural attention? We are not quoting the question, but simply giving its purport. Undoubtedly those evils can be, to a large extent, prevented when their nature and origin are understood; and similarly, though perhaps less certainly, the blossoms of fruit trees can be, to a material extent, hardened—or sufficiently so to enable them to escape destruction by a passing frost to which others might succumb.

If this were not so, why is it that a plantation of several Apple trees in well-chosen varieties planted at Chiswick nearly twenty years ago have never failed, in spite of varying seasons, to give good crops of fruit, and in most years very abundant crops, while other trees in the gardens have often been barren? As there is a reason for everything, there is naturally a reason for that disparity. The trees which bear unflinchingly are on a surface-rooting stock. A multitude of fibres ever dividing in firm fertile soil produce firm, short-jointed, fertile wood; and if the branches of the trees are so thinly disposed that the sun can shine between them—every leaf, so to say, being directly exposed to its influence—a maximum amount of starch will and must be manufactured, and this and other mineral matter deposited and stored in the buds and the stems—ten times more than is possible when a thicket of growths is produced by constantly shortening the branches for cutting the trees into shape, and driving strong roots downwards, as robust summer growths will do, and the more certainly if the surface roots are either starved out by the lack of an occasional top-dressing or dug out by the reckless use of the spade.

It should never be forgotten that as the roots of trees are so are the branches. If the parts of a tree within the ground are long, strong, and fibreless, so are the parts above ground, long, strong, and tissueless; and if the leaves are made in a crowd, each endeavours to stretch itself out for reaching the vitalising light which the "cultivator" denies it, becoming apparently large and strong, but really thin, weak, and tender; then the blossoms (if any) are weak and tender in turn, for though the petals may be showy they will be flimsy, the essential organs weak, the pollen faulty, and the whole inflorescence vanishing under a whiff of frost or a few days of bright sun, leaving not the semblance of fruit behind. Now grasp the converse—a mass of small fibrous roots imbibing what the trees need, and producing not strong, long succulent stems, but short substantial growths; every leaf being free from its neighbour and the sunshine glistening on it, comparatively small in area, but stout, thick, and "hard," will do its wondrous work in preparing and depositing nutrient matter in bud and stem; and the essential organs of the plentifully formed flowers will be like the leaves, firm, structurally perfect, with pollen well developed, the whole tree and every part of it being in

the best condition for passing through a time of trial without the loss of the whole of the hoped-for fruit.

Thus it will be perceived by those who think the matter out on the lines suggested that the cultivator may do something towards turning the promise of May into fruition in the case of such of his trees that are under cultural control. But how? In a very simple way. There is nothing complex or elaborate about it, no mysterious manipulation, but just the exercise of rudimentary common sense. Start the trees right and keep them right. Shorten them somewhat after planting for originating the requisite branches, then be content with what may be thought too few, rather than doing more shortening for producing too many. With the branches absolutely clear of each other when in full leaf they will form blossom buds if not shortened, and will divide naturally for forming sufficient branches in most cases; cut them back closely, then blossom formation is prevented, and fruitless growths promoted.

"But surely if the young branches get strong we must cut them back," say some persons—or at least they do it. No, it may be the *worst* thing that can be done, at least if the too strong growing young tree is not dug up and replanted. This replanting is usually the *best* thing that can be done, and then there may be a little branch-shortening for balancing a tree. Get it into bearing, then use the fruit as a lever for governing the growth. If this is inclined to be robust let a good crop remain to subdue it; if growth is slow and likely to be weak, remove sufficient fruit to relieve the pressure and let the branches extend. Avoid stunting the tree by overloading it in infancy. If it make a foot of stout short-jointed extension growths as well as supporting fine fruits, few or many, and these growths are at least a foot asunder, a good habit will be formed—fruitfulness without exhaustion. A plantation of such trees will give little further trouble. The pruning will practically amount to thinning, the summer culture to hoeing, with an occasional surface dressing as the crop and growth suggest, pointing over the ground at the end of the season for sweetening the soil and neatness sake, but not mutilating the roots.

It is in that easy way that this Chiswick plantation has been rendered so productive year after year. The trees grew for a time at about 6 feet apart, half of them being eventually removed for extending the plantation and affording needed room for the remainder. Each variety has been allowed to assume its natural form. There has been no pruning into ideal uniform shape, as that would have militated against productiveness. The trees have been pictures of beauty of late, and if a bountiful crop of fruit does not follow it will be the first failure.

Another thought arises. Some reader may attach importance to the particular kind of stock on which the trees are established, and fancy that this is the secret of the success achieved. Mr. Barron does not think so, for a very good reason. Some rather extensive experiments are tending to show that there is not so much magic in stocks as is popularly supposed. The productive trees described are on the French Paradise, but several others on different kinds of stocks for showing their distinctive influence, might be said to be growing provokingly alike if they were not doing so uniformly well, which is *not* provoking.

## AMONG THE ALPINES.

THE "merrie month of May" has again rolled round, and with it in their simple beauty the alpine and rock flowers. As each season comes we have something fresh to study and admire, every bloom with a beauty peculiar to itself, and as they arrive we are apt to think that this or that reaches our ideal of a flower until it fades and something else bursts forth, perhaps in form and beauty entirely different to its forerunner, but still it has its own charm, which silently appeals to us in language so irresistible that we feel obliged to give up all thought of forming an ideal, and are content to welcome and admire them all as they come and go.

The Hyacinths, Daffodils, and Tulips with their brilliant colours have barely passed away, when, to fill the gap thus formed, there come the alpine and rock flowers with their much more simple, but no less charming beauty. Unlike the former they seem

almost too modest to show themselves, and love to hide away in quiet sequestered nooks, to such an extent in fact that it is often a puzzle to find them. This love of solitude seems to bear out the words of the poet Gray, when he says, "Full many a flower is born to blush unseen."

That they are not, however, always grown under these conditions was proved in a recent visit to Dulwich Park, where they may be seen blooming in profusion sufficient to raise the enthusiasm of any true lover of the species. "Alpines in a London park?" I fancy I hear some reader exclaim. Yes, my friend, and such a collection that you would have to go a long way to excel. In recent issues of the *Journal of Horticulture* I have endeavoured to give some idea of the flowers in the metropolitan parks in the West and East, but at Dulwich, in South London, the display, though equally effective, is of a very different character.

The rockeries are situated in the most conspicuous places, chiefly facing the main entrances, and in the character of their formation it is easy to see that artistic rockwork was not the end in view, but rather to provide a suitable home for the plants, and indeed in this the point has been gained, for in spite of the severity of the past winter they look exceedingly healthy, and present such a variety and profusion of bloom that cannot fail to be appreciated by the public, for whose sole benefit they are provided under the auspices of the London County Council.

So varied are the conditions under which rock plants grow that there is hardly a conceivable position which cannot be made beautiful by careful planting, some delighting in the deepest shade, while on the other hand others luxuriate in the brightest sunshine. Very conspicuous along the rockeries at Dulwich are the bright yellow flowers of *Alyssum saxatile compactum* (Gold Dust). So well known is this free-blooming variety that it seems needless to dwell on its beauty, and so striking is it that no rock garden could be considered complete without it. *Saxifragas* are to be found in such numbers that it would be difficult to attempt to describe every variety, so I shall be content with naming a few of the most striking.

Very pleasing in effect is *S. Wallacei*, which for the number and purity of its charming white flowers, in addition to its dwarf compact habit, cannot fail to attract special attention. *S. pyramidalis* is certainly one of the finest of the genus, though scarcely yet in full bloom, throwing up as it does tall pyramid-like flowers (from which it takes its name) resembling somewhat a cloud of foam. Very different in character, but no less pleasing in its pure simplicity, is *S. muscoides purpurea*, producing its large numbers of delicately coloured flowers from cushions of compact verdure. *S. Burseriana* and *S. (Megasea) crassifolia* are of course over, though the latter by its handsome foliage relieves any monotony that might otherwise exist.

*S. Stansfieldi* and *leptophylla* are both pretty whites, while in the mossy-like foliage of *S. hypnoides* there is a wealth of beauty independent of the flower. Very distinct is *S. Macnabiana*, as the foliage, of a whitish tint, has the appearance of being studded with beads. A very pretty and free-flowering variety is *S. Aizoon minor*, while may be seen a curiosity in *S. peltata*, with its tall conspicuous spikes of flower, which come before the plant makes its new leaves. *S. decipiens* is chiefly noted for the thick carpet-like form in which it grows, and in *S. zealandica* we have a pretty climbing variety indispensable in its capacity for covering rocks. *S. Andrewsii* bears a charming flower, and has large handsome foliage. The verdure of growth and brightness of the blooms of *S. Haworthii* formed a bright contrast, and the tall white flowers of *S. incurvifolia* swayed gently in the breeze. Amongst many others of the genus which go to make up the complement of *Saxifragas* at Dulwich may be mentioned *S. rotundifolia* with its greenish white leaves, *cochleata*, *capillaris*, and *oppositifolia*.

In addition to the above many other flowers claim attention. There is *Aubrietia Campbellii* in its intense vigour covered in great profusion with its violet-purple flowers of dwarf habit, and in a shady corner was noticed the rosy purple flowers of *Primula cortusoides*. *Iberis sempervirens* is very effective with its pretty white blooms, and the graceful flowers and leathery leaves of the *Epimediums* (more commonly known as Barrenwort) add variety to the collection. *Phlox setacea* is truly at home at Dulwich, its dwarf compact masses of evergreen foliage covered with bright rose flowers being particularly effective. Growing close by is *P. procumbens*, with purplish-green foliage studded with clusters of lilac-coloured blooms, and very charming also in its creeping habit is *Veronica rupestris*.

Among the *Sedums*, all of which have a beauty peculiar to themselves, may be mentioned *brevifolium*, *kamtschaticum*, the ever popular *glaucum*, *montanum*, *grandiflorum*, rightly named from its fine yellow blooms, and *album*, one of the most pleasing, clothed as it is with pretty white flowers. Mention must be made

of *Spiraea filipendula*, with its Fern-like foliage surmounted by double feathery blooms.

*Androsace sarmentosa* occupies a prominent position. It is a most interesting species, having downy leaves and flowers of a bright rose centred with white. Another plant adding its full share to the display is *Tiarella cordifolia* or "Foam Flower," as it is commonly called from the density of its feathery white blossoms. *Armeria maritima alba* is a charming alpine with pretty white flowers; as also is *Arabis albida variegata* of the same colour, the foliage being described in the name. None of the whole genus is deserving of higher comments than *Geum montanum*, which produces a mass of star-like yellow flowers on stalks sufficiently tall to make them very effective.

*Silenes* in variety are perfectly at home here, amongst others being the evergreen form of *alpestris*, covered with white blossoms; *acaulis alba* of the same colour, and growing in moss-like tufts, being no less beautiful. In many places the rockery is clothed with dense masses of the pretty *Omphalodes verna*, and *Dielytra spectabilis* (Bleeding Heart) also finds a place. Many of the *Thymuses* are worthy of comment, amongst others being *montanus*, *coccineus*, and *lanuginosus*.

A pretty peep in the park is the "Snake's Lane" (why so called I fail to imagine), rendered extremely so at this period of the year by the presence of many of the above alpines. Unfortunately, the severity of the winter has totally destroyed the Wallflowers, which are usually so conspicuous here, but in spite of this it is quite a feature. Along one side are stumps of trees, dotted diffusively about and covered with Ivy, from the base of which may be noticed peeping forth clumps of Primroses, Lily of the Valley, and Wood Hyacinths, together with large masses of the *Asperula* or common Woodroff.

Alpines are not the only flowers grown, as *Polyanthuses*, *Auriculas*, and late Tulips are planted here and there, while large spaces covered with blue Forget-me-nots form a picture in themselves. *Funkias*, *Pulmonaria officinalis* and *Scillas* were also noted, and growing profusely on several of the aforementioned stumps is the simple white *Clematis montana*.

Flowering and ornamental trees and shrubs are largely grown, and will in the future add considerably to the beauty of the park. Among the former the Double-flowering Cherry is very fine, and the blossoms of *Pyrus japonica* and *P. Malus floribunda* form exceedingly bright contrasts. With the Laurels and other tender shrubs the frost has played havoc, and many present a pitiable appearance.

In conclusion, Dulwich may be safely called the garden park of London, and every part of it tells of constant attention and cultural skill. Situated in a pleasant district with air fresh and clear, it has of course advantages over many other such places of its kind in the metropolis, and the inhabitants of the southern district have every reason to feel proud of this pleasant resort. Any notes on Dulwich would be incomplete without mention of the able superintendent, Mr. W. Bailey, not only for the efficient manner in which he carries out all duties connected with his office, but for the kind and courteous manner in which he deals with all with whom he comes in contact, and amongst others—WANDERER.

## BOTHIANA.

(Continued from page 401.)

### LANGUAGES.

"A little learning is a dangerous thing,  
Drink deep, or taste not the Pierian spring."

THE first experience of self-imposed tasks is one of irksomeness. Physical tastes and mental desires are not in harmony. Passing this crucial stage a spirit of tolerance ensues, to be succeeded by that love for the work which sweetens all labour. As weeks, months, and the varying seasons roll away, not any opportunities will be lost nor means neglected for progression. Happy and satisfied must the young student feel when reaching this stage of the journey. Most difficulties have been conquered, but the greatest victory is that gained over self. From hence not any spurring is required; in fact, a little restraint may be actually necessary. Temptation in a new form may assail you from a least expected point. More ambitious subjects than those advanced may lure you from work far from completion. The modern languages must ever have a fascination peculiarly their own when noting that the possession of one (or more) places its owner on a pedestal above his fellows. French and German, the first the language of chivalry and courtesy; the latter of the higher schools of philosophy, the arts, and sciences; how desirable are these. Yes, how few of us in the bothy could hope to attain

even mediocrity in the study of either, and that probably at the expense of sacrificing more important—if less showy—subjects.

Individual temperament must play a prominent part in bothy tuition. The most eager desire for knowledge if uncontrolled by wisdom is like a ship without a rudder. Rather keep to the high-ways and avoid the by-ways in your endeavour to reach the goal. Duty, according to circumstances or seasons, makes frequent calls on the leisure hour. These will be met with a cheerful response, and are reasons sufficient to clip ambitious projects, and confine them within reasonable bounds. Also bear in mind that one subject too many may prove the breakdown to all.

Should you feel equal to attempting anything beyond our good old mother tongue, try your 'prentice hand at Latin, which is relevant to the science of botany and the art of gardening. I would more strongly press its claims on you, were it not for those reasons already adduced. However, a slight knowledge of the Latin tongue will serve to digest many of our hard-sounding plant names, and will then impress on you the desirability of being acquainted in some measure with it can you spare time for it. The vigorous and healthy tone imparted to the mind by exercise will probably enable you to be the best judge of future requirements. The pole star of reason, rather than meteoric flights of fancy, will then light the road on which we part company. Yet, I am loth to leave you until your attention has been called to a very different subject, but a very important one—viz., habits.

#### HABITS.

“As the twig is bent, so is the tree inclined.”

Habits, good or bad, are the garments woven in youth which must perforce be worn through life's journey to the grave. True, it is never too late to mend bad ones nor to cultivate good ones; but a mended thing is but a poor thing at best, and the tear remains. The moral power if granted later on in life to amend, which I fear is seldom the case, is accompanied by remorse that a superficial view might endorse the proverb that “It is better to live in a fool's paradise than in a wise man's purgatory.” But this aspect of the case must not, cannot be tolerated by an educated mind. Our ideal of life must be a high one; the very nature of our work and thought should make it so. There is not, I presume, a gardener in existence who does not, in each and every subject under his hand, endeavour to improve on his methods of culture as the seasons wax and wane.

How much more should it be the constant endeavour to sow in the seed time of bothy life and to cultivate such things, such habits as may be harvested to advantage later on. The motive cannot be an entirely selfish one; such must be in some measure shared by another rising generation. It is a question I would not enter into dogmatically. It is a question I am diffident of entering on at all; but it is one of such high importance to you, my young brother of the craft, that I feel you should not be deprived of the smallest iota that my pen, though all too feebly, may be able to convey to you. Would that it could bring to you in letters of gold the blessings attendant on good habits, or show up in letters of fire the bitter fruits of bad ones. Experience is a dear school; need you be of the class who will learn in no other?

From the extent of this subject, the varied phases of it, and the delicate handling many of them require, a more pretentious pen than mine might fail to do it justice. An outline weakly drawn is the most I can offer. You, and you alone, must fill it in, for who can fathom the mystery of the human heart? To each, and to all of us, temptations come in varying shape and form; some from within, others from without. Of the latter, should you have happily taken up in serious earnestness the course of bothy studies, some will be avoided. Others will, by the strengthening of mental vision, be seen by you in their true colours, whilst all will be brought to your notice by “The still small voice.” You will do well to heed it. Intelligence can hardly fail to understand much that cannot be expressed; yet some side lights bearing on your welfare now, and success hereafter, may escape notice.—  
AN OLD BOY.

(To be concluded.)

#### GARDENERS' TULIPS.

I HAVE ventured to entitle the remarks that follow “Gardeners' Tulips” in order to distinguish them from the refined forms grown by Tulip fanciers, and which are beyond the reach of most gardeners. Those to which I wish to draw attention are cheap, and therefore may be cultivated in numbers; easy of culture, consequently suited to all gardens; exquisitely beautiful, and on that account indispensable. Species and varieties are numerous, and every one that I have flowered has possessed good qualities

that has rendered it desirable to grow. A fairly good collection therefore affords very much pleasure.

Like the beauty of Poppies, that of Tulips is erroneously thought to be evanescent. In our northern climate, at least, the flowers are quite as lasting as those of Daffodils or Irises; and filling, as they do, the void betwixt all but the late kinds of the former, and the earliest of the summer flowering Irises, they have among garden bulbs a distinct position of their own. Moreover, where the early single and double Tulips are forced, as well as grown out of doors, their season extends to quite six months. I began last November with Duc Van Thols, and it will be nearly, if not quite, the end of June before the latest will be past. Out of doors last year, for instance, the season extended to four months; this year it will be shorter, as spring was quite three weeks later in coming.

The cultivation of Tulips presents no difficulties. A friend of mine grew them for years most successfully on a clay of so strong a nature that the garden walls were constructed of bricks manufactured out of the garden soil. *Tulipa sylvestris* grows wild here and flowers annually, growing in a wet clay. Going to the other extreme, I have another friend whose garden is a bit of rock hidden by a thin layer of soil, and here also Tulips succeed. In our own case the soil is light, some of it gravelly, but provided sufficient manurial aids are given they grow, flower, and increase. Parrot Tulips, for instance, during the many years I have grown them, have not once failed to bloom. The bulbs, however, must not be allowed to remain for too many years without being divided and transplanted. The ideal method no doubt would be to lift and replant every year, but it is impossible with other work pressing to do this, and a triennial overhaul will meet their requirements. The bulbs may be lifted either when the foliage dies down or in the autumn. Unlike Daffodils they do not root when left in the ground, and early lifting is in consequence of less importance. Though I have planted them later I consider the first or second week in November as the latest limit for planting. The uncertainty of the weather at that season and the condition of the soil each point to the wisdom of not delaying planting longer than the time named.

Though Tulips are gorgeously beautiful as garden flowers, I cultivate them primarily for cutting. In order to secure a long season and also to find space for a large number, I have them planted between lines of Gooseberry bushes, underneath the branches of Apple trees, on north borders, and some in special beds. The value of the flowers for decorating apartments is great, while when cut no flower travels better. It is necessary, however, to select for this purpose unexpanded blooms. If a number is required for any special purpose, the flowers, if cut young, keep in the same condition for a week at least if laid out on paper in a cool room and kept moist. A sheet of paper laid over them obviates the necessity of applying water oftener than once in three or four days. The merit of this method consists in the buds remaining at exactly the same stage as when cut, whereas those placed with the ends of the stalks in water expand, though very slowly. When packing to send a distance the flowers are first tied in bunches, then each bunch is wrapped round tightly in a sheet of thin paper, and the whole laid closely together in shallow boxes or hampers.

Some Tulips, though very pretty, are so dwarf that they are of no value as cut flowers. Of these one of the brightest is the narrow-leaved *linifolia*. The earliest to flower are *elegans* and *retroflexa*, the latter soft yellow in colour, and each of the segments curving backwards in the most charming manner. The other is bright crimson, with the flowers of much the same shape, but perhaps less graceful. A week or so later a number of sorts expand, and among them is *elegans alba*, a very pretty flower; *albiflora*, cream coloured; *vitellina*, a species with flowers of a sulphur shade mixed with green. Following these is *amoena*, a most charmingly coloured kind, whitish yellow flamed with carmine; *fulgens*, intensely bright flowers on very tall stalks; *Golden Eagle*, bright yellow and carmine; *Picotée*, white with rosy edgings, and much like *elegans alba*.

The Parrot Tulips, with their quaintly scalloped petals, curiously marked with many shades of green, red, and yellow, also flower with these, also the earlier of the breeder section and the show varieties. For cutting selections of the latter can be purchased very cheaply. Those called by the Dutch *rose bybloemens* are, I think, the prettiest of all. The ground colour in these is white, and the markings of all shades from rose to carmine. The breeders again are of much value, and are to be had in different hues. Among the latest to bloom there is none brighter or more useful than the old *Gesneriana*. This increases so rapidly that the bulbs require to be lifted and divided every second year. *Golden Crown* is a very good yellow form; but the finest, as also the latest yellow, is *Bouton d'Or*. The colour is deep and bright, and altogether few kinds are equal to this. *Rosacea alba*, *billietina*,

and *virginalis* are species which are late flowering, and also well worth growing.—R. P. BROTHERSTON.

[Mr. Baylor Hartland has sent us a box of Tulips, which admirably confirm the remarks of our correspondent respecting the decorative value of these flowers. Some of the varieties named by Mr. Brotherston are included, with one or two others which we fail to identify.]

ORCHIDS AT SUNNINGDALE PARK.

ABOUT two years ago an opportunity was afforded of an inspection of this collection, and it proved so good and full of promise that it was recently revisited. The collection then showed excellent and discriminating choice of sorts, and also the presence of a master hand in Orchid culture. To-day, while it is still in its infancy, it comprises some rare plants, not alone as regards the number in commerce, but also from the point of view of excellent cultivation. For the improvements in the Sunningdale Orchids credit must be accorded to Major and Mrs. J. Joicey, their son, Mr. J. Joicey, and also to the gardener, Mr. F. J. Thorne, who looks after them with such indefatigable and praiseworthy zeal.

Numerically this collection can never attain to the standard of the Burford and The Dell collections as the accommodation is too limited, but this is not of particular consequence so long as the improvement in quality that has gone on during the past two years is maintained, as it must do while such an amount of interest is concentrated on it. Orchids alone cannot command the whole of Mr. Thorne's attention and time, as it is incumbent on him to provide everything pertaining to the garden, but reference in this column can only be made to the Orchids, so the remainder has been relegated to a future issue. To particularise all the species and varieties would obviously be an impossibility, therefore a few only will be named as possessing some peculiar merit, either of colour, rarity, or cultivation.

We will accompany Mr. Thorne in a hurried peregrination through the houses, and see what there is to be seen, and it is apparent from the confident manner in which he pilots you that he knows he has something worth showing. A plant of *Odontoglossum* or *Miltonia vexillarium* in an 8-inch pot first attracts attention, but it is not until it is placed on the floor that its full merit is recognised. It is then seen to carry an enormous number of spikes, and counting reveals thirty-nine, each averaging seven blooms on a spike. What a picture it presents with its healthy growths and bright rose-hued flowers. Words could scarcely convey

FIG. 70.—ODONTOGLOSSUM CERVANTESI DECORUM.

the full beauty and the appreciation felt on beholding it, so grand, so magnificent; indeed, it is perfection, than which more cannot be said. There are numerous other plants of the same sort, not perhaps so large, but all in splendid health and carrying fine spikes of perfectly formed flowers. These alone are worth a long journey to see, and it is probable that one would have to travel a very long way before one could meet with such examples.

*Dendrobium atro-violaceum* is rarely seen in such superb condition, and the Orchid Committee of the Royal Horticultural Society did rightly in according to the Sunningdale plant a cultural commendation when it was staged at the Drill Hall a few weeks ago. The specimen is now, and has been for the past nine weeks, carrying three spikes of blooms, each admirably formed and beautifully coloured. The richness and form of the lip are perhaps the best features, though the size and evident health of the plant are matters of surprise to many growers who have cultivated it with scant success. The writer delicately hinted that this plant with the one particularly referred to in the preceding paragraph would be acceptable to him if Mr. Thorne had done with them, but received a look of astonishment at the presumption. And the plants—well, they stayed where they were.

One of the best features here are the *Cypripediums*, of which there are numerous varieties of a very high order of merit. Amongst these Mr. Thorne has made some very interesting crosses, and it is hoped that the results will be sufficiently good to repay

FIG. 71.—CYPRIPEDIUM GODEFROYÆ (?) LEUCOCHILUM. (See p. 433.)

him for his time and labour. *Niveum* is represented by superb form, while *Exul* in better character is seldom seen. Remarkably handsome is a very dark *barbatum*, as also are a number of varieties of *villosum*; *superiliare* is perfectly at home, and *caudatum* has petals fully 30 inches in length. This is a grand flower, well worthy all the care and attention bestowed on it. Though these do not by any means represent all the *Cypripediums* grown, they must, with the bold and striking *Elliottianum*, suffice to permit of reference to other sections.

As we make progress in our inspection we come to the *Odontoglossums*, and amongst them find very many to admire. One plant from a cross between *Pescatorei* and *crispum* is now carrying two spikes, one of ten and the other of six blooms, each chastely beautiful in colouration and of splendid form. Equally noticeable are plants of *luteo-purpureum*, *maculatum*, *cordatum*, and numerous others, all in the best of health and condition. Particular mention amongst so many handsome sorts may still be made of a superb form of *Cervantesi decorum* (fig. 70), which was perfectly formed and marked. There are some hundreds of *Odontoglossums* of various species and varieties, all in the best possible state of health.

*Oncidium*s, too, are a grand sight, the immense spikes of brightly hued flowers denoting health and strength. Perhaps the best of all was *ampliatum*; though numerous, others were very fine. *Cattleyas* are not at present carrying many flowers, but the stock is composed of some of the best sorts extant. A grand variety of *Skinneri* attracted attention, as also did a superb plant of *Cymbidium Lowi*, while a very pale form of *Vanda teres* elicited much admiration. The upper sepal is very pale rosy white, the lower sepals almost pure white, and petals blush.

It would not be doing justice if these notes concluded without a reference to the Dendrobiums, which are largely grown for floral decorations. In fact all the Orchids are more or less pressed into this service, and are very highly appreciated. A very beautiful flower is that of *D. chrysotoxum*, and the same may well be said of *D. c. suavissimum*. Equally as attractive, though not perhaps so showy, is *D. Pierardi latifolia*, which is now wreathed in its delicately tinted blooms. These are but three out of many, but they must suffice, at any rate for the present.

Before leaving the Orchid houses, of which some are new and more will soon have to be erected if the collection, as it is hoped it will, continues to grow at the present rate, we remarked on the extreme cleanliness and tidiness that prevailed, and which certainly materially improved the general effect. The plants are as clean as the structures, no evidence of insect pests being readily perceptible. This freedom from such enemies must, to a certain extent, account for the great substance of the growth and the leathery texture of the leaves, for these could not come from plants that had their energies sapped in any way.

Master of the cultivation of Orchids is Mr. Thorne, and it is apparent that he is thoroughly engrossed both in their growth and their improvement. Some day it is hoped another chance will arise of a visit, and when it does it will be seized, as affording pleasure and instruction at one and the same time.—W.

#### SALE OF THE HOLLY LODGE ORCHIDS.

THIS fine collection of Orchids, brought together by Mr. W. Bown, Birmingham, was disposed of on the 8th and 9th inst. by Messrs. Protheroe & Morris. Comparatively low prices were the result. Mr. J. Earle, a new amateur grower, was the principal purchaser, whilst a smaller complement of the choicer varieties were secured by Mr. W. B. Latham for the Botanical Gardens, Edgbaston. Messrs. Cypher of Cheltenham purchased a grand specimen of *Cymbidium eburneum*, which last year produced thirty-five spikes of blossom.

The major portion of the collection went Londonwards, including a huge specimen of *Cattleya Mossiæ* with over 500 bulbs. Among other large specimens sold, mention may be made of particularly a grand plant *Epidendrum prismatocarpum* with 150 bulbs and growths. Excellent health appeared to prevail over the collection generally, and reflecting much credit on Mr. J. Palmer, the accomplished and painstaking gardener.

#### JUDGING AT SHOWS.

A CORRESPONDENT, who seems grieved because he was disqualified at a show last year, says he is "getting out of patience" in waiting for the report of the Judging Committee. He seems to have a grievance against certain Judges both in hardy flower and fruit classes, and he "wants something settling about Tomatoes." The Judges may or may not have been in fault, all depending on the terms of the schedule and their interpretation. Our friend will have to wait a little longer for the report he covets, and in the meantime may ponder over an extract we take from the "Journal of the Royal Horticultural Society."

"After turning this question [of judging] over and over in my mind," says Mr. James Douglas, "I found it to be one of the most difficult subjects I ever attempted. It has been my lot several times to judge an entire exhibition single-handed, and I have managed to get through it in good time for the admission of the public. This, the practical side of the question, is one thing; explaining to others how to go and do likewise is another; but, having been successful as a practical man, I will do my best to put on paper something of the 'Principles of Judging,' in order to afford at least a theme for discussion.

"The first point to consider is the framing of the schedule. This should be done with great care, as it must be the guide both of exhibitors and judges. Under the heading of 'Rules and Regulations' every point ought to be so definite and exact that no mistake may be excusable and no difference of interpretation possible. Moreover, the schedule must always be interpreted by what it grammatically says, and not according to the preconceived ideas, either of exhibitors or judges, of what it ought to say or mean.

"The four words, 'species,' 'kind,' 'sort,' 'variety,' are often used quite indiscriminately, sometimes even being interchanged one with another in the same schedule without any regard whatever to any difference of meaning. For instance, in the case of hardy herbaceous plants, the word 'variety' has been used when 'species' was intended. If either of the words 'varieties' or 'sorts' are used, an exhibitor would be within his rights if he staged only two or three 'species' or 'kinds' of plants in a collection of, say, twenty-four varieties. He might exhibit half a dozen varieties of Delphiniums and as many Phloxes, but if the word 'species' or 'kind' is used he may not exhibit more than one variety of each.

"Another question that may be asked, and not unfrequently is asked by judges, is, What is a fruit? and what a vegetable? The only possible way, I think, to decide this question, with due respect to grammar, truth, and equity, is to lay down and assert a principle, and say that fruits used in a green state, and as vegetables only, may only be shown as vegetables; but if a ripe fruit of any kind is used both as a vegetable and as a fruit it may be shown in either category. The only fruit that I know of at present which may be shown both as a fruit and as a vegetable is the Tomato, which truth forbids us to exclude from fruits and general use claims as a vegetable.

"In this place it may be well to remark on the folly of judging fruit by appearance only; it is about equal to the folly of judging flowers by their scent only. Appearance is a great point with fruit, so is scent with flowers, but neither is the chief point. The chief point with fruit is flavour, with flowers beauty. A blind man may have the sense of smell very acutely, but no one would trust him to judge flowers; and yet men judge fruit by sight only! I do not say that it is always necessary to taste a fruit in order to judge of it correctly. The great majority of fruits a good judge has no need to taste; he has sufficient knowledge of the quality and flavour of the fruit from the variety; but an unknown variety, however good looking it may be, should never go untasted.

"Of all evils, that of judging either flowers, fruits, or vegetables by size only is the worst. Size should in many cases be considered an actual demerit when the objects exceed certain standards well known to all good judges. Overgrown Potatoes, Cauliflowers, and Cucumbers are always left out in a close competition, and in every case quality should come first. The same remark holds good with fruit. Not the largest bunches or berries of Grapes, but first flavour and then colour should be given the highest points. A big Melon counts for nothing when compared with a medium sized one of superior flavour. The same with Pears and Apples. The Winter Nelis or Seckle amongst Pears would win against some varieties four times their weight and far more beautiful in appearance. So also would Cox's Orange or Ribston amongst Apples maintain the foremost place, on account of their superior quality, against the size and beauty of Blenheim Orange or Peasgood's Nonesuch. Even in flowers size can at the best hold only a third place. Paul Néron amongst Roses would never win in the class for Roses of any one variety; it is large enough, but lacks form and substance of petal. Size in a Carnation is, I know, by some considered the principal point, but no good judge would put size first unless it was accompanied by substance of petal and good form. Men are beginning to learn that even Chrysanthemums may be too large, and there are not wanting signs that in the not distant future mere size will not receive quite so much prominence as heretofore.

"No man can judge fruits, flowers, or vegetables aright unless he has a good knowledge of the different varieties. It is much easier to obtain good specimens of some varieties than it is of others, and the man who sets himself up as a judge should know how much skill has been required to obtain the productions placed before him, and good specimens of a difficult subject should certainly, in my opinion, receive an extra point to only equally good specimens of a subject that presents no difficulties of cultivation."

#### MODERN GRAPE GROWING.

(Continued from page 379.)

##### PLANTING THE VINES.

MANY things have to be known and thought over before one can advise as to the planting of Vines. Are the Vines to be of the first importance, and will everything else that may be grown in the house or in the border be secondary? Is the fruit wanted of first-class quality, or will a large quantity of fairly good fruit satisfy? Is it desirable to have the fruit as soon after planting as possible, or is it, what is most common nowadays, a mercantile speculation, and the object to get as quick a return as possible for the outlay? There are so many ways and seasons for planting Vines, each of which perhaps has its merits under special circumstances, that it will be necessary to allude to most of them.

If Vines alone are to be grown, there will be little or no return the first year, but where a large sized house is in existence it is a general practice to grow something else during the first, if not, the second year. I know many people have an idea that you can grow a miscellaneous collection of things continually besides the Vines, and do them all well. I have sometimes seen a marvellous collection of plants in a small house, and have been surprised at the results achieved, but it is very seldom indeed that you will see any one thing done in this way up to the highest standard, and very often the poor Vines get the worst of it.

There can be no objection to merely housing a variety of plants in a vinery during the winter that require a temperature not higher than 45° to 50°, but any attempt at keeping the house going with flowers, or storing tender stove plants, is sure to end in disaster to the Vines. I was once called to give an opinion as to the ailments of some Vines which were thought to be infested with phylloxera. It was early in the spring, after a very hard winter, and the Vines had made long weak growths, with here and there on some of the rods a little bunch of Grapes, or rather what looked like a hybrid between a bunch and a tendril, and some of the canes had none at all. The foliage was thin in texture and pale in colour, and when the sun shone it went down like a tame rabbit's ears.

It was plain at first sight that whether there was phylloxera or not there was enough to account for the disaster without it. The house was full of plants in flower, including Pelargoniums, Bouvardias, and Euphorbias. I asked where the roots were supposed to be. The answer was, "Outside and inside."

On digging down outside we found a few, but very few, healthy roots of the previous summer's growth, but of course there was no sign of new growth. How could there be when the soil was very little above the freezing point? It was as I had imagined, there was no disease and no insects, the house had been kept warm all through the autumn and winter for the sake of producing cut flowers and flowering plants to furnish a conservatory, and the Vines being inside had of course started early into leaf, had exhausted their stored up supply of material, and there was nothing more forthcoming till such time as the summer sun should have warmed the soil of the outside border. The roots supposed to be in the inside borders of such houses are generally non-existent. Now, there were four vineries in the establishment, and the Vines at one time, judging by the size of their stems, had evidently done fairly well, but the times and the people had changed, and now two of the houses which contained the oldest Vines were ruined, and the others, if the same system is persevered in, will soon follow. The most surprising thing was that everything excepting the Vines bore the stamp of good cultivation, while the Vines themselves were disgraceful.

The lady of the establishment frankly owned, when the cause of failure was pointed out, that it was her own fault, and promised to give up at least one house, where the Vines should have the first care. But how many ladies and gentlemen are there who are not so reasonable, but who rather attribute failure to their gardener's incompetence, when they have been brought on by their own acts? Sometimes you may see a thing done well in a place by a man who has just one particular hobby, but if you see two or three totally different things done well, you may be sure that the man is capable of doing most things well if he only has the chance.

In older times it used to be the practice to draw the Vines outside the house and bind them securely with haybands during the winter, taking them inside again some time in March, and this old plan has much to recommend it where the house has to be used for tender plants in the winter.

The Vine will stand much bad treatment, but there are some things that it will rebel against. A gentleman said to me this spring, "I wish you would tell me what is wrong with my Vines; they had done fairly well till last year, and then the Grapes were so bad that I was glad to give them away to the school children to get them out of my sight." I asked particulars about the border. It was outside the house, sloped sharply to the south, was about 4 feet wide, with a gravel walk in front, and "my gardener" always grows his early Lettuces on this border. I concluded that as the roots had been chopped off continually in the so-called Vine border they had taken refuge in the gravel walk, and during the hot dry summer of 1893 had been starved, and showed the effects of it in the following year.

I recommended taking off as much of the hard surface of the walk as could be done without much injury to the roots, top-dressing it with some good loam, crushed bones, and bonedust, and grow the early Lettuces elsewhere, or buy a pennyworth as wanted from one of the numerous shops close by. Imagine spoiling a house of Grapes, and perhaps also the Vines, for the sake of two or three dozen Lettuces, yet I believe such practice is not very uncommon, and then the proprietor exclaims, "I cannot think how it is my Grapes have done so badly!"

—WM. TAYLOR.

(To be continued.)

### PRESENT FLOWERING PLANTS.

WHERE a good collection of perennials are cultivated the borders and rockery may be made to look gay during April and May. The advantage of this class of plant over that of the ordinary biennial is a very distinct one following such a severe winter, when so much destruction has been dealt to Wallflowers and other plants. No part of the garden is more interesting than this, where so much variety of form and colour are obtainable. I give the names of some of the plants which are highly effective during the period named.

The Anemone family is an extensive one, comprising many showy and useful kinds. A mass of the deep blue appenina, the paler coloured blanda, the rich orange-yellow of ranunculoides, the pure white nemorosa flore-pleno, and the somewhat strangely formed and quaintly coloured pulsatilla, form an interesting and varied group. All are dwarf, suitable for the rockery or the front of the herbaceous border, easily grown, and rapidly increased.

Epimediums are not cultivated nearly so much as their merits deserve. Not only are their flowers interesting, but the foliage is extremely useful for cutting. The first to open is the pure white niveum, followed by the pale yellow lutea and Mariesi, all dwarf sorts, with richly coloured leaves. No more showy plant could be imagined at this season of the year than *Doronicum austriacum*, with its profusion of old gold coloured blossoms. The Bitter Vetch, *Orobus vernus*, is seldom seen in an ordinary private garden. Its purple and blue blossoms heavily veined with red are produced in showy masses. *Adonis vernalis* is not often seen growing in luxuriance; it dislikes a wet position and stagnation about the roots. Between two stones on the rockery it seems to find its requirements. In such a position it flowers freely every year.

*Corydalis nobilis* is the best of the Fumitories, and is well worthy a place in any garden. The pale yellow, green tipped blossoms are showy. *Dicentra eximia* is capital for the front of the herbaceous border, where it blossoms freely for several months. Its reddish purple drooping flowers are borne on thick fleshy stalks. *Ranunculus amplexicaulis*, with its heads of large pure white flowers, is attractive, and deserving of attention in all gardens. Globe-flowers are numerous now in shades of colour. One of the best is *Trollius Ledebouri*, rich orange yellow, not quite so deep perhaps as *asiaticus*, but larger individually. *T. Gibsoni* is deeper than *asiaticus*, and therefore deserving of extended culture. *T. napellifolius* is a large form of *T. europæus*, but a shade paler in colour perhaps.

*Polemonium Richardsoni* is of compact growth, and profusely covered with fine clusters of pale blue flowers. Of Irises we have *pumila*, growing barely 6 inches high, having rich purple flowers. Of Aubrietias *Leitchlini*, dark crimson, and *Hendersoni*, dark purple, are smothered with bloom—beautiful objects for rockery or elsewhere.

*Potentilla salisburyense* is a pretty plant, growing but 4 inches high, and bearing rich yellow single flowers. *Auricula Golden Gem* must not be passed lightly over. For the herbaceous border its golden yellow flowers are borne in profusion. Flowering now as freely as can be seen is a splendid proof of its hardiness and suitability to the purpose named.

—E. MOLYNEUX.

### EXPRESS GRAPE GROWING.

LAST week's Journal contained an interesting and instructive letter from the pen of Mr. John Thomson, which confirms much we should naturally have expected from the son of so eminent a gardener as his late father. I have seen many fine samples of the Clovenfords Grapes, and I am pleased to hear that these famous Vines are still in such a satisfactory condition.

Mr. Thomson states that their Vines planted in May, June, and July did so well, and ripened their wood so thoroughly, that all of them could have borne heavy crops of Grapes the next season. This I readily believe: the temporary Vines did bear a heavy crop, and finished the fruit splendidly. The only difference in Mr. Thomson's case and mine was that he did not fruit his permanent Vines, and I did, and was rewarded with a crop of first-class Grapes.

I referred in my letter of last week to a house of splendid young Vines I saw at Gordon Castle in the autumn of 1877. I have received a communication from Mr. Charles Webster, the present gardener, who was appointed successor to his late much-respected father, and in which he makes the following statement, viz., "The vinery you refer to I remember well assisting to plant; but having left for Dalkeith the following spring I could not say how many bunches each Vine carried, though I know they were fruited and the crops finished well." After giving details of the planting, Mr. Webster concludes by stating, "I quite agree with you that young Vines can be cropped the first season after planting with no bad effects to their future welfare, as I have myself recently proved."

It would be interesting to know how many of your correspondents have tried the experiment. As an ounce of practice is worth a pound of theory, I am afraid we often get a good deal of theory without much practice; let them go hand in hand, and then we shall make progress. We are apt to run in the rut for no better a reason than that our fathers and grandfathers did so before us. What has become of the bottom heat theory in Vine borders, which was the right and proper thing twenty-five or thirty years ago?

I am inclined to believe that we have even yet much to learn in Vine culture. I can see many changes taking place in both private and market gardens, and more especially in the latter. I notice that old Vines are being discarded and replaced by young ones, that the large and expensive borders are being dispensed with and replaced by small and inexpensive ones, which can be cleared out and replaced in a very short space of time without losing a season or crop.

I think everything must be done on the express system in these days, although I cannot lay claim to the above title, as I have put forward nothing particularly new. I have endeavoured to state a few plain facts as briefly and intelligently as I can, with the hope that it may encourage others, who still cling to the old theory, that they may with safety try the newer system, which must be coupled with judgment and discretion in the cropping and general management of their Vines.

—W. INNES, *Derby*.

IN the articles on this subject, which are of great interest to market growers, showing the wonderful crops that Vines well grown can carry, I notice a most significant omission—viz., What did these wonderful crops of Grapes realise per lb.? It is not enough to say that they carried so-and-so and finished well, when opinions differ so much as to what is a good finish in a house of Grapes. The money they fetch in the open market is the all-important point. Perhaps Mr. Innes will say what his averaged per lb. I saw a house of Gros Colman last year which was the heaviest crop I ever saw of any Grapes. It was its second crop borne along about 12 feet of rod, and all the bunches were left on the Vines, many shoots carrying three and four bunches. The house was about 300 feet long, and carried 2700 bunches, which to appearance would average about 1½ lb. each. They never finished, and would make one sick to look at them, half green and red in December, though I was surprised to see even this finish on such a crop. They brought in open market 1s. 1d. per lb., but I do not know if all the crop, or only a part of it, was fit to sell.—MARKET GROWER.

**EVENTS OF THE WEEK.**—The event of the week for horticulturists, not alone of London, but of all the country, is the Temple show, which opens on Tuesday, May 21st, and continues during the two following days. Reference will also be found to it in another paragraph. The Southern show of the Royal National Tulip Society will be held on the first day of the Temple show.

— **THE WEATHER IN LONDON.**—As is noted in another paragraph the weather in the metropolis during the past week has been very hot and summer-like. During Sunday night a shower of rain fell, but did not continue sufficiently long to penetrate into the ground, which is now in many places becoming dry. A heavy fall of rain would now do a great amount of good.

— **WEATHER IN THE NORTH.**—The week following the 7th inst. has been one of fine weather with bright sunshine, tempered occasionally by coldish east wind. On Sunday, which was dull throughout, several gentle showers fell; Monday was extremely bright and warm; Tuesday morning dull with cold wind from the west.—B. D., *S. Perthshire*.

— **THE TEMPLE SHOW.**—We are requested to announce that the Fruit, Floral, and Orchid Committees will meet at the Temple Gardens on Tuesday, May 21st, and that certificates and awards will be granted as usual for meritorious exhibits; but we are further requested to state that "such awards cannot under any circumstances be issued from the Secretary's tent until Wednesday, May 22nd."

— **WELLINGBOROUGH HORTICULTURAL FÊTE.**—On Friday, July 25th, this fête will be held, and in the section for plants, flowers, and fruits several excellent prizes are offered. Prizes of £10, £6, and £3 are offered for twelve stove and greenhouse plants, distinct, and the competition should be strong. In the fruit section £2 are offered as a first prize for six varieties of fruits. These classes are open to all, but there are several open only to gardeners, others to amateurs, and others again to cottagers. The Hon. Secs. are Messrs. C. J. K. Woolston and T. Pendered, Wellingborough, from whom information may be had.

— **FRUIT PROSPECTS IN SCOTLAND.**—So far as my observation extends there is every prospect of an abundant fruit crop in Scotland this year. In the gardens of Logan House there is an imposing wealth of bloom. In my own garden, which has the advantage of great shelter, the Apple, Plum, Cherry, and Pear trees are white with blossoms. (I use this expression because white predominates, though pink in many instances equally prevails.) A Czar Plum in the centre of the garden, and a Morello Cherry on the west wall, are veritable pictures. There is nothing in Nature more beautiful than such trees in perfect bloom. The season is also balmy and benignant, and highly favourable for the development of the flowers into the fruit.—DAVID R. WILLIAMSON.

— **ROYAL BOTANIC SOCIETY.**—The first of the annual series of botanical lectures was given recently, Mr. G. W. Bell presiding. Taking as her subject "Fruits and Seeds: Their Structure, Means of Protection, and Dispersion," the lecturer, Miss Styan, treated in a popular manner the methods adopted to protect and disseminate fruits and seeds. While some were supplied with sails to move through the air, others had hooks and anchors or a screwing apparatus by which they were able to bury themselves underground, out of sight, many of these contrivances showing such remarkable ingenuity that, as the lecturer suggested, it was difficult to come to any other conclusion than that plants were able to think. In this country we had several examples of hooked fruits among our native plants, but the Cleavers and Burdocks of our hedgerows were not formidable like the fruits of the South African Grapple plant, which have been known to destroy even the lion itself. The fruits, some 4 or 5 inches in diameter, are covered with sharp, claw-like appendages; while endeavouring to remove these from the skin the animal gets them fixed in its mouth, and being unable to take food dies of starvation. These lectures are fixed for the Fridays in May and June, and are free to all visitors to the gardens.

— **THE ROYAL GARDENERS' ORPHAN FUND.**—Friends of this excellent charity, which is deserving of all possible support, will be pleased to hear that the late Mr. George Taber bequeathed to it £100 in the form of four £25 shares in the well-known seed business of Messrs. Cooper, Taber & Co. of Southwark Street. We also learn that Mr. Sherwood has undertaken to subscribe the requisite amount annually for the support of one of the children who failed to be elected as a beneficiary of the Fund at the last annual meeting.

— **HYACINTHS AND SEDUM.**—For producing a pleasing effect Sedum glaucum makes an excellent carpet for growing Hyacinths. The glaucous tint of the Sedum is especially fitting to the various colours of the Hyacinths above. It does not appear to matter whether the Hyacinths are growing in a mass of one colour only in a bed or whether the colours are mixed, the effect appears to be the same—satisfactory. A thick carpeting of Sedum is much more pleasant to look on than the naked soil. Besides, with the Sedum there is no danger of low-growing Hyacinths becoming splashed with soil from heavy rains.—E. M.

— **FLOWERS ON MRS. SMEE'S GRAVE.**—Mr. G. W. Cummins has shown us some beautiful photographs of wreaths and other floral emblems taken in the churchyard at Beddington. The display was remarkably profuse, and the flowers of a choice nature. An arching spike of *Cymbidium Lowianum* deserves special notice. It was cut and placed in Mrs. Smee's room a fortnight before she died; it was then exposed on the grave night and day under bright sun and chilly nights for a fortnight, the stem not in water, but made to form an arch over a handsome wreath. It was then taken in and placed in water, and is still fresh—a remarkable instance of floral persistency.

— **THE WEATHER LAST MONTH.**—April was bright with scarcely any frost, and a drier month than usual. The wind was in a northerly direction fourteen days, and in a southerly direction fourteen days. The total rainfall was 1.68 inch, which fell on sixteen days, the greatest daily fall being 0.41 inch on the 25th. Barometer—highest reading, 30.194 at 9 A.M. on 12th; lowest, 29.018 at 9 P.M. on 6th. Thermometer—highest in the shade, 64° on 21st, 24th, 29th, and 30th; lowest, 27° on the 13th. Mean of daily maxima, 55.30°; mean of daily minima, 38.33°. Mean temperature of the month, 46.81°. Lowest on the grass, 21° on the 13th; highest in the sun, 144° on the 24th. Mean temperature of the earth at 3 feet in depth, 43.56°. Total sunshine, 159 hours 35 minutes. There was one sunless day.—W. H. DIVERS, *Belvoir Castle Gardens, Grantham*.

— **DEATH OF MR. WALKER OF THAME.**—By the death of this well known horticulturist the gardening world has lost, not only one of its most prominent members, but one of that band of quiet workers who, without blowing their own trumpets, have tended so much to advance the interests of horticulture. Mr. Walker was one of those who devoted himself to florists' flowers, and at the metropolitan exhibitions his collections of Tulips, Dahlias, and Roses showed with what intelligence and skill he carried out their culture; but I believe that he will be best remembered by the magnificent boxes of *Maréchal Niel* which he exhibited at the metropolitan spring shows, their large size and magnificent colouring always elicited the praise and admiration of all visitors to the shows. Mr. Walker was a man of very quiet and unassuming manners, but his work was recognised by a large circle of acquaintances who will greatly mourn his loss. Mr. Walker died from an attack of apoplexy on the 8th inst. He was sixty-four years of age.—D., *Deal*.

— **DEVON AND EXETER GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.**—The Committee has fixed the fourth Wednesday in July (24th) as the date of the summer outing for the year, and by permission of the Right Hon. Lord Poltimore, Sir W. H. Walrond, Bart., M.P., and Sir J. H. Amory, Bart., the members will be enabled to visit Poltimore Park, Bradfield, and Knightshayes, all of which places are noted for the horticultural interest they possess. The following is the programme as arranged:—To meet at Bedford Circus at eight o'clock, and proceed in four-horse brakes, *via* Whipton and Pinhoe, to Poltimore. Passing through the gardens and pleasure grounds, the party will rejoin the brakes and proceed to Bradfield. After a halt of about two hours or so there, inspecting the gardens and grounds, the journey will be resumed for Knightshayes. After a short stay at Knightshayes, Mr. Moyle's, Angel Hotel, Tiverton, will be reached, where a substantial tea will be provided at five o'clock. The return journey will be made from Tiverton for Exeter direct, *via* Exe Valley, leaving the Angel at seven o'clock.

— WE learn that the presentation of the Veitch medals will be made at the meeting of the Royal Horticultural Society on Tuesday, June 11th, at 3 P.M., by the President, Sir Trevor Lawrence, Bart.

— THE Directors of the New York Institution for the Instruction of the Deaf and Dumb have in contemplation the education of the inmates in horticulture: The experiment will be watched with great interest.

— VIOLA AND PANSY CONFERENCE.—We understand that, as previously suggested, a Conference of Viola and Pansy growers will be held on the 29th inst., in connection with the show of these flowers to be held in the Botanical Gardens, Edgbaston, Birmingham, on that date.

— FLORAL NOMENCLATURE.—The practice of naming flowers after eminent public characters occasionally leads to the display of a certain amount of unconscious humour. Thus in an illustrated manual for the garden and farm, published by a firm of seed merchants in Adelaide, South Australia, under the heading of *Chrysanthemums* was the following:—"W. E. Gladstone, a showy and effective variety, crimson and violet, brilliant but erratic."

— FRUIT PROSPECTS IN MONMOUTH.—In this district prospects of a heavy crop of fruit are very promising. Apples, Plums, and in fact fruit trees of all kinds are laden with blossom, and the heavily bloomed orchards give the country a pleasing appearance. Pear trees have all been full of flower, which, however, fell earlier than is usual. With bush fruits and Strawberries it is the same, and if no check follows an abundant supply is expected to be the result.—J. H.

— CEYLON TEA AND COFFEE.—The exports of these products in 1893 show a marked increase in the output from that flourishing colony over the preceding year. The Governor's report for 1893 is most interesting, and shows that the "Paddy tax," a direct tax on the food of the people, was removed that year; public works were instituted and largely carried out, and trade increased generally. Of Coffee 55,423 cwts. were exported in 1893, as against 43,338 cwts. in the previous year; while 82,269,353 lbs. of Tea were exported in 1893, as against 72,279,985 lbs. in 1892.

— THE WEATHER AND THE CROPS IN GUERNSEY. — Since reporting to you last we have had a fortnight of very brilliant weather, which has brought on produce of every kind, indoors and out, at an amazing pace, so that we are (much sooner than was expected) within measurable distance of the full Tomato season. Already a fair number of small parcels are being shipped, and every day henceforward will see a substantial increase in these. So far fair prices have been realised for these in England. French Beans and early Peas have also done fairly well, but the second sowing of Radishes came in too late to realise anything like a paying return. Flowers also to some extent are becoming too numerous to pay the senders, excepting it is something of a special nature. Potato digging (in the more sheltered situations) will commence as soon as this month is out. Very few forest trees, excepting the Horse Chestnuts, are yet in leaf. There is plenty of grass in the meadows and pastures; corn also, what little there is grown, is looking very well. Fruit prospects are fairly good.—X.

— INSECTS ON FRUIT TREES.—These form the subject of a leaflet issued by the Board of Agriculture. Apple, Plum, and Damson trees, it is reported, are being specially attacked by caterpillars of several species of moths, chiefly the winter moth. The latter at first are greyish, with black heads, and so small as to escape notice unless attention is specially directed to them; in their later stages the caterpillars are green, or yellowish green, with whitish stripes and brown heads, and nearly three-quarters of an inch long. Syringing the trees with certain mixtures are recommended, particularly in respect of Plum, Damson, and small Apple trees, and fruit bushes. Fruit growers may be interested to know that the mixtures specified by the Board of Agriculture are as follows:—1, The extract of 7 lbs. of quassia, obtained by boiling quassia in water, to 100 gallons of water with 5 lbs. of softsoap. 2, The extract of 5 lbs. of quassia to 100 gallons of water, with 5 lbs. of softsoap and 5 pints of petroleum, well stirred. 3, The extract of 4 lbs. of quassia to 100 gallons of water, with 4 lbs. of softsoap and 4 pints of Calvert's carbolic acid, No. 5. 4, Six lbs. of softsoap and 2 lbs. of finely ground hellebore, and a quart of petroleum, boiled and well stirred together. This is sufficient for 100 gallons of water. Those who desire to have fuller particulars can obtain copies of the leaflet free of charge and post free on application to the Secretary, Board of Agriculture, 4, Whitehall Place, London, S.W.

— THE PASQUE ANEMONE.—I see Mr. Arnott has pointed out a singular typographical error in my article, about which I was about to write you. The "black grub," asked about on same page (403), I presume is the larva of some moth, probably a noctua.—J. R. S. CLIFFORD.

— FRUIT PROSPECTS IN FRANCE.—The orchards in the districts round Paris now present a mass of bloom such as has seldom been witnessed. Pear, Cherry, and Apple trees are alike loaded with blossom. The season is unusually late, but there is every prospect of a splendid crop providing the weather continues favourable.

— ASPARAGUS IN THE VALE OF EVESHAM.—The past few days of hot weather has caused the Asparagus grown in the Vale of Evesham to come on at an enormous rate. It is hardly possible to keep it cut before becoming run. The increase has caused prices to fall low. On Thursday last, 9th inst., 8s. per bundle (120 heads) was the average price realised in the local auction market. It is computed that 300 more acres have come in for cutting this year in this neighbourhood.—ALFRED G. GROVE.

— A GOOD WINTER LETTUCE.—I send for your inspection a sample of Sutton's Winter White Cos Lettuce, which has been grown out of doors without the slightest protection. I had about 300 plants pricked in a small border during the latter part of September, and they have nearly all stood the very severe winter. I am now able to cut splendid Lettuces, like the one enclosed.—SYDNEY J. CHALK. [It is very fine indeed, resembling an excellent specimen of the Paris Cos.]

— FLOORS CASTLE. — I think your Belgian correspondent (page 403) has somewhat misapprehended the meaning of the incidental passage in my article on Floors Castle, its gardens and romantic environments, to which he refers. I did not say anything intended to indicate that its modern name of Floors signified "flowers." It was the ancient title of the castle (Fleurs) which I interpreted thus, as he will find by referring again to my contribution. The older, and as I think more beautiful, name appears in the "Gazetteer of Scotland" for 1842, which I have beside me here. I do not doubt, however, that your correspondent's interpretation of the modern name of the Duke of Roxburghe's palatial residence is absolutely correct. I am glad that he appreciated my article.—DAVID R. WILLIAMSON.

— SUMMARY OF APRIL METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS. — Mean temperature of the month, 47.3°. Maximum on the 23rd, 65.4°; minimum on the 13th, 26.7°. Maximum in the sun on the 10th, 121°; minimum on the grass on the 8th, 18°. Mean temperature of the air at 9 A.M., 47.9°. Mean temperature of the soil 1 foot deep, 46.2°. Nights below 32°, in the shade, six; on the grass, fourteen. Sunshine, total duration in the month, 140 hours, or 34 per cent. of the possible duration. We had three sunless days. Total rainfall, 2.18 inches. Rain fell on ten days. Approximate averages for April:—Mean temperature, 45.4°; sunshine, 123 hours; rainfall, 1.65. A fine and mild month, with warm days, but no very hot ones. Rather more rain than usual, but it fell on a small number of days. Vegetation is making fair progress. Fruit blossom of all kinds very abundant, except Apricots, which are thin. Queen wasps are very numerous this year. Alpine and herbaceous plants do not appear to have taken any harm during the last severe winter, as they are growing and blooming very strong and bright.—J. MALLENDER.

— NEW SOUTH WALES FLOWERING PLANTS AND FERNS.—We have received from the publisher, Mr. Chas. Potter, Government Printer, Phillip Street, Sydney, part I. of a work from the pens of Messrs. J. H. Maiden, F.L.S., and W. S. Campbell, F.L.S., entitled, "The Flowering Plants and Ferns of New South Wales." The introduction says, "As far as possible, each part will contain illustrations and descriptions of two forest trees (consequently of economic value), and of two flowering shrubs or smaller plants selected without any utilitarian considerations, but because of the beauty or scientific interest of their flowers or foliage." Such a work, well produced as is the copy before us, should prove of great use to botanists and others all over the world. Part I. contains admirably executed coloured plates of *Telopea speciosissima* (the Waratah), *Eucalyptus corymbosa* (the Bloodwood), *Actinotus Helianthi* (the Flannel Flower), and *Acacia glaucescens* (the Coast Myall). Accompanying each plate are several interesting particulars regarding origin of nomenclature and uses of the plants. The price of the part is 2s. 6d. each to subscribers, or 3s. 6d. to non-subscribers. Particulars may be had from the publisher.

— GARDENING APPOINTMENTS.—Mr. J. King, for the last nine years general foreman at Bryanston Gardens, has been appointed head gardener to H. J. G. Lloyd, Esq., Itchell Manor, Crondall, Hants. Mr. James Dymock, late foreman in The Gardens, Devonhurst, Chiswick, has been appointed head gardener to B. Wentworth Vernon, Esq., Stoke Bruerne Park, Towcester.

— NOXIOUS GASES AND VEGETATION.—We understand that an action brought by Messrs. Pennell & Son against the Lincoln Brick Company for damage to young trees in their nursery at Low Fields, Bracebridge, by the emission of sulphurous fumes from the Company's adjacent works, and which action was postponed from the last Assizes, has been amicably settled, the Company agreeing to pay the sum of £100 to Messrs. Pennell & Son.

— EUCALYPTUS AMGYDALINA.—A Melbourne contemporary states:—"Victoria now claims the glory of holding the biggest of all the living big trees in the world, so far as height is concerned. In the Dandenong district, at Fernshaw, has recently been discovered a specimen of Eucalyptus amygdalina, which reaches the enormous height of 380 feet before throwing out a single branch, and is 430 feet to the top, having a girth of 60 feet at some distance above the ground. Some idea of what a height of 430 feet represents may be gained from the fact that this Gum Tree, if growing by the side of the Houses of Parliament, at Westminster, would overtop the clock tower by exactly 100 feet."

— WAKEFIELD PAXTON SOCIETY.—Ald. Milnes presided, and Mr. J. G. Brown, of Outwood, occupied the vice-chair, at a meeting of this Society, held on the 4th inst. There was an unusually good attendance, and an exceedingly interesting meeting. Mr. T. Pitts, gardener to Mr. D. B. Kendall, J.P., of Thornhill House, Walton, delivered a capital lecture on "Spring Bedding Plants," in which he gave much valuable advice, based on practical experience, with reference to the best varieties of plants for spring bedding. The lecture, which was delivered in a pleasant chatty style, was attentively listened to, and apparently much appreciated, and it provoked one of the longest and best discussions which has taken place at the Society for some time past. Both professional and amateur gardeners took part in the discussion, and put numerous questions to Mr. Pitts, who promptly and fully replied to them. The discussion had reference to the growth of most of the spring favourites, but it drifted mainly to the popular Wallflower, and it appeared that many growers of the sweet and old-fashioned flower had lost large numbers of plants by the strong winds and very severe frost of the past winter. The Auricula, Polyanthus, Primrose, Forget-me-not, and white Arabis were strongly recommended, one speaker saying that nothing looked better in spring than a bed of white Arabis mingled with scarlet Duc Van Thol Tulips. Many other kinds of pretty and sweet flowers, which can be grown at little cost and trouble and without glass, and are most accommodating, were also recommended. A vote of thanks was accorded to Mr. Pitts for his lecture.

— POTATO TRIALS IN SURREY.—Those of our readers who may be interested in Potato trials as object lessons for the people will find a fuller account than can be given here of what is this season being done in Surrey if they will turn to the pages of our contemporary, "Garden-Work." These trials form but other evidence, if such be needed, of the strong sympathy with gardening as a rural vocation that animates the Technical Education Committee of the Surrey County Council. They have, so far, been conducted by Mr. A. Dean, who has planted every tuber of the seventy-three varieties obtained, and in various parts of the county. Altogether some 130 rods of ground have been planted, the earliest planting being at Mitcham on April 19th, when ten rods of land, sandy, clayey, and boggy each, were got in. Later, in the same district, at Brandon Hill, other ten rods on chalk were planted, and in all cases with the same varieties and from the same sources. Other land was planted at Richmond; two plots, one for varieties and one for manure trials; at Chertsey on stiff land; at Milford on sand; at Woking on sandy bog; at Dorking on a chalky marl; and last of all, so late as May 11th, because unavoidably deferred, at Englefield Green on a very sandy soil, yet fairly good and holding. In some cases the land had been dressed with animal manure, in other cases superphosphate, kainit, and nitrate of soda in equal parts were given along the furrows after planting. It is hoped that as most of the trials adjoin allotment groups they will excite considerable interest, and thus enable the workers to see varieties hitherto to them unknown, and, no doubt, in many cases great improvements on older varieties.

— BAMBOO CULTURE.—A Charleston, North Carolina, correspondent believes that the Bamboo could be successfully and profitably grown on the abandoned Rice fields of that region. By growing our own umbrella handles we should have no question as to whether Bamboo was wood or grass.

— LARGE PUMPKINS.—Three enormous Pumpkins (says the "Australian"), weighing in the aggregate 392 lbs., have been exhibited at the door of a seedsman in Melbourne. They were grown in the neighbourhood, and the heaviest one, weighing 1 cwt. 12 lbs., was of the large yellow variety, the other two specimens being of the ironbark kind.

— CARROTS AND SULPHUR.—My experience with the above, both when sowing and sprinkling the surface at various times after, has never been successful in preventing the flies depositing eggs and their subsequent maggots. Once I was in high spirits when the Carrot tops remained healthy until a week before the Carrots were ready for drawing, when, lo! they collapsed suddenly before I had one good root.—W. T.

— THE COMPENSATION IN NATURE.—It has been noted that where the summer season is comparatively short, and the winter season long, Nature starts the earlier flowering plants in the most surprising way, and on the other hand runs the autumn flowers far into the winter season. In Siberia, says a transatlantic contemporary, a large number of plants will resist early frost, and continue to bloom for a considerable time after the temperature has fallen below freezing point. One of the most beautiful and gorgeous of these is the Aster tataricus—a plant growing some 3 feet in height, and bearing an immense profusion of bright purple flowers. In the writer's garden it made a great show, even up to the 1st of November. The same may be said of the Maximilian Sunflower, a native of the north-western part of our territory, which was also gaily in bloom with the Aster tataricus. A selection of these late flowering plants, grouped in a distinguished manner in some large public garden, would attract a multitude of interested visitors.

— THE ASH AND THE OAK.—It is gratifying to find, so far as my experience has gone, that no one has, in referring to the probable nature of the coming summer, introduced the old and stupid adage respecting these trees. As there are few of these forest trees that are not raised from seed we may find in them all great variation, and as much perhaps in the Ash, usually the latest of all trees to expand leaf buds, as in any others. I have this year seen the Horse Chestnut on precocious forms literally in full bloom, and Ash trees near with not a burst bud on them. That fact serves to show how glorious a tree for early foliage is the Horse Chestnut. Probably not more than usual, except that so far the spring has been free from fierce wind storms; but somehow the foliage of trees seems never to have been more beautiful than this year, or the varying tints of green more charming. Still, this appreciation is probably most due to the fact that spring is with us the opening of a fresh scene in leafage. How great is our gain over that of a country of perennial foliage.—D.

— THE LATE MR. MACDONALD.—I received the other day from my friend Miss Woodhead the sad news of the death of her honest and excellent gardener, Mr. MacDonald of Norwood Green, Hipperholme. He was but little known in the horticultural world, and probably none of the horticulturists in the South was aware of his existence, and yet he had under his care one of the best collections of Auriculas in the North of England. When, after the death of her excellent brother, Miss Woodhead removed to her present abode, now thirteen years ago, she placed her extensive collection under Mr. MacDonald's care, and well and faithfully did he carry out the task allotted to him. Some years ago I made a pilgrimage to Norwood Green, and had the opportunity of seeing both the collection of Auriculas then out of bloom, and also of having a good talk with Mr. MacDonald. I gave an account of my visit at that time in the pages of the Journal, and have very little to add to what I then stated. Not only the Auriculas, but the greenhouse and out of door gardening were well managed. Mr. MacDonald—a modest unassuming man—seemed just the sort of person suited for the place, and enjoyed the complete confidence of his kind and sympathetic mistress. He died on April 29th, and was interred on May 3rd, exactly thirteen years after Mr. Woodhead—a somewhat singular coincidence. He was in his sixty-fourth year, and was hale and vigorous when I saw him. He will be a great loss to Miss Woodhead, who will find a difficulty in replacing so valuable a servant.—D., Deal.

— THE AGRICULTURAL RESOURCES OF RUSSIA.—M. Bataline, Director of St. Petersburg Botanic Gardens, in a recently issued report, gives some idea of the immense undeveloped agricultural resources of Russia. He states that in the Caucasus, along the shore of the Black Sea, is a wide area of land more fertile than any other in Russia, and where Grapes, Olives, and other fruits, tea, and corn would flourish. The vegetation is rich, but hardly any attempt has been made to cultivate this fertile country since the Russian conquest of the Caucasus in 1864. With the exception of two villages, where are some large gardens, there is little sign of cultivation in a province where thirty years ago were broad cornfields, extensive orchards, and a flourishing people.

— BEES PUNCTURING FLOWERS.—Bees puncture many other flowers than Beans. Aquilegias are mutilated by them. I am much obliged for the reply given by Mr. W. Cuthbertson (page 404), but scarcely fall in with him that the shaking of the blossom by the bees aids in fertilising the Bean. It was the general opinion at one time that the humble bee punctured the base of the blossoms for the sole benefit of *Apis mellifica*. I turned my attention to that, wondering why comparatively few humble bees could get over so much work, and why they did not appropriate the honey instead of labouring for other bees. I soon made the discovery the honey bees did the puncturing for their own benefit as well as a small beetle. I cannot say when the bees puncture or enter the blossoms in search for honey, but it is reasonable to suppose that they puncture only when the honey is scarce. Beans secrete much honey at the base of the leaves, which the bees gather readily. If honey and blossoms are the attractions for insects to assist fertilisation, what then is the use of the honey at the axils of the leaves?—OBSERVER.

— MAY WEATHER.—Last week was one of the sunniest that has ever been experienced in these islands. Over a very large portion of Great Britain the aggregate duration of bright sunshine amounted to between seventy and eighty hours, giving a mean daily proportion of ten to eleven hours. At Cambridge the total duration for the week was as much as eighty-eight hours, or rather more than twice the ordinary average. Even at Westminster, where the operation of the sunshine recorder is too often interfered with by mists or smoke, the total duration last week was no less than eighty hours, or 75 per cent. of the possible amount. So large a proportion for a whole week has only been registered once in London in the course of the past fifteen years. That was in the second week of May, 1893, when the proportion of the possible amount of sunshine in London was 1 per cent. higher than in the past week. With this exception the proportion has never exceeded 70 per cent., and in eight years out of the past fifteen it has not once exceeded 65 per cent. The presence of so much bright sunshine last week resulted, very naturally, in high day temperatures, the maximum readings over the inland parts of Great Britain being frequently above 70°, and in some few instances above 75°. In London the thermometer in the shade rose to 70° and upwards on four days out of the seven, while on Thursday last it reached 76°. The latter point was, however, eclipsed on Sunday, when, in spite of a rather cloudy sky, the shade temperature rose to 79°, or 17° above the average for May, and 7° above the average for July or August. Out of the past twenty-five years there have been only six in which the temperature in London during the month of May has risen so high. The highest May temperature registered in London during the past quarter of a century occurred on the 26th of the month in 1880, when the thermometer rose to 86°. Such a temperature as was recorded in the heart of the City at one o'clock on Monday morning (65°) has not been experienced thus early in the month for years. Indeed, since 1891 the only instance of the thermometer touching that point at midnight in May was on the 28th of the month in the spring of 1892. Taking the whole of last summer the thermometer only thrice stood as high in the early hours of the morning, and those three occasions were all in the month of July.—("Daily News.")

#### THE R.H.S. EXAMINATION.

I TRUST we shall learn through the columns of the *Journal of Horticulture*, and from many sources, now that you have published questions set at the recent examination, what is generally thought of them as a test of practical and theoretical knowledge in gardening. It would be absurd to say of any of them that they were abstruse or difficult. So far as I can see in them they are such as any intelligent gardener might have answered with comparative ease, whilst some amateurs would not find them exceedingly difficult.

Probably there are many who have ere now read the questions, who, shrinking at the time, now think they were very foolish not to have sat

for the examination. I cannot conceive of young men who have their way to make in the calling who would not be eager to seize the opportunity to sit, because if no pecuniary good eventually resulted, and I think that could hardly be the case when a young gardener did well, still undergoing the ordeal of an examination would be productive of great good, and must render the candidate more fully conversant with much in gardening that perhaps hitherto he has not studied or even practised.

One very estimable gardener, a man of mature years, whose work I had previously seen, and whom I was anxious should sit, told me that he was specially desired in another direction not to do so, because some less experienced men would to some extent regard him as a competitor, and thus damp their energies. In any case he did not sit. Another gardener, who had previously done first-class paper work, seems to have refrained from sitting because the nearest centre was so far from his residence. In that case only one candidate (a schoolmaster) sat; but I think, from what I know of him, that he will not have done badly.

Talking to an esteemed gardener in Surrey the other day, he remarked, "I wonder that head gardeners, where they have two or three or more young men under them, do not both specially encourage these youths not only to attend horticultural lectures, but also to sit for the R.H.S. examination." In that view I fully concur. I do not say, of course, any compulsion should be exercised, but moral suasion should be employed to those ends. Young men may not find in gardening that perfect or highly paid vocation they wish, but at least they are extremely foolish, once they are right into it, not to try and make the very best of it that offers. Their ages range from twenty to thirty years, perhaps, and yet there is not in the kingdom an intelligent gardener three times the age who will not admit that all there is to know in gardening has never been acquired. It does therefore seem to be folly to neglect the aids which to-day furnishes, whether in books, lectures, classes, examinations, or in whatsoever way found.

I have found numbers of cases in which old and experienced men have admitted how much they have learned through lectures, even if little in mere work at least much in theory, and in opening up new veins of thought and aspect. To such men as these lectures are sources of real enjoyment as well as of improvement. The stubborn man, who encases himself as it were in armoury of cold disdain, and offensive egotism, will neither attend lectures nor learn from any source. He is a fool unto himself, for no persons are so mentally blind as those who will not see.

That is a sort of feeling that may come of age, but should never be a characteristic of the young man. If he is wise he will try hard to obtain useful knowledge from any source, for he never can tell when he may find it useful. How often is it he who has a chance to drop into some better position finds that lack of knowledge heavily handicaps him, and loses for him the post to which he aspired. All this is too true, and much to be deplored.

Would that we could get head gardeners everywhere to interest themselves much more actively in connection with this annual R.H.S. examination, and try to induce their young men to become candidates. The number of these should be ten times as many as are now presented. The examination is of course open to all, but it is essentially a gardener's examination all the same. It is therefore all the more a matter for regret that as such it is not far more widely utilised.—A. D.

#### EARWIGS FLYING.

ALTHOUGH I willingly reply to "W. R. Raillem's" request on page 408, I feel bound to say that I do not see the object of his remarks.

That in surrounding Chrysanthemum plants by water earwigs are practically precluded from attacking the plants is an undoubted fact experienced by those who pursue this course. Whether they suffer from hydrophobia, or are too indolent to use their wings, I am unable to say, but that they rarely get on to my plants while so protected is sufficient for my purpose; but "W. R. Raillem" must not assume I state that they do not fly upwards, as all I say is "there need be little fear." But after all, whether they fly at all matters little to me, unless they would all fly to the south-west of England. Unfortunately these insects account for an hour or more of my time every night from May to November, which is doubtless funny to "W. R. Raillem," and I have thought that I have seen thousands make use of their wings in the manner described by me, but I would tell your correspondent that I have the greatest dislike to touching these insects with my hands, and always use forceps, and that I have never seen them open their wings in the daytime, although I assume the night is referred to.

As to "W. R. Raillem's" inquiry, "Will 'Entomologist' be kind enough to say whether an earwig can fly over an inch or two of water, or as high as the leaves of a Chrysanthemum plant?" Why not. I only speak of its customary habits.

Perhaps I may remind "W. R. Raillem" that our old "barndoor" has also a "splendid pair of wings," and although there are two or three of us who have done the funniest thing that he has heard of for a long time, I do not think that need surprise him, nor myself, inasmuch as the funniest part of it all is that the "Earwig Baffler" is not mine, but that of some other funny person (see page 341).

And, lastly, as to the libel on the poor cuckoo, why I heard a girl once say, "Oh, mamma, I heard the cuckoo this morning, it went pe-wet, pe-wet." Libels on birds or animals are not, however, infrequent, as I bear in mind the reply of the man who received a kick from a donkey and said that he took it from whence it came.—H. BRISCOE-IRONSIDE, *Burgess Hill*.

## ROSE MARÉCHAL NIEL.

I FAIL to see why "W. R. Raillem" (page 406) should be so much surprised at my recommending gardeners to increase their stock of this fine Rose by grafting, as the plants produced by this means are in no way inferior to budded or own-root plants for forcing. The only difference is that by grafting we can propagate quicker than in any other way, and this was my reason for advising it. There is no need to keep the plants in pots; they may be so grown or planted out according to requirements. If a clean healthy growth is made, and this well ripened, flowers in abundance will be produced, and there is no reason why grafted plants should not succeed if trained on the lines laid down by "W. R. Raillem."—H. R. R.

IN an old lean-to greenhouse owned by Mr. White, Havant, is growing a very fine plant of Maréchal Niel. The blooms do not exhibit that rich colouring so much admired in this Rose, but they possess much substance of petal, and are extremely useful to Mr. White in his business as a florist. The plant was budded on to a Gloire de Dijon growing on its own roots, having been raised from a cutting.—E.

## ROSE LA FRANCE.

THE engraving (page 407) faithfully represents this charming Rose as seen at its best. For growing in 4-inch pots to give one, and sometimes two, blooms on each a year old, it is a capital variety. Cuttings 4 inches long taken in May from plants that flowered in April root readily inserted in sandy soil and plunged in a gentle hotbed. Shade must be provided until roots are formed, or callusing will be retarded. If the cuttings are inserted several in one pot they will require potting separately when well rooted, and should go direct into the sized pot named. Grown steadily in a cold frame for a time, afterwards giving them a sunny spot out of doors for the remainder of the autumn to mature the growth, these plants will produce excellent blooms during April and May.—M.

## ROSE MRS. W. J. GRANT.

I AM glad to note "W. R. Raillem's" vigorous protest against the renaming of this fine Rose, and also to find that protest supported by your editorial note. I have already expressed in your columns my determination to show and recognise it only under the name originally given to it, and I earnestly hope that all members of the N.R.S. at least will do the same.

Some to whom I have spoken on the subject say, "Oh, but if a man buys the entire stock of a new Rose, surely he may call it what he likes?" The reply to this is that it depends on the circumstances of the case. If a selection is made from a number of unnamed and unexhibited seedlings the purchaser may certainly do as he likes, but that was not the case with this Rose. The raisers had, I suppose, obtained permission to name it after the wife of one of the ablest rosarians this country has known; they had exhibited it under this name throughout an entire season, and under this name it had received many F.C.C.'s, and the highest honour a new Rose can obtain—viz., the gold medal of the N.R.S.

Under these circumstances I submit that the purchaser had no right to ignore everything that had gone before, and to attach the name of his daughter to the Rose. His doing so appears to me, unintentionally, no doubt, to be a direct affront to the raisers, to the lady whose name the Rose properly bears, and to the N.R.S., whose medal it has received, and I am sorry to find from the report of the latter just to hand that they think so little of their own awards as to recognise the new title in the list printed on page 72, and to print the legitimate name as a secondary matter.

I should like to ask, Is the Rose, which, as "Mrs. W. J. Grant," received the gold medal eligible to compete for another medal under a fresh name? If not, why is that new name officially recognised by the Society?—J. B.

[We repeat that the name under which the variety was honoured as described is the true name of the Rose. It is the name first recognised and recorded, and according to established rule it ought to prevail.]

## A QUIET CORNER.

LIFE in general, particularly to those engaged in its more active pursuits, now and again brings the desire to escape from it—to stand aside as it were for a brief space, and in quiet meditation review the passing procession in all its kaleidoscopic changes. This privilege is enjoyed according to individual views of life, and according to the standpoint from which it is viewed, whether from congenial or uncongenial surroundings. To those patrons of the art of gardening who seek, and invariably find in it, those soothing influences which make life worth

living, gardeners are especially privileged to contribute in no small degree. Apart from cultural skill, prudent management, and the items conducive of a successful exposition of his profession, a man's inventive faculties are afforded ample scope in the field of his work to enlarge the gratification derived from it.

Such passing thoughts, pertaining rather to the philosophic than the practical, may be admissible, for the pleasures of gardening are not yet eclipsed by the search for profit, nor will they probably ever be so, as the benefits derived from this form of relaxation are heavy on the credit side of the balance-sheet. Coming to the more practical side of the question there are but few gardens which do not give facility, either indoors or out, for the further exercise of that "Art which doth aid Nature." The garden is a place of many corners, quiet corners too, yet not so according to the interpretation the text is capable of, that is, suggestive of repose sought for through the medium of graceful and appropriate surroundings.

Apart from these considerations there are reasons worthy of this subject receiving some attention from those who find the architect and builder of some plant house or conservatory has left his—the gardener's—views entirely out of the question. How often is to be found in some conservatory attached to a dwelling house everything desirable, save the one important matter, that of providing a healthy home for plants. Many find this a never-ending source of trouble in keeping up those appearances it is here of all places so necessary to maintain. Details of such are too well known to encroach on space. Houses in which the most able cultivators fail to do justice to themselves, and are unable to give satisfaction to their critics. Yet, it is often possible at a small expense, with taste and ingenuity, for the gardener to convert his *bête noir* into a thing of beauty with a considerable lessening of the strain imposed on him hitherto.

Miss Armstrong's picture (fig. 72) is an illustration to the point in question, for such work obviously is suited to any house or corridor which may be termed ugly by reason of an obtrusive end or back wall. This illustration, speaking for itself, requires no explanation; but, if I may be permitted to say so, would more vividly impress the beautiful, as here seen, if the unlovely—of which so many examples are frequently to be met with—could be here depicted in the same practical manner. Nothing so forcibly impresses the pleasing as the want of it, and he who has to stand the fire of criticism aligned through the drawing-room windows into the conservatory knows well where the shoe pinches.

At first sight, with some conservatories (alluding here to those attached to a building), difficulties may present themselves in altering existing things. For instance, it may be thought desirable that damp soil or rockwork should not come in contact with the walls of the dwelling. With such difficulties I have had to deal with in the conversion—from my point of view—of an ugly conservatory into a quiet corner which is now generally admired by those more competent to judge than myself. It is not, I admit, an altogether worthy object in seeking to avoid trouble, but when that is of the perennial kind and can be abolished for good and all, then with that object alone it is desirable to do so. Trouble in this case meant work, a never ending endeavour to keep a house presentable with plants which was able to reduce the majority of them to a pitiable state in the shortest time.

With a side wall next a reception room it was thought well to avoid the possibility of damp, hence the rockwork was built up independently with an intervening space. A water tap at hand suggested a fountain, and to this end a portable tank was utilised, and stood on the floor at the base of the rockwork wall and finally enclosed in the same material, thus making it a part and parcel of the principal erection. A junction with the waterpipe carries water to the top of the wall, whence it trickles or dashes down according to desire into the basin below, keeping it full, and escaping by an overflow over the marginal rockwork to an unseen drain.

Seedling Ferns, Lycopodium, Begonias of the Rex type, with Ficus repens and Tradescantias, for which ample provision was made for planting, fairly revel under these conditions, and a fine Dicksonia—which hitherto had appeared to exist only on sufferance—now crowns the whole with a luxuriant canopy of fronds. So with some large Palms and other permanent plants, which soon showed the beneficent effects of the presence of water and moisture-yielding rockwork. It is not always desirable to let well alone, if the way is presented to do better and further improvement was made by abolishing all pots, transferring the specimen plants into tubs and covering these with virgin cork. Other corners in the same house were similarly treated, and where stone could not be employed virgin cork gave means to the end.

Similar work to suit varying conditions needs not to be carried out on any hard and fast lines. Some idea of the floor space available for the foundation of it is necessary to have, then as the work proceeds it will be found self-suggestive. The builder may certainly, probably will, transgress in the ethics of expert rockwork building, in fact my work prior to completion provided the text for a sermon by an interested friend on strata, but Ferns and creepers have long since veiled those imperfections from inquisitive eyes. A few baskets of that charming pendent Fern, *Gymnogramma schizophylla gloriosa*, show to advantage above, and an old iron garden seat, bereft of a leg, is permanently

bolstered up in a quiet corner with more rockwork, and backed up with cork, to the benefit of those seeking quiet moments.

The expense of this conversion was practically confined to the cost of half a ton of Portland cement, and the work was done at intervals

is that the water from syringing can percolate from summit to base, thus preventing the pockets being waterlogged.

The quiet corner illustrated must serve as an excuse for this solo on that unpleasant instrument, one's own trumpet, yet it may call the

FIG. 72.—A QUIET CORNER.

during the absence of the family. This is mentioned, as probably more hurried building would have been less satisfactory. On some days not more than five or six pieces of stones were fixed, and to attach some pieces to advantage it was found necessary to secure them in position until the cement had hardened. Another point should be mentioned

attention of some in a similar predicament. Some perhaps whose thoughts when noting it will revert to "that confounded conservatory which kills the plants," or "that ugly corner in the plant house." Should it do so, I respectfully suggest "Go thou and do likewise."—FREEMASON.

#### JAPANESE NOMENCLATURE.

UNTIL the present year floral hero worship was entirely unknown to the native Japanese grower of Chrysanthemums. He almost always selected poetical or fanciful names for his plants, such as Cherry on the Peak, Moon in Frosty Night, Snow on Pine, Sea of Setting Sun, Cascade of Thousand Fathoms, Moon in the Window, A Thousand Sparks, Eye of a Snake, and the like; but taking the cue from western florists, I observe that one Japanese grower, probably as a compliment to some of his victorious countrymen in the recent struggle between China and Japan, has adopted the following for his novelties of 1895:—Admiral Ito, Count Yamagata, General Nodzu, and Marshal Oyama.

#### ITALIAN CHRYSANTHEMUMS.

A Chrysanthemum fancier in the States inquires of me in a letter just to hand for the names of some German and Italian authorities on the popular flower. Although there have been shows in Germany I have never heard of any horticulturist who has a special claim to be considered an authority; but perhaps some of your readers who have more to do with that country than I can help with the desired information. With respect to Italy there are three raisers who have sent out some seedlings, and most of these have been imported into England; but when autumn has arrived, and inquiry has been made for the Italian novelties at our trade growers, the results have been by no means promising, and I doubt whether half a dozen could be found in the hands of our English growers.

#### THE OLDEST CHRYSANTHEMUM.

Everybody knows that the first large flowering Chrysanthemum was called the Old Purple, and was introduced from China into Europe in 1789, and was figured in the "Botanical Magazine," plate 327, in 1796. Having recently purchased an old French book in four volumes, entitled "Elémens de Botanique," I naturally turned up the index for Chrysanthemums.

I found a coloured plate of a variety that does not resemble the one in the "Botanical Magazine," as it represents a small dull red flower of the single type with a yellow centre, about 2 inches in diameter. It is called Chrysanthème d'Automne, but no varietal name is given, and by the appearance of the book and the letter-press reference to the plant as having been grown in French gardens for several years, I am inclined to think that both plates quoted are intended to depict the same flower.

None of the four volumes has any title page or date, nor does an author's name appear. Can any reader of the Journal supply me with particulars of the "Elémens de Botanique?" In size it is a small quarto.

#### HAIRY CHRYSANTHEMUMS.

I note what "E. M." says on page 410 about these varieties, and have never believed that they would create more than a transient feeling of interest. Some of the pure white varieties when grown in bush form, and with a large number of flowers, as I have once or twice seen them, may be very useful for filling vases for indoor decoration. *Enfant des Deux Mondes* in particular has a special value in this way. Some of the others, however, are of dirty washed-out colours that will never please the eye either of visitor to the shows or artistic decorator, and the end will no doubt be, as "E. M." says, that the whole race will find a permanent resting place on the rubbish heap.

But that event has not yet come to pass. Mr. Jones of Lewisham catalogues twenty-one kinds, nearly all of which I have seen and closely examined at one time or another, and which may certainly be pronounced as the best. The Americans who successively puffed up Mrs. Alpheus Hardy, Louis Boehmer, and several others seem to have dropped the race of hairy Chrysanthemums entirely this year. In Chrysanthemums as in many other matters this proverbially hard-headed nation rarely do much for empty honour or fame. If there are no dollars to be obtained the matter is dropped for something more remunerative.

On the continent the growers seem to delight in cataloguing all they can get hold of, and so we find in Simon Delaux's new list three series of the hirsute section, comprising a total from all sources of seventy-two different varieties.—C. H. P.

#### ROYAL HORTICULTURAL SOCIETY.

MAY 14TH.

THOUGH some beautiful Orchids were exhibited, also charming collections of hardy flowers, fine stands of Roses, glowing Cannas, superb Lilacs, and several Daffodils, yet Tulips undoubtedly predominated, and the designation applied by a visitor of "Tulip Day" did not appear inappropriate. Messrs. Barr & Son and Veitch & Sons had Tulips of all heights, sizes, and colours in which these flowers are seen, from the gorgeous Gesnerianas and Darwin's to the delicate Picotees and quaint Parrots; while Mr. Bennett-Poë had an excellent collection of the refined

florists' varieties, Messrs. Barr having also many in this section. It was observable that the visitors were much interested in the displays, and the great decorative value of Tulips appeared to be generally admitted.

FRUIT COMMITTEE—Present: T. Francis Rivers, Esq. (in the chair); with Messrs. G. Bunyard, H. J. Pearson, H. Balderson, G. W. Cummins, J. Cheal, J. T. Saltmarsh, J. A. Laing, W. Bates, T. Glen, G. Wythes, F. Q. Lane, G. Reynolds, J. Smith, G. Norman, E. Gilman, J. Hudson, A. Dean, and J. Wright.

With the exception of the new *Strawberry Laxton's Leader* and sundry Cucumbers, the Committee had very little to do on the present occasion. With reference to the Strawberry mentioned, we have nothing to add to our description of it on page 411 last week, where a fruit is illustrated. It was not expected, as was there suggested, that fruits would be kept sufficiently firm for placing before the Committee; but Messrs. Laxton were out in their calculations, and for those that were exhibited a first-class certificate was unanimously awarded.

Mr. S. Mortimer, Rowledge, exhibited several fruits of a new Cucumber, also fruiting stems. The variety was named *Marvel*, presumably because of its great productiveness. The fruits are below medium size, well shaped, and of good colour. Allen's Favourite Cucumber was shown by Messrs. James Veitch & Sons—large, fine fruits. The variety has previously received an award of merit. Mr. James Vert sent very large dark green fruits of Vert's Favourite Cucumber. The Committee recommended that, if practicable, a trial of Cucumbers should be conducted at Chiswick, to include the above named and other varieties, for determining their qualities and distinctiveness under similar cultural conditions.

Mr. E. Gilman, Ingestre Gardens, sent a fruit of *May Prolific* Melon, the result of a cross between *Hero* of Lockinge and *Ritcbing's Perfection*; very juicy and sweet, but not sufficiently high flavoured to merit a special award. Mr. G. Wythes sent from Syon House very fine and highly coloured fruits of the *Amsden June Peach*, and a cultural commendation was unanimously granted. Mr. J. F. McLeod, Dover House Gardens, Roehampton, sent a large bundle of Asparagus, and received a vote of thanks.

The Horticultural Travelling Structures Co., Limited, exhibited a model of a span-roofed house on rails, which moved to and fro with great freedom. The Committee thought that a good method of testing the practical value of the plan would be to have a structure of full workable size in operation at Chiswick over Strawberries or other crops.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); and the Rev. H. H. D'Ombraïn, with Messrs. J. Fraser, O. Thomas, C. T. Druery, H. B. May, H. Herbst, R. Dean, J. Jennings, C. E. Pearson, J. D. Pawle, G. H. Engleheart, H. Bennett Poë, C. E. Shea, H. J. Jones, E. Beckett, C. Blick, E. Mawley, G. Paul, G. Gordon, G. Nicholson, J. W. Barr, and J. Walker.

Messrs. Tbos. S. Ware, Tottenham, staged a very showy group of plants and flowers, amongst others being thickly bloomed plants of *Spiræa japonica nana compacta*, *S. palmata*, and *S. astilboides*, *Saxifraga pyramidalis*, *Cypripedium pubescens*, *C. calceolus*, *C. acaulis*, and *C. montana*, *Ranunculus aconitifolius plenus*, *Orchis fucifolia*, *Gladiolus The Bride*, and others. Tulips were also represented in many bright and showy flowers. Several large showy plants of *Pæonies* were included in the group, as also were *Iris La Blanche*, *Chrysolora*, *Queen Victoria*, and *White Queen* (silver Flora medal).

Messrs. J. Cheal & Sons, Crawley, Sussex, staged an interesting group of hardy flowers, amongst others being *Spiræa confusa*, *Pyrus Malus floribunda*, *Pyrus Riversi*, *Mountain Ash*, *Berberis vulgaris purpurea*, *Doronicum Harper Crewe* and *D. Clusi*, *Cerasus domestica pleno*, *C. Sieboldi rosea pleno*, *Syringa persica alba*, *S. alba grandiflora*, *Azalea mollis*, together with pretty bedding *Violas Rob Roy*, *Countess of Kintore*, *Duchess of Sutherland*, *Goldfinch*, *Trentham Purple*, *Countess of Hopetown*, *Duchess of Fife*, *Blue Cloud*, and others (bronze Banksian medal).

Mr. J. Fitt, gardener to Earl Cowper, staged exceptionally fine flowers of *Lilac alba grandiflora*. Mr. George Mount, Canterbury, sent a fine collection of Rose blooms, conspicuous amongst which were *The Bride*, *Niphetos*, *Catherine Mermet*, *Duke of Edinburgh*, *Ulrich Brunner*, *Mrs. John Laing*, *La France*, *Lady Mary Fitzwilliam*, *Général Jacqueminot*, *Baroness Rothschild*, *Fisher Holmes*, and *Madame Gabriel Luizet* (silver-gilt Banksian medal). Mr. Hudson, gardener to Messrs. de Rothschild, Gunnersbury House, Acton, staged a pretty display of *Rose Turner's Crimson Rambler*, and also fine spikes of bloom of *Cercis siliqua-trum*.

Mr. A. Harding, gardener to the Marquis of Huntly, Peterborough, sent sprays of *Aucuba japonica* in fruit. Mr. A. Waterer, Woking, staged *Lilac L. Spathe*, and *L. alba grandiflora*. Mr. G. F. Wilson, Weybridge, sent a flower spike of the dwarf *Rhubarb*, *Rheum Moorcroftianum*. F. W. Moore, Esq., Botanic Gardens, Glasnevin, sent several curiosities—namely, *Brownea Ariza*, *Acanthephippium javanicum*, *Darlingtonia californica*, *Strophanthus dichotomus*, and hybrid *Sarracenas*.

Messrs. John Laing & Sons, Forest Hill, staged a very creditable group of *Gloxinias*, interspersed with *Maidenhair Ferns* and *Palms*; conspicuous amongst the former were *Majestic*, *John Laing*, *Mrs. Laing*, *Leopard*, *Lord*, and *Killingdon*. The plants were exceedingly well grown, and the flowers fine and of good substance. Included in the exhibit were several well-flowered plants of *Streptocarpus Royal Purple*, and *Caladiums Rose Laing*, *Pauline Guichard*, and *La Duchesse* (silver-gilt Banksian medal).

Messrs. W. Paul & Son, Waltham Cross, exhibited a small but very

creditable stand of Roses, particularly striking amongst which was Empress Alexander of Russia, a new variety raised by the firm, being of a pretty reddish bronze; other fine blooms were Clio, Corunna, Queen Mab, and Sylph. Messrs. Paul & Son, Cheshunt, staged a fine collection of Lilac and Rhododendron blooms, amongst the former being President Carnot, La Tour d'Auvergne, Madame Lemoine, Madame Kreutzer, President Grevy, Virginité, Lemoine flore-pleno, and Souvenir de Louis Spathe. Amongst the latter Mrs. Charles Butler and others were very fine. Cannas were well represented in the group with Tom Thumb, Comet, Progression, Miss Sarah Hill, Cheshunt Yellow, Charles Moore, Mrs. Tasker, President Chandre, L. E. Bally, and others.

Messrs. John Peed & Sons staged a compact group of Ferns and foliage plants, amongst others being Caladiums William Bull, Triomphe de Comte, Reine de Danemark, Linne, Charlemagne, and Mrs. Harry Veitch; Begonia Arthur Malet, Strobilanthes Dyerianus, Dracaena Sanderiana, and D. Lindenii (silver Banksian medal).

Messrs. Jas. Veitch & Sons, Chelsea, exhibited a magnificent collection of Tulips in bloom in great variety of colour. Amongst the Parrot variety were lutea major, Constantinople, Perfecta, Mark Graaf, Café Buren, Preciosa, Coffee Colour, and Rubra major. Amongst the byblœmens were Czar Nicholas, Reine des Fleurs, La Grandesse, Osman Pacha, and Graaf Buren; the hizarres being well displayed in Everet Kroschell, President Thiers, Wilhelmina, Sir M. Montefiore, and others. Other varieties were Picotee, Summer Beauty, Queen of the Reds, and Bouton d'Or. The same firm also sent a few choice Caladiums—namely, Marquis of Camden, Lord Derby, Sir William Broadbent, and Sir Julian Goldsmid (silver Flora medal).

Messrs. Barr & Son, Covent Garden, staged a large and effective group of Tulips and other hardy flowers, the whole of which were of an exceedingly high order, the former consisting of such varieties as Yellow Rose, Picotee, fulgens, Striped Beauty, Roe Pomponne, Yellow Queen, elegans alba (award of merit), vitellina, flava, Gesneriana, alba marginata, Golden Beauty, Goldflake, macrospeila, Coffee Colour, Crimson Beauty, and Perfecta. Among the Darwins were Purple King, The Sultan, Dorothy, Gipsy Queen, Bronze King, Queen of the Lilacs, Early Dawn, May Queen, and Queen of the Brilliants, all of which were exceptionally fine. In a collection of breeder Tulips the principal varieties were Music, Lord Frederick Cavendish, Agnes, John Heap, Sulphur, Annie McGregor, Excelsior, and Miss Foster. The rectified collection was composed chiefly of Duke of Devonshire, Mahel, Dr. Hardy, Aglaia, Sir Joseph Paxton, Black Diamond, George Hayward, Lord Denman, Gold Cup, Holmes' King, Princess Royal, Masterpiece, Hero, Charles Tait, Adonis, Mrs. Jackson, and Industry. Amongst other flowers were Androsace sarmentosa, Phlox setacea atro-purpurea, and nivalis, Primula japonica alba, Aubrietia Eyrei and rosea, Arenaria montana, Genista Andreaana, and several single Pæonies of distinct colour (silver-gilt Banksian medal). Mr. McIvor, gardener to R. Maitland, Esq., Conrie Castle, Dunfermline, Fife, staged a group of Auricula and Polyanthus flowers. Messrs. Saltmarsh & Son, Chelmsford, sent flowers from a seedling Lilac, Syringa vulgaris ruberrima. Mr. J. F. McLeod, Dover House Gardens, Roehampton, sent an exceptionally large plant of Medinilla magnifica. A group of Canary Island flowers were sent by the Director of Kew Gardens, consisting of Statice Bonegali, Ranunculus cortusæfolia, Cineraria cruenta, Cytisus racemosus, and Cytisus filipes.

#### COMPETITIVE CLASSES.

In the special class for a group of Daffodils, for which prizes were given by Messrs. Barr, the first was awarded to Mr. G. McIvor for a collection in which were N. Major, Glory of Leiden, Mrs. Vincent, Odorus Rugulosus, Mrs. Langtry, Duchess of Westminster, Queen of Spain, poeticus ornatus, Frank Miles, Leedsii, Little Dirk, Duchess of Brahan, and others. The second prizes fell to C. J. Backhouse, Esq., St. John's, Walsingham, Darlington, the flowers not being so fine as in the former case.

Mr. Downes, gardener to J. T. Bennett-Poë, Esq., Cheshunt, staged some grand Tulips in the class for a collection of English amateurs' varieties. Amongst the best were Mabel, both in the breeder and rectified state, Talisman, Dr. Hardy, Sulphur, George Hayward, Queen of the North, and Sir J. Paxton (superb). There was no other exhibitor in the class.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); and Dr. Masters, with Messrs. J. O'Brien, De Barri Crawshay, H. M. Pollett, M. Protheroe, H. J. Chapman, J. T. Gabriel, C. Pilcher, Ed. Hill, T. W. Bond, W. Cobb, J. Douglas, S. Courtauld, F. Sander, T. Statter, T. B. Haywood, and H. Ballantine.

Mr. W. Stevens, gardener to W. Thompson, Esq., Walton Grange, Stone, sent a small but choice collection of Orchids in variety. Particularly noticeable were Odontoglossums crispum The Bride, very fine; Ruckerianum ocellatum; Andersonianum, Thompson's variety; Rossi rutescens, cordatum aureum, and Cattleyas intermedia alba, very fine; and Skinneri alba (silver Banksian medal). From De B. Crawshay, Esq., Sevenoaks, came a handsome form of Odontoglossum crispum named Florrie, O. Halli xanthoglossum, O. Andersonianum, and a grand Cattleya Mendeli, named by special permission Princess of Wales, and which was deservedly accorded an award of merit.

Three Orchids were sent by Messrs. Hugh Low & Co., Clapton, comprising Lælia purpurata Russelliana, L. p. Schröderæ, and a fine hybrid Cypripedium called Gertrude Hollington, which is described below. Mr. H. J. Chapman, gardener to R. I. Measures, Esq., Camberwell, received

a first-class certificate for Cypripedium Godefroyæ (?) leucochilum (see below).

A very fine plant of Odontoglossum cirrhosum came from Mr. G. W. Cummins, gardener to A. H. Smee, Esq., The Grange, Wallington; and W. Cobb, Esq., Tunbridge Wells, sent Cattleya Mossiæ, Dulcote's variety, which, though very fine, did not receive an award. Blooms of Cattleya Clæsiana were exhibited by Mr. Johnson, gardener to Thos. Statter, Esq., Stand Hall, Manchester.

Mr. J. Davis, gardener to J. Gurney Fowler, Esq., Glebelands, South Woodford, staged Cattleya Mendeli leucoglossa (award of merit), C. Mendeli Glebelands variety, and also two flowers of C. Mendeli. Mr. J. Pierce, gardener to Mrs. Langton, Hillfield, Reigate, showed a plant of Cirrhopetalum Macraei, and received a botanical certificate, while Mr. B. Dunn, gardener to H. Weetman, Esq., Little Haywood, received a cultural commendation for a plant—a species of Phaius.

Mr. W. Rapley, gardener to H. Grinling, Esq., Harrow Weald House, Stanmore, staged Cypripedium tortilis and C. Wallisi, both in excellent form. An Odontoglossum, the result of a cross between maculatum and cordatum, was shown by Messrs. F. Horsman & Co., Colchester.

The largest and finest collection of Orchids was arranged by Messrs. Jas. Veitch & Sons, Royal Exotic Nursery, Chelsea. It was an exceedingly diversified and interesting exhibit, comprising Epidendrum O'Brienianum roseum (award of merit), Cypripedium hellatum, Dendrobium thyrsoflorum, Lælia purpurata, Odontoglossum Ruckerianum, Cattleya Mossiæ, Maxillaria Sanderiana, Chysis chelsoni, Cymbidium Lowianum, Cattleya Schröderæ, Oncidium concolor, Dendrobium infundibulum, Lycaste cruenta, Oncidium ampliatum majus, O. superhiens, Odontoglossum cordatum, O. crispum, O. triumphans, Dendrobium glomeratum, Cypripedium caudatum Wallisi, C. Euryale, C. orphanum, and numerous others (silver Flora medal).

#### CERTIFICATES AND AWARDS OF MERIT.

*Cattleya Mendeli leucoglossa* (T. Statter).—This is a handsome form of Mendeli with delicately rose-tinted sepals and petals. The outer portion of the lip is pure white, the throat being striped and flushed yellow. The lip is charmingly fimbriated (award of merit).

*Cattleya Mendeli Princess of Wales* (De Barri Crawshay).—The petals of this very beautiful Cattleya are broad, substantial, and of a rosy white shade, deeper at the tips, the sepals, which are narrow, being of the same colour. The lip is a superb feature, it is splendidly fimbriated, and of an exceedingly rich purplish maroon with a pale yellow throat striped with crimson (award of merit).

*Cypripedium Godefroyæ (?) leucochilum* (H. J. Chapman).—This is a superb flower, with a milk-white pouch. The dorsal sepal is broad and very substantial, and having a white ground colour, with reddish-chocolate markings. The petals have also a white ground, but the markings are in this case somewhat duller in hue. They are broad and strong. This variety is faithfully portrayed in fig. 71 (page 423), which was sketched at the Drill Hall (first-class certificate).

*Cypripedium Gertrude Hollington* (H. Low & Co.).—This is a hybrid, the result of a cross between ciliare and bellatum. The petals are broad, very heavily spotted brownish-red on a whitish ground. The dorsal sepal is white, tinged green, and striped dull red; the pouch is of medium size, and of a dull red colour (first-class certificate).

*Epidendrum O'Brienianum roseum* (J. Veitch & Sons).—The colour of this Epidendrum is a very intense, deep rose, that is very pleasing (award of merit).

*Lilac La Tour d'Auvergne* (Paul & Son).—This is a very handsome variety with large flowers and trusses. The colour is reddish lilac, and the blooms are very sweetly scented (award of merit).

*Odontoglossum crispum The Bride* (W. Thompson).—The sepals and petals are pure white and of perfect form, while the lip, which is edged white, has a yellow patch with occasional brown blotches (award of merit).

*Sambucus racemosus plumosus foliis aureus* (R. Wezelenburg and Son).—The leaves of this variety are narrow, very deeply cut, and of a pale yellow colour (award of merit).

*Tulipa elegans alba* (Barr & Son).—This is a white variety of the well-known and popular elegans. It is edged quite in Picotee fashion with bright rose (award of merit).

#### THE LECTURE.

A pleasant episode in the day's proceedings was an interesting and instructive lecture on "The Plants and Gardens of the Canary Islands," by Dr. Morris of Kew, and illustrated by dissolving views. In speaking of the climate of the islands, the lecturer said it was all that could be desired, the mean temperature being 60°. A map was displayed showing the relative position of each island; the coasts are all bold and rocky, the aspect being singularly grand and majestic. The first knowledge of the islands commenced with Humboldt, who wrote graphically of them in one of his works. The land is cultivated at a considerable expense, as all has to be irrigated with water which comes from the mountainous regions and is stowed in large tanks.

In the lowlands such cultivated plants as Bananas, Vines, and Sugar Canes are to be found, while at a high altitude where the atmosphere is naturally cooler, Laurels, Hollies, and such like trees grow profusely, and beneath their branches Cinerarias and other charming flowers are perfectly at home. In regions higher still, above the cloud level, scarcely any plants at all are to be found. Several varieties of English Ferns, American Aloes, tree Fuchsias, and Pepper trees are among other plants of the Canaries. Views were depicted of many of the native plants, amongst which were Euphorbia canariensis, which grows in

large masses on the roughest rocks; the Dragon Tree, supposed to be one of the oldest and most famous trees in the whole world, specimens of which are now growing at Kew; the Canary Palm, *Filix canariensis*; and the Tree Heath, *Erica arborea*.

*Pinus canariensis*, which is indigenous to the island, is a handsome tree, and the wood is largely used in the construction of balconies. Views were given of botanic and other gardens in the Canaries, which were very beautiful, each having a decidedly tropical appearance. Dr. Morris showed specimens of several flowering plants which are natives of these regions, such as *Ranunculus cortusifolius*, one of the prettiest of the species, growing well in mountainous districts, Wallflowers are found at a high elevation, and *Cineraria cruenta*, a fine flowering plant, is seen in great numbers.

Statice of several varieties hail from these climes, as also does the Marguerite, which is so largely grown for window decoration, together with *Cytisus racemosus* and *filipes*, both of which are well known in English gardens. About 100 plants, natives of the Canary Islands, are now growing at Kew. A picture and description was given of the Royal Palm of Cuba, or the Travellers' Joy, as it is more often called from the fact that it accumulates and stores water, which by wayfarers is much appreciated. A massive Fig tree was also depicted which produced large fruits in great numbers, but which unfortunately were unfit for food. The lecturer gave a graphic description of journeys through the islands, and mentioned many plants that make their home there, amongst others being Myrtles, Bougainvilleas, Orange and Lemon trees, Euphorbias, Aloes, Cacti, Eucalyptus, and *Araucaria excelsior*. He dealt at some length on the climatic influences, soil, and conditions under which many of the native plants grow, and in conclusion of his most interesting lecture was accorded a hearty vote of thanks.

### THE PHYSIOLOGY OF PLANTS.

WE have recently received a very useful book—namely, "A Popular Treatise of the Physiology of Plants," written by Dr. Paul Sorauer, Director of the Experimental Station at the Royal Pomological Institute in Proskau (Silesia). The work has been translated by F. E. Weiss, B.Sc., F.L.S., Professor of Botany at the Owens College, Manchester, and is published by Longmans, Green, & Co., London. The book is lucidly written in plain language, easily understood, and the teaching imparted is well depicted in thirty-three illustrations. The author has grasped the whole subject in an exhaustive and comprehensive manner, giving a thoroughly scientific account of the functions of the various organs of plant life, and at the same time dealing with practical applications of the principles of vegetable physiology.

Professor Sorauer, in addition to being an authority on the diseases of plants, was for many years the director of an institution which had in view the scientific training of gardeners and agriculturists. It might have been in this capacity that he became aware of the existence of a long-felt want, which his book supplies—viz., imparting scientific knowledge in language easily understood and comprehended by the ordinary class of gardeners, and his book is worthy a place in every gardener's library. The author has carefully avoided any mixing of subjects, thoroughly dealing with one before proceeding to the next.

He commences by showing what conception a gardener should form of a vegetable organism, and what the functions are of the various organs of a plant, and in dealing with the structure of the root takes in rotation the absorptive portion, the root tip, the conducting portion, and the process of conduction. The nutrition of the root is thoroughly dealt with, showing what substances must be present in the soil for the continuous nutrition of plants; the effect of the nutritive substances on the plant, and the form in which they enter it; also the way the root finds the nutritive substances in the soil. It is shown how soil can be improved so as to obtain the best crops, how the nutrition of pot plants may be effected, and the way in which roots obtain their necessary supply of air; moreover, the author shows how roots should be treated in transplanting, pruning, and in repotting.

The stem is next taken, showing the structure of the same, and how its functions are performed. After which comes the leaf, explaining which cells are the most essential, how the leaf is developed, and the important mission it has to fulfil. The author goes on to show why the growths of cultivated plants must be pruned, what is the least injurious form of a cut, and how summer pruning differs in its results from that of the winter. Also the effect of the different methods of pruning, and how it must be conducted to regulate the development of the tree.

Propagating is an interesting subject, showing what is meant by, and the use of layering; the rules that should be followed in rooting cuttings; the objects in view during the process of budding and grafting, and how the operation should be performed, and to what extent scion and stock influence each other.

The theory of watering shows why special attention should be paid to this operation, after which follows an exhaustive chapter on the flower, showing of what parts it consists, how single and double blooms are developed, and how a gardener can determine such development. The formation of fruits and seeds are also explained, and the conditions governing their production elucidated. In short the book is extremely interesting and very instructive. The following extract will indicate its character:—

#### HOW SHOULD ROOTS BE TREATED IN TRANSPLANTING?

"In the treatment of the roots of our cultivated plants we must first consider what part the root plays in the economy of the plant; and

secondly, whether it is of economic value for us. In the case of annuals, it is the rapidly growing absorptive and fixing organ; in perennials, besides absorbing the water contained in the soil, it serves also partially as a storehouse for reserve material, which the plant wishes to keep for the next vegetative period. In fleshy or tuberous roots, the storage function lasts for the greater portion of the life of the plant.

"Its chief function is as an organ of absorption for the nutritive solutions of the soil. It is self-evident that, other things being equal, the development of the upper portions of the plant, especially of the assimilating leaves, will depend upon the amount of nutritive substances which are absorbed. Conversely, the greater development of the leaves will result in a greater production of organic matter (assimilated substance), and, therefore, more of this plastic matter will reach the root system, and supply it with the means for producing new ramifications.

"The above-mentioned reciprocity must always be taken into account. If sickly plants with few leaves, or no leaves at all, are able to form new roots, and if, on the other hand, plants with feeble or damaged roots are able to produce new leaves, it is obvious that such a growth must take place at the expense of reserve material which is stored up in the main axis of the plant.

"In the treatment of plants which are restoring their root system by the production of accessory roots, the first rule is to so reduce the work of the leaves that it is in harmony with the activity of the roots.

"This rule is not confined to pot plants, but applies equally to plants grown in the open. The former may be placed during the period of root development in close damp houses or frames, so that the amount of their transpiration is reduced, and, therefore, corresponds with the reduced absorption of the root system.

"In trees and bushes which are transplanted the root system is always injured; the most apparent injury is the absence of the root tips and of the absorptive region immediately behind them. In the case of such a reduction of the absorptive root tips, it is evident that the plant would possess too large an amount of foliage if all the branches which had been formed were left intact. How can the root system, which has been damaged and cut in taking it out of the soil, absorb sufficient water for the full development of all its leaves? However much we may water the root, it will be of little avail; it may even be injurious to the plant, as the saturation of the soil with water may cause decay to set in at the cut ends. We must emphatically contradict the view which is still held and acted upon by some, that in transplanting trees and bushes the branches should be left unpruned.

"Transplanted woody plants must have their crowns reduced. It is only a question as to how the pruning should take place, so as to assist as much as possible the speedy formation of new roots. If we assume the roots to be properly pruned, the production of adventitious roots depends upon the excess of food substance formed in the leaves over their consumption. This excess will find its way down the stem into the root system. Again, other things being equal, the amount of assimilated food matter available for the roots will depend upon the rapidity of development of, and upon the amount of work done by, the foliage. The more rapidly, therefore, we can produce a large number of actively functioning leaves, the sooner will the stem be in a position to pass down material for the formation of new roots.

"But with regard to a rapid and strong development of leaf surface the several buds of a branch behave very differently, and we may take it as a rule that the uppermost buds of every branch are the first to develop and produce the largest amount of leaf surface. We must, therefore, leave intact some branches, reducing the intervening branches to one-half or one-third of their length, according to the amount of damage of the root system. In this way we secure the development of a number of leaves at the ordinary time, and consequently a certain amount of new assimilated food substance. For these few branches the amount of sap absorbed is quite sufficient, and the development of adventitious roots begins near the cut ends of the rootlets before the buds of the pruned branches, which only form a small amount of leaf surface, have begun to open. The absorptive organs will, therefore, have increased in proportion to the new leaf surface. The method of 'partial pruning' deserves the preference for transplanted trees and bushes."

### ARGON IN PLANTS.

I AM indebted to Mr. G. Abbey for the trouble he has taken (page 412) in replying to my query on page 388, *re* the above subject. In the original article on "Plant-forming Elements," we were informed that "argon enters into the composition of plants;" the fact stated by Mr. G. Abbey—namely, that argon is present in plants, can only be proved by experiments similar to those carried out by Professor Ramsey, and as he failed to obtain it, we must either suppose that Mr. Abbey has been more successful than the learned professor, or it is merely an assumption on his part.

The information given in the first part of Mr. Abbey's reply is simply a repetition of the statement made by the discoverers before the Royal Society. His statement respecting the discovery of hydrogen and the composition of water by Cavendish, Scheel's observation that a mixture of hydrogen and oxygen will explode, and also the very remarkable statement that "ozone . . . is due to the union of oxygen with phosphorus" are interesting, but I fail to see that this is an answer to my question. Anyone with the most elementary knowledge of chemistry would not expect to find ozone in the vicinity of manure heaps, and are perfectly familiar with the properties of nitrogen. This is, however,

begging the question. Mr. Abbey has made a definite statement that "argon is found in plants." Professor Ramsey says that up to the present time it has not been found, and he has carried out experiments to prove the fact. Mr. Abbey says, "Surely we ought to be satisfied with . . . Professor Ramsey's statement." Quite so, for we shall then accept the fact as true that "argon has not been found in plants or animals." Mr. Abbey says, "Surely I had authority for my negative statement." Yes, I had the words of Professor Ramsey's statement "that argon was not yet found in plants," and I considered I ought to accept that as true until it could be proved by experiments to be not so.

I asked Mr. Abbey on page 388 if he would tell us something more about this newly discovered element, doubting not he would be able to do so, but on reading his reply I must own that I failed to find anything which proved that argon was present in plants. Mr. G. Abbey says, "All chemists acknowledge that there is some unrecognised element present in the nitrogen as derived from air, plant, and animal analysis, and that element as regards air has been shown by Professor Ramsey to be argon." Then why could not Professor Ramsey get argon from the nitrogen derived from plants and animals by the same means that he got it from the air? In conclusion, I wish to say when reading the article on "Plant-forming Elements," I was, no doubt, like many other readers of your paper, interested to find that the element argon entered into the composition of plants, for there is always something interesting about a new thing, but I was very disappointed to find nothing further mentioned in the article named, hence my inquiry in the reply to which I cannot find any facts to uphold the statement that "argon enters into the composition of plants."

Mr. G. Abbey quotes that "plants in the first instance lived in an atmosphere of nitrogen," and yet he stated on page 332, "plants cannot live if confined in an atmosphere of pure nitrogen." Which is correct? I should like to say more in connection with the primary atmosphere, but I am afraid it would be going outside the question.—W. DYKE, *Turnford, Herts.*

#### LEPTOSPERMUM BULLATUM.

THE correspondent who inquires after this plant will find it very charming. It is hardwooded, and will grow freely in any ordinary glass structure and bloom most profusely. The flowers (fig. 73) are pure white, and so abundantly are they produced that in some instances the narrow dark green leaves can scarcely be seen. This *Leptospermum* grows quickly in a compost of peat, sand, and light turfy soil, the only special care it needs being good drainage and judicious watering.

#### LIVERPOOL NOTES.

##### NEW PARK FOR WAVERTREE.

FOR many months past a large army of workmen has been employed in draining and levelling the large piece of land adjoining the L. and N.W. Railway embankment at Wavertree, in all over 100 acres. The work has been done in no stinted manner, every precaution being used to set it out to the best advantage. This part of the work being completed, new roads were cut, forest trees planted, handsome stone entrances erected, such as we had not in Liverpool, and all cottage property in the immediate neighbourhood put in thorough repair.

Speculation was rife as to what use the ground was to be put, also the name or names of those who were paying for the work, but all to no purpose, and so for months what was known as "The Wavertree Mystery," was kept a profound secret until the last meeting of the Liverpool Council, when Mr. Rhind, the Surveyor in charge of the ground, offered on behalf of an anonymous donor, the whole of the 108 acres to be used as a public park and playground for the people of Wavertree, with cottage property likely to bring a yearly income of over £400, the latter to be given towards the maintenance of the park.

Needless to say the magnificent gift was unanimously accepted by the Lord Mayor and the Council. A meeting of the Parks and Gardens Committee was held on Wednesday 8th, when much gratitude was expressed for the liberality displayed by the generous donor, whose gift to the city by the presentation amounts to between £80,000 and £90,000. Of the park itself, the one aim seems to have been to provide the greatest amount of space for the people without sacrificing it in any way to useless ornamentation.

This, with the handsome gift of the new conservatory in Sefton Park by Mr. Yates Thompson is sufficient proof that public spirit is not yet dead as regards Liverpool. The work of erection of the conservatory is being rapidly pushed forward by Messrs. Mackenzie & Moncur of Edinburgh, and the Committee felt that in consideration of two such splendid gifts in one season that there ought to be more than a formal opening. And so the name of the donor of the Wavertree Park remains a mystery still; but he can rest assured that, although his name may be hidden, he has conferred a countless treasure to hundreds of poor people who think of the true spirit in which it is given.

##### STRAWBERRIES AND AMARYLLIS AT KNOWSLEY HALL.

Never at any time has it been my good fortune to see such a splendid crop of Strawberries in pots as I saw at Knowsley Hall recently. La Grosse Sucrée, Keen's Seedling, and Royal Sovereign were the varieties grown, the former showing at a glance how useful it is for early work,

whilst the latter is one of the greatest gains we have had for years. These two are to be grown for early work alone, and Mr. Doe has good reason to be satisfied with the choice he has made. Before leaving them I may remark that they were from runners laid in from the previous season, potted in 4½-inch, and transferred to 6-inch pots. The thought strikes one of the time and trouble that could be saved if when cleaning the beds, after the fruit is gathered, a few runners of each kind were laid in, how much easier would be the work of potting, instead of having to trample between rows already laden with fruit to layer the season's stock.

Amaryllis, too, are a great feature, the late respected head gardener, Mr. F. Harrison, who is now enjoying honourable retirement, having for years made them a special study. Mr. Doe is fully alive to their merits for many purposes of decoration, and is carrying on the good system of culture which has made Amaryllis at Knowsley famous in the past, and which will maintain the standard in the future. There were about 800 in bloom at the time of my visit.

#### TWO USEFUL SPIRÆAS.

Perhaps amongst the numerous flowers that have helped to adorn our conservatory for many weeks past none has come in for a greater

FIG. 73.—LEPTOSPERMUM BULLATUM.

share of attention than *Spiræas astilboides* and *compacta multiflora*. The former with its long slender feathery spikes of purest white blooms is invaluable either for conservatory work, cutting, or house decoration, its foliage being so distinct. *Compacta multiflora* I grew for the first time last season, a second trial convincing me that it is indispensable in every way. We have had several plants which looked almost like dwarf *Celosias*, so beautiful were the spikes. Though not so pure as *japonica*, many of the single spikes will yield almost as much flower as could be got from a medium-sized clump of *japonica*. For forcing, too, they are everything to be desired.

#### A PRETTY COMBINATION.

Too often, I fear, we overlook the beauty derived from some of the easier grown flowers and their adaptability for harmonious blending from a decorative point of view. In looking over my notebook I came across the following:—"Bouquet in a florist's shop in town, Michaelmas Daisy var. *amellus bessarabicus* and Marguerite Rêve d'Or—a pretty combination." Yes, as I write, I fancy I can see it before me; the rich lilac purple of the Aster adding more lustre to the golden Marguerite, with tiny bits of *Asparagus plumosus* peeping here and there. It was all so simple, yet how beautiful, with no hothouse

accommodation to bring them to perfection, for either will grow and flower profusely during the summer. As the present time is not too late to buy plants, readers of this might do worse than invest in a few of each.—R. P. R.

### ROYAL BOTANIC SOCIETY.

UNDER favourable weather the first summer show of this Society was held at Regent's Park on Wednesday last. The exhibits, instead of being staged in the orthodox style so often seen, were pleasingly dotted about on mounds in a large tent. In the competitive portion the exhibits were but few, many of the classes being entirely empty. The miscellaneous exhibits of nurserymen and others were numerous and varied, and added much to the beauty of the show, some of the groups of Roses and mixed plants being exceptionally fine.

Mr. T. S. Ware, Tottenham, was first for a group of hardy herbaceous plants, which consisted chiefly of *Doronicum Clusi*, *Primula Sieboldi*, *Saxifraga pyramidalis*, *Alyssum saxatile compactum*, *Spiraea japonica nana compacta*, *Spiraea palmata*, *Phlox canadensis*, *Pink Her Majesty*, *Cypripedium calceolus* and *pubescens*, *Saracenia flava*, and others. Messrs. Paul & Sons, Cheshunt, were second with a collection neither so fine or varied as the former.

Mr. T. S. Ware was also first for group of tuberous-rooted Begonias, the plants being well grown and crowned with fine flowers. Amongst many others were Victory, Rosebud, Princess May, Challenger, Samuel Pope, Miss Dora Richards, Mr. John Fowler, Baroda, Bexley Gem, Novelty, Leviathan, Viscountess Cranbrook, and Miss Dolly Fell. Mr. C. Turner, Slough, was a good first for collection of Pelargoniums, the plants being large and thickly bloomed. The chief varieties were Sultana, Martial, Maid of Honour, Lady Isabel, Princess Teck, Joe, Ellen Beck, Mystery, The Shah, Spotted Beauty, Fanny Gair, Rosetta, Purity, Rosy Morn, Symmetry, Magpie, and Fireball. Mr. G. Bond, gardener to S. F. Fisher, Esq., Streatham, was first for a group of Gloxinias, the second prize falling to Mr. R. Scott, gardener to Miss Foster, The Holmes, Regent's Park.
