## TO OUR READERS.

---

WHEN we penned our few words of greeting to readers and writers on the completion of our half-yearly volume last June, we had to deplore many and great losses to Strawberries and other crops by a memorable frost which had recently occurred; but we had also to record, as if in compensation, fields and gardens full of verdure and Roses unfolding for the shows. Generous showers had followed the frost, and the wounds it caused healed more quickly than at one time was thought possible.

We have not, at the close of another year from then, to note a case of history repeating itself. We had, it is true, a wave of cold in the early part of May; but though it did some damage, it did still more good by holding in check advancing vegetation, as well as in preventing the increase of insect enemies just emerging for their work of destruction.

Let one instance of the "value" of the keen easterly gale be recorded. The summer-like days preceding it brought out a horde of caterpillars in a plantation of Gooseberries. In forty-eight hours—estimating the amount expended in labour in combating the enemy, and the destruction it wrought—the loss incurred was computed at £100. At the critical juncture came the rushing arctic wave, and in another forty-eight hours not a caterpillar could be found. The gain to the cultivator was not less than £500, and probably very much more, for he was enabled to sell 2000 bushels of fruit that bid fair to cease swelling, and to shrivel on the branches. That was *his* compensation, afforded in a natural way by the bitter frost wind which he at first deplored as such an unfortunate visitation. This one case is large enough, and definite enough, to show that out of what may be regarded at the time as a great misfortune good may come. Let no one, then, be disheartened at the moment by a temporary check, as impediments may in reality be "blessings in disguise."

After the "rest" that vegetation received, first in February and then in May, followed by unclouded sun, the advance of the Roses was rapid—too rapid for many southern growers to exhibit the most magnificent blooms at the shows where they have been hoping to win high honours, and this year they would almost seem to stand at a disadvantage against growers in the cooler north, where fields and gardens are so full of verdure. Still, it is little short of marvellous to note how well in past years men of ability and resource have triumphed under adverse conditions; and we will hope that all who strive with a zeal that is admirable will have a full share of the honours in the campaign which has already commenced—the absorbing and delightful tournaments of the Rose.

Equally strong is our desire that success will attend the efforts of all—gardeners and amateurs—who are seeking to obtain it in other departments of gardening; and if we can be helpful by the help of others who are so able and willing to aid, we shall be thankful, for to be *useful* in the wide and important domain embodied in its title has ever been the object of the *Journal of Horticulture*.

INDEX.

- ABBOT, J. D., presentation to, 9  
 Acacia ovata, 237  
 Acineta Humboldtii, 476  
 Address, new year's, 1  
 Africa, British Central, climate and productions, 351  
 Agathæa coelestis, 345  
 Age, preparing for old, 327  
 Agriculture, technical education in, 30; Royal Commission on, 336  
 Allamanda fruticosa, 30, 48  
 Alpine flowers—making and planting rockeries, 224, 247, 315; among the, 420  
 Amaryllises, putting, 41; Mrs. Montefiore, 236; A. Prince Edward, 236; at Chelsea, 317; not satisfactory, 395  
 Amateur Gardeners' Association, National, 32  
 Amelanchier florida, 475  
 Ammoniacal liquor, 107  
 Anderson, death of Mr. C., 73  
 Anemone patens ochroleuca, 543  
 Anemones, the Aldborough, 271; bianca, 362; pulsatilla, 404  
 Augæum fespipedale, 223; A. eoumenum, 224  
 Annals for summer bedding, 180  
 Anona reticulata (Custard Apple), 175  
 Anthracite coal, 174  
 Aphides, jotting on, 13  
 Appeal courts *versus* judges, 56  
 Apples, pruning, 21; too many, 29; heavy, 31; heavy, four silver medals for one dish, 57; scab, prevention of, 74; Burr-Knot, 98; and Pears, reduction of varieties of, 170; Roundway Magnum Bonum, 172; cooking, 226; marketing, a hint from America, 413; blossom, 455; flies from trees, 483; and stocks, 475, 498, 520, 539  
 Apple scab, petrolcum for, 337  
 Apricots, pruning, 124  
 Aquatic house at Glasnevin, the, 187  
 Argou, 412, 434, 435  
 Asclepias nivea, 312  
 Ash and the Oak, the, 428  
 Asparagus, 135; raising plants, 218; and Sea-kale, salt for, 416; in the Vale of Evesham, 427  
 Asters in pots, 127  
 Atmospheric moisture, 492  
 Auricula and Primula Society southern show, 367  
 Auricula, 375; northern show, 391; notes on, 544  
 Avenue planting, 221  
 A woman's thoughts on woman's work, 93  
 Azaleas, 114, 39, 110; John Weathers, 236; after flowering, 534  
 BACHELOR'S BUTTONS, 403  
 Back walls of vinerias, plants for, 178  
 Baines, the late Mr. T., 294  
 Banana fruits ripening, 152  
 Baskets, ornamental, 58  
 Beans, growing for show, 232; Kidney, forcing, 487  
 Bedding, spring, difficulties of, the, 225; winter, 274, 291  
 Bees—notes on, 19, 40, 61, 106, 193, 240, 394, 553, 569; a retrospect, 19; sea-onabe hints, 19, 40, 174, 262, 282, 324, 369, 415, 439, 464, 507, 570; hints for 1895, 40; hunger swarms, 40; the weather, 61, 126, 151, 174, 369; in brood, 61; enemies of bees, 61; repairs and improvements, 83; rearing queens, 84, 126; marketing honey, 126; four brood, 151, 440; looking forward, 151; useful appliances, 152, 240; apiarian notes, 196; prospects of 1895, 196; notes on wintering, 217; varieties, 240, 369; superstition in bee-keeping, 240; young bees, 234; fastening comb foundation, 232; the apiary, 282, 324, 483; unsatisfactory, 282, 348; future preparations, 302; straw skep *versus* frame hives, 302; youthful queens, 324; the season, in prospective, 347; flowers for, 394; fertilising Bees, 404; fertilising flowers, 429; strong swarms, 462; Pnic *versus* British, 462; covers for hives, 462; chloric dropical fever, 455; a retrospect, 456; swarming, 507; prevention of swarming, 508; ventilating floor, 530  
 Beet es, gold coloured, 530; on Rose and Apple, 554  
 Begonias, raising, 83, 486; in iron-roots for bedding, 175, 349; winter flowering, 373; Samuel Pope, 520  
 Belvoir Castle, spring garden, 482  
 Ben-bamia fragifera, 213  
 Birkenhead and District Gardeners' Association, 47  
 Birmingham, a visit to, 515, 533  
 Birmingham Gardeners' Mutual Improvement Society, 333  
 Birds, where do they go, 9  
 Bl. grub, 493  
 B. note, Mr. R. D., and his critics, 59  
 Bonæa Sch. öleriana, 287  
 Bonæa, notes on, 62; the use of, 107  
 Books, second-hand, 62; review of Sorauer's "Physiology of Plants," 434  
 Border, herbaceous, the, 32  
 Boronia heterophylla, 414  
 Bossæa tenuicaulis, 433  
 Botanic (Royal) Society, gardens of, 29; spring show, 299; Regents' Park Gardens, 274; second spring show, 366; summer show, 436; Floral Fête, 501  
 "Botanical Magazine," the, 94  
 "Botanist's Illustrated Pocket Book," the, 293  
 Bothnia, 330; reading, 376; writing, 377; drawing, 399; 400; languages, habits, 422, 453  
 Brassica Lawrenceana, 275, 287, 331, 353  
 Brassica tribe, insects attacking the stems and roots of, 554  
 Broomhead, Mr. M. T., death of, 115  
 Brussels Sprouts, 232  
 Bulbs, the flowering of, 335  
 Burlingtonia fragrans, 331  
 Butterflies, spring, 405  
 Butter, tainted, 336  
 CABBAGES—a lucky escape, 228  
 Cacti treatment, 115  
 Calanthes, Veitchi at Hook's Nest, 67; Veitchi, 157; and their culture, 247, 275  
 Calceolarias, herbaceous, 92  
 Calochortus Benthami, 549  
 Camellias, buds falling, 127; in tubs, 175; leaves spotted, 348; reticulata, 337, 358; after flowering, 554  
 Campanula grandiflora pumila, 125  
 Carbolic acid and eelworms, 21  
 Carbon tubs from electric lights, 29  
 Carnoons, culture of, 240  
 Carnations and Picotees, 543  
 Carnations, ru tin, 161; notes, 257, 356; border, 369; tree, rooting, 432  
 Carrots and radishes, 61  
 Carter, Mr. John, death of, 7  
 Casasetum imperiale, 25  
 Catepillar, on Lime trees, 283; protrusion of, 448  
 Cattleyas, guttata Prunzi, 10; and Lænas, watering, 62; Triana culture, 67; P. c. valliana magifica, 235; Perivaliana, 307; intermedia, 331; Lawrenceana, 331; citrina, 339; C. Triana Princess Beatrix, 339; C. Mendell, 339; Mendell, Princess of Wales, 452; treatment of, 455; gigas Sandersæ, 544  
 Cauliflowers, early, 133; growing, 232  
 Celery for exhibition, 310  
 Celmisia spectabilis, 533  
 Case after a convict, a, 49  
 Check to vegetation in May, the, 443  
 Cherries, Morello, on walls, 33  
 Cherry house, the, 368  
 Chevening Park, Sevenoaks, 336  
 Chickweed and rheumatism, 133  
 Chimonanthus fragrans, 84  
 Chinese sacred Lines, 105  
 Chiswick Gardens, 500  
 Chrysanthemums—Bride of Maidenhead, 12; lessons of the past sea on, 12; Japanese up to date, M. Molneux's analysis, 23, 38; the best thirty-six, 24; twenty-four, 58; twelve 5; Year Book, 19, 120, 163, 190, 212, 233, 297; Princess Victoria, 69, 100; election of new Japanese, 70; election of decorative varieties, 70; fertilisation of, 78, 121, 139, 163; National Society, 100, 233; Committee meetings, 163; M. n. de R. y-Dellet, 100; Sheffield Society

- CHRYSANTHEMUMS—continued.  
 190, 120, Japanese up to date—a critique 100; Madame Desgrange, 106; Rugby show, 120; Coventry snow, 120; a plea for the Ancient-flowered sorts, 120, 139, 168; Japanese decorative varieties—Princess Blanche, 120; Viscountess Hambl-don, 120; new varieties, 139; L. Canning, 139; looking ahead, 139; nomenclature at shows, 168; Japanese, audit, 190; National Society's annual general meeting, 190; decorative, 233, 311; Primrose Hill Chrysanthemum Society, 233; early flowering border, 277; cultural jottings, 297; an earwig trap, 311; the National Chrysanthemum Society's Jubilee exhibition, 311; baffling earwigs, 311, 363; nomenclature, 363; short notes from America, 363; late flowering, 387; hairy, 387; new for 1895, 387; the Chrysanthemum in art, 387; in vases, 410; late-flowering varieties, 410; hairy sorts, 410; new Anemones, 410; an American Chrysanthemum annual, 410, 430; Japanese nomenclature, 432; Italian, 432; the oldest variety, 433; hairy sorts, 432; the Imperial Chrysanthemum show, 440; an April show, 483; gnats destroying, 487; cutting down, 508; distribution of new, 520; new from Japan, 520; annual outing of the N.C.S., 520; Mrs M. M. Johnson, 550; in Australia, 550; recent, 550; American, 550; Madame Lucien Chauvé, 550  
 Chemical terms, 197  
 Cider Makers, National Association of, 229  
 Cider making, 403  
 Cinerarias, Picotee-edged, 312  
 Cissus discolor, 167  
 Clematis montana, 498  
 Cleome neptaphylla, 79  
 Clerodendrons, three good, 212; flowers falling, 273, 293  
 Clethra alnifolia, 273  
 Cnaphaloxanthus Daupieri, 335  
 Cilyias and Caladiums (Ling's), 393  
 Cockchafer gnats, 81  
 Cockroaches, 318  
 Cockscow culture, 153  
 Cologne cristata, culture of, 45; flaccida, 130; lamellata, 223; pandurata, 377  
 Cold in May, the, 413  
 Collins, Mr. Char es, death of, 5; the late, 45; fund for the late, 95  
 Columbine, a good white, 473  
 Confusion in gardens, 183  
 Congested house, 177  
 Conservator, what is a, 394  
 Coreopsis grandiflora, 433  
 Corner, a quiet, 430  
 Corn salao, 297  
 Corrosive sublimate, 41, 303  
 County Council superannuation scheme, 327  
 Court of appeal, proposed, 34  
 Covent Garden, foreign flower market at, 29

- Crops, constituents, 348; crowding, thinning, and assisting, 467  
 Crowley, Mrs. P., death of, 496  
 Crowea saligna major, 57  
 Crystal Palace shows, 183, 258  
 Cucumbers and Melons, raising and growing, 82  
 Cucumbers, 301; growing, 239; clubbing, 241; plant damping off, 263; phenyle for, 282, 324; young leaves turning yellow, 283; plants and eelworm, 303; profitable culture of, 308; about, 358, 439; trials of, 458; plants stationary, 508; unsatisfactory, 509  
 Currant (Black) enemy, Phyllobius calearatus, 74  
 Castard Apple culture, 175  
 Cuttings, striking or rooting, 404  
 Cyclamens, at the Aigburth Nursery, 38; flowers deformed, 197; culture of, 247; at Fulmer, 342; disbudbing, 394; failing, 395  
 Cymidium eburneo-Lowianum superbum, 157  
 Cyripediums—Leannum, 10; awandnum, 10; niveum, 25; niveum and chalk, 67; Mrs. Fred Hardy, 111; Godschlannum, 223; C. Fowlerianum, 236; Chamberlainianum, 452; bellalulum album, 513  
 DAFFODILS as pot plants, 182; amongst the, 188  
 Dahlias, notes on, 225; twelve Cactus, 263; twenty-four show, 263; analysis, Mr. E. Mawley's, 265; single, 471  
 Daisies, Ox-eye, 17  
 Daphne indica, culture of, 193  
 Dean, Mr. Wm., death of, 270, 296  
 Dear old Journal, 136  
 Delphiniums, about, 32; culture of, 341  
 Dendrobiums, noble, 10, 210; crassinode Bergerianum, 111; D. aggregatum, 112; speciosissimum, 211; capillipes, 202; Amsworthii, 223; D. Cassiope Ashwoth's variety, 236; D. Apolo grandiflora, 236; D. eadsum v. rginate, 236; A. olog andiflora, 245; pulcherrimum, 353; D. noble in baskets, 353; propagating, 377; D. Cambridgeanum, 377; Waralannum, Baron Schröder's variety, 454; treatment of, 455; D. musure, 564  
 Desmodium penniniflorum, 15  
 Devon and Exeter Gardeners' Mutual Improvement Association, 31  
 Dictamnus Fraxinella, 32

## NEW YEAR'S ADDRESS.

I WAS visiting in a distant part of my parish last week when I suddenly found myself in the midst of a stag hunt; my mare, which is not venerable, but what the dealers call "aged," began to sniff, snort, and plunge, and although I believe she is guiltless of ever having been in the hunting field, seemed as if she would like to rush into the fray. She, however, very soon cooled down and went along at the steady pace befitting a country parson's horse. So when I was told the other day (notwithstanding my suggestion that they should put the matter into a younger and fresher hand) that I was wanted to write the New Year's address, I felt as if somewhat of the old fire was in me; but, alas! I come down from those heights, and if the readers find me going on in the old steady pace they must lay the blame on my imperious master, the Doctor, who says I *must* go on. It is the tendency of advanced years to take a somewhat gloomy view of events; Lord Beaconsfield used to say "old age is a regret," but I am thankful to say that I am no pessimist; I do not think the days past were better than our own, and I am sure, so far as horticulture is concerned, we have never had such wealths of beauty to cheer us as in this last decade of the nineteenth century. In every branch of gardening there is continued progress, and if in some cases from year to year it appears slight, it is because we have attained so near to perfection there is little space for improvement left. All parts of our globe are now laid under contribution, and our plant collectors will soon find themselves in the position of Alexander the Great as he stood on the Indus and sighed that he had no more worlds to conquer.

But in dealing with horticultural matters one must, of course, allude to the centre of all scientific and practical gardening in England—the Royal Horticultural Society. I need hardly say that under its present able management it has fulfilled its mission. The most regrettable point connected with it has been the long and serious illness of its able, courteous, and indefatigable Secretary—the Rev. W. Wilks. All who know how much the Society is indebted to him will feel that no greater calamity could happen to it than his enforced retirement; and I am thankful to be able to say that the prospect of his being able to continue at his post is assured to us, and we may hope that the use of that famous voice that he had may be quite restored to him.

So far as the exhibitions of the Society have been concerned, the Temple Show was remarkable in extent, variety, and beauty; a magnificent collection of plants was once more brought together; it was opened under Royal auspices, as His Royal Highness the Duke of York attended on the first day, and it was a great financial success. In another department the Society made a new departure—namely, that of holding a great autumn fruit exhibition at the Crystal Palace. It was perhaps not a favourable year for the commencement of such an enterprise, for although there was a bountiful yield of Pears, Apples were a very irregular crop; still there was a magnificent display, and much discussion was originated on the question, "Does fruit-growing pay?" No doubt an immense stimulus has been given to the cultivation of fruit in this country, and provided people do not expect too much, substantial good must result from a more intelligent and extended culture of Pears and Apples. The usual fortnightly meetings have been most interesting, and afforded the opportunity

for raisers of new varieties and introducers of new plants to bring them under the notice of the public. Alas! I fear that this last word is a misnomer, for anything more disheartening than the attendance at the Drill Hall could not possibly be conceived. Beside the Committees one sees about twenty or thirty persons in attendance; even those Fellows who live in London do not take the trouble to attend, and yet it is no exaggeration to say that there are opportunities for obtaining a sight of all the newest and best productions in horticulture which no other place can give.

There has not been much alteration in fashion with regard to those flowers most in favour. Orchids still hold the pre-eminence amongst those favoured ones who have no need to consider too closely their expenditure in these matters, while for us commoner people the Rose, Carnation, Dahlia, Chrysanthemum, and Begonias are still the most popular plants. The extent to which new flowers and plants generally are brought forward may be gathered from the fact that nearly 600 certificates were granted in 1894, and one may perhaps ask doubtingly whereunto this will grow. Who, for instance, will give a place to the eighty-one Chrysanthemums which have been certificated? or will the twenty-six Dahlias, many of which were of the Cactus section, find a permanent place in the garden? or will they be elbowed out by newer varieties in 1895? With regard to the Carnations, most of them are of the border varieties, and the liberality with which Mr. Martin R. Smith has distributed his carefully hybridised seed amongst the members of the National Carnation and Picotee Society will perhaps lead most growers of these popular flowers to wait and see what their own plants produce. Of the 120 seeds kindly sent to me by Mr. Smith not one has failed, and having now that number of "stocky" plants I may cheerfully await their blooming, and not encumber myself with others which may not be anything better. It may surprise many to find that twenty-six Begonias obtained certificates, since so many persons are contented with plants raised from seed after the manner of Cinerarias and Calceolarias. The new section of Chrysanthemums of which Mrs. Alpheus Hardy was the forerunner has had the addition of new flowers, such as Hairy Wonder and Mrs. W. J. Godfrey, and just as the Chinaman has been bowled over by the Japs in the far East, so for some years have the Chinese incurved varieties given way to the Japanese; but during the past year several promising sorts have been added to the former section. It is noteworthy, also, that English raisers, such as Mr. Shea and Mr. Owen, have been very successful in hybridising and raising new varieties; in fact, here, as in many other plants, the difficulty will be, what shall we select for our own growth?

Recurring again to Orchids, the three groups which seem to be most favoured are Cattleyas, Odontoglossums, and Cypripediums, and to these three groups ninety-nine certificates were granted, being about one-sixth of all the certificates which have been given during the year. As far as this is evidenced there is no diminution in the rage for Orchids and the desire for novelties. There are two plants which, though not certificated this year, were much better shown than before, and are likely to be very extensively grown; these are *Lilium Henryi*, the beautiful yellow speciosum from North China, and *Richardia Pentlandi*, the beautiful yellow Arum from South Africa; the former robust and perfectly hardy, the latter requiring some care to grow it successfully in a greenhouse.

With regard to the general progress of horticulture and the Societies by which its interests are promoted, there can be no doubt that the past season has been a most trying one in many cases. The depression which has now spread, as most people foresaw it would, from the agricultural to other branches of industry in our country, has been one cause, while the wet and ungenial summer (if summer it may be called) has upset the calculations and reversed the balance-sheet of many a Society.

Those special Societies which are connected with the metropolis and are not entirely dependent upon their own resources have fared fairly well. The Chrysanthemum, Rose, Carnation, and Dahlia Societies came out of the ordeal unharmed; but throughout the country many are in an enfeebled state, and of these not a few will probably succumb. The general taste for and love of plants have, however, in no way diminished, and the enormous supply of cut flowers to Covent Garden Market, which was so well shown in the able paper read by Mr. Assbee before the Horticultural Club, evidences an ever-increasing demand and a consequently ever-increasing supply; and this, not as some people imagine, from abroad, but from our own islands. And though it is to be hoped that we shall never equal the extravagance of the old Romans in these matters, and although perhaps in the case of flowers for funerals the practice has run rather wild, we may all hail with satisfaction the continuance of the custom so beautiful and tasteful as that of the use of cut flowers.

A season in greater contrast to that of 1893 it was impossible to conceive. It disappointed the hopes both of the agriculturist and the horticulturist. The hopes of the former were frustrated by the heavy rains of July, August, and September, and of the latter by the sharp frosts of May. The rosarians had to tell their sad tale of loss and disappointment, and the continued wet following the drought of 1893 revealed to us many a gap in our gardens. Alpines and many herbaceous plants suffered extensively; many plants were out of character and flowered at the wrong time, and I think we may safely say that any which withstood these two consecutive seasons may be fairly considered as hardy, especially if by hardiness we understand not merely the power of resisting frost, but those many atmospheric changes to which our variable climate treats us. We have learned some of our best lessons in combating these difficulties, for in horticulture, as in other things, "sweet are the uses of adversity," and yet there are some contingencies which we find it almost impossible to provide against. Suppose, for instance, that we had known that frost of the 20th of May was sure to come, what could the Rose grower have done to save his plants from its destructive power? and perhaps it as well that we should also learn that lesson of our impotence.

Horticultural literature still maintains its high position, and I think the venerable chief of the *Journal of Horticulture* may be congratulated on the continuance of its position, not only as a gardener's friend, but especially as the organ of the amateur. There has been no addition to the number of horticultural journals; indeed, there are now more than the most greedy reader can possibly get through week by week; but, then, as their contents are so varied each lover of his garden will be sure to find something suited to his wants. It may possibly be said that the "Index Kewensis" can hardly be regarded as pertaining to horticulture; but I think this is a mistake, for Kew has been the means of introducing amongst us many beautiful products from various quarters of the earth, and we do like to know from whence they came and when first brought under notice. The third volume has been published during the past year, and is a monument of painstaking industry of which the Editor and the Royal Gardens may both alike be proud. "The Book of the Rose," which has recently been given to the world by the Rev. A. Foster-Melliard, is a most valuable monograph which will be widely read and much appreciated, and may justly claim the title which it proudly assumes of being "The" book of the Rose. Nor can I omit noticing a charming little volume issued during the past year by my neighbour Mr. Alfred Austin, entitled, "The Garden Which I Love." Its delightful style and poetic fancy are calculated to entice many a person who has a garden to take example from the author in his love for and cultivation of hardy herbaceous plants. There is nothing in the position and surroundings of the garden of the old Manor House of Swinford which may not be found in many a country house, and which only requires the love and tender care

which have been bestowed upon this garden to make them a source of pleasure and happiness to their possessors.

To all who are interested in the welfare of the gardener, it is satisfactory to look back on the success of the two institutions which have been established for his benefit. The old and favourite institution of the Gardeners' Benevolent and its younger sister the Gardeners' Orphan Fund have both had a satisfactory year, and this is the more so because all our benevolent and philanthropic institutions are deploring the falling off of their funds. The only regrettable point in connection with these gardeners' societies is that a larger number of gardeners do not belong to them. If more of them joined they would help the societies, and the sympathy of others would be more called out.

And now one comes to the most melancholy part of the review of the past year, and calling over the death roll. Early in the year horticulturists were startled by the announcement of the deaths of two men very different in their age and position, but both keen horticulturists and both valued for their social qualities. William Ingram of Belvoir, and Walter Williams of Salisbury, the former the accomplished head gardener of Belvoir Castle, whose gardens he made famous by his keen sense of artistic beauty, and more especially by what he called his spring bedding, for which he became famous everywhere. He had spent a long life in the intelligent pursuit of his calling which he so much loved. Many had seen Mr. Williams only a few days before his death, full of the energy and hopefulness which characterised him, and could hardly believe the sad news that this vigorous young life was extinguished. During the year the deaths among prominent horticulturists have not been many, but some well known names are amongst them, such as Joseph Rust the sturdy old gardener of Lord Abergavenny, Mr. Sibray of the firm of Fisher, Holmes & Co., Sheffield, and Mr. W. H. Gower whom all Orchid and Fern lovers will mourn for, for he was continually giving the results of his experience in the gardening papers. Then followed Mr. Witherpoon, a successful self-taught gardener in Durham; and last on the roll with startling suddenness, the gentle spirit of Mr. Charles Collins of the *Journal of Horticulture* passed away.

And thus, in looking over the past, the year closes around us with its chequered stories of joy and grief, gladness and disappointment, and we have now to look forward for another year, happily not knowing what may befall us in it. But I think this I may say, that as amongst those things that have combined to lighten the burden we are all called upon to bear, gardening is with all its pleasures, has been amongst the most potent elements; I may, from my own experience, encourage all who love the same pursuits to go on in any branch of it in which their fancy may lead them. To the younger members of our craft I would especially say a word of encouragement. It is well I believe for all men, and especially young men, to have a hobby, and what hobby is more delightful or more elevating than the garden? There are so many fields in which you can bring your energies to bear, and whether it be fruits or flowers there is scope for originality and new successes. But let all be done in a reverent spirit. Do not, as the heathens did, deify Nature, and make gods and goddesses of tree and flower, but let all lead you up through Nature to Nature's God, and many of you will find when worried with the affairs of life your flowers have a lesson to teach you, and so using the words of one of the contributors of the *Journal* in a pleasant little volume which he (the Rev. D. R. Williamson) has lately published.

"Oh, Thou, that with the joyful dost rejoice,  
And sorrowest with the sorrowing—not in vain,  
Be Thou my consolation, till God's voice  
Shall call my spirit to its home again."

And so now the old fogey bids you all farewell, it is not unlikely that this is the last time he may be able to address you, and so he wishes you all to carry away with you the expression of his sincere good will. He has many friends amongst you and many corre-

spondents whom he has never seen, but to whom our common love has been a bond of sympathy; and so, being a parson, he may close with the expression of hope that you may be led through all the scenes of earthly life to look forward to that home where "The tree of life is for the healing of the nations," and so to our venerated chief and his able coadjutors and the contributors who have so much tended to keep up the character of the Journal, and to its readers, young and old, I wish a very Happy New Year.—D., Deal.

### THE STATUS OF THE TOMATO.

ONLY general acceptance can enable the Tomato to be admitted to the select circle of fruits. If in relation to its consumption we had begun with it in the same way that public taste seems tending, we should have placed it in the category of dessert fruits at the first. Unfortunately, we began by using it as a cooked vegetable, and from that low status it seems very difficult to lift it, in spite of the fact that its improvement has been so remarkable. It seems very probable that in a few years, whatsoever experts or authorities may determine, that public opinion and taste would settle the matter by including Tomatoes amongst dessert fruits, and as such admitting them to our tables. Once so full a recognition of the proper status of a Tomato be made then its exhibition status must follow suit.

The Tomato occupies an unique position amongst garden products because of its various uses. It is consumed very largely in its ripe uncooked condition as is any other fruit. It is also eaten, and largely too, as a salad, and not least it is consumed as a cooked vegetable. No wonder then if its status presents elements of uncertainty that it can never be dissociated from vegetables seems certain. Its position in that respect is too far assured, and its uses as a salad and as a cooked vegetable compel that position. But on the other hand it is in every sense as much a fruit botanically as is anything eaten, and if partaken of in a raw ripe state as are Apples and Pears, then does it seem to be just as much a fruit as are either of those, for they too are largely partaken of in a cooked form, as sauce or stewed, without in any way losing status. The question raised by Mr. Wilks is getting an old one, as it is constantly being asked, but the oftener it is asked the greater does it seem to be insured of settlement.

After all, the solution seems chiefly to lie with framers of schedules, because the matter seems to have interest only in connection with exhibition competitions. In all other respects I know of nothing to prevent persons showing or calling Tomatoes under the heading of fruit, or whatever they like. Then the framers of schedules may ignore the claims of Tomatoes to be classed as fruits altogether, and admit them and classes for them only under the head of vegetables; or they may place them under the heading of fruits, making them admissible in fruit classes only; or they may do the more reasonable thing—not only leave it quite optional with exhibitors of collections of fruits to include Tomatoes, but include one or more classes under the fruit section for the smaller fruited forms that are so handsome on the dessert table.

The setting up of a rigid *non possumus* seems to be both arbitrary and undesirable. It looks as if there were efforts made to check the use of the Tomato as an ordinary ripe raw fruit, than which nothing could be more ungenerous or ridiculous. One very special need in relation to Tomatoes now is not in the direction of prolificacy or beauty. It seems impossible to advance in either direction, although we yet may. It is in the production of higher flavour that we want to see an advance, although most good Tomatoes have in their season very agreeable flavour now. But our palates are hardly content with ordinary flavours. We are always craving for something high or piquant. Our palates have been demoralised by rich fruits, Pine Apples, Muscat Grapes, rich Pears or Apples, strongly flavoured Nectarines and Plums; also by constant use of meats and condiments and liquors. With such competition the Tomato seems almost tame and insipid, yet to a purely natural palate its soft flesh and juicy nature are delicious. It does not tempt to a feast, much less to a gorge; but it is delightfully refreshing and satisfying.

The more we bring up our children to natural tastes and habits the better they will in later life learn to appreciate the mild unstimulating flavour of Tomatoes, but if they are to be almost fed on sweets and cakes, then only will they be content in later life with fruits that have the strongest of flavours. As it is, bad are the Tomatoes that are not more pleasant eating than are myriads of Melons, yet the Melon holds a strong position in fruit classes, and is constantly found in collections. I hesitate not to say, with all respect to others' opinions, knowing from long experience how

deceptive the most beautiful looking Melons may be when cut and tasted, and how few out of the whole have real edible merit, that I should regard a pretty, well ripened dish of rather small Tomatoes at any time as preferable to a Melon that may be absolutely worthless.

I hope that the suggestion that the Tomato may be freely admitted into both sections, fruit and vegetables, at shows will soon be universally adopted.—A. D.

### GENTIANA KURROO v. BREVIDENS.

THIS plant is but of recent introduction into England, having reached us as late as the year 1892 from St. Petersburg. The specific type, *G. Kurroo*, *Pneumonanthe Kurroo* of D. n., was imported only a

FIG. 1.—GENTIANA KURROO VAR. BREVIDENS.

few years earlier in 1879 by Mr. Bull. Sir Joseph D. Hooker locates the plant in the Western Himalayas, between Garwhal westward to Kashmir, where it is described as one of the most ornamental of the local herbaceous perennials. It flourishes between the elevations of 5000 to 8000 feet, the brilliancy of the foliage, the delicate azure blue of the limbs of the corolla sprinkled in the throat of the tube with pearly white, making it a noticeable feature.

The specific name is distinctly happy, being euphonious, and perpetuating the name given it by the natives of Garwhal, to whom the plant is well known, and of medicinal use. This is due to the bitter principle present in the roots, in common with other species of the genus, though it is to be hoped with less fatal results to its existence on the Himalayan slopes than to its congeners on the European Alps, whence the species alluded are rapidly being removed by the collectors of Gentian roots for herbalists.

It is distinctly, from its dwarf spreading habit, and the brilliancy of its colouration, and the lightness and brightness of its tufted leaves, a considerable acquisition for the rockery. The flower stems lie prostrate on the ground for about half their length, varying from 4 to 8 inches, the coriaceous leaves growing from 3 to 5 inches long. Their shapes may be seen in our engraving (fig. 1) made from a plant which

flowered in the Royal Gardens, Kew, in the beginning of July. As Mr. Nicholson gives October as the month of flowering, this period probably covers a considerable part of the later half of the year.

### WHAT TO FORCE.

IN many gardens, where a continual supply of flowers has to be kept up through the winter months, the above question is one of daily growing interest. Chrysanthemums with all their beauty and increasing popularity will soon become things of the past, and attention must necessarily turn to other floral species to take their place, in order that the demand for flowers may be met. In most cases the supply of forcing bulbs, such as Hyacinths, Tulips, Lily of the Valley, and Freesias, are quite inadequate in themselves, so that flowering shrubs that will stand the strain of forcing have to be cultivated for this express purpose, and if care and economy be studied a varied and ample supply may easily be maintained.

*Deutzia gracilis* has long been a great favourite, and still claims first honours on the list of flowering plants. It can be readily forced, and blooms with the utmost freedom, its long sprays profusely covered with pure white flowers always attracting admiration. Where a large number of plants is available it is best to force them in small batches, in order that a constant supply may be insured during the winter. Many a failure in *Deutzia* cultivation is owing to the fact that the plants do not receive the care and attention due to them after the flowering period is over, a time when most forced plants have rather a hard lot.

If the *Deutzia* requires potting it should be done immediately after the flowers fade; this will encourage fresh growth. The major part of the next season's bloom depends on inducing the plants to throw up long shoots from the base; but in addition to this, all breaks from the main stems become thickly covered with bloom. The plants should, if possible, be kept in a warm house until growth is completed, and when weather permits be placed out of doors in the full glare of the sun in order that the wood may get thoroughly ripened, without which the next season's flowering will prove a failure.

*Spiræa japonica* is another useful old favourite, closely competing with the *Deutzia* in popularity. It is easily forced and grown for cut flowers or as a decorative plant, for which purpose it has few equals, the bright green foliage adding so much to its decorative qualities. The plants should be placed in a cold frame after forcing and protected from frost, and if the stock is limited and required to be increased the clump should be cut in two, and planted about a foot apart in a piece of spare ground and left for at least one winter, when they may again be taken up for forcing.

*Staphylea colchica* is one of the later additions to the forcing stock, but is so well known that comments are almost needless. The peculiar fragrance of its creamy white flowers is in itself sufficient to place it in the front rank of forcing plants. Its treatment after flowering should be similar to that of the *Deutzia*, though some gardeners advocate planting it out during the summer months. It throws up long sprays of growth after flowering, which should be slightly shortened back in order that the limited number of buds will develop better, and so throw out more substantial trusses of flower the following season.

*Azalea mollis* in a forced state throws up a profusion of bloom that is doubtless very useful, but the extreme delicacy of the flowers in a cut state and their short-lived beauty are great drawbacks to its cultivation, and where the plants are available the bright yellow *Azalea pontica* is much more useful. This forces freely, though not so rapidly as *A. mollis*, and is the sweetest of all *Azaleas*. As a cut flower it is a great favourite, for in addition to its fragrance it is very substantial and stands well in water. Careful attention should be given after flowering to encourage the young growths, and when weather permits the plants being placed out of doors they should be planted in a nursery bed consisting of peat, leaf mould, and sand, where, if judiciously managed, a supply for forcing may be continually maintained.

*Rhododendrons* form a very useful addition, especially where large supplies of cut flowers are necessary. The best variety for early forcing is *R. caucasicum roseum*, a bright rose colour, and for a later succession are *caucasicum pictum*, with fine trusses of rosy pink flowers; and *Cunningham's White*, a free flowering variety with pure white blooms. If the plants are protected until frosts are over, they may again be planted, and will suffer little or nothing from being forced.

There are many other plants in addition to those mentioned all suitable and useful for forcing, but space will not permit further reference of them at present. The keynote of success in forcing plants is careful and judicious treatment during the period immediately following their flowering.—GEO. HOLLINGWORTH, *Alton Towers*.

### HARDY FLOWER NOTES.

As we wander into the garden in these short days we are greeted with no blaze of colour. In this respect the greenhouse has certainly the advantage, as under its shelter and with its genial warmth many plants may be in flower. But although tempted for a time to admire the brightness of the denizens of the greenhouse, the heart of the one who is wedded to hardy flowers cannot stray long from the plants he cherishes, and to them he gladly turns again as they grow with the free air of heaven above and around. It is true that this air is too often chill, and that ere we may venture to leave our firesides to sally into the garden we must assume additional garments. But though the air may be unkindly, and give us only a chilly greeting, these pets of ours in the borders, and more especially on the rockeries, seem to give us a warm welcome. Mayhap it is that we know them so well that each change in their appearance is noted; that here one seems swelling into bud, and that there another is showing a faint colour through the chink which shows that the calyx begins to open. These things we love to see and to study, thinking all the while that it may be that these flowers, which, as the poet says, "enjoy the air they breathe," feel pleasure in knowing that their modest charms are recognised and minister to our enjoyment of life. Well, it may be so, for are there not "more things in heaven and earth than are dreamt of in our philosophy?" Enough, however, of these thoughts, and let us see what have called them forth and compelled their utterance. Few are the blossoms which this season yields, and of the few a large proportion have either lingered too long, or have unsuspectingly essayed to bloom before their due season. The former look unhappy, as if they missed the longer days with which they are accustomed, while the latter we view with admiration, tempered by the fear that their reign of beauty shall be but short.

Of the flowers which dally upon the stage one may mention briefly a few. Flowering through some perpendicular rockwork behind a small sunken nook devoted to *Trilliums* and a few other moisture lovers is a plant of one of the varieties of *Campanula muralis*, whose neat leaves and pretty blue flowers give us a sense of pleasure as we pass them by or stop to look at their beauty. This is a good wall plant, and useful in many positions. On the upper terrace of a rockery is a plant of *Achillea argentea*, which has a few heads of its white flowers still expanded, although not so fine as in brighter weather. Very neat is its silvery foliage also. On another rockery a number of the pretty white flowers of *Potentilla alchemilloides* are very pretty, although the leaves are getting past their best. On a level border a few seedlings of *Crocus speciosus* are in flower, their more mature companions being no longer in bloom.

In another place one or two blooms of the neat little *Colchicum umbrosum* still linger, their light purple flowers being welcome as ever. A few plants of *Godetia* still show flowers and look wonderfully well, and near them and on another border the perennial *Anthemis tinctoria* and *A. tinctoria pallida* produce their yellow Marguerite-like blooms. Here and there, too, a few other annuals, such as *Cornflowers*, *Marigolds*, and *Chrysanthemums* emulate the *Godetias*, while perennial *Chrysanthemums* remain in flower. Other stray loiterers there are, which seem unwilling to depart and give a few spikes or single blossoms. Among these may be mentioned *Veronica Lyalli*, *Lychnis diurna fl.-pl.*, and a little *Veronica* which goes under the name of *corymbiflora*, but its true specific name I have not yet ascertained, the name generally applied being only a garden one. A late-produced spike of *Oenothera Lamarckiana* has been in bud for a time, and makes one wonder if a short period of brighter weather might not induce it to expand its yellow flowers. The probabilities are not in favour of this, for a period of severe weather may arrive at any time, and this would soon shatter our visionary hopes. Like the flowers themselves we are apt to delay as we think about them, and a short notice of some which have come before their due time is perhaps more worthily due than is any praise to the laggards.

There is a pathos in the look of these precocious flowers which we cannot but feel, a wistful look which seems to express silently, yet impressively, the thought that they have come to cheer us in dark days, knowing all the time that some biting frost will bring them to premature decay. These flowers are mostly of the Primrose family, and very beautiful are they, whether *Polyanthuses*, *Cowslips*, *Oxlips*, or true *Primroses*. There are yellows of two or three shades; whites, some almost pure, and others of a creamy tint. Some, too, there are which are almost crimson in their brightness, and *Lilacs* and *Pinks* are not absent, their colours being much enhanced by the yellow centres. One which at a distance looks as if coloured to imitate a velvet of deep brown is pleasing on a rockery, and two or three *Jacks-in-the-Green* with their green ruffs remind one hopefully of the

coming of the Winter Aconite with its cheery little flowers. It seems, however, to wish to remain "dead to the world" for a little longer. Among the precocious Primulas is a plant of Siebold's Primrose, which from the middle of November has displayed a truss of flowers, that have withstood weather of a kind which would have destroyed them had it come in their due flowering season.

Crocuses, of which there are a few in flower, and which, with a little shelter and when crowded together in a clump, stand the weather better than would be believed. To some the Crocus is only beautiful when expanded, and it is only on a few days at this season that their tastes can be gratified. The writer, by close companionship with this flower, has learned that even at other times a clump of their coloured cones is full of attraction. At the time of writing this two clumps of *C. longiflorus* are nearly all that are in flower, but the lilac and yellow displayed on the outer segments of the closed flowers give a bit of welcome colour; while when open the bright lilac flowers are very beautiful, and are rendered more attractive by the scarlet anthers and yellow filament.

One can hardly understand why it is the case, but if good authorities are to be believed, the Snowdrops of November and December bloom with us earlier than in their native lands, although these are much further south. I know there are some, as true lovers of flowers as myself, who look askance on these unseasonable flowers, as they call them. I think, however, if they could only see a few in their gardens in the last months of the year, their beauty would so appeal to them that these Greek Snowdrops would no longer be looked on as aliens, but become welcome friends. Very chaste and beautiful are those now in flower in my garden—harmonies of white and green we love to see as we stroll along the garden walks.

With the passing remark that *Helleborus niger*, the Christmas Rose, and *Erica carnea* flowered before the end of December, it is needful to pen a few lines upon other features of interest, which depend not on beauty of flower, but of leaf, and are more in evidence in the rock garden than in the borders. The old wall behind one of the rockeries and the rockwork itself are marked with lichens and patches of mosses. The former are black and brown, grey of varying depth, and green of different tints, some almost orange in hue. The latter, too, are of different shades, and very beautiful with their velvet-like appearance. The hand of Nature has given us these things of beauty masked, and we have sought to rival or enhance them by our choice of these plants of larger growth with which the rock garden is furnished. Among these there are silver-greys, velvety-greys, and greys of duller tints. There are some well-nigh black and greens of all kinds, some so approaching blue or bronze that we are almost afraid to class them with the greens. Then we have variegated plants, and those which have the green of their leaves marked or zoned in different shades. Of some of these things I had intended to speak when I took up my pen, but other thoughts in connection with my theme have sprung into being, and taken too much space. There are, however, mounds of Mossy Saxifrages, as soft and velvety as the mosses themselves, and as bright in colour. There are blue-green *Acanas*, silvery encrusted Saxifrages, glaucous Sedums, grey Alyssums, and glaucous tufts of spiny Pinks. Endless, indeed, are the tints which may be seen in fresh or in withered leaf. Equally unlimited are the forms of these leaves, which are of all manner of shapes, sizes, and variety of texture. Some are round, some pointed, some ovate, some are smooth, others rough, and others again wrinkled. To tell of all these things as we see them is, indeed, an impossible task, and would weary the reader. Say not, however, that hardy flowers have no interest in winter! Skies may lower, winds be keen, and the sunlight be hidden from view, but among the plants, and only seen by those who love them, there is much to encourage. A calm delight they may give, but it is no fleeting one, and remains with us till the gloom of winter is past, and these plants now at rest have clothed themselves with blossoms of exquisite beauty.—S. ARNOTT.

#### DEATH OF MR. CHARLES COLLINS.

It is with extreme regret that we have to record in our first issue of the year the sudden death of an able, trusted, and respected member of our staff, Mr. Charles Collins. He was engaged in the preparation of the last issue of the *Journal of Horticulture* on Monday, December 24th, the pages of which were completed for press on that day, the articles having been placed in type on Saturday, in view of the Christmas holidays. Mr. Collins was in his usual health, happy and cheerful, looking forward to spending a pleasant Christmas-tide with his family. No doubt his hopes were realised on Christmas Day, the last day but one that he spent in life on earth. On the succeeding day, Wednesday, he with his wife's parents, also two young children, went

from Hornsey to Forest Gate to spend the day with a relative. On returning to the station at night he carried a child, and died as he was entering the train. He may have hastened somewhat, though he would not be likely to "rush" for the train, because he had been warned by a medical man not to do so, his (Mr. Collins') father having died from heart disease; but whether he hurried or not the exertion was too great for him, and hence this most grievous fatality. A gardener who knew our deceased coadjutor long and intimately has written to us as follows:—

"Charles Collins was a native of Hampshire (Otterbourne), and commenced his gardening career under Mr. Summers at Sandbeck Park, in the year 1880. After a stay of about three years he went to Wortley Hall, Sheffield, under Mr. Simpson; from there he went to Howick Castle, Northumberland, under Mr. Inglis. As a youth he was most energetic and painstaking, and a keen observer of everything connected with horticulture, always willing and anxious to assist in whatever was required of him. His motto was, 'Whatever thine hand findeth to do, do it with all thy might.' This he acted up to through life, and what a lesson may be learned from his life!

"He was left fatherless at an early age, and had to turn out in the world to earn his living, while having an impediment in his speech (resulting from an attack of scarlet fever) he was placed at a disadvantage when compared with many other youths. He, however, made up his mind to overcome all difficulties. During the long winter evenings he devoted many hours to study—reading, writing, drawing, and arithmetic. This was in the early days of his both life. During the summer evenings he might be seen making notes in the kitchen garden of the cropping, and of whatever might possibly be useful. After a few years' experience he was ambitious to be a journalist, and occasionally wrote for the gardening press. He learnt shorthand, and was a good verbatim reporter. He also studied French and German, so that he could decipher what was written horticulturally in either of those languages. He was ever mindful of others. The ink is scarcely dry on the letter received from him only a day or two since asking assistance with reference to a brother in the craft, and now the post brings word that the hand which wrote that letter is laid cold in death. Cut off in the prime of life, the memory of Charles Collins will be cherished by all who knew him."

We may add that Mr. J. Simpson, observing the young man's aptitude with his pen, and recognising that the defect in speech must naturally prejudice him as a gardener, advised his assistant to make himself proficient as a writer for the press. The advice was good, and followed assiduously. He eventually obtained employment under Mr. T. W. Sanders on "Amateur Gardening," acquitting himself well. Mr. Collins then passed to a position on the "Gardeners' Chronicle," by the kind and distinguished Editor of which paper he was recommended to fill a vacancy which occurred on the staff of the "Journal of Horticulture." Here, for nearly three years, he gave complete satisfaction as a reporter, paragraphist, reviser of MSS., and proof reader, while now and then, as time permitted, he would write an admirable article on a seasonable subject worthy of a prominent position over his initial of "C." He was, in a word, a true horticultural journalist. He had acquired the invaluable habit of taking pains and making his literary work as faultless as possible.

After thoughtful and persevering practice in the choice of appropriate words for the construction of sentences he developed a style of writing at once accurate and "readable"—prime essentials in press work, for no matter how valuable may be the information contained in an article it is useless for publication if not conveyed in acceptable literary guise. It is most creditable to the intelligence and care of gardeners that so many of them approach the desideratum so nearly that it is a pleasure for editors to supply the finishing touches; and we have never known a gardener who has mastered the art of imparting sound information in the most correct and agreeable way who has not benefited by the acquisition. Tedious the process may be at first to many, but every step in advance makes the next step easier, and eventually the position is won by those who persevere the same as Mr. Collins did. He habitually wrote his reports of shows quickly, fully, and accurately as he walked along by the side of the exhibits, and had only to tear the leaves out of his book, and send them to the printers, seldom any corrections being needed when in type. This is a habit that has to be acquired by all the staff reporters of the *Journal of Horticulture*, as the quickest method for getting the work out of hand and the easiest to the narrator.

Thus, as the friend of Mr. Collins suggests, "lessons may be learned from his life"—lessons in devotion to the attainment of an ideal, of diligence in duty, excellence in work, as the result of persevering endeavour, and in the end success. His work was his delight, and no man was happier in the discharge of his duties than he; and now that his promising life is ended, at the turn of thirty years, it is pleasant for all his associates in it to feel that not one unpleasant word has passed between them and he who was called so suddenly away. Mr. Collins had a charming disposition. He thought no evil, and we venture to say that no one ever heard him utter a disrespectful word towards any person. One who constantly met him at the London shows and meetings undoubtedly expresses the sentiments of many in these words in a letter to hand:—"Mr. Collins was one of the most gentle and kindly fellows I ever met, and everyone who knew him will mourn his loss most deeply." Another justly describes him as "a man of extreme kindheartedness, and though his life has been beset with illness at home he never complained."

The illness referred to in his family has been of the most serious

nature, prolonged for years, and to him most costly; and though his salary exceeded that of the great majority of head gardeners, it has only been by the exercise of extreme prudence that all domestic wants could be met. Yet he did his best to provide for the future by joining benefit societies, such as the admirable Gardeners' United Provident Society, and now his payments will be returned to his widow less the moiety due to the general sick fund; but he had not long been a member. A particular misfortune is that he was too late by a fortnight in effecting a Government (Post Office) life insurance, and only his payments can consequently be refunded. Still, he did what he could, and a few pounds are due from two or three societies. In the meantime immediate wants have been met, one warm-hearted reader of and writer in the *Journal* having sent a cheque for £10 "in case it might be useful." It is gratefully accepted by the afflicted widow, Mrs. Collins, as are a few small sums from other friends.

If there was one kind of duty more agreeable to her husband than another, it was in attending the general meetings of our charitable institutions for the purpose of reporting them and making their benefits known to the world. All the reports of the Gardeners' Royal Benevolent Institution, the Royal Gardeners' Orphan Fund, and the United Horticultural Benefit and Provident Society during recent years were from his pen.

We have said Mr. Collins was a diligent man. He had no waste moments. He was in the habit when he had five minutes to spare of taking up a number of the *Journal* as if in search of an idea and jotting down his thoughts on slips of paper—another lesson. Some he left on his table, as he evidently found no opening for them during the pressure of Chrysanthemum time. We give a few as samples—lessons from the life of one, which, so far as we know, and we speak after much reflection, was as near as can be expected in the frailties of human nature, blameless.

It appears that Mr. Collins had often when in health expressed a strong wish to rest near the parental home of his much-loved wife, and his remains were therefore interred in Manthorpe Churchyard, Grantham, on Tuesday the 1st inst., the *Journal of Horticulture* being represented by his close friend and fellow worker Mr. Horace J. Wright.

#### POSTHUMOUS NOTES.

##### LOOKING BACK.

I OBSERVE "J. B. R." some time ago bemoaned the fact that early flowering Chrysanthemums were not represented as they should have been at the Aquarium Show in September. That is so, and like your correspondent, I was disappointed with the exhibition as a whole. There were unquestionably plenty of Dahlias, rich and glowing in all their brilliancy, but of Chrysanthemums—well, the least said the better. Whilst gazing at a stand of dozen blooms, for which a first prize had been awarded, a bystander remarked, "Well, if I had been Mr. ———, I should have left those flowers at home." The blooms were certainly only third-rate in quality, but had everyone "left their flowers at home" there would have been no Chrysanthemums. This would have made matters worse than they were. But considering the hundreds of varieties of early Chrysanthemums now in cultivation, and the splendid season they have had, it is curious that they were not shown in better condition. September exhibitions are not, I fear, going to be a source of strength to the N.C.S.

##### LONDON SPARROWS.

The sparrow question appears to be like Tennyson's brook—going on for ever. "An Afflicted Suburban Amateur" is not alone in his troubles. Another suburban amateur whom I know can sympathise with your correspondent. His sparrows are as cheeky and as misbehaved as they possibly can be, so much so as to become pests. Last spring this enthusiastic amateur decided to lay his little back garden down with turf, as the sparrows will not agree with his ideas of gardening. Steps were therefore taken to sow grass seed, this being done about the end of March. But alas! the sparrows watched the operation, and immediately pounced down upon the seeds. Being determined to thwart their designs the amateur purchased fish-netting and covered the ground, but it was no use. As the seeds were germinating the sparrows swarmed on the ground, and made their way through the netting. The result was a very poor crop of grass, bare patches being more prevalent than green verdure. In May more seeds were purchased and sown, but it was only by close watching to drive away the birds that a respectable sward could be obtained. The same with my Crocus blooms, and I have even seen sparrows peck Carnation foliage all to pieces. Many times have I wished that the London sparrows were as good as Mr. Witherspoon's, but they are not, and—well, they are a nuisance.

##### APPLES—PROFIT AND LOSS.

There have been enormous crops of Apples and Pears in various parts of the country, and, strange as it may appear, some growers wished they were not so plentiful. One can hardly be surprised, however, at this when it is taken into consideration the extremely low price realised for the fruit. I saw Apples sold for 2d. and 3d. per stone of 14 lbs. in the market of a medium-sized town in Lincolnshire. One poor man informed me that he had brought about 8 stone of Apples from a distance of nine miles, and the cost of conveying himself and the fruit was 1s. Under these circumstances it will be seen that the vendor had a shilling for his trouble and day's labour. The Apples were fairly good examples of Keswick Codlins, and tons of other early

varieties were being sold in the same market. This is an instance in which it may be said that fruit-growing is not profitable, but there is another side to the picture. At Christmas last year I saw fine specimens of Bramley's Seedling sold in the same market for 3s. per stone, which appeared to please the seller greatly. The moral of this is that it is useless sending fruit to the markets when there is glut, and moreover, by growing varieties that will keep, fruit culture is a profitable investment. The experience of others on this point would be interesting.

##### HEAVY APPLES.

What is the weight of the heaviest Apple on record? The "big Gooseberry" is practically played out, but paragraphs have been going the round of the daily Press that certain growers have produced Apples of enormous size and weight this year. As announced in some previous comments of mine, Mr. Woodward of Barham Court Gardens exhibited a Peasgood's Nonesuch Apple which weighed 22 ozs. at the Agricultural Hall. Then came the announcement that Mr. Payne, gardener at Wells Palace, Somersetshire, exhibited twelve fruits of the same variety at Bath, these weighing in the aggregate 15 lbs. The largest Apple was 16 inches in circumference, and weighed 22 ozs. These were shown at the Royal Aquarium, and a silver medal was awarded for them. They were unquestionably fine Apples, being so richly coloured, and a few remarks from Mr. Payne concerning the treatment he has given his trees would doubtless be appreciated by many readers of the *Journal*. It is not everyone who can grow a dozen Apples that win two silver medals besides first prizes. But verily there is "nothing new under the sun." In the *Journal* of December 15th, 1892, page 523, it was recorded that Mr. W. Salcombe, Ticehurst, had grown in the open air a Peasgood's Nonesuch Apple which measured 16½ inches in circumference and weighed 26 ozs. The heaviest on record that I know of was shown by the late Mr. Samuel Barlow at the Guildhall show in 1890; but this fruit, which was stated to weigh 30 ozs., had been grown under glass.

##### LOOKING FORWARD.

The season has not been on the whole a salubrious one, yet many a man who has now a little time for reflection can take a retrospective view of his work with pride. The earnest worker has this year succeeded in producing a brilliant display in the flower garden, as well as excellent crops of fruit and vegetables. I do not mean to infer that there are indolent gardeners, because men who are indolent are not worthy of the name of "gardener," but rather to give a hint to young and old to be on the alert for another season. A little forethought often prevents much trouble and annoyance, and the past summer has taught lessons which every gardener who is a keen observer may turn to good account in the future. Men who win success are those who look ahead, form high ideals, and persevere.—C.

##### CLEANING VINES.

My article on the above subject (page 535 of the 13th ult.) seems to have upset "Erica's" peace of mind. I am sorry for that, as my notes were written to assist anyone in need, and not to provoke the opposition of persons following different methods. Years of observation have convinced me that the work is often carried out thoughtlessly, and that denuding Vines of bark is detrimental to their well-being, as is proved by the greater increase in the size of stems of Vines not peeled, in comparison with those treated otherwise; this is evidence that one is better nourished than the other. From the better nourished Vine we naturally look for the best results; that is why I like to see Vine rods well clothed with bark.

Vines stripped of their bark must expose the returning elaborated sap more to the varying conditions of the atmosphere than when excessive transpiration is prevented by a thick coating of outer bark. All Grape growers with whom I am acquainted who aim at "first class" excellence practise what I am advocating, and the argument adduced above is, I think, sufficient to show that peeling Vines is prejudicial to attaining the highest standard of cultivation. Grapes good enough for home consumption are produced under the peeling process, I am well aware, but that does not prove it is the most correct method. Why not improve in one matter of detail, and so make another step towards securing the highest possible results? Modifying the ways of Nature to suit our requirements is a different thing to unnecessarily destroying the tissues of Vines. As I stated before, the outer bark is given to protect the internal tissues, and any unnecessary interference with it upsets the functions of the plant more or less.

I am glad to say I have only once had to deal with mealy bug on Vines, and that in the capacity of a subordinate. If I had the enemy to deal with now the condition of the Vines would be my guide as to how I should proceed. I am acquainted with many different modes of cleaning Vines, but those treated as I advised, and attended to promptly in other matters of detail, can be kept as free from pests, and produce as good results, as from any other treatment that I have seen. If matters are very bad, I readily grant the treatment must be conducted to meet the case, not adhering to any particular line of action. The treatment pursued by me is attended with every success, and I have no reason to alter my methods, but any person is, of course, free to adopt any other practice he may think best.

It would be interesting to know something of "Erica's" credentials as a Grape-grower, as he criticises my article very keenly; so wishing him a good New Year, I will await the information.—J. J. CRAVEN.

**THE WEATHER IN LONDON.**—Christmas has come and gone since our last issue was prepared for press, and until last Saturday the weather was very mild. On that day, however, a little snow fell, this being also the case on Sunday. Monday and Tuesday were bright and cold, while in the early hours of Wednesday there was a slight fall of snow. At the time of going to press the weather is somewhat dull and cold. One or two degrees of frost have been registered in the City, but in the suburbs it has been more severe, 10° having been experienced.

— **THE WEATHER IN THE NORTH.**—With the gale of Friday night, almost equalling in violence that of the morning of the 22nd, the weather has undergone a seasonable change. In some of the northern districts much snow has fallen, and roads have been blocked up. While the higher hills have been heavily covered the lower ground in S. Perthshire is but slightly whitened, and for the last three days, up to Tuesday morning, frost of from 4° to 7° has been registered. —B. D., *S. Perthshire*.

— **MESSRS. JAMES VEITCH & SONS** of the Royal Exotic Nursery, Chelsea, have given their procuration to Mr. James Herbert Veitch (who has been with them for several years) and to Mr. John Gould Veitch, sons of their late partner Mr. John Gould Veitch. The training of the two gentlemen named fits them admirably for sharing in the conduct of the great business with which they are now formally identified.

— **DEATH OF MR. JOHN CARTER.**—We learn with much regret that Mr. John Carter of Keighley died on Monday, December 24th, after a very short illness, being in his sixty-ninth year. Mr. Carter was an active and genial man—a thorough nurseryman, having special knowledge on hardy trees and shrubs. He was the introducer of the excellent Raspberry Carter's Prolific. The business will be carried on by Mr. Edward Carter, but under the name by which it has so long been known in the horticultural world.

— **THE NATIONAL AMATEUR GARDENERS' ASSOCIATION.**—The Committee in carrying out the suggestion made at the last monthly meeting, have arranged for the first meeting in 1895 to take place at the Memorial Hall, E.C., on Tuesday, January 8th, at seven o'clock instead of New Year's Day. In coming to this decision they believe the general convenience of the members is being studied. On this occasion Mr. H. A. Smith will give a paper on hardy annuals, and this promises to be a very useful one.

— **FORESTRY HONOURS.**—The "honours diploma" for the science and practice of forestry has been granted by the Grand Ducal Forestry College at Eisenach, in the Duchy of Saxe-Weimar, to Mr. James William Watt, in which Government Academy of Forestry he has been studying. As his name indicates, this dux of the Government Academy of Forestry is the eldest son of Mr. James Watt, J.P., Knowefield Nurseries, Carlisle. Prior to taking his course of study at Eisenach Mr. James William Watt had worked for one season at a large seed establishment at Erfurt, in Germany. Having now taken his degree in forestry he will henceforth be associated with his father, who is widely known to agriculturists as the head of the eminent seed and nursery firm of Messrs. Little & Ballantyne, Carlisle.

— **VEITCH MEMORIAL FUND.**—At a meeting of the Trustees, held on the 19th ult., it was resolved that £10 be granted to the Lindley Library Fund; that silver medals be presented to James Bateman, Esq., F.R.S., "the father of amateur Orchid culture;" to Mr. F. W. Moore, Curator of the Royal Botanic Gardens, Glasnevin, in recognition of his valuable services to botany and horticulture; and to M. Victor Lemoine of Nancy, for his services as a hybridist, and that a Veitch medal and prize of £5 be placed at the disposal of each of the following horticultural societies—viz., the Royal Caledonian, the West of Scotland, York Gala, and Worksop, for products to be competed for at their respective shows, subject to the approval of the Trustees. It is particularly requested that all communications respecting the Veitch medals and prizes should be addressed to the Secretary, Mr. A. H. Kent, 44, Doria Road, Fulham, S.W.

— **MR. EDWARD L. GREENE**, Assistant Professor of Botany in the University of California, has been appointed Professor of Botany in the new Catholic University of America, in the city of Washington.

— **THE MILD WEATHER.**—As showing the mildness of the season, a Long Sutton (Lincolnshire) correspondent reports that a few days ago there was a swarm of bees on the farm of Mr. H. M. Proctor of Spalding, at Sutton Crosses. Such an event in December is believed to be unparalleled.

— **WE regret to record the death on the 19th ult. of Professor ALLEN HARKER**, of the Royal Agricultural College, Cirencester, at the age of forty-six. Mr. Harker was a popular and successful teacher, and did good work, not only at the College but in connection with County Council Technical Education schemes both in Gloucestershire and Bedfordshire.

— **WHERE KEW MEN GO.**—The influence of the Royal Gardens at Kew on other botanic gardens is strikingly shown in a list of the staffs of botanical departments and establishments at home, and in India and the colonies, given in the "Kew Bulletin," Appendix III. Disciples have gone from Kew to the ends of the world to become directors or curators of botanic gardens; indeed, almost every garden seems to have on its staff someone trained at Kew, or recommended by the Director there.

— **KITCHEN GARDEN WALKS.**—My thanks are due to Mr. C. Foxon (page 561) for supplementing my recent remarks on edgings. Without going so far as to consider concrete strips the best "edgings obtainable," I fully agree that they are good in every way, and must admit that it was quite an oversight on my part not to have recommended them in my previous article on this subject. In my younger days I served in two extensive gardens in which concrete strips were in use as edgings, and in both cases they were entirely satisfactory.—KENTISH MAN.

— **THE FORM OF MINIATURE VIOLAS.**—The Viola Conference, in deciding that miniature Violas, in order to be regarded as belonging to that section, should not exceed 1½ inch in diameter, of course meant in width, as was readily understood by everyone present. It was not regarded as a necessity that all blooms should be absolutely circular, although recognising form as a great point; still, in some of the varieties perfection of form is closely attained already. It is a very wise rule and laid down as law just in time, for we should otherwise see the two sections, the large flowered and the miniatures, get hopelessly mixed in the numerous seedlings which have come under notice. I hope to see the "Violetta" type of growth and flowers preserved as much as possible in the miniatures, and that we shall also as much as possible keep out the Pansy blood from our large flowering Violas. We want them of the type of Bullion, Countess of Hopetoun, Sylvia, True Blue, and others of the same habit.—W. DEAN, *Hon. Sec. of the Viola Conference*.

— **PASSIFLORA PFORDTI.**—As far as I know only two kinds of hardy Passion Flowers are now in general cultivation in British gardens—namely, the well known *P. cœrulea* and the more recently introduced white flowered form known as Constance Elliott. A third variety under the above name is now being distributed by a leading London nursery firm. The name, however, I believe to be merely an unauthorised synonym for a beautiful hybrid, raised about seventy years ago in Mr. Masters' garden at Canterbury, by fertilising the flowers of a fine West Indian species named *P. alata* (the Winged) figured in the second volume of the "Botanical Magazine," on plate 66 as far back as 1788, with the pollen of the common hardy variety *P. cœrulea*. This hybrid when it bloomed showed the characteristic features of both parents, and was named *P. alato-cœrulea*. It is well figured on plate 848 of the tenth volume of "Lindley's Botanical Register," which was published in 1824, and is there said to be nearly if not quite hardy, having withstood the frosts of that winter in the open air trained to a wall without injury. My reason for believing that the plant now offered as *P. Pfordti* is merely *P. alato-cœrulea* under another name, is that in the new edition of "Johnson's Gardeners' Dictionary," published last year by Messrs. Wright and Dewar, *P. Pfordti* is given as a synonym of *P. alato-cœrulea*. I have reason to know that the authority for this statement is Dr. Maxwell T. Masters, F.R.S., the greatest living authority on the family of the Passion Flowers. I think the name of *P. Pfordti* should certainly be dropped, as it is unrecognised at Kew.—W. E. GUMBLETON.

— WEATHER IN NORTH FLORIDA.—Extraordinarily cold weather prevails in Northern Florida, and has caused damage to the Orange and other crops estimated at 3,000,000 dols. The weather is the coldest experienced since 1835, and thick ice has formed in many places.

— ENGLISH FILBERTS IN AMERICA.—Another small consignment of 500 lbs. of the best English Filberts, which are imported in the husks, has just been sent to a well-known American firm. They come in small barrel packages, each of which contains 100 lbs., and sell at retail for 50 cents a pound. These Nuts have none of the dryness or toughness of the ordinary Filberts, but have a crispness and delicacy of flavour which is altogether distinct.

— BERMUDA LILIUM GROWERS.—It is announced that the large growers of bulbs of *Lilium Harrisii* in the island of Bermuda have consolidated under the name of the Bermuda Bulb Company, with Mr. Frank Pierson of Tarrytown, New York, as general agent for America and Europe. The object of the combination is, says the "Garden and Forest," to keep prices firm, to supply high-grade bulbs only, and to correct the competition in cut flowers.

— MESSRS. DOBBIE & CO. AND THEIR EMPLOYÉES.—The annual social gathering of the employés of the firm met together, by invitation, in the Public Hall, Rothesay, on the evening of December 28th, Mr. Burnie (one of the partners) presiding, supported by Mr. Wm. Cuthbertson, also a partner, 120 sitting down to tea. In a brief practical address the Chairman alluded to the growth of the business since it was established by Mr. Dobbie; and in addition to their extensive seed grounds at Beaulieu, in Hampshire, a large tract of ground has been taken at Orpington, in Kent, for seed growing.

— THE BLACK CURRANT "MITE."—Writing from Kingston, Mr. E. L. Martin says—"Would you kindly afford space to draw the attention of all who grow them to the condition of the Black Currant bushes? I have found the Black Currant mite (*Phytoptus Ribis*) both in my own garden and in that of a friend a short distance away, and as we obtained our bushes from different sources, it is probable that the pest is already widely spread in the neighbourhood. Although the mite is invisible to the naked eye its presence is easily known by the abnormal swelling of the buds it has attacked. These vary in size from a small pea to a bean, and all such swollen buds should be carefully picked off during the winter and burned."

— CHOICE ONION SEED.—So anxious are seed growers to secure very fine and handsome bulbs of various choice Onions for insuring good seed stocks, that exceptionally high prices are paid for them. It not infrequently happens that in seed production these bulbs materially fail, as, for instance, last year the produce of a score of huge Ailsa Craig, which should have been at least a pound, was not more than a couple of ounces. This was due perhaps to imperfect setting of the bloom owing to excessive rains, perhaps to planting the bulbs in too rich soil, and thus generating a coarse stem growth that is productive of late and imperfect flowering. That these fine bulbs do reproduce exceedingly fine stock there can be no doubt whatever; hence their value. It is a noteworthy fact that whilst these huge bulbs, because so essentially watery, usually keep badly, they are this winter found to be keeping better than are the main crop bulbs. That is perhaps due to the fact that whilst main crop Onions ripened so badly, early planted out ones had a long season, and ripened in good time.—A. D.

— SAVOY CABBAGES.—The other day I saw large breadths of Savoy Cabbages, white and bursting, literally useless, and only fit to form food for sheep or cows. The same sort of thing may have been seen in many private gardens also. This comes of the rigid adherence to rule of thumb which characterises so many Cabbage growers who year after year sow seed in March and put out the plants in June or July, so that they may grow strong, produce large heads, and be ready for cutting in the autumn. That is just when such Cabbages are not wanted. When hard weather has, however, intervened and spoilt them, then good fresh Savoy Cabbages would be most valuable. As a contrast to this sort of provision I could but notice what I saw the other day at Hackwood Park, Basingstoke, where Mr. Bowerman had from two quite late sowings of Sutton's Improved Dwarf Curled Savoy large breadths of beautiful fresh, green heads, just turning in, and such as would give delicious small heads for the next three months. These were planted out quite thickly and gave a large number on a comparatively small area of ground.—A.

— DEATH OF MRS. HARRIS.—The many friends of Mr. George Harris, Alnwick Castle Gardens, will extend to him their sympathy, as we do, on the death of his wife, who was very dear to him, on the 21st ult. Mrs. Harris was forty-four years of age, and leaves eight children under fifteen years old.

— RAINFALL IN SUSSEX.—The total rainfall at Abbot's Leigh, Haywards Heath, Sussex, for the past month was 2.09 inches, being 0.65 inch below the average. The heaviest fall was 0.68 inch on the 7th. Rain fell on fourteen days. Total for the twelve months 35.45 inches, which is 4.80 inches above the average. The maximum temperature was 52° on the 14th; minimum 25° on the 4th. Mean maximum, 45.12°; mean minimum, 35.05°; mean temperature 40.08°, being 2.77° above the average. An open month, with little frost and no snow.—R. I.

— AMERICAN FLOWER STORES.—According to an American contemporary, nowhere else in the world are the first-class retail florists' stores so attractively and beautifully arranged with plants and flowers, or so brilliantly lighted up in the evening as they are in that country, and notably in New York. And not only are the flowers the very finest—even a selection of the finest—that can be produced, but the exceedingly pretty, neat, and tasteful way in which they are put up in boxes to be delivered to customers makes the flowers appear doubly fresh and choice; indeed, on opening the box one often has a feeling that it is a pity to disturb the blossoms, they look so sweet and dainty nestling there.

— NURSERY VICISSITUDES.—The Leith Walk Nurseries, Edinburgh, and the firm of Dicksons & Company, are well-known throughout Scotland and beyond its borders, yet like many others, especially the older ones, the devouring march onwards of the builders think nothing of clearing away a nursery. The firm of Dicksons & Company was established about 120 years since, but about twenty years ago the Leith Walk Nurseries were required for building purposes, and the offices were removed to their nurseries at Pilrig Park; now a further removal has to be made from there, as a new railway will be made through the nurseries this year, and the firm have been awarded £10,500 as compensation. The site of the new nursery of the firm will be at Liberton, on the south side of Edinburgh.

— WAKEFIELD PAXTON SOCIETY.—There was scarcely an average attendance at the last meeting of the Paxton Society held at the Woolpacks Hotel. Mr. B. Whiteley presided. Mr. Pitts, head gardener to D. P. Kendell, Esq., J.P., of Walton, delivered a brief but most interesting lecture, particularly to amateur gardeners, on "When and How to Pot and Water Plants." Mr. Pitts began by impressing on his hearers the importance of having their plant pots thoroughly clean both inside and outside. He strongly denounced the custom of colouring the outside of the pots, as it closes the pores, and he asked his hearers not to forget good drainage. The soil most suitable for potting such plants as most amateurs generally grow should consist of turf, leaf mould, and sand. Some hardwooded plants require firm potting, and others would do with looser potting. He advocated neatness and tidiness in all gardening operations, and strongly recommended amateurs not to fall into the common practice of watering too freely, growing too many varieties of plants, or too large a number. A hearty vote of thanks was given to Mr. Pitts for his interesting lecture.

— THE METROPOLITAN PUBLIC GARDENS ASSOCIATION.—This Association held its monthly meeting a few days since, when it was announced that the formation of the riverside garden at the Wharf, Battersea, was progressing very favourably. It was agreed to take steps towards the laying-out of a piece of land in Canning Town, E.; to offer £100 towards the laying-out of a disused burial ground in Chapel Place, Bermondsey; to endeavour to secure two desirable vacant sites in Walworth and Deptford, the Fishmongers' Company having promised £600 towards the former; to offer to make a garden on the Albert Embankment; and to offer to lay out an additional piece of Allhallows Churchyard, London Wall. Amongst other matters brought forward were negotiations for the opening of Arbour Square, E., Munster Square, and Clarence Gardens, N.W., the churchyards of Bromley-by-Bow, E., and St. Mary, Battersea, S.W., and the New River Company's garden in Canonbury; the provision of some open spaces in Southwark; the laying-out of St. Mary Magdalene's ground in Chiswick, and the Friends' graveyard in Bermondsey; and the acquisition of a recreation ground in Hermit Road, Plaistow, E., towards which the Association had collected nearly £300 during the month, leaving a balance of £792 necessary to complete the purchase money.

— PRESENTATION TO MR. J. D. ABBOTT.—A very interesting meeting took place at Eynsford on the 21st ult. on the occasion of presenting a purse and illuminated address to Mr. J. D. Abbott on his vacating the position of head gardener at Lullingstone Castle, the country seat of Sir Wm. Hart-Dyke, Bart., M.P. There was a large gathering of friends and neighbouring gardeners. Mr. R. Cannell was unanimously elected to preside, and after having explained the object of the meeting, stated he had great pleasure in handing Mr. Abbott such a high token of respect and goodwill from sixty-eight subscribers. Mr. Cliffe, gardener to Sir Henry James, Q.C., M.P., also expressed similar sentiments. Mr. Abbott responded in a few well chosen words, thanking all most heartily for their kind wishes towards him.

— GRAPES ON OPEN WALLS IN KENT.—As promised I send a few particulars about Grapes for the open air, south aspect. The following sorts for this purpose were planted in 1858 and 1862—Esperione, Royal Muscadine, Buckland Sweetwater, Black Hamburgh, and Foster's Seedling. They were planted in the open spaces between wall trees, soil a light sharp loam. Long ripened canes have been left in pruning where space permitted, otherwise young wood was left from 1 to 3 feet. They were reduced from year to year, as Peaches and other trees required the space. The Vines bore good crops of excellent bunches of Grapes up to 1893. Some have since been removed for alterations of the walls. The weight of some bunches as sent to the table were, Royal Muscadine, 1 lb.; Esperione, 1 lb.; Black Hamburgh, 1½ lb.; Buckland Sweetwater, 1 lb., large berries; Foster's Seedling, nearly 3 lbs. Grape tarts were much enjoyed by the family from the fruit that did not ripen well in bad seasons.—ONE OF THE OLD SCHOOL.

— POTATOES IN IRELAND.—Details of the Government measures to avert an Irish Potato famine are now made known. To prevent delay the Government, through the Local Government Board for Ireland, are prepared to advance money without interest to Guardians for the purchase of seed Potatoes. The various Boards have received instructions as to the quantities of seed which may be sold to tenants whose land is valued at or under £15, and they have been urged to obtain sufficient security for the payment of the price of the seed sold. An abatement of one-fifth is to be made in the price of all seed which is paid for in cash. It is intended to propose to Parliament that the amounts due to the Guardians on account of any seed sold shall be paid by two equal annual instalments, the first of which shall be leviable as a special rate with the first ordinary Poor Rate made after the 1st of July next, and the second instalment as a special rate a year later. The loan will be repayable by the Guardians to the Board of Works by two equal instalments in August 1896 and 1897 respectively.

— CHRISTMAS FLOWERS AT BELVOIR.—Mr. W. H. Divers sends to the "Times" on the 29th ult. the following list of plants that were flowering in the open at Belvoir Castle on Christmas Day, 1894:—Aconite, yellow (*Eranthis hyemalis*), Anemone blanda, Anemone hortensis, Aubrietia græca, Andromeda floribunda, Antirrhinum majus, Arabis albida, Borago officinalis, Berberis Beali, Carnation (white seedling), Chimonanthus fragrans, Chrysanthemum (nine varieties), Daisy (single and double), Eccremocarpus scaber, Escallonia punctata, Furze (common single), Geranium Robertianum, Garrya elliptica, Helleborus niger, Helleborus hybrids, Honesty, Iberis gibraltaria hybrida, Jasminum nudiflorum, Laurustinus, Lamium maculatum, Morina longifolia, Meconopsis cambrica, Magnolia grandiflora (not expanded), Marigold (common), Myosotis dissitiflora, Othonna cheirifolia, Polygala Chamæbuxus, Polyanthus (in variety), Primrose (common yellow), Primrose (double lilac), Rhododendron (in variety), Roses China (in quantity), Tea, and H.P., Scabious, Saxifraga ligulata, Snowdrop (common), Stock, Tussilago fragrans, Vinca minor, Violet (common Russian), Violet (double Lady Hume Campbell), Wallflower (Belvoir Castle Yellow), Wallflower (Miss Hope, double yellow).

— SHIPLEY HALL, DERRY.—When visiting these gardens a few days ago I was very much astonished at the extensive alterations that have taken place during the last few years. With Mr. Elphinstone (Mr. G. M. Mundy's talented gardener) as a guide and companion nothing could prove more enjoyable to a British gardener than a walk through the magnificent glass structures under his charge. Everything is the picture of cleanliness and high cultivation. The Vines, Peaches, and Figs are already on the move, and in one house could be seen thousands of Lilies of the Valley and Roman Hyacinths in full flower. The Orchid houses are bright with such kinds as *Dendrobium formosum*,

*Wardianum*, and *nobile*, some of the latter measuring 3 feet 6 inches through; *Cattleyas*, *Lælias anceps* and *Sanderiana*, *Odontoglossums crispum* and *vexillarium*. The *Anthuriums* are a great speciality, and Mr. Elphinstone told me that in a few years they hope to have a unique collection. The plants are of good size, and well grown in a temperature from 55° to 60°. Amongst them I noticed *A. Mundyanum*, *A. sanguineum*, *A. Wardi*, *A. Palmeri*, and others. The adjoining house was devoted to *Eucharis* and *Nepenthes*, the latter including *N. mixta*, *N. Courti*, *N. Chelsoni*, *N. lanata*, and *N. Morgani*. The corridor and model fernery are as pretty as ever, and the handsome conservatory contains some scores of massive Palms and Tree Ferns, the back wall being covered with *Bambusa violascens* and *B. virida metake*, the whole giving a charming tropical appearance.—GEORGE BURROWS.

— WHERE DO OUR BLACKBIRDS GO?—In "Birds of the Wave and Woodland," Mr. Phil Robinson says, "They rear, in nearly every case, two broods a year—that is to say, there are every year five times as many blackbirds as the year before. According to this, starting with a single pair, a garden ought to have at the end of five years 1400, and at the end of ten years, supposing that one-half died each year, something over 2,000,000 blackbirds. Or, supposing they only rear one brood, there would be over 7000. Suppose the cats eat 6000, there would still be the preposterous number of 1000 left. Where, then, I ask, do all the blackbirds go? It is quite certain that each pair, as a rule, hatches five birds, yet the number of blackbirds does not increase. So that if we say there are only 10,000 pairs of blackbirds in Great Britain, there are at least 50,000 killed or made away with every year. 'Then what are they hatched for?' my child friend might ask. 'For cats,' would be my reply. And yet it seems absurd that 100,000 blackbirds should be hatched every year just for cats to eat. All of which is a mystery to me."

— THE ROYAL GARDENERS' ORPHAN FUND.—The last committee meeting of the year of this admirable charity was held on Friday night last. There was a large attendance, William Marshall, Esq., the Chairman of the Fund, presiding. Contributions amounting to £85 11s. 9d. were announced as having been received since the last monthly meeting. Among the sums mentioned were £50 10s. 2d. from a concert at Altrincham; £5 from the Bristol Chrysanthemum Society; £5 from the Scottish Horticultural Association; £2 from the Stockport Chrysanthemum Society; £7 5s. from Ware, and £5 5s. from Mr. Herbst, as well as smaller amounts from collection boxes. The list of candidates (fourteen) for the benefits of the Fund was read and approved, and out of these six (only six) will be elected at the general meeting to be held at the Cannon Street Hotel on February 8th. A discussion ensued as to the eligibility of the children of persons who had been gardeners, but who were not working as gardeners when they died. The decision, in such cases is, under the rules, vested in the Committee, and a motion to the contrary was not carried. A proposition moved by Mr. Wynne, and seconded by Mr. Wright, that members of Committee to be eligible for re-election must in the future attend at least three meetings during the year, was carried. Mr. Richard Dean very properly asked if all the Vice-Presidents were annual subscribers to the Fund, to which the answer was "No." Foreseeing that something was likely to happen, another question was quickly put, "Are they life members?" which elicited the reply of "Yes," and Mr. Richard Dean was satisfied. Mr. Richard Dean then announced a discovery, in tones tremulous and pathetic, of something having appeared in the *Journal of Horticulture* "last February" which did not please him. He evidently forgot for the moment that the *Journal of Horticulture* does not exist for the purpose of pleasing Mr. Richard Dean alone (though always ready to recognise any good work of his that may be apparent), but as the Committee took no notice of what looked like a solemn impeachment, Mr. Richard Dean collapsed. A commendable trait in the character of smart men who make discoveries of time-worn delinquencies is that which may be described as the happy collapse. The Chairman, in his genial way, brought the meeting to a most harmonious close, every member wishing success to the splendid institution (which dispenses about £800 a year in supporting fatherless children), the Royal Gardeners' Orphan Fund. Yet eight widows of gardeners—worthy and respectable men in life—have to be denied the benefits of the charity, and there are by far too many others. Let all help them who can, and start, in some way to be locally devised, at once. Mr. Barron, the Secretary, believes that a large number of small contributions may be collected for the beneficent object in view, and so does the *Journal of Horticulture*, whether Mr. Richard Dean likes what it says or not.

#### CATTLEYA GUTTATA PRINZI.

THIS is a very charming variety of the old *C. guttata*, and one which will find favour with many growers. The markings of the flowers, as may readily be seen in fig. 2, are very distinct and pleasing. The sepals and petals are delicate creamy yellow, spotted with violet, while the lip is of a bright magenta shade. It was exhibited at the Drill Hall on the 11th ult., by Mr. E. Hill, gardener to Lord Rothschild, Tring Park, when it was deservedly accorded an award of merit by the Royal Horticultural Society.

#### CYPRIPEDIUM LEEANUM.

Few hybrid *Cypripediums* have shown more variations than the above. Originally raised about ten years ago by Messrs. Veitch

FIG. 2.—CATTLEYA GUTTATA PRINZI.

and Sons, from *C. Spicerianum* and *C. insigne*, it has since been improved by crossing the best types of these well-known kinds, many fine varieties being the result. The dorsal sepal in all these varieties is intermediate between that of its parents, being similar in shape to *C. insigne*, but having the dark line as in *C. Spicerianum*. In habit it resembles the latter, and like it may be grown in the *Cattleya* house in the usual compost as recommended for this genus. The flowers are produced on long slender scapes during the winter months and last well if kept in a fairly dry atmosphere. A superb variety I saw recently, appropriately named *giganteum*, had the dorsal sepal 3 inches across, pure white at the apex, with numerous bright mauve spots near the base. The petals were  $3\frac{1}{2}$  inches in length, lemon yellow, the pouch brownish red, the whole flower glossy as if varnished. Other choice varieties are *C. L. superbum*, *C. L. Masserellianum*, and *C. L. maculatum*. The latter has the sepals spotted with bright purple. *C. L. biflorum* is smaller, but, as the name implies, usually produces twin-flowered scapes.

#### DENDROBIUM NOBILE.

The earliest plants of this grand old *Dendrobe* are now in full beauty. Most growers like to have "a bit of noble" in at Christmas, and very bright and pretty it is at this season. The type is among the best known Orchids in existence, and certainly too familiar to need description. It thrives either in pots or baskets

in the warmest house while making its growth, and should afterwards have as long a season of rest as possible. Like the majority of the genus *D. nobile* must be well exposed to the sun, the latter part of the season especially, to ripen the growth thoroughly and lay the foundation for flowers in spring. The flowers may be enjoyed over a period of quite five months if sufficient plants are grown and introduced to heat successively. If any plants are wanted at a given date they should be placed in heat about eight weeks previously; this will give them time to come to their true colour, which does not always appear at first. The pruning system so freely discussed a few years since has been often advised for this Orchid, but I fail to see the advantage of it unless the growths are wanted for propagating. The pseudo-bulbs of Orchids are Nature's storehouses of nutriment for the subsequent needs of the plants, and to cut these away must to some extent weaken them, the good examples produced by the system notwithstanding.

#### NOBILE VARIETIES.

Some of our best *Dendrobiums* have been raised by crossing *D. nobile* with others, as, for instance, *D. Ainsworthi*, *D. Leechianum*, and *D. splendidissimum*, while the species is itself variable. *D. nobile albescens* is a pretty form, the sepals and petals being nearly white, the lip similar, with the usual purple blotch in the throat. *D. nobile alba* is pure white, with the exception of the lip marking; this is extremely rare and valuable. A variety named *Ballianum* has been described as wholly of a very light blush, without any markings in the throat whatever. *D. nobile Cooksonianum* first flowered at Heathfield House, Gateshead—hence its synonym, *Heathfieldianum*, and has since appeared in several other collections. In this variety the petals have much the same appearance as the lip, the deep purple blotch appearing on each, giving the plant a very distinct and striking appearance when in bloom. *D. nobile nobilius* is the grandest of all, and a truly magnificent Orchid; in colour it is tinted with bright rosy crimson, with the blotch in the throat of the deepest purple. The original plant of this Orchid is said to have been bought for a shilling, whereas it is even now a scarce and valuable variety. *D. nobile pendulum* is a deep coloured large-flowered form of a pendulous habit of growth. Other good varieties are *Wallisi*, *elegans*, *intermedium*, and *rubellum*.

#### CYPRIPEDIUM AMANDUM.

This is one of the older hybrids, the result of a cross between *C. insigne* and *C. venustum*. The foliage is deep green, with very faint markings, as in *C. venustum*; the flowers have somewhat the appearance of the latter species. The dorsal sepal is yellow, with green stripes, and many dark purple spots at the base. The petals are yellowish and brown, with deep crimson purple spots. The pouch is bright yellow, overlaid with purple and greenish lines, inside bright golden yellow. This Orchid thrives best in a temperature a little below that of the *Cattleya* house. It should be potted in peat, chopped sphagnum, and loam fibre with a few pieces of limestone; it requires plenty of water all the year round. It must be shaded from bright sunshine, and no water must be given over the foliage. It flowers in November and December, lasting several weeks in good order, thus brightening the new year.—H. R. R.

#### THE CHINESE PRIMULA.

I THINK we may safely say that this is the most important of all our winter-blooming plants, and when well grown *Primulas* last for a long time in flower. As Birmingham heads the poll in the cultivation of these plants, as evidenced every November at the annual *Chrysanthemum* show, it may be of use to some readers to detail the method adopted in the Birmingham district by the successful exhibitors. In the front rank of successful growers Mr. C. H. Herbert, the manager of the Sparkhill Nurseries, must take a front place, for he carried off all the first prizes in November for both single and double *Primulas*; and in the opinion of eminent men well known in the horticultural world who were present, such grand specimen plants could not be seen at any other exhibition in the kingdom.

His method of culture is this. He sows the seed as soon as it is matured and gathered. This is a very important point in securing free germination and stout seedlings. It is sown thinly about the end of August in 48-size pots, about three-quarters of an inch from the top, so as to allow a piece of glass to be placed over it, and the pots are placed on a shelf in an intermediate house. As soon as the seedlings can be handled they are pricked off into small 48-size pots; by the end of October they are ready to be placed singly in 60-size, and are kept in a house with a temperature of from 40° to 45°. In the early part of December the plants are shifted into 54-size pots, and still kept in a house of the same

temperature, air being admitted at all times excepting in very severe weather. The plants are kept there until the end of May or early in June, and are then shifted into 7½-inch pots, inside measurement, for flowering. The pots are only three parts filled with soil at first to allow of top-dressing, which I shall refer to presently. This is a most important point in *Primula* culture, quite opposite to what is generally practised, as when we see the plants on the surface of the soil on a level with the rim of the pot, and with short sticks round the plants to keep them steady, a practice altogether abandoned by the Birmingham growers.

The plants are then placed near the glass in a cold frame, the frame being so mounted that air can be freely admitted at top and bottom; in fact, the lights are never closed. The plants remain there until some time in September, according to the weather, but are never watered until really needed, strictly avoiding too much moisture and providing ample drainage. Syringing is not resorted to, and the plants want very little attention during the summer, just growing them as hardy as possible, and that the foliage is not injured. In very sunny weather a light shading is employed and an abundance of air afforded.

The plants are top-dressed early in August, filling the pots nearly to the rim. This serves two purposes—encouraging the formation of surface roots from the base of the stems, and steadying the plant so that sticks are unnecessary. Burying the base of the plant in this way may seem to be an odd practice to some, but I may as well say here—try it.

The plants intended for exhibition, or as fine specimens, are placed in a well-ventilated, light span-roofed house in September, the lights opening on both sides, as well as the house being provided with top ventilation, air being constantly admitted, except when very severe frost is experienced. Heat is turned on if the weather is very damp, but air still remains, and of course a little heat is afforded in very frosty weather, but when *Primulas* are grown hardy, as I have indicated, a little frost does not seem to hurt them. Under such treatment the plants make steady progress, producing large stout foliage of unusual thickness, and of a good colour, clean, and free from any blemish on the margin, as is so often seen. But to have perfectly well grown symmetrical specimens the foliage must be carefully pegged down so as to allow free play to the trusses of flower buds, as they will then rise freely, the buds thus unimpeded by the foliage becoming large and well formed, the mass of bloom being also easily trained with scarcely any trouble so as to form a pyramidal head of flowers.

The soil used is good turfy loam, leaf soil, and thoroughly decayed cow or stable manure in equal parts, kept as rough as possible for the purpose, and about a 54-size potful of Clay's fertiliser or guano mixed with 6 bushels of the compost, adding a sprinkling of old crushed mortar and sand, so that the soil may be kept open and porous to allow the water to pass readily away. The roots like the old mortar, and water-logged plants very soon go wrong. The pots are well drained, and the crocks slightly covered with moss, thus keeping the drainage quite free from the soil. The pots are quite clean when used. No liquid manure is given in the early stages of growth, not until the plants push up their flower trusses, then a little guano or Clay's fertiliser is dissolved to form a weak solution. Such manures are never used in the dust state, as that leads to a clogging of the soil.

With this treatment Mr. Herbert, year after year, secures superb specimen plants 2½ feet through, and from 18 to 20 inches above the pots. They bloom in October, and through the winter from seed sown in August of the previous year, perfect pictures of health and admirable culture, the flowers ranging from 2 to 3 inches in diameter.

At the late Chrysanthemum show in the Birmingham Town Hall Mr. Herbert had in his winning twelves some fine seedlings now being circulated, which will bring him fame as a raiser, such as Princess May, Duke of York, Fairy Queen, and Mont Blanc, all very beautiful. Her Majesty is also a grand flower. The Birmingham standard enforces size, form, and great substance in the flower, freedom of bloom, and robust habit in the plant. The example figured is from a photograph.

—WILLIAM DEAN.

## INTERVIEWING A NOTED GRAPE GROWER.

IN my communication on page 578 last week I gave the credentials that entitle Mr. J. J. Craven to the above description, but I ought to have said he won the prizes there named at Trentham. Passing from the subjects before mentioned I asked Mr. Craven what he had to say about the depth of Vine borders? He replied: "I think 2 feet 9 inches ample, as a rule, with about a foot of drainage. In light soils if borders are made of less depth, especially inside, they dry too quickly, but cultivators should be guided by local conditions. I work to no hard and fast rule. Borders should never be sunk to the ground level, but raised partly above it,

FIG. 3.—A BIRMINGHAM PRIMULA.

especially in low damp positions. When so made they are warmer and promote more vigorous root action."

What do you consider a good compost? "Good loam, lime rubble, charcoal and bonemeal mixed in proportion to the quality of the loam is very good, but not too much charcoal as it is apt to go sour. I do not believe in employing wood ashes in making borders, on account of the danger of fungus arising from small twigs not thoroughly burnt or charred. I have had bad experience of fungus attributable to that cause, and would prefer to use it as a top-dressing. Spent Mushroom beds and leaf soil I would not employ for the same reason. Vines should be planted 4 feet apart to obtain the best results, spreading the roots out as far as practicable, and not planting with the ball of roots nearly entire."

We next touched upon the pinching or stopping of young

Vines, and Mr. Craven said they should be stopped at two joints above where they are to be cut down, then allowed to make as much growth as can be exposed to light, or to grow at will the first year. He is not particular as to stopping two joints beyond the bunch of Vines in bearing, or to one or two more. Care is taken in the case of Vines with feeble root action not to rub out the bud at the point of the lateral or sub-lateral, as it is considered better to encourage such Vines to grow freely for a season or two, and crop lightly. The utmost pains is taken at all times to preserve the foliage in the best possible condition during active growth, as injury to the leaves means poorly elaborated sap, consequently impaired vitality. When vigorous Vines show abundance of bunches his practice is to cut off all the largest to begin with before flowering, leaving very few more than will finally remain for the crop; the whole energies of the Vine is then centralised to that end.

Temperatures received our attention now. Much heat during the flowering period is not approved of. The atmosphere of structures are kept in a congenial state, and so long as the temperature is sufficiently high to disperse the pollen that is regarded as sufficient. Vines suffer in parching atmospheres, and in Mr. Craven's opinion a good set of fruit depends more upon well nourished buds the previous season, with good root action, than upon temperatures. Vines, he says, should be grown steadily from start to finish, so as to solidify every tissue, with air judiciously applied on all favourable occasions.

You ask about various manures? "Well, I should vary the food as the Vines and condition of the soil indicates. This result can only be obtained by a close study of the plant. Vines here are rarely watered twice with the same kind of food. Thomson's chemical Vine manure is good. I believe too much liquid manure is detrimental to finish of the fruit, especially in Hamburgs. In point of first class finish a plain substantial diet is by far the best."—R. P. R.

(To be continued.)

#### OLEARIAS.

WE have pleasure in publishing the following notes, the first from Mr Divers in answer to an inquiry, the second by the closely observant Mr. W. E. Gumbleton:—

##### OLEARIA GUNNIANA.

THIS plant was at one time known as *Eurybia Gunniana*, but the latter name is now discontinued. It is a beautiful evergreen shrub with grey foliage and white Daisy-like flowers, which are produced abundantly in attractive sprays during May and June. Being a native of Tasmania it is only partially hardy in Great Britain, and is liable to be killed during severe winters; it should therefore be planted against a warm wall, where it can also have a little covering during severe frost. It is not particular as to soil provided it is not a stiff clay, but a well-drained site should be chosen, and if the soil does not naturally contain any small stones it is advisable to mix some small pieces of limestone or broken bricks with it when planting, as these will materially assist the plant to withstand the cold weather. Messrs. Veitch, of Chelsea, grow this *Olearia* well in their Coombe Wood Nursery. A good plant of it at one time grew in the Edinburgh Botanic Gardens (see page 519) and is probably still there, but it is by no means commonly met with. When once established in a suitable position it grows freely. Upwards of eighty species of this family have been described, but very few of them are under cultivation, and much confusion has occurred among the names of them.—W. H. DIVERS.

##### OLEARIA DENTATA.

AS the above-named shrub has recently been referred to in your columns by Mr. Divers of Belvoir and also by another correspondent, I think it may interest some of your readers to know that the shrub in question is not *O. dentata* at all, but what is figured in the "Botanical Magazine" on plate 7065 under the name of *O. macrodonta*, which name had to be coined for it at Kew some years ago, when I sent flowering specimens there to be named. This name, however, has now had to be cancelled, as the shrub was found to be identical with what was known in New Zealand as *O. ilicifolia*, which name of course it must henceforth bear in all correctly named shrubberies and collections. There is another species of *Olearia* in cultivation in some British gardens under the name of *O. ilicifolia* with much smaller and more acutely crimped leaves, and more straggling whitish flowers of but little beauty, but this also is incorrectly named, its correct name being *O. myrsinoides*. I grew it for several years, but have now lost it without much regret. The true *O. dentata* is figured in the vol. 93 of the "Botanical Magazine" on plate 5973, and is a most beautiful shrub with large cupped pale rose-coloured flowers. It is a native of New South Wales, and alas! not hardy in the United Kingdom save in one or two exceptionally favoured localities such as the Scilly Isles, whence I have received it from the celebrated gardens at Treco Abbey, but could not keep it alive through the winter even on this mild seaboard of the South of Ireland.—W. E. GUMBLETON.

#### CHRYSANTHEMUM BRIDE OF MAIDENHEAD.

THIS Japanese Chrysanthemum is undoubtedly a seedling from *Avalanche*, and closely resembles its parent in many respects. *Avalanche*, like all Japanese varieties that have been in cultivation ten years, is gradually deteriorating in constitution. The quality of its blooms are nothing as compared with those produced for the first few years. In spite of the number of white flowered Japanese Chrysanthemums, we cannot afford to lose altogether one of the type of *Avalanche*. *Bride of Maidenhead* comes then at an opportune moment to take the place of the old favourite as an exhibition flower. So closely do they resemble each other that I should not like to advise an exhibitor to stage blooms of the two as distinct.—E. MOLYNEUX.

#### LESSONS OF THE PAST SEASON.

ALTHOUGH many exceedingly fine specimens in the Japanese section were seen during the past season, it cannot be said that, taken as a whole, Chrysanthemums were equal to those of some previous years. Exhibitors are inclined to say year after year, "I do not remember having staged a better twenty-four than this." They are too apt to forget the new varieties that very much enhance the appearance of a stand as compared with some that are now ignored by exhibitors.

Having seen many collections of plants during the growing season, and the blooms produced by the plants at exhibitions, I am confirmed in the opinion that plants which are denuded of their primary leaves to any extent by the end of September never produce satisfactory results. I have also noted where the plants were well clothed with foliage of the proper kind, and all other cultural details attended to at the right moment, the best blooms were produced. Readers of the *Journal of Horticulture* must not suppose that all the good blooms find their way to the exhibition tables. In a garden in Devonshire I saw the finest example of Charles Davis that I met with in a long tour of the best shows. The remarkably healthy foliage which this plant carried beyond the day when this bloom was cut was another instance of the advantage of perfect leaves to aid the plants in supplying the expanding blooms with the desirable nutriment which brings them to perfection.

Much loss of the foliage is traceable to the long-continued wet and sunless weather experienced at various times throughout the growing season. An excess of moisture at the roots during periods of adverse weather has much to answer for. Chrysanthemums are moisture-loving plants no doubt, but they can have too much at the roots all the same. The plants will withstand more dryness in the soil than many persons imagine.

Mildew has been a primary cause of loss of foliage in some collections of plants this season. This fungus has been particularly active, and where in the slightest degree neglected has done irreparable injury to the plants. Neglect to apply the usual remedies instantly is a mistake which many persons have had to pay dearly for this year, and should prove a reminder for another season.

The employment of pots considerably larger than is necessary has in several instances nullified other good points in culture. Especially was this noticeable with plants of the Queen family. Many of them were growing in pots 10½ inches in diameter, certainly 1½ inch too large, especially in a season like the past. Plants growing in large pots have not the same opportunity to mature their growth as those in smaller pots; they more resemble those growing in the open. Without maturity obtained gradually it is useless to expect satisfactory results.

As was to be expected after such an unfavourable season for the growth of the plants, complaints of the blooms damping was rife. The premature decay of the blooms was decidedly more active where the precaution of warming the hot-water pipes, especially during the night, was neglected. It is a well known fact that a cool surface condenses atmospheric moisture. If cultivators still ignore this truth, and persist in acting contrariwise, they court failure and disappointment.

It is hoped that beneficial lessons have been learnt during the past season on the subject of staging the blooms in a more sensible manner. Less of the "flopping" plan has been seen, and the more rational method of raising the blooms a few inches above the stands more generally adopted. In spite of the great advantages supposed to accrue from the use of enlarged stands these have not been made so much use of as might have been expected. Perhaps exhibitors have found that it is a mistake to arrange blooms upon a stand that is much too large for them.

I observed that many of the leading exhibitors employ auxiliary tubes for the purpose of raising the back row of blooms well above those in front, so that every part of them could be seen, and not only the blooms, but the water in which they were placed was raised also. This is a step in the right direction; any plan that raises the blooms out of the water is not a sensible one.

Exhibitors who do not adopt rational methods of naming their blooms would do well to take a lesson from those who do. Many exhibitors

are much too careless in this respect. Some of them simply write the names of all the blooms in one class on a slip, it may be half a sheet of notepaper, and lay it on the stand, to be swept off by the first crowd of visitors that pass by. I trust all those who practise this slovenly method of naming their blooms will take a lesson from others who improve their stands by a simple wire and card arrangement, not forgetting neatness in writing and accuracy in spelling. The way in which many names are rendered is deplorable.—E. MOLYNEUX.

### QUESTIONS FROM INDIA.

WOULD you please reply to the following queries in your valuable paper, and oblige?—I find that after *Chrysanthemums* have finished flowering that I am out of flowers for November and December—rainless, cloudless months, with a temperature ranging anywhere from 30° to 70° Fahrenheit in the twenty-four hours. Snow covers the ground all January and February, melting in March, when Snowdrops, Hyacinths, Crocuses, Narcissus, Primulas, and other flowers immediately appear. No greenhouses or flower pots available. What bulbs (or seeds) should I get that will afford plants to flower in November and December?

How are Figs and Filberts propagated? I should be glad of rather full, easy, and plain directions as to how to increase the number of my Figs and Filberts, also Japanese Khakhi, a sort of Persimmon (*Diospyros Kaki*)?

Though all English and French fruits do well here, Apples especially, I cannot get Plums to grow up into big healthy trees, though they produce plentifully fruit of good size, flavour, and colour. They always look sickly and dwarfed. The soil to the best of my belief is composed of sand and humus. Clay spreading does not appear of much effect, nor ashes, farmyard manure, or fowls' dung. What agricultural chemical manure would you advise my giving the Plums to produce large healthy trees, like my Apple, Pear, Peach, Apricot, and Cherry trees? Ten years ago I put down one Raspberry and one Blackberry, now they are worse than the rabbit in Australia. I cannot again eradicate them dig as I may.

The extreme annual temperatures here are (in the year) from 20° to 85° Fahrenheit in the shade; elevation 6500 feet above sea level; sunlight eleven hours on the longest day, seven hours on the shortest day; latitude 32° N.; longitude 77° E. of Greenwich. January, February, and March rainy months (snow or rain); April, May, and June dry months; July, August, and September rainy months; October, November, and December dry months. Wheat and Barley sown in September and October, reaped in June.

With respect to the Apple from India, R. C. Lee (page 369, October 23rd, 1890), I sent you, I have since discovered it was a Blenheim Orange. I have Warner's King. They grow a large size here, from 1 lb. to 2 lbs. in weight, left to themselves, without any care or attention; but it is a worthless Apple, as it will not keep.

The natives of India will not buy Apples, because they say they are not sweet enough. Which is the sweetest Apple grown in England? Is it Sugar and Brandy? I have all the sweet Apples you mentioned for me some years back.—A. BANON, *Kulu, Punjab*.

[*Chrysanthemums* keep up a supply of bloom in this country till Christmas and after under glass. The late varieties would probably answer your purpose to a certain extent, but as you want variety it is likely the following would flower at the time you name:—*Cyclamen hederæfolium*, *C. h. album*, and *C. coum*; *Helleborus atro-rubens*, *H. orientalis*, *H. niger* and var. *angustifolius*, and *altifolius*; and *Schizostylis coccinea*. Wallflowers from early sown seed would probably flower during the late autumn, and as a wall plant *Jasminum nudiflorum*. *Freesia refracta* and var. *alba* bulbs planted in July might also afford serviceable flowers, but it is always difficult to get any flowers (except under glass) at the "fag" end of the season. Perhaps some of our correspondents can add to or improve the list.

Figs are easily increased by cuttings, layers, or suckers. Choose for cuttings the most short-jointed parts of the previous year's growth of any handy length, say 6 to 9 inches, with an inch or two of the old (two years) wood attached, removing the buds from the part to be buried in the soil, which should be two-thirds the length of the cutting. If inserted outdoors in October, or as soon as the leaves fall, in sandy soil, and some litter is thrown on the top in severe weather, uncovering when the frost and snow are gone, the cuttings will start into growth with the early summer and be fit to transplant by the autumn. All that is needed in layering is to bring a branch down to the ground and lay about 6 inches of the two-year-old wood in the soil, securing it with a peg, and the young wood to a stake in as upright position as possible without breaking. After a summer's growth the layer will be sufficiently rooted for detaching from the parent and planting where required. Fig trees generally throw up young shoots from the base below ground; these, if carefully removed with a portion of root-stem (its own) and roots attached in the autumn or early spring, often make useful plants.

Filberts are propagated by suckers and layers. The suckers are usually produced abundantly by Filbert trees, and against these the cultivators wage war, as the more suckers, as a rule, the fewer nuts. When, however, stock is required, the most promising suckers are let grow—those most distant from the stems. These, in one year, form nice plants, if left two years are strong and fit to set in the permanent quarters. They are detached in autumn with as much root as possible, and planted where desired. Layering is seldom practised; for that

purpose it is necessary that the tree or trees be cut off close to the ground, so as to cause the production of a number of shoots, which are layered when one or two years old, each shoot being bent down to the ground, cutting it about half through behind a bud upwards, splitting the shoot about an inch and inserting that part 3 or 4 inches in the soil, securing there, and with the cut part open with a peg, making the soil firm. After a year's growth the layer will be well rooted, and may be detached and planted in its permanent quarters.

*Diospyros Kaki* is readily increased from seed, or particular varieties may be propagated from cuttings of half-ripened wood, inserted in sandy soil, kept moist and shaded, or ripened shoots (with a heel) will generally strike if inserted in the autumn.

As a chemical manure for the Plum tree use bonemeal, five parts (lbs. or cwts.), kainit, three parts, mixed, applying 2 ozs. per square yard (or a little more), 4 lbs. per rod, 5½ cwt. per acre. This is best given in the early winter, and pointed in very lightly. When the buds commence swelling in the spring supply nitrate of soda (powdered) at the rate of 2¼ lbs. per rod, but it is best to apply the quantity at two dressings, half at the time named and the remainder as soon as the fruit is set.

Golden Harvey is one of the richest of British Apples, being "one of the best for cider; and from the great strength of its juice, the specific gravity of which is 1085, it has been called the Brandy Apple"—(Dr. Hogg's Fruit Manual). Sugar and Brandy, however, excels it for "taste"—sweetness; it is considered by some persons to be so sweet as to be sickly. It is esteemed in Lancashire as the sweetest of summer Apples, but it is not so good everywhere as it is there.]

### NATIONAL ROSE SOCIETY.

I AM not about to gratify Mr. Grahame by attempting to answer his attack, which he pleasantly describes to some of us as driving a big nail into the coffin of the N.R.S. I suppose it is big enough to go through me first and then to finish off the Society. I do not feel any the worse for it, and expect the Society will survive it. I, however, have two observations to make; the first is that I am very much surprised that Mr. Grahame should think it worth his while to notice its proceedings either at the annual meeting or at the Committee, the former of which he describes in his correspondence as a teapot meeting, and the latter as a screaming farce; the second is that in both of the cases in which I had to act in opposition it would have been far more in accordance with my personal feelings to have taken a different course. Of course my judgment may have been wrong, but my motives were simply what I thought best for the Society.—D., *Deal*.

### N.R.S. SOUTHERN PROVINCIAL MEETING, 1896.

MAY I say a word or two on this subject in reply to Mr. Jeans' letter? If priority of claim has anything to do with the selection of a locality Reading surely may expect to be considered. I believe, as a matter of fact, that it was the first town with which negotiations were carried on with reference to the 1894 show, but Windsor put in such a strong claim that Reading for the moment lost its chance. The Reading Rose growers (I only wish there were more of them!) were naturally disappointed, but took comfort in the belief that at the first chance their town would have the coveted honour of welcoming the N.R.S.

Immediately after the November Committee meeting I had an intimation that if Reading now renewed the invitation for 1896 it would probably be favourably considered. An invitation was sent accordingly, and Mr. D'Ombraim attended a Committee meeting of the Reading Horticultural Society the day before the N.R.S. general meeting, with the result that he was able to say at the meeting that the matter was taken up *con amore*. Not only was there no dissentient voice heard, but everyone I spoke to expressed themselves strongly in favour of the proposal.

The fact of the meeting, according to Mr. Grahame, being only a "glorified Committee meeting" seems to me rather to add weight to its decisions.—J. T. STRANGE, *Local Secretary, Aldermaston, Reading*.

### RULE 13.

MR. GRAHAME in his letter of last week's issue respecting rule 13 kindly takes up the cudgels for the trade. I think that in these days of progress the men who come to the front as big men are large-minded enough not to ask for protection from the small amateur, well knowing that the wider the love of flowers and flower growing spreads the better for them, and that no little petty rule is needed to defend the strong from their weaker brethren. I think if Mr. Grahame were to ask the big men "What protection they wanted," the answer would be, Protect me from my friends, who look on our silent strength as a proof of weakness.

In answer to the personal reference (a great mistake I venture to think on Mr. Grahame's part), I have never exhibited under false colours, nor do I intend to do so; but knowing that rule 13 is widely set

at naught, I cannot see the use of allowing it to remain a dead letter, at the same time its enforcement would lead to endless dissension, and be most prejudicial to the interests of the Society. Doubtless the rule was originally framed as a protection for the small grower and in order to prevent large growers from sweeping the board.

The new and most sensible regulations for dividing exhibitors into classes according to number of plants grown by them has rendered the original rule quite obsolete. These regulations seem all that is necessary, bad faith in keeping them is easy of proof; while the distinction between amateur and professional when two-thirds of the flowers exhibited in the amateur classes are grown by professional gardeners is simply ludicrous. The true amateur is not afraid of meeting professional skill, but professional numbers, and would be quite willing that the professional gardener should compete against him with flowers grown in his "own cottage garden."

I plead in the best interests of the Society, and for the welfare of all true amateurs, in the hope that every year may see the membership of the National Rose Society largely increased, and the pleasure experienced by the enthusiastic Rose grower more widely known.—A. F. GRACE.

#### THE CURRENT QUESTIONS.

THE Rose analysis may, I think, as "Storm in a Teacup" suggests, be now dropped. I would only point out to Mr. Mawley that what I suggested was not the doing away with his present system, but merely the adding beside it, in a separate column, the actual figures.

I should advise "Gleaner" to entirely mistrust his friend's account of meetings in future, as he has in two cases at least managed to make members say exactly the opposite of what they did say, which does not tend to a right view of things. He says that on my resigning my seat on the Committee I was proposed as a Vice-President, and that "to raise a laugh, the prospective Vice-President replied 'That is what I wanted.'" I hope that if I had been cad enough to think such a thing I should not have been so stupid as to say it. What I did say was "Sorry I spoke," honestly intended at all events to mean the exact opposite of what is attributed to me, though no doubt poorly and insufficiently expressed. But I could not at the moment think of anything else to say. I could not return thanks before I had been elected.

Then as to the gardeners—surely there is here a misunderstanding. I took the resolution to be against gardeners showing their employers' flowers in their own names only, and that the right would still remain to them, as heretofore, of showing in their employers' names with their own (if necessary) added as gardeners. This resolution I voted for, and shall continue to do so, if that is what was meant.

Then as to Mr. Grace's extraordinary letter, "Gleaner's" friend states that Mr. Lindsell said "he would read the paragraph from page 536, although it rather gave his case away." I understood Mr. Lindsell to say (I was sitting actually next him), "it rather gave *his* case away," meaning, of course, Mr. Grace's. That Mr. Grace's letter did give his own case away seems to me to be plain enough; in fact I fancied it, I regret to say, a stronger argument in favour of the enforcement of regulation 13 than the terms of Mr. Lindsell's motion. We shall be happy to hear "Gleaner's" own ideas, and his comments upon what he has heard with his own ears, but this hearsay business he will find unsatisfactory to himself as well as others, for we shall hold him responsible.

Mr. Grahame well points out the astounding position taken by Mr. Grace, of which a great deal more must be heard. Surely "Storm in a Teacup" does not realise it. He has made another shocking bad shot, and he must not call me "parabolic," for that is his own parable this time. Mr. Grace (page 536) does not object to regulation 13 itself, but to Mr. Lindsell's motion that it "shall be repealed or enforced." He tries, in an astonishing manner, to point out reasons why it should not be enforced, but does not suggest or apparently approve of its repeal.

Another absurd point is that there is nothing which Mr. Grace says the humble amateur wants to do which he may not do at present, for he does not mention exhibiting. He may grow, and prune, and bud, and sell his Roses as much as he likes, and nobody will interfere with him. It is only when he wants to exhibit as an amateur that regulation 13, as it stood before, is against him. And how on earth then could Mr. Lindsell's motion "that it be repealed or enforced" have any "disastrous effect" upon him or anyone else, unless he deliberately purposes to exhibit contrary to the regulations?

I am sorry to disagree with Mr. Grahame upon a minor point in this matter. He says (page 566) "It is not an amateur's duty to fight their (*i.e.*, the trade-growers') battles." Now I think it is, and my idea of the National Rose Society is that amateurs *should* make it their business to defend the rights and privileges of the trade when infringed by amateurs, for it is very difficult and awkward for the trade to speak in their own defence. And I feel sure that the professionals on the other hand would, if any case should arise of the rights of amateurs being infringed by a member of the trade, defend us in like manner.

I hope to be permitted still to wear in general the old coat ("W. R. Raillem") which I have become used to, but on this occasion I am forced by "Gleaner" to sign myself.—A. FOSTER-MELLIAR.

P.S.—I am very sorry the above communication was not in time for last week's number, as it is not pleasant to feel that such an extraordinary imputation as that of "Gleaner's" has been left unanswered. Mr. Grahame (p. 585) "congratulates 'Gleaner' on his most admirable *résumé* of the proceedings"; but when it is remembered that Mr. Grahame acknowledges he was not present at the meeting, and that "Gleaner" gives us to understand, in his opening and closing sentences, that he was not there either, the value of such commendation may be fairly appraised.—A. F. M.

#### NATIONAL ROSE SOCIETY—THE PORTSMOUTH ROSE SHOW BLUNDER.

THE *exposé* by Mr. Jeans in the last issue of the Journal (page 585) of the action of the Secretaries (as I consider Mr. Mawley is involved in these proceedings) in the Portsmouth question should cause some mental perturbation to these officials if they are capable of properly seeing the wrong they have done, in a most discourteous way, to those interested in that proposed meeting. Both the Secretaries were well aware, and for some time, that Mr. Spittal was strenuously exerting himself to get the Portsmouth authorities to invite our Society to hold their southern show there in 1896 (more than six weeks ago I saw the correspondence that had then passed between Mr. Mawley and the Vicar of Havenstreet, Isle of Wight), so I distinctly say that there has been little short of a deliberate cabal got up, and the Reading folk, who have no claim so soon after the Windsor show, *sought* after in order that the offer of the Portsmouth Council might be opposed.

The reason for the rejection of Portsmouth, I suppose, was given by Mr. D'Ombraïn at the annual meeting, as he seems to have been the prime mover in opposing everything; but it would not bear one minute's investigation, and I can only assume that it was stated with the belief that no one in the room had any knowledge of the true position. I hear it was stated that Portsmouth has little or no proper railway facilities. That such an assertion could be accepted by any business men (and I assume that the trade members of the Society call themselves business men), with any knowledge of the railways in this country, passes my comprehension. As a mere matter of fact, which can be easily tested by reference to an "A B C" or a "Bradshaw's Railway Guide," two railways run directly to Portsmouth—*viz.*, the Brighton line and the South-Western. The Brighton line is in direct communication with the North-Western at Clapham Junction, both railways using the same platform; and it is also in direct communication with the Great Eastern, Metropolitan, Midland, and Great Northern at New Cross. The South-Western is in direct communication with the Great Western, of which fact I should think even children (not to speak of grown-up people or so-called business men) are aware, as Her Majesty the Queen invariably goes over the Great Western Railway and runs on to the South-Western when going to the Isle of Wight, twice every year. I think this answers the imprudent assertion, safe enough when stated before an audience apparently unable to see its absurdity, that Portsmouth has not good railway facilities. However, it is plain that this assertion was merely used as a means towards an end, and that end was, for some occult reason, to have the southern show at Reading—eighteen miles from Windsor, and no more a southern town than Gloucester! I most unfortunately was unable to be at the meeting on the 13th ult.; no other subscriber to the N.R.S. who is a member of the Stock Exchange was present, it being the payment day of an important settlement, otherwise I certainly should have flatly contradicted this untrue statement about want of railway facilities to or at Portsmouth. But is not the foregoing fiasco on a par with everything which has most recently, not to speak of the past, been characteristic of the management of the National Rose Society?

In one of your contemporaries some months ago I compared the progress of the Royal Horticultural Society since 1887 with that of the National Rose Society in the same period. The contrast is absolutely ludicrous. Progression *v.* Stagnation. Why is it so? Because one Society is managed by capable men; that their Secretary is a man of indomitable perseverance and grit, one of the ablest managers of any Society in England, well seconded by his Assistant Secretary, and that the R.H.S. is run on business principles. In contrast I may sum up the position and management of our Society in one line—it is just the opposite of the R.H.S. The policy of one Society is fixed, that of the other is vacillating. What is done at one N.R.S. Committee (when you can find where it is sitting!) is frequently undone at another. What is considered an exploded system, such as having two Committees, in one year, is applauded and restored the next, and so on *ad infinitum*.

An anonymous correspondent writing recently to you stated that the Society was to be congratulated on its doing so well in 1894, because trade has been in a disastrous state. I do not suppose your correspondent is an authority on financial matters. In fact he plainly shows by his statement that he is not so. If any of your readers know anything about city affairs, they know that both in the press and in private circles it has been long accepted as correct that trade in 1894 has improved and still maintains that position. This is to be read daily, weekly, and monthly in the city papers and magazines, and it is quite true. The "Financial News," in its review of the year, published on December 31st, closed with the following sentence: "The year closes with every indication of improving trade and encouraging conditions, and the New

Year will dawn to-morrow with more hopeful auguries than it has been our lot to chronicle since the calamitous crisis which darkened the close of 1890." Anyone who is observant knows this for himself—and yet now has the N.R.S. done? Gone back in membership and financial position. What is the cause? That there is no "go" in it, that its local Secretaries and its management do not work in an intelligent way, and not in my view for its best advancement, and that their recent action to one of our most valued members and other blunders, such as that of the postponement of the annual meeting, have only intensified the disgust felt by many. By whom was that annual meeting attended? By thirty-seven persons, thirty-three of them on the Committee!

At one time no man was more enthusiastic to advance the Society's interest than I was. I have proved my interest in a substantial manner. I would gladly give further proof of my interest in the Society as distinct from its management; but the action of the senior Secretary in securing the non-election of Mr. Machin to the Vice-Presidentship, on a plea of "no room," which he immediately stultified by proposing another member for the position, and the action of both Secretaries in regard to the Portsmouth Town Council, would drive all enthusiasm, or the interest remaining, out of me even if I could believe that their conduct when exposed, as it has now been by Mr. Jeans and "Gleaner," meets with the approval of anyone who considers he takes the slightest interest in the well-being and progress of the National Rose Society.—CHARLES J. GRAHAME.

#### THE MAY FROST.

THE severe frost which did so much damage to rosarians about May 21st seemed at the time to call forth many inquiries as to what steps should be taken with the plants. Some growers recommended cutting the injured shoots off, others advised waiting until the trees had made a natural break, and then removing what was absolutely dead.

Fortunately my Roses were only very slightly touched, and therefore I cannot speak with much personal experience; but as many of my friends were badly hit, I was able to see how the two methods answered.

The conclusion I arrived at was all in favour of the latter mode of treatment—viz., leaving the plants until they commenced to break of their own accord. This plan I know was not generally adopted, as Mr. Grahame, in your issue of June 7th, page 455, wrote that he had at once pruned away all frost-bitten shoots, and as he was supported by Mr. Lindsell he had the highest authority on his side. The specimens I saw which were cut back never seemed to recover until the autumn, but those left alone soon recommenced growing. Doubtless the severe pruning was too great a shock to the plants after the great check they had received from the frost.

We, of course, all hope that such a disastrous visitation is not in store for us again next year; but as there is frequently a sharp frost towards the end of May, I think many of your readers would like to know what to do if similarly situated. Perhaps some of our big growers will kindly give us the benefit of their experience and advice?—R. M. D.

#### ANALYSING THE ANALYSIS.

ALTHOUGH rival queens have entered Flora's kingdom the recent discussion—the analysing of the analysis—plainly shows that *Rosa regina* is *par excellence* the Queen of Hearts. A rosy subject is apt to resolve itself into a thorny one. Yet it is pleasing to observe in the varied criticism of the analysis, that the labour entailed in its construction has not been overlooked. As one afar off taking a distant—mayhap a broader—view of the question, I may be permitted to present as aspect of it possibly not apparent at close quarters.

Some measure of credit being allowed to the labour side, it may also be added that "E. M." has shown a liberal spirit in laying bare his analysis to the skeleton: although, to him, it must have been a foregone conclusion that in doing so he exposed himself to sharper criticism than when submitting the body *in toto*. He has shown how the summing up was arrived at. Others have defined the methods they would employ, and what is the result of this dual arithmetic? Practically, the difference consists in that obtaining betwixt six and half a dozen. From the very nature of this, or any subject so elastic as these we have to deal with, considerable margin must be allowed. It is impossible to arrive at that accurate computation obtainable from mathematical data. In our subjects natural forces are ever present with their tendency to upset man's calculations. Such being the case we have no basis so firmly fixed but what is capable of being swayed by individual opinion. That we want the truth goes without saying. Failing that we must fain be content with the nearest possible approach to it.

All will allow the educational value of an analysis. It is its birth-right. It may also be conceded that criticism, conducted on the lines that this has been, is only secondary to it in value and importance. The disputatious points which have arisen appear to have sprung more from the method of compilation than from the results obtained. It is obvious that these gentlemen who have analysed the analysis are, by reason of their ability to do so, so happily situated as to least require the knowledge it is intended to convey. Yet they will not, I am sure, hastily overlook the fact, that behind them is the great mass of Rose lovers also seeking the truth. That these were catered for by Mr. Mawley in preparing his analysis appears to contain the gist of the whole question. Strong meat is doubtless suitable for giants, yet I think that "E. M." taking a comprehensive view, *pro bono publico*, endeavoured to present his dish in that form best suited to the digestive powers of men of less calibre, though as keenly interested.

"W. R. Raillem's" happily expressed metaphor (page 536) in the

"cup that cheers" is to the point from that point of view. Sugar at discretion for those who are discreet. These are experts able by force of superior knowledge to clothe the naked truth in rational dress. Yet not so with all. Younger people cannot claim the prerogative of their elders. Hence Mr. Mawley in sugaring for them has sacrificed the cultivated tastes of the few to the requirements of the many.—E. K.

#### DESMODIUM PENDULIFLORUM.

A PLANT far too seldom seen in English gardens is that depicted by the illustration (fig. 4). It forms in soils suited to its requirements, and these when in full flower have a singularly graceful appearance.

FIG. 4.—DESMODIUM PENDULIFLORUM.

The drooping character of the shoots is shown in the woodcut, and a large specimen laden with its bright purplish crimson flowers has a charming effect.

#### FAILURES IN FRUIT GROWING.

VERY many years ago I had the pleasure of meeting Mr. Mechi of Tiptree Farm celebrity. As is well known he tried various experiments in farming, some turned out well and were of advantage to the farming public by way of putting fact over theory, others were failures. Talking with Mr. Mechi one day as to what people had to say about or of him he said, "Yes, I know I have made mistakes like many others in what I have tried to do, but I have laid it all before the agricultural world. What was theory I made practice. It turned out wrong, I lost by it, but the people were warned and thus profited by my loss. They ought rather to thank me than jeer at me, as some have, because I have tried to show what will pay and what will not."

I thought there was much truth in this, and I think so now. If a man tries methods of production under certain conditions, and he finds they fail and he loses, that man does a lasting good to the community

if he gives his full experience. He is not to be jeered at nor flouted, as Mr. Mechi wisely observed, if he makes his failures known as well as his successes. Both benefit the public by being known. And this is so in Mr. R. D. Blackmore's case. He tells us of his failures in fruit-growing, and what the loss has been to him, and yet for this, one writer with an obliquity of mental vision that I am unable to understand, says, "It seems to me that the advice of Mr. Blackmore is not only mistaken but unpatriotic." Where is the mistake? He has grown fruit on his own land for forty years for market purposes. He says, "I began with the idea of living on the proceeds." In this he was disappointed—grievously disappointed. Instead of gain he has lost—lost thousands of pounds in the forty years. Then his "candid friends" tell him that he knows nothing about it. Well, I know Mr. R. D. Blackmore, and if after forty years' practice he knows nothing about it, all I can say is, that close observation, long and careful treatment of his trees, and the bringing to bear on the question a powerful and clear intellect ought to have made him an adept in these long years of thought and toil, and I may add with the love of fruit-growing.

Next I will take the assertion of "Spes in Futuro" that he is "unpatriotic." It is a well-known fact that no two people see alike, nor think alike, nor act alike; therefore I may be pardoned if I side with my dear good friend Mr. R. D. Blackmore, and in so doing I say this, I think his action was very patriotic. He has toiled in the heat of the day, and he knows the cost. He tells the people "This is what I have done, and in doing this, this is what I have lost. I tell you not because I am benefited in the telling, but that you, knowing what I have done, may not go into the matter blindly as I did, but with your eyes open. I expose my affairs to you for your good, not mine. I have no interest in telling the nation how and what I have lost, but you have in knowing, because you can profit by learning where I failed." Surely there is nothing but patriotism in this. I think so, and I honour my friend for it.

There was no need for him to tell of his losses, but for the public's good he has done it. He has done it bravely and well. Jeer at him if you will, any of you, all of you interested or otherwise; gird at him, read his truly pathetic letter where he says, "Well, gird away." He is convinced, he is honest in his convictions, and his truthful honesty of character, his deep sincerity, his manly upright nature would not let him withhold his practical knowledge from those he loves so well. I mean the English people. Sneer at him you little ones because you do not understand the magnitude of the deed, but honour him for it you greater minds. Honour to the man that outspeaks the truth as he knows it, sees and feels it. Such a man is, in my belief, Mr. R. D. Blackmore.—HARRISON WEIR, *Iddlesleigh*.

#### JOTTINGS ON APHIDES.

I HAVE read "Entomologist's" article on aphides on page 560 (last vol.) with much interest. With many of the facts stated I am well acquainted from researches. I am not quite certain as to the hybernating of the viviparous Plum aphid (*A. pruni*). I have found them in mild winters in January on the blossom buds taking nourishment from the base or neck, and supposed they must have climbed to that position from underneath the trees in grass orchards.

The common Primrose is a favourite winter hybernating situation for one species of aphid of a pale green colour; by taking up a few roots from woods at this season of the year the insects will be found on the under side of the foliage. Whether these are the forerunners of the great army of Plum and Hop aphides I am unable to say, not having minutely compared them.

I find the common brown scale or coccus very prevalent on Red Currant bushes at Kenilworth, some branches almost coated over, but the male referred to by "Entomologist" I am unacquainted with, and would like to learn more about it. The Black Currant mite and American blight, or woolly aphid, are also very destructive in certain districts visited by me in Warwickshire, and also the nut phytoptus on Filberts. Many trees I find ruined for the present until fresh growth is produced by pruning off the infested parts and burning them.

Some years ago "Entomologist" gave us some interesting information on silkworms and moths. Would he be kind enough to say where eggs can be obtained, and whether it is probable that they would become valuable if exported and reared at Chicago, U.S.A.?—JAS. HIAM.

#### POINSETTIAS AT LEIGHTON.

MUCH the best display of these popular plants I have seen for some time are under the charge of Mr. P. Mann, gardener to W. H. Laverton, Esq., late High Sheriff of the county of Wilts. What winter-flowering plant is there, apart from the Chrysanthemum, that possess so many claims for decorative work, dinner-table, ball-room, or general use? In December even Chrysanthemums cannot vie with them not approaching the brilliance of the Poinsettia. This is more particularly emphasised when the cultivation of the plant is above the ordinary standard of excellence as in the case under notice.

The vigorous and healthy condition of the plants is remarkable, some being nearly 6 feet in height, and I think the average of all would be 5 feet. No larger than 7-inch pots are used, and among the collection I did not observe more than two or three old plants, the others being all early summer-struck cuttings. The girth of the stem of the strongest plant was 3 inches near the pot, and the finest bract measured 20 inches in

diameter. Whether it is a superior form of the type, or the outcome of good culture, I do not know; but there appeared a greater freedom in the character than is usually seen. There was not the compactness of the early form, nor the irregular habit of the latest one, that has such a distinctly bright colour. The colour, form, and time of flowering seemed to be altogether intermediate, and whether it is accounted for in the distinctness of the variety, or superior cultivation, there is certainly a claim for the highest commendation in the general excellence of the plants as I saw them.

Mr. Mann pins his faith apparently on the thorough ripening of the stock plants after they have ceased flowering, for they are rested on a shelf in an intermediate house, open to all the sunlight available, and this must be done without any extreme in the matter of root treatment and moisture. From well ripened wood comes sturdy cuttings, and these kept well up to the glass until they have gained the desired length are rooted in 2-inch pots, filled with a mixture of loam, leaf mould, and sand. Peat in small proportion, too, is used in the final potting, as are also a few crushed bones. Whether chemical manures of any kind are requisitioned I did not learn, but I was told that natural liquid manures were very sparingly given. Poinsettias are very sensitive to extremes of root or atmospheric treatment, as everyone knows who has to grow them; and the general condition of the Leighton plants testify in a marked manner to the care they had bestowed on them throughout the season. Their summer quarters after they are rooted is in cool pits, which are ventilated in accordance with the state of the weather, and in the autumn a small structure is almost exclusively devoted to them until their floral heads are developed, when they find employment in the conservatory and house.—W. S.

#### LIME.

I AM much obliged to "W. D., *Turnford*," for his valuable information (page 586, last issue), but hardly think he has fully explained my men's rooted antipathy to lime, for the simple reason that I never, of course, expected them to apply so powerful a chemical with their hands a bit more than any other manure. If, however, lime "causes soreness and cracking of the skin," I suppose moving it at all, especially if there be any wind, produces the deleterious effects "W. D." describes. I would therefore ask if it could not be slaked in one large heap on arrival from the kiln, instead of on the land in small heaps? But then, is slaked lime as effective as quicklime? Indeed, is it of any greater power or value than chalk.

"W. D." apparently propounds a new doctrine—viz., that lime is *per se* a soil fertiliser. Hitherto those advocating its use, whether in print or elsewhere, have confined themselves to recommending caustic lime as an insect destroyer. "W. D." does not appear to consider it so. My query was whether, if applied in sufficient quantity to kill wire-worm, slugs, chrysalids, and other injurious denizens of the soil, it would not also destroy those microscopic forms of insect life which it is every gardener's endeavour to preserve and protect from injury. Otherwise, how is it one so often hears the remark that lime "burns the soil?" Gas lime now seems difficult to procure, owing to new processes having displaced its use in gas-making.—INQUIRER.

WILL you please correct the mistake made in the article—viz., "Lime" (page 586, line 22). It should read "Lime acts on soils in various other ways, for it is in itself a direct plant food, large quantities being taken up by growing crops as a nitrate of lime, it decomposes the organic matter present in soils, &c." The comma following the word crops should be placed after the word lime.—W. D., *Turnford*.

#### THE ORIGIN AND HISTORY OF SAXIFRAGA WALLACEI.

AS I am aware that the Botanical Society of Edinburgh does not confine its attention to matters of purely scientific botany, but takes a great interest in everything relating to horticulture also, I need scarcely apologise for bringing under your notice the subject of the origin and history of a now well-known plant, namely, *Saxifraga Wallacei*. I am the more anxious to place this subject before you, seeing that doubts still exist in the minds of many both as to the parentage of the plant and its raiser; and being acquainted with its history from the beginning, I am able to speak with some degree of confidence on the subject. In 1873 Messrs. Jas. Backhouse & Son of York sent out two new *Saxifragas*—*S. Maweana*\* and *S. Wilkommiana*. These were described by them as "two new species of the *S. palmata* section, with showy tufts of large pure white flowers, on stems 6 to 10 inches high." They added that, though nearly allied to each other, they are quite distinct, and might be regarded as two of the finest of the group. The first of these, *S. Maweana*, has now practically gone out of cultivation; but the second, *S. Wilkommiana*, is still grown.

Some two years after they were sent out, the late George Wallace, of the Dean Cemetery, Edinburgh, succeeded in raising from them a *Saxifraga* now usually known in plant catalogues as *S. Wallacei* of gardens. This plant has become very widely known, and it is,

\* *S. Maweana*, *Baker*, figured in the "Botanical Magazine," t. 6384, was discovered by Mr. P. B. Webb, of Paris in 1827, "in its only known habitat, rocks of the Beni Hosmar range of mountains opposite Tetuan," in Morocco, "at about 2000 feet elevation." He regarded it as a form of *S. globulifera*. It was not recognised to be a new species until Mr. Maw gathered it in 1869, and it was introduced into cultivation by him.

perhaps, one of the best of its kind, whether for bedding purposes or as a pot plant. It has some qualities which mark it as an improvement on both parents, since it lasts longer in bloom than *S. Maweania*, and is of much superior habit to *S. Wilkommiana*, while it possesses a sweet scent but faintly present in either parent. Messrs. Dicksons & Co. procured the original plant from the raiser, and at once proceeded to increase it, preparatory to sending it out. As many as 10,000 pots of it have been in stock in Messrs. Dicksons' Nurseries at one time, for, although the plant very rarely seeds, it is easily grown from cuttings. It was distributed all over Britain and throughout the Continent of Europe, as well as in America.

As already stated, doubts have been thrown on its origin and history, and it is chiefly to set these doubts at rest, and to give honour to whom honour is due in the raising of it, that I have ventured to bring this subject before the members of the Botanical Society. I trust the plant will long keep alive the memory of its raiser—one who, though but a humble horticulturist, was, throughout a long life, a keen and enthusiastic lover of plants.—J. GRIEVE.—(*Transactions of the Botanical Society of Edinburgh.*)

### OX-EYE DAISIES.

No doubt for cutting purposes flowers of these 5 inches across do seem too large. One of the faults of *C. latifolium* is its stiffness, and the lacinated forms of *C. maximum* far surpass it in beauty. I believe the great merit of the new variety of *latifolium* lies in its uses for garden effect. Flowers of 5 inches across are not inordinately large on a plant 10 feet high, a height which this large form will attain in good soils. I am told that *filiforme* is the proper spelling of this name and not *filiformis*.

"A. D." (page 539) is quite right in his wishes for the use of common names. But for the confusion which would arise with the popular *Chrysanthemum sinense* we might cut the Gordian knot by saying *C. filiforme*, and so on. But then we have *Elaine* and *Duchess of Abercorn* to deal with, and the confusion with those of the other species would be certain to come in. I fear we shall thus require to keep to *C. maximum filiforme*, *C. m. Elaine*, *C. m. laciniatum*, and *C. m. Duchess of Abercorn*. For garden purposes the use of the "m" would suit well enough. I understand the Rev. C. Wolley Dod's large variety was named *C. latifolium "A1."* Possibly this was only a provisional name, but I do not know that any other has been given by its raiser. I should much like to see the increase of varieties with lighter and more elegantly formed flowers. *C. leucanthemum (semi-duplex)* is a distinct variety, which it is to be hoped may lead to others of a similar but better form.—S. ARNOTT.

### OVERTOWN.

THIS fine house and gardens, the residence of Lord Overtown, is situated on the south-west corner of the Kilpatrick Hills, about 600 feet above the sea level; and, as seen from the town of Dumharton, looks beautifully sheltered amongst the trees and the high hill at the back. After walking about two miles from the above town we find ourselves at the entrance of the new drive, which is yet in an unfinished state. Nothing is being spared to make this new approach substantial in character. It is  $1\frac{1}{2}$  mile in length, and the contractor has had many difficulties to overcome. The ground through which the drive passes is intersected by a deep glen in two places, one part being filled up to the depth of at least 100 feet, and the other is to be spanned by a substantial bridge in keeping with the architecture of the mansion; and at one corner of this bridge a large rockery is in course of erection. As we stand on the terrace in front of the house we have one of the finest of the many lovely views to be seen from the Kilpatrick Range, Dumharton. Its majestic rock and the River Clyde, with its far reaches on either side, make this view sublimely grand.

The real object of our visit was, however, to see two different classes of plants—viz., *Chrysanthemums* and *Calanthes*—through the kind invitation of Mr. Forbes, who has had charge of these gardens for the last twenty-seven years; and I can confidently say a finer group of *Chrysanthemums* and a finer collection of *Calanthes* have rarely been witnessed. As we suddenly came in front of the hexagon-shaped conservatory, and beheld the *Chrysanthemums*, we cried, "That's grand." The plants were arranged in a group on the floor in the centre of the house, and were clothed with foliage down to the pots. The plants in front were about  $2\frac{1}{2}$  feet high, and gradually rose to the height of 6 feet at the back, and so disposed that each bloom showed itself to the fullest advantage. These were large, and scarcely a had petal was to be seen. This was remarkable considering the lateness of the season (November 30th). Many of the best varieties of the Japanese, incurved, and reflexed families were represented. Mr. Forbes stated that most of the plants were cut back during the month of May; also that this was the second lot of plants so grouped, the earlier being considerably dwarfer.

We passed on to see the *Calanthes*. These occupied the whole side of a span-roof house 24 feet long. There were five rows of plants, principally in 7 and 8-inch pots, and what a sight! every pot just coming to its best. Three varieties are grown—namely, *C. Veitchi*, *C. vestita rosea*, and *C. lutea*. The majority of the spikes were 3 feet in length, and the colours very bright. *Veitchi* appeared to be of a deeper and better colour than is generally met with; this probably owing to good

culture and position. On the other side of the house the stage was filled with a general collection of Orchids, looking the picture of health, several in flower and others throwing up strong spikes.

There was much more to see, all denoting the best of management, particularly the large fernery, with the water rippling over the pebbles and the fish darting about. *Dicksonias*, *Calatheas*, *Todeas*, and other plants also looked quite happy and at home. We were sorry when the shades of evening stole upon us. But should any persons interested in horticulture or bee culture be in the vicinity I am sure Mr. Forbes will make them welcome, and show them the work that he and his assistants are so ably carrying on.—W. RUSHTON, *Coehno.*

### FRUIT FORCING.

**Vines.**—*Early Forced in Pots.*—In order to secure well-set bunches the temperature should be somewhat brisk during the flowering stage,  $70^{\circ}$  to  $75^{\circ}$  by day and  $65^{\circ}$  to  $70^{\circ}$  at night being maintained, and an advance of  $10^{\circ}$  to  $15^{\circ}$  allowed from sun heat, admitting air moderately, always without inducing an inrush of cold air, which stunts the growths, crippling the foliage, and sometimes producing rust on the berries. As soon as the fruit is set the Vines should be well supplied with liquid manure, and have surface dressings of rich compost, maintaining a genial atmosphere by damping the paths two or three times a day, and occasionally with liquid manure, keeping the evaporation troughs regularly charged. Let the berries be thinned as soon as they are fairly set, removing the smaller, but remember they do not swell so large at the early part of the season as later, or as those of planted-out Vines.

*Early Forced Planted-out Vines.*—Great care is necessary to avoid chills, such as those resulting from injudicious ventilation, or admitting air too freely after a dull and cold period. In bright weather a moderate amount of ventilation will suffice to insure a change of air, which should be effected without lowering the temperature. With the foliage increasing root action will be excited, and should be encouraged by supplying water or liquid manure in a tepid state. Disbud, and tie the shoots down before they touch the glass, not being in too great a hurry in stopping nor restricting to a certain number of joints beyond the bunch, but extend the growths so as to insure well-developed foliage without overcrowding. Remove superfluous bunches as soon as choice can be made of the best, avoiding overcropping. Keep the house at  $70^{\circ}$  to  $75^{\circ}$  as the flowers open, and maintain a rather drier condition of the atmosphere.

*Houses to Afford Ripe Grapes in June.*—The Vines that are to supply these should be started at once, the outside border being protected with sufficient leaves, fern or litter to exclude frost. The inside border must be watered sufficiently to be evenly moistened to the drainage. Damp the house and Vines two or three times a day when the weather is bright, but in dull weather once or at most twice a day will be ample. The temperature should be  $50^{\circ}$  to  $55^{\circ}$  by artificial means, and  $65^{\circ}$  from sun heat.

*Succession Houses.*—Midseason Vines ought always to be pruned, and the houses thoroughly cleansed by the new year, and where late Grapes have been cut the Vines should be pruned with as little delay as possible. Cut to a plump bud as near the main stem as possible. There may be two eyes or more, which will cause the spurs in course of time to become long, but it is easy to train up young canes for displacing any rods that have the spurs too long. Rub off loose bark, for it does nothing but harbour insects, and wash the Vines with softsoap and water, not using a stronger solution than 4 ozs. to a gallon of water. If the Vines have been infested with mildew dress them with flowers of sulphur, formed into a creamy consistency with skim milk, and apply with a brush; or if the Grapes were attacked by "spot" use a solution of sulphate of iron, 1 lb. to a gallon of water. Remove the surface soil or mulching, and supply fresh material. Keep the house cool, but if utilised for plants the temperature, artificially, must not exceed  $45^{\circ}$ ; indeed, plants that require safety from frost only should be placed in vineries when the Vines are at rest.

*Late Houses.*—Vineries in which Grapes are hanging should have a dry atmosphere and a mean temperature of  $45^{\circ}$ . Examine every bunch frequently, and remove all decayed berries. Ventilate the house on fine dry mornings, and keep it closed when the weather is damp. It is a better plan, however, to cut the Grapes, inserting the ends of the shoots in bottles of water, secured in an inclined position, so as to admit of the fruit hanging clear of the bottles. Any dry room will be a suitable place where an equable temperature of  $40^{\circ}$  to  $45^{\circ}$  is maintained. This will admit of the Vines being pruned and the house cleaned.

**Cherry House.**—This having been closed last month, as advised, and frost excluded from the house, gentle excitement will have taken place, and fire heat may now be applied so as to maintain a temperature by artificial means of not more than  $40^{\circ}$  at night and  $45^{\circ}$  in the daytime, advancing  $10^{\circ}$  from sun heat, ventilating at  $50^{\circ}$ , and closing at

that point. Ventilate very freely in mild weather, and avoid hasty treatment in the early stages of growth. Make sure that no deficiency of moisture exists in the soil, and see that trees in pots are not neglected for water. Sprinkle the trees and house occasionally in the morning and afternoon in bright weather, but avoid keeping the trees dripping with moisture, and ventilate a little, constantly, as a close atmosphere weakens the blossoms even when they are enveloped in the scales of the buds. Cherries can hardly be brought on too slowly in the early stages of forcing. Trees started now and having been forced before will give ripe Cherries at the end of April or early in May, but those forced for the first time will not ripen their crops so early by a fortnight or three weeks. Early Rivers, Black Tartarian, and Governor Wood are excellent varieties.

**Strawberries in Pots.**—The plants started in December should be closely scrutinised for aphides, and if there be the least trace extirpate the pests by repeated fumigation. A keen eye should also be kept on the growths for the first speck of mildew, when promptly apply flowers of sulphur thereto, and brush the hot-water pipes over lightly with a cream formed of it and skim milk. The fumes from sulphur are potent in the destruction of mildew, and the plants and fruit are not disfigured. A temperature of 50° to 55° at night, and 60° to 65° by day, will bring the plants forward as quickly as is safe, allowing an advance of 10° to 15° from sun heat. Lose no opportunity of admitting air, as the trusses are the boldest and the flowers the strongest when the foliage has abundance of light and air. A close atmosphere induces soft tissues, weakly organs of fructification, and deformed, ill-shapen fruit.

Place a number of plants on shelves in Peach houses or vineries started about this time. Rectify the drainage of the pots, remove moss or other matter from the surface of the soil, and wash the pots clean. Surface dress with an approved fertiliser mixed with a little loam, or use three parts superphosphate, two parts powdered saltpetre, and one part ground gypsum, mixed. Apply about a teaspoonful to each pot, after top-dressing with rich soil, and wash in. Noble and Auguste Nicaise are excellent for introducing now to fruit in April, but both President and Sir Joseph Paxton excel them in quality. To maintain a succession of plants La Grosse Sucrée and Vicomtesse Hericart de Thury must be introduced at the same time.

**Melons.**—Seeds should be sown at once for the first crop. They are best placed singly in 3-inch pots about two-thirds filled with soil, covering about half an inch, plunging the pots in a bottom heat of 80°, placing a square of glass on each pot to bring up the seeds quickly, and removing it directly the cotyledons lift the soil. Good fibrous loam and leaf soil in equal parts gently pressed down form a suitable compost for the young rootlets, the pots being efficiently but not excessively drained. Keep the plants near the glass, not allowing them to become drawn. Ripe fruit from a sowing made at this time may be expected early in May or sooner if the weather be unusually favourable. Scarlet Gem (scarlet-flesh), and Pineapple (green-flesh), are excellent in quality, but the fruits are small. Blenheim Orange, Sion House, Eastnor Castle, and Longleat Perfection are also excellent. There is no end of varieties, every grower having some special favourite.

**Cucumbers.**—To secure plants for growing in frames or pits heated by fermenting materials seeds should be sown now for February plantings, the materials for which ought now to be in process of sweetening for making up the beds. Where no convenience exists for raising plants a bed of leaves and stale manure should be made up forthwith, the seed to be sown as soon as the bed affords a bottom heat of 90° and top heat of 70° to 75°. A sowing made at this time will afford fruit in April onwards, the plants being put in the fruiting beds early in February and well attended to with linings and coverings.

**Cucumbers in Houses.**—Seed sown now, as advised for Melons, will afford plants fit to place in their fruiting quarters in about a month, and such plants will afford fruits from the beginning of April or earlier, and maintain a liberal supply during the late spring and early summer months.

Young plants just coming into bearing must be cautiously cropped, assisting them to swell their first fruits by removing staminate blossoms and superfluous fruits. Trim plants in bearing twice a week, removing all weakly and exhausted growths, retaining as many of the young growths as can have space for expanding their foliage, but overcrowding tends to certain disaster. Stop the shoots one or two joints beyond the fruit, but young plants should be allowed more freedom, always avoiding overcrowding. Maintain the night temperature at 65° to 70°, 70° to 75° by day, with a rise of 10° or more from sun heat, admitting a little air at 80° if the external air be warm and soft, but if cold and sharp it is better to allow the temperature to advance a little higher than admit cold air to reduce it, even when the sun is powerful. If canker appear run quicklime into the affected parts and repeat as necessary. A little sulphur, brought to the consistency of cream with skim milk, and brushed on the hot-water pipes will keep down red spider, white fly, and mildew. It must not be overdone, just a light coating being sufficient. Maintain a genial moisture by damping the floor in the morning and afternoon. Supply liquid manure about once a week or at every alternate watering, always slightly warmer than the bed.

**Tomatoes.**—Where plants have to be raised from seed to produce the earliest supplies of fruit, the seed should be sown now rather thinly in light soil, and placed in a house where there is a temperature of 60° to 65°, with an advance of 10° to 15° from sun heat. The seed

pot should be placed near the glass, so that the seedlings may come up strong and be kept sturdy. When large enough to handle place singly in 3-inch pots, and from these transfer to 5-inch, when they become well rooted, keeping them well down in the pots. From these they can be transferred to the bed, which should insure a depth of about 15 inches, and under that rubble for drainage. A ridge about a foot wide at the top, and the whole length of the house, will be sufficient for planting in, the plants being set about 18 inches apart, and trained on the single cordon system to wires about 1 foot from the glass. Fruit will show right along from the first truss, therefore do not stop the lead until the last truss is produced according to the extent of space, and keep off all side shoots. Good loam with a fifth of well-decayed manure will grow them well, but some lime rubble, a little wood ashes and charcoal are advantageous. A 2 feet width of border is ample, the plants being earthed as the roots protrude, making the soil firm. Surface dressings and liquid manure can be given when the crops are swelling.

**Growing in Pots.**—Instead of planting out, the Tomatoes can be placed in 10 or 12-inch pots from the 5-inch, placing low enough for top-dressing with fresh soil. The plants will come into bearing quickly, and can be fed to any extent after the first trusses are secured.

**Cutting Plants.**—The cuttings for supplying the plants are inserted in September, and kept near the glass in not larger than 5-inch pots, in a temperature of 55° to 60° with a rise from sun heat. If the plants get too tall a little damp moss placed around the stem just below the leaves will soon be filled with roots, below which the stem may be severed and the dwarfed plants placed in 5-inch pots. In a temperature of 60° to 65° with 10° to 15° advance from sun heat, they are soon ready to transfer to the final pots, with fruit showing, so that they afford ripe fruit several weeks earlier than those raised from seed. A night temperature of 55° to 60°, 60° to 65° by day, and 70° to 75° from sun heat, and ventilation from 65° will keep the plants sturdy and progressive. When in flower ventilate rather freely, and rap the base of the truss to distribute the pollen. About one-third of the leaf may be pinched off to afford light, practising it early, and with liberal supplies of liquid manure the fruit will attain a good size.

#### THE KITCHEN GARDEN.

**Mushrooms.**—It is at midwinter when Mushrooms are in the greatest request in many private places. As yet beds in unheated structures as well as those outside have not ceased to be productive; but a period of intense cold would quickly stop further growth for a time, and it is then when a little fire heat does good service. Too often it is turned on more freely than desirable. From 50° to 55° answers well, and any considerable increase on those figures is detrimental to the quality and quantity of the Mushrooms produced. Where fire heat is employed the beds should be frequently examined with a view to giving a thorough moistening with warm water directly they approach dryness. Once allowed to become very dry it is scarcely possible to remoisten the manure, and the Mushrooms will soon cease to appear accordingly. On the other hand saturation must be avoided, as this destroys the spawn.

**Open-air Mushroom Beds.**—These ought to be uncovered as little as possible during cold weather. If they are producing mark where last uncovered and gather from the next width, re-covering with litter as quickly as possible. Heavy rains have penetrated through quite heavy coverings of litter, and unless the latter is changed for drier material frosts will reach the interior of the beds; not that this will destroy the spawn, but it will stop productiveness for some time to come. Besides, unless the litter is changed the beds will become too cold and saturated for the spawn to survive.

**Tomatoes.**—The autumn and early winter has been favourable to the preservation and growth of late-raised plants. Instead of keeping these in a semi-starved state in small pots they ought now to be either given a shift into larger, or they may be placed direct where they are to fruit. The earliest crops can, as a rule, be had by pot culture, the exceptions being when ridges of soil can be placed on a staging along the front of a forcing house, training the plants up the roof in either case. Ten-inch pots are large enough for a single fruiting plant at this early date, and these should only be three parts filled with soil, this allowing good room for top-dressings later on. A rather rich compost should be used for potting. A mixture of two parts of roughly broken-up fibrous loam to one part of horse droppings with a sprinkling of fish-bone manure added is not too rich, but for ridges less manure is needed. The soil ought to be warmed and made firm about the roots. "Leggy" plants should not be buried deeply, the better plan being to lay them down, so as to bring the heads where they are wanted and cover the naked stems with soil. In the course of a few days the buried stems will emit roots freely, and be a source of strength rather than weakness. The temperature of the house may range from 55° to 60°, but avoid creating a moist atmosphere or disease will soon be observable.

**Raising Tomato Plants.**—If seed is sown now or early in January it ought to be possible to have ripe fruit from the plants in April or early in May. For these early crops the slightly corrugated varieties such as Frogmore Selected, Early Ruby, and Webb's Sensation are to be preferred, as these are the freest setters, and the two first named ripen well in advance of most other varieties. Challenger, Ham Green, and Duke of York are all suitable for affording a good succession of handsome fruit. Sow the seed thinly in 6-inch pots, using fine sandy soil, as the roots are least injured when shaken clear of this at potting

time. Give a gentle watering and plunge in brisk bottom heat. Soon after the seedlings appear transfer to shelves near the glass in a forcing house. When they have formed a pair of rough leaves, shake them out, and either place singly in 2½-inch pots or in pairs down the sides of larger pots. Plunge in a mild hotbed and afford top heat of 65° or thereabouts. Thus treated they will soon recover from the check given, and after a few days' existence nearer the glass they will be ready for a shift into larger pots or for their fruiting quarters.

**Market Growers' Houses.**—Too often these are crowded with a variety of pot plants, which greatly interfere with the more profitable occupation of growing early crops of Tomatoes. The borders ought now to be in the course of preparation for Tomato plants. If there is a good depth of workable soil underneath, some of this ought each season to be brought to and mixed with the surface soil in the process of bastard trenching—the shovellings of that portion loosened. Tomatoes are great impoverishers of the ground, and something ought to be done each season towards restoring the fertility taken out of it. Much solid manure, such as that obtained from farmyards and stables, is apt to promote rank and non-productive disease-inviting growth of the plants, but a light dressing forms a good adjunct to an application of chemical manures. It has been found that an early dressing of the latter applied just prior to planting gives better results than later applications. Tomato manure may consist of four parts superphosphate to two of muriate of potash, and one of nitrate of soda. These should be thoroughly well crushed and mixed, then forked into the surface at the rate of 4½ ozs. to the square yard. Should the plants give signs of failing vigour before the end of the season apply nitrate of soda alone, at the rate of 1 oz. per yard. Where the soil is thin, and cannot therefore be improved by trenching, bring in a heavy dressing of fresh loam. After a few years the soil gets "Tomato sick," and if it cannot be completely or largely changed, then pot culture ought to be resorted to, in order to give the old soil a rest and a chance to recover. The woodwork and glass in the houses should have a thorough cleansing, and painting the houses every third or fourth year is desirable.

#### PLANT HOUSES.

**Poinsettias.**—If the heads are cut while the plants are in strong heat the foliage flags at once, and the bracts do not last very long, but if given a lower temperature and a little air they last well in a cut state. When gradually hardened these plants will retain their foliage in the conservatory, and last for a long time in good condition if kept rather dry than otherwise at their roots. If given too much water the roots fail, and the foliage turns yellow and quickly falls. Plants from which the bracts have been removed should not be placed direct from a warm house into a cold one, or they may go off. They should be gradually hardened and then kept dry.

**Allamandas.**—Roof plants that have practically done flowering may be well cut back, and all the foliage removed, so that as much light as possible can reach those plants that are grown beneath. Every ray of light possible is necessary for these plants at this period of the year. Allamandas should be kept dry after they are pruned; the abrupt cutting back and removal of foliage does not appear to be in the least injurious. Our plants flower most profusely under this system of treatment.

**Bougainvilleas.**—Plants which have been kept dry in cool houses and at their roots, and are shedding their foliage, may be well pruned back. All weak growths may be removed, and strong ones not needed for furnishing the plant cut back to one eye. Strong shoots needed for main branches should have all the unripened wood removed from them. Keep the plants dry at their roots until they are started into growth. At the same time do not allow the wood to shrivel from over-dryness.

**Clerodendron Balfourianum.**—The earliest of these having enjoyed a good rest may be started in the forcing house where the temperature ranges about 65° at night, if slight bottom heat can be given them all the better. These plants will do in the same pots for several years, provided they are top-dressed with rich material and liberally supplied with stimulants during the growing season. When repotted they need more care than either Allamandas or Bougainvilleas. They should be started into growth before repotting, and the old ball reduced by about one-third, taking care of all fibry roots. Two-thirds fibrous loam, and one-third made up of leaf mould and coarse sand with the addition of a seventh of decayed manure, form a suitable compost. Very little water is needed previous to repotting, and very little beyond syringing afterwards, until the roots are active and the plants growing freely. Those which are going to rest or are resting must not be placed in a lower temperature than 55° or they may never start into growth.

**Euphorbia jacquiniæflora.**—Plants in flower should be hardened on the principle advised for Poinsettias, then they will stand without the least injury the temperature and conditions of the conservatory. On no account should they receive too much water while in this position. Few plants are more conspicuous in the conservatory, rising above others of a dwarf nature. The racemes of brilliant flowers are also effective for light arrangements on the dinner table. This plant is not grown in such numbers for furnishing purposes as it deserves.

**Stephanotis floribunda.**—After having been fully exposed to the light and kept moderately cool, the plants may be thinned out and all unripened wood removed. It is a mistake to leave them too crowded, or after they once commence growth they soon become a dense mass.

Under these conditions it is almost impossible to keep them free of mealy bug. Infested plants should be removed from the trellis and thoroughly cleansed, the trellis and woodwork of the house also painted with petroleum. Subsequently well syringe the plants with petroleum and water, 1 oz. of the former to each gallon of the latter, several times before growth commences. Keep the temperature about 50° and the soil dry enough to induce complete rest. This combined with thoroughly matured wood will result in a profusion of flowers another season.

**Plumbago rosea.**—As the plants go out of flower and the stock is ample, half may be thrown away, the remainder being cut hard back for yielding cuttings for next year's stock of plants. If only partially shortened the first growths produced will terminate with flowers, but when severely pruned vigorous growths are certain to follow. The plants are liable to be attacked by thrips, and should be well washed with a solution of tobacco water or other insecticide before they are placed in the position in which they are to stand to yield cuttings.

**Adiantum cuneatum.**—The fronds of this Fern are always in demand, and the supply even from cool houses will gradually begin to diminish after this date. It is a good plan to keep a number in a cool airy structure, and if the fronds are used from these the plants are ready for starting again into growth by the close of the year. Plants so treated and cut clean over are showing signs of growth already. If these are placed in a temperature of 60° they will grow rapidly, and in a very short time produce useful fronds for cutting. The drying process to which these plants are sometimes subjected is a mistake. Do not pot the plants when fronds are needed as early as possible, but when they commence growing give them soot water in a clear state, or a little artificial manure. Nothing is better than the former, while the latter acts beneficially when applied in small quantities.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### A RETROSPECT.

By the time this appears in print the eventful year of 1894 will have passed away and 1895 will hold the sway. 1894 saw the last of many cherished friends and old bee-keepers, while not a few youthful ones have joined the ranks.

The low temperature of the summer, with the mild autumn, greatly in contrast to the late winter and early spring months, has afforded many lessons to horticulturists as well as to bee-keepers, being disastrous alike to plants, flowers, and bees. The latter with us had to be fed up to the last week in July, and at the Heather got little or no honey till the end of August and beginning of September. With me it has been a record year, as I have had the most equal and heaviest hives I ever possessed, due entirely to having them strong at the right time; and had I kept my hives at the Heather till the middle of October they would, I believe, have been heavier than any hives ever recorded in this country.

Hardy spring flowers had scarcely expanded their blossoms ere a storm destroyed them, and this continued till June, the only exception being the soft, silky *Sisyrinchium*s, which came into bloom at a time for them to show their beauty for many days. Daffodils, Snowdrops, and others had their foliage so destroyed that there were in consequence many blanks where but for these causes we would have had numbers of blooms. Plants such as *Hepaticas* only began to grow in April, when their succulent leaves became an easy prey to the myriads of aphides which infested nearly every plant. So that I have to enumerate them amongst my departed friends.

A severe gale on the evening of the 21st and the morning of the 22nd December wrought much havoc. Christmas came as an average summer day, smiling with beauty, as if laughing to scorn the destructiveness of the late gales. Not only was it cheering by the bright sunshine, but by its genial warmth of 59°. To the bees the day was one of extra merriment, for not only did they avail themselves of the opportunity to sport in the sunshine, but searched the various flowers for pollen.

The mildness of the season has caused bees to breed a little earlier than they usually do. Young bees are now appearing in some hives, while in others in a normal state the drones have been permitted to live up till date, which in both instances tends to shorten stores, a state of affairs that bee-keepers must bear in mind, as success depends very much on preventing any stoppage of breeding when once it has naturally begun.—A LANARKSHIRE BEE-KEEPER.

#### SEASONABLE NOTES.

ALL hives should now be examined for any leakage that may have taken place, and steps at once be taken to make all rain and

damp proof, as after the late boisterous weather the roofs that have not been securely fastened down have in many instances been lifted off and carried some distance, and the covering blown in all directions. All damp covers should be taken off and dried before being replaced on the hives, as no stock can remain healthy if condensed moisture is allowed to remain in the hive.

Stocks should now be examined to see that they are not short of stores; this is done by rolling the quilt off two or three of the outside frames; look down between the frames, and if there are a fair amount of sealed stores they are safe. The covering can be replaced, and not a bee will be disturbed. No smoke will be needed, and a few minutes will suffice to examine several colonies. Make a note of any that appear to be short of stores, as after the open weather we have had bees have consumed more than is usually the case when the weather is severe. Bees have been daily on the wing, and such cleansing flights is of great advantage, and tend to the general health of the stocks.

The weather having kept mild so long, no bees have been lost, as is often the case when snow has fallen and lain on the ground for several days, and the sun has shone brightly for an hour or two in the middle of the day. The bees have been tempted to leave their hive, falling on the snow never to rise again, becoming numbed in a very short time. Strong colonies are sometimes very much reduced from this cause. When there is danger of this happening it is well to close the entrance for an hour or two during the middle of the day, and no harm will happen to them; but it is better if they have ventilating floor boards.

I do not find it advisable to feed with syrup at this time of the year, as the bees will die of starvation, although the syrup may be close to the brood nest. It is better to feed with candy for the next three months. This is made by using one pint of water to 5 lbs. of granulated sugar. Put it in a saucepan and set over a slow fire, stir carefully and boil for a few minutes. To know when sufficiently boiled, take a little out with a spoon and drop it into cold water. If it remain liquid boil a little longer, as when ready it will set in cold water. It should then be taken off the fire and the saucepan stood in a vessel of cold water. Stir incessantly until the whole gets into a thick pasty state, then pour off into saucers, or any shallow dish, in which a piece of thin paper has been previously placed. When quite cold turn out of the moulds, place as required directly over the brood nest under the quilt of any of the stocks that require feeding, covering the whole up warm. These may be replaced as occasion may require, and the stocks will be perfectly safe. It is better to err on the safe side by giving plenty of stores.—AN ENGLISH BEE-KEEPER.

PRESENTATION TO "A LANARKSHIRE BEE-KEEPER."—On the 21st ult. the Blantyre Bee Club and its guests, representing Larkhall, Cambuslang, Hamilton, and Renfrewshire, sat down to an exceedingly well-purveyed dinner in Mr. Struther's, High Blantyre. Mr. Pearson, of Rutherglen, presided in a most genial way, giving an excellent speech, full of sense and humour. Thereafter Mr. Wilson delivered a kindly address, detailing how much help they, the novices, had required, and what difficulties were met in bee culture, but how quickly these vanished whenever Mr. William Thomson was asked to assist them, so now he handed over a watch and chain to be a memento to him of their appreciation, and he trusted Mr. Thomson would be long spared to go out and in amongst them and enjoy the delights of bee-keeping, helping everybody, and writing instructions for many readers. Mr. Thomson replied, and said that though somewhat put out by the unexpected presentation, and though able to speak till morning on bees, he was unable to express his feelings at their kindness and the manner in which they had joined in this token of goodwill, and all from his own district. He then, amidst much cheering, proceeded to narrate his bee-life, how ere his seventh year he had been interested in bees—detailing with zest the methods in vogue now and then. He graphically sketched the old times with the present, showing how much bee-keepers were helped by parcel-post transmission of queen bees from all countries; while steamers and railroads made going to the Heather a simple task to-day.

#### GARDENERS' CHARITABLE AND PROVIDENT INSTITUTIONS.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—*Secretary*, Mr. G. J. Ingham, 50, Parliament Street, London, W.C.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—*Secretary*, Mr. W. Collins, 9, Martindale Road, Balham, London, S.W.

ROYAL GARDENERS' ORPHAN FUND.—*Secretary*, Mr. A. F. Barron, Royal Horticultural Society's Gardens, Chiswick, London, W.

Hogg & Robertson, Dublin.—*Seed List for 1895.*

Chr. Lorenz, Erfurt.—*Illustrated Catalogue for Gardeners and Amateurs.*

H. & F. Sharpe, Wisbech.—*Wholesale Seed Catalogue.*

Stuart & Mein, Kelso, N.B.—*Amateur Gardening Guide.*

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Labels (B. S. B.).**—Your letter has been forwarded, in accordance with your desire.

**Examinations (A. E. O.).**—If you will send your full address a letter will be sent to you. The address given is possibly not quite complete.

**Oil Stove (The Boy).**—Success with the stoves you name is very much a question of management—cleanliness of the wick, the best oil, and not overheating. We have known some persons succeed with them, but others fail. We should prefer a different mode of heating a house in which Orchids are intended to be grown.

**Hyacinth Roots Decaying (C. O.).**—We are unable to account for this misfortune except on the possibility of something deleterious in the soil, either when it was mixed or given in watering. We have no doubt, however, that one of the plants would have grown and flowered very well, as the roots were in much better condition than the other. This tends to suggest that there has been some mishap in watering. We should allow the soil to become drier than is usual, then give two or three good waterings with pure water in the hope of "washing" the soil and leaving it more healthy for the roots. We think you will not have a total failure.

**Caustic Soda and Potash Solution for Washing Fruit Trees (J. E.).**—Only one thing can be meant by caustic soda (NaHO), a white, opaque, brittle substance, with a fibrous texture. This you may obtain of most druggists, or they will procure it for you in various strengths, 98 per cent. being the strongest. Washing soda (Na CO<sub>3</sub>IOH<sub>2</sub>O) is a different substance, and not suitable for the purpose. The caustic soda and potash solution must only be used at the strength named for Plum trees, for bush fruits have not nearly such thick rinds as the larger fruit trees, and it should be reduced to 8 gallons, or if the growths be soft to 10 gallons. The substances do not require boiling, but merely dissolving, the solution being applied by a spraying apparatus in mild weather, but when the bushes are dry, damping them thoroughly, but not excessively. It has been found effectual where used.

**Carbon Nibs from Electric Lights (Perth).**—You will get nothing more, nor indeed so much, out of the small pieces of carbon than from charcoal, which is not a manure, but from its absorption of manurial matters is considered to benefit crops. Its chief value consists in its porosity, sweetening properties, and keeping the soil open. Its carbon is of no use to plants as food, for it is insoluble, practically indestructible, and supports only certain very low forms of vegetable life. Considering the hardness of the carbon points we should consider them of little gardening value.

**Plum Trees not Setting Fruit (Yorkshire).**—The trees have probably suffered from drought at the roots, a common occurrence with those against walls; the buds are thus neither well developed nor can the flowers attain a perfect condition. The rains, however, were abundant in the autumn and early winter, so that the trees can scarcely lack water now, except it be close to the wall, where it would certainly not do any harm to supply liquid manure copiously when the buds commence swelling. We would also advise thinning the blossom if very abundant, and cross-fertilisation of the flowers would be attended with great benefit; indeed, we have known cases in which it has been

thoroughly successful, the pollen of one tree, even of the same variety, being more potent on another than of its own blossoms. This is a tedious process, but we know of nothing better. Bees in passing from one tree to another cross-fertilise the flowers and secure a good set of fruit as a rule.

**Repotting Marantas (Beginner).**—If the plants require attention in the way you suggest, it should be done during the present month, so that they will have a chance of establishing themselves again before the sun has much power. If they are left till about the middle or end of the following month the sun often proves too strong for them, and they flag severely. These plants will do in the same pots for years provided the drainage is good and the soil about their roots in a sweet condition; but the liberal supplies of water needed during the growing season soon renders the soil unfit for them. They unquestionably thrive best when they are repotted annually. When turned out of their pots and the drainage removed the old soil should be worked from amongst the roots by washing it out in a tank of tepid water. This necessitates the plants being allowed to drain for some hours before they can be repotted. Many of the varieties do well in a compost of fibry loam, one-seventh of manure, charcoal broken according to the size of the plants and pots, with an addition of coarse sand. Others do better in rough peat, the fibrous portion of loam only, and charcoal in lumps. After potting plunge the plants where a night temperature of 65° can be maintained, syringe them freely, but water with great care until the roots are active. The pots used should be liberally drained.

**Manure for Tomatoes — Carbohc Acid and Eelworms (Grower).**—As the plants were clubbed at the roots last year, and Tomatoes have been grown in the same soil for four consecutive years, it would be the best plan to entirely remove it, and supply fresh in its place. Many Tomato growers find it pays to make an exchange of soil a good spit deep at less distant periods, and in your case it seems desirable in order to get rid of the eelworms. That, however, you may partly, if not wholly, effect by the use of carbolic acid, using about 2 ozs. per square foot, that quantity being added to a pint of water, sprinkled on the soil, and when soaked in mix the soil thoroughly by stirring and turning to a depth of 18 inches, repeating the operation in about a fortnight. The soil, however, will not be fit to plant anything in for some time, and the plants set in it after six weeks have elapsed will not start freely. As a manure for application to the soil as it is you may use the following:—Superphosphate of lime, five parts or lbs.; kainit, three parts; nitrate of soda, two parts; mix, and apply 10 ozs. per square yard. It may be mixed with the soil to a depth of 12 to 15 inches; it certainly will not add to the comfort of the eelworms, but the probability is that it may destroy them, while it will benefit the plants placed in the soil.

**Pruning Apples and Pears (D. W.).**—The instructions to which you allude on the page cited are correct, but the trees referred to are those which in summer pruning had the growths cut back to five or six leaves. The advice to "prune in July to two or three buds" was not given in the *Journal of Horticulture*, and in the case of most trees such pruning is too close, and may cause buds to start into growth in the autumn that ought not to do so till the spring. Your trees can need little pruning now, assuming that the subsequent growths resulting from the July pruning were pinched in due time. However, you may cut back the snags to dormant buds. As you wish to have fruitful trees regardless of shape you should have the main branches about 18 inches apart, pruning or thinning in summer to prevent overcrowding. Some of the most productive Apple and Pear trees with which we are acquainted were cut back twice after planting for securing sufficient main branches for bearing. These are 2 feet asunder and their extremities have never been shortened; neither have the trees been summer pruned in the usual way of cutting back all the shoots, but a branch has been taken out here and there when it unduly obstructed the sun shining through the trees. When the sun can shine between the branches and reach the basal leaves of summer shoots, that is sufficient for inducing fruitfulness. The pruning of the trees in question is quickly done after the leaves fall, and the branches are studded with fruit spurs from base to extremity. With the main branches of fruit trees too close together, as many are, if not most, then summer pruning, judiciously carried out, is beneficial, as the trees would be mere thickets—a crowd of useless shoots and worthless leaves—and consequently the trees must be essentially fruitless in character. Keep the heads of the trees open in the summer, but do not cut the shoots back so closely in July.

**Names of Fruits.—Notice.**—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any

beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. (*Inquirer*).—1, Vicar of Winkfield; 2, Not known; 3, Josephine de Malines; 4, Beurré d'Aremberg. (*S. J.*).—Baronne de Mello. (*G. C.*).—1, Winter Hawthornden; 2, Alfriston; 3, Cox's Orange Pippin.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*J. E.*).—1 and 6, Cupressus Lawsoniana; 2, Thujaopsis dolabrata; 3, Cedrus atlantica; 4, Picea cephalonica; 5, Juniperus virginiana variegata. (*Florist*).—Cattleya Trianae delicata. (*D. P.*).—1, Salvia Heeri; 2, Linum trigynum; 3, Justicia flavicoma. (*Amateur*).—Gesnera cinnabarina. (*Fern Lover*).—1, Pteris tremula; 2, Cyrtomium falcatum; 3, Adiantum tenellum; 4, Asplenium flaccidum.

SAFE FARMING.

Is there such a thing now as safe farming? Safety from heavy losses, any degree of certainty of a profit, of such a return on capital invested in it as to render it still a desirable

occupation? Without hesitation do we answer Yes! and in doing so we give full recognition to the gravity of the situation; to the difficulties which have grown up—are still growing; to the radical change which is bound to come both in farm management and in the sale of farm produce.

There are two things especially on which safe farming in the present and future depends—*i.e.*, individual effort and general combination. With judicious change on the farm there must be co-operation of farmers. By all means let us have an equitable adjustment of railway rates and relief from the burden of taxation now on the land, but do not let us regard either form of relief as a primary remedy for depression. If we get either, or both, corn will still be cheap, foreign produce of all kinds will continue to pour in upon us. We hold that throughout the struggle with adversity to which so many worthy farmers have succumbed, the common mistake has been looking without rather than within for a remedy. Let us look the situation squarely in the face, endeavour to grasp its full significance, and then set ourselves to see what the remedy is and how to apply it.

To take Wheat, how can any farmer expect it to answer under ordinary conditions now? Recent computations show that at the present time there are two and one fifth million quarters of Wheat in the United States of America, and over seven million quarters of Wheat in the Argentine Confederation, from whence it is said that Wheat could be imported and sold at a profit in this country at 12s. a quarter. But, then, it is not a question of the Wheat produce of one or two countries. Take the market report of any week, or, to be more definite, of a fortnight ago, and we have 1,225,000 quarters from United States Pacific ports, 240,000 quarters from Russia, 232,000 quarters from United States Atlantic ports, 230,000 quarters from Australia and New Zealand, 190,000 quarters from the Argentine Confederation, 91,000 quarters from India, and 60,000 quarters from Chili. How, we ask, in the face of such facts, dare we venture to sow Wheat unless we have an exceptionally good market for Wheat straw?

Many a shrewd man is turning the low price of corn and feeding stuff generally to account for his stock in this way:—Very much of the land once devoted to Wheat is now in temporary pasture, only enough of it being ploughed for home requirements in the way of roots, Cabbage, Kale, green Maize, Oats, Rye, Vetches, and perhaps a few acres of Peas. Then by rearing only really well bred stock in which early maturity is a certainty, by the exercise of proper care in feeding and general management, and by the judicious purchase and use of a wholesome dietary of mixed food, the stock is sold at a profit. We have heard much talk about the low price of beef at the great Christmas Fair at Islington on December 17th, but having regard to the exceptional cheapness of food for fattening cattle we see no just cause of complaint. Compared with the great Christmas Fair of 1893 there was a falling off of a farthing a pound in the lowest quotation and 1d. a pound in the highest. Again we say, Rear only good stock, buy sound corn at the lowest wholesale rates, feed well, shelter well, keep on the calf flesh, for depend upon it there's money in it.

We have heard quite enough about cheap corn and bankruptcy; let us see if we cannot render 1895 remarkable for cheap corn and prosperity. There is quite enough foreign competition in our markets to keep down prices; be ours the endeavour to take full advantage of such prices for our cows, cattle, sheep, pigs, and poultry. Only all must be good; there must be no inferior animals of any sort upon the holding where safe farming is to prevail. It costs no more—nay, it does not cost so much to feed well bred stock as it does inferior animals. There is a sure market, too, for spring chickens, for winter eggs, for prime porkers, for first-class cheese and

butter. For the latter we must have co-operative factories; anything like the uniform quality of Danish butter cannot be had from the ordinary farm dairy. The fact that we pay something like £12,000,000 a year for imported butter ought to be an incentive to reform that is so possible and so certain in its results. We pay to Denmark alone about a third of that amount, with another million for bacon and £400,000 for eggs. Such a radical change as we aim at cannot be effected in a year, but much may be done. Where shall we begin?

WORK ON THE HOME FARM.

For farm work to go well and smoothly there must be some really skilful labourers, and in order to retain such men there must always be work for them. At midwinter there is some difficulty about this, and our old Suffolk friend who fills his barns with corn for the men to thresh with flails when they cannot work upon the land in winter, may be thought to be behind the times in this matter, but he assures us it cost no more than the threshing machine, and it enables him to keep his men upon the farm. We are entirely in sympathy with him in this matter, and we should be even if the outlay involved something beyond the cost of hiring and using the threshing machine. We have recently had a shelter hovel built over the horse gear of a tenant which he had in daily use for cutting chaff and roots and pumping water. In the provision of all reasonable shelter, of field gates, and of help with fencing, a landlord is wise to assist his tenants, also in the matter of draining. In connection with what we have said about the wisdom of allowing the men to thresh corn stored in barns with flails, we may mention the cost of threshing by steam, winnowing, measuring, and placing in sacks is 1s. 10d. per quarter, and men with flails ought to earn a fair wage at something like this price.

See now that all farm tools, implements and vehicles are examined and put into a thorough state of repair. Now is the time to have repairs of mowing and tedding machines done—not just before hay-making begins. A coat or two of paint on waggons and carts is a preservative and prevents decay. Keep also a sharp outlook upon gate fastenings and farm buildings, have little faults and blemishes seen to at once, make it part of good management to keep everything in repair, and have good order and neatness maintained everywhere, but especially at the homestead. Estate artificers cannot often be spared for the home farm, and it is well to have a handy man able to do trifling repairs, to tar iron fencing and woodwork, or to paint if need be.

EXPERIMENTS ON PERMANENT PASTURE.—An interesting report has just been issued giving the results of experiments on permanent pasture carried out by Mr. F. J. Lloyd, F.C.S., on behalf of the South-Eastern College, in connection with the Kent and Surrey County Councils. The object of the experiments was to discover what constituents the light soil of the farm was most deficient in, and what manures could with most advantage be applied to supply the deficiency. The report contains an exhaustive account of both experiments and results, and is well worth careful perusal by grass land farmers.

REMARKS.

23rd.—Bright sunshine all morning; fair afternoon; milder in evening, with rain from about 8 P.M. to midnight.  
 24th.—Dull all day, and generally drizzly.  
 25th.—Mild and dull throughout.  
 26th.—Overcast all day; showers in evening.  
 27th.—Almost cloudless throughout  
 28th.—Slight fog early; frequent sunshine from 10.30 A.M. to noon; cloudy afternoon, with high wind; gale and slight rain at night.  
 29th.—Showers early; bright sunshine from sunrise to noon, then rain squall and alternate cloud and sunshine after; showers in evening.  
 Temperature still above the average, but rather cooler than the previous week.  
 —G. J. SYMONS.

THE election which I had the pleasure to conduct last year was so much appreciated that, acting on the invitation of the Editor of the *Journal of Horticulture*, I have again secured the co-operation of the leading growers and exhibitors of Japanese Chrysanthemums to carry on the useful work. The yearly increase of varieties necessitated the extension of the number this year to thirty-six. When we consider that no less than 178 varieties were named for the thirty-six list, the extension appears justifiable, and is distinctly a proof of how wide personal taste travels. With a view of rendering the election thoroughly representative, the number of electors was increased to seventy, as against forty-two last year, and as will be seen when the individual returns are published, the opinion of cultivators, not only in England and Scotland, but in Wales and Ireland also, was invited, and they freely responded. From numerous letters received it would appear that growers greatly appreciate the knowledge gained as aiding them in the selection of varieties for the current year. The original date fixed for closing the election was December 15th, but an extension of one week was granted for the benefit of a few who, through pressure of home duties, were unable to respond earlier.

Complaint was made last year that those persons who simply grew Chrysanthemums for decoration were neglected. A selection of varieties for this purpose has therefore been added, and from the returns received should prove a success. The addition of new varieties in a list by themselves will afford instruction in the purchase of this section, and the fact of no less than 154 being named in the compilation of the twelve required proves how difficult it is for a person without experience to make a selection, especially when situated far away from a horticultural centre. To assist those last named the election was mainly instituted, and I am pleased to find that our efforts are appreciated, and to those who co-operated I tender my hearty thanks for their valued aid. Several electors suggest that next year the incurved section should be included, as the number of varieties has increased considerably during the last ten years.

Although there are seventy electors, only sixty-nine votes are recorded to any variety in the thirty-six list, which appears somewhat strange at the first glance. The explanation is, one elector confined his selections to twenty-four and twelve varieties.

A few remarks on the position attained by certain varieties may not be out of place. In the thirty-six list Vivian Morel, Charles Davis, and Mdlle. Thérèse Rey are equal in the number of votes gained. It would be difficult to imagine a better type of a Japanese Chrysanthemum than either of those named. Not only do they possess size, but refinement; and added to this the habit of growth is a recommendation of no mean order. When we consider that the variety bearing my name has been in existence eight years and still comes within one vote of the maximum it should be gratifying to the raiser, especially when we know that the constitution of Japanese Chrysanthemums usually deteriorates so quickly. Sunflower still holds its own as a yellow flowered variety, in spite of perhaps more opposition than in any other colour.

Miss Dorothea Shea has steadily advanced until it occupies the tenth place in the list. Etoile de Lyon obtains sixty votes, a sufficient proof that it still has admirers. Viscountess Hambleton,

despite the difficulty experienced first in obtaining cuttings, and secondly in its tendency to set premature buds, has secured no less than fifty votes, which proves that its merits are appreciated. Niveus, a pure white flowered variety, occupies a prominent position, seeing that it is comparatively new, equalling the old favourite Avalanche. Boule d'Or, introduced as far back as 1882, just secures a place, which is a distinct tribute after twelve years' service.

The selection includes all forms or types of Japanese, if I except those with hirsute florets, a section not generally in favour. The list contains few sorts that can be found fault with on the score of quality, excepting Mrs. E. W. Clarke and Mrs. C. H. Payne. These two I do not personally regard with favour, as under ordinary culture the blooms display a want of refinement. The selection of twenty-four varieties is an admirable one, and an exhibitor who could stage that number in the best condition would be extremely hard to beat. Not only in this list but also in the twelve pride of place is still occupied by the two favourites, Vivian Morel and Charles Davis. Many more interesting comparisons and comments could be made, but I fear too much space has already been occupied.

I am indebted to all my coadjutors for the assistance they have so willingly given, and also for the excellent suggestions tendered by many of them, and a few of which are embodied in the following letters. That eminent authority, Mr. W. H. Fowler, writes:—"It is quite impossible to place them in their order of merit. There is such a large number of good sorts now that it is very difficult to pick out as small a number as thirty-six or twenty-four. I should think you would be giving much more assistance to growers by asking for the best sixty or seventy-two varieties. The country growers are much indebted to you for the time and trouble you take on their behalf. Why not try seventy-two after this?" Mr. Martin Standing says:—"I am glad you are again making a selection of Japanese Chrysanthemums, and I am also pleased to see the decorative sorts mentioned." Mr. A. Haggart writes:—"I have great pleasure in forwarding my selection. Twelve varieties of the decorative section is not enough. This is a most useful and interesting class, and deserving of more recognition." Mr. James Myers says:—"I shall be most interested in the returns when published." Mr. G. Foster writes:—"As so many new varieties come to the front every year it is a matter of great difficulty for experienced persons to select the best." (I would add how difficult it must be for the inexperienced!)

Mr. E. Beckett says:—"I think your idea excellent, and it will, I feel sure, be much appreciated by all who are about to form a collection, and also to many who are anxious to revise their lists." Mr. A. Coombes writes:—"Extending the number is a step in the right direction. I fancy next year you will have to make it forty-eight. I am pleased you have taken the decorative section in hand." Mr. Inglefield says:—"I think these returns are most interesting and serviceable to all growers, and a sure method of weeding out inferior varieties." Mr. Charles Lawton writes:—"Our list of incurved sorts increases yearly. Would it not be well to give the best twenty-four and twelve in that section another season? Such a selection would be much appreciated by recruits as well as by veterans."

Mr. Donald Forbes follows in the same strain. "I am more interested in what would be the best stand of twenty-four incurved, and hope it will be published later." Mr. Quarterman says:—"I am anxiously awaiting your report before making up my collection." Mr. R. Pinnington remarks:—"The *Journal of Horticulture* commenced a good work when it began to point out worthless varieties of fruit; but in publishing returns of the best Chrysanthemums it is doing a still greater." Mr. J. Hughes expresses himself thus:—"I think all Chrysanthemum growers (beginners in particular) are greatly indebted to you for the election, which must prove of great assistance."

From Wales the two following communications show in what way the election is valued. Mr. J. Dumble writes:—"It is impossible to over-estimate the importance and usefulness of last year's selections, and amongst growers in Wales there is an anxious desire to see another list at an early date." Mr. R. S. Williams says:—"I am greatly in favour of the system of analysis, and believe it is of great value to all. I know many cultivators who are waiting to see its publication before placing their orders for new varieties. It is not only valuable to beginners, but to old hands also."

Scotland sends the following testimony:—Mr. W. Rushton writes:—"I am confident last year's election was a benefit to many. The extension made will certainly enhance its usefulness. My opportunities are limited in seeing new varieties, therefore many of us in the north find these lists of the greatest value." Mr. Andrew Smith says:—"I can assure you the selections were both helpful and highly appreciated." Mr. D. Stewart, Cove, Dumbartonshire, writes:—"I have pleasure in submitting a list of Chrysanthemums which I consider best for culture in this district, exposed as we are to the Atlantic breezes."

Several cultivators in Ireland have lent able assistance. Mr. Hugh Crawford says:—"I think every Chrysanthemum grower is indebted to you for all the trouble taken." Mr. D. Crombie writes:—"I wish you much success in this most laudable object." Mr. John H. Cumming inquires:—"Could there not be a similar selection made with the incurved section?"—EDWIN MOLYNEUX.

We subjoin the selection of the thirty-six varieties, arranged as they are in their order of merit, and the remainder, as compiled by our able contributor, will be given in a future issue. We desire to thank him and all who have co-operated with him in this election.

#### VOTES FOR THIRTY-SIX VARIETIES.

69	Vivian Morel	14	Duchess of York
69	Charles Davis	14	Mdme. Octavie Mirbeau
69	Mdlle. Thérèse Rey	14	Beauty of Castlewood
68	E. Molyneux	14	W. W. Coles
67	Colonel W. B. Smith	13	Miss Anna Hartshorn
65	Mrs. C. Harman Payne	13	Golden Wedding
64	G. C. Schwabe	13	Van den Heede
63	Sunflower	13	Silver King
63	Mdlle. Marie Hoste	13	John Shrimpton
61	President Borel	13	H. L. Sunderbruch
60	Etoile de Lyon	13	Mdme. Carnot
58	Florence Davis	12	Préfet Robert
54	Miss Dorothy Shea	11	Souvenir de petite Amie
52	Stanstead White	11	Puritan
52	W. H. Lincoln	11	Miss Maggie Blenkiron
52	Louise	11	Gloire du Rocher
51	Duke of York	10	Violetta
51	William Seward	10	Mdme. Charles Capitant
50	Viscountess Hambleton	10	Lilian B. Bird
47	Avalanche	10	Alberic Lunden
47	Niveus	9	Mdme. Ad Chatin
44	William Tricker	9	Le Prince du Bois
43	Robert Owen	9	Mrs. Dr. Ward
38	Mrs. Falconer Jameson	8	Mdme. Ricoud
38	Lord Brooke	8	The Tribune
38	Primrose League	8	W. G. Newitt
36	Eda Prass	8	Mrs. E. S. Trafford
35	Charles Blick	6	Lady Saunders
34	Waban	6	J. S. Dibben
34	Mrs. E. W. Clark	6	Mdme. Cambon

1	Président Armand	1	Madame J. Laing

#### TOMATOES AND THEIR CULTURE.

THE Tomato, *Lycopersicum esculentum* (Nat. Ord., Night-shades), is a native of South America, and was introduced 1596. Tomatoes, as is well known, are grown both under glass and in the open air in British gardens.

##### HOUSE CULTURE.

The Tomato succeeds the best as a rule in soil of a light sandy nature. It is rather an accommodating plant, provided there is ample light, heat, and not too much moisture in the atmosphere. A span-roofed house, with the ends north and south, is suitable for Tomatoes, because the plants are able to receive sunshine on each side of the house—the east side in the morning, the west side in the afternoon. It is a question whether Tomatoes can have too much light, provided they receive abundance of air and water.

RAISING PLANTS.—For the first crop sow seeds early in January in a temperature from 60° to 75° Fahr. The seeds may be sown in pans, shallow boxes, or 6-inch pots. Sow thinly; 1 inch from seed to seed will not be too far apart, and one-fifth of an inch will be quite deep enough for covering. As soon as the germinating seeds are seen to lift the soil place near the light, to cause the young seedlings to become sturdy in their early stages of growth. A compost of three parts loam, one part leaf soil or spent hops, one part sand, and half part burnt garden refuse is suitable for sowing in, the pots to be one-third filled with drainage.

Do not allow the seedlings to become crowded before taking them out of the seed pots, because when they are allowed to become matted together, roots and leaves, two or three weeks of valuable time is lost in growth early in the season which cannot be regained. It is of much advantage to the young plants to keep the glass clean over them. The young plants do very well in the above compost when three are placed round the sides of 3-inch pots until they become well rooted, then each plant ought to be placed in a 3-inch pot separately thus early in the season. Always endeavour to keep the plants as near the glass as possible. Out of 3-inch they may be placed in 6-inch pots; out of the 6-inch into their fruiting pots, which may be 10 or 11 inches in diameter.

SOIL AND POTTING.—The soil for potting the plants from 3 to 6-inch pots, also for fruiting in, may consist of four parts

loam, one part old lime scraps, half a part of burnt garden refuse, incorporating 1 lb. of bonemeal to 2 bushels of the compost. Always make the soil firm when potting or planting Tomatoes. There are thousands of plants ruined every year through planting in loose rich soil. Leaf soil is almost ruin to Tomato plants. In such a medium they make rampant growth at the expense of fruit, while an invasion of fungoid enemies is invited. When potting provide ample drainage; 2 inches in depth for a 12-inch pot will not be too much, to be covered with rough turf or moss. In potting or planting out in houses only fill two-thirds of the space with soil, leaving the remaining third for top-dressings. After the plants have set a good crop of fruit, rich top-dressings enable these to swell to maturity in less time than without such aid. Plants in beds ought to have a root run of about 18 inches, 12 inches only being provided at the time of planting, and made firm, with good drainage below. Train to single stems 15 to 18 inches apart.

**WATERING AND STIMULANTS.**—Watering requires to be carefully done. An over-supply to newly planted Tomatoes is ruinous, while too little causes the leaves to curl and turn a spotty brown colour. I am no advocate for pruning off the main leaves from the stems of Tomatoes. Tomatoes will not set a full crop of fruit when short of water. I have found nitrate of soda of great assistance in setting (when leaf soil is not used), 2 ozs. of the nitrate to 3 gallons of water, given twice a week for a fortnight or three weeks, or as long as the plants appear to require extra assistance by a stimulant. The Tomato cannot long remain in good health in a close damp atmosphere, than which nothing is more favourable to the dreaded *Peronospora infestans*, which causes the fruit to turn black as well as the leaves. We know what conditions of the atmosphere are favourable to the *Peronospora*, therefore those conditions we ought to endeavour to avoid at any cost. This is done by judicious ventilation and maintaining a somewhat dry atmosphere, keeping the plants at the same time regularly supplied with water. When full crops of fruit are swelling some good fertiliser will be of great assistance. A little, and often, is the safe practice to carry us on to a successful termination in growing a crop of Tomatoes.

**FORMULA FOR TOP-DRESSING.**

Nitrate of soda	...	...	...	...	4 lbs.
Superphosphate	...	...	...	...	10 lbs.
Muriate of potash	...	...	...	...	4 lbs.
Bonemeal	...	...	...	...	7 lbs.
Iron sulphate	...	...	...	...	1 lb.
Burnt garden refuse	...	...	...	...	28 lbs.

Mix all the ingredients; give a dressing of loam, half inch thick, over the roots, then apply the manure at the rate of 2 ozs. to the square yard and water thoroughly once a fortnight; give a dessert spoonful once a fortnight to the plants in large pots.

**OPEN AIR CULTURE.**

For raising Tomatoes to plant outside about the first week in June, also for growing a summer crop under glass, sow the seed and treat the young plants the same manner as for early fruiting. The first week in March is early enough for those to make a first sowing who have not the convenience for early fruiting. The plants require growing as near the glass as possible, also to be established in 6-inch pots without loss of time to enable them to have a bunch or two of fruit set and swelling before they are planted outside. Prior to this the plants will require hardening three weeks or a month in cold frames.

It is a good plan to plant above the ground level, as the roots will then be warmer. They may be planted against bare south walls, or grown against trellises similar to Raspberries across south borders, the rows 4 feet apart, 18 inches plant to plant. When they have set a crop of fruit they will require a stimulant, the same that is recommended for indoor plants being suitable, also the same kind of soil as that recommended.

**VARIETIES OF TOMATOES.**—These are legion, growers generally preferring their own selection. I fine Eccles Champion one of the best; Glenhurst Favourite, Challenger, Conference, Ham Green Favourite, Golden Queen, The Conqueror, Hathaway's Excelsior, Vick's Criterion, and a host of Perfections all have their admirers.

One of the greatest pests to Tomato growers in this neighbourhood is the white fly (*Aleyrodes vaporariorum*). I only know one antidote that will keep the pest in check in houses, and that is fortnightly fumigations with tobacco paper until they are cleared out.

**SUMMARY.**—There are two or three cardinal points which must not be overlooked to be successful in Tomato growing. First, do not keep a close moist atmosphere; second, do not use animal manure, or only in very small quantities, but chemical instead; third, do not plant in light rich soil, enrich the soil when

you have secured a good crop of fruit by top-dressings—a little and often is the rule to follow; fourth, do not let the plants suffer by want of water; fifth, keep a dry warm airy atmosphere if possible.

I am sorry to say that the eelworm attacks the roots of Tomato plants. I do not think there is any cure, but we may mitigate the effects a little by giving small doses of nitrate of soda weekly, 1 oz. to the gallon of water.—G. PICKER, *Gardener to F. R. Pease, Esq.*—(Read at a meeting of the Hesse Gardeners' Improvement Society.)

**CATASETUM IMPERIALE.**

I HAVE the pleasure of sending you a flower of the new *Catasetum imperiale*, *Lind. et Cogn.*, of which we have a plant in bloom with a fine spike of fourteen flowers. I regret very much not having had the opportunity to exhibit this magnificent form at a meeting of the Royal Horticultural Society. It may interest the readers of the *Journal of Horticulture*. I certainly believe it to be the grandest *Catasetum* yet introduced. It was flowered from a recent importation of *Catasetum Bungei*.—J. LINDEN.

[The woodcut (fig. 5) represents the flower sent to us, the colour of which is ivory white, the lip being very bold in appear-

FIG. 5.—CATASETUM IMPERIALE.

ance and heavily stained with brownish red, while the upper sepals are spotted with the same dark colour.]

**LANIUM BERKELEYI.**

THE third species of this curious little group, which Lindley considered as a section of *Epidendrum*, though Bentham afterwards elevated it to the rank of a distinct genus. It was found in a clump of *Cattleya guttata* by Major-General E. S. Berkeley, Spetchley, Bitterne Park, Southampton, with whom it flowered in January, 1891; and now Messrs. F. Sander & Co., St. Albans, have also flowered it among their Brazilian importations. It is easily distinguished from *L. Avicula*, *Benth.*, the other Brazilian species, by its much longer and narrower pseudo-bulbs and leaves, and less branched raceme. The flowers are light green with numerous minute red brown dots on the sepals, petals, and base of the column.—(“Kew Bulletin.”)

**CYPRIPEDIUM NIVEUM.**

**CYPRIPEDIUM NIVEUM** is one of the most delightful of all *Cypripediums* when it is happy and in full flower, its elegant white flowers, sometimes speckled all over with tiny purple dots, being without equal in the genus. But it is a bad plant to manage in most collections, being more liable to the dreaded Orchid disease

known as spot than any of its congeners. A contributor to the "Garden and Forest" says he has been told by a friend who has seen it growing wild in the islands off the Malay Peninsula that it is always found growing on the face of limestone rocks not far from the sea, its roots nestling among the débris formed in little depressions in the rock, and its leaves exposed to full sunshine. It becomes completely dried up for a portion of the year, but when the wet season returns it soon recovers and flowers profusely. No doubt we fail with this plant through growing it in the ordinary peat mixture in a moist, shaded house, and keeping it watered all the year round.

### ORIENTAL LILIES.

THE reign of the Lily is almost co-extensive with that of the Rose. One of its many interesting families, the Ixiolirion, blooms contemporaneously with the earliest China Roses, which in our gardens are the first to develop their delicate flowers. Here the Siberian Lily, *Lilium davuricum*, appears in June, followed successively by *croceum* and *Thunbergianum*; then by *candidum*, *longiflorum*, *Martagon*, *auratum*, and *speciosum*, of which the last mentioned is the latest of all, often persistently blooming in the dreary confines of November, and continuing till its flower buds, for lack of ripening sunshine, are unable to expand.

There are many recent introductions from China and Japan, which have been named and duly classified by the great authority on Eastern plants, Mr. Baker of Kew. Such for example are *Lilium Henryi* and *Alexandrae*, the origin of which has not yet, as far as I can learn, been clearly ascertained, but the longer I live the more am I persuaded that of all existing Lilies for garden decoration *Lilium candidum* is the best. It is not, of course, so gorgeous in its colouring or imposing in its dimensions as *auratum*, nor have its flowers the size or far-shining splendour of *longiflorum*, but on the other hand it is a stately and exceedingly beautiful Lily. It produces a larger number of exquisite blooms; its flowers do not become tarnished by the agency of insects and the inevitable dispersion of its pollen, as do those of its great rival *Lilium Harrisii*, and thus its remarkable purity is unstained. If we would behold it in its full glory we should see it in the summer twilight, when the solemn shadows of evening are beginning to descend. Even when darkness is folding it round it glows with a lustrous beauty which the lover of Nature may intensely experience, but cannot describe. Can it then be said with truth that the Rose is "unapproachable," and "brooks no rival near her throne?" Nowhere is the Madonna Lily more majestic in her mien, or more dazzling in her chastity, than when she is standing with a most imperial aspect in the presence of the Rose.

*Lilium longiflorum* is, for reasons I have indicated, much better for distant than for near floral effect. I do not know what may be its attractiveness when confined to a conservatory from an entomological point of view; but this, at least, I can verify from experience, that when grown in the open air its great trumpet-like flowers are almost constantly haunted by most pernicious insects, that give its pollen a very wide circulation, and work on their outward surface to the destruction of whatever beauty pertains to its flowers. This I have very great reason to regret, for no Lily is more numerous in my garden, where it is luxurious in growth and tropical in habit, and where it also multiplies with marvellous rapidity. It would be the most beautiful and impressive of all Lilies if the strong winds of early autumn and the monstrous regiment of insects would but leave it alone. But even under these trying and often irritating conditions it is admirable when distance, almost redeeming by concealing its considerably modified complexion, lends enchantment to the view. He who grows it for this specially artistic purpose will be amply repaid. But he must not permit its affectionate offspring, which have a tendency to become overcrowded, to remain in those circumstances for any length of time; for otherwise the permission of this questionable privilege will come to have a very deteriorating effect.

*Candidum*, which does not so rapidly increase, is by no means very appreciative of frequent disturbance or subtraction; but *longiflorum*, which has manifestly considerably greater generative capability, is all the better occasionally of having its offspring, generally much too numerous, judiciously separated, that thus through isolation they may acquire greater strength.

*Auratum* is a Lily of a somewhat different nature; it does not increase with the same rapidity, and can seldom be expected to survive for many years. *Platyphyllum* is perhaps an exception to this general rule, which nevertheless cannot be too carefully remembered by him who desires to have successful *auratums* every year. He must plant new bulbs occasionally, at least, to accomplish this result. Doubtless those imported, however formidable in dimensions, have for obvious reasons a much shorter life in European gardens than those which are home grown. That they

find the long voyage from Japan to Great Britain somewhat exacting, and even demoralising, cannot be doubted by the most sanguine cultivator of these. Planted in many instances as late as February, they flower, under favourable conditions of soil and atmosphere, wonderfully the first year; but thereafter, as if completely exhausted by their efforts, they miraculously disappear, and the place that once knew them they adorn no more. This is the moral which is taught us by their premature decay: that unless they have leisure for the work Nature has assigned them—viz., that of root production, evanescence must be their destiny and death their sudden doom. They greatly resemble the pupils of Dr. Blimber in "Dombey and Son," whose intellects were forced in that august institution as if in some vastly overheated conservatory, with disastrous results.

Among the most admirable of Oriental Lilies for vitality and endurance are *excelsum* and one of its parents, *chalcedonicum*, perhaps better known as the Scarlet Martagon, *tigrinum splendens*, much cultivated for its remarkable brilliancy at Kew, and nearly all the existing varieties of *speciosum*, of which the most artistic is *L. Krætzleri*. It is, however, a fine weather production; a cold, wet summer like that of 1894 is inevitably injurious to the upper roots, and therefore also to the flowers, which long ere they reach their full development commence to decay.

The great Martagon family has a wide circulation. It chiefly exists in Central and Southern Europe; but *L. canadense*, on the other hand, as its name signifies, is a native of Canada; *columbianum* of Oregon, *Humboldtii* of California, *tenuifolium* of Siberia, and *Szovitzianum* of Asia Minor. Of these I think the most impressive in its beauty and stateliness is *Lilium Humboldtii*. If more widely cultivated it would soon become exceeding popular, if only in virtue of its unique complexion, which is deep golden yellow distinctly shaded with purple, a colour which, however, is somewhat arduous to define.

*Lilium Henryi*, which comes to us from China, is the latest addition to my interesting collection. It may be described as a *speciosum* of apricot hue, of vigorous nature, and very floriferous. In this and other respects it is strongly contrasted to the Indian Lily *Nepalense*, which I cultivated last year, and then remorselessly relegated to oblivion. The latter demands a conservatory, grows rapidly to an imposing height, and then produces with obvious difficulty two solitary flowers; which, however beautiful, are destitute of fragrance, and cannot be compared to those of *auratum*, *longiflorum* or *speciosum* for impressiveness of aspect or splendour of effect.—DAVID R. WILLIAMSON.

### INTERVIEWING A NOTED GRAPE GROWER.

(Concluded from page 12.)

HAVING briefly discussed the questions of soil, pruning, dressing, and other matters in routine, the questions of the splitting of the berries, colouring, and watering of borders were next touched on. Split berries, Mr. Craven considered, were the most common on Vines in heavy soils. In light soils a fear of watering on account of cracking was apt to cause the skins to become hardened, so that when water must be given if the crop is to be finished the sudden flush of sap causes the skins to expand too suddenly. Damp atmospherical conditions also cause it. He waters the Vines steadily through the season, continuing until the Grapes are finished. Black Grapes, he remarked, colour best under shade, but not too much for the thick-skinned kinds, as they require longer and higher feeding than the midseason varieties. The borders are watered as long as the foliage remains green. A ruinous practice is to allow them to become dust dry. Yet they can be over-watered so as to become sour. The most certain remedy then is to lift and relay the roots in fresh soil. Outside borders should have protection against excessive wet.

"You say you would lift and relay. What is your idea as to the best way to proceed?" This was the reply to that question. "If the roots are deep they should be raised, as no compost will draw roots up through a foot or more of soil. If the roots are fibreless I would lift and relay horizontally in borders one-third the original width, notching strong roots here and there, from whence fresh feeding roots will be emitted in due course. Where roots are in fairly good condition, but the border impoverished, I would not hesitate to cut straight through it—say, 8 or 9 feet from the Vine stem, and lift to within 3 feet, relaying the shortened roots in new compost. This will cause branching fibres to issue close home, and not merely at the extremity of the border. When lifting is not carried so closely to Vines I have known Grapes shank badly and never finish. Thus one has by degrees a whole border full of roots, which border can be added to as they extend. As proving what can be done in this direction, we had Vines here

which had not been disturbed for twenty years that were treated as described, even while Grapes were hanging on them, and first prizes have been won with Grapes from these Vines several years in succession at the leading exhibitions in the country."

To those remarks of Mr. Craven, I may add the rods were 18 feet in length when the lifting was done, and the border inside the house. A light shading with limewash and syringing prevented the leaves flagging, fresh root-action thus commencing at once. The border is now 9 feet wide, with an addition of 3 feet this season. We next discoursed on the subject of late summer growth. Mr. Craven thought this should not be encouraged except where Grapes, through force of circumstances, are not ripe. From the end of August to the middle of September all growth, he said, should be finally suppressed and gradually shortened back as the wood gives indication of ripening. Then roots also ripen and are preserved throughout the winter ready for action in the spring. A most important point.

Mr. Craven thinks correspondents who often advise pruning to several eyes from the main stem lose sight of the question whether the Vines or borders are capable of finishing such extra large bunches as are then likely to be produced. By this practice the Vines get unsightly. The nearer the bud is left to the main rod at pruning time the better the supply of sap to the lateral. It does not circulate so well up old knotted spurs. Under proper management a good bud is generally found at the base of each lateral, the bunches from such buds being compact and well finished.

Mr. Craven went on to say, "Denuding Vines of bark at cleaning time is an unnatural practice, and detrimental, as may be observed in the difference of those so peeled and others more rationally treated. The rods can be cleansed by washing them with fairly strong soapy water, syringing it off shortly afterwards. Cutting out growth wholesale is a barbarous practice, and will cripple the best of Vines in time." The last question related to red spider, and for this sponging with moderately strong soapy water in which a little sulphur had been mixed was recommended, sulphuring and heating the pipes being too parching, and syringing marking the fruit.

In conclusion, I would say that the above remarks embody the practice which has made the Allerton Priory Grapes famous. Many would say that perhaps the Vines are not heavily cropped, but I can answer that they bear abundant crops, and trust that this record of Mr. Craven's good work and methods may be interesting and useful to some readers of his "auld freen," the *Journal of Horticulture*.—R. P. R.

## THE FLORISTS' TULIP.

[By JAMES W. BENTLEY, Hon. Secretary to the Royal National Tulip Society.]

### CHAPTER IV.

(Continued from page 557.)

THE glass lights are placed closely together on the framework above the beds immediately after planting. They are securely tied down to the rails on which they rest; if this precaution is neglected they will probably be found blown off and wrecked during windy weather. The sides and ends of the beds are left completely open and unprotected until all the plants are out of the ground, which is generally about the beginning of March. From this time more care is necessary if the bloom is to be in good condition.

As the plants grow the guard leaves of the foliage fall back, and leave a hollow in the middle of the plant, from which in due time the bud rises. Rain and drip are very likely to fall into this hollow, which is sufficiently watertight to hold all that it can contain for a long time, and so a cup of cold water is formed in the heart of the plant, and at the bottom of the cup is the young bud. The constant presence of the water is bad enough, but when frost comes the water freezes, and the tip of the tender young bud becomes frozen too, and permanently crippled in some way or other. The injury to the bud may not be apparent for some time; it may rise clear of the foliage, and look perfectly right, but as it begins to increase in size and show its colours the character of the mischief done becomes visible. In some varieties the tops of the three outer petals remain perfectly green, the power of expansion observable in the rest of the petal is paralysed in the green tips, and the flower is rendered unsightly and worthless; in others there is no absolute disfigurement of this kind, but the growth of the three outer petals is arrested, and they remain dwarfs, whilst the three inner ones that have been protected somewhat keep growing, and a most ugly appearance is produced.

The glass coverings to the beds prevent to a great extent water lodging in the heart of the plants, but in spite of it many will be found in very wet weather full of water. The beds should be looked over at frequent intervals, and this water removed. It can

be drained away by gently separating the leaves with the hands, or blown out by means of a glass tube.

On frosty nights, if the frost be at all severe, the beds should be further protected by having the sides covered with mats or stout canvas. I use canvas made of jute, about 45 inches wide, and wrap it all round the outsides of my beds; the posts which support the framework carrying the lights support the canvas in a vertical position, and being all in one piece the canvas is soon put round, and the collection made snug for the night. No covering is put on the glass lights, and the open space between the two beds is left unprotected also.

In very stormy weather, or when the bitter east wind roars through the land for many days together, the canvas screen is kept up on two or three sides both night and day. The effects of continued wind on the tender green foliage are cruelly severe. The succulent leaves, withered and broken, become unable to perform their functions, much to the detriment of both flower and bulb. In such weather the canvas may be kept up on two or three sides for days together; the glass is allowing the plants to have both light and what sun heat there may be, and abundance of air reaches them.

When the plants are all well up it is a good plan to stir the surface of the beds between the rows with a stick of hard wood, or a dull pointed iron skewer, taking great care not to injure any of the leaves or stems. Plants that are going to bloom are easily distinguished from non-bloomers soon after appearing through the soil; the former show two or more leaves, while the latter send up one leaf only, and are technically known as *widows*.

If the morning prove sunny after a severely frosty night, the canvas should be kept up for a while, as frozen plants suffer much injury when exposed at once to the sun, and should be allowed to thaw gradually in the shade.

As the flower stems rise more care will have to be taken to protect from strong winds, as the buds are easily damaged by being knocked against each other when swayed roughly about. Late April or early May frosts must be specially guarded against by the protective means before mentioned; if they are severe enough to bow down the tender green heads mischief to the marking is almost certain to ensue, and in all probability the quest for "good feathers" at blooming time will be a vain one.

In the latter part of April or the early days of May the enthusiastic grower begins to see the first fruits of his labours. The buds commence to alter in shape and size and show signs of colour and marking. Every day his experienced eye detects fresh beauties and probably fresh disappointments. Now he will find out whether his culture and care have been good, and if reassured on this point each day will bring a succession of new delights, and for a few weeks he will be unfit to associate with the ordinary varieties of his species, to whose dull minds his outpourings in praise of his "feathered Paxton" or his "flamed Talisman" will seem like the ravings of Bedlam.

As the plants come into bloom they must be protected from the direct rays of the sun, which is easily done by covering the glass lights with thin calico. This calico once on may remain as long as the plants are in flower. If the beds are in a situation very much exposed to the sun it may also be necessary to put up a screen of similar calico on the outside of the beds. Direct sunlight and heat cause many varieties to flush, that is the petals become suffused with the marking colour, and all distinctive marking is lost. They also cause the anthers of some varieties to become stained, and shorten the life of the flowers considerably. Strong winds must, of course, be guarded against at blooming time by the usual canvas or calico screens at the sides of the beds.

Tulips grown and protected in the manner described, especially if the soil be of a retentive nature, need little watering. The roots are deep below the surface, and even if the top covering soil for 2 or 3 inches be dry deeper down the bed is most likely to be damp enough. If, however, it is considered that the Tulips need water, rain water should be used, and it should be carefully given, by being poured gently from a watering can, without a rose on the spout, held almost close to the ground, so as to avoid wetting the plants. To be of much use a considerable amount must be given, a mere wetting of the surface of the bed being of no benefit to the deep seated roots. About the middle of April a watering with weak old liquid manure may be given with advantage if the plants seem to be short of robustness, but if the growth is strong and vigorous it will be well to withhold it. All watering should be done preferably in the evening, when the weather is mild and the sky cloudy.

It may be well now to recapitulate the advantages of the glass light method of protection over the older method, which is still in use by some growers. The rain is kept off and the drip falls clear of the beds, the dryness of the foliage and soil in early spring is assured, and the evil effects of frost thereby minimised; all danger to the plants and buds by hailstones is entirely avoided, and light

and air are freely admitted, no matter how bad the weather may be. The foliage and flowers are kept clean, and both stem and leaves are covered with a fine bloom like that on the skin of a Grape. There is no drawing or forcing of the plant, and little or no difference in the time of blooming as compared with Tulips grown entirely unprotected. The saving in labour to the grower is immense; the constant watchfulness inseparable from the old system is reduced to a minimum, and thus Tulip culture is made more acceptable to this ease-loving age.

By a few growers the glass protection has been carried still further by growing the Tulips in a permanent glass house. The Rev. F. D. Horner adopts this plan, and uses a glass house which contains two beds and is about 12 feet wide, 50 feet long, and 8 feet high in the middle of the house. The glass sides are 4 feet high, and they, as well as the glass in the ends, are removable. The glass roof remains on always, but the sides and ends are only affixed as blooming time approaches, and even then are kept wide open except in windy weather. This "glass umbrella," as Mr. Horner calls it, has proved, to use his own words, "a perfect paradise" for Tulips.

I have seen the idea carried still further at Petersfield, Hants, where the late Mr. Lloyd grew his large collection in two spacious greenhouses warmed only by sun heat. The Tulips were in full bloom at the beginning of April; and at first sight the thousands of large flowers opening in the genial air and rising from most luxuriant foliage, uninjured by weather in any way, made one almost envy the possessor of such a house. But on further examination it became apparent that although every care had been taken to insure their well-doing, and numerous standard sorts were grown, there was scarcely a correctly marked flower in the whole collection. Not a single approach to a feathered flower could be seen, and the thousands of flames were with two or three exceptions heavy, dull, and muddled in their markings. The bulbs when taken up were large, but too light in weight for their bulk and rather soft. They were also liable to sudden death both in the plant and bulb state. I could not help coming to the conclusion that the glass-house culture was the sole cause of everything that was wrong, and that the unnatural conditions had induced what might fittingly describe as apoplexy in the collection.

Glass-house culture must, in my opinion, be pronounced quite unsuitable, and although I by no means include Mr. Horner's "glass umbrella" in this condemnation, I am inclined to think that the system of protecting by glass lights is about as far as it is desirable to go. Mr. Horner has, without doubt, produced under his "umbrella" some of the most magnificent Tulips ever seen, but continued culture in this manner year after year has, I think, a tendency to develop in some degree the evils so prominent in the case of Mr. Lloyd's Tulips, not so much as regards the health of the bulbs as the marking of the flowers.

The blooming period may be said to last for six weeks, and although the Tulip is supposed by the many to be a short-lived flower, I think I may say the most enthusiastic grower finds the time long enough. It is a period of great enjoyment and much work. Every bloom is inspected carefully and compared with the Tulip book, and notes on its quality or any other desirable particulars duly entered there. If the grower be an exhibitor the great question, as May draws on, of what flowers will be ready and fit to show will have careful consideration. If seedlings are to be raised, suitable parents for fertilisation have to be decided on, and the decisions carried out. Visits are exchanged with other growers, and bargains made about mutual exchanges or purchases. Soon the day arrives when the grower, with his flowers carefully packed, starts full of hopes and fears for the annual exhibition held by the Royal National Tulip Society, which is the event of the year to him, for no matter whether he stands high in the prize list or not, he meets his brethren gathered from far and near to do honour to the flower. The Society, which has existed for nearly half a century, although now neither numerically nor financially strong, still quietly flourishes, and is a bond of union among all good Tulip growers, which is sundered only by death.

(To be continued.)

### NEW YEAR'S GREETINGS.

"GET thee gone, 1894!" Such are the words with which your correspondent "E. K." bids adieu to the dying year, now counted among the past. Rather a hard good-bye some may say, who perchance have reason to review the past year with thoughts of satisfaction and gratitude; but be that as it may, old Father Time passes slowly yet surely onward, innocently oblivious of the maligns or praises that may be showered upon him. Let us, therefore, be content to "Let the dead past bury its dead," and give the New Year a joyous welcome, not with gloomy fears and dull

forebodings, but rather with high hopes that success will crown all our carefully planned schemes and honest endeavours.

From a gardener's point of view the New Year comes as a fresh awakening. We must brood no longer over the disappointments, or chuckle over the successes of the past year; but be "Up and doing," as the tide has once more turned, and we can see looming in the distance spring's busy days, followed by the ripening and in-gathering periods of summer and autumn, and so our thoughts should be diverted from what has been to what is to come.

Preparations must now be made that success may follow, and though in all our efforts we are ruled to some extent by the caprices of an ever-changing climate we can by our efforts contribute our share to the vast concern which makes up the success of seedtime and harvest, and trust and hope for Nature to do her part. In every department of the gardening world the machinery must be set going—indeed, if it has ever been stopped. In the fruit gardens and orchards we shall soon commence talking of prospects, so that all seasonable work, such as pruning, cleansing, dressing, and replanting, should be pushed on with such dispatch as weather permits.

The kitchen garden likewise claims attention. Conclusions have to be formed where each and every crop shall be located, and operations commenced for the preparation of the ground for the same. Seed supplies must be attended to, and numberless other details known only to the gardener himself, so that everything may be in order and nothing found wanting when spring's warm sunshine and gentle showers arrive. In the pleasure garden it is the same. Shrubs perhaps require shifting and pruning; there may be new beds to be made and fresh turf to be laid; walks perchance require gravel, and drains want opening; fresh peeps of landscape may be formed which in later summer days shall call forth expressions of admiration. The new year reminds us that time flies fast, and now is the day for such operations.

Turning to the glass department there is the same general awakening to activity. Early Vines and Peach trees will now of course be in a state of growth, and in the case of succession and late houses the pruning and cleansing of trees and houses, top-dressing and renovating of borders, should be pushed forward and brought to conclusion as speedily as possible in order that there may be no scurry as busier days advance. Then there are the Chrysanthemums; we have hardly done thinking about them, and yet New Year says we must begin again, and perhaps in the cuttings as they are put in, we can see in imagination all the form of a silver cup or some other diploma of merit.

It seems early to talk yet of summer bedding, but the new year reminds us that there is much propagation to be done in order that our supply may not be short when planting time comes, and so it must have its share of attention, and we picture in the mind's eye what the future designs shall be, and make preparations accordingly. Thoughts also turn to future crops of Melons, Cucumbers, and Tomatoes; if not already done, seed should be sown at once and frail young plants nursed through the cold days that follow, in order that early fruit may be gathered.

And so we welcome the New Year, with bright hopes and anticipations together with the duties and responsibilities which it brings, and when its turn comes to glide away into the silent past may we part from it with thoughts of regret and still of satisfaction, that our brightest hopes have been realised and highest ambitions attained.—GEO. HOLLINGWORTH, *Alton Towers*.

### MESSRS. SUTTON & SONS' PEA ALBUM.

THIS eminent firm are to be congratulated on the production of their very beautiful Pea album, the illustrations of which are all correct photograph copies, and therefore depict exactly the forms and sizes of the pods of the various Peas illustrated. Purchasers of varieties here pictured will find this album valuable as enabling them to compare the pods and foliage of their grown plants of any sort with the photograph illustration as published by the firm. In illustrations of this kind the fanciful tastes of the artist have no room for play. What is pictured is what is grown, and the samples are absolutely perfect and true to character. That is a method of illustrating garden products which all will appreciate. If the days of the imaginative sketcher in garden catalogues are gone for ever, horticulture will have much cause to rejoice. Apart from all this, however, the great Reading firm have done a handsome thing in issuing not merely a Pea list, but a drawing-room album of garden products. Such a publication helps greatly to lift such things into a higher level—in fact, rather into the region of art than of mere prosaic culture. I rejoice to see this publication and these excellent illustrations, as gardeners will rejoice, even more perhaps, at the introduction of such splendid sorts of Peas.—D.

[We have received a copy of the album referred to by our correspondent, and are able to say that his references to it are well merited; it would, in fact, be difficult to overpraise the work either in respect to accuracy in representation of the twenty-two varieties of Peas portrayed or the superb artistic finish of the work.]

**EVENTS.**—At this season of the year the horticultural world, so far as shows are concerned, is not very busy. The Royal Horticultural Society hold a meeting at the Drill Hall on Tuesday next, while on Thursday, 17th inst., the fifth-sixth annual general meeting of the Gardeners' Royal Benevolent will be held at Simpson's Hotel, 101, Strand, commencing at 3 P.M.

— **THE WEATHER IN LONDON.**—The weather in London during the past week has been very different from that in the northern counties of England and Scotland, where heavy snow storms have prevailed. Though there has been practically no snow here the weather has been clear and frosty all the week, but no severe frosts have been experienced. Two or three degrees in the town and slightly more in the suburbs is about the average. On Monday it was 4° warmer in London than at Nice, in the south of France. At the time of going to press the weather is dull, cold, and foggy.

— **THE WEATHER IN THE NORTH.**—The year opened with a beautiful winter day, and, with the exception of a slight thaw on the 2nd, the first week has been seasonable throughout; frost of from 7° to 13° on Tuesday morning having been recorded. The country is under a thin covering of snow, and occasionally the northerly winds have been piercingly cold.—B. D., *S. Perthshire*.

— **THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.**—The fifty-sixth annual general meeting of the members of this Institution will take place at Simpson's, 101, Strand, London, on Thursday, January 17th, 1895, when fourteen pensioners will be added to the funds—eight by resolution under Rule 3, and six by the votes of subscribers. The poll will open at 3 P.M., and close at 4.30 P.M. precisely. The voting papers have all been issued. Any subscriber who has not received a copy will oblige by communicating with the Secretary. After the annual meeting, and at the same place at 6 P.M., the usual friendly supper will be held, presided over by Mr. George A. Dickson, of Chester. The Committee will heartily welcome to this gathering any friends and supporters of the Institution who may desire to be present, tickets for which may be obtained on application to the Secretary, George J. Ingram, 50, Parliament Street, London, S.W.

— **THE GARDENS OF THE ROYAL BOTANIC SOCIETY.**—At the meeting of the Fellows to be held on the 12th inst. the opening of these Gardens to the public will be discussed. In August last a resolution was carried at the annual meeting recommending the Council to consider the expediency of admitting the public to the Gardens on week days on payment at the gates. The Council has since decided to so open them on Whit-Monday, a concession which many of the Fellows deem quite inadequate, and Mr. Rubinstein, the mover of the original resolution, and for some years Honorary Auditor, has given notice that at the general meeting to be held on the above date he will move that after March 1st the Gardens be opened on Monday, Thursday, Friday, and Saturday in each week on payment of 6d., and other days 1s.

— **TOO MANY APPLES.**—We are sorry to hear, says the "Field," that a proposition made at the Horticultural Society by Mr. Rivers, to limit the great number of dishes shown by nurserymen to fifty kinds, was defeated. That number is fully twice too many, and we regret that nurserymen will continue in their own way showing huge collections of Apples, instead of fixing their attention on the really essential kinds, and giving us good stocks of them in all shapes for real fruit-growing, as distinguished from making collections of Apples—the two things being wholly different. We mean good stocks of Apples that are of first quality in all ways. While our growers are confused by a medley of varieties, the American grower is quietly pouring into our markets thousands of barrels of Newtowns and Baldwins. Many English growers have Apples about them which they do not even know the names of, and half the Apples described as first-rate in the catalogues are second-rate or inferior. We feel sure that it would be the best service to the trade to pursue that course which would enable growers, landowners, planters, and all connected with land to get a stock of healthy trees of the best quality for our country. By far the greatest obstacle to that is

the bulky catalogue, as, owing to its influence, the worthless fruits are grown everywhere. [We think Mr. Rivers' proposition was not defeated, but carried by a large majority of votes by the Fruit Committee.]

— **THE ICE HARVEST AT WINDSOR CASTLE.**—At Windsor Castle a number of the Crown labourers have been engaged in filling a great well under the north terrace near the Winchester tower with thick ice which had been collected from the Royal skating pond. The well holds about 200 tons. The ice therein, and in another receptacle under the east terrace, is stored for the use of the Lord Steward's department.

— **CLEANING VINES.**—Probably many of your readers, like myself, would be glad to see the above subject well thrashed out in your columns, for when doctors differ, who is to decide? Mr. J. J. Craven's success as a Grape grower and exhibitor evidently shows that his method is not far wrong. Still we should like to see other noted Grape growers' opinions on the subject. Will they oblige us?—H. CHARMAN, *Trusthorpe Manor, Mablethorpe*.

— **GARDENING APPOINTMENTS.**—Mr. George Jordan, till lately gardener to Rev. H. A. Berners, Harkstead Rectory, Ipswich, has been appointed head gardener at Shortgrove, near Newport, in Essex, by J. Bailey, Esq. Those who are acquainted with Mr. Jordan feel confident that he will give a thoroughly good account of himself in this extended sphere of action and greater responsibility. Mr. Stuart Compton has been appointed head gardener to T. D. Eden, Esq., Beamish Park, Chester-le-Street, Durham.

— **ROYAL HORTICULTURAL SOCIETY'S MEETINGS IN 1895.**—A correspondent desires to know the dates of the above meetings, and rather chides us for not publishing them, especially as he "casually saw a list in another gardening paper some weeks ago." We can only presume that there has been either a mistake or miscarriage, as we were informed by the officials of the Royal Horticultural Society early last year that it is the "custom of the office to post matter for the press on Mondays, so that all the papers receive announcements the same week." This is a good and fair custom, but we have not yet received the list desired.

— **THE KEW TEMPERATE HOUSE.**—The great Temperate House, or Winter Garden, at Kew, was commenced in 1860. In 1861 the octagons were finished. In 1862 the centre block was completed. The original design included two wings. These, however, were never erected, though the raised terrace was prepared for them. The Treasury has now sanctioned the erection of the southern wing, and the proposed works are being already taken in hand. It is proposed to maintain in this a warm greenhouse temperature, so as to allow an adequate cultivation of many economic and large succulent plants, of which the existing accommodation afforded them at Kew does not permit the satisfactory development.

— **A FOREIGN FLOWER MARKET FOR COVENT GARDEN.**—There is a shed approaching completion in the open space abutting on Tavistock Street, which will accommodate when finished the stands of the dealers in foreign flowers. Hitherto these dealers have had no portion of Covent Garden Market set apart for the sale of their goods, and it has been considered that in many ways it will be an advantage to have this part of the trade carried on in a separate building. The building, which measures about 60 feet by 40 feet, and is perhaps 30 feet in height to the apex, is situated at the eastern end of the open market, therefore it is but a step or two from the flower market—the centre of the home flower trade of London.

— **WINTER TOMATOES.**—There is no difficulty in having plenty of good Tomatoes from old plants that have set fruit well in September, ripening up to the end of November. Later they become very scarce, and it is difficult indeed to have good fruits from the middle of December until the end of March, even under the most favourable conditions. For that reason I was particularly pleased to see a nice crop of fair sized and handsome fruits on a dozen of plants that were growing close under the roof in a span house at Hackwood Park on December 28th. These plants were raised from seed sown early in August, and now in 8-inch and 9-inch pots. Some good coloured fruits had been gathered, and there were on the plants a capital succession. As the plants were in the way of nothing, their growing cost hardly anything. The variety was one of the Perfection type, smooth and handsome. Happily it is now found easy to fruit in winter smooth-fruited strains, as it is the old deeply sutured forms that some gardeners still grow, and yet have so little value.—A. D.

— WE learn that the Director of the Royal Gardens, Kew, has been elected an honorary member of the New Zealand Institute in recognition, amongst other grounds, of the aid he has so cordially rendered to botanists in the British Colonies.

— SOCIÉTÉ NATIONALE ET CENTRALE D'HORTICULTURE DE FRANCE.—We learn that Mons. D. Bois, one of the assistants in the Botanical Department at the Jardin des Plantes, has been elected Editing Secretary to the above Society in place of the late Mons. Duchartre.

— A GIANT OAK.—There exists an Oak at Pilkallen, whose dimensions ought to be recorded. At the base it measures  $7\frac{1}{2}$  yards in circumference, while it is between 90 feet and 100 feet in height. The age of this huge giant has been estimated at 1000 years, and every spring it is covered with a beautiful crown of leaves, so dense that neither rain nor snow can find their way through it. Last year, says the "Gartenflora," two limbs removed from it furnished sufficient wood to construct a mill. For a century past this giant has been close upon its present dimensions. From time immemorial the inhabitants of the district have always seen a stork's nest constructed in the thick branches.

— ROYAL METEOROLOGICAL SOCIETY.—Two meetings of the Society will be held at 25, Great George Street, Westminster, on Wednesday, the 16th inst. The first will be an ordinary meeting for the election of Fellows and the transaction of ordinary business, and will commence at 7.30 P.M. At it the following paper will be read:—"The Gale of December 21st-22nd, 1894, over the British Isles," by Charles Harding, F.R.Met.Soc. At 8.15 P.M. the annual general meeting will commence, when the report of the Council will be read, the election of officers and Council for the ensuing year will take place, and the President (Mr. R. Inwards, F.R.A.S.) will deliver an address.

— FRUITING OF AN ALLAMANDA.—I am forwarding you a seed-pod of an Allamanda, and would be glad to know if it is unusual for these plants to fruit, as it is the first one I have ever seen. It was not observed until the beginning of September, and was then as large as it is now. I have taken about two dozen seeds from the pod, but send you one or two.—W. J. IRELAND, *Sedgwick, Kendal*. [It is certainly very uncommon for the Allamanda to bear fruit, though no doubt many of our readers will be able to cite instances. We trust you will be successful in raising some plants from seeds, but we are doubtful, as neither the seeds nor the pods were nearly ripe when taken. Perhaps you will let us know how you progress? For the benefit of those readers who have not seen the fruit of this plant, we might add that it is about the size of a hen's egg, and thickly covered with stout, somewhat blunt, spines.]

— MAKING ICE.—The "Daily News" says:—"The Niagara Hall Company in York Street, Westminster, are showing how the treachery of our winters may be defied. They have opened a skating hall, laid with real ice. There are 10,000 square feet of it in a circular arena, with lounges around, and a gallery above for spectators. While the temperature of the hall is maintained at a stage that enables the skater to cast aside wraps and skim around bareheaded, the ice is always hard and dry and in excellent condition; and the freezing machinery, having served the hall, is capable of providing a surplus of pure ice for the market. Eight tons of ice must be made per day to keep the rink in perfect state, and the processes of producing cold, or rather absorbing heat by the compression of ammonia gas, are not the least interesting of the attractions of Niagara Hall in its most recent development.

— SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, IN DECEMBER.—Mean temperature of month,  $40.8^{\circ}$ . Maximum on the 13th,  $53.4^{\circ}$ ; minimum on the 1st,  $26.1^{\circ}$ . Maximum in the sun on the 20th,  $79.3^{\circ}$ ; minimum on the grass on the 21st,  $19.2^{\circ}$ . Mean temperature of the air at 9 A.M.,  $40.2^{\circ}$ ; mean temperature of the soil 1 foot deep,  $41.5^{\circ}$ . The number of nights below  $32^{\circ}$ , in the shade, eleven; on the grass, twenty-one. Total duration of sunshine in the month, thirty-four hours, or 15 per cent. of the possible duration. We had fourteen sunless days. Total rainfall, 1.39 inch. Rain fell on fifteen days. Average velocity of the wind, 12.9 miles per hour. Velocity exceeded 400 miles on ten days; fell short of 100 on five days. Approximate averages for December:—Mean temperature,  $37.1^{\circ}$ ; sunshine, thirty-two hours; rainfall, 1.97 in. It was the warmest December since 1876. No snow or frost of consequence till the last few days. The gale on the 22nd did much damage to timber, buildings and stacks. For eight hours, from 9 A.M. to 5 P.M., the average velocity of the wind was 60.5 miles per hour.—J. MALLENDER.

— DEATH OF MR. WILLIAM BARRON.—We regret to announce the death on the 27th ult. of Mr. William Barron, for many years in business as a nurseryman and landscape gardener at Sketty, Swansea, an elder brother of Mr. A. F. Barron of Chiswick.

— THE WINGED PHYLLOXERA.—Professor Rathay, in a paper read at the Viticultural Congress at Vienna, combats the notion that this is destructive to the Grape Vine on the ground that the insect lives only four days at the hottest season of the year; another condition being that there must be no wind. The flight of the insect is feeble, and moreover it deposits unisexual eggs, a fact which militates much against its multiplication.

— VANILLA CULTIVATION IN MAURITIUS.—A correspondent in Mauritius calls attention to the fact that the cultivation of Vanilla, which has hitherto been one of the staple products of the island, is rapidly diminishing, and will soon be a thing of the past. The cause has been put down to the continued robbery of the Vanilla estates by the Indian immigrants; but the real reason of the discontinuance is the increasing competition of the Vanilla grown in Bourbon, which can be produced there at a much cheaper rate, owing to the soil being more suited for its cultivation. The planters also complain that the fluctuation in prices, says the "Chemist and Druggist," per kilo render the article a very speculative one.

— LARNE HORTICULTURAL SOCIETY.—A general meeting of the members of this Society was held recently, Mr. Charles Howden, Invermore House, presiding. The Hon. Secretary's report showed that there was still left a credit balance in the Society's favour of £11 1s. 10d. The total receipts, including subscriptions for the year, amounted to £138 6s. 4d., and the prize list payments and aggregate expenditure in connection with the show to £128 4s. 11d. The thanks of the meeting were passed to Mr. D. A. Nelson for the manner in which he had discharged the duties of Hon. Secretary for the past year, and the report and balance sheet were adopted. The appointment of office-bearers for the ensuing year was deferred till first meeting in January.

— TECHNICAL EDUCATION IN AGRICULTURE.—Increased facilities for instruction in the science and art of agriculture are gradually being given to the Technical Education Committees in various parts of the country. We are glad to see it announced that Earl Cowper, Chairman of the Hertfordshire County Council, has offered to place a farm of nearly 300 acres, with residence and buildings, at the disposal of the Council, rent free, for the purpose of providing practical instruction in agriculture, on condition that the County Council stock the farm and work it. Lord Cowper has also undertaken to erect a laboratory and the necessary dormitories. A sub-Committee of practical agriculturists has been appointed to consider his Lordship's offer and report to the Council on it.

— WAKEFIELD PAXTON SOCIETY.—The Wakefield Paxtonians spend pleasant Saturday evenings all the year round, but on the last Saturday night in each year their proceedings are unusually interesting and enjoyable. At the last meeting in the year 1894 the large room, which had been seasonably decorated, was quite filled with professional and amateur gardeners, florists, botanists, and naturalists. Alderman Milnes presided, and the vice-chair was occupied by Mr. B. Whiteley. The proceedings, which occupied about three hours, assumed the form of a concert, the vocalists being a good contingent of the members of the newly formed Wakefield Harmonic Society. In an interval between the first and second parts of the concert Mr. and Mrs. Radcliffe entertained the company to supper, and the seasonable generosity was greatly appreciated.

— THE WEATHER LAST MONTH.—December was milder than usual, and the first snow of the season did not arrive until the 29th. Fog was prevalent until the 10th, and after that date rain was recorded daily, with only two exceptions, until the end of the month. The wind was in a westerly direction twenty-four days. Total rainfall was 2.12 inches, which fell on twenty-three days, the greatest daily fall being 0.43 inch on 11th. Barometer—highest, 30.41 at 10 P.M. on 27th; lowest, 28.906 at 9 A.M. on 22nd. Thermometer—highest in shade,  $52^{\circ}$  on 13th; lowest,  $27^{\circ}$  on 31st. Mean of daily maximum,  $44.80^{\circ}$ . Mean daily minimum,  $35.67^{\circ}$ . Mean temperature of the month,  $40.23^{\circ}$ ; lowest on grass,  $22^{\circ}$  on 1st and 9th; highest in sun,  $77^{\circ}$  on 29th. Mean temperature of the earth at 3 feet in depth,  $43.38^{\circ}$ . Total sunshine, 43 hours 5 minutes; eleven days were sunless. A thrush was heard singing on Christmas Day, and many varieties of hardy flowers were in bloom, owing to the mild season, the temperature having fallen below  $32^{\circ}$  only five times since October 23rd, and the lowest since that date being  $28^{\circ}$ .—W. H. DIVERS, *Belvoir Castle Gardens, Grantham*.

— **WOOLTON GARDENERS' MUTUAL IMPROVEMENT SOCIETY.**—The usual fortnightly meeting was held on Thursday evening in the Mechanics' Institute, Mr. J. Stoney presiding. A very comprehensive paper entitled, "Notes on Herbaceous Plants," which dealt with culture and kind, and provoked a good discussion, was read by Mr. Llewelyn Jones, gardener to W. Pilkington, Esq., J.P., D.L., Roby Hall, Liverpool.—R. P. R.

— **THE AMERICAN PEPPERMINT HARVEST.**—Although relatively small when compared with other crops it is of considerable importance. In the State of New York the area in 1894 devoted to the cultivation of Peppermint was 3000 acres, and the yield of oil about 65,000 lbs. In Michigan and Indiana 12,000 acres are returned as under this herb. The prices obtained for the essential oil were last year nearly 50 per cent. less than those obtained in 1893.

— **DECEMBER WEATHER IN SOUTH WALES.**—The following is a summary of the weather here for the past month. The number of days on which rain fell was eighteen. Total depth, 4.82 inches; maximum, 0.92 on the 21st; minimum, 0.01 on the 26th. Snow fell on the 29th. There were fifty-three hours five minutes of sunshine, and fifteen sunless days. Sharp frosts were experienced during the last few days of the month. The wind was in a westerly direction the greater part of the month. The total sunshine for the year was 1075 hours 35 minutes. Highest monthly total, 147 hours 30 minutes in March; lowest, 14 hours in January. There were 121 sunless days in the year. Total rainfall for the year, 61.92 inches; greatest monthly total, 8.54 inches in October; minimum, 2.15 inches in September; maximum for any twenty-four hours, 2.12 inches, on July 24th; average for the last eight years, 45.30 inches; maximum in that time, 63.30, 1891; minimum, 28.12, in 1887.—W. MABBOTT, *The Gardens, Gwernllwyn House, Dowlais, S. Wales.*

— **THE YORKSHIRE GALA.**—At the thirty-seventh annual meeting of the guarantors and life members of the Grand Yorkshire Gala, held at Harker's York Hotel, the Chairman (Alderman Sir Joseph Terry, J.P.) presided, and there was a large attendance of members. The Chairman congratulated those present on having again met under encouraging auspices. He was pleased to announce that, in accordance with their usual custom of electing as life members those gentlemen who had recently served the city as Parliamentary member or as Sheriff, that Mr. J. G. Butcher, M.P., the Sheriff (Dr. Tempest Anderson, J.P.), Mr. W. W. Hargrove, J.P., and Mr. H. Leatham, J.P., had been elected life members. He was pleased that the Association's deputation had secured the Bootham Asylum field for the holding of the Gala, on similar terms to those of previous occasions. He then proposed the election of the Lord Mayor (Mr. Alderman W. McKay) as President for the present year; Mr. Councillor Border seconded, and the proposition was unanimously carried. Mr. Alderman Milward then proposed the re-election of Sir Joseph Terry as Chairman. Sir Joseph had taken a great interest in the welfare of the institution, and he (the speaker) was sure that as long as he identified himself with the Association it would prosper. Mr. M. Cooper seconded the proposition, which was unanimously carried. Sir Joseph tendered his thanks for the compliment. Mr. Councillor L. Foster proposed the re-election of Mr. E. Rooke to the position of Vice-President, Mr. G. Kirby seconded, and the proposition was unanimously carried. On the proposition of Mr. M. Cooper, seconded by Mr. H. Scott, Mr. Joseph Wilkinson was unanimously re-elected Treasurer. Mr. Charles W. Simmons, on Mr. Councillor Dale's proposition, which was seconded by Mr. Balmford, was re-elected Secretary. Mr. Dale complimented Mr. Simmons on the way in which he had discharged his duties. The following gentlemen were elected to form the Managing Committee for the present year:—Mr. Councillor R. Anderson, Mr. G. Balmford, Mr. J. Blenkin, Mr. Councillor S. Border, Mr. J. Biscoombe, Mr. G. Browne, Mr. Alderman Clayton, J.P., Mr. J. W. Craven, Mr. M. Cooper, Mr. H. C. Day, Mr. Councillor R. P. Dale, Mr. Councillor L. Foster, Mr. G. Garbutt, Mr. J. G. Hodgson, Mr. J. J. Hunt, Mr. A. Jones, Mr. G. Kirby, Mr. T. M. Lambert, Mr. Alderman Milward, Mr. Councillor E. W. Parnell, Mr. H. Scott, Mr. W. S. Sharp, and Mr. J. B. Sampson. The Floral, Financial, and Entertainment Committees were elected, and the following grants were made:—For prizes to the floral exhibition, £600; for music, £120; for fireworks, £100; for balloon, £60; and for amusements, £175. The amounts are similar to those of last year, with the exception of the last, which is increased. A vote of thanks to the Chairman, proposed by Mr. Alderman Clayton, seconded by Mr. Councillor Border, and duly replied to, concluded the business of the meeting.

— **THE RAINFALL AT STIRLING.**—The rainfall here for the last month was 3.445 inches, which fell on twenty-three days. The greatest fall on any day was 1.050 inch on the 21st. In no day throughout the year has there so much rain in so short a time—ten hours. The mean maximum temperature was 44.1°, the mean minimum 33.3°; the highest maximum was 54.5° on the 13th, the highest minimum was 42.2° on the 11th; the lowest maximum was 37.2° on the 31st, and the lowest minimum 25.7° was also on the 31st. We had eight nights below 32°. Altogether it was a good month for pushing forward outdoor labour, no sharp frosts interfering with it.—G. M. D.

— **DIFFERENT FROM ENGLAND.**—Victoria, says the "Echo," was visited by a remarkable heat-wave lately, the degree of heat registered in Melbourne being higher than anything yet recorded since the founding of that city. At the government observatory in Melbourne on November 27th the thermometer registered 152° in the sun and 106° in the shade, and the intensity of the heat was responsible for a good deal of sickness in the way of partial sunstrokes and kindred affections. In other parts of the Colony the heat was also excessive; in fact, the heat-wave appears to have passed right across the southern portion of the Australian Continent, from west to east, growing in intensity as it went along, Victoria of course getting the worst of the visitation.

— **HEAVY APPLES.**—I notice on page 6 of your last issue a few remarks about heavy Apples, and as the weights of the outdoor Apples there mentioned did not reach those of fruits grown by Mr. W. H. Bannister of Cote House, Westbury-on-Trym, Bristol, I herewith send them. Among the fruit of Peasgood's Nonesuch, grown on a young bush tree in the open in 1893, largest weighed 28 ozs.; two weighed 3 lbs. 7½ ozs.; six weighed 8 lbs. 13½ ozs., and twelve weighed 15 lbs. 13 ozs. Mr. W. Garaway, Bristol, weighed them. Representatives of the "Bristol Times and Mirror," tested the figures and published the weights in their paper the following day.—W. STADDON, *Stoke Bishop, Bristol.*

— **MR. COLLINS.**—Readers of this paper will, I am sure, agree with me that by the death of this gentleman we have lost one of our most promising writers. Like many more, whenever I have read any of his articles, I have been struck by the great lessons that he has tried to instil into the minds of the gardening fraternity. There has always been a tone with them so pleasing, instructive, and encouraging, whatever the subject might have been. This is the sort of thing we want in these pushing times. I was asked the other day by a gentleman, "Does the art of gardening correspond with the times?" to which I answered, "Yes, a thousand times yes; go to our shows and see the exhibits of Roses, Chrysanthemums, vegetables, and fruits; they will speak for themselves." Just at the moment I had the Journal in my hand, and opening it, pointed out an article of Mr. Collins', which I asked him to read as a specimen of our literature, and after doing so he said this is the kind of thing we want in all our professions—more harmony and less discord, or, in other words, we want all the sound advice possible, and less *personal* criticism.—G. BURROWS.

— **DEVON AND EXETER GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.**—The annual supper of the Devon and Exeter Gardeners' Mutual Improvement Association was held on Friday last. Mr. T. E. Bartlett presided, and Mr. Jas. Weeks and Mr. James Andrews occupied the vice-chairs. The loyal toast was duly honoured. In proposing "The Devon and Exeter Gardeners' Association," the Chairman remarked that it was a happy feature that the Society had lost no member from death since its commencement. During the four years of its existence it had done good work. It was an organisation which the gardeners much needed. It promoted good fellowship, and by being brought together they could be mutually helpful to one another. One man was not, as a rule, well acquainted with every branch of horticulture. Many of them were specialists in some branches, and in this way one could be exceedingly helpful to another. He was pleased that during the last session the young members had contributed some interesting papers—a fact in itself which showed that the Society was doing good work. Mr. Andrews, in response, said the Society had done good work among gardeners, and he was sorry to say there were many in the immediate neighbourhood who hesitated to join. Both old and young gardeners could learn a good deal by enrolling themselves. The papers which were read, and the discussions which ensued, had a great educational value. Those relating to fruit culture, in particular, were extremely valuable. By excursions to the principal gardens of the district they had had opportunities of picking up many useful hints. Songs were sung by Messrs. Scott, Meyer, Wylde, Webb, Rossiter, Lansdale, Toby, and others.

— A STRANGE CHRISTMAS POSY.—Mr. Henry Lewis writes from West Ashling, Chichester:—"It may interest many of your readers to know that here the weather has been so unusually mild for the season that I was able to have on my table yesterday twenty-five sorts of sweet-scented flowers, all gathered out of doors, and furnishing good perfume—among them Roses, Carnations, Pinks, Wallflowers, Passion Flowers, Double Stocks, Jasmine, Fuchsias, Sweet Williams, Verbenas, and Lobelias."

— DECEMBER WEATHER AT BROUGHTY FERRY.—The weather of December continued very pleasant up to the morning of the 29th, when we had the first taste of real wintry weather, with a fall of snow which put a stop to all outside work. We had a storm of wind of unusual severity on the 22nd, and another on the 28th. The mean temperature of the month was 38.7°, being 2.6° above the average mean of the last twenty years; and although we often heard remarks on the mildness of the month, it was forgotten that December 1893 was still milder, the mean temperature of which was 39.4°, but it was the last three days of the month which reduced the mean, the maximum thermometer in these days only recording 36°, 35° and 33° respectively, and with the exception of these three days must be considered a record mild December in this district. The rainfall for the month was 1.72 inch, being exactly the average of December for the last ten years. The total rainfall for the year was 29.20 inches, which is about the average of the last twenty years (29.25 inches). I may add that the weather for this month, January, so far, has been of a very wintry nature with frost and snow, with very cold northerly cutting winds. The frost has not been intense considering the season. The hardest record was 13° on Saturday morning last.—J. M. C.

— "SWEET-SCENTED FLOWERS AND FRAGRANT LEAVES."—Under this title Messrs. Sampson, Low, Marston & Co. have produced a very pretty and, we surmise, a popular book with amateurs. In the tone of the binding, in general get-up, and more particularly in the sixteen coloured illustrations, it is a most desirable object for the tables of those who combine æstheticism with a love of flowers. The bulk of the work is taken up with an alphabetical arrangement of fragrant plants under their scientific names. This, we venture to think, is a mistake. Had the scientific names been subordinated to the popular ones the book would probably have found greater favour with the class for which it is intended. Unfortunately, too, there is no index to the popular names. The uninitiated, therefore, in seeking for *Smilax* (*e.g.*) will not find it except by accidentally lighting upon *Myrsiphyllum asparagoides*, which will be a revelation to them. Unluckily, too, the printer's reader presents it as "*Simlax*," which should be corrected if the work reaches another edition. Notwithstanding, however, the exceptions which we have taken, much remains to be commended. The text elucidating the names, especially those of the most popular flowers, is agreeable and instructive, and should conduce much to popularising the knowledge of horticulture. Mr. Donald McDonald, the author, is to be congratulated on his efforts, for he has produced at once an attractive and a very readable book on a topic which is yearly growing in favour.

— NATIONAL AMATEUR GARDENERS' ASSOCIATION.—The first meeting of the new year took place in the Board Room, Memorial Hall, Farringdon Street, E.C., on Tuesday evening last, the 8th inst., when there was a very satisfactory attendance of members. Mr. T. W. Sanders, F.R.H.S., occupied the chair on this occasion. Mr. H. A. Smith of Lewisham read a paper on the cultivation of hardy annuals. The paper was listened to with considerable interest, and the lecturer concluded with giving a list of the best plants to grow. Many questions were asked, and a good discussion ensued. A vote of thanks was also accorded Mr. Smith for his admirable paper. The exhibition, although not a large one, contained several products of exceptional merit, and in point of numbers, as well as in quality, was a distinct advance on previous years. Fourteen new members were elected, and this should be considered satisfactory, as the Association is now entering on the fifth year of its existence. A vote of condolence with Mrs. Chas. Collins was unanimously carried, and a subscription list was opened to which members were invited to subscribe. Mr. Collins joined the Association at its inception, and had been a regular attendant at the meetings. His gentle and unassuming manner, as well as his gift as a clever horticultural journalist, made him many friends, and his loss will be keenly felt at the meetings of the Association. Mr. D. B. Crane, 4, Woodview Terrace, Archway Road, Highgate, N., is the Hon. Secretary, and will be pleased to forward particulars of what the Association is doing to any inquirer.

## THE HERBACEOUS BORDER.

AS winter gives place to spring, and spring to summer, so we must of necessity divert our attention from the beauties of indoor gardening to the more natural and interesting feature of floriculture—namely, outside work. I do not of course wish to infer that we should by any means neglect or ignore the claims of the glass department, but we must not forget the claims and charms of the herbaceous border. The mind dwells with delight in winter on hardy flowers of summer, and some at present haunt the memory.

DELPHINIUMS.—What can be more beautiful than Delphiniums or Larkspurs, with their long stout spikes of bloom towering above all other plants, the colours varying through almost every shade of blue, from the lightest silvery lilac to the deepest indigo. For the back of the border or in the foreground of shrubberies they are about the finest and most showy plants obtainable. If the flower stems are promptly removed as soon as the first display is over successional spikes of bloom will be produced, thereby very materially lengthening the flowering period. Let us then think of obtaining good collections of these stately border flowers.

DICTAMNUS.—The Dictamnus, or Burning Bush, as it is often called, is one of the most interesting and beautiful of perennial border plants. It forms a handsome bush from 2 to 3 feet in height, and nearly as much through, each shoot carrying a long terminal raceme of curious red flowers. At a certain stage of development the flowers are said to exhale a strong balsamic ether, which will ignite at the approach of flame, hence the name Burning Bush. The experiment may easily be tried after dark on a dry, still night. There is a white-flowered variety also.

IRIS.—The numerous species and varieties of Iris now in cultivation comprise a large and most interesting group of hardy herbaceous plants, remarkable for their curiously constructed flowers and immense variety of colour. There are two distinct sections of the Iris, easily distinguished by one having creeping rhizomes, the other being bulbous rooted. The extreme hardiness, ease of culture, and adaptability of the former section to various situations are points greatly in its favour; and there are few hardy plants that are more worthy of recommendation to cultivators; yet I think the bulbous kinds are the more beautiful, and when flowering in clumps at intervals along the herbaceous border few plants can excel them in beauty. Do not forget to plant a good assortment.

PYRETHRUMS.—No words of mine can overpraise these popular border plants. They are especially to be recommended for the adornment of the hardy flower garden, and worthy of extended cultivation. Although the single varieties are mostly in demand, being more light and graceful for decorative purposes in a cut state than the doubles, yet the latter must not be ignored, as they are decidedly effective in the garden.

VARIOUS PLANTS.—The beauty of many lingers in the memory, but I can only briefly refer to a few at present. For instance, there are the majestic Hollyhocks, which in their way have no rivals; Campanulas of sorts, Asters or Michaelmas Daisies, perennial Phloxes, *Lathyrus latifolius*, and its white variety. These, if planted at intervals, have a pleasing effect. *Eryngium amethystinum* and *giganteum* are handsome in foliage as well as in flowers. *Hesperis matronalis* and *H. m. alba*, the purple and white Rocket, are worthy of a place in every collection. *Rudbeckia Newmanni* is one of the finest of our autumnal flowering herbaceous plants, its bright golden-yellow flowers with black discs being most useful for cutting purposes. *Achillea Ptarmica alba plena*, *Aquilegias* of sorts, *Centaureas*, *Hemerocallis* or the Day Lily, and *Lychnis* of sorts should all find a place in the herbaceous border, *L. viscaria rosea plena* being particularly handsome, and lasting a long time in beauty. These are a few flowers to keep in mind by intending planters.—GEO. PARRANT.

HAVING in previous notes given the names of some of the taller growers for the back of the border I will now augment their number, and then follow with plants of dwarfer habit. *Tritoma Uvaria* is very showy in the autumn, but does not like root disturbance; *Ferula glauca* is a conspicuous plant, the stem being singularly glaucous; *Campanula pyramidalis* (the Chimney Campanula) is a grand old plant, the flowers lasting a long time in beauty; this is also useful for pots. The above, with the former list, constitute a goodly number of the taller growers.

We now come to the next line, with plants ranging from 3 to 4 feet high. Of these I content myself with a concise list of the best varieties, merely naming their colours as a guide. *Anemone Honorine Jobert*, or *japonica alba*, white; *Campanula persicifolia alba*, also double white; *Gypsophila paniculata*, fine for cutting, white; *Rudbeckia Newmanni*, yellow; *Dictamnus Fraxinella* (Burning Bush), peculiarly scented, purple and white; *Spiræa aruncus*, white; *Phlox decussata*, with its many hybrids, indispensable, owing to their rich and varied colours; *Oenothera Youngi* (Evening Primrose), yellow; *Lobelia fulgens*, scarlet; *Hemerocallis flava*, yellow; *Dielytra spectabilis* (Lyre-flower) pink, a well-known favourite; *Lychnis chalcedonica*, bright scarlet; *Aquilegias*, most beautiful and delicate tints are to be found amongst the hybrid flowers of this section. Amongst the bulbous plants *Lilium candidum*, white; *Gladioli*, the garden hybrids of which are very numerous and beautiful; *Fritillaria imperialis* (Crown Imperial), well known. I should also mention *Lilium tigrinum* as most brilliant during late summer.—GEO. DYKE.

## OXERA PULCHELLA.

A CORRESPONDENT writes seeking information about *Oxera pulchella*, which has been recommended to him as a climber for the warm conservatory. It is a plant but seldom seen, though it was

immense cymes of white flowers usually about Christmas. They are freely produced, both axillary and terminally, on the ripened wood. Therefore, to secure the proper ripening of the wood the plant must be afforded plenty of light; indeed, it cannot have too much, even full exposure to the sun will not injure it. Train it on the glass end of a

FIG. 6.—OXERA PULCHELLA.

exhibited some years ago when we made a sketch of it, and which we reproduce (fig. 6) for displaying its character. Writing anent *O. pulchella*, Mr. F. Ross, the exhibitor of the spray shown, said:—“The *Oxera* is an extremely free-growing shrubby climber, producing

house up a rafter, or along the ridge of the house, say where there is a lantern top, as these are the positions which would suit it best. Our plant, both this and last year, had by far the finest flowers on the glass end of a cool stove, where the temperature during winter is kept at

about 55° to 60°. A fair degree of temperature such as I have mentioned is necessary to flower it, although the plant will live through the winter in ordinary greenhouse temperature; but under such treatment we failed to flower it, and it was not until it was moved to its present position two years ago that anything satisfactory was done with it. It flowered the following year and again this year about the same time—Christmas. It is by no means particular as to soil, but a good friable loam seems to suit it best.

"It is easily propagated in the usual way, either by cuttings or seeds, which, judging from what I have seen of it, are produced rather freely; but cuttings inserted round the edges of a pot in sandy soil and placed in a propagating frame root in a few weeks, and if potted and liberally treated may be expected to flower in about a year, much depending on the time of year at which the cuttings were inserted. As far as I am aware, this is the first and only plant which has flowered in England—possibly in Europe—and is not yet, I believe, in the trade; Sir George Macleay having brought the plant to England when travelling abroad a few years ago."

### HOME FOR THE HOLIDAYS.

#### AMERICAN METHODS.

HOLIDAYS in the home gardening world are perforce of circumstances connected with the work of the festive season not very common, and a trip of some 3000 miles to see the "old folks at home" is less common still. It is perhaps worth recording with a few notes derived from a young gardener who two years since set out for "the West" to find work, dollars, and new ideas in a Boston nursery. He appears to have won a considerable moiety of each, and of the latter I was particularly interested in. This—the working experience—was confined to Roses and Chrysanthemums grown for cut blooms in the Waban Rose Conservatories, Natick, Mass., seventeen miles inland from Boston, U.S.A. About 40,000 Roses are grown in thirty-five houses, varying in length from 100 to 350 feet, and from 18 to 30 feet wide. These houses are heated by steam, and particular attention appears to be given in the matter of temperature, airing, and watering. The principal varieties grown are—Teas, Catherine Mermet, The Bride, and Bridesmaid; Hybrid Teas, Meteor and American Beauty; H.P.'s, Ulrich Brunner and Général Jacqueminot. These are planted out in shallow beds of soil of but a few inches in depth, resting on benches of timber raised from the ground to a convenient height for working operations. Stimulant in the form of bonemeal is liberally supplied, and the whole of the plants are cleared out annually, and new stock reared from cuttings in reserve houses take their place.

Some 12,000 Chrysanthemums are planted out in three large houses about mid-June. These are grown on single stems only for one big bloom. Addition of new varieties is made each season. Cutting for the Boston market, where all the flowers grown here are consigned, commences about October 20th, and finishes the first week of December. Having some vague notions of the tropical heat summer commands in this part of the globe, this question of growing Chrysanthemums planted out under glass is, to say the least, interesting. I was also gratified by some cuttings which my enthusiastic young friend brought with him, accompanied by the compliment that "the boss" who gave them to him said, "Now, I guess you'll give these to some old fogey over there who will not root them till next summer." But of that *nous verrons*. Eugène Dailedouze is amongst those sent, and my visitor said it is superior to Golden Wedding. Forty-five dollars per month is the nursery pay; but it was easy to glean that a good deal of energy and close attention to duty under extremes of climate is required in exchange. Still, my young friend, when asked if he would care to remain on this side, said, "Wal, I guess not; it is rather too slow." Hence he returns to "the West," and I think he might do worse.—E. K., *Dublin*.

### DIFFICULTIES IN EXHIBITING—PROPOSED COURT OF APPEAL.

I AM surprised that nobody has responded to the kind invitation you gave in your issue of 13th December to discuss the above subject in your columns. Perhaps "everybody has been waiting for somebody else to begin." I have advocated for some years the appointment of appeal judges for our agricultural, horticultural, and other shows as the only means of putting an end to disputes and closing the mouths of inveterate grumblers who never get fair play (?)

There are many people in the world who think it a very great honour to be appointed to adjudicate at a show of any kind, and will accept an appointment and the responsibility connected therewith although they know little or nothing about the subjects they have to judge. There are others again, who are themselves keen competitors, that are very anxious to be taken out as judges, not so much for the empty honour of the post as to be in a position to help those who will help them. If the work of these gentlemen was subject to be reversed by appeal judges the first set would not in many cases accept the responsibility, and the second would be very chary of deviating from the straight line lest an aggrieved party might appeal, with result of their decisions being reversed and their shortcomings exposed.

To work the appeal court without unduly prolonging the misery it

would be necessary to have the appeal judges in a room or tent convenient to the building or marquee in which the show was held, and to allow the competitors to remain in the show during the judging ready to lodge their appeals as soon as each class was judged, or if there was not room in the place where the show was held to call in the competitors in each class as soon as the judges gave their decision. To prevent wholesale appeals it would be necessary, as proposed by Mr. Crabbe, to require each appellant to make a deposit—say the value of the prize claimed if it did not exceed half a guinea; I think any higher sum would be likely to deter many competitors who really had a grievance from seeking an appeal. If an appeal was successful the appellant would get back his deposit, and of course get the prize claimed, and if not the deposit would be forfeited and go to the funds of the society.

The greatest difficulty in working the appeal system would be in the event of the judges awarding an exhibit the first prize which should not have been in the running at all. For instance, if the appeal system had been in operation at the Royal Caledonian Horticultural Society's show of September last, where the judging of the Fancy Pansies took everybody by surprise, the first prize being awarded to a tray that I may safely say none of the competitors, not even the owner of it, ever dreamt of it getting a prize. In that case there certainly would have been two or three appellants. Say that three had appealed against the decision of the judges, and all claimed the first prize, they could not all have been successful—that is, they could not all have got the first prize, but if the appeal court adjudged the exhibits of all the three appellants better than the one that was awarded the first prize by the first set of judges, and awarded them the first, second, and third prizes, all three should be equally entitled to have their deposits returned.

Some people affect to believe that there is no such thing as favouritism or partiality with judges, but it is one of the worst features of our show system. The good grower will not often succumb to the cadger, and if he does at a time, he often does not know whether the "stuff" that beat his was honestly shown or not, and it is said that what a man does not know does him no harm, but how shocked he is when he suffers an unmerited defeat at the hands of dishonest or incompetent judges, and has no remedy.—C. K., *Gargannock*.

[This letter opens out a new view of the subject that was introduced, and a very wide one, as it appears to suggest a reserve set of judges for every show. Would they not all want to be in the appeal reserve?]

### MR. BLACKMORE'S CRITICS.

DOES not "Landowner" (page 586) with all other of Mr. R. D. Blackmore's critics, make the mistake of regarding that eminent writer's fruit references too seriously? It seems to be overlooked that Mr. Blackmore owes his high reputation, not to fruit at all, but to books; that he is a distinguished romancist, and as such it is difficult for him to avoid investing, what to most persons may seem to be a very prosaic theme, with a certain amount of romance. Very much of allowance has to be made for that feature in Mr. Blackmore's fruit criticisms; it is, indeed, a case where the proverbial grain of salt looms large. Now, so far from being regarded as a practical grower of fruit for sale, Mr. Blackmore is really a fruit experimentalist, and he has chiefly devoted himself to Pears, which seem to be pomologically—I do not say profitably—his favourite fruit; and there are few varieties known to commerce, especially of French sorts, that he has not grown and tested at Teddington.

It is obvious that work of this kind cannot be undertaken profitably, not even by a nurseryman. It is all speculative and experimental, and its reward is found in the great fund of information it furnishes, whilst to an earnest pomologist experimental work of this kind is ever attended with profound interest and pleasure. No doubt Mr. Blackmore has found, as others have found, that two-thirds of the Pears he has tested have been worthless, and in that respect alone the Teddington trials have perhaps been as useful for horticulture as they may have been, in another sense, profitable to some traders. Let it be said that neither in soil nor situation is Teddington an ideal place for hardy Pear culture. It is flat, not far from the Thames, and on the stiff London clay, and all experience has served to show that these are far from being the best of cultural conditions.

The Thames Valley soil, though growing trees very well up to a certain age, is very apt to produce weak sappy wood, engendering canker and non-fertile buds later, hence the older Pear trees become the less profitable they are. Mr. Blackmore has most of his trees somewhat densely planted, much more so than is ordinarily the case, especially where under fruits are grown in conjunction. Many of the trees have run up freely to a great height, and it is obvious that unless the ground be more abundantly fed the supply of food must be rapidly exhausted. Practically the trees largely may be said to be free pyramids run wild, for they have that aspect, and whilst sometimes cropping heavily, it is doubtful whether there are not far too many varieties, and probably much of the fruit far from being first-class. I cannot answer, nor am I entitled to answer, the queries which a "Landowner" so practically puts. He is not content to be put off with generalities. No doubt a visit to the Pear gardens, I think some 7 acres in extent, would furnish the best information and test how far, as a certain peer remarked the other day, Mr. Blackmore was entitled to the dignity of being the largest fruit grower in the kingdom. For that silly remark, however, a peer and not Mr. Blackmore is responsible.

Let it be clearly understood that hardy fruit culture as conducted at Teddington, bears no more relation to fruit culture on practical market lines than does a picture shop to the National Gallery. No

greater failure can well be looked for than when persons, clever in other directions, embark capital in a trade for which they have only a faddish fancy and no practical knowledge. Sir Walter Scott found that out to his cost, and he was, or is not, the only eminent romancist who has had similar experience.—A. D.

“THE ROSARIAN'S YEAR BOOK.”

WE have to acknowledge “The Rosarian's Year Book for 1895,” which, as most Rose growers know, is ably edited by the Rev. H. H. D'Ombraïn. The frontispiece is a life-like portrait of Mr. Edward Mawley, Mr. D'Ombraïn's co-secretary. The body of the work contains articles on the following subjects by the authors mentioned, “Does Exhibiting for Money tend to Demoralisation?” Mr. C. J. Grahame; “The Rose and the National Rose Society in 1894,” the Editor; “Neglected Roses,” Mr. A. Piper; “Hybrid Tea Roses,” the Editor; “An Up-to-Date Rose Garden,” Mr. Geo. Paul; “The Book of the Rose; a Review,” Mr. C. J. Grahame; “The Hardiness of Tea Roses,” Mr. D. T. Fish, N.R.S., F.R.H.S.; “Rose Culture in the North Midlands,” Mr. H. V. Machin; “The Rose Weather of 1894,” Mr. E. Mawley, F.R.M.S. The work is published by Messrs. Bemrose & Sons, Ltd., 23, Old Bailey, and remains at the same price as before, 1s.

NATIONAL ROSE SOCIETY.

IT would have been better for Mr. D'Ombraïn's own standing with the Society than from any idea of gratifying me, as “D., Deal,” says (page 13), that he should have replied and explained his position in regard to his attitude at the annual meeting, more especially in regard to his opposition to Mr. Machin on the plea of no room, and his immediate *volte-face* in favour of Mr. Foster-Melliâr, and also his extraordinary action to Mr. Jeans and the Portsmouth Town Council.

It is unusual in a public discussion to refer to a private letter, and it is considered to be in very questionable taste to do so, but “D., Deal,” refers to one I wrote to him, not to “some of us.” This letter he distorts, as I said Mr. D'Ombraïn had by his action put some nails into the N.R.S. coffin. My letter in your issue of the 27th December, which Mr. D'Ombraïn thinks refers to what I wrote to him in regard to “driving a big nail into the coffin of the N.R.S.,” has nothing to do with anything as yet published. It refers to quite another matter, which for the present I withhold, but am ready to bring forward at any moment.

Our senior Secretary, with a complacency which is charming, finishes his letter by saying, “My motives were simply what I thought best for the Society.” That is—first, he considers it best for the Society that he should say at the annual meeting that the V.-P. list was long enough already, and for that reason oppose one gentleman of high social standing and a leading rosarian, and within five minutes support the claims of another rosarian for the same position of V.-P. Secondly, that it is “best for the Society” to hold a show at Reading in 1896 within eighteen miles of Windsor, where the Southern Show was held in 1894, when an offer had been received from the Town Council of our leading naval seaport to hold the meeting in their town.

Mr. D'Ombraïn does not vouchsafe to Mr. Jeans the courtesy of one word of apology or explanation, and his apologist, Mr. Strange, fairly gives our senior Secretary away.

Both Mr. D'Ombraïn, who was in communication with Mr. Jeans and Mr. Mawley, who was in correspondence with Mr. Spittal, knew as well as your readers, last October that the Portsmouth Town Council had passed the resolution to invite the N.R.S. to Portsmouth in 1896. Mr. Strange with, a simplicity of mind which does him credit, while it is amusing, lets the cat out of the bag, as he says, “Immediately after the November Committee I had an intimation that if Reading had renewed the invitation for 1896 it would probably be favourably considered.” In the cause of good faith and in the real interests of the Society I ask our members to again read Mr. Jeans' letter to you in the Journal of the 27th December, page 585. I think a more remarkable misuse of authority than this invitation by the officials to the Reading rosarians has never been perpetrated, and as a man of thirty-three years business experience I can say with the absolute conviction that I am right, that such a proceeding would never be permitted in a public company.

I shall be much surprised if the gentlemen more immediately interested in the lamentable occurrence at the recent annual meeting and prior thereto, are willing to ignore the indignity placed upon them. In any case the letter of Mr. Strange leaves the matter now fully exposed to the light of day, and the fact of Mr. D'Ombraïn specially attending the Reading Committee shows what he had made up his mind to do, although he told Mr. Jeans to stay away from the annual meeting, and soothed him with the impression that his interests were safeguarded.—CHARLES J. GRAHAME.

N.R.S. TROPHY CLASSES.

IN the early autumn of last year there was a good deal of correspondence in your columns on the above subject with a view to a possible re-arrangement of certain details. But one phase of the subject was

not touched, and as it is a matter in which an improved arrangement might quickly and easily be made I should be glad to see some expression of opinion on it. The challenge trophies are held for one year only, and then, unless the exhibitor is strong enough and fortunate enough to repeat his success, they pass into other hands, leaving no tangible memento of the victory once gained. This certainly seems hard, and I know some of the winners feel it very much. Writing to me some time ago one gentleman who has twice won the amateur trophy said, “During the last twenty years I have had fifteen challenge cups in my possession, and yet, now that I have partially given up exhibiting, I have nothing whatever to show for my pains.”

With a view, therefore, to avoiding this state of affairs, and providing permanent satisfaction to the winners in these important classes, I should like to suggest that in addition to the challenge trophies to be held for the year, the gold medal of the Society, to remain the property of the winner, should be given as the first prize in each of them. If I am told that these medals cost £2 apiece, and that five of them (three at the C. Palace show and two at the Northern) would mean too great an addition to the prize fund, then I would say that while the amount of the second, third, and fourth prizes remains the same, the money for the first prize might be reduced by £1, and thus the expense of the medals be jointly borne by the funds and by the trophy winners.

I would not omit the trade growers from the proposed arrangement, because as a matter of business it is of even more importance to them than to amateurs. Our good old friend, Mr. B. R. Cant, has secured the trade trophy six times, and he, rightly enough, makes the most of this fact; but if, when visitors call on him, he could open a neat little case and say, “This is my collection of N.R.S. medals awarded to me when I won the challenge trophy,” it would be of far more value to him than just a line in an advertisement.

I feel somewhat diffident about broaching this subject, because I am never likely to be an aspirant to championship honours; but if other exhibitors, and especially those more immediately concerned, think favourably of the suggestion and will give us their views on the matter, I think it might be brought before the Committee with a fair prospect of being adopted in this year's schedule.—J. B.

[The suggestion appears worthy of consideration.]

REGULATION 13.

MR. GRACE does not clear up the mysteries of his first letter in his second one, but he “gives himself away” as freely as before. He tells us now that he has never exhibited under false colours, but his first letter shows that he at least sympathises with those who do, for he says (page 536), “To enforce it (Mr. Lindsell's resolution) means the exclusion of scores of ardent amateurs,” and I cannot see how the enforcing the regulation would exclude them, unless they wished to show contrary to its provisions. What does he call this sort of thing—showing in amateur classes under false pretences and contrary to the regulations, and trusting, I suppose, that no one will have the moral courage to denounce it? That he himself is not wanting in courage is plain, for I should not have thought it possible that anyone would dare to write in defence of such a thing, and complain of its being found fault with. I had no idea that there were any provable cases of infraction of the rule, but he says he knows it is widely set at naught. I will not be behind him in moral courage, and will say openly what I call it—dishonesty. I am quite sure the Society has never meant that this regulation should be a dead letter, and I will do all in my power to enforce it.

Mr. Grace says (page 14), “Doubtless the rule was originally framed as a protection for the small grower and in order to prevent large growers from sweeping the board.” Certainly not. What possible connection is there between the two subjects? It was obviously framed for the definition of an amateur as opposed to a professional. Why, it is one of the most important regulations in the list. It is, and always has been, the most burning and difficult question in any amateur association, and every such society which has had to deal with it (as, for instance, the Amateur Athletic Association and the Amateur Rowing Association) has met the difficulty successfully only by making the line between amateur and professional most hard and strict, and enforcing actual punishment for every infraction of the rules.

A little further on (page 14), it appears that Mr. Grace calls private gardeners “professionals.” Here again he is in conflict with regulation 13. Amateurs are those who do not sell. If they do sell they are, for exhibition purposes, not amateurs but professionals. There does, however, for a moment appear a glimmer of reason in the complaint that poor amateurs, who have no assistance, have to contend against trained and taught gardeners backed by wealth and plenty of help; but he once more gives his own cause away by saying (page 14), “the true amateur is not afraid of meeting professional skill but professional numbers,” though in the same paragraph he had already alluded to “the new and most sensible regulations for dividing exhibitors into classes according to number of plants grown by them,” which was expressly framed to prevent the small man being overborne by numbers.

Mr. Grace so well displays the weakness of his own case that it seems hardly necessary to point out that the experienced amateur is by no means afraid of private gardeners, however large their establishments may be, knowing that, with very few exceptions indeed, they have so much other work to do as to be unable to beat the amateur who makes

a specialty of the Rose. Such amateurs who have no gardeners, as, for instance, Mr. Pemberton or Mr. Page Roberts, Mr. Grace would, I suppose, have no objection to contend with; but he would find them even more doughty opponents than what he calls "professional" gardeners.

In fact, Mr. Grace's letters, as I said last week, have given far clearer proof of the necessity of vigorous action being taken in the matter of regulation 13 than Mr. Lindsell's resolution itself did, for they have shown, what was unknown to me, and surely to others also, that there really are some who set the laws at defiance, and others who wish to do so. I consider this the most important point in connection with the welfare of the Society that has come before it during the dozen years or more that I have been a member; and I heartily hope that everyone who has the common sense to see that no society can afford to let its own regulations be thus set at naught, will unite to follow up the spirit of regulation 13 by bringing every such provable act under the notice of the Committee.—W. R. RAILLEM.

#### THE N.R.S. AND PORTSMOUTH.

It is unpleasant to be drawn against one's will into a public controversy, but the letters which have appeared in your columns seem to leave me no option; and I hope the N.R.S. will understand that I meant nothing but good to the Society in the part I took. Mr. Jeans of Shorwell, the Secretary of the Isle of Wight Rose Society, has already pointed out the advantages which Portsmouth offers as a place for a great Rose show. It is a town of 170,000 inhabitants, with a large proportion of villa residents. It is convenient for almost all the southern Rose growers. The show might be held early in the season, so as not to come into competition with any other. There was no need for "strenuous exertion" to induce the authorities to entertain the scheme; as a matter of fact, one day in last September I had a few minutes' conversation with the Chairman of the Portsmouth Parks Committee, which has the charge of such exhibitions. He entered into the scheme heartily.

The Parks Committee agreed to take the matter up, and were anxious to do everything to make the show the great success which it promised to be. They said there would be no difficulty as to a guarantee. They have the power to close the public parks for such shows, and they offered the park close to the town railway station, or, in case of bad weather, the great Drill Hall, which is well lighted with windows in the roof, and is supplied with tables and all things necessary. They made a point of the Isle of Wight Rose Society joining them, and holding our annual exhibition as part of the Portsmouth Show.

The Mayor was away from home in September, but in October the matter was brought before the Town Council, and the resolution to invite the N.R.S. for 1896 was passed. There was a mistake on the part of the minute clerk which delayed the forwarding of the formal notice of the invitation for some weeks. But on October 18th I sent Mr. Mawley a copy of the newspaper report of the resolution, with a letter explaining the circumstances and the advantages which Portsmouth offered. I had a courteous letter from Mr. Mawley in return. We, in the island, thought that all was settled, and that not only the show would be conspicuously successful, but that the N.R.S. would gain many fresh members.

Now, in your last issue (page 13), I read in a letter of Mr. J. T. Strange, Secretary of the Reading Horticultural Society, "Immediately after the November Committee meeting I had an intimation that if Reading renewed the invitation for 1896 it would probably be favourably considered. An invitation was sent accordingly."

Your readers will understand that the N.R.S. Secretaries had in their hands the printed report of the Portsmouth resolution, and were acquainted with all which the Town Council offered long before the November meeting, and long before they invited Reading to send in an application. They may say I had no position in the matter. I acted as a member of the Isle of Wight Committee. Our Society was deeply interested, and the show would have been our show as well as that of Portsmouth. If the Secretaries had not determined to reject the Portsmouth invitation they would have communicated with the Chairman of the Parks Committee, whose name and address they had.—JOHN SPITTAL, *Havenstreet, Ryde.*

WHEN a well-known bishop, at a public dinner, received the contents of a hot soup plate down his back from a clumsy waiter, he is said to have exclaimed, "Is there any layman here who will express my feelings?" Portsmouth seems to have taken an opposite course, and a shrill voice of complaint proceeds rather from a clerical source. The Isle of Wight takes the adjacent island of Great Britain under its protection.

Mr. Jeans appears, like myself, to be a very old acquaintance of Mr. D'Ombra. I almost wonder that like myself he does not view with surprise and strong disapproval the strange tone of discourtesy now from time to time adopted and used towards both of our Honorary Secretaries. "Disgust," "outrageous treatment," "it is difficult to find the right word," evidently very difficult. These expressions, I submit, are not necessary to calm discussion, and hardly likely to conduce to it. Mr. D'Ombra and Mr. Mawley have slowly and surely built up the N.R.S. to its present commanding height, and common courtesy, to say nothing else, at least demands that they are given credit for justice and straightforward dealing.

With regard to the question in point, I think it lies in a nutshell.

The whole of Mr. Jeans' contention falls to the ground if Portsmouth fails to show "priority of application." What are the facts of the case? Mr. Strange shows, on page 13, that Reading invited in 1893, Windsor also invited and gained the day, the Reading invitation standing over. Mr. Strange repeated it on the first opportunity, and it has been virtually accepted. Portsmouth invited in 1894; if it has to wait a year also, what is there to complain of? It was, no doubt, a great misfortune, from his own point of view, that Mr. Grahame "was unable to be at the meeting of the 13th," but I hardly see, if he had been, how he could have altered these facts.—ALAN CHEALES.

MESSRS. JEANS and Grahame have poured out their wrath on the executive of the N.R.S. for what they have done, or have not done, in the above connection, but there are just three facts to which I should like to call their attention and that of any of your readers (if there are any) who may be led to suppose that the aforesaid executive have been very remiss in their proceedings.

The first is, that although we have heard and read a great deal in the past two years or so as to what Smith has said to Robinson, and what Jones has written to Brown on the subject, yet, up to the present hour, no official communication whatever from the Portsmouth authorities has reached the N.R.S. Committee.

The second is, that Portsmouth is a three-days show, while one of the regulations of the N.R.S. is to the effect that no show held in connection with it shall extend beyond one day. Here again we have had many *ex parte* statements as to what the Portsmouth authorities would do, but again nothing official has ever come before the Committee.

The third is, that Reading (so far from being invited to apply, as your correspondents suggest), applied for the show to be held there in 1894, renewed their application for 1895, and repeated it for 1896.

To sum up the position, then, we have on the one hand Reading so much alive and earnest in the matter that they make definite official application three times over; and on the other hand, we have Portsmouth so careless and indifferent, that while they appear to have talked about it for two years, they have never yet put themselves in official communication with the N.R.S. Under these circumstances is it in any degree surprising or reprehensible that the Committee should have chosen the former? Nay, more, could they possibly have accepted an invitation which has never been given?

Both your correspondents labour under the disadvantage of not having been present at the annual meeting, and they are, therefore, betrayed into the error of writing dogmatically on matters of which they know nothing except from hearsay evidence. But Mr. Grahame excels himself in this respect, for he devotes nearly half his letter to an elaborate attack on what he imagines (his own words are "I suppose") Mr. D'Ombra to have said about the railway communication with Portsmouth. He will perhaps be surprised to hear that neither Mr. D'Ombra nor anyone else at the annual meeting said a word on this subject one way or the other! All that was done was to report that the Committee had received invitations to hold the Southern show at Reading and the Northern at Ulverston in 1896, and had provisionally accepted them; and then it was proposed and seconded that these arrangements be confirmed, and this was carried without discussion. The terms "imprudent assertion," "untrue statement," and "*fiasco*," which Mr. Grahame bestows on what Mr. D'Ombra did not say at the annual meeting, therefore apply absolutely and only to his own epistle.—J. B.

[We think it will soon be time that this discussion ended, and if the Secretaries of the N.R.S. state that no official application has been made by the Portsmouth authorities for the show in question to be held in the busy seaport town that will end it. Obviously the above letter cannot be regarded as official. We have many times intimated that needlessly strong language or taunting allusions, by whomsoever used or employed, do not strengthen a case, but weaken it in public estimation.]

#### GLEANINGS.

MR. FOSTER-MELLIAR has done exactly what I wished. I invited corrections where they might be needed; at the same time I do not see why the "old coat" had to be taken off. No mention was made of Mr. Raillem, and now I note for the first time that "Raillem" is just "Melliar" the other way about. Was the famous rosarian looking for an opportunity of declaring himself? The time is opportune. I have just bought Mr. Foster-Melliar's beautiful and useful "Book of the Rose," and it will not be prized the less now that I see it was written by "W. R. Raillem."

But to the correction (page 14). It is accepted with thanks. I was informed that "everybody appeared to be talking at once, and it was not easy to catch exact words." Perhaps someone else may have said, in the way of pleasantry, "just what he wanted" to raise the laugh which I am to'd everyone might be expected to hear. Mr. Foster Melliar has taken seriously what was not so intended. But is it not a fact that many a man has often said in the way of banter the very opposite of his desire, his hearers well knowing this at the time? "W. R. Raillem" is not always as dry as dust, and it seems evident he said something, which he describes as "no doubt poorly and insufficiently expressed," or the words "sorry I spoke" would be meaningless. However, my blundering jocularly is withdrawn, and there ends the matter, no one being a penny the worse.

Mr. Foster Melliar (with his coat off) sets me a puzzle. I am invited to "comment on what I have heard with my own ears;" yet this "hearsay business will be unsatisfactory." Why then the invitation? I certainly did hear with "my own ears" from the mouth of my friend who was at the meeting, and I know he would not willingly mislead. I could not hear with my "own ears," long as they are, the original speakers, because that "waiter at the Windsor" caused the date of the meeting to be changed. What more natural than that I should ask one who was present to give me a narrative of the proceedings? Has not Mr. Foster Melliar ever made inquiries of a similar nature when he was interested in certain proceedings at meetings which he was unable to attend? If not, his bump of inquisitiveness is not so largely developed as is that of humanity generally.

But seriously, if any gentleman did not want a position that he was entitled to fill he would not be bound to accept it (except that of High Sheriff), and if he did want it, as he might very properly and reasonably do, without being a "cad," would it be otherwise than frank and honourable on his part to say so? Is it not commendable on the part of a man, no matter in what worthy connection, to aspire to a higher status? I think so, decidedly. If I were a curate, and wanted to be a vicar, I should see no harm whatever in letting my desire be known; or if I wanted to be an M.P. I should not mood silently over my ambition if I had a chance of being elected.

I have had the pleasure of attending I do not know how many annual meetings of the N.R.S., and the proceedings were to me enjoyable. I might have even enjoyed the last, though I am told it was a "bewildering affair" at times, and that something like a spirit of cliquism appeared to be in the air. This is a pity. It is not the way to strengthen a Society, and there should be no animosities "under the Rose," whatever little differences may now and then arise on lines of policy.

As my comments on what I "hear with my own ears" will as "hearsay business be unsatisfactory," I fear I must forego the pleasure of making Mr. Foster Melliar "happy" by accepting his invitation, and it will, I think, be better in future, if I venture to comment again, only to do so on what I see with my own eyes in print. I am bound, however, to consider, and not without regret, that there seems to be a certain amount of danger in tilting with men who are under the gentle influence of the Rose.—GLENER.

#### RANUNCULUS PARNASSIFOLIUS.

THIS is a charming and beautiful alpine (fig. 7) very dwarf in habit, with deep green radical leaves and comparatively large white flowers borne on bold peduncles. It is a native of the Swiss and Carinthian Alps and the Pyrenean mountains, and though always scarce in England, has been long known. Messrs. Kennedy & Lee introduced it as early as 1769, but there is no record that they succeeded in flowering it. Mr. William Curtis was more fortunate in 1797, as recorded in the "Botanical Magazine" of October 1797. He received roots of this and several other rare and curious plants from M. Neckar de Saussure in 1796, and obtained blooms the following June from which his characteristic figure was taken. He grew it in a small pot of loam and bog earth. Mr. Donn of Cambridge grew the plant in 1818. Messrs. Loddiges found it prosper and multiply abundantly in sandy loam without any winter protection, giving it abundance of water in the summer, rearing the young plants both from the ripened achenes and by division of the roots.

#### THE FIRST NUMBER OF THE NEW YEAR.

I DO not know how it is that the first number of the *Journal of Horticulture* for the new year appears of more than usual interest. Whether it is that its readers and writers are specially addressed, or whether the turning over of a new leaf has aught to do with it. Anyway, it has been so to me in years that have come and gone, and this year I venture to say that many who have ere this scanned its pages cannot fail to share in the feeling. From first to last it is pregnant with matter, much of which engenders thoughts difficult to express in words. It is gratifying to find in the leader the honoured pen tenderly touching on the past, the present, and the future. This panegyric of the dead year breathes a spirit of forgiveness for its faults that few of us workers are generous enough to accord to it. Whatever divergence of opinion its doubtful character gives rise to, but one wish can prevail amongst those who read it—viz., that this year may deserve more compliments, and that its character, when revealed in the fulness of time, may, too, be summed up and signed by "D., Deal."

In the leader one is prepared for the brief biography of the bright young life foreshortened on the path of duty. Simple and eloquent is this sketch of a gentle life (page 5) so early closed. Does not the final paragraph of it, in which he anticipates his last resting place, convey the feeling that he was—though cheerfully fighting the battle of life—conscious that the summons from it might be, as it was, sudden? So it

appears to me, hence in those posthumous notes which follow a halo of interest and solemnity is thrown over them, apart from their intrinsic value. For "True and fervent are the prayers that breathe forth from the lips that fade with coming death." Farewell, the gentle pen!—"A long farewell!"

Amongst the pens contributing to this unusually interesting number, it is pleasing to note a gathering so fairly representative over the well known names or well known initials. Amongst those I miss is the able one of "Y. B. A. Z." Let us hope that it is still as vigorous, e'en though these remarks should bring down a long threatened chastisement, for the Roses still bristle with thorns, and promise some friendly skirmishing to come, but by all means let it be "friendly," not acrimonious.—E. K.

#### FEEDING PEARS.

No fruit responds so readily to good treatment as Pears, and where old varieties seem to be running out, a new lease of life is given to them

FIG. 7.—RANUNCULUS PARNASSIFOLIUS.

by applying ground bones and potash. Without doubt these are the two essential constituents of the soil that the Pear trees exhaust, and when they can no longer draw them from their surroundings they refuse to produce saleable fruits. After many years of experience I can safely say that all of the Pear trees of an old orchard can be revived almost beyond recognition by the annual application of potash and ground bones.

The process I have found the most serviceable is to apply about 400 lbs. of muriate of potash with 800 lbs. of ground bone per acre each year. One-half of this mixture is applied in the autumn and the other half in the spring. Crimson Clover seed is sown with the dressing in order to give the necessary nitrogen. This repeated several years in succession brings the orchard up to a condition where excellent crops of Pears can be depended on every season.

Lately many of our standard Pears have been degenerating, and even on good soil they fail to produce the paying crops that they should. The fruits are small, tasteless, and apt to be knotty and poor generally. Our autumn fruits are usually poor and insipid, and if better Pears could be produced at this time of the year there would be a better general demand. Autumn and winter Pears are susceptible of higher and more delicious flavours if we only give them the right cultivation and attention. The comparative difference between the fruits of the same variety of Pears taken from two orchards is sufficient to convince one of the truth of this remark. Not a few are so poor that one can hardly believe

that they came from the same stock as the other delicious specimens plucked from trees that have been manured for several years. Herein lies the difference.

It is a crying need of the time that orchardists should get out of the old ruts and educate the public up to the use of better fruits. In this way the consumption will increase. We can only do this by abandoning the old idea that Apple, Pear and other orchard trees will take care of themselves. They need cultivation and close attention just as truly as do the vegetables, grains or other farm products. Fruit-growing requires as much scientific study as grain-growing or cattle-breeding, and the sooner this is generally recognised the better it will be for this industry.—S. W. CHAMBERS (in "American Cultivator.")

### LIVERPOOL NOTES.

#### THE CORRIDOR AT CLEVELEY—A PLEASING COMBINATION.

IN noting the Chrysanthemums some time ago I mentioned that they were arranged in the corridor—about 700 plants, admirably grown by Mr. Cromwell. A beautiful combination was presented by mixing *Salvia splendens* and the charming single white Chrysanthemum Miss Mary Anderson. The *Salvias* are propagated early in the season, afterwards receiving treatment almost identical with the Chrysanthemums. This useful old winter-flowering plant, with its glowing scarlet spikes, as seen growing at Cleveley, asserts its decorative value in a way which cannot be mistaken.

#### CYCLAMENS AND GESNERAS AT AIGBURTH NURSERY.

However much I felt inclined to speak in glowing terms of the successful way in which Cyclamens are cultivated by R. P. Ker and Sons, I should still fail to describe their full beauty as autumn and winter-flowering plants. Houses and frames are similarly occupied with plants sturdy in foliage and strong in spike, until many thousands are reached, in pots from 4-inch to 7-inch, all denoting the fine strain which visitors are wont to see at our leading shows. Already there are numerous scented varieties being carefully looked after, the odour being almost similar to the *Daphne indica*. I cannot pretend to deal with Cyclamen culture here, but the seed is sown in pans in August, using a light soil. When the seedlings are ready to handle they are transferred to thumb pots, the soil containing a fair amount of sand. A little warmth with careful watering constitutes the treatment through the winter, early spring seeing them shifted into pots of various sizes. At the present there are many thousands of healthy vigorous plants in small pots, but nothing in the nature of coddling is resorted to.

Gesneras were in fine condition. Good culture had been the rule, consequently the velvety leaves—some self-coloured, others beautifully marked—showed the spikes of flower to advantage. Could they be seen oftener in such condition, with every leaf perfect, they might yet be held in higher estimation by many plant lovers. A variety almost lost to cultivation was very pretty—*G. chromatella*, with elegant spikes, the flowers being rich yellow in colour, which told to great advantage against the scarlet-orange shades of other varieties.—R. P. R.

### HETHERLEE HOUSE,

THE Monmouthshire seat of W. S. Ogden, Esq., is situated about two miles east of the town of Newport. The mansion, a spacious and substantial building, with a noble appearance, commands fine scenery as far as the eye can perceive towards the Bristol Channel.

In viewing the flower garden we notice at a distance some fine Wellingtonias, Cedars, Conifers of kinds, also fine specimens of shrubs, which form an effective foil to the flowers when in beauty. From the carriage entrance to the mansion a flight of steps leads down to a most artistic pleasure garden, kept in the best style. Very pleasing are the rockeries well filled with suitable plants in great variety, and on the grass are flower beds mingled with specimen Conifers and choice shrubs, which appear to receive great attention.

The conservatory, west of the mansion, is furnished with a good collection of plants and Ferns, with a few baskets of Orchids in suitable places along the centre of the house, and on each side are tasteful rockeries, well furnished with Ferns. From this we pass to another large flower garden containing large beds and herbaceous borders, surrounded with shrubby borders and specimen trees.

Another handsome flight of steps leads to the range of glass, ornamental vases here and there with beautiful flower borders form a beautiful frontage to this magnificent range of glass. The Peach house is 80 feet long, 15 wide, and 18 high, the trellis commencing about 2 feet from the front, curves to about the centre of the roof. The house, being a three-quarter span, is covered with healthy trees and produces excellent crops of fruit. Along the centre of this house is a bed planted with Camellias, which are full of buds, set among dark green foliage, and on the side stages are Primulas admirably grown in 5-inch pots.

The fernery, which is well stocked, contains some huge plants of *Adiantum farleyense* and *A. cuneatum*, the sides being covered with cork and rockwork. The stove comprises a grand collection of Palms, Ericas, Crotons, Ferns, and flowering plants. A large number of Orchids of various kinds also show that they receive good cultural attention. The vinery is a long lean-to, planted with Black Hamburgs, Black Alicante, Gros Colman, and Muscat of Alexandria, the crops and quality of fruit reaching a high standard of excellence, and the wood beautifully

ripened for similarly fine fruit another year. There is a very large intermediate house, which at the time of my visit contained a grand collection of Chrysanthemums.

The kitchen garden is well stocked with vegetables and fruit trees, the espaliers around the walks and the wall trees all affording evidence of cultural skill. Mr. Ogden evidently takes the greatest interest in his magnificent garden; and, as in the past we shall hope in the future, to have the privilege to see its produce win honours at our shows. Mr. Ogden is to be congratulated in securing in the open class at Maindee Chrysanthemum show first prizes for trained and for untrained plants against such strong competitors as Mr. Steadman and Mr. Giddings. The Primulas from Hetherlee, which took first and second honours, were grand plants in 5-inch pots, and one mass of bloom. Mr. Prosser, who has had charge of these gardens for the last four years, is a man of unquestionable ability, and he made the quick march round very pleasant to—EXHIBITOR.

#### HARDY FRUIT GARDEN.

**Pruning and Manuring Raspberries.**—All the pruning which should be necessary now to Raspberry quarters consists in thinning out the canes to not more than half a dozen to one stool, leaving the vigorous and stouter. Tie them securely to the central stake, or if grown in espalier rows trained to wood or wire dispose them equally over the trellis. The tips may then be taken off to the height of the stakes or trellis, the wood in strong plants being usually ripe and hard to that height, 4 to 5 feet in most cases. Some prefer to have the plants fruiting from the base upwards. In that case the canes must be shortened at various lengths. Cut off the superfluous wood just above a bud and in a short slanting direction, so that the cut is scarcely seen. Long conspicuous cuts are unworkmanlike, and the pith left eventually dies back, leaving an unsightly snag.

Raspberries are usually furnished with abundance of feeding fibres or rootlets near the surface. It is unwise to fork or dig among these; therefore, pick out any strong weeds which may have established themselves, and then spread a layer of rich manure over the soil. The central space between the rows when not occupied with roots should be lightly forked and some manure buried; but if the rows are close this may not be possible without destroying the fibres. In favourable weather liquid manure can also be applied, which will furnish the soil with increased food for appropriation in the summer.

**Strawberry Beds.**—On light open soils a good dressing of manure may be spread between the plants, first applying a dusting of soot round the crowns, which will help to destroy slugs as well as invigorate the growth when a move is made in the spring, a further stimulant then being applied in the form of nitrate of soda, 1 oz. to the square yard. On cold, heavy soil, if a mulching of manure was not given early in the autumn, it will be well to defer it until the end of February or later, but soot can be applied at any time. Young vigorous plants in rich soil will need no manure at present. When the surface soil is dry a Dutch hoe may be run lightly through it with beneficial results, not going too closely round the plants.

**Manuring Fruit Trees.**—Old fruit trees need the most assistance from manurial applications. Of chemical manures slow decomposing kinds are best applied in the autumn and winter. A mixture of bone-meal and kainit may be spread over the roots at the rate of 3 ozs. to the square yard, lightly pointing the surface first to admit of it being washed in equally. Good farmyard manure partly decomposed and laid under the spread of the branches 3 inches thick soon has its virtues washed into the soil. It also naturally attracts the roots to the surface. Fruit trees ought not to be too freely manured before they begin to bear, therefore young trees that are growing vigorously in good soil should not at present be further stimulated at the roots. For such trees a mulching in the summer suffices, this conserving the moisture in the surface soil and keeping the roots from descending too low. By these means the fibrous character of the roots is retained, fruit buds soon form and fruitfulness ensues, while at the same time adequate wood growth for extension is produced. When in full bearing condition the health and fertility of the trees must be maintained by periodical surface dressings.

**Pruning and Nailing Morello Cherries on Walls.**—Trees grown in fan shape will have abundance of young wood ready for training in, whether the old bearing shoots of last year have been cut out or not. The latter should, therefore, if not already done, be dispensed with to make room for the younger shoots, training these in from the basal parts as far as possible so as to keep the trees well furnished. Nail or tie in the young shoots 2 to 4 inches apart, leaving them unshortened. Before training dress the trees with an insecticide and wash the walls.

**Renovating Orchards.**—Old orchards are frequently too crowded, the number of trees being in many cases far in excess of what should

occupy the ground. Added to this the branches are almost invariably allowed to remain too thickly placed, with the result that they bear very indifferently. One tree allowed free extension, with abundance of light and air passing through it in the summer, is better than many crowded together on a similar extent of ground. The first step towards renovation ought to be to thin out the trees, followed by judicious regulation and pruning for several years. Thus a transformation may be effected in the value of the trees, which will well repay for the trouble expended.

**Renovation by Grafting.**—An excellent way of improving old trees is to head them down now, and in the spring graft scions of approved varieties on them. This system of renovation is applicable to Apple and Pear trees which are in a healthy condition, but not good varieties. The scions for grafting should be cut this month, laying them in moist soil or sand under a north wall to retard their growth until the sap flows freely in the stocks. Strong limbed trees which are headed down for the purpose of grafting ought not at present to have the branches shortened to the exact point where the grafts must be inserted, but left about a foot longer, reducing them to the desired length just prior to adjusting the grafts.

#### FRUIT FORCING.

**Peaches and Nectarines.**—*Earliest House.*—The chief thing to aim at is the fertilisation of the flowers, which, having developed in a comparatively genial and well ventilated atmosphere, have opened well and are well furnished with pollen. Raise the temperature to 50°, if it has been lower through the night, as soon as possible after daybreak, and maintain it at that figure during the day by artificial means, putting on a little air so as to induce a circulation without causing a draught. Maintain a genial condition of the atmosphere by damping the paths and borders in the morning and early in the afternoon of fine days. By ventilating early with a suitable temperature the trees are kept in steady progress, the blossoms become perfect, and fertilisation is readily effected. The pollen can be distributed by means of a camel-hair brush, feather, plume of Pampas Grass, or shaking the trellis. Varieties deficient in pollen should have some applied from others. The night temperature must now be 50° to 55° in mild weather, permitting a fall of 5° through the night in severe weather, 55° by day from fire heat, advancing to 65° from sun heat. Increase the ventilation freely above 55°, but not so as to lower the temperature, and close at 65°, a few degrees advance from sun heat being beneficial.

Disbudding must not be done hurriedly, but any strong shoots of the previous year having a tendency to push growth in advance of the others may be commenced with first, removing the growths on the upper side of the shoots, and then reducing the side shoots to the number required, namely, one from or near the base as possible for to supplant that now fruiting, and another or more above or on a level with the fruit, and which should be pinched at a few inches of growth, or if the shoot be an extension leave growths at about every 15 or 18 inches to form the bearing shoots of next season, continuing those with the leader intact. Disbudding, however, should be commenced before the shoots are an inch long, and be continued at short intervals until no more shoots are left than will be necessary for furnishing the wood of the ensuing season's bearing. Afford due supplies of water to inside borders, and protect the roots outside with dry material. After the fruits are set an occasional syringing will assist the trees to cast the remains of the blossoms, yet avoid heavy syringings, which have a tendency to weaken the growths.

*Second Early House.*—The house to afford ripe fruit early in June must now be started, employing fire heat only to maintain a day temperature of 50°, raising it early to insure the development of the blossom with light and its due airing, increasing the ventilation at 55°, avoiding cold currents, and allowing an advance of 5° to 10° from sun heat and corresponding ventilation. A night temperature of 40° to 45° is sufficient until the blossoms are well advanced for expansion, when it should be gradually raised to 50°. Syringe the trees in fine weather in the morning and early afternoon until the flowers show the anthers, when damping the borders and paths will be sufficient, admitting a little air constantly, with a gentle warmth in the pipes. When the pollen becomes ripe artificial fertilisation may be resorted to. If water is wanted give a thorough supply, affording liquid manure in a tepid state to weakly trees. Where the blossom buds are superabundant remove those on the under side of the trellis.

*Succession Houses.*—These should be kept as cool as possible by free ventilation. The house to be started early in February should now be closed, furnishing full supplies of water to the borders, merely excluding frost, and ventilating fully above 50°. Push forward the pruning and dressing of the trees in late succession houses, thoroughly cleansing them, securing the trees to the trellis, ventilating and keeping them as cool as possible. If necessary give a supply of water at the roots.

**Pines.**—For supplying ripe fruit in the spring and early summer the plants of such varieties as Smooth-leaved Cayenne, Charlotte Rothschild, and Black Jamaica, that showed fruit in October and November, are good; but these Pines seldom start in sufficient number at that time, and any starting now will not be ripe by May and June. Plants, therefore, of the Queen, Enville, and Providence varieties, which require less time to arrive at perfection, should now be induced to start their fruit. Select from the successional stock plants that have been subjected to somewhat cool and dry treatment, choosing those with an enlarged base and a tendency to open in the centre. Place such plants in a light house or pit, and plunge them in a brisk bottom heat of 85° or 90°, the atmospheric heat ranging between 60° and 70° at night, according to external conditions, allowing 5° to 10° more by day under

favourable circumstances. A genial atmosphere should be maintained about the plants by occasionally damping cool surfaces about the house, steam from hot-water pipes being very pernicious. Examine the soil about once a week, applying liquid manure or water with a little guano in it when needed, and at no other time.

**Figs.**—*Early Forced Trees in Pots.*—When the terminal buds have fairly started increase the temperature gradually during mild weather, it being most beneficial when derived mainly from solar heat, and should always be aimed at in preference to promoting growth during dull weather, and in a high night temperature. The advance must, of course, prevail all round, but that of the night should be 5° to 10° less than that of the day. With the trees coming into leaf maintain a night temperature of 55° to 60°, give a little air at 65° when the morning gives promise of an increase from sun heat, and keep through the day under its influence at 70° to 75°, closing sufficiently early for the heat to rise to 80°. Syringe the trees and walls twice a day according to the state of the weather, and damp the floors in the evening when the day is unfavourable for the afternoon syringing. Give attention to the fermenting material, taking care that the heat about the pots does not exceed 70° to 75°.

*Early Forced Planted-out Trees.*—To have fruit ripe at the end of May or early in June the house must be closed at the new year. The border should be properly moistened down to the drainage. A night temperature of 50° and 55° by day artificially is sufficient to commence with, allowing an advance from sun heat to 65°, but with ventilation from 55°. Syringe the trees twice a day with tepid water or a few degrees warmer than that of the house, always allowing the trees to become dry at night, and on dull days modifying the syringing in accordance with the atmospheric conditions.

*Succession and Late Houses.*—Proceed with the pruning, thinning, and shortening the wood that has reached the extremity of the trellis, so as to give room for the successional growths, and wash the trees with warm soapy water. In the case of scale use a petroleum emulsion formed of 8 ozs. softsoap dissolved by boiling in half gallon of water, and on removing from the fire add 1 gill (quarter pint) of petroleum, mixing well, and dilute to 2 gallons with boiling water. Apply with a stiffish brush, and so as to dislodge the scale. Thoroughly cleanse the woodwork and glass, and limewash the walls, adding a handful of flowers of sulphur to each pailful of the limewash. Remove the old mulching, and supply a mixture of lumpy loam, with a fourth of decayed manure, and sixth of old mortar rubbish. Keep the house cool and dry.

#### PLANT HOUSES.

**The Forcing House.**—With proper management there is no need to prepare a house for forcing plants into flower before this period of the year. It, however, should be done without delay if leaves in a dry state have been stored in readiness, and if there is a bed in the structure it should be filled with leaves and a little manure mixed through them. A bed of dry Oak or Beech leaves give a gentle heat for a long time. By no other means do plants come into flower so freely as when forced by standing or being plunged amongst fermenting material of this nature. When litter is not freely employed the house may be filled with Lilacs, Prunuses, Azaleas of kinds, Deutzias, Spiræas, and many others, while bulbs of various kinds may be stood or plunged amongst them. The gentle moist heat arising from the leaves will be ample at first. During very cold weather the temperature may be maintained at 50°. When hardy plants, including bulbs, are subjected to too much heat at first they do not grow with the same freedom as when gently excited. Lily of the Valley is an exception, and must be placed in a brisk heat to force it out early in the season. All plants should be removed from the forcing house just before the flowers expand, as they are invariably more fragrant, of better colour, and last considerably longer either when cut or for decoration in their pots. Only gentle heat is needed to bring forward Epacris if they are not coming sufficiently fast into bloom. Where a number of kinds are grown there is always some flowering from the early part of October until the end of April or later.

**Late-flowering Epacris.**—Those that were cut back late last season will not have made strong lengthy flowering shoots. These should have the flower buds removed as soon as they are large enough, and repotted if they need more root room, but not cut back. We have always found that our best plants are those which have about 1 or 2 inches of growth on them at this period of the year. Plants in this condition, potted early and exposed to full light and air during the growing season, frequently make growths 2 to 3 feet in length, sturdy and well ripened, and consequently flower profusely.

**Erica candidissima.**—Market plants of this variety that flower well cannot readily be had in the same condition the following season. If cut back, allowed to start into growth, then repotted and given an extra season, removing any flowers that appear, they make splendid plants. The same may be said of *E. hycmalis* that are cut back late. They often only make short growth, which flowers profusely if allowed to do so, and, strange to say, these plants have much better coloured flowers than those grown for market. If the flowers are removed and the plants allowed to extend their shoots good stock will be produced with shoots 18 inches to 2 feet in length. Keep these plants perfectly cool, give abundance of air and water carefully, but never allow them to become dry.

**Azalea indica.**—Keep the main stock of these plants perfectly cool and they will rest more naturally. Dryness at the root and in the atmosphere is detrimental to the well-being of these plants. During the period of rest few plants resent fire heat more than Azaleas. If,

except when we have occasion to force them into flower, we treat them more as hardy plants we should find better and healthier examples in most gardens. The plants should be watered carefully and syringed occasionally to keep their foliage free from thrips. They do best standing on a cool, moist base, where fire heat only employed to exclude frost.

**Salvia gesneræflora.**—Where this is grown the flower buds will just be visible, and the plants, if well rooted, will be benefited by a little chemical manure applied to the surface of the soil. On no account should they suffer from an insufficient food supply, or the flowers will be small. Cuttings from near the base may be taken, inserted in thumb pots, and rooted under hand-lights in a cool house. They make larger and better plants than those rooted in heat in the spring.

**Chrysanthemums.**—Where large blooms of exhibition quality are needed cuttings should be inserted without delay. Good sturdy shoots in small pots will root freely in sandy soil and a little leaf mould, watered, and then placed under hand-lights in a cool house. Keep the hand-lights close, and use no fire heat except to exclude frost. Very few go off under this treatment. The cuttings intended for bushes need not be inserted for some weeks yet. Weakly cuttings seldom root freely, or if they do the best results are not obtained from them.

**Callas.**—Plants that are already throwing up their spathes will soon unfold them if placed in gentle warmth. They should not be forced in strong heat, as the plants become weak and the flowers are often poor in colour. Wherever they are forced a little air daily when the weather is favourable should be given in order to maintain the plants as sturdy as possible.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### HINTS FOR 1895.

A FEW days ago whilst searching amongst old bee literature for information I discovered several articles by a great author on bee matters, two of which I take as my text. One article advocated the theory that bees had first to store their honey in the empty cells in the lower part of the hive, after which it had to be carried to the supers, in order that it may be "ripened" and made fit for use. The other advised the removal of combs and contracting the hive, so that the honey would be stored at once in the supers!

In order to keep on the right track, yet to move forward, I advise all concerned, whatever their calling may be, while sticking fast to what they know to be good, to strike off the beaten path, make search, and experiment after truth and knowledge in lines of their own. Bees must have attention, but do not require the amount nor expense we read of. To avoid both, they should be attended to at the right time, and everything studied with economy.

Bees do not need more help from man to carry on the internal economy of the hive than to provide them with a comfortable dwelling containing ample provisions, which will tide them over from September to May or June. During that time, if kept wind and water-tight, and if no disease is present, there will be no dead bees to stop the entrance, or along with damp to make the hive a putrid mass. Feeding bees at times they do not require it, is tantamount to giving medicine to man—doing good when necessary, but harm when it is not.

As important as the above towards profit is the size of the hive. Every bee keeper should know, but judging by such writings as I have quoted above, many persons have not this very essential knowledge or they would not recommend hives which have barely room to contain 20,000 eggs, larvæ, and sealed maturing bees, so that instead of 4000 bees hatching daily there cannot be more than 1000 in the height of the season. On these points rests nearly the whole matter of successful bee-husbandry, but which few comparatively speaking act up to.

1894, so far as I have observed, has not given anything new, but rather a harking back to old things. Because bees do well and please their masters, the latter should learn whether they cannot do better. In these times of great competition we cannot afford to do things by halves, or to have any shortcomings whatever, whether it be in the production or in the produce; therefore, "whatever is worth doing, let it be done well."

Young queens, it must be borne in mind, are of the greatest moment so far as profit is concerned, and bee-keepers should not keep them longer than twelve months. I have had queens six years of age, but they were kept as breeders. Commence to raise queens as early in the season as circumstances will permit to take the place of swarmed queens in old stocks, or to supersede any which may be to the mind of the bee-keeper not in accordance with his wishes.

It does not matter, so far as fertility or longevity is concerned, whether queens are raised during May or September. Late-bred queens in some seasons do not mate, and in all cases queens are less fertile after they have deposited eggs from January till June, so that at the last date it is advisable to depose those which have done their best, and introduce a young but fertilised one.

Before closing I wish to emphasise the fact that bees are young, metaphorically speaking, until their wings become defective, so that the more rest bees have the longer they are kept young. Feeding and stifling bees in too small hives are both means to a bad end, and must be stringently avoided.—A LANARKSHIRE BEE-KEEPER.

#### HUNGER SWARMS—SEASONABLE NOTES.

A CORRESPONDENT reports a swarm of bees in December, and the event is believed to be unparalleled. This no doubt would be what is termed a hunger swarm, which is not at all uncommon at this time of the year, more particularly when the weather is mild, the bees having consumed all their stores; and if they remain in their old quarters it would mean death to all of them, so Nature very wisely warns them to seek a better home.

The result is they swarm and cluster on a neighbouring bush, and are hived by some intelligent bee-keeper, who probably has a few spare combs of sealed stores, or if no sealed stores are on hand, some frames of fully drawn out combs. These with a cake or two of candy as advised last week, will cause them to at once settle in their new home, and if kept warm and dry, will come out strong and healthy the following spring. It would be useless putting a swarm of that kind into an empty hive at this time of the year, as it would be impossible for them to build combs, and they would soon die of cold and starvation.

With the advent of the new year a sudden change occurred in the weather. High winds were followed by a fall of snow and severe frosts. As there is considerable warmth under a covering of snow, so long as the frosts last, it is not advisable to clear the snow off the tops of the hives, but directly a thaw sets in all should at once be removed, as the moisture from the slowly melting snow will penetrate through the smallest crevice much more than it ever does from a downpour of rain.

It is better to clear away the snow from the entrance of the hive daily, as those that have no porch to protect the entrance will be blocked. This will often entice the bees to the floor board, many of them will be numbed, unable to return to the cluster, and will die. In strong stocks the heat from the bees in the hive will cause the snow to melt at the entrance, which will not be an advantage to the colony, as the drier they are kept the better.—AN ENGLISH BEE-KEEPER.

## TO CORRESPONDENTS

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Fruit Trees and Frost (D. R. W.).**—If the trees are "laid in," that is if a trench made and the roots placed in it (the trees being close together) and then well covered with unfrozen soil, there they may remain till the frost departs, and the ground is in good condition for planting. If the ground is "like iron" when the trees arrive they will not be injured by remaining in the bundles just as they come for a week or ten days. If they can be placed in a shed the bundles may be opened, liberating the tops, but retaining the packing material round the roots, and if this is slightly damp, and further covered thickly with dry litter to exclude frost, the trees will sustain no injury. We have had them similarly stored for more than two months, and in taking them out for planting in spring found numbers of white rootlets starting in the litter. Planting was done quickly, yet carefully, with these rootlets quite fresh, the long branches shortened, and the trees made as good growth as could be desired in the summer.

Maggots Injuring Ferns (A Thirty Years' Subscriber).—The house in which your Ferns are growing is infested with a destructive weevil—a brownish beetle-like creature not often seen in the daytime, as it feeds in the dark. If with the aid of a light you can catch the weevils, by shaking the plants over a white sheet, for better seeing the enemy fall, you may then prevent the deposition of eggs which hatch out the maggots. Lemon oil is said to destroy them without injury to the plants. See also what is said on corrosive sublimate in answer to another correspondent.

Red Spider on Vines (Subscriber).—Vines that are infested with red spider may, after having been pruned and all loose bark removed, be washed thoroughly with a solution of softsoap, 4 ozs. to a gallon of water. Apply with a brush, reaching well into every crevice and angle, being careful not to damage the buds, but wash the rods or canes well about the "eyes." The washing does much good, especially if used tolerably hot, but not over 120°. After this the Vines may be dressed with Gishurst or other approved insecticides, which, to be safe and effectual, must be used according to the printed instructions accompanying them.

Potting Amaryllises (N. S. P.).—The bulbs may either be potted now or in February, but if the operation is carried out at the present time the soil must not be more than moderately moist, and after potting water should be withheld until they are started into growth, an indication that they are becoming active at the roots or fresh ones being emitted. The worst possible place for them is the hot-water pipes, as the soil will not only become too dry, but be subject to varied heat, which is not favourable to a free production of roots, on which the future growth in a great measure depends. Place them in the manure-heated frame, and keep them without water, the bulbs being potted in moderately moist soil, until they are advanced for flowering and pushing fresh growth, when they can be gradually withdrawn from the hotbed and placed in the house. The steam will not hurt the bulbs, only it must not be rank or excessive.

Berried Solanums (Amateur).—You had better not cut back your plants until April, as you have only a window in which to keep them, then by the time fresh growths push the weather may be warm enough for their being placed in a very sheltered position outdoors, protecting them from frosts which may occur in May, and cutting winds. More than half the old soil should be removed from the roots after fresh growth starts, repotting firmly in good turfy loam, a sixth part of crumbled manure, and a tenth of wood ashes. The pots may be plunged just over their rims in a sunny border for the summer, standing them on smaller pots in the ground to prevent worms passing to the roots. They must be watered as needed, which will not be half so frequently as if the pots were exposed. Clear soot water is good for Solanums when the pots are filled with roots. Some persons plant them out towards the end of May, lifting carefully, and potting firmly in September, watering well, sprinkling the foliage, and letting the plants stand in the shade for a time for keeping the leaves fresh and inciting quick root action. We have seen fine plants grown in that way, but all persons do not succeed alike. You might try both methods, and so gain experience that would be useful to you in after years.

Preventing Eelworm in Tomatoes—Corrosive Sublimate (F. W.).—As you do not find corrosive sublimate solution at a strength of 1 oz. to 30 gallons of water in the least injurious to delicate plants in pots, such as Adiantums and double Primulas, you may safely use it for disinfecting soil intended for Tomatoes at the rate of 1 pint of the solution to each superficial foot of soil placed level and 15 inches in depth, sprinkling with the solution, and when soaked in mix the soil thoroughly, so as to incorporate the whole evenly. If there be a suspicion of eelworm in the soil you may use the corrosive sublimate solution at double strength, 1 oz. to 15 gallons of water, sprinkling on each square foot about 1 pint of the solution, which will impregnate the soil to a depth of 12 to 15 inches if it be moist (as it should be) at the time, and if the whole be turned in the course of a few hours afterwards, the admixture will be assured. Tomatoes will bear an even stronger solution, but it is not wise to apply it, for the nitrifying bacteria are certainly retarded, if not destroyed, by the dressing. The manure you mention will be a valuable one for Tomatoes, 4 ozs. per square yard not being too heavy for a first dressing, and pointing into the soil before planting; afterwards use 2 ozs. per square yard, and wash in.

Peach Tree Buds Falling (Anxious).—The buds on the shoot sent were essentially faulty, and did not contain the rudimentary parts of the flower. One of the specimens, examined carefully by the microscope, had no stamens, and in another there were the usual staminate parts, but without any trace of the pistillate organs. There was not any evidence of parasitic attack from either vegetable or animal micro-organisms. The cause of the buds falling is this imperfect flower-formation in embryo, for what the bud is in that state so will the blossom develop, but as the buds are defective they are shed by the tree similar to other abortive embryos. It is a very interesting and little understood phenomenon, though occurring to a greater or lesser extent annually in gardens where Peach and Nectarine trees are grown under glass. The soil being moist now will not save the defective buds from collapse, as the mischief is caused at a much earlier date—that is, when the transformation takes place from a wood to a blossom bud, and is one of those things that neither science nor practice can unravel satisfactorily. We may say, however, that certain things are known to induce perfect bud formation, and their neglect its opposite, the

chief consideration being a firm and rather strong soil, which lies compactly, promoting a fibry root formation, stout, short-jointed wood, and double or triple buds at most joints. The remedy for refractory trees is lifting, firm and rather strong loam, with judicious after management. That is the course we advise, as the wood is somewhat long-jointed, rather sappy, or not well ripened, but this is not the sole cause of the buds falling, as over-maturity of the buds is a common cause of many failures in early Peach forcing.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (J. H.).—Chimonanthus fragrans. (A. B.).—1, Cypripedium insigne, very poor form; 2, Dendrobium cretaceum; 3, Lælia anceps. (B. O. K.).—1, Petasites fragrans, the Winter Heliotrope; 2, Zygopetalum Mackayi; 3, Catasetum citrinum. (M. S. T.).—1, Dicksonia antarctica; 2, D. squarrosa. The Bouvardia is Alfred Neuner. (Ignoramus).—1, Polypodium aureum; 2, Polystichum aculeatum; 3, Asplenium diversifolium; 4, Nephrolepis tuberosa. (Richard).—1, Anthurium Scherzianum; 2, Asparagus plumosus.

TRADE CATALOGUES RECEIVED.

COVENT GARDEN MARKET.—JANUARY 9TH.

MARKET quiet. Heavy supplies of Grapes still on hand, prices unaltered.

FRUIT

Table with columns for fruit types (Apples, Grapes, Lemons, Peaches, Plums, St. Michael Pines, Strawberries) and prices in shillings, pence, and farthings.

VEGETABLES.

Table with columns for vegetable types (Beans, Beet, Carrots, Cauliflowers, Celery, Coleworts, Cucumbers, Endive, Herbs, Leeks, Lettuce, Mushrooms, Mustard and Cress, Onions, Parsley, Parsnips, Potatoes, Salsafy, Seakale, Scorzonera, Shallots, Spinach, Tomatoes, Turnips) and prices in shillings, pence, and farthings.

AVERAGE WHOLESALE PRICES.—OUT FLOWERS.—Orchid Blooms in variety.

Table with columns for flower types (Arum Lilies, Azalca, Asparagus Fern, Bouvardias, Carnations, Chrysanthemums, Eucharis, Gardenias, Geranium, Lilac, Liliun longiflorum, Marguerites, Maidenhair Fern, Mignonette, Orchids, Pelargoniums, Primula) and prices in shillings, pence, and farthings.

PLANTS IN POTS.

Table with columns for plant types (Arbor Vitæ, Aspidistra, Chrysanthemums, Cyclamen, Dracæna, Erica, Euonymus, Evergreens, Ferns, Ficus elastica, Foliage plants, Lycopodiums, Marguerite Daisy, Myrtles, Palms, Poinsettia, Primulas, Solanums) and prices in shillings, pence, and farthings.

### PROFIT AND LOSS.

In a review of crop and stock possibilities for the New Year we were reminded of the fact that some profit is still forthcoming from most farm produce under really good management. This thought was followed by the very natural one, What is good management? Under test of our title of Profit and Loss, good management is certainly not simply making the best of things as we find them, but rather in a careful beginning and subsequent persistent effort to maintain a high standard of sound practical management on the whole of the farm. This does not point at all to fanciful high farming, but to land well tilled, well cropped, well stocked; to an avoidance of that which is inferior or at all doubtful in land, seed, and live stock. Home farmers have to make the best of it in the matter of land, but then they are generally able to carry out improvements with a free hand; there is the fault, therefore, if poor land is not enriched, or heavy land not rendered permanently porous mixed soil.

To tenant farmers who intend hiring a farm at Lady day we say, Start well by avoiding all farms having the land much out of condition, or with insufficient outbuildings at the homestead and in the meadows. Keep well within your means; never forget that it is the man having reserve force in a good balance at the bank, who is able to bide his time in selling and to take advantage of bargains in buying. It is precisely the having to sell farm produce at a sacrifice that first cripples and eventually ruins many a man. The proverbial £10 an acre may and does answer under favourable conditions, but in a preliminary calculation of ways and means regard should be given to the possibility of losses or sickness among live stock, and to an unfavourable first season for crops. Bearing this in mind we would with say £600 of capital, rather hire 40 acres of really good land than 60 acres of inferior land, or even if there was choice of as much as we liked of the best land, common prudence should lead us to keep to the lesser quantity. Start fair also by not "taking it out of the land" the first season, nothing is more foolish or suicidal in farm management than this. It is something in these hard times to get hold of land that is really in good heart.

Having been so fortunate, we begin on the principle of sustained fertility, and knowing that no crop can be taken from the land without some diminution of its store of plant food, we take special care to replenish such waste by the judicious application of a dressing of manure for the next crop. This rule in cultivation, this safe guide to cropping, applies with equal force to every crop—not only on arable land, but meadow land too. "But," says the beginner, or rather our new tenant, "how am I to enforce the rule at the outset, when the outgoing tenant leaves very few manure heaps behind him?" The answer, though simple, is worthy of being printed in letters of gold; it is, Use pure chemical manure in well-balanced proportion, taking particular care to include the three essential elements of plant food—nitrogen, potash, and phosphoric acid—in the mixture as a safeguard, because you cannot be certain if the soil is more or less deficient in any or all of them. By all means use special mixtures for special crops, but for a general safe dressing use one-eighth nitrate of soda, one-eighth sulphate of ammonia, one-eighth steamed bone flour, one eighth muriate of potash, and one-half mineral superphosphate, at the rate of, say, 4 cwt. per acre.

Give equal care to the selection of live stock—avoid all inferior or badly bred animals. In cows, seek for deep milkers

yielding rich milk; in cattle, store beasts of reliable breeds; in horses, sound useful animals; sheep without taint of foot rot; swine selected for a special purpose—either for bacon, or porkers, or both. Berkshire, Tamworth, small and middle whites all claim attention. For general purposes we have found black Suffolk sows crossed with a middle white boar excellent, just as good in its way as crossing Suffolk ewes with Hampshire Down tups. Both crosses afford a sturdy vigorous progeny, soon growing into money. The same rule of selection applies to poultry. Avoid mongrels all round, get young healthy stock of breeds of high repute, cross-breed with judgment, weed out all inferior stock persistently, keeping only that on which a profit is possible. Observe, we avoid mention of anything like pedigree stock, because it is only under exceptional circumstances that an ordinary farmer can expect it to answer; but a well-selected pedigree animal may prove a profitable investment if turned to account in the right way for breeding purposes.

### WORK ON THE HOME FARM.

Mild weather till Christmas enables us to have numbers of new laid eggs without special care, but with the change to colder weather, warm food, and extra care for the laying hens became necessary. Avoid turning them out in cold weather. If a well sheltered run can be contrived it is good for them, otherwise if they can have access to a covered light dry place, with plenty of short litter on the floor, they get ample exercise if some mixed corn is thrown among the litter. Some peat moss litter, with corn thrown among it every morning, is also an excellent thing for them, as they scratch it over for the corn; they dust themselves among it, and it is an excellent deodoriser in a fowl house. Exclude all cold draughts, and do not forget to close openings along the eaves, through which cold air is often suffered to come in strong currents on the fowls when they are roosting. This is a suitable time of the year to look closely into the matter of table poultry, in view of any possible improvements this year. The cross of Dorkings and Indian Game, which we have so often recommended to our readers, has had special attention drawn to it lately at the exhibitions of dead poultry. Plump breasts, small legs, delicate flavour, the very perfection of table birds, are the result of this cross. Every home farmer ought to provide a full supply of such table chickens. Reference to the pages of "Poultry" will enable them to see where to procure both Indian Game cocks and Dorking hens.

Go carefully through store cattle in the yards; see if all are keeping up condition; consider if any change can be made advantageously in the dietary. Withdraw any beasts at all unsatisfactory; place them apart, and see that they have special treatment. If our advice at the beginning of winter as to grouping of store beasts (placing only animals of the same size together) had sufficient attention, each beast ought to have been able to hold its own, and to get ample food and shelter. But where any delicate, weakly, or undersized animal was thoughtlessly placed with larger beasts it will have probably fallen off in condition through being driven from its food by the other beasts. A little observation will convince anyone that such bullying goes on very frequently when cattle are confined to winter quarters.

### METEOROLOGICAL OBSERVATIONS.

### REMARKS.

- 30th.—Sunny early; frequent sprinkles of snow from 10.30 A.M. to noon; bright sunshine all afternoon, and clear cold night.  
 31st.—Generally sunny, but occasional intervals of cloud; clear cold night.  
 1st.—Bright sunshine all day; fine night.  
 2nd.—Heavy snow from 7 A.M. to 8 A.M.; bright sun from 10.30 A.M.; snow lying in shade all day.  
 3rd.—Wet snow from 2 A.M. to 5 A.M.; fine sunny day; cloudy at times in evening, and slight snow showers.  
 4th.—Slight snow or sleet showers early and till 10.30 A.M.; bright sun with occasional intervals of cloud from 11.30 A.M.  
 5th.—Overcast all day; occasional flakes of snow falling.  
 A cold and rather dry week.—G. J. SYMONS.

ESTABLISHED 1832.

# ANT. ROOZEN & SON'S SPRING CATALOGUE

For 1895,

OF

Vegetable and Flower Seeds

AND

**BULBS AND PLANTS,  
IS NOW READY.**

Will be sent post free on application to their Offices at OVERVEEN, near HAARLEM, HOLLAND, or to their General Agents—

**Messrs. MERTENS & CO.,**  
3, CROSS LANE, LONDON, E.C.

**SIX SUPERIOR VEGETABLES  
WORTH GROWING.**

### BLAIR'S PROLIFIC CUCUMBER.

A handsome Show variety, very prolific, colour deep green. Mr. SPEED, Penrhyn Gardens, says, "A grand Cucumber for either winter or summer use. I have grown it this season, and like it very much." Per Packet, 1s. 6d.

### DUCHESS OF YORK MELON.

Fruit medium size, white flesh, colour golden, finely netted. A grand exhibition variety. Per Packet, 1s. 6d.

### PRINCE ALBERT VICTOR MELON.

One of the best grown, bright yellow, partially netted, flesh white and thick. A grand variety. Per Packet, 1s.

### EGERTON PEA.

The best late cropping Pea grown, height 4 feet. Mr. UPJOHN, Worsley Gardens, says, "I find it one of the most prolific and enduring croppers I ever met with. I have been gathering from July to October 20th." Per Quart, 1s. 6d.

### NORTHERN BEAUTY TOMATO.

An abundant and continual bearer, free setter, very early, intense deep crimson colour, and large handsome smooth fruit. Per Packet, 1s.

### PRINCE ALBERT VICTOR TOMATO.

Fruits large, flesh very solid, grand flavour, colour bright crimson. A very heavy cropper. Per Packet, 1s. 6d.

Descriptive Priced CATALOGUE Free on Application.

**DICKSON, BROWN, & TAIT,**  
Royal Seed Establishment,  
**MANCHESTER.**

No. 760.—VOL. XXX., THIRD SERIES.

**T**HIS renowned Handbook consists of 170 pages of finely illustrated matter, including full cultural directions for nearly all classes of Flowers and Vegetables. Free by Parcel Post for 6d.

The "Dundee Weekly News" says of it:—"This well-known work has again made its welcome appearance for the season, and no one who desires to attain to some measure of success in the keeping of a garden, or has the ambition to distinguish himself as a competitor at the flower shows, should neglect procuring a copy. The advice given is sound, practical, and, above all things else, easy to understand and follow, and in these respects it is of much more real use than many expensive guides. Messrs. Dobbie & Co., the celebrated Rothesay Seedsmen, are the publishers.

One of the most successful professional gardeners in England says of it:—"Messrs. Dobbie's Catalogue and Competitors' Guide is vastly ahead of ordinary Catalogues. It is a most trustworthy Guide to the culture of Flowers and Vegetables."

An amateur of long standing writes:—"Your Catalogue is of great service. I would not take 5s. for it if I could not get another."

Messrs. DOBBIE & CO., Seed Growers and Florists to the Queen, Rothesay, beg to inform the readers of "The Journal of Horticulture" that a copy of the Twenty-eighth Annual Edition of "DOBBIE'S CATALOGUE and COMPETITORS' GUIDE" will be forwarded to any address per parcel post on receipt of SIXPENCE in Stamps.

Please apply early.

**DOBBIE & CO.,**  
ROTHESAY.

### ROOTS IN WINTER: DO THEY WORK?

**T**HIS is a question of much interest, and the commonly accepted opinion that Grape Vines make no apparent root growth until the plants are well covered with foliage would appear to be decisive on the point. But provided the soil of Vine borders is kept throughout the winter in a slightly moist condition, at any time very fine young roots may be found for the looking. A little consideration, however, brings us face to face with facts which throw more than a shadow of doubt as to whether the Vine, assuming it makes no root growth in winter, prove the case. It is plain that what is termed "resting" cannot mean a cessation of all the functions of a tree; because during the whole period in which deciduous trees are bare of foliage there is a progressive growth of buds, this being more marked in the case of fruit buds than of wood buds. From the beginning of December till the latter part of January growth is very slight, but still it is discernible. Previous to and after the period mentioned growth is plainly evident. We hear and read of stored up sap, but what it is, or what part it plays, no one can tell. This, however, is certain. A tree may be pruned at any time after the fall of the leaf without evidence of the sap being present, but let the operation be delayed until a few weeks previous to the time when the tree should exhibit outward signs of growth, and sap is so abundant that it flows from every wound. The only medium by which the supply can be obtained is the roots, yet we are to believe there is no growth of roots until weeks afterwards.

The Peach may be enlisted to furnish an illustration. Grown out of doors Peaches do not cast their buds, but when in glass houses they do under certain conditions, the chief of which is soil dryness. If a Peach border is allowed to become dry at any time during the period of rest the result is always the same, for when the buds arrive at a certain stage of growth they drop off the tree. This shows that at least the Peach requires something more than stored-up sap. In addition to this negative teaching, the Peach furnishes a positive illustration. A Peach tree cultivated in a pot, when repotted in the autumn, after the crop has been gathered, continues to make new roots during the winter. This fact is generally known, and would be decisive on the point, even if no other case could be found; but every well-cultivated tree in a garden can show evidence that roots are not inactive during winter. Do not, however, go to old trees whose roots have to be

sought for at unknown depths, but to young trees which are attended to annually, and the soil will be found to contain a network of the finest fibrous rootlets, every one exhibiting unmistakable signs of activity. In the winter, and when the soil has softened after frost, I have found on many kinds of fruit trees roots in a state of activity.

During the last winter I had an opportunity of noting a very striking example of root action. Some young trees were lifted in November, and owing to circumstances could not be replanted at the time. The balls were packed round with littery straw, and were not again touched until after the middle of January. The deciduous trees comprised a Japanese Maple, a Cydonia, and two deciduous Cypresses. The Cydonia proved the more active winter rooter, for the ball bristled with white rootlets, but the others also were furnished with growing roots. I have repeatedly examined young fruit trees received from a nursery and planted in November, and in January the roots were plainly in a growing state. I do not doubt that it is not always possible to find trees in this condition, but I would rather blame the cultivator for this than the trees. The former frequently leaves the roots exposed to the air, instead of either planting at once or protecting them until they can be planted, and he does not always smooth with the knife the broken ends of roots.

Should the objection be made that trees having only a few thick, fibreless roots, if planted in the beginning of winter will survive as well as trees with a solid ball of fibrous roots, the fact cannot be gainsaid. But they survive with a difference. The first mentioned will not respond in the same manner as the latter to the call of spring. Life in the first case has been no more than preserved, and no provision made for the future. In the other, the buds will have been to a certain extent provided for. Not so much, however, as in the case of trees that had been left in the ground untouched, and which are ready for the new season with floral organs fully equipped, with wood buds ready to develop into full leafage, and shoots ready to extend with the lengthening days. These well-marked differences between each of the three classes of trees can be accounted for only by the condition of the roots. The trees with roots intact begin the season with foliage and flower in the best condition. Those transplanted with a mass of fibrous roots exhibit in flower and foliage the effects of the check, while those having no fibrous roots, but merely bare underground stems, require much care so that they may be kept alive during the summer.

In practice every intelligent gardener acts on the principle that roots are active in some degree throughout the winter. Trees are purchased at the fall of the leaf; they are chosen as much with reference to the fibrous nature of the roots as for the appearance of the tree; planted as early as possible in winter; staked to keep the roots from moving, and mulched to protect the roots, and at the same time to enrich the soil. Experience has shown that the above is good practice, and it has been carried out for centuries. No doubt trees are most accommodating, but I would much prefer to leave over the planting which could not be done in November until spring, so as to allow them to have full advantage of what we term the "resting" period. I had a happy illustration of the success of late spring planting so recently as 1892, when I planted 150 Apple trees in the first week of April. I have had young trees succeed as well in the first year as these did, but never better. They came from a well-known fruit nursery 200 miles distant by rail, and arrived as fresh as if they had been lifted in our own garden. I took extra precautions, no doubt, for each tree, root, and stem was immersed in a solution of loam, cow manure, and water. A little good compost was allowed for trees, and they were watered, in all, three times. Many of them set fruit, which, of course, was nearly all removed, and the shoots they made would average quite 3 feet in length. They were examples of doing with hardy trees what is often done with Grape Vines—that is, planted near the stage of growth when the buds are rapidly swelling. I have

no doubt they would have succeeded equally well if the buds had been at the bursting stage; indeed, last spring I obtained from a nursery a score of large Laburnums with the buds bursting, and with care in planting, and in watering afterwards, they grew and flowered well.

It is evident that an affirmative answer to the question heading these notes has a distinctly practical bearing on cultivation. The dryness of inside fruit borders is seen to be inimical, inasmuch as it prevents the progression of certain changes in the buds of the trees, and more particularly as regards fruit buds. In short, the trees are starved. There is, moreover, good reason shown for pruning fruit trees directly the leaf falls. Early pruning of trees grown under glass is particularly advantageous, for it is plain that the removal of unnecessary shoots allows those that are left to receive the greater benefit. In other words, by removing surplus growths at the end of a season the tree is discharged from making provision for buds which in any case must be cut off, and thus the legitimate buds gain advantage.

Again, it must follow that manurial mulchings of whatever nature applied to fruit trees in the autumn shall be productive of benefit at once, and not prospectively as some persons think. It also shows that old trees requiring to be root-pruned are better done in detail in the summer than in the winter, because in the former case a year is gained with at the same time less chance of injury to the trees. When root-pruning is carried out in the winter the growth of the tree during the next summer is affected, and fruit buds are the work of the autumn. If, on the other hand, stout roots are cut back during the early summer the tree will be in much the same condition the following autumn, as the winter-pruned tree would be a year later, and the comparative activity of the new roots produced, as the effect of root-pruning will provide fruit buds for the coming year.—B.

## TAKING STOCK.

IN the busy world of commerce, where success depends so largely on method and accuracy in the conduct of affairs, periodical stock-taking has long been recognised as an absolute necessity to the continuance of prosperity. This is a fact so generally acknowledged that negligence in the matter among firms or individual business men is looked on as a sign of present unstableness, if not a precursor of future collapse. This commendable practice of stock-taking has not yet become universal in private gardens, although in a certain sense it has long been pursued in many, and may with advantage be more generally followed in the future.

With the beginning of the year one of the most important matters to demand attention is the overhauling of the seed-room, to take stock of the reliable (and unreliable) seeds on hand, and then determine how many more will be required, so that the seed order may be made up and dispatched without delay to insure a speedy execution. To a young gardener in his first head place the difficulty of making out the seed order so as to have about the right quantity of the various kinds of seeds is one that must be grappled with, for if attended to in only a haphazard fashion the chances are that far too many seeds of such vegetables as Salsafy, Leeks, Endive, and sweet herbs will be ordered, and insufficient amounts of main crop vegetables, such as Turnips, Onions, Carrots, and Beet. This latter state of affairs causes much annoyance at sowing time, by deferring the completion of the work till a further supply of seeds is obtained. On the other hand, should considerable quantities be left it is not good policy to rely on them entirely the following year (unless they are first tested in moderate heat), because if any particular sowing should fail it usually means a break in the supply of produce.

Sometimes the work of making out the seed order is made easy by reference to the orders executed in previous years; but too often, when entering on new duties, a gardener finds nothing of the kind to guide him. Then, again, some families have a great partiality for certain vegetables, which must in consequence be grown in far larger bulk than is necessary in another garden of the same size where such abnormal demands do not exist. These seemingly unimportant details amply repay the little trouble involved in making inquiries about them. When the requirements of an establishment are once ascertained the matter is usually plain sailing.

With a view to helping those who may at the present time be somewhat puzzled as to the right quantities of seeds to order I will give as nearly as can be ascertained the amounts required for a kitchen garden of an acre. It will then be easy to accurately calculate the quantity to order for gardens of any size:—Peas, early, 1 quart; second early, 1 quart; midseason, 2 quarts; late, 1 quart; Beans—Broad, early, 1 quart; Longpod, 1 quart; Kidney, 1 pint; Scarlet Runners, 1 quart; Cabbage, Brussels Sprouts, Broccoli, Borecoles, 2 ozs. each, in several varieties; Savoy, Leek, Endive, 1 oz. each; Onions, 6 ozs.; Carrots, 3 ozs.; Turnips, 4 ozs.; Celery, two varieties,  $\frac{1}{2}$  oz. of each; Spinach, 1 quart; Beet, 4 ozs.; Parsnip, 2 ozs.; Lettuce, in three varieties, 3 ozs.; Scorzonera,  $\frac{1}{2}$  oz.; Radish, Long and Turnip, half pint each; Mustard and Cress, 1 pint each; Parsley, Curled, 1 oz.; Shallots, 1 lb.; sweet and pot herbs, packet of each. On the principle that everything can be done more economically on a large than on a small scale it will be found, for a garden 10 acres in extent, the quantities of the various seeds required may be set down at an average per acre slightly less than those given.

It is a difficult matter to estimate with accuracy the quantities of flower seeds required for gardens either large or small, as so much depends on the way in which annuals and biennials are used. In some places the summer bedding is now almost entirely done with these, and in others they are confined to patches in a mixed border. If, however, a plan for the bedding arrangements the following season is thought out beforehand no great mistakes ought to be made in securing the requisite number of plants, always making a point to err on the side of plenty, so as to be able to help a neighbour who may happen to be less fortunate.

In each department of the garden stock-taking should in turn take place, so that past failures may be profited by and the causes avoided. The whole stock of bedding plants should be carefully looked over, note taken of any which are in an unsatisfactory state, or of which the number is extremely limited. In such instances things may be greatly improved by placing the plants in extra heat, and by commencing the work of propagation as soon as possible. On the other hand, if the chances of increasing the stock to the necessary extent seem very remote a suitable substitute may be looked for, and propagated accordingly. In the reserve garden, too, many things claim attention. Spaces may be marked off for the propagation of hardy edging plants for flower beds and borders, as I find it is an excellent plan to always have a stock of these in readiness, as they seem to be wanted at all seasons of the year. If the ground is prepared as soon as the weather permits the stock of any particular kind may be lifted, divided, and replanted in March, and is then ready for use next autumn if required.

Quarters of ground from which Spiræas, Dielytras, and Deutzias have been lifted, may be manured and dug so as to be ready to receive similar plants as soon as they have completed their growth and been hardened after forcing. It is much better to plant them out again somewhat early in the spring should the weather prove open, than to keep them in pots till June, often without enough water being given them, which treatment brings them into a stunted condition from which they take several years to recover. Let it, however, be clearly understood that all forced plants ought to be properly hardened before being again planted out, and that favourable weather in April or May be chosen for planting.

Notes may also with advantage be made now of the various spring bedding plants, of which a largely increased stock is required, so that when lifted from the beds by-and-by division and replanting to the required extent may be carried out. Now that the work of clearing leaves from lawns and shrubberies has been completed, any unsightly places or gaps should be noted, and the plants for filling them ordered, so that these odds and ends of planting may be completed as soon as possible.

In the kitchen garden a careful survey will be necessary, as a little close attention now may prevent the occurrence of a break in the supply. To illustrate this point let me give a few practical examples. At early spring time it is usual for Parsley to be scarce. In all instances in which this is likely to be the case, if good roots are lifted at once, planted in boxes, and placed in heat, in a few weeks good pickings may be obtained from them. Again, a scanty supply of Lettuce may be greatly augmented by sowing in heat at once and transplanting the seedlings in a frame placed over a hotbed. If this hotbed is made up now, while the newly sown seeds are germinating and the plants growing into the right size for transplanting, the frame may be planted thinly with Lettuce lifted from a warm border. By thus surrounding them with conditions under which constant growth can be made at a time when those in the open air are dormant the supply is considerably increased, because the frame-grown plants attain a greater size before being cut for use.

In the plant and forcing houses a careful scrutiny will show

which plants and crops require special attention to keep up the necessary stock during the year. Old Crotons and Dracænas may be cut down, the tops inserted as cuttings, and in the case of the latter the stems laid in cocoa-nut fibre refuse to induce them to send out young shoots. Good numbers of *Panicum variegatum* and the different varieties of *Tradescantia* and other trailing plants must be inserted, so that they will be ready for removal from the propagating cases by the time this operation begins in earnest.

The sowing of Cucumber, Melon, and Tomato seeds for the production of early crops also demands attention. If a minute inspection in the way above indicated is made all round notes may be taken of work requiring attention later on, and by thus arranging it in a systematic manner early in the year much may be done towards turning the failures of past years into incentives to success in the present one.—D. W. C.

MILTONIA JOICEYANA.

THIS charming Orchid is a natural hybrid between *M. Clowesi* and *M. candida*. Mr. F. J. Thorne, gardener to Major Joicey, Sunningdale Park, who exhibited it at the Drill Hall some time ago, and received a first-class certificate for it, writes:—"Miltonia Joiceyana (fig. 8) thrives admirably in the same temperature as its supposed parents. The growths have two spikes each, with from twelve to

FIG. 8.—MILTONIA JOICEYANA.

eighteen flowers. In habit it resembles *Miltonia candida grandiflora*, but is much stronger. It was purchased at Messrs. Protheroe and Morris's salerooms amongst some *Odontoglossum ramosissimum*, and as that variety."

MESOSPINIDIUM SANGUINEUM.

THIS charming little plant was a surprise to me recently in a neighbouring collection of Orchids, as I have before seen it flowering only in the summer. The spikes are produced from the bases of the oval, furrowed pseudo-bulbs, and bear from six to nine flowers, each about an inch across. In colour these are a bright pink with a lighter centre. The genus *Mesospinidium* was established by Professor Reichenbach, and by this name the plants are generally known, although correctly they belong to *Cochlioda*, of which the best known is the comparatively recent introduction, *C. Noezliana* (*M. sanguineum*). The plants thrive in a compost consisting of good peat and sphagnum, and may be treated otherwise similar to *Odontoglossums* of the cool section.

CULTURE OF *CÆLOGYNE CRISTATA*.

It is often urged against Orchids that many of them, if not unsightly, are at least not ornamental when out of flower. Although to an enthusiast in their cultivation this fact does not detract from

their value in any way, most people will look more favourably on an Orchid which is always more or less attractive to the eye. This *Ceologyne cristata* certainly is, in fact it possesses nearly all the qualities that go to make a first-rate Orchid, and for this reason will no doubt be always popular.

The culture of this Orchid is very simple, but a few points need consideration to obtain the best results. Many growers use a good proportion of loam in the compost, and the good results attained show that in skilful hands this treatment is right. I should not, however, advise anyone uninitiated in Orchid growing to use this material to any extent. A much better article in my estimation is half-decayed leaf mould, used in equal proportions with peat and chopped sphagnum, with a more abundant admixture of charcoal than most other species require. This mixture will be found quite substantial, while at the same time affording abundant capacity for aëration, and the way the roots enwrap the compost will surprise many who have been in the habit of using heavy close mixtures.

The plants may be grown in pots, shallow pans, or baskets, according to the convenience or fancy of the grower. Shallow pans are, however, most frequently used, and probably most suitable. A good deal of care is required in fixing the plants, it being necessary to dispose the flowering pseudo-bulbs as equally as possible over the surface of the pans to produce well-balanced specimens. The pans must be well drained and loosely filled with compost to a convex mound. The pseudo-bulbs can be kept in position by pegging down the rhizomes with wire pegs or hairpins. Then proceed to cover the roots with the more fibry portions of the compost, diobling it in firmly and neatly around the pseudo-bulbs. Carefully avoid snapping off the young growing points, which are very brittle. After potting, the plants must have no water at the roots for a week, but be frequently dewed from the syringe.

*C. cristata* is often attacked by a small brown scale, which is very difficult to eradicate, and also by red spider if the atmosphere is at all dry. These must be kept under, or the foliage will be disfigured and the plants injured in health. With regard to temperature, it is one of the most accommodating of Orchids, thriving in a warm, intermediate, or even a comparatively cool house. The best position, however, is a cool shady corner in the *Cattleya* house, with plenty of water while growing and frequent sprinkling overhead. While at rest less water is required, but the pseudo-bulbs must not be allowed to shrivel, or weak growths and few flower spikes will be the result.—H. R. R.

#### THE LATE MR. CHARLES COLLINS.

AS evidence of the esteem in which our late much-respected coadjutor was held by members of the gardening press generally, apart from the "Journal of Horticulture," a meeting has been held of his friends, who are connected with the whole of our contemporaries, with the object of raising a Fund for the assistance of his afflicted widow and the two small children she is unable to support. Mr. G. Gordon presided. It was resolved that

"In consideration of the services rendered to horticulture in his journalistic work by the late Charles Collins, of the high respect in which he was universally held, and of the fact that owing to the long-continued ill health of himself and his wife he was unable to make adequate provision for his family, who are in deep distress, a fund be opened for their benefit."

For the purpose of carrying out this excellent project a Committee was appointed, consisting of the whole of the permanent staffs of horticultural journals, with Dr. Maxwell T. Masters ("Gardeners' Chronicle"), Chairman; Mr. B. Wynne ("Gardening World"), Vice-Chairman; Mr. G. Gordon ("Gardeners' Magazine"), Treasurer; and Mr. T. W. Sanders ("Amateur Gardening"), Hon. Secretary. Any readers of the "Journal of Horticulture" who may wish to contribute to this very deserving case may send their contributions, no matter how small, either to any member of the gardening press who may be personally known to them, or to either of the well known gentlemen named above, and all such amounts will be immediately acknowledged.

We are particularly gratified by this unity of effort in a most worthy cause, as it is alike a graceful tribute to the memory of Mr. Collins as well as evidence of sympathy with his widow, and of the harmonious manner in which pressmen work together in the discharge of their duties. We commend this project to the attention of all who may not have done something in a direct manner to meet the exigencies of this inexpressibly sad case, and shall rejoice in its success.

**THE WEATHER IN LONDON.**—The weather in the metropolitan area during the past week has been very varied. On Thursday and Friday of last week sharp frosts were experienced, while on Saturday there was a slight fall of snow. Sunday morning brought a rapid thaw, which, with the exception of a short time in the evening of that day, has been maintained. Monday and Tuesday were dull and damp, and at the time of going to press a light rain was falling, and the weather was very mild.

— **THE WEATHER IN THE NORTH.**—Very severe weather has been experienced in Scotland during the past week. The most serious snowstorm of the last fifteen years has occurred in the North. In the South about 8 inches of snow fell, and the thermometer in one district registered 4° below zero. In the centre of the country the snowfall was slight, and the frost averaged about 21° for three days. On the afternoon of Saturday a change set in. Sunday was bitterly cold with sleety showers. On Monday afternoon and evening rain fell pretty heavily, and Tuesday morning was fair, with the thermometer at 35°.—B. D., *S. Perthshire*.

— **ROYAL HORTICULTURAL SOCIETY—COMMITTEE ON JUDGING.**—We are informed that the Council of the R.H.S. has requested the following gentlemen to act on the proposed Committee on judging at shows (see page 7 of the report, 1894-5), viz., Messrs. Barron, Bennet, Blair, Bunyard, A. Dean, Dunn, Douglas, Findlay, Gordon, Laing, Marshall, McIndoe, Moore, G. Paul, Outram, Shea, Smith of Mentmore, Thomas, D. Thomson, Wilks, and Wright. The first meeting of the Committee will be held at the Society's office, 117, Victoria Street, on Monday 21st, at 2 P.M. The distant members will, we presume, mainly help by correspondence, as they may do most usefully, and it may be expected that other authorities who are specialists may be appealed to as occasion may arise for their co-operation. The work will, of necessity, occupy a considerable amount of time, and must be done well.

— **UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.**—The quarterly meeting of this Society was held on Monday evening last at the Caledonian Hotel, Adelphi, Strand. Mr. Joseph Wheeler presided. Twelve new members were elected, and four others nominated. Two deaths took place during the last month, one being Mr. Charles Collins, who died suddenly on December 26th at Forest Gate Railway Station, and his widow being left in distressed circumstances the Committee granted her £10 from the Benevolent Fund, in addition to the amount standing to her late husband's credit. The other member who died was Mr. Arthur Locke, of Welby, who had been on the sick fund seventeen weeks. The amount standing to his credit will be paid the widow according to rule. The proposed increase in sick pay was discussed, and a requisition signed by members present to call a special meeting in March to alter the rule bearing on the point. The Treasurer was instructed to invest £400 in West Bromwich 3 per cent. Stock, and a very cordial vote of thanks to the Chairman ended the meeting.

— **THE WAKEFIELD PAXTON SOCIETY.**—On Saturday, Jan. 5th, there was a fair attendance of members at the Society's room, and Mr. H. S. Goodyear presided. Mr. J. Eastwood, of Stanley, was the essayist, his subject being "Bees and their Life History." A very beautiful series of limelight lantern views was shown by Mr. Harold Parkin in illustration of the lecture. The microscopic slides showing the marvellous adaptations of bees for the performance of their various functions were specially remarkable. Mr. Eastwood, who is an experienced bee-keeper, very lucidly explained the best methods of bee culture, gathering of swarms, driving, and taking honey. He strongly condemned the cruel and unnecessary practice of killing bees in order to take the honey, and showed how easily the honey may be secured and the stocks of bees preserved through the winter. With a little care and attention bee-keeping might be made very profitable, and there were few hobbies which afforded such delightful opportunities for studying the wonders of Nature. Messrs. Burton, Hardwick, Emmett, and the Chairman, took part in a discussion, and afterwards votes of thanks were given to Mr. Eastwood for his lecture, and to Mr. H. Parkin for showing the views.

— **THE WEATHER IN EAST YORKSHIRE.**—Mr. G. Picker informs us that on the 10th inst. the thermometer registered 24° of frost, and on the following morning 25°.

— **THE Société Nationale d'Acclimatation de France** has, we understand, conferred its medal of the first class (Medaille de Première Classe) on Mr. J. Simpson, The Gardens, Wortley Hall, for his book entitled "The Wild Rabbit in a New Aspect," published by Messrs. Blackwood & Sons, Edinburgh, some time back.

— **RAINFALL IN CAMBRIDGESHIRE.**—Mr. Arthur Bull, Bernard House, Cottenham, informs us that the rainfall there for the last six months was as follows:—July, 2.29 inches; August, 2.42; Sept. 1.99; October, 2.18; November, 3.94; and December, 1.48 inches, making a total for the year 1894 of 23.05 inches. This is light in comparison with the quantities recorded in many districts last year.

— **AT a recent meeting of the WILLIAMS' MEMORIAL TRUSTEES,** Dr. Masters in the chair, it was decided to offer large silver medals at the following shows to be held during 1895:—Newcastle-on-Tyne, for the most meritorious specimen flowering plant; Richmond, for the best collection of vegetables: Crystal Palace Autumn Fruit show, for the most meritorious collection of fruit; Trentham, for the most meritorious collection of fruit. A sum of 2 guineas was also voted to the fund being raised for the benefit of the Lindley Library.

— **THE HESSLE GARDENERS' MUTUAL IMPROVEMENT SOCIETY**—At a meeting of the above Society held on January 8th a paper was read on "Insect Pests and their Eradication," by Mr. F. Mason, gardener to A. Smith, Esq., Woodleigh. Mr. Mason described their mode of existence, and the injuries they do to fruit trees and plants. Their attacks on plants, he said, are at times excessive, and can be met with successfully only when means are used that are based on a knowledge of the habits of the injurious species.—F. L. T.

— **THE EAST ANGLIAN HORTICULTURAL CLUB.**—Five years since this Club was instituted for the express purpose of furthering horticultural intercourse amongst its members, and it is now purposed increasing its usefulness by the formation of a lending and reference library. The Club numbers 100 members, and the addition of a library will, it is felt, advance the interests of the Club and add to its membership. Mr. F. Upstone, Exchange Street, Norwich, is working hard to develop this feature by means of gifts, donations, and purchases.

— **ROYAL BOTANIC SOCIETY.**—At a well-attended meeting of the Society, held on Saturday afternoon, a suggestion by Mr. Rubenstein was considered as to the admission of the public to the Gardens on payment. Although out of order as a motion, the suggestion was entertained by the meeting at the instance of the Chairman, Mr. W. Bell Sedgwick, in order that the matter might be discussed, and at the conclusion of the proceedings the suggestion was put to the vote, and lost by a large majority. Three new Fellows were elected, and the nominations of six others read for ballot at the next meeting.

— "OLD SUBSCRIBER" writes:—"Apropos of the paragraph on page 30 on 'A Giant Oak,' where is 'Pillkallen?' And may I also ask, in reference to another paragraph on 'December Weather at Broughty Ferry' (page 32), where is this latter place? because in statistics of the weather it is desirable to know where they emanate from." [Pillkallen is a German town, situated almost on the Baltic borders of Russia. It is only a short distance from Tilsit, on the river Memel, a town renowned for Buonapartic associations. Broughty Ferry is on the Frith of Tay, near Dundee, about fifty miles north of Edinburgh. The Inchcape Rock, on which is built the lighthouse of that name, is adjacent to Broughty Ferry.]

— **PRECOCIOUS VEGETATION.**—The frost came in good time to check exuberant and unseasonable growth on the part of trees and shrubs, but especially Roses. These hardy plants are always amongst the first to break prematurely, hence they perhaps most often come in for a sharp pinch. However, when vegetation is particularly active in one direction it soon becomes so in other things, and much harm may be done through having mild growing weather in midwinter and severe frost in the spring. Now that we have had a spell of frost in midwinter there is reason to hope that undue developments will not again give trouble, although the present wave of cold may be of short duration and soon be followed by one of exceeding mildness. At any rate, without being unduly severe around London, the recent frost was very reasonable, and, therefore, productive of much good. A disaster always follows upon precocious vegetation, whilst winter restfulness is equally productive of safety.—D.

— **MR. C. D. RUDD** has sent the first shipment of fruit (by the latest Cape mail steamer) for the season. It consists solely of Apricots, which were landed in splendid condition.

— **GARDENING APPOINTMENTS.**—Mr. Moxham has succeeded Mr. S. Castle as grower of Grapes and other produce to Messrs. A. & J. Quertier, Ashford Vineries, Fordingbridge, and Mr. Macdonald has succeeded Mr. Moxham as gardener to Admiral Foley at Packham, Fordingbridge. Mr. John Hayes, who has been for some time foreman in Castle Ashby Gardens, has been appointed by the Marquis of Northampton, K.G., to succeed the late Mr. Henry Birch as head gardener.

— **CHISLEHURST GARDENERS' ASSOCIATION.**—On Tuesday evening, January 8th, the members of the Chislehurst Gardeners' Association had a most enjoyable meeting, when Mr. McKercher, Holloway, delivered a very instructive and interesting lecture on "Insectivorous Plants," illustrated with diagrams and specimens of *Sarracenia*, *Nepenthes* and *Drosera*. A hearty vote of thanks was accorded Mr. McKercher, and a hope expressed that they might hear him again at some future time.—R. F.

— **THE DEVON AND EXETER GARDENERS' ASSOCIATION.**—The programme of this Society for the spring of 1895 is now complete. Papers are to be read on "Stove and Greenhouse Flowering Plants," by Mr. G. Lock, Crediton; "Melons and Cucumbers and Their Culture," by Mr. Edwards, Whipton; "Cultivation of Early Vegetables," by Mr. E. Sparks, Pynes Gardens; and "Foliage Plants and Their Culture," by Mr. G. Camp, Culver Gardens. One evening is devoted to short essays by the younger members of the Association, and on March 20th the Society holds its Hyacinth and spring flower show. The last meeting of the session is reserved for a review of the papers read.

— **THE BIRKENHEAD AND DISTRICT GARDENERS' ASSOCIATION.**—The second annual soirée was held on Tuesday, 8th inst., in aid of the funds of the newly formed Gardeners' Mutual Improvement Association. There were over 300 gardeners and friends present, and a most enjoyable evening was spent. The first item of the evening's entertainment was a good dinner, at which His Worship the Mayor (Alderman Thomas Shaw) presided, supported by Mr. James Smith (of the Palm Grove Nurseries) as M.C. The evening's entertainment was a great success, and will result in over £10 being handed over to the funds of the new Association.

— **TORQUAY DISTRICT GARDENERS' ASSOCIATION.**—The above Society held its third annual dinner on Wednesday, January 9th, at the Exeter Hotel, Torquay. Over ninety were present, and the President (Dr. R. Hamilton Ramsay) occupied the chair. The Hon. Secretary (Mr. F. C. Smale) stated, in reply to the toast of the Society, that it had never been in a more flourishing condition than at present, 140 members had joined since the commencement, and the meetings this session were much more numerous than formerly. There would be a substantial balance in hand at the end of the session. The evening was a great success, the attendance being much larger than on the two previous similar occasions.—F. C. S.

— **DUNDEE HORTICULTURAL ASSOCIATION.**—The first meeting for the session was held on Tuesday, January 8th, in the Technical Institute. An address was given by the President, Mr. James Simpson, Dalhousie Nurseries, Broughty Ferry, on the "Propagation of Plants." In dealing with this subject, Mr. Simpson considered that this department of horticulture was by far the most important and responsible of the gardener's work. Patience and method were specially required, as well as careful observation in the smallest details, and thoughtful execution of even the simplest operations were most essential to success. Everything should be clean and sweet. Plunging material in the propagating cases should be often changed frequently and kept fresh. The germination of seeds was dealt with, and propagation by cuttings was fully discussed, many important hints to growers being given. The subject of grafting was carefully described, with the best methods to adopt for a successful issue. At the close Mr. Simpson was cordially thanked for his address. The meeting was well attended, and a considerable number of new members were proposed for election. Through the kindness of J. Martin White, Esq., of Balruddery, Patron of the Association, the use of a room has been granted, free of charge, in the Technical Institute for the purpose of holding the meetings of the Association. Mr. White gave a number of handsome volumes on horticulture and other allied subjects as a donation to the Association's library, which is also to be placed in the reading room of the Technical Institute, where any member may spend a quiet hour's reading if he feels inclined.—J. M. C.

— THE ANNUAL DINNER OF MESSRS. WILLS & SEGAR'S EMPLOYEES was held at the Chelsea Town Hall, on January 5th, when upwards of seventy were present. Mr. Wills, in replying to the toast of the firm, said he saw a number of faces who had been working for them since the firm was in its infancy, and who had helped to secure what success had been made.

— BIRMINGHAM GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—On the 7th inst. the annual meeting of this Association was held under the presidency of Mr. W. B. Latham. Mr. A. W. Wills was unanimously re-elected President, and Professor Hillhouse was appointed Vice-President. The whole of the retiring Committee were re-elected with the exception of Mr. W. Earp (late head gardener to Mr. Joseph Chamberlain), the vacancy being filled by Mr. J. Haynes. Mr. W. Gardiner was elected Assistant Librarian, and Mr. W. Eades, the Assistant Secretary, was appointed a member of the Committee.

— SHERBORNE GARDENERS' MUTUAL IMPROVEMENT SOCIETY.—The usual monthly meeting of this Society was held on the 9th inst., when there was a good attendance, presided over by Mr. J. H. Dalwood. Mr. J. Pooley read an interesting and instructive paper on "Soils," explaining the different kinds of soil which existed in various parts of the kingdom. Mr. Adam Stewart characterised the paper as a really good one, it dealing with the fundamental principles of the subject, and he hoped the papers which were given in connection with that Society would act as a stimulant in the subjects in which they were so deeply interested.

— SOCIÉTÉ FRANÇAISE D'HORTICULTURE DE LONDRES.—On Saturday last the sixth annual dinner of this Society was held at 4, Old Compton Street, Soho. Mr. J. H. Laing presided, being supported by Mr. Geo. Schneider, Mr. Geo. Nicholson of Kew, Mr. T. W. Sanders, Mr. C. Harman Payne, and a much larger attendance of members than usual. After the Chairman's address, in which he congratulated the Society on its continued prosperity, Mr. Schneider replied, pointing out the valuable services rendered to the Society by the genial Chairman, who had introduced a large number of members and made contributions to the Society's library for which they all felt grateful. Mr. Schneider also expressed pleasure at the appreciation of the Society's work, which the visitors testified by their presence on that occasion, and their health was proposed and very cordially received. Mr. G. Nicholson and Mr. Harman Payne replied in French, expressing their great interest in all that concerned the Society and French horticulture generally, and Mr. T. W. Sanders also bore testimony to the good work the Society had done. It may be useful to mention that the Société Française d'Horticulture de Londres was established to assist young French gardeners in obtaining situations in England, and to do the same for young English gardeners in France, so that they may each gain a wider knowledge of their profession and improve themselves in the two languages. The Society has an excellent library of horticultural works, and its members occupy important positions in all parts of the world.

— LIVERPOOL HORTICULTURAL ASSOCIATION.—On Saturday evening last the seventh annual dinner of members of the above Association was held at the Adelphi Hotel, under the presidency of the Hon. Treasurer, W. Fletcher Rogers, Esq., who was supported by Mr. T. White, Chairman of the Association, and Mr. R. W. Ker. There was a large attendance, including about 120 of the leading gardeners of the district. After the usual loyal toasts Mr. R. W. Ker proposed that of the Liverpool Horticultural Association. In an excellent speech he spoke of the necessity of more vigour being infused into the working, urging the members to seek for more support from the Council, and instead of holding the summer show in Sefton Park to try and secure the enclosed portion near the Botanical Gardens, also to get up a guarantee fund, to which he promised his support, to enable them to bring down one of the Guards' bands, which would give a stimulus to the Association such as it had never before seen. Mr. Ker's remarks met with the greatest approval. Mr. Fletcher Rogers, in dealing with the finances, said he was sure all would be pleased to hear that the funds were in a better position than last season, this he attributed to the fact that there was no spring show. He hoped that all three shows would be held this year, and that they would be prosperous. He also mentioned the beautiful show of Chrysanthemums which were open to the public in Sefton Park, also of Mr. Yates Thompson's munificent gift of a new conservatory, for which he felt all interested in gardening ought to be thankful. After Mr. Ker's speech there was a decided tone of enthusiasm displayed amongst all present for the welfare of the Association.—R. P. R.

— AXMINSTER AND DISTRICT GARDENERS' MUTUAL ASSOCIATION.—The first annual dinner under the new rules took place on Thursday, 10th inst., the Rev. Mr. Newman occupying the chair, with the Secretary (Mr. Chapple) in the vice-chair. After the loyal toasts were honoured, Mr. Hales gave the toast of the evening, "Success to the Society," and referred to the benefits derived from it. He was pleased to hear that the number of members were steadily growing, and hoped that the season coming would be a successful one.

— HALF-HOLIDAYS FOR GARDENERS.—These are certainly becoming more and more popular, and in many large private horticultural establishments all the employes, save those on duty for the time being, are allowed a half-holiday on Saturdays. In public establishments the parks, under the London County Council, have taken a lead in this matter, and now we are informed that the Kew authorities have made a similar departure. There are at present on the Kew staff some forty-four young gardeners employed in various departments—not all in the houses as formerly—and of these eleven will enjoy a Saturday afternoon's relaxation each week, so that each has one afternoon off every four weeks. The half-holidays commenced on Saturday, January 5th, 1895, and are sure to be much appreciated.

— FRUITING OF AN ALLAMANDA.—I see on page 30 a letter from Mr. Ireland, who sends you a fruit of Allamanda, and asks if it is usual for this plant to fruit. If the fruit had been left on the branch till the spring, when the pod was commencing to crack, then the seed sown, I have no doubt there would have been a number of seedlings in the summer. Ten years since I had a plant of *A. Wardleyana* fruited, from which I raised the free flowering and scented *Williamsi*. I had thirty seeds, and every one germinated. I potted one for myself and another plant was sent to a friend in Westmorland, from whom Mr. Williams procured it. The remaining plants I threw away for want of room. The plant I have fruited four years in succession. Every year I raised one seedling per pod, but no variety is so free as *Williamsi*. The leaves of the seedlings vary, some being very narrow, others broad.—W. WHITEHEAD.

— ANCIENT SOCIETY OF YORK FLORISTS.—The annual general meeting of the Ancient Society of York Florists was held in the Agricultural Club Chambers, York, on the 8th inst. Mr. A. Simpson presided, and there was a large attendance of members. The minutes of the last annual general meeting were read and confirmed. The Secretary, Mr. J. Lazenby, read the Committee's annual report for the year 1894, of which the following is an extract:—"The year has been exceptionally propitious as regards the operations of the Society. Through the kind efforts of the Society's Chaplain, the Rev. H. Vyvyan, Their Royal Highnesses the Duke and Duchess of York have graciously done us the honour of becoming patrons, as also has the Archbishop of York. There is a considerable increase of subscribing members, the number being 642, and about fifty new names for the coming year, as against 600 last year. The receipts for the year amounted to £555 7s. 11d., and the expenditure having been £519 5s. 6d., there was a surplus on the year's working of £36 2s. 5d., which, added to last year's balance, made a total balance of £199 2s., and a total income of £718 7s. 6d. The usual six shows have been held during the year with very encouraging results. The Chrysanthemum show exceeded all previous records in number of exhibitors and in excellence of exhibits." The report and balance sheet were adopted. Alderman Sir Joseph Terry was re-elected President of the Society. The Rev. H. Vyvyan was unanimously re-elected Chaplain. Lord Mayor of York (Alderman W. McKay), the City Sheriff (Dr. Tempest Anderson, J.P.), and Mr. Robinson were elected Vice-Presidents for the year. Mr. J. Pillmoor was nominated for the office of Junior Steward, and elected. Mr. G. Lamb, Treasurer, and Mr. J. Lazenby, Secretary, were unanimously re-elected to their office. A vote of thanks was proposed to donors of special prizes who had thus afforded liberal aid, which was unanimously carried, it being mentioned that most had renewed their offers, and so evincing their confidence in the management; £70 was voted for prizes be granted to the five minor shows. It was decided that the prize money for the Chrysanthemum show to be held 20th, 21st, and 22nd of November be £150 exclusive of specials. The following gentlemen were elected to form the Committee for the present year:—Messrs. A. Simpson, R. McIntosh, T. E. Abbey, E. Staines, W. Clues, W. L. Appleton, W. Bean, G. Hudson, J. Key, E. Everard, W. Clarke, W. Todd, G. Cowper, J. Rodwell, J. Dawe, J. C. Milburn, W. C. Milburn, and T. Smith. The meeting concluded after a vote of thanks had been accorded to the Chairman.

— **BROWNEA CRAWFORDI.**—This plant is again flowering in the Palm House at Kew, and a few days ago it carried seven huge clusters of deep salmon or rosy-red flowers and numerous unexpanded heads. The terminal clusters are from 6 to 10 inches across, and contain sixty or more flowers each 2 inches long, and the beauty of these is enhanced by the long and conspicuous red stamens, of which each bloom has eleven.

— **THE WEATHER IN CO. DUBLIN.**—Mr. Moore, writing from the Royal Botanic Gardens, Glasnevin, to the "Irish Times," on the 10th inst., says:—"The night of Tuesday last, the 8th inst., was the coldest night registered since 15th December, 1882. On Tuesday last the thermometer, in a regulation screen, fell to 11·6, indicating 20·4° of frost. On the night of December 15th, 1882, the number of degrees of frost registered was 22·4, the thermometer falling to 9·6." Last week also given us the heaviest snowfall since January, 1865. Considerable damage appears to have been done amongst evergreens and Coniferae, to what extent is not yet easy to see. In an open part of the lawn the depth of snow was 17½ inches.—E. K.

— **LAWNS FOR AMERICA.**—With the increasing development of civilisation in the States, there is a pressing demand for lawns such as adorn our country residences and suburban villas; and as the American gardeners find it extremely difficult to raise lawns from seed in many parts, one of their government experimental stations has actually voted a sum approaching £200 to meet the expenses of an expert, who is now on a foraging expedition to this country, and actually taking turves from our old parks and commons—choosing the choicest piece of fine grass he can lay hands on. If reports are correct, he has shipped many heavy loads for the purpose of ultimately putting a verdant surface on the burnt-up face of his sun-cured country. As he has been here before on the same errand, no doubt the initial experiment was successful, or his enthusiasm would not be so great. What next?

— **THE RUSSIAN WINE HARVEST.**—During the last season the Russian wine harvest gave a total yield of 100,000,000 gallons of wine of various qualities, all of which was produced in European Russia, with the exception of 75,000 gallons from Turkestan. The chief wine-growing regions are the Caucasus and Bessarabia. The Caucasian vineyards cover a total area of 230,000 acres, and those of Bessarabia 154,000 acres. The other principal wine-growing districts are the Crimea and the governments of Kherson, Podolia, Yekaterinoslav, the Don country, and Astrachan; but for home consumption and local sale wine is raised in nearly the whole of the southern and south-western governments. In European Russia there are altogether about half a million acres under wine culture. During recent years France has become the largest foreign importer of Russian wines, which she uses chiefly for blending purposes.

— **EXCITING CHASE AFTER A CONVICT.**—The village of Sproughton, near Ipswich, has been the scene of an exciting occurrence. Shortly after one o'clock in the morning of the 9th inst. Mr. C. W. Bragg, the coachman to the Rev. A. Foster-Melliar, having put up his horse on returning home from a party, found a man standing in the henhouse in his cottage garden. He asked the intruder what business he had there, of course, and was promptly knocked down by way of reply, the man then running away. Bragg called for help, and pluckily started in pursuit. His cry of alarm was fortunately heard by a young fellow lodging at his cottage, named Bailey, who is groom to Colonel Woodward, and was at one time in the Gordon Highlanders. In naked feet, with nothing on but shirt and trousers, Bailey soon joined Bragg, and they pursued the man at break-neck speed across a 20-acre field, newly ploughed and hard from the frost. The runaway jumped the hedge on the far side, but fell into the ditch; his pursuers were on him in a twinkling, and a desperate fight followed. Bragg was twice kicked on the head, being thereby rendered nearly insensible, and Bailey was bitten in several places. The last-named was too good a soldier, however, to let his man go, and eventually the postmaster (Mr. Charles Mee) coming to their assistance with a rope, the prisoner's arms and legs were bound, and he was conveyed to the gaol at Ipswich. He was at once identified as a ticket-of-leave man named Soar, who was sent to penal servitude for burglary three or four years ago. On that occasion he gave the police a rare chase, getting away and swimming twice across the river Gipping before he was captured. Bragg is a brave man, and Mr. Foster-Melliar's good helper at Rose shows, and not less brave was the tenacious Bailey. "The wars of the Roses" are as nothing in comparison with this struggle with and victory over a savage burglar.

#### THE NATIONAL ROSE SOCIETY AND PORTSMOUTH.

WITHOUT intending to enter into the present controversy, I would point out that your correspondent, "J. B.," is in error in saying that "neither Mr. D'Ombraim nor anyone else at the annual meeting said a word on this subject"—i.e., the railway communication with Portsmouth. The question of the selection of the town for the southern show in 1896 was brought up almost at the close of a meeting, which had been long, and not without exciting episodes, and in certain parts of the room a little conversation was going on which may have prevented your correspondent from clearly hearing everything that was said. Certainly remarks concerning the bad cross-country railway communication with Portsmouth reached my ears, but by whom these remarks were made I am not prepared to say. I wish to limit my intervention to the record of this single fact, and to say the subject might well receive the editorial *quictus* now.—ONE WHO WAS PRESENT AT THE MEETING.

WITHOUT taking much notice of your anonymous correspondent, "J. B.," I may say that I can place implicit confidence on those who furnished me with the account of the annual meeting, as they are gentlemen, and men of undoubted probity, position, and intelligence. "J. B.'s" letter is full of statements without any basis, except his own imagination. You, sir, very properly say, "if no official application has been received" (from Portsmouth), that will end the matter." But suppose it is just the other way, what then? You also state that strong language does not strengthen the case, but this is a case where great indignation is felt, and I, for one, must decline to withdraw a word I have written on this subject.—CHARLES J. GRAHAME.

[We have not suggested that Mr. Grahame should withdraw anything, nor certainly do we withdraw one word of our appendage to "J. B.'s" letter on page 36. Taunting remarks, by whomsoever made, are incompatible with harmony of personal feeling, which should prevail even in keen discussions on matters of public interest. Long experience in public controversies has also thoroughly convinced us that language which is "needlessly" strong is *not* the most effective. Either Portsmouth did, or did not, make an application of the nature suggested. "J. B." says distinctly that "nothing official has ever come before the Committee" from Portsmouth; and thereupon asks "Could they (the N.R.S. Committee) possibly have accepted an invitation which has never been given?" Those are definite statements, and are the more remarkable, as following an equally definite statement furnished to us by Mr. Jeans, page 585, December 27th, namely, that one of the Secretaries of the N.R.S. informed him that "the question of place for 1896 was submitted to the annual general meeting, and Reading chosen by an unanimous vote on account of priority of application"—over what application? We are bound also to notice that in the same letter of Mr. Jeans that his friend informed him "the place of the southern show would not be dealt with at the general meeting, but in committee." We should not think of reflecting on the opposite nature of these statements, because we have often known questions brought before a general meeting which were not expected to be discussed there even up to the moment of the meeting being held. But so long as conflicting statements remain unexplained disquietude is bound to prevail. We have no feeling in the matter in dispute whatever, and lean neither to one side nor the other. We have given both sides equal opportunities for expressing their views. It is now clearly in the power of the Secretaries of the N.R.S. to settle the controversy, because they can speak, as no one else can with equal authority, both as to the accuracy, or otherwise, of the statements of "J. B." (who is, of course, convinced of their truth), and their reconciliation with the citations from Mr. Jeans' letter, and these with each other. The case is now in a nutshell, and cannot be very difficult to deal with by the officials. N.B.—Since the foregoing was printed we have received the following explanation from Mr. Mawley. It appears from this letter that both Mr. Jeans and "J. B." were misinformed on questions of procedure; but mistakes are incidents of life. The discussion had better end now, and Portsmouth's turn will no doubt come in time.]

#### N.R.S. SOUTHERN SHOW IN 1896.

THE leading facts as regards the above exhibition are as follows:—During 1893 applications for holding the Society's southern show in their respective districts in 1894 were received from Reading and Windsor, and ultimately that from Windsor was accepted. In November last the question of the southern show in 1896 was brought before the Committee, and the rival claims of Portsmouth and Reading duly considered. At this meeting Mr. Spittal's two letters to one of the Secretaries were read, no direct application from Portsmouth having up to that time been received. The Committee decided in favour of Reading, and Mr. D'Ombraim was requested to proceed to that town in order to make further enquiries. At the annual general meeting the same question was again brought forward, and the decision of the Committee confirmed. At both meetings, as far as I was able to judge,

there appeared to be an almost unanimous feeling in favour of the show being held at Reading in preference to Portsmouth. No application was received from Portsmouth until November 29th. — EDWARD MAWLEY, *Hon. Secretary.*

#### NATIONAL ROSE SOCIETY.

WE are requested to publish the following resolution, passed unanimously by the Committee of the National Rose Society on Tuesday, the 15th inst., "That the Committee of the National Rose Society, having had under consideration the statements lately made in the *Journal of Horticulture*, beg to express their unabated confidence in their two Honorary Secretaries, and endorse the action which they have taken as to the fixtures for 1896."

[This is received while our pages are being made up for press, and it settles the whole controversy.]

#### ROSARIANS' DIFFERENCES.

IF it were not that the discussions which so freely crop up in the pages of the *Journal of Horticulture* in relation to Roses and their exhibitions, evidence so much of the frailty of human nature, many readers might regard them as interesting or amusing. Why association with the Rose should create such singular divergences of opinion even on the most trivial matters as Rose correspondence discloses, is one of those things no "fellah" outside the amateur rosarian circle can understand. I specially note that these sharp and often acrid discussions are shared in by amateur growers and exhibitors alone. Men in the trade wisely and carefully hold aloof. Probably they, consisting so much more largely of practical business men, and perhaps too of philosophers, find nothing to differ about, and prefer to live harmoniously. Somehow it would seem as if the flower was the portion of the trade, and the amateurs enjoyed only the spines. We do not find Chrysanthemum or Dahlia, or Auricula, or Carnation growers girding at each other in the way that rosarians do; and therefore we are driven to the conclusion that it must be the thorn of their favourite flower which excites their temperaments. They appear, too, to make such a great "to do" over small things, that it seems somewhat venturesome to indite a column in the pages of the *Journal* concerning Rose exhibitions or the N.R.S., so I content myself with a "short and sweet" par, or I might be "in for" a "taste of the briar."—AN OUTSIDER.

#### CURRENT QUESTIONS.

I AM pleased to receive "Gleaner's" apology, though I cannot call it a well-grown specimen, shown in "the most perfect phase of possible beauty." He says (page 37), "There seems to be a certain amount of danger in tilting with men who are under the gentle influence of the Rose." Well, if "tilting" means representing a man as saying something worse than foolish, which happens to be the exact opposite of what he did say ("sorry I spoke" of course referred to my resignation as committeeman), it is well to be reminded that Roses have thorns, though they do not scratch unless assaulted.

It is not necessary to occupy the valuable space of the *Journal of Horticulture* by pointing out the difference of "hearsay" evidence from what is heard with a person's own ears; and the extraordinary paragraphs of "Gleaner" on this subject may be left unanswered.

"J. B.'s" suggestion (page 35) as to the addition of gold medals to the champion trophies is, as the Editorial note says, worthy of consideration. It may, however, be urged that past winners *have* something to show—viz., their names in the list of the N.R.S. Report, and graven on the trophies themselves. And also, that if carried out it would be rather hard on those who are now past winners, particularly on anyone who, like a great friend of mine, has held one of the trophies once, but sees very little prospect of repeating his triumph. I think that the whole of the value of the gold medal should be deducted from the money prize; and, if this were agreed on, it might be added that any past winner might buy as many gold medals as he had won trophies. This would be fair to all, and would leave little objection to the suggestion offered.—W. R. RAILLEM.

#### MAY FROSTS.

I WOULD strongly commend to "R. M. D." (page 15) the course of procedure which has already seemed to him the wisest in the case of severe May frost. I think he will find that Mr. Grahame was subsequently inclined to think he had been rather too precipitate. A week of growing weather will often make a considerable difference in the general appearance of the plants; sometimes for the better, but oftener for the worse. Still, it is generally impossible to tell how far the injury has extended till the plants begin to grow again, and a slight stimulant, with plenty of hoeing is desirable, to make the plants start again and show where they are alive, as soon as possible.

The just-formed buds are the most liable to be injured; those that have got hard can stand a little frost, but very few of the buds which are in existence at the time of a frost strong enough to kill any of the leaves are likely to come to any good. The shoots that have not formed buds will be all right if they have not been "stopped"—that is, if they grow again from the extreme tip as they did before—even if several of the leaves have been destroyed. A shoot that has been stopped and breaks from the side buds only is not likely to produce show flowers that season, but it should be cut back to the topmost strong pushing bud, and restricted to that growth only.

I recommend preventive measures by study of the thermometer with

local weather experience; and, when danger signals are clearly displayed, turning out all hands, by lamplight if necessary, to lightly cover with anything or everything that may be handy—muslin, green boughs, or even newspapers. For remedial measures, I quite think, as above, that patience is the only thing for the first week or so. I am not quite certain on this point, and am always ready to learn; but not, in this case only, by experience.—W. R. RAILLEM.

#### DO MONEY PRIZES TEND TO DEMORALISE?

IN your columns recently, and also in the new issue of the "Rosarian's Year Book," Mr. C. J. Grahame raises the question of the advisability of exhibiting Roses for money prizes—that it tends to demoralise the exhibitors. It seems to me that Mr. Grahame is mistaking a symptom for the disease. The question is a much larger one and altogether different. Nor do I think the symptom to be anything like as bad as he believes it.

My experience as a Rose exhibitor was very short and very pleasant. It extended over some four years, including local shows of more or less importance, and one of the N.R.S., and I am still in touch with the shows of the latter. I never met with anything but kind consideration and assistance at the hands of my fellow exhibitors. They would always advise me as to how to improve my box, would lend me their watering cans in case of need, and, if I were short of time, would help me to stage. This, too, frequently by persons whom I had never met before. The love of the Rose was a sufficient introduction and bond and claim on their services.

Nor was it that they felt my blooms were not to be respected, for, out of the nine boxes I have staged five have won first prizes, two second, and one third. I distinctly did not, under these circumstances, find the competitors, to quote Mr. Grahame, "probably as disagreeable as is possible when prospects are not rosy." This is the first time I have advertised myself, and I could not do it now were it not that the record is an important factor in gauging the goodwill of Rose exhibitors.

I have, however, had a long experience—eighteen years—in a much larger field of competition—rifle shooting. There certain competitions have money prizes; others articles. The "frame of mind," the "discord," referred to by Mr. Grahame were certainly present here as they are in Rose showing, but whether a ten-pound note, or a clock, or a cup was the prize, made not the slightest difference. Nor did the money prize prevent a like show of courtesy to that above referred to. To take only one instance, the last time I shot at Wimbledon I was squadded at 600 yards in the competition for the Queen's prize with a man whom I have never met before or since. Observing that I had no telescope to note the exact position of my shots on the target he offered me his, and we used it alternately throughout. At the end of that competition I had won £5.

No! Exhibitors and competitors have been sore at times and always will be, let the guerdon be what it may. Let pride of position alone be the prize, and the case will not be altered. But the soreness is little more than skin deep, and with nearly everybody soon passes away, and looking deeper we find sincere and hearty greetings whenever and wherever the competitors may meet, and the formation of lasting friendships. Human nature is not so bad as it is painted, and human nature is what Mr. Grahame is tilting at.—ARCANUM.

#### MUSINGS.

"The time has come to speak of many things."—"Alice in Wonderland."]

SO says the walrus in that charming book both for youngsters and children of a larger growth, and indeed the contents of Nos. 1 and 2 of our *Journal* for 1895 will probably induce many of us, at least those those who may be afflicted with the *cacoëthes scribendi*, to write when they cannot speak. I am not on all points agreed with Mr. C. J. Grahame, although we were fellow tilters at the Rose analysis. I like the *noms de plume*. I like the effort to find out the who's who, and to tack together the writer and his *nom de plume*. I must confess I have failed egregiously in "W. R. Raillem." Why, I know not, certainly not from any bulls in his writings. I had pictured our friend as a resident in the Green Isle. I am glad to find out my mistake, and to learn that "W. R. Raillem" is much nearer home, and so the hope rises that one of these days we may meet and know each other in the flesh. Rosey friends may have their storms and perhaps their thorns, but after all some of my dearest friendships have been made through the queen of flowers, and so I put up willingly with a thorny puncture now and again.

Surely one such letter as those of Mr. A. F. Grace is sufficient to show the necessity of settling what is meant by an amateur. Like "W. R. Raillem," I utterly fail to see that the division into classes by fixing a certain number of plants has anything to do with the rule that an amateur must not sell Roses or buds. I have already hinted at the possibility of this numerical test being evaded, and it seems to me patent that the persons who would evade the selling test, as Mr. A. F. Grace seems to imply many do, are the very persons who would be likely to do the other. What, I would ask, should be the true feelings of a gentleman? Surely not to join a society the rules of which he knows, and then deliberately to set those rules at defiance. I confess that the numerical matter is one that is not quite so easy to settle. I apprehend most of us amateurs, if asked straight off how many plants we possessed, would under-estimate the number—not wilfully perhaps; but, then, in the moment of victory the temptation is greater, and the conqueror is apt enough to lessen the numbers of his conquering troop, and augment those he has vanquished. I was once judging at a Rose exhibition, and chafed the gardener of a friend on exhibiting with

thousands against some competitors with their hundreds. "Oh!" said he, "you are stretching it rather talking of our thousands; we might have 1500 plants." Knowing this to be an absurd estimate, I laughed heartily. Some hours after I was standing near his stand (six) of one variety; they were Merveille de Lyon. I acknowledge I am not a great admirer of this Rose (it is too fond of looking at the judges), and the white is very often too rakish looking—too used up—to suit my taste; but these were grand blooms—perfect, and of course easily first. I was admiring them with some of the other prizewinners in the class, and we agreed that we had never seen a better stand of the Rose. Just at the moment the man came up, and I praised them warmly, saying I had never seen a better lot. To the amusement of my friends, who had also overheard the previous chaff as to the big battalions, he replied, "Well, we ought to be able to show that pretty well, we have 500 plants of it." "Why," I replied, "that is pretty cool; you said just now that you had only about 1500 plants altogether." "Ah! well," he remarked, "we must have more, for we have 500 of that, and the same quantity of A. K. Williams, and several others! 1500 is soon made up." Mr. Grace would doubtless disapprove of one in the trade showing against himself as an amateur; yet why should one regulation stand and the other be set aside—by exhibitors, not by the Committee?

Trophy classes. Well, being only a "little 'un," they are classes I leave to my betters; but I do think the suggestion of "J. B." as to the gold medal in addition to the trophy is sound, and should be carried out in one or other of the methods suggested by him. It is on the principle that holds in many societies, that the president on the conclusion of his year of office should be added to the list of vice-presidents. The great honour has passed away from him, but the halo of the honour hangs about him still for the rest of his life, just as the gold medal would always be a reminder to everyone that the possessor of such medal had been a trophy champion. Certainly I would not omit the trade from similar mementoes.

Our queen of flowers is a thorny beauty, but are her devotees more cantankerous than others? I hope not, and I trust "Gleaner" will alter his judgment, especially as it is a "regret" to him, and learn that the danger of titling with men under a rosey influence is not so very alarming—the thorns do not go deep. Pray induce him to "glean" again. I can assure him there is plenty of hearty good feeling in spite of thorns in the way.—Y. B. A. Z.

#### REVIEW.

*The Book of the Rose.* By the Rev. A. FOSTER-MELLIAR, M.A. London: Macmillan & Co.

THREE hundred and thirty pages of matter in fourteen chapters, thirty illustrations save one, excellent paper, and clean easily read print—such in brief is the character of the "Book of the Rose." There are many works on Roses mostly good, and all different. For exhaustiveness Mr. William Paul's bears the Palm, for humorous chattiness Dean Hole's stands alone, while some are severely practical, more or less dry and didactic. Yet there was room for another just such as this, and we shall be very much surprised if the sale does not prove its wide acceptability. It is not a cheap compilation to be glanced through once and put aside, but a work of permanent value to be treasured and studied for the information that it contains. It appears to be a history of the actual work of an earnest and successful rosarian, one who is evidently not afraid of soiling his fingers or scratching his hands if he can develop the greatest attainable beauty in the flower he loves.

The "Book of the Rose" is essentially useful, yet entertainingly written. The author seems to half regret that he has not put more "fun in it." It would have been a pity if he had done so, at the expense of those practical details by which he admits being "overmastered." It is the thoroughness that is stamped on every chapter, the evident desire to be useful in explaining the methods which have proved successful, and pointing out errors for avoidance, that invests the work with value. It is at the same time decidedly readable, and it would have been much less so if so-called "fun" had been sprinkled on every page. There is only one Dean Hole. It was at one time the fashion of writers to try and imitate him, but it was useless. The wishy-washy period of Rose literature thus incited has happily passed away, and we are glad that there is nothing in this latest work on the Rose to lead to its resuscitation.

"The Book of the Rose" is mainly a book for exhibitors, or perhaps it would be more correct to say for those who are or may be animated with the desire to do all that can be accomplished by cultural skill in the production of "glorious Roses," worthy of being honoured with cups and medals by experienced and exacting adjudicators. On this point the author says:—

"I write for enthusiasts, for those who make a regular hobby of their Roses, and think of them as fondly and almost as fully in January as in June. There are not a few such, even among amateurs, in all ranks, and some of them, much handicapped perhaps by soil, situation, or circumstances, still retain their ardour, though not meeting with much success. The man of business, who rises at daybreak to attend to his Roses before his day's work in the town; who is quite prepared if necessary to go out with a good lantern on a November night to seize a favourable condition of soil for planting at once some newly arrived standards or dwarfs; and who later in the winter will turn out in the snow after dark to give some little extra protection that may be required for his beds; this is the sort of man for me, and for the Rose as well."

And our author would like the "man" to grow his own Roses—that is, do all that he can for them with his own hands, not paying someone else to do the thinking and working, and then the owner glorying in the blooms as if he (and not the other man) had produced them. When he actually does this, only having assistance for heavy work and in times of pressure, then does he reach the ideal; for, to cite again:—

"He will thus become a real amateur, a true son of Adam, and genuine brother of the back-ache, with many thorns in his fingers and rough and hardened hands; but his Roses will be truly his own, he will have won them, and under the Creator will actually have made them himself. And not only will they seem to him brighter and purer and sweeter than any other Roses, but he will probably find, in comparison and competition, that they are better than those of his brother amateurs who do not personally attend to their plants; and it will be a great thought for him that other far richer men may have grand and glorious gardens, but that he in his humble little plot with his own hands raises some of the finest Roses in England."

After useful references to "situations and soil" for Roses, also instructions on planting, follows an excellent chapter on manures. In recommending that no manure be mixed in the upper layer of soil, but all to be placed from 8 to 24 inches down, and below all the roots when planted, the author does not think many Rose growers will agree with him, so he provides for them, and well too, in subsequent instructions. Some growers of Roses believe in the practice of trenching the ground and placing all the manure at the bottom of the trenches, as they find when the roots get down into it the plants grow strongly and produce fine blooms. Our author does not bury manure deeply for the roots to penetrate, as he is all for keeping them near the surface (page 53), there to remain for the rising moisture (by capillary attraction) bringing to them the virtues of the manure in solution for appropriation, as the bulbs are fed in Holland. Undoubtedly the bulbs benefit by the enriched moisture as it rises through the soil, but the roots do not "remain" near the surface for it, but go right down into the manure, even to the depth of 4 feet, and the roots of Roses have a habit of doing the same. This our author appears to know very well, because he objects to placing manure and soil in layers "after the fashion of a sandwich," because of the bottom layer of manure "getting the roots too deep" (page 53). That some of the virtues of deeply buried manure are brought upwards in the rising moisture is no doubt quite true, but that the roots of plants will wait near the surface for it is rather a new notion. Most of the virtues of deeply buried manure would be washed into the subsoil, if porous, and lost to the plants if the roots did not go down and imbibe it, thus preventing its escape. This is an interesting and also an important subject, and a searcher after truth such as our author is must be one of the first to desire that his views should be fairly examined.

Very trite are his remarks on chemical manures as founded on the analysis of the ashes of the Rose, which is given, showing that potash lime and potash are the dominant constituents; but as the author correctly says:—

"The first thing to remember is that there is one most important item not found in ash analysis, and that is nitrogen, for which in a chemical formula the uninitiated must look for the words 'nitrate' or 'ammonia.' Nitrogen is the stimulant which gives life to the whole, like the spark of fire which gives such mighty power to the loaded cannon, or, to use more humble imagery, the penny in the slot which sets the whole elaborated machinery in motion. Mere nitrates, such as nitrate of soda, show immediate and wonderful results on unexhausted land, when all the plant wants is a start; but it is like drawing a cheque upon a bank, a capital way of supplying the needful as long as the bank is replenished accordingly, but otherwise not a mode of raising money likely to be successful for long; so the nitrate makes the mineral stores, such as potash and phosphates, available if they be there, but cannot replace them."

Not less interesting are his remarks and deductions relative to influences that the minerals mentioned exert on the wood, the roots, and the flowers of the Rose; while sound are the remarks on liquid manures. On this subject one point is brought out that is overlooked by not a few gardeners. We are told "it is wrong" to conclude that "because a plant is the strongest in the bed it therefore wants the least of the liquid manure; on the contrary, it wants, because it can use, the most."

Our author is evidently a thinking man as well as a close observer. This is apparent in the opening paragraphs in the able chapter on pruning. In pruning for exhibition blooms he tells us the whole of his dwarf plants in beds are every year "swept clean away nearly to the level of the ground." Why? Because

"By watching an unpruned Rose tree, either wild or cultivated, it will be found that the first strong shoot flowers well the second season, but gets weaker at the extremity in a year or two, and another strong shoot starts considerably lower down or even from the very base of the plant, and this soon absorbs the majority of the sap, and will eventually starve the original shoot, and be itself thus starved in succession by another. A Rose in a natural state has thus every year some branches which are becoming weakened by the fresh young shoots growing out below them. This is one of the principal reasons why pruning is necessary. A Rose is not a tree to grow onwards and upwards, but a plant, which in the natural course every year or two forms fresh channels for the majority of the sap, and thus causes the branches and twigs above the new shoots to diminish in vitality. It seems better, therefore, to speak of Rose plants than of Rose trees, especially since standards are now less used, and so many new varieties are dwarf in their growth."

The question of stocks is fully, but not too fully, discussed, and illustrations given, which admirably display the character of the roots of the three kinds most generally employed—namely, those raised from Briar cuttings, Manetti cuttings, and seedling Briar stocks, the former

generally finding the most favour with Mr. Foster-Melliar, for the reasons given in the book. He seems to reason on everything, and tries to prove most things in practice, and thus it is that his pages are so useful and so fresh.

Following the chapters referred to are others on "Pests," and how to "catch 'em" by the author's favourite insecticide—finger and thumb; "Roses Under Glass," very well done; "Propagation," fully treated; "Manners and Customs" of varieties, the most complete and accurate descriptions of Roses ever written; "Selections of Varieties" for rosarians, with the inevitable "Calendar of Operations," but commendably concise in under a dozen pages of readable reminders of when the various details explained in the book should be carried out.

The photographic illustrations are very beautiful, from Mrs. Orpen's shower bouquet as the frontispiece to the same lady's buttonhole bouquet at the end; and not less so are the portraits of several exhibition blooms, the varieties of which would be distinguishable without the names.

By favour of the publishers we give one illustration from this "Book of the Rose," not because it is the most beautiful by any means, but for two other reasons—firstly, because the author has not ignored picturesque garden Roses, and, secondly, because we happen to be

notable volume, and probably no one will be found to quarrel with the author for his use of the definite article in its title.

Perhaps the feature which, more than any other, differentiates this book from its compeers is Chapter XII. (which besides being the most important is the longest in the book), in which the author, taking up the N.R.S. Catalogue of exhibition Roses, gives a careful and detailed account of the "manners and customs" of every variety. The habit and peculiarities of growth and leaf and flower are all treated of; the beauties of each flower extolled; and then, in many cases, the author goes on with—"but," and there follows a faithful pointing out of the defects, either of flowering or growth, or both, of these varieties, so that both sides of the picture are presented in each case. After the matter of this chapter first appeared as notes in the *Journal of Horticulture* I wrote to the author that no more valuable contribution to our Rose literature had appeared during the past ten years, and now that it is presented in its permanent form there is no reason to revise this judgment. The Tea and Noisette classes are treated with the same fulness as their H.P. brethren, and it will certainly not be the fault of the author if in future beginners in Rose culture, or any others, are found wearying themselves and cumbering their gardens with varieties which give a satisfactory return, say once in a septenate. The illustra-

FIG. 9.—AN AYRSHIRE WEEPING ROSE.

acquainted with the specimen in question, which was described in our columns a few years ago. If it is not the finest standard Rose in Britain it is, we suspect, the finest budded, and grown to its present dimensions, by a farmer—one of those men who are never satisfied unless he does all things well that he undertakes, and thus he has a seat in one "local parliament" in his district, and his accomplished helpmeet in another. We allude to Mr. and Mrs. Ismay Fisher of Sturton, near Brigg, Lincolnshire. The present dimensions of the Rose are—height, 12 feet; diameter, 15 feet; and the circumference of the Briar stem, 12 inches. As will be perceived the specimen is faultless in shape, and when covered with thousands of delicately tinted flowers it is a picturesque object on the lawn. It is the Ayrshire Rose Ruga.

We have only one more remark in reference to the work of Mr. Foster-Melliar, and it is this:—All persons who love the Queen of the Summer that holds sway throughout his pages, and who desire to see her charms displayed in fullest beauty in gardens or exhibitions, should not be happy till they severally and individually own this extremely attractive and emphatically useful "Book of the Rose."

#### A CRITIQUE.

UNTIL the autumn of last year the rosarian had for his guidance (apart from a number of small popular handbooks) two great works upon his favourite flower—viz., "The Rose Garden," by Mr. W. Paul; and "A Book About Roses," by Dean Hole. But now a third has been added to these in the work under notice, and in future, when the ardent amateur refers to his authorities as Paul, Hole, and Foster-Melliar, he will mention them in this order with reference only to priority of publication; for it would be an invidious selection indeed which should assign their order of merit. The book is undoubtedly a valuable and

tions, showing typical blooms of fourteen different varieties, are also an important adjunct to this chapter and to the book.

Our author will not at once carry all practitioners with him in all that he advances; but then, perhaps, he does not desire to do so. Certainly he has not sacrificed any of his opinions in an attempt to accomplish this. This is especially the case in the chapter on manures, where some decidedly novel ideas are presented. After all these years of heavy annual top-dressings of solid manure, in all the Rose gardens of the country, it is a little startling to be told in effect that the practice is useless, and that all our labour and material have been wasted. And after all we have read and heard and been taught as to the desirability of keeping roots near the surface, and that the best way of doing so was to provide the manurial sustenance there, it comes almost as a shock to be told that the only proper place for the manure is at a depth of 2 feet below the roots of the trees, and that even the old "sandwich" method of manure and soil and manure and soil has nothing to recommend it. But with a grower so successful at the exhibition table as Mr. Foster-Melliar it is useless to dispute the correctness of this, or any other, detail of practice. To every possible objection he has—"np his sleeve"—the unanswerable reply, "Look at my results." And some of us would probably find it almost as difficult to explain away that formidable list of successes, gained (presumably) under the disputed treatment, as to account for our own failures with more orthodox methods. The details as to the time and manner of applying certain separate elements, in accordance with the advancing requirements of the trees, and the prevailing conditions of the atmosphere are most carefully and elaborately given.

These are the most prominent chapters in this valuable work, or at least they are all to which space will allow of detailed reference; but

the chapters upon Stocks (and in this connection the illustration showing the differing styles of roots upon Briar cutting, seedling Briar, and Manetti is a feature as useful as it is novel), Propagation, Exhibiting, and other matters will be found full of useful information, not merely to the beginner but to the more experienced grower, and all bear the impress of the hand of one who, before sitting in the study to write the book, has gone into the field and the garden and done the work. The only hindrance to the widespread popularity of the book is the peculiar price. However, all Rose growers must read the book.—J. B.

master. He came south, and took charge of the gardens at Wrotham Park, Barnet, more than fifty years ago, and displayed consummate ability in the conduct of all the departments. Flowers, fruit, and vegetables were alike grown well, but he achieved the greatest fame in Grape-growing, especially perhaps in the renovation of old Vines, in which work he was a pioneer.

Mr. Thomson eventually took charge of the Duke of Buccleuch's gardens at Dalkeith, and while there he wrote his admirable treatise on Vine culture. This proved the foundation of the success of many a

FIG. 10.—MR. WILLIAM THOMSON.

#### DEATH OF MR. WILLIAM THOMSON.

It is our sorrowful duty to announce the death of one of the greatest practical horticulturists of the century, Mr. William Thomson of Clovenfords, in his eighty-first year. Mr. Thomson was in his usual health, mentally and physically vigorous till the 2nd inst., when he slipped on a piece of ice and fell heavily, receiving a severe shaking. A chill followed, pneumonia supervened, and he expired on Saturday morning last, the 12th inst.

We have no details of Mr. Thomson's early life, but think he received part of his training as a gardener at Bothwell Castle, and lived to become one of the foremost exponents of the art of which he was a

gardener in the production of the princely fruit, and the name of Mr. William Thomson became an honoured one throughout the country. In 1890 we referred to Mr. Thomson and his work as follows in referring to the last edition of his treatise:—

"The veteran cultivator and effective teacher, Mr. William Thomson of Clovenfords, has been growing Grapes such as have seldom, if ever, been surpassed, between fifty and sixty years, and twenty-eight years have elapsed since the first edition appeared of his 'Practical Treatise on the Grape Vine' (Blackwood). Practical it undoubtedly is, as it is a record plainly and clearly told of his actual practice and its excellent results. It is impossible to estimate the amount of good that has been done in the Grape-growing world by the publication of this work.

Gardeners all over the kingdom have been made wiser by its teaching, and Grape-growing was never so well understood before as it became after its appearance."

We at the same time published his portrait, which we now reproduce, and he had changed but slightly in appearance since the photograph was taken. As we are preparing for press we find the following record of Mr. Thomson's life and work in the "Scotsman":—

"Mr. Thomson's ancestors were located for generations in the Border county of Roxburgh, where Mr. Thomson was born in 1814, but his father having been appointed land steward on the estate of Maclaine of Lochbuie early in this century, the family were brought up in the Island of Mull. There Mr. Thomson served his apprenticeship as a gardener under Mr. Wilson, afterwards wood manager on the Penrhyn estates in North Wales. Leaving his island home, Mr. Thomson acquired experience in his profession, like all young gardeners of his time, in serving as journeyman and foreman in various good gardens in Scotland, ultimately being employed in the latter capacity under Mr. Andrew Turnbull at Bothwell, the seat of the Earl of Home in Lanarkshire. This place was then one of the most famed in Scotland as a school for horticulture, and especially for the cultivation of hardwooded greenhouse plants; the collection of Cape Heaths being one of the very finest in this country, and remained so until the death of Mr. Turnbull about a decade ago.

"Young Thomson reaped the full advantage of serving under such a distinguished horticulturist as Mr. Turnbull, and when he had completed his service at Bothwell Castle he was appointed gardener to the Hon. Mr. Byng, at Wrotham Park, in Hertfordshire, about the year 1839. There he remained for sixteen years, and acquired great experience as a horticulturist as well as a contributor to horticultural literature, then in its infancy. During that period he was well known at the great horticultural shows, then in the hey-day of their fame, in and around London, taking an active part as an exhibitor and a judge, and acquiring considerable reputation as an authority on Grapes and their successful cultivation. On the retirement of Mr. Charles McIntosh from the charge of the Duke of Buccleuch's gardens at Dalkeith in 1855 Mr. Thomson was appointed his successor, and in that prominent position in the gardening world he fully maintained his skill and reputation as a leading horticulturist of the times. As editor for some years of the "Scottish Gardener," he did much to stimulate a taste for gardening among the community, and especially among his professional brethren, on his favourite topic, the cultivation of the Grape Vine. While at Dalkeith he also wrote a manual on the Vine and its cultivation, which is still a trustworthy authority on the subject.

"Always a keen and successful competitor at the shows of the Edinburgh Horticultural Society and of the Royal Caledonian Horticultural Society, where he won many prizes for the excellence of his exhibits, he turned his attention to the raising of new varieties of fruits and flowers, and in the latter years of his career at Dalkeith he was successful in raising the two well-known varieties of white Grapes—the Duke of Buccleuch, a large, luscious, golden-berried variety, much relished by those who prefer a mild-flavoured, juicy Grape; and the Duchess of Buccleuch, a handsome hunched variety, with smallish golden berries of the richest flavour. He also raised two other seedling Grapes which appeared in commerce while he was at Dalkeith—viz., Golden Champion and White Lady Downe's, but neither is much grown at the present time.

"Mr. Thomson remained for sixteen years at Dalkeith, leaving there in 1871, when he established the Tweed Vineyard at Clovenfords, near Galashiels, the fame of which has spread far and wide among Grape growers. In latter years he has been assisted by his sons in the business at Clovenfords, where, besides the growing of Grapes on a large scale, a fine business has been created in Orchids and other high-class plants, as well as in an excellent artificial manure, to which much of Mr. Thomson's success as a Grape grower is attributed. Since he established himself at Clovenfords Mr. Thomson created around him quite a little town of industry, where formerly there was a mere hamlet, with the usual country inn, and blacksmith and joiner's shop of the neighbourhood. He has all along taken a keen interest in horticultural affairs, and was a regular attendant at the shows of the Royal Caledonian Horticultural Society, where his well-known robust figure with white hat was always a centre of rally to a crowd of his gardening friends and the general horticultural public. At his leisure time he was a frequent contributor to the "Scotsman" of interesting articles on various topics, from the cultivation of Grapes to the rearing of poultry and other useful arts—so wide was his knowledge and comprehensive his mind. Mr. Thomson was an elder in the *quoad sacra* parish church of Caddonfoot, and was a member of the parish School Board."

Mr. Thomson's remains were interred at Caddonfoot on Wednesday, 16th inst. He leaves two daughters, most estimable ladies, and one son, Mr. John Thomson, who has taken a leading part in the Clovenfords business for some time. The late Mr. William Thomson was a man of bright intelligence, sturdy independence, great knowledge, as well as strong common sense, and his name is deeply graven on the tablets of horticulture.

## FLORAL FACTS AND FANCIES.—7.

SOME unknown individual chose for the motto of the Mistletoe flower, "I surmount all obstacles," by no means inappropriate when the habit of the plant is regarded, since it grows and thrives in the face of difficulties which seem likely to extinguish its early life. At the outset—under natural conditions—its seeds depend upon the agency of birds for their distribution, and during the first three years the growth of the plant is very slow. Then, as the male and female flowers are separate, fertilisation is brought about either by the wind, or more probably by insect visitors. Bees are drawn to them, it is stated, because they have a peculiar honey-like odour; also they are conspicuous. But we may reckon that not one person

in ten thousand of those not living in the districts where the Mistletoe is grown has ever seen the flower.

On the host of traditions connected with the plant itself we must not dwell. It was revered by many Pagan nations, regarded as a protection from wounds and the influences of evil spirits, also a cure for various diseases, though it has been queried lately whether the Mistletoe of our British ancestors was the species familiar to us. Some think it must have been *Loranthus europæus*, which frequently grows on the Oak; *Viscum album* seldom. From a long list of trees upon which it has been found, there is proof that its favourites are the Apple, Hawthorn, Black Poplar, and Willow. Just now, when Christmas decorations are being removed, there is an opportunity to experiment with Mistletoe berries. It is only necessary to place each berry in some crack or depression in the bark, and cover it with a bit of bass to protect it from birds. In the West of England some folks have successfully grown the plant upon Hawthorn hedges, or as an adornment along avenues of Limes and Poplars.

To a very different plant belongs a significance similar to that of the Mistletoe. It is a native of hot climates, well known in Egypt, Greece, and Italy, and which thrives with us; but it is not often seen in gardens. The *Acanthus* was thought to represent genius overcoming difficulties, because, like some other plants, it has a power of adapting itself to circumstances, and when checked from extending in one direction strikes out upon a new course. It was the growth of an *Acanthus* around a flat tile in a manner rather unusual that suggested to Callimachus the idea of the Corinthian column; and from the extensive use made of it by the ancients when drawing designs on furniture, vases, and robes, the *Acanthus* has also become a symbol of art in action. Old Pliny recommended the plant as an ornament for lawns and borders, our poet Milton introduces it amongst those that shaded the bower of Eve.

Probably few people now, in decorating churches and houses at the seasons of Christmas and new year, pay any attention to the significance of the foliage and flowers that are used; but by our ancestors much regard was given to this. Not having at command, however, any plants growing under shelter in winter, their choice was necessarily limited, and even of evergreens they had but few. Prized because it was a holy or sacred tree, the Holly claimed a conspicuous place which is still given to it; besides, from a peculiarity of habit, it stood as an emblem of "foresight." Clinging to a tree even in decay, the Ivy represented "friendship" unshaken by misfortune, and its arms have sustained many an ancient wall during centuries. A line in one of the quaint old carols highly commends the Ivy, "For all bale she is bliss," how we do not exactly know. A wreath of it was also deemed a fitting tribute of honour to bestow upon a poet. In Greece, at one time, the bridegroom held, at the wedding ceremony, a bough of Ivy, representing unshaken attachment. Rosemary, frequently worn at funerals as an emblem of fidelity, and of remembrance, too, according to Shakespeare, was sometimes used in church decoration, fresh or dried, for the sake of its fragrance, if not for its meaning. Some old writers state that this plant was a symbol of "repentance" or sorrow as well.

Relying chiefly for decoration on the plants of woods and lanes, our ancestors gathered the wild Clematis (the "Traveller's Joy"), conspicuous by its feathery sprays, as a winter adornment, and it is even yet employed in decoration, though it is emblematic of "artifice." The reason is, that beggars at one time used to produce sores by means of the acrid juice, which is similar in effect to that of the Buttercups or Crowfoots. But the handsome exotic with purple flowers is taken to represent "beauty," though the evergreen variety is, oddly enough, a symbol of "poverty." With the Clematis, the long runners of the Woody Nightshade or Bitter Sweet, sometimes green in winter, were occasionally mingled—a plant that is regarded as an emblem of truth, because, if chewed, the juice is at first bitter; but a sensation of sweetness follows. More, as Dr. Tyas adds, it has a preference for shady places, and is like truth, because she now and then abides at the bottom of a well! To us, probably, an array of Hazel rods would have no particular significance, but when the catkins began to appear on them they were formerly cut, to be displayed as the tokens of "reconciliation" and "peace" amongst Christians. The idea came from the ancients, for the wonderful caduceus, or magic rod of the deity Mercury, was supposed to be of hazel wood. According to the legend, he and Apollo came to the human race while all were savages, and, after the god of music had softened with divine harmony the hearts of men, Mercury, by the influence of his rod, prompted brotherly kindness, the love of country, and the desire for commerce, as being a bond which would finally unite all nations.

We find that certain groups of plants have uncomplimentary characteristics attached to most of them. Thus, the Hellebores,

one species of which, under its name of Christmas Rose, is a welcome flower at this season, represent "backbiting" or slander; and their relative, the Winter Aconite, with its green frills and yellow centre, tells of "misanthropy." The Columbine, a native plant, of which we have some pretty garden varieties, stands for an emblem of "folly," through a fancied resemblance of the petals to a fool's cap and bells. That was not the only fancy it suggested, for the English name reminds us the flower was also likened to a nest of young doves, and the Latin one indicates that to some it suggested the talons of an eagle. Chaucer, the father of English poetry, speaks admiringly of the Columbine; and Spenser remarks upon its variety of colour: In this family, however, the Monk's Hood, a flower which might be wisely banished from our gardens because of its poisonous qualities, represents "chivalry," the hood having also a resemblance to a knight's helmet. Amongst the flowers that were carefully gathered by our forefathers in summer, to be kept for display in winter, the Amaranth was conspicuous, sacred to love or friendship, and a symbol of immortality.—J. R. S. C.

### PEELING VINES.

MANY of your middle-aged readers will bear witness that I have been a strenuous opposer of stripping Vines of their bark; possibly some of them will even give me credit for making some barbarian pause before he continued the cruel practice. What will my friends say then when I confess that last winter I stripped all my Vines of every particle of outer bark? At any rate there is this advantage, I can say something about both sides of the question. Then what is the excuse for this acknowledged barbarity?

For some years now I have been very much troubled with red spider. It may be from mismanagement, but certainly it is not the result of laziness or lack of attention. I have had to do with this enemy on several occasions before I undertook my present charge, but I could generally manage to dislodge it before the season was out, and start the following spring with a clean bill of health. But now it is different. Not only does the detested little thing take possession of indoor plants, but it also claims in warm seasons many of the common weeds in the hedgerows and neglected spots, especially Nettles and Bindweeds.

I think the lightness of our soil has something to do with it, and when I say that before the physical condition of our Vine borders was changed by adding a large amount of clay, they had often to be watered twice a week during the summer, while those at Longleat would go with advantage without water for three weeks at a time. It will be seen there is a considerable difference. The latter also have 10 inches of drainage entirely across the house, while those I am now dealing with have no more drainage than a ploughed field, in fact only one drain pipe through each border.

But to return to the spider. During 1893, after dressing the stems in the winter with petroleum and other things thought to be obnoxious to animal life (we cannot dress them thoroughly in the autumn while the leaves are green, or the thing would be simple enough, because the fruit is always in the way of that), painting and reglazing the house, besides removing everything likely to harbour insect life, we found in the early summer that the enemy again showed a very bold front. Every leaf in two large compartments was sponged on both sides with soapy water four times during that memorable summer, but although we worked as those only work who intend to win, I must confess that the spider was the victor, and many of the leaves were rendered useless when they were wanted to give the finishing touch to the Grapes.

After pruning and dosing the stems rather heavily we started searching for the enemy's winter quarters. Loose bark was stripped off, but nothing could be seen. Then we proceeded further, and with the handle of a budding knife a commencement was made to take off carefully everything to the inner bark, and then we found the enemy in force mostly in the axils between the spurs and the main rod—not eggs, but bright scarlet fellows snugly laid up for the winter where neither cold nor damp could reach them. We then determined to proceed, and after stripping the poor Vines of their jackets they were operated on with scrubbing brush and soapy water. I am happy to say that some of the Vines have not had a red spider on them since, and we are encouraged to hope that this season, as there is as yet no rough bark on the stems, we can complete the victory.

So much for the spiders, now what about the effects of the operation on the Vines? Well, they started vigorously, and looked very promising, so much so that I began to think that perhaps after all the stripping was not quite such a bad thing as I had imagined. But as growth proceeded and the weather became warmer it was seen that the leaves which were large as usual showed signs of flagging. I forgot to say that the stems were dressed with

a paint made of clay, softsoap, soot, and water. This was to shade them, as well as to make them distasteful to insect life.

The flagging grew worse. Black Hamburgs and Gros Colmans showed it the most. We gave some of the stems a thick dressing of clay and cow manure, but it made no difference, and they did not seem to really recover before stoning time. Of course, this flagging told on the size of the berries, and possibly had the season been hot and dry like 1893 it would have had a still more marked effect. The Grapes mostly coloured and finished very well, but the loss of weight was considerable.

I think under the circumstances it was best to take off the bark, but I trust I shall never have to do such a thing again. Most of the Vines were ten years old, and had stems thicker than a man's wrist. I daresay with weakly grown Vines, such as have shoots and leaves only half or perhaps a third the size of mine, the effect would not be so marked. These have not such a large amount of stored up material to start with in the spring, consequently they make a weaker start, and when the time comes for them to commence drawing supplies from the roots their wants are not so great as Vines possessing a greater amount of vigour.—WILLIAM TAYLOR.

I was glad to see Mr. Charman's note (page 29) with regard to cleaning Vines, and hope that someone will respond who can give us some useful information. I have been much interested in the notes by "R. P. R." on Mr. Craven's work. He does not appear to be troubled with mealy bug, or he would find that peeling was a necessity, however much he might be against it on principle. I should like to see a note from someone who has tried the gas tar mixture for mealy bug, to ascertain whether it has been successful, and if so, how it is made and applied.—D. R.

I DOUBT if peeling the canes during the cleaning process is so detrimental to the well-being of the Vine as Mr. Craven (page 6) would lead one to suppose. The best Grape grower I know personally is in the habit of taking every particle of bark off, as he is much troubled with mealy bug, and I have seen him go so far as to take the scale off the eyes if he thought one of the enemy had escaped. Nor did he think it necessary to employ only his experienced men, as the garden labourers used to take part in the general operation; and I think I can say without fear of contradiction, and I am sure Mr. Iggulden and Mr. Austin will bear me out, or anyone else who has visited the Bath and Bristol shows, when I say that for finish, size of bunch and berry, few better examples are shown anywhere than are those at the foregoing places by Mr. Nash of Badminton.

I had the pleasure of looking round this much-improved garden last September, and was very much struck with his magnificent Alicante and Muscats. When I say he beat that veteran exhibitor, Mr. Chaffin (gardener, Mr. Taylor), readers will be able to form an idea what they were like. I was surprised to see the inside borders covered about 2 inches deep with soft gravel, which Mr. Nash assured me—providing the borders were full of roots—was a capital thing, as it kept the houses cool during the summer months.—WM. POTTS, *The Grove Gardens*.

I REGRET that Mr. Craven (page 6), has taken my remarks in the light of being a "severe criticism" of his article on page 535. Mr. H. Charman in his remarks on page 29 has put the object of my remarks in a nutshell, which I trust will be carried out. Mr. Craven also wants my credentials. Does he not know that there is many a gardener who grows good Grapes which are never seen on exhibition tables by the desire of their owners? Mr. Craven is fortunately privileged to show, and myself and other readers of the Journal rejoice in his success, and I for one would like to give him a fraternal shake of the hand. Well, brother Craven, my right to ask a question through the pages of the Journal (with the Editor's permission, which I have never known him refuse), is that I have been a reader of its pages for upwards of sixteen years, and an occasional contributor as well. As to my ability as a gardener that is quite safe in the custody of my employer. I trust this subject of cleaning Vines will be taken up by other growers, and some up to date opinions expressed. I trust, Mr. Editor, you will not pass a severe judgment on me when I say I pass on the Journal to my young men in the bothies, who are anxiously anticipating a discussion on this subject. In doing so I am following the example of a good gardener, who is still growing good Grapes.—ERICA.

[Every gardener ought to help the young men under him in the best way he can, and they should give the best possible services in return.]

### THE PROPOSED NATIONAL VEGETABLE EXHIBITION. REPORT OF THE PROVISIONAL COMMITTEE.

THIS report was presented to the General Committee at a meeting held at the Royal Aquarium, January 15th, 1895.

In accordance with a notice kindly inserted in the horticultural papers, a meeting of persons interested in the proposal to organise a National Exhibition of Vegetables during the present year was held at the Crystal Palace on September 29th last, and was presided over by Mr. Henry Balderson. A small provisional Committee consisting of Messrs. R. Dean, G. Gordon, G. Wythes, B. Wylne, J. Wright, and

J. Hudson, with Mr. Balderson as Treasurer, and A. Dean as Secretary, was appointed to make certain preliminary inquiries and arrangements, and report later to a meeting of the General Committee.

The first step taken was to issue 100 copies of a circular inviting co-operation: These were sent out to well known seed trade houses, nurserymen, amateurs, gardeners, market gardeners and others. In response came about seventy replies, all favourable, some promising pecuniary support. The Committee felt that this result justified farther procedure, and the next step taken was to seek an interview with the General Manager of the Crystal Palace with respect to the universal desire expressed that the show might be held there. The interview was accorded, but the result was disappointing. The General Manager could not give any encouragement to the proposal, as an African exhibition is expected to occupy the usual available space at the Palace next summer and autumn.

Baffled in that direction the Committee empowered Messrs. R. Dean and B. Wynne to interview the General Manager and Directors of the Royal Westminster Aquarium, and these eventually agreed to furnish all the space possible, including tabling, also publication, for the proposed show, and give a donation of £10 towards expenses; the show to last three days, and to be held during the second week in September next—a very suitable and acceptable time. These proposals the Provisional Committee agreed to accept, subject to the approval of the General Committee, and also to the determination being arrived at to hold the show. The Royal Aquarium does not offer the illimitable space of the Crystal Palace, but it is at least far more accessible, and is exceedingly central. Still farther, of all horticultural exhibitions held in or about London, those held at the Royal Aquarium always receive the fullest mention in the general press, a matter of some importance to those taking part in the exhibition.

On the strength of this arrangement the Committee agreed not only to convene this meeting, for the privilege of holding which the Committee desire to offer the General Manager of the Royal Aquarium grateful thanks; but also to rough draft a suitable schedule of classes and prizes. This was accordingly prepared, revised by the Committee, and placed in Mr. H. M. Pollet's hands to print. That gentleman, through his manager, kindly undertook to furnish a dozen slip copies of the same when set up, for distribution, amongst some of the leading seed firms favourable to the exhibition, with the request that they would kindly consent to give the prizes in one or more classes.

It was hoped that in this very practical way it would eventually be possible to ascertain to what extent the seed trade might be depended upon to furnish that financial help without which the exhibition would become impracticable. The results, so far, may be briefly stated. Messrs. Sutton & Sons, of Reading, declined on the ground that their promise of help was practically conditional on the show being held at the Crystal Palace. Mr. C. Fidler, of Reading, replied by offering all the prizes in Classes 4, £7 10s.; 16, £3 17s.; 19, £3 17s.—a total of £15 4s., a most generous offer that merits warmest thanks. Messrs. Hurst & Sons declined to give prizes on the ground that, as a wholesale house, they would not be justified in occupying ground properly belonging to the retail trade. Messrs. Carter, Page, & Co., London Wall, have promised prizes. Messrs. Harrison & Sons, Leicester, have promised all the prizes in Class 18—£3 17s. Messrs. J. Laing & Sons, of Forest Hill, were the first seed firm to hail with approbation the proposed show and promise assistance. Messrs. Cannell & Sons, Swanley, are giving the matter consideration, and will no doubt provide prizes if the exhibition is otherwise well supported. Messrs. W. Johnson & Sons, Boston, have kindly offered 2 guineas, to be given in prizes as the Committee may determine, and if cash runs short would be willing to increase that sum. Messrs. Jas. Carter & Co. have written to say that their principal is at present from home through ill health, but they hope to offer some prizes. Messrs. Dobbie & Sons have written to intimate that their southern representative (Mr. Fyfe) would attend the meeting. The schedule as drafted contains a sum of about £160 in prizes.

It is computed that to meet expenditure incidental to the publication of schedules, entry cards, postage, stationery, advertisements in gardening papers, certain exhibition expenses, Judges' lunch, &c., that a sum of at least £50 will be needed beyond the actual sum required for prizes. To meet this there is the sum of £10 offered by the Aquarium Company, and about £10 already promised in smaller amounts by various members of the General Committee. Practically altogether to meet an expenditure of at least £200, the amount promised is roughly £40; it is therefore for the meeting to determine how far it may be advisable to proceed, or otherwise. The Committee think that it should be practicable to raise another £20 to £25 by obtaining advertisements for the schedule, by payment of entrance fees by exhibitors, and by letting certain spaces on the ground floor for tabling to seed houses desirous of making displays of produce. It need hardly be said that the most generous donors of prizes would be entitled to the first consideration in such case.

These are the chief results of the efforts that have been put forth by the Provisional Committee. It now remains for the meeting to determine whether the proposed exhibition shall be proceeded with. If it be so determined, then the schedule of classes as printed must be adopted, an Executive Committee of a representative character elected to carry out the project to a successful issue, and there must be so large a number of prizes guaranteed as to render the work of the Executive comparatively easy.—ALEXANDER DEAN, *Sec. pro tem.*

[Mr. A. Dean announced that about another £12 had been received towards the prizes and general funds, bringing the amount to £52, Mr.

Dean at the same time tendering his resignation, which, after much discussion, was accepted with regret. Mr. E. Molyneux, Swanmore Park Gardens, Bishop's Waltham, consented to act as Secretary until another meeting of the Committee had been held, and in the meantime undertook to take all possible steps to secure the balance of the amount needed to make the show a success, and it was decided that when Mr. Molyneux had done his utmost in the matter he should call a meeting if possible on the same day as a Drill Hall show was being held. The meeting then, after passing a vote of thanks to Mr. H. Briscoe Ironsides for presiding, was adjourned.]

### SEASONABLE WORK.

WHEN the ground is hard with frost, and the atmosphere is free from mist, is pure and bracing, there are few vocations that are more productive of enjoyment than is gardening. Very pleasant indeed, if protected by rough clothing and leather gloves, is it to be amongst the trees and thin out branches; work that always requires to be done early where practicable, but which, all the same, is very unpleasant work when the trees are wet and slimy and the ground is soft and saturated. When the ground is hard then it is very enjoyable. To perform all the thinning, then the faggoting and clearing away may be somewhat laborious and rough work, but then it is in frosty weather so exhilarating and enjoyable. The appetite earned by such labour amply repays for the roughness of the work, and when there has been collected a good store of all sorts of vegetable refuse that has become half decomposed, what exceedingly healthful pleasure is there found in taking advantage of the hard frost to wheel this refuse on to the ground and spread it about beneath the trees and bushes, that later it may be forked in.

There are some gardens in which animal manure is so abundant that little thought is taken with regard to vegetable accumulations. That is, however, an unfrequent condition of things, and generally vegetable refuse that will decay is collected and stored—weeds, trimmings, refuse, anything—and if this be treated with sewage, also when turned occasionally on the approach of winter, well dressed with soot, it is surprising what a valuable manurial compound is provided, and how specially useful it is to dig about fruit trees and bushes.

It is surprising also how much vegetable matter may be accumulated in this way during a year, and how useful it becomes for dressing in the winter. It is not in every garden where decayed tree leaves are too numerous, but even these do not furnish the same variety of plant food that is found when something of everything is accumulated and utilised.—AN OLD HAND.

### APPEAL COURTS VERSUS JUDGES.

I NOTE what "C. K., *Gargannock*," says (page 34) on his court of appeal. Oh, dear! a generation ago I suggested this in your pages in the matter of poultry, and got properly laughed at for the suggestion. All the same, I still believe it would save many untoward affairs. It is agreed, I imagine, by all that a glaring mistake on the part of judges greatly lessens the *éclat* of an exhibition. Unless an exhibitor has a very great command over himself he is apt, and perhaps not unnaturally, to use rather strong language, not, as Rev. A. Cheales observes, quite ecclesiastical. It would be a good thing all round to avoid these. Such errors, for instance, as "C. K." notes at the Royal Caledonian Horticultural show. I suppose that the very best judges do occasionally make glaring errors that a tyro would detect. They are not always in the same condition for work, and there is also a possibility of error which has nothing whatever to do with the judging. Who cannot see that it is quite possible that the judge, who is putting down the numbers of the exhibitors, may be a little distraught at the moment and put down a wrong one? Should there be no such exhibitor's number in the class the secretary detects the error, but should there be such a number, then that number and the exhibitor marked by it becomes the prizewinner. Now, if before a card were delivered to the attendant satellite in waiting for the judge's awards it were first given to another judge ready in waiting, such errors might be set straight, and as he would glance over the awards at the same time any glaring error would cause him to call the appointed judges aside, and ask whether such decision was their intention. I do not think it would be wise to allow exhibitors in such appeal, say, to "claim" first prize. Let them, after depositing a fixed amount, ask to have the class rejudged by another judge, who, if disagreeing with the awards, should then confer with the original judges. Something of this kind of appeal is now permitted in most rifle competitions on payment of a deposit, which is forfeited if no error has been made; but I still recollect, and sometimes smart over the memory, of hitting the target, which was seen to hit by a telescope, but the marker marked not, and being registered a miss I lost £15.—SHOOTER.

THE request for the appointment of courts of appeal from the decision of judges is doubtless based on the famous declaration, "I appeal from Phillip drunk to Phillip sober," the inference being that when judges give awards not to the liking of certain exhibitors they are drunk with bias, whilst the reserve court of judges must of necessity be composed of impartial men. Does not that strike us as being too ridiculous? There are many of us who have had very wide experience in judging who have heard very little indeed of these whines and complaints on the one hand, or of the dreadfully immoral nature of some

judges on the other. A precious compliment is paid to judges when it is proposed to have their decisions supervised, and perhaps altered, by another body of, probably, in no sense superior men. If this body of reserve judges be superior in knowledge and more virtuous why not engage them to act as the primary judges at once?

What a miserable lack of common knowledge must prevail in those localities where judges are selected by committees and then are capable of making awards entirely at variance with common sense! One cannot help concluding but that such dreadful things must exist chiefly in the imagination of some disappointed competitor rather than in reality. If mistakes are made, and some are, they almost always arise from an error of judgment in looking at things from a different standpoint, but very rarely indeed through sheer ignorance, and still rarer from wilful dishonesty. It must be remembered that if ever such decisions are given that the executive which selected the judges is as much to blame as are the judges themselves; and if thus capable of making such blunders in selecting their first court of judges, how can they be fitted to select the court of appeal judges?

Anyone who has watched the results of appeals in our law courts must often have been puzzled and confounded. A court of two judges decide one way. A court of three judges reverse that decision, yet a higher court of some four or five judges reverse the later decision, and that being the final one is of necessity accepted, but there is absolutely no proof as to what might have happened were there still a fourth court of appeal to give a decision. The fact is, so long as there are fresh courts to be consulted so long will decisions be overturned.

Obviously in horticulture, as indeed in all things submitted to competition at exhibitions, courts of appeal are utterly impracticable and impossible. Let the best men obtainable be employed as judges, and let their names be published in the schedule, then will it be open to any person to refuse to submit his products to the decisions of these men if he chooses. If on the other hand he does, then he has no course but to honourably abide by and accept their awards.—A. D.

#### CROWEA SALIGNA MAJOR.

A FEW years ago most good collections of hardwooded plants contained one or more Croweas, but such is not the case at present, it being the exception rather than the rule to see them. This is very unfortunate, as they are most useful and of the greatest floriferousness, blooms being seen at almost all times of the year. One of the finest varieties is *C. saligna major*, of which a spray is represented by the engraving (fig. 11). It is a form of the species *C. saligna*, which is a very useful, free-flowering and strong-growing plant; but the individual flowers are not so large as the variety named above. Another form, also with large flowers, is named *stricta*; but the colour is much lighter, being a pale delicate pink, while in *C. saligna major* it is a rich deep rose. The temperature of an ordinary greenhouse suits the Croweas very well, and they are easily grown plants, succeeding in ordinary fertile soil in well-drained pots.

#### HEAVY APPLES—FOUR SILVER MEDALS FOR ONE DISH.

UNDER the "Posthumous Notes" of a much-lamented writer, on page 6, reference is made to the Peasgood's Nonesuch Apples that I exhibited from Wells Palace Gardens. I am very pleased, as suggested, to give a few particulars about the tree and fruit, also to enclose a photograph of the tree, such as it is. Ten years ago I procured this tree in a small state with other sorts. As we had a long wall near the Palace moat, against which other kinds of fruit did not flourish, it occurred to me that the position was too cold for the more tender fruits, I therefore planted the Apples. Stations very much larger than usual were prepared, and a compost of half old lime rubbish, the other half consisting principally of burnt refuse, good turfy loam not being obtainable. In 1887 the tree bore a few Apples. In 1888 its fruits secured the first prize at Wells, Street, Taunton, Exeter, and Bristol. Several prizes were taken at smaller shows onwards till 1892, when first honours were secured at Wells, Street, Weston-super-Mare, and Exeter. In 1893 our Apples were first at Wells, also at Bath, winning a silver medal at Bath. During the same year they won a silver medal at the Royal Aquarium, the Banksian medal at the Royal Horticultural Society, and silver medal at the Forestry Exhibition (Earl's Court), or four medals for the same dish of Apples. The tree has been well looked after, watered in dry weather, mulched in spring with manure, and twice in the summer a good sprinkling of nitrate of soda was given, with occasional applications of stable manure. The fruit was remarkable for high colour, and although last autumn was so dull and wet the Apples were as highly coloured as we ever had them. One Apple turned the scale at 22½ ounces, with a crop of fifty-two fruit similar in size and shape. The tree is trained fan-shaped, similarly to a Peach, but the branches are very much wider apart than is customary in training Peach trees.—J. B. PAYNE, *Willsbridge, near Bristol*.

[Though the Apples referred to are not the heaviest on record, we have no recollection of one dish of Apples gathered from one tree winning four medals, and we suspect this is a "record" triumph. The photograph represents an informally trained tree, with wall space

visible enough between the branches. All the leaves were thus exposed to the direct action of light, and this with a good fibrous rooting system, encouraged by mulching, also generous feeding, brought about the gratifying results, or in other words sound culture brought its reward. Mr. Payne has recently left Wells, and the following is what we read in the "Western Gazette" about him. "During his long sojourn of eighteen years as head gardener at the Palace, Mr. Payne made many friends. His skill as a first class gardener is undoubted, and it was due to him in a great measure that the Chrysanthemum show was started. For six consecutive years he also managed to take the first prize for groups, and many other first prizes besides. He has also acted at other shows as judge, and his awards have always been found

FIG. 11.—CROWEA SALIGNA MAJOR.

sound. Under his care the Palace gardens and grounds were kept in perfect condition." Mr. Payne has certainly displayed sound cultural skill in the production of the deservedly honoured Apples in question.]

#### LIME.

IN reply to "Inquirer"—viz., lime (page 16), as most gardeners know the lime could be slaked in large heaps as well as in small ones, providing a sufficient quantity of water were present. In asking this question, did it not occur to "Inquirer" that if the lime were slaked in one large heap it would be much more difficult to move and spread (owing to its dusty character) than if put on the land in small heaps?

"Inquirer" thinks that lime should not be slaked before being put on the land; it would be interesting to know how he would apply it (owing to its lumpy nature when brought direct from the kiln) if it were not slaked previous to use? He also asks, "Is it (slaked lime) of any greater power or value than chalk?" Yes, considerably, for they are entirely different from each other, the former being a hydrate, the latter a carbonate of lime. The hydrate is able to decompose the organic

matter in soils, a property possessed by chalk only to a very small extent. Hydrated lime has the power of uniting with the same amount of carbon dioxide as quicklime to form carbonate of lime, by this I mean that weight for weight the quicklime would take more carbon dioxide than the hydrate; but if we took two equal amounts of quicklime, slaked the one, and not the other, they would then each be capable of uniting with the same volume of carbon dioxide, but hydrated lime is not quite so caustic in its properties as quicklime, consequently it would take longer for the hydrate to accomplish this chemical union.

"Inquirer" goes on to say, "I apparently propound a new doctrine, that lime is *per se* (by itself) a soil fertiliser." I think that this shows that "Inquirer's" reading has not been of a very scientific nature, or he would have seen explained the part lime takes as a plant food, for without lime is present no plants will grow in any kind of soil. As most writers and teachers of agriculture describe its action fully, it would be well for him to look this matter up, and he will see that lime is looked on in agriculture, not as an insect destroyer, but as a valuable plant food. I should like to know how much lime we should want to apply to land to kill such insects as wireworms and some of the chrysalids? I have never seen sufficient dressings used to kill the above insects, and I think it is practically impossible to do so. The micro forms of insect life (so called by "Inquirer"), those he wishes to protect from injury, are not, as a matter of fact, insects, but belong to a group of fungi known as the Schizomycetes, and belong to the vegetable kingdom.

When bodies chemically unite heat is formed (this is well illustrated when water is put on lime), hence the remark "that lime burns the soil," for when lime is put on soils containing organic matter (which generally consists of carbon dioxide, water, and ammonia) they decompose it, uniting it with the carbon dioxide to form a carbonate; this we may term a process of slow burning. Many chemical changes take place when lime is applied to soils which do not concern us now.

I think we may assume that lime decomposes the organic matter, which is part of the insects' food, and so drives them away to parts unlimed, and we rid ourselves to some extent of these insect pests; such insects as slugs and caterpillars may be destroyed if lime comes in direct contact with them. If the Editor will allow I will give a more complete account of the action of lime on soils, and its use as a plant food.—W. D., Turnford, Herts.

[The Editor will willingly admit the extended notes suggested for the information of "Inquirer" and many other readers of the *Journal of Horticulture*.]

ORNAMENTAL BASKETS.

PERHAPS nothing adds more to the furnishing of the stove, green house, or conservatory than a variety of well-furnished baskets suspended from the roof, and where decorations are largely carried on those who are in the habit of using them will amply testify to their usefulness in adding an air of finish and gracefulness to drawing-room decoration.

In choosing specimens for basket culture endeavours should be made to select only such plants as are light and elegant in growth, anything stiff or formal looking entirely out of place under these circumstances. For the benefit of anyone uninitiated in the art of basket culture perhaps the following notes will prove beneficial. Wire baskets of all sizes and shapes are easily obtained, but round bowl-shaped ones of medium size are generally used. The interior of the basket should first be lined with stiff growing moss, such as is often found under Beech trees, with the green side outwards, and then filled with suitable soil prior to planting.

When grown in baskets for summer use there is nothing more useful than *Selaginella uncinata*, which is known to almost everyone. Its graceful trailing habit makes it particularly adaptable for this purpose, and if grown in a shady position, protected from the strong rays of the sun, the bluish green tint of its foliage is very charming, changing as autumn approaches to a bright golden colour. Owing to its deciduous habit it should be kept in a cool greenhouse during the winter months. Another useful acquisition is *Pteris serrulata*. The fronds of this Fern are of a light green colour, long, pendulous, and very graceful for ornamental baskets. *P. cretica* is also suitable, being a distinct variety, with fronds upwards of a foot long. Among the *Adiantums* both *cuneatum* and *gracillimum* are very suitable, but perhaps even more so is *A. caudatum*. It is light and elegant, with fronds about a foot long. *Cheilanthes spectabilis*, a native of Brazil, forms a charming object for this purpose, being an evergreen variety, and in every way acceptable. *Woodwardia orientalis* is well worthy of mention, with graceful fronds ranging from 2 to 4 feet long, from the upper surface of which springs a profusion of bulbiform plants.

In spite of their deciduous habits both *Davallia canariensis* and *D. bullata* are charming. Of naturally wandering habits, the fronds are of a rich shining green, rising from a creeping caudex covered with reddish-brown scales, and makes them, without doubt, among the prettiest of East Indian Ferns. *Isolepis gracilis* and *Sibthorpia europæa* are also useful for basket cultivation, and cuttings of *Tradescantia* placed underneath the baskets add considerably to the elegance and effect.

If flowering plants are desired, *Achimenes* are amongst the most useful for summer use. The best method is to place the roots in shallow boxes to start, and when they are a few inches high prick them in over the surface and all round the outside of the basket, which will quickly become furnished and form a pleasing appearance when covered with bloom. *Saxifraga sarmentosa* is a charming plant for cultivation in

baskets, its trailing habits, profuseness of growth, and the elegant beauty of its simple white flowers, all being recommendations for this purpose. Ivy-leaved Pelargoniums, Canary Creepers, Fuchsias of drooping habit, Rex and Tuberos-rooted Begonias, Marguerites, and many other plants may also be employed with advantage.—G. HOLLINGWORTH, *Alton Towers*.

JAPANESE UP TO DATE.

IN continuing the analysis of the Japanese Chrysanthemums from page 24 of our last issue we present the selections for the twenty-four and twelve, and these will be found interesting, as showing the wide differences in the opinions of our leading growers. The selections for twelve new varieties and twelve decorative must be deferred to a future issue.

TWENTY-FOUR JAPANESE.

## EUPHORBIA JACQUINÆFLORA.

THIS charming and graceful winter flowering plant is not cultivated to the extent it deserves. Its slender but erect growing habit, with racemes of intense scarlet flowers arching over in natural form, set off by the profusion of bronzy green leaves, make a very pleasing object.

It is of easy culture, but requires very careful attention. After flowering dry off the old plants, shortening the growths ready to start again early in March. Numbers of young shoots are quickly produced, which for propagating purposes must be taken off close to the stem when about 4 inches long and placed five or six in a 3-inch pot. The compost should be of a light sandy nature, and the pots after the insertion of the cuttings may be placed in a close propagating frame where a good bottom heat is maintained. When well rooted gradually harden off, keeping the young plants well up to the light. As the young plants attain strength they must be shifted into well-drained 54-sized pots. The soil now should consist of three parts good turfy loam, one part thoroughly decomposed manure and leaf mould, with sufficient sand and old mortar rubbish to keep the soil porous. A temperature from 55° to 65° will be found most suitable for the plants at this stage.

When the pots are well filled with roots another transfer to 6½-inch pots is desirable, and these will be large enough to make good useful plants either for decorating or cutting purposes. After the plants have made sufficient growth to necessitate tying place one stick in the centre of the pot and attach the shoots lightly so as to allow the blooms to hang naturally and gracefully. This plant also succeeds well planted out in a well drained border, in a light and sunny position, where an equable temperature is at command. If well treated it will make abundance of growth and produce numbers of flowers. The most important detail in the cultivation is careful watering. If water is used too freely the leaves turn a sickly colour and fall, leaving only unsightly plants. When the pots are well filled with roots an occasional application of soot or liquid manure will greatly assist the development of the flowers.—C. H. H.

## MR. R. D. BLACKMORE AND HIS CRITICS.

ALLOW me to make a few remarks on the statement of "A. D." in your last issue in respect to the fruit-growing of Mr. R. D. Blackmore. He there says it is a "mistake of regarding that eminent writer's fruit references seriously." That may be "A. D.'s" opinion, but I and a large number of others do take these references seriously. "A. D." states that Mr. R. D. Blackmore "invests the subject with an air of romance." Does he? There is nothing in this way, I think, when he simply gives the prices he makes and the losses he has incurred. It must be admitted there is something fascinating in the very words "fruit-growing." They lead one into visions of trees covered with bloom, and to be succeeded by numbers of beautiful and highly coloured fruit.

From what I glean, people generally think all that they have to do is to plant, to wait for the time of bearing, gather the fruit, and reap the reward in the shape of profits; but then there is the selling and "the prices." Mr. R. D. Blackmore does not complain of his crops, but the money they realise in the markets. "A. D." has asserted that after all Mr. R. D. Blackmore's experience in growing fruit that he does not grow it well. Meeting one of the best fruit growers of the day, and one who also frequently acts as judge at the large flower and fruit shows, I asked his opinion of Mr. R. D. Blackmore's fruit, and the growing of it. His reply was, it was "very good, and his trees well managed." This fully coincided with my own conclusions, and also that of others; therefore it is the price that is beating Mr. Blackmore.

Your correspondent further says Mr. R. D. Blackmore was not noted as a fruit grower and of good knowledge of fruit. Why, then, was he selected for one of the Fruit Committee of the Royal Horticultural Society? It is well known that before Mr. R. D. Blackmore wrote of his losses he was quoted and lauded for what he was doing. Now that he treads on the ground of others nothing is too bad for him, and why? Because he told the truth, the simple truth.

Then it is asserted that Mr. R. D. Blackmore "is far from being regarded as a practical grower of fruit for sale." He began by trying to make a living by it, and he has now had forty years' experience. Surely, there is something "practical" in all this. Again, he is described as a fruit experimentalist. Mr. R. D. Blackmore certainly has tried various sorts of Pears, but only two small trees of a sort, and even all these did not turn out worthless, but of this nothing to the extent "A. D." wishes others to believe, and which happily they do not. Then the soil is alleged as being bad, on cold London clay, instead of which the ground is good, with a natural drainage, being 3 feet of loam on gravel. Now as to the fruit, Mr. R. D. Blackmore has grown "Pitmastons" on his standards weighing over a pound each, with Doyenné du Comice of 14 ozs., and the varieties principally in full bearing are good market kinds, Williams' Bon Chrétien, Doyenné du Comice, Beurré Hardy, Louise Bonne of Jersey, Souvenir de Congrès, Marie Louise, and others. Mr. Blackmore's fruit ground at Teddington is 10½ acres.—H.

## ROYAL HORTICULTURAL SOCIETY.

JANUARY 15TH.

THE first meeting at the Drill Hall on Tuesday last did not bring a very large muster of either flowers and fruits, but the quality throughout was very good. Orchids were seen in fair numbers, but the exhibits for the Floral Committee were very few.

FRUIT COMMITTEE.—Present: Philip Crowley, Esq. (in the chair); with Dr. Hogg, and Messrs. T. F. Rivers, G. Bunyard, T. J. Saltmarsh, H. J. Pearson, Jos. Cheal, J. H. Veitch, G. W. Cummins, W. Pope, A. Dean, C. Ross, J. A. Laing, W. Bates, J. Hudson, G. Wythes, F. Q. Lane, J. Smith, G. Reynolds, and R. Fife.

Messrs. J. Cheal & Sons, Lowfield Nurseries, Crawley, staged a collection of Apples, all in excellent condition. Among the most prominent were Lord Derby, Warner's King, Frogmore Prolific, The Queen, Cox's Pomona, King of Pippins, Col. Vaughan, Emperor Alexander, and Golden Noble. A few Pears, including Catillac, Duchesse de Nemours, and Verulam, were staged by this firm (silver Knightian medal).

The stand arranged by Messrs. J. Laing & Sons, Forest Hill, was very interesting, and comprised forty dishes of Apples in distinct varieties. Bismarck, Striped Beefing, Lord Derby, Alfriston, Mère de Ménage, Beauty of Kent, Emperor Alexander, Golden Spire, Wellington, and Flower of Kent were particularly conspicuous (silver Banksian medal). Mr. W. Gradwell, 4, Manor Road, Tottenham, sent sticks of Tottenham Early, but no award was made. A dish of Tomatoes was shown by Mr. J. Gray, Anglesey, North Wales, these also being passed.

FLORAL COMMITTEE.—Present: W. Marshall, Esq., in the chair; with the Rev. H. H. D'Ombraïn and Messrs. J. Fraser, O. Thomas, J. Laing, H. Herbst, R. Dean, C. T. Drury, H. B. May, J. H. Fitt, G. Stevens, W. Bain, J. Jennings, J. D. Pawle, H. Cannell, Chas. Jeffries, C. E. Pearson, C. E. Shez, C. Blick, H. Briscoe-Ironside, E. Beckett, and H. J. Jones.

The most prominent exhibit for the Floral Committee was that of Messrs. Sutton & Sons, Reading, and which comprised Primulas and Cyclamens. The range of colour seen amongst the Primulas was very great, and included whites, blues, reds, and pinks. The double varieties were Alba Magnifica, a new variety, well named; Heliotrope, Rosy Queen, Carnation Flake, and Double Blue; while the singles were represented by Grenadier, Giant Pink, Giant Rosy Queen (award of merit), Brilliant Rose, and Pearl. An award of merit was accorded to this firm for their strain of Cyclamen Salmon Queen. All the plants in this exhibit were splendidly grown, and the flowers of the highest quality (silver Flora medal).

Messrs. H. Cannell & Sons, Swanley, sent a few plants and flowers of Chinese Primulas, including many of their well-known varieties. The same firm also showed fine blooms of Cinerarias and spikes of Canna Queen Charlotte.

A plant of Pteris tremula Howelli was shown by Mr. H. Howell, Queen's Nursery, Hammersmith. The utility of Chrysanthemum L. Canning was well shown by the freely flowered plants sent by Mr. Owen Thomas, Royal Gardens, Windsor (award of merit).

Messrs. W. Paul & Son, Waltham Cross, sent a handsome plant of *Rhododendron ponticum foliis purpureis* (first-class certificate, see below). An award of merit was accorded for *Chrysanthemum Janette Sheaham*, staged by Mr. D. Sheaham, Wimbledon, which is described below. Plants of *Nicotiana affinis variegata* with its showy leafage were staged by Messrs. J. Laing & Sons, Forest Hill, as also were a few Ferns and Palms.

Messrs. Collins Bros. & Gabriel, Waterloo Road, sent plants of Carnation James Collins, and Mr. J. May, Summit, New Jersey, blooms of Rose Mrs. Pierpont Morgan, for which he received an award of merit. *Lachenalia quadricolor maculata*, from Mr. F. W. Moore, Glasnevin Botanic Garden, was awarded a first-class certificate, while *Dermatobotrys Saundersi*, from the same source, was passed.

Fred Hardy, Esq., Cheshire, showed a plant of *Cypripedium Bellina*, and also one of *C. Laurocortisi*. C. L. Ingram, Esq., Godalming (gardener, Mr. Bond), sent a plant of *Cattleya Percivalliana alba*. W. Cobb, Esq., Henley-on-Thames, received an award of merit for *Cypripedium nitens superbum*, which is described below. A plant of *C. Boxalli Cobbi* was also sent by this exhibitor.

A small collection of Orchids was arranged by Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, and comprised *Dendrobium Wattianum*, *D. chrysodiscus*, *D. xanthocentrum*, *D. Hebe* (a cross between *Ainsworthi* and *D. Findleyanum*), *D. nobile*, Burford var., *Masdevallia Courtlandiana*, *Lælia autumnale alba*, *Phalænopsis Schilleriana*, *P. Aphrodite*, and numerous others.

The largest collection of Orchids was that of Messrs. F. Sander and Co., St. Albans, and contained some exceptionally good forms. *Cymbidium Winnianum*, *Lælia anceps Sanderiana*, *L. a. Hollidayana*, *Cypripedium Madame Georges Truffaut* (award of merit), *C. Mrs. Fred Hardy* (award of merit), *C. J. H. Berry* (award of merit), and many others.

S. G. Lutwyche, Esq., Beckenham, sent two *Cypripediums*, both varieties of *insigne*. H. Graves, Esq., Orange, New Jersey, secured an award of merit for *Cypripedium Henry Graves, Jun.* (see below). T. Statter, Esq., Stand Hall, Manchester, exhibited a few plants of *Cypripediums*, in which a good form or two was noticeable. Messrs. J. Veitch and Sons, Chelsea, showed three *Cypripediums*, and received two awards for *C. minosa superbum* and *C. Norma*, for descriptions of which see below. *Phalænopsis F. L. Ames* was exhibited by Mr. E. Hill, gardener to Lord Rothschild, Tring Park; and *Lælia anceps*, Rosefield variety, by De B. Crawshay, Esq., Sevenoaks. An award of merit was accorded to Mons. Jules Hye, Leysen, Ghent, for *Cypripedium Madame Jules Hye*. E. Ashworth, Esq., Harefield Hall, Wilmslow, staged spikes of *Lælias* in variety, and also one or two *Cypripedium* blooms.

A first class certificate was adjudged to *Lælia anceps Crawshayana*, staged by De B. Crawshay, Esq., and a plant of the sweetly scented *Cymbidium Traceyanum* from Mr. J. Prewett, Swiss Nursery, Hammersmith, attracted attention. *L'Horticulture Internationale*, Brussels, showed a number of very faded flowers of *Cattleyas*.

#### CERTIFICATES AND AWARDS OF MERIT.

*Lachenalia quadricolor maculata* (F. W. Moore).—This is a handsome variety with fair sized flowers, the tips of which are bright maroon in colour (first-class certificate).

*Lælia anceps Crawshayana* (De B. Crawshay).—The colour of this variety is very rich, and the flowers are of good size and substance. The sepals and petals are deep rose, the lip being deep velvety crimson. The throat is yellow, veined with crimson (first-class certificate).

*Odontoglossum nebulosum candidissimum* (Fred Hardy).—The sepals and petals of this variety are almost pure white, as also is the lip, with the exception of a streak of yellow close to the throat (award of merit).

*Primula Rosy Queen* (Sutton & Sons).—A large flowered single variety of great substance. The colour is a very pleasing soft rose (award of merit).

*Rhododendron ponticum foliis purpureis* (W. Paul & Son).—This is a seedling from the type. The foliage is very rich, deep reddish brown in colour, and the habit of the plant is compact (first-class certificate).

*Rose Mrs. Pierpont Morgan* (J. N. May).—This is a sport from *Madame Cusin*, with deep rose coloured flowers (award of merit).

*Chrysanthemum Jannette Sheaham* (D. Sheaham).—This is a sport from *Princess Blanche*, and has yellow flowers of good shape. The habit of the plant is dwarf, and it is very floriferous (award of merit).

*Chrysanthemum L. Canning* (Owen Thomas).—This is a floriferous, late, pure white variety of much use for late flowering (award of merit).

*Cyclamen Salmon Queen* (Sutton & Sons).—The name of this strain admirably tells its colour. The plant is dwarf, and the foliage beautifully marbled (award of merit).

*Cypripedium Henry Graves, Junr.* (H. Graves).—This is the result of a cross between *Lawrenceianum* and *Marshallianum*. The prevailing colour is dull rose, the dorsal sepal showing traces of white (award of merit).

*Cypripedium Mimosa superbum* (J. Veitch & Sons).—This is a very handsome hybrid, obtained from *C. Arthurianum* and *C. Spicerianum*, the first-named being the pollen parent. The lip and petals are dull brown with darker markings, and the dorsal sepal is green with brown spots and a white edge (award of merit).

*Cypripedium Norma* (J. Veitch & Sons).—The result of a cross between *C. x Niobe* and *C. Spicerianum*. The petals are narrow and twisted, the colour being pale green with brown dots and stripes. The

dorsal sepal is white, flushed deep rose, and the lip a deep greenish brown (award of merit).

*Cypripedium Madame Georges Truffaut* (F. Sander & Co.).—This is a very handsome form, with a large, deep, brownish red lip. The petals are long, and of a green colour, heavily spotted brown. The dorsal sepal is dull white, flushed rose, and veined with brown (award of merit).

*Cypripedium nitens superbum* (W. Cobb).—This is a fine variety of the type with large beautifully coloured flowers (award of merit).

*Cypripedium Madame Jules Hye* (Jules Hye).—This is a form with a large lip of brownish red. The petals are green, with brown markings. The dorsal sepal is rosy red, flushed white (award of merit).

*Cypripedium Mrs. Fred Hardy* (F. Sander & Co.).—This is a charming cross between *superbiens* and *bellatulum*. The colour throughout is greenish-white, heavily spotted maroon. The lip is a dull white with markings of maroon (award of merit).

#### FRUIT FORCING.

**Vines.**—*Early-forced in Pots.*—As soon as the fruit is set attention should be given to thinning, commencing as soon as the berries are fairly swelling, watering copiously with liquid manure. Encourage growths above the fruit, yet only as much as can have exposure to light. Surface dress with short manure, and when roots are emitted from the collar some turves may be placed around the runs, extending a couple of inches inwards and outwards, so as to be on the fermenting material. The temperature should range from 65° to 70° at night, 70° to 75° by day, and 80° to 85° from sun heat, admitting air from 75°, and closing early so as to raise it to 85° or 90° with sun heat, damping available surfaces at closing time, or early in the afternoon. Syringing over the foliage ought not to be practised, as there is always a danger of the water leaving a deposit on the berries, which spoils the appearance of the Grapes when ripe.

*Early Houses.*—Great care is now required in ventilating, so as not to admit draughts of cold air, which cripple the foliage. Disbud and tie down the shoots before they touch the glass. In stopping do not confine to any orthodox number of joints beyond the bunch, but extend it so that an ample and even supply of foliage will be insured, yet do not crowd the house with more than can have full exposure to light. Remove all superfluous bunches, overcropping and overcrowding of the foliage being most adverse to satisfactory results. When the Vines come into flower maintain a night temperature of 65° to 70°, and 70° to 75° by day, and a rather drier atmosphere.

*Houses Started at the New Year.*—Protect the outside border from frost, an abundant supply of leaves, litter, or fern being necessary to prevent chill from snow. Sprinkle the Vines frequently; maintain a temperature of 50° to 55° at night, 60° to 65° by day, ventilating freely above 65°. The rods and canes of young Vines should be slung in a horizontal position, or lower at the extremity, to secure a regular break.

*Houses of Late Grapes.*—These may now be removed to a dry room, where they will keep quite as well as if left on the Vines. Cut the bunches with as much wood as can be spared, and place the stems in bottles filled with clear rain water, each containing a few bits of charcoal. Fix the bottles in an inclining position, so as to admit of the berries hanging clear of their sides, and they should be so far apart as not to allow the bunches to touch each other. Keep the temperature of the room at about 45°, examining the Grapes occasionally for decayed ones, which must be carefully removed. Prune the Vines, dressing the cuts carefully with patent knotting or best French polish. Cleanse the house thoroughly, and dress the Vines with an insecticide or combined fungicide. Admit air freely in favourable weather, seeking to give the Vines as long and complete rest as possible. When the borders are not satisfactory, lift the Vines and relay the roots in fresh compost. Where the Vines have inside and outside borders the renovation may be accomplished without loss of crop by renewing the former one year and the latter the next.

**Strawberries in Pots.**—Proceed steadily with plants that are not required to give fruit at a particularly early stated time, especially in severe weather; 50° to 55° is ample for those started in December, and 60° to 65° by day, erring if at all on the safe side, the low; therefore 5° less in cold weather, and in the absence of sun, is advisable. Ventilate whenever there is a chance. The trusses rise boldest and the flowers are strongest when the plants have the foliage well elaborated. Close atmosphere induces soft tissues, weakly organs of fructification, imperfect sets, and deformed ill-shapen fruit.

Introduce more plants to shelves in Peach houses and vineries started about this time. Rectify the drainage of the pots, remove moss or other matter from the surface of the soil, and wash the pots clean. Surface-dress with an improved fertiliser mixed with a little rich soil, or use fresh horse droppings rubbed through a quarter-inch mesh sieve, and give each pot about a half teaspoonful of the fertiliser, which will be

washed into the soil fast enough. Strawberries require phosphoric acid, potash or soda, and nitrogen, therefore the manure should consist of bone superphosphate five parts, sulphate of potash three parts, and nitrate of soda two parts, mixed, taking care to have the nitrate finely powdered. Noble is an excellent variety for introducing now to fruit in April, also Auguste Nicaise, the latter being the brighter fruit. Royal Sovereign is a finer Strawberry than either for quality, and Scarlet Queen is esteemed in some places for its excellent flavour. President, Sir Joseph Paxton, and Sir Charles Napier may also be introduced, and the very desirable, but seldom forced, variety Lucas. To maintain the succession of fruit unbroken plants of La Grosse Sucrée and Vicomtesse Hericart de Thury must also be introduced at the same time.

#### THE KITCHEN GARDEN.

**Preparing for Forcing.**—Forced vegetables are always appreciated, and must be forthcoming in considerable numbers in many places. Some few can be most surely and easily had with the aid of houses and fire heat; but a good stock of pits and frames, as well as an abundant supply of hotbed material, is indispensable, or at all events of the greatest service. A large heap of leaves ought, where possible, to have been collected ready for mixing with and moderating the more violently heating stable manure. If the latter alone has to be used then it must be thrown together, and remain till the heap is quite hot in the centre, when it should be turned inside out and once more allowed to become hot, this being repeated a third time with a view of dissipating all rankness. Never allow the heap to attain what may be termed a "white" heat in the centre, as this quite spoils the material for either hotbeds or manurial purposes; but turn the heaps before overheating takes place, also gently watering any dry portions of the manure that may be met with. When leaves are to be largely mixed with the manure the latter need not be so long in preparation, and if the mixture is thrown into a large heap for a few days fermentation will commence, and a gentle heat be observable directly the hotbeds are formed. Peat moss litter by itself heats somewhat violently, always supposing it is not allowed to become very wet. It can, after careful preparation, be used alone, but is more effective mixed with three times its bulk in leaves.

**Soils for Hotbeds.**—Those who force vegetables ought always to prepare an ample supply of soil for the purpose. A rich compost is not desirable: Sandy soil suits Carrots, Potatoes, and Radishes admirably, a little fresh loam being added for Kidney Beans, Turnips, Peas, and Cauliflowers. Sifted material from a heap of old potting soil, fine loam from the stacked heap, and ashes from burnt vegetable refuse make a mixture that is of the greatest value for seed boxes and beds.

**Carrots and Radishes.**—These cannot well be forthcoming too soon, and a good sized frame or two or three lights in a pit might be made ready for sowing at once. Form a hotbed 3 feet in depth in the front, and 6 inches higher at the back, and make it somewhat firm, a lasting rather than a strong heat being most desirable. Place enough short manure on this to raise the soil well up to the glass, and cover with 6 inches of the fine soil recommended. Close the lights, mat over till the heat has risen, and directly it is seen there is not much likelihood of overheating taking place sow the seeds. Form shallow drills with the edge of a short measuring rod 8 inches apart for the Carrots, and between these draw other drills for Radish seeds. Should the soil be somewhat dry, give a gentle watering after the drills are opened rather than after the seeds are sown and covered. Sow either Parisian Forcing, Early Horn, or Nantes Horn Carrot thinly, and either the Forcing Turnip-rooted, Wood's Frame and French Breakfast Radishes, or some of each may be sown very thinly, as Radishes fail to form roots quickly if at all crowded. Cover with fine soil, keep close, and protect till the Radishes appear, after which admit all the light possible, and give a little air during warm days.

**Potatoes.**—For these deeper frames and more head room in pits are required. Form the hotbed as advised in the case of Carrots, and cover with 9 inches of soil. The early short-topped Ashleaves, Sharpe's Victor, and such like varieties are most suitable for forcing, and medium sized tubers ought to be first started in a moist heat or forcing house, planting them with the strong primary sprout well advanced. When the soil is warmed through, open drills 15 inches apart and 6 inches deep with the hand, and dispose the sets from 6 inches to 8 inches apart. Partially mould over at first, just covering the sprout. Hard forcing should not be attempted, and dryness at the roots ought to be guarded against. Potatoes may also be gently forced in pots and boxes. Pots 8 inches in diameter or a size larger are suitable for the front stages and back shelves of newly started vineries and Peach houses, while boxes 9 inches in depth and the same in width answer well for standing on borders of the same class of houses. Place one fairly large previously sprouted tuber rather deeply in each pot, and allow room for a top-dressing to be given by the time the growth reaches the level of the rim. In the narrow boxes place a single row of tubers 6 inches apart, and treat similarly to those in pots. A sprinkling of superphosphate of lime, and either soot at the same time or nitrate of soda a month later, may well be added to the light loamy soil used for Potatoes in pots and boxes. Keep the soil uniformly moist, water being given more freely after the haulm has become strong.

**Forcing Lettuces.**—Some of the best Lettuces of the season may easily be had in April with the aid of a mild hotbed and frames or pits. Early Paris Market, Golden Queen, and Commodore Nutt Cabbage Lettuces all force admirably, and when cut are so crisp and as to require careful handling and packing. Sow in pans and place in brisk heat

to germinate. Before the seedlings become drawn and weakly place them on a shelf near the glass in an intermediate temperature, where they will continue to make good progress. If sown thinly there will be no necessity to prick them out temporarily, but they may be dibbled in where they are to grow when large enough to handle. Prepare a firm, mild hotbed, on this set a shallow frame, and three parts fill this with a good loamy compost. When well warmed through, prick out the Lettuce 5 inches apart, and give a gentle watering. Keep somewhat close at first, ventilating more freely when the plants are growing strongly. If the soil is rather poor sprinkle a light dressing of nitrate of soda or other quick acting nitrogenous manure among, but not over, the plants, and water in. When the plants touch each other all round, one-half should be cut out for immediate use, and the rest, if kept moist at the roots, will then attain their full size and heart beautifully. Young Lettuce leaves mixed with well blanched Chicory and Mustard and Cress form a presentable salad. Sow seed of Paris White Cos in boxes or pans somewhat thickly every week or so, and place in gentle heat or on a mild hotbed to germinate, afterwards transferring to shelves in gentle heat. The plants, when about 4 inches high, may be cut over for salad purposes, much as if they were so much Mustard and Cress.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### THE WEATHER.

SINCE the beginning of the year the weather has been of a very wintry nature. On the morning of the 10th the thermometer stood at 5°, and on that of the 11th 10° below freezing point. The barometer has been steady for some time at 29.50°, but is falling with signs of a change, which will be welcomed by most people.

#### FOUL BROOD.

The question of foul brood has been much discussed of late, and the Government have been urged to take steps to have an Act passed for its suppression. The object to rid the country of the disease is a laudable one, but we cannot disguise the fact that the same individuals who are so clamorous for Government interference have shared not a little in spreading the disease. They have condemned straw hives, and yet they were the only ones they publicly demonstrated and manipulated with at their exhibitions, every one of which I attended, saw foul broody combs from them cast in the fields, and the bees from neighbouring apiaries working on them.

As bad, too, was the practice of keeping bees shut in their hives during the whole time of the shows, which lasted about a week. I have several letters in my possession from influential gentlemen complaining of "the cruel practice." A great many gentlemen are encouraging their gardeners to keep bees, but they would probably resent any inspection of their grounds. I certainly should resist any interference with my hives between the months of September and May, on the assumption that robbing might be induced and bees and brood chilled to death. During the other portion of the year loss of honey would accrue in fine weather. Nor is that all: no stranger would manipulate my hives to my satisfaction. Should I have to submit to ruined hives? How are hives to be inspected? They cannot be diagnosed like diseased animals.

I can see the force of any person who may think himself aggrieved at a neighbour's supposed affected hive applying to the Court for an inspection to be made, at the same time lodging a deposit to cover all damages and expenses if no disease be present. The question is one of great importance to the country and to bee-keepers, and it is to be hoped that they, as a body, will be listened to, and that their opinions will have the consideration they deserve.—A LANARKSHIRE BEE-KEEPER.

#### ENEMIES OF BEES.

DURING the winter and early spring stocks of bees in whatever hives they are placed should be carefully watched to see that they are not molested in any way. The chief culprits are mice, and the blue tit (*Parus cœruleus*), and the great tit (*Parus major*), and these where numerous, if not destroyed, will do a great amount of mischief in a short time. If mice once gain an entrance to a hive and are not disturbed, they will soon destroy the combs and consume all the stores, the bees eventually dying through starvation. I have on several occasions seen strong stocks in straw skeps in cottage gardens destroyed from this cause.

The tits do not enter the hives but waylay any stray bees that may from any cause have ventured outside. If the bees do not come out of their own free will, the birds endeavour to entice them out, by going from one hive to the other, alighting on the floor

board, and giving two or three sharp taps at the entrance. If the weather is not too cold odd bees will come out, to be at once seized and carried to the nearest bush and devoured. The head, wings, and sting are discarded, the abdomen being the only part consumed. They quickly return to the hive and the operation is repeated over again, and it is surprising the number of bees a few of these birds will destroy in a short time.

When the ground is covered with snow it is easy to see the mischief that is going on. I have sometimes seen the ground literally covered with the remains of several hundreds of bees when the snow has remained on the ground for a few days. At this time of the year I always keep a number of spring mouse-traps baited with a piece of bread dotted about among my hives, and these will invariably catch both the mice and tits. Sometimes I have caught over two dozen in one week, and having a number of stocks near a plantation the tits are very numerous.

Sparrows, too, are troublesome; but they will take them when on the wing. Toads will fatten on them during the summer, when the heavy laden bees drop on the ground near the entrance to their hives, about which the toads are often found; but I do not think it advisable to destroy toads, as they do a great amount of good in the garden.—AN ENGLISH BEE-KEEPER.

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Tomato House (Cantab.).**—By all means make provision for abundant side as well as top ventilation.

**Seedling Potatoes (R. M.).**—New varieties of Potatoes do not receive any recognition of merit from the Fruit Committee of the Royal Horticultural Society until they have been grown with others in the Society's Gardens. If you write to Mr. A. F. Barron, R.H.S. Gardens, Chiswick, London, he will supply you with all requisite information for attaining your object. We are obliged by your communication.

**Second-hand Books (Distressed).**—No matter how good the condition of the books may be, they can only possess second-hand value. This, however, varies with the demand for books and their condition. As a rule the best amounts are obtained by offering spare books of the kind you name locally, and letting them be examined by persons

interested in gardening. All those you mention are useful. If there is a gardeners' improvement association or horticultural society in your district, it might be worth your while writing to the secretaries on the subject. We have duplicate volumes of the whole of the books, and therefore more would be superfluous here.

**Garden Charities (W. S.).**—Your letter displays the kindness of your heart and your sympathy with the afflicted. Our gardening charities do indeed need all the support that can be accorded them; and you will be glad to know that the demands on them are in various ways constantly being brought before that section of the public from which help may be expected. The Secretaries are very zealous, and lose no opportunities that give promise of increasing the funds for the relief that is so urgently needed both by aged gardeners and widows in affliction. We hope you are a local helper in inducing persons in your neighbourhood to become subscribers.

**Peach Buds Forward (Rosarian).**—There is nothing wrong, so far as we can detect, with the buds; they have a good hold of the wood, and are somewhat forward, but not more so than many others this year, in consequence of the late mild weather. It would be very unwise to start the trees, because the buds are swelling, as they will not take the least harm, but be all the better for coming on slowly, the flowers being stronger and the set better than when they are brought forward rapidly. The house should be freely ventilated, fully at and above 50°, and fire heat need only be used to exclude frost, though a few degrees of that would not do any harm till the blossoms show colour, when, of course, it must be excluded. The crop will not be lost by the condition of the buds, but the wood is not very firm—it seldom is in young trees, and steady growth is the more to be desired.

**Mushroom Beds Failing (A. J.).**—There does not appear anything the matter with your preparation of the material and treatment of the beds, but it is very unwise to mix old with new material, as the old is not likely to produce and retain warmth so well as fresh and properly prepared. If all the "spawn" is like that sent it could not produce Mushrooms, as the sample is entirely devoid of mycelium; but whether it has contained any we are unable to say. You should have sent some of the "brick" as received from the vendor, and then we could have given a decisive opinion as to its containing live spawn or not. The temperature at which you spawn the bed is rather high, and the appearance of some Mushrooms in button form and non-progress afterwards indicates either that the spawn was weak, or the bed overheated, the latter being as likely to be the cause of the failure as the former.

**Watering Cattleyas and Laelias (R. B.).**—In watering these plants always be guided by the appearance of the roots and the state of growth. When "in sheath" is rather a vague term, as much depends on the species. *Cattleya Mossiæ*, for instance, is in sheath while at rest during the winter; *C. labiata autumnalis* and *C. Gaskelliana* on the other hand, flower on the current year's growth, so that while resting they bear no flower-sheath. When advancing for bloom the great majority of Cattleyas and Laelias like a rather high temperature, with adequate moisture at the roots, as indicated by the great growing points of the latter. Give all the air possible without draughts, also not letting the temperature fall much below 65° by day. This will prevent a close moist atmosphere, as these Orchids thrive best in an airy spacious house. Keep the atmosphere of the case as dry as possible at this season, and wipe the glass inside to avoid drip.

**Mites on Bones (S. W. N.).**—The bones swarmed with the mites, which feed for the most part on animal substances, such as bones, cheese, and similar matter, but they do not confine their attacks to these matters, for they can and do feed on vegetable substances, such as flour, with little less gusto. It is *Tryoglyphus siro*, which may or may not feed on living vegetable matter, the evidence being negative so far, but this mite is certainly found associated with decay in vegetable matter; yet it may not be the cause of the decay. It is difficult, however, to connect any other organism with the decayed tissues, though the subject is a strained one, and nothing for certain known of the cause of the tissues perishing. We should not use the bones until they had been exposed to heat, say on a wood fire, placing them on the hot embers and covering them with the same. The slight charring would not injure the bones in the least; indeed, they may be used along with the wood ashes with great advantage in Vine borders.

**Slug-infested Ground (Dorset).**—The best plan would be to procure some freshly burned lime, lay it in small heaps convenient for spreading, and cover it with a little soil. The lime will gradually absorb moisture and slake, and when that is effected—the lime being hot and floury—spread it evenly on the ground and point in with a fork as soon afterwards as practicable. In such bad cases as yours one bushel of quicklime per rod of ground should be used, selecting mild and fair weather for applying the lime. If inconvenient to use the lime you may employ nitrate of soda at the rate of 1 lb. per rod, giving the ground a dressing before sowing or planting, and again when the crops or plants are starting into growth. It may be used on all crops with benefit, and will not injure any provided it does not rest in their growing centre or on the leaves. For plants in frames you may use lime water, placing a peck of quicklime in a tub and pouring on 30 gallons of water, stirring well, and letting stand forty-eight hours or more, then sprinkle on the plants after dark with a rose watering can, employing the clear lime water only. It is equally efficacious in the open ground, and by persistent use thoroughly efficacious.

# VEITCH'S SUPERB ONIONS

## VEITCH'S MAIN CROP.

This is a most desirable and perfect strain for exhibition or table use, and though generally grown for a main crop, is also an excellent keeper.

Per Ounce, 1s. 6d.

## VEITCH'S SELECTED GLOBE.

A very handsome globe-shaped variety, heavy cropper and excellent keeper, and forms an excellent companion to our Main Crop.

Per Ounce, 1s. 6d.

For full descriptions of the above, and many other CHOICE NOVELTIES & SPECIALITIES, see SEED CATALOGUE for 1895, forwarded gratis and post free on application.

## JAMES VEITCH & SONS,

ROYAL EXOTIC NURSERY,

CHELSEA, LONDON, S.W.

## SIX SUPERIOR VEGETABLES WORTH GROWING.

### BLAIR'S PROLIFIC CUCUMBER.

A handsome Show variety, very prolific, colour deep green. Mr. SPEED, Penrhyn Gardens, says, "A grand Cucumber for either winter or summer use. I have grown it this season, and like it very much." Per Packet, 1s. 6d.

### DUCHESS OF YORK MELON.

Fruit medium size, white flesh, colour golden, finely netted. A grand exhibition variety. Per Packet, 1s. 6d.

### PRINCE ALBERT VICTOR MELON.

One of the best grown, bright yellow, partially netted, flesh white and thick. A grand variety. Per Packet, 1s.

### EGERTON PEA.

The best late cropping Pea grown, height 4 feet. Mr. UPJOHN, Worsley Gardens, says, "I find it one of the most prolific and enduring croppers I ever met with. I have been gathering from July to October 20th." Per Quart, 1s. 6d.

### NORTHERN BEAUTY TOMATO.

An abundant and continual bearer, free setter, very early, intense deep crimson colour, and large handsome smooth fruit. Per Packet, 1s.

### PRINCE ALBERT VICTOR TOMATO.

Fruits large, flesh very solid, grand flavour, colour bright crimson. A very heavy cropper. Per Packet, 1s. 6d.

Descriptive Priced CATALOGUE Free on Application.

## DICKSON, BROWN, & TAIT,

Royal Seed Establishment,

MANCHESTER.

No. 761.—VOL. XXX., THIRD SERIES.

THIS renowned Handbook consists of 170 pages of finely illustrated matter, including full cultural directions for nearly all classes of Flowers and Vegetables.

Free by Parcel Post for 6d.

The "Dundee Weekly News" says of it:—"This well-known work has again made its welcome appearance for the season, and no one who desires to attain to some measure of success in the keeping of a garden, or has the ambition to distinguish himself as a competitor at the flower shows, should neglect procuring a copy. The advice given is sound, practical, and, above all things else, easy to understand and follow, and in these respects it is of much more real use than many expensive guides. Messrs. Dobbie & Co., the celebrated Rothesay Seedsmen, are the publishers.

One of the most successful professional gardeners in England says of it:—"Messrs. Dobbie's Catalogue and Competitors' Guide is vastly ahead of ordinary Catalogues. It is a most trustworthy Guide to the culture of Flowers and Vegetables."

An amateur of long standing writes:—"Your Catalogue is of great service. I would not take 5s. for it if I could not get another."

Messrs. DOBBIE & CO., Seed Growers and Florists to the Queen, Rothesay, beg to inform the readers of "The Journal of Horticulture" that a copy of the Twenty-eighth Annual Edition of "DOBBIE'S CATALOGUE and COMPETITORS' GUIDE" will be forwarded to any address per parcel post on receipt of SIXPENCE in Stamps.

Please apply early.

DOBBIE & CO.,  
ROTHESAY.

## Journal of Horticulture.

THURSDAY, JANUARY 24th, 1895.

### MAKING FLORAL WREATHS.

THE pleasing custom of sending wreaths or crosses as a last tribute of regard to those who have passed away continues to be done as much if not more than ever; nor is it likely that a custom which appeals so gently to the finer feelings of human nature, and helps to lighten the burden of grief by surrounding the sufferers with sympathy, will ever fall into desuetude among civilised people, for what can better soften the sadness of these solemn times, or speak in a truer spirit of hopefulness of the great hereafter than flowers, those fragile emblems of a Creator's power?

Gardeners are frequently called on to make wreaths for such occasions, and it behoves them to carry out the work to the best of their ability, because the results of their efforts are placed side by side with floral devices of various descriptions, many of which are contributed by professional florists of repute, who invariably have abundance of the most suitable flowers for the purpose to select from. This, combined with the expertness in making up which comes from constant practice, insures the production of an artistic and well-finished device, beside which one of meagre appearance cuts but a sorry figure. "Aim high" should therefore be the gardener's motto when carrying out work of this description.

Many different methods are resorted to in wreath-making, and equally good results may be obtained in various ways. Wire frames may be purchased cheaply, and answer the purpose for which they are intended admirably; flat rings of wood of the required diameter also do very well. I prefer, however, to make my own frames. Galvanised wire about the thickness of that employed for wire fencing answers well for wreaths 18 inches or 2 feet in diameter; for smaller ones slightly thinner wire will do, and at any time when no wire sufficiently stout is at hand the difficulty is easily overcome by using it of double thickness, simply twisting it together so as to form a circular frame, and if necessary to still further strengthen it binding it together with thin wire. I seldom, however, find it necessary to do this. When this part of the work is completed a

true circular shape can readily be obtained by hammering a little here and there.

A good coating of moss should next be fastened in the frame, green carpet thread or wire answer equally well for this purpose. On one side the moss may be left with a rather flat surface, and on the other full and rounding. Should a large wreath be required, *i.e.*, one 3 feet or upwards in diameter, it is a good plan to use two rings, and place one inside the other an inch or two apart, fastening them together by means of wood bound on at intervals, and thin wire interwoven all round; a firm circular base is then obtained, which when formed into a wreath will not lose its shape when handled. Several large wreaths sent out by florists which have come under my notice were, to my mind, far too "shaky" in this respect, and the only advantage that could be claimed for them was that they were somewhat lighter in weight than others of the same size made substantial enough to retain their proper form.

The next matter requiring attention will be the wiring of the flowers, but before doing this it will be necessary to settle what method of fastening them on the foundation shall be adopted. Some wreath makers bind them on with wire, and practically finish each part as they proceed; others bind on a fringe of Fern, and fasten the flowers by thrusting the mounting wires through the moss, and then turning the ends and pushing them into the moss again. As far as appearance goes equally good results may be obtained by either method, but as the latter is the most expeditious way of doing the work I prefer it, notwithstanding the fact that some object to it on the score that the flowers sometimes fall out of position. This, however, is more imaginary than real, and only occurs when the work has been improperly done. Should it be decided to fix the flowers on the framework in the way I have just described, they must be mounted on rather stout wires of good length.

When making very large wreaths it is a good plan to wire each flower separately, then make them into little bunches before securing them to the stout wire. To make a good wreath built up well in the centre abundance of flowers are required, for although it is essential that a light surface be obtained, this should not be secured by arranging the flowers so thinly that the wires and moss are visible between them. Wreaths which sometimes look well at first sight will not bear close inspection by reason of this defect.

The lightness of surface so desirable ought to be obtained by employing comparatively heavy flowers for a groundwork, and dotting them, so as to form an upper surface, with lighter ones. Chrysanthemums, Camellias, Tulips, Eucharises, Gardenias and Callas are all excellent for groundwork, and Roman Hyacinths, Lily of the Valley, Jasmines, Spiræa japonica, Freesias, Marguerites, and numerous species and varieties of Orchids, as well as many other flowers when in season, are admirably adapted for giving lightness. Some flowers, by reason of the boldness of their outline, make beautiful wreaths without the admixture of other flowers. Callas and *Lilium Harrisii* rank among the best for this purpose. Violets are also in much demand, sometimes because of their delightful perfume, at others because they were the favourite flower of the departed ones; but from an artistic point of view wreaths made entirely of them do not compare favourably with others made from the various kinds of pure, rich, white flowers.

Some wreath makers, in my opinion, make the mistake of using too much greenery on the surface. A delicate green Fern frond here and there enhances the beauty of the whiteness around, but the bulk of the greenery ought to be employed as a fringe. When Fern fronds are scarce the use of some of the lightest forms of *Cupressus Lawsoniana* will help to economise without detriment to the general effect.

In packing wreaths for long journeys stout boxes ought to be used, and these large enough to admit of the wreaths being placed in the bottom without crushing the extremities of flowers or

Fern. To secure in position, two strings should be passed under the flowers, tied to the foundation, then drawn through holes bored in the bottom of the box, and tied on the outside. It is also advisable to have printed or written on the lid, "Please cut the string at the bottom of the box (on the outside) before taking out the wreath."

During frosty weather boxes containing wreaths should be lined with cotton wool and tissue paper. The lids must also be lined inside with the same materials, held in position by means of tacks, then if the paper forming the inner lining of the box is drawn slightly over the outer edges of it, when the lid is placed on and secured with string the whole of the lining will be held in position without resting on or disfiguring the enclosed flowers.—H. D.

### FORWARDING THE WORK OF SPRING.

WHETHER gardens are large or small each season brings with it its own particular work. We can nevertheless by looking ahead and making the most of the time and labour at disposal forward considerably the work of spring. When the weather is showery at this season, the men waste a great amount of time in running backwards and forwards in sheltering from the rain, and to all appearances enjoy it, indeed some of them would rather get wet than be closely employed in washing and cleaning the houses and sheds. Yet this work must be done, and it should be done now. With clean houses and clean plants we look forward for a good start when the growing season arrives. The present is also a good time to repair broken trellises instead of later in the season, or to replace them with new ones if necessary. If the timber is cut to the right sizes labourers can make trellises as well as joiners, often in less time and certainly at a cheaper rate. If the trellises are to be used in warm moist houses dry material should be used, to be well painted with red lead and oil as they are put together, then coated with other colours according to fancy. For many purposes painting is unnecessary. Sheds and the men's room should be thoroughly cleaned, when they will be presentable for twelve months.

In other departments tools can be looked over, repaired, cleaned, painted, and those worn out replaced by new ones. All should be in readiness for use when needed in the spring. Watering cans and barrows also come under this head, and when repaired should be protected by a coat of paint. There is generally time and opportunity for doing work of this nature where a keen desire exists to have all things in order. Seed and cutting boxes should be ready for use to prevent delay when that is most dangerous. When all is in readiness work at the busy season proceeds quickly. Stakes are often crowded away in a confused mass, and instead of repointing, sorting, and tying them in bundles of various sizes they have to be sorted when needed: others also have too often to be sent for when urgently wanted for Carnations, Chrysanthemums, and a host of other plants. This is a mistake, and all possible provision for the season should be made now. A few might easily be pointed by each man in the morning and perhaps again at night before it is quite light enough to commence the ordinary indoor work, or after it is too dark in the afternoon. The stakes soon dry if the pointed end is inserted in a pot of sand, and should then be tied into bundles weekly. An adequate supply of labels and pegs must also be prepared.

Charcoal can be sorted in sizes ready for use, all pots washed and stored away; crocks, too, for all important work should be washed. If a little more attention was paid to this matter we should have fewer water-logged plants; use dirty crocks and the drainage soon becomes choked. The crocks can be sorted by passing them through sieves of various sizes, then, when the potting season arrives, the labour in draining the pots is reduced to a minimum. Peat can be pulled ready for use as needed for Orchids, and the small particles shaken out will come in useful for small Ferns and other plants that require a little peat. Loam may be broken up, and this with leaf mould stored ready for use.

Manures of various kinds should be under cover, and when dry enough passed through sieves as opportunity offers. The supply of chemical stimulants may be ordered for use when wanted; but it may be well to note that superphosphate of lime if kept very long after being manufactured partially goes back to the insoluble condition.

It is surprising with what facility work can be done during the busy months of the year when everything needed is ready to hand, and it is only by the exercise of foresight that the best can be made of the labour provided, which is little enough in most gardens.—WM. BARDNEY.

LÆLIA ANCEPS CRAWSHAYANA.

At the last meeting of the Orchid Committee at the Drill Hall, only one first-class certificate was awarded, and this was for the variety so well depicted in the woodcut, fig. 12. This is a magnificent form of *L. anceps*, and has unusually broad petals, the colour of which is a very rich rosy-purple. The sepals are long, and the shade is somewhat paler than the former. The lip is singularly handsome, the outer portion being of the richest velvety crimson hue, while the throat is yellow veined with beautiful crimson-brown. It is a superb variety, and thoroughly deserving of the honour conferred. It was exhibited by De Barri Crawshay, Esq., Sevenoaks.

THE LATE DUCHESS OF MONTROSE'S ORCHIDS.

As will be seen from an advertisement Messrs. John Cowan and Co., Liverpool, have purchased the Sefton Lodge, Newmarket, collection of Orchids, and that a priced catalogue of them is being prepared, of which copies will be posted to applicants on the 26th inst. It will be remembered that a particular purchase of these plants created some interest among the horticultural and legal community a few years ago.

CALANTHE VEITCHI AT ROOK'S NEST GARDENS.

While on a visit to Mr. Friend, the able manager at these fine old gardens, I was struck with the grand display of *Calanthe Veitchi*. Seldom, if ever, have such magnificent specimens been seen of this beautiful winter-flowering and decorative Orchid. Mr. Friend had a group of about sixty plants, all in the best possible condition, many of the spikes measuring 5 feet 8 and 5 feet 9 inches in length, bearing between sixty and seventy flowers, which I could count at the time of my visit. The colour was excellent, and the finish beautiful. Orchids are evidently grown well in these gardens, as I saw a great many others in the best possible condition, including some grand masses of *Dendrobium nobile*. A few remarks on the management of *Calanthes* from Mr. Friend would, I feel sure, be of great interest to readers of your valuable paper.—WM. PENTON.

CYPRIPEDIUM NIVEUM.

In the Orchid column of the *Journal of Horticulture* (page 25) there is a note on the delightful little *Cypripedium niveum*, in which it is spoken of "as difficult to manage" and "liable to the dreaded Orchid disease known as spot." Of this latter I am not so certain, as I do not think the dying off can possibly be attributed to disease, but simply dwindling away for lack of support, which it does not find in the ordinary peat and sphagnum diet.

Having been most successful in cultivating *C. niveum* and its allied species *C. bellatulum*, I am in a position to prove wherein most growers fail. About six years ago a few small pieces came under my care, these being potted in peat and sphagnum. Instead of increasing in size, they became gradually smaller, and I feared I should lose the whole of them. Eventually, and as a last resource, they were repotted. The compost consisted of limestone from the carboniferous formation, loam, and a little peat and sphagnum, working a few small pieces of limestone in the latter. I may mention that the limestone was used in place of crocks for drainage, filling the pots to within an inch of the rims.

Almost immediately the plants commenced to improve, until now they are healthy, and both grow and flower very freely. My opinion is that when the plants have failed, although limestone may have been used, it is on account of this latter not being of the proper description—i.e., from the carboniferous formation. I have

also a plant that has no compost at all, the roots being simply bedded in the limestone and surfaced with moss. If anything, this plant is thriving better than the others. The moss retains the moisture, or rather, keeps the stones from drying.

Water, on account of the material they are potted in, is poured into them daily, and during the spring and summer as well. The roots for the size of the plants are wonderfully large, and they entwine themselves amongst the limestone and cling very tenaciously, demonstrating as plainly as possible that it is the limestone alone, and not any humus-forming compost, on which they thrive.

Some years ago I remember reading of this *Cypripedium* succeeding where the grower had added a fair proportion of loam, using crocks in the ordinary way for drainage. Possibly the success was through lime in a sufficient quantity being present in the loam.—A. YOUNG.

CATTELEYA TRIANÆ.

ALTHOUGH not widely distributed geographically in comparison with some other species, this beautiful winter blooming *Cattleya*

FIG. 12.—LÆLIA ANCEPS CRAWSHAYANA.

is extremely variable, hardly two plants bearing flowers exactly alike. At least fifty varieties have been described, and many of them figured in the *Journal of Horticulture*, but as many of these are very rare and some absolutely unique, no good purpose would be served by describing them. Suffice it to say that they vary in colour from pure white, through many shades of pink, rose, and magenta to deepish purple. The largest flowers measure upwards of 8 inches across the petals, and it must be a very poor form indeed to be less than 5 inches.

*C. Trianæ* should be grown in a structure heated in the summer to 60° by night, and by day about 70°, rising 5° or 10° higher by sun heat. The winter night temperature must be kept as near 55° as possible, and never be allowed to go below 50°. As little shading as possible should be given, and this must be provided by moveable blinds. The larger the house and the farther in reason the plants are arranged from the glass the less shading will be required and the better the plants thrive.

The compost for *C. Trianæ* should be used in a somewhat rougher condition than most Orchids require, and must consist of the best materials only. About three parts of peat to one of sphagnum, with abundance of small crocks and charcoal, will suit

admirably. The plants should be potted soon after flowering, using thoroughly clean pots two-thirds filled with drainage. For the larger plants a small pot may be inverted over the hole of the larger one, and the space around and above it filled with crocks; this makes them lighter to handle, and insures a free passage for the water. The drainage must be covered with the rougher portions of the sphagnum to prevent the peat being washed downwards by watering.

Fix the plants in position, allowing the base of the leading pseudo-bulbs to be about an inch above the level of the pot, and proceed with the dibber to lay the compost evenly and firmly about the roots. See that the plants are so firmly fixed, by staking and tying if needful, that they cannot rock, or the young brittle roots are very liable to be snapped off in moving the plants. The ends of the moss and peat must be clipped off neatly, and the compost left a little higher in the centre than around the rims of the pots. Water very sparingly at first, giving more as the roots begin to run in the new compost, but avoid at all times wetting the pseudo-bulbs more than is absolutely necessary. When growing freely the compost should never be very dry, but if frequent syringing between the pots is practised, it will not be necessary to give water at the roots oftener than twice or thrice a week, according to the weather. A free circulation of air is of the greatest importance in growing Cattleyas, and during the summer months the lower ventilators should be partly open day and night.

*C. Trianae* is subject to the attacks of white scale, which must be kept in check by sponging, or the appearance and health of the plants will suffer in consequence. I have described the treatment of this Orchid somewhat in detail, as it is similar in many respects to that required for all the labiate group of Cattleyas. The chief difference is that the summer and autumn blooming species, as the true *C. labiata*, *C. Gaskelliana*, and others, require repotting in the spring instead of immediately after flowering. A few kinds, too, like rather more heat, as mentioned in these pages under the headings of the respective species. The resting and growing seasons must be decided, but the plants ought not to be over-dried or allowed to shrivel.

Imitate Nature as far as practicable by a gradual increase and fall in the temperature in the spring and autumn, and remember that although the plants in a house must, to a certain extent, be treated collectively, the individual wants of each separate plant should always be kept in mind.—H. R. R.

#### MUSHROOMS IN PEAT MOSS AND SAWDUST.

I HAVE not had experience with peat moss for Mushroom growing after it has been used as litter, but perhaps my practice of sawdust used in the same way, and afterwards for making Mushroom beds, may be helpful to "R. C. W." (page 518). At first I had considerable difficulty in getting the beds to bear regularly, and I thought if sawdust was used in the loose boxes I should have to give up Mushroom growing, but by working the materials about more, and having the heap turned daily for a fortnight, and adding chopped turf, also Oak or Beech leaves, well mixing all together, I have had good beds of Mushrooms, and have them at present bearing well. I called on a neighbour, Mr. Dalby, at Greenham Lodge, near Newbury, a few months since, and he had good Mushroom beds in bearing. They were covered with turf cut thin and beaten down like miniature lawns, but of course the growth was blanched. He assured me that the Mushrooms came cleaner, more free from grit, and the beds continued longer in bearing than when cased with soil in the ordinary way. I have since tried the plan, and so far it answers very well.—R. M., *Newbury*.

#### MARGARET CARNATIONS.

THE Margaret Carnations are comparatively easy to cultivate, and from one packet of seeds a great variety of colours may be obtained, many of which are almost equal in beauty to the best named varieties. Grown as a pot plant for greenhouse or drawing-room adornment it has few superiors. Graceful in habit, and throwing up a profusion of flowers, the sweet scent and bright colouring cannot fail to attract admiration.

If planted out during the summer, taken up before the severe frosts set in, and placed in a light airy house, an abundance of bloom may be obtained during the greater part of the winter, the usefulness of which, those who are in the habit of treating it thus can amply testify. The best mode of cultivation I find is to sow the seeds during February and March in shallow pans, a light compost being used, and the seeds thinly covered with fine soil. Place in a moderate heat until the plants are large enough to be handled, then put singly in small pots, and place in a cool house close to the glass. When they again want potting the number required for pot plants should be placed in well-drained 6-inch pots in a compost consisting of stiff loam, leaf mould, and sand, with a little decayed manure added. A cool-house shelf or frame will then suit them admirably, and as they grow attention should be given to staking and tying. If green fly asserts itself a light fumigation will be found necessary.

The remainder of the plants not required for pot culture may be

planted out on any light sunny border, to be taken up and potted in the autumn for winter flowering, and by this means a continuation of bloom may be kept up far into the winter months. Care should be taken when lifting the plants to insure their having good balls of earth attached, for if the roots are broken they will turn sickly and die. A comparatively dry atmosphere will be found most suitable for wintering the plants, from which, under favourable circumstances, an abundance of bloom may be obtained.—G. HOLLINGWORTH, *Alton Towers*.

#### HARDY FLOWERING TREES AND SHRUBS.

ALMOST every garden, no matter what its pretensions, has a shrubbery, and frequently this is the most interesting feature of the place. In a well-managed shrubbery there always appears to be something fresh, some object of interest that one has not noticed before. By judicious planting a good supply of flowers may be had during the whole of the year. I am sorry to say, however, many of our shrubberies are more of the character of wildernesses during the winter, when, by reason of the dullness every effort should be made to make the garden as bright and cheerful as possible.

As year succeeds year an enormous number of new flowering trees and shrubs are introduced to notice, and a good many old and almost forgotten kinds are rescued from an undeserved oblivion. These, of course, tend to swell the list to such a formidable extent that one scarcely knows where to begin. I have decided, however, to make no mention of trailing shrubs and those which must be grown as wall plants, neither, despite their undoubted utility, shall I refer to Conifers.

#### WINTER FLOWERING KINDS.

For convenience, I shall divide my subject under four headings—Spring, Summer, Autumn, and Winter—and as winter is with us I will begin with that season. As one would naturally expect, the list of winter flowering trees and shrubs is short, but nevertheless there are sufficient to make a grand show. The best known, and I think I may say the most useful, is the *Laurustinus*, and it is so well known as to need no description. Another shrub equally well known and beautiful is our native *Furze*, *Ulex europæus*. *Ulex europæus flore-pleno*, the Double-flowered Gorse, is still more beautiful, and when it does well its masses of golden flowers completely cover the plant.

The Cornelian Cherry, *Cornus mas*, is quite a picture in February. This is a small-growing tree, about 15 feet in height, and bears a profusion of bright yellow flowers, which appear a short time before the leaves. *Erica carnea* is not nearly so well known as it deserves to be. This dwarf hardy Heath produces its whorls of pale red flowers in great profusion early in January, and frequently in December. The *Daphne* is a very useful shrub, and a good supply of sweetly scented flowers may be obtained from January to July. *D. mezereum* is probably the best known, and is deservedly popular. The flowers are produced early in February, and vary in colour from pinky white to red. *D. laureola*, the Spurge Laurel, bears its greenish yellow flowers in January. Its chief recommendation is the early date of flowering.

#### SPRING FLOWERING KINDS.

*Magnolia conspicua* is the most beautiful of all the early flowering trees. Its height will range from 20 to 50 feet. The flowers are of good size and shape, white, often tinted with purple, and very fragrant. The leaves appear somewhat later than the flowers, and are of a beautiful pea-green colour.

Of spring flowering shrubs the foremost position must be given to the Ghent Azalea. The variety of colour is very wide. There are pure white, bright red, pinks, and yellows represented. To be really effective Azaleas should be planted in masses, and are very beautiful in the flowering season. In the morning, and again in the evening, the perfume is delicious. Then there are the Rhododendrons. We have *R. arboreum* with its white and rose flowers, and the rose-coloured *R. dahuricum* open in March, followed by a succession of most beautiful and useful flowers of almost all colours, finishing with *R. caucasicum*, rose-coloured outside and white within, in August; and *R. album* with its rather small white or cream-coloured flowers as late as November. At this period (spring), we have the Horse Chestnut with its abundant spikes of pinky-white flowers, which contrast finely with the rich green of its ample foliage. The Judas Tree, *Cercis siliquastrum*, is well worthy of a place. Its rosy-purple flowers clothe the branches in May, and are followed a little later by the peculiarly shaped leaves. The Flowering Dogwood, *Cornus florida*, bears flowers of a greenish yellow, which are surrounded by an involucre of large white bracts.

The Thorns are sufficiently numerous to require a long chapter to themselves, but as they are so well known I will content myself with giving the names of a few varieties most worthy of cultivation:—*Crataegus Azarolus*, *C. coccinea*, *C. crus-Galli*, *C. Douglasi*, *C. flava*, *C. oxyacantha punicea* and the double form, *C. pyracantha* and *C. tanacetifolia*. *Halesia tetraptera*, the Snowdrop Tree, is very welcome, as also is *Laburnum vulgare*. *Magnolia acuminata* is not met with nearly so often as it should be, for apart from its flowers, which are rather insignificant, it is a fine handsome tree, 45 or 50 feet high, bearing oblong leaves quite 8 or 9 inches long. *M. glauca* does not attain the noble height of the former, but its fragrant white flowers make it very desirable, while *M. grandiflora* is more usually seen as a wall plant. There are also such well-known trees as the wild Cherry, Bird Cherry, the Common and Portugal Laurels, and numerous others, all very beautiful in their places.

Amongst spring-flowering shrubs we have *Andromedas* and *Berberises*. The Allspice (*Calycanthus*) is not nearly so well known as it deserves to be. It has a very graceful habit, and the flowers, which vary in colour from the dark crimson of *C. occidentalis* to the lurid purple of *C. floridus*, are deliciously scented. The genus *Cornus* has a considerable number of worthy varieties. *C. alba* bears white flowers in May; the tips of its branches have a bright red tint, and it has white fruit in the autumn. *C. sanguinea* owes its name to the colour of its branches. The *Cotoneasters* are so well known as to need scarcely any description, their bright berries being very attractive during the winter. *C. microphylla* is the best known, and of it Loudon says that "grafted standard high on the Thorn this shrub forms a singular and beautiful evergreen tree." *C. bacillaris* is of different habit to the former. Its clusters of beautiful white flowers on upright branches render this shrub even more attractive in the spring than in the winter. *Cytisus albus* (the white Spanish Broom) is of easy culture, and in May is one mass of pure white flowers. *C. Adroini*, *C. nigricans*, and *C. scoparius* are good examples of the yellow Brooms, and the colour may be varied with *C. albus incarnatus*, which is of stronger growth than the white variety, and bears very pretty rose-coloured flowers. *C. purpureus* is a dwarf shrub, and, as its name implies, has purple flowers; and *C. scoparius Andreanus* is very showy.

The majority of the *Deutzias* are among the most hardy of our dwarf flowering shrubs. *D. crenata* will attain a height of 6 or 8 feet, and in the spring is covered with white flowers; the double form of this is very handsome. *D. gracilis* is well known, and is more usually grown as a pot plant, but, if planted in a moderately warm corner, flowers very freely. *Weigela rosea* is well worthy a place in every shrubbery. It flowers about the middle of April, and the colour varies from a pure white to a deep pink. There are several forms, notably *D. rosea Lava'li*, with bright crimson flowers; *D. rosea candida* is pure white; and *D. grandiflora*, which is of stronger growth than *D. rosea*, and bears larger flowers somewhat later in the season. The *Ericas* are very useful, their dwarf habit making them particularly valuable for the edge of the shrubbery. *Pæonia Moutan*, the Tree Pæony, was introduced from China and Japan in 1789. The first introduced had single flowers, but now there are many beautiful varieties, both single and double, in cultivation. The best known and most useful of the *Philadelphus* is *P. coronarius*, the Mock Orange or *Syringa*. *P. grandiflorus* flowers about the end of June, and the first-named a month earlier.

The Flowering Currant, *Ribes sanguineum*, is an old favourite. *R. cereum* is not so well known. This is a dwarf variety, which from a little distance has the appearance of a Gooseberry bush. It is of very neat growth and has no spines. *Robinia hispida*, the Rose Acacia, bears its large rose-coloured flowers in May. *Syringa vulgaris*, the common Lilac, is a common shrub, and an old favourite that was introduced from Persia and Hungary in 1597. Amongst the best varieties of Lilac are *S. persica*, *S. japonica*, and *S. vulgaris alba*.

#### SUMMER FLOWERING KINDS.

The varieties of summer flowering trees and shrubs are not nearly so numerous as those which flower in the spring. There are, however, a good many that commence flowering at spring time and continue throughout the summer, and in some instances into the autumn. *Ailantus glandulosa*, the Tree of Heaven, was introduced from China in 1751. It is a tall tree, frequently reaching 60 feet in height, bearing greenish-yellow flowers of rather an unpleasant odour. The bronze foliage of *Catalpa bignonioides* renders it very conspicuous, and in July when in flower it is one of the most ornamental trees that we have. The flowers are borne in spikes at the tips of the branches, and are large and numerous. *C. speciosa* is taller, more erect, flowers earlier, and is more hardy than the former. Few dwarf shrubs are more beautiful than *Choisya ternata*, and it is usually quite hardy in the south and south-west. The Gum Cistus when planted in a slightly sheltered position thrives well, especially if by the side of a pond, when it will easily reach a height of 5 or 6 feet. Its white flowers resemble a single Rose, but do not last long. The *Kalmias* usually thrive well in Devonshire. *K. latifolia* especially is extremely useful for cutting from, as also are *K. angustifolia* and *K. hirsuta*, both of which are dwarf, neat growers. There are a good many varieties of Privet worth cultivating. The flowers are usually white, and the purple berries in autumn are very conspicuous. *Ligustrum ovalifolium* is largely grown as a hedge. *S. vulgare* is very fragrant, and has several good varieties, such as *L. v. buxifolium*, *L. v. fructu-luteum*, *L. v. sempervirens*, and *L. v. variegatum*.

*Pernettya mucronata* bears its white bell-shaped flowers in July, and they are succeeded by attractive purple berries. The leaves are small and prickly, and the young branches have a pinky tint, which in winter enhances its value. *Rhus typhina*, the Stag's Horn Sumach, or Vinegar Tree, has large hairy leaves, and masses of peculiarly formed greenish-yellow flowers. The Common Elder (*Sambucus nigra*) is highly ornamental, its masses of flowers and shining black berries being very effective. The Golden Elder, *S. aurea*, is not so extensively planted as it should be. By pinching the young growth it may be kept dwarf, and the foliage a golden colour through the summer. *S. n. laciniata* and *racemosa* are both worth growing. *Spiræa ariæfolia* is a very graceful shrub, its nodding panicles of yellowish-white flowers being very elegant. *S. Douglasi* and *S. gracilis* are also excellent. The Guelder Rose (*Viburnum Opulus*) is well known, and justly popular. It is a native shrub, and produces great numbers of white flowers, that are succeeded in the autumn by clear scarlet berries, and these, together with the bright colour of the autumn foliage, make it an object of great beauty.

#### AUTUMN FLOWERING KINDS.

None of the autumn-flowering trees and shrubs is better known than *Arbutus unedo*, the "Strawberry Tree," not so much on account of its flowers as of its fruit, from which it receives its name. *A. Menziesi* is worth a place if only on account of the sweet scent of its flowers. *Andromeda dealbata* only requires to be better known to be appreciated. This shrub grows about 4 feet in height, and the whole of it, stems and leaves, are of a pleasing grey colour. *Aralia manshurica* was introduced from China in 1866, and, like many plants from the Celestial Empire, has a curious appearance. The flowers are white, and borne in long racemes. The flowers of *A. spinosa* are produced in October in large panicles. *A. Sieboldi* needs no description. *Clerodendron trichotomum* bears very fragrant white flowers in September. This is a strong growing shrub about 8 feet in height, and is very distinct in appearance. The flowers of *Daphne cneorum* are of a very bright pink and deliciously scented, and it has the rather unusual, but very acceptable, habit of flowering twice, first in April and again in September, which is a great point in its favour. *Hamamelis virginica* commences flowering in October and continues until February.

*Olearia Haasti* is a very pretty dwarf shrub. The flowers are white and produced in flat clusters. *Lespedeza bicolor* should be more often met with. Its flowers are borne in racemes, and are of a bright red purple in colour.

Numbers of other flowering trees and shrubs have doubtless been omitted, but those mentioned may be taken as amongst the very best, and are such as will, I am confident, find favour with everyone.—(Read by Mr. A. C. Bartlett, Dropmore, before the Maidenhead Gardeners' Association.)

#### THE CHRYSANTHEMUM YEAR BOOK.

WE have received a copy of this well-printed, attractively illustrated Year Book, edited by Mr. C. Harman Payne, F.R.H.S. It consists of eighty-eight pages of letterpress. The frontispiece contains an admirable portrait of Sir Edwin Saunders, F.R.C.S., F.G.S. The Holmes Memorial cup and Kingston vase, as well as the N.C.S. challenge shield, are represented. A few new Chrysanthemums are depicted, also a stand of blooms as exhibited in 1854, and which would not win high honours now. There is a varied assortment of matter by able writers, and the new annual is worth its price—a shilling. It is published by Mr. E. W. Allen, 4, Ave Maria Lane, E.C., and can be had from the Secretary of the National Chrysanthemum Society.

#### PRINCESS VICTORIA.

I AM sending you a few flowers of Princess Victoria Chrysanthemum which I think are the best I have seen at this season of the year. No special cultivation has been afforded, nor have the plants been (as you will see) disbudded. This variety ought to be a great acquisition for market growers and general decorative purposes—they are flowers of good substance, and white.—G. INGLEFIELD, *Tedworth*.

[The clusters are very beautiful, the central flowers 4 inches, the surrounding flowers 3 inches in diameter; florets smooth, gracefully drooping, creamy white, with the faintest suspicion of a rose tint. We have seen no better examples for wreaths, vases, or general decorative purposes at this season of the year.]

#### NATIONAL CHRYSANTHEMUM SOCIETY.

THE General Committee of this Society held a meeting at Anderton's Hotel on Monday last, when Mr. R. Ballantine presided. After the minutes of the previous meeting had been confirmed a large amount of attention was devoted to business of a formal nature, concerning alteration of rules and other matters requiring to be dealt with by the annual meeting. The schedule sub-Committee recommended the appointment of the following Judges at the Society's shows in 1895. For the October show.—Mr. E. Beckett and Mr. G. Langdon. For the November show.—Plants, Mr. Lync and Mr. Prickett; incurved blooms, Mr. G. Gordon and Mr. J. W. Moorman; Japanese, Mr. Edwin Molyneux and Mr. J. Parker; table decorations, Mr. J. Bevan and Mr. J. Hudson; fruit and vegetables, Mr. A. F. Barron and Mr. J. Tegg. For the December show.—Mr. W. H. Lees and Mr. H. Briscoe-Ironside. Several new members were elected, the Secretary announcing that during the year 1894 fifteen societies were affiliated, and a total of 141 Fellows and ordinary members elected up to the 31st December.

The Society's new work, entitled the "Chrysanthemum Year Book," was announced as having been published since the last meeting, and can be obtained of the Secretary. A vote of thanks to the Chairman brought the meeting to a close.

#### HIGHGATE AND DISTRICT CHRYSANTHEMUM SOCIETY.

THE annual general meeting of the above Society took place on the 15th inst., the President, Percival Hart, Esq., presiding. The Treasurer submitted the balance-sheet, which showed an income of £124 11s., and a balance in hand of 6s. 5d. The President, in moving that the balance-

sheet be passed, congratulated the Society on being able to commence the year with a balance in hand, and also on having Lady O'Hagan as an additional Lady Patron. The Secretary presented the report for the year, which stated that, notwithstanding the wet and unfavourable summer, the exhibition was pronounced by visitors, subscribers, and the Press to be one of the best exhibitions that the Society has held. Votes of thanks having been passed to the President, Vice-Presidents, and donors of special prizes, and officers, the election of officers for the present year took place, and resulted as follows:—President, Charles Catling, Esq.; Treasurer, Mr. J. M'Kerchar; Secretary, Mr. W. E. Boyce; Auditors, Messrs. G. Atkins and G. W. Smyth. The eleventh annual exhibition will take place on October 31st and November 1st next.

#### JAPANESE UP TO DATE.

THE selections of varieties for the twelve new varieties and twelve decorative are appended hereto. It will be seen that even greater diversity of opinion is expressed than has been the case with the selections previously given.

#### VOTES FOR TWELVE NEW VARIETIES.

30	Duchess of York	2	Primrose League
23	Mrs. W. H. Lees	2	Reine d'Angleterre
23	Miss Maggie Blenkiron	2	Good Gracious
21	Madame Carnot	2	Eda Prass
20	Niveus	2	Autumn Tints
14	H. L. Sunderbruch	2	Mrs. H. J. Jones
14	Duchess of Wellington	2	Charles Cox
14	Mrs. E. S. Trafford	2	Alice Seward
14	Louise	2	W. G. Newitt
13	Mons. Panckoucke	2	Henri Jacotot Fils
13	Rose Wynne	2	C. Lawton
13	Hairy Wonder	2	Black Prince
		2	Col. Bourne
		2	Mrs. Airdrie
11	Mrs. W. J. Godfrey	2	Mons. Georges Biron
10	Commandant Blusset	1	Yellow Primrose League
8	Wilfred Marshall	1	Mrs. H. T. Drewett
8	Souvenir de Petite Amie	1	Lady E. Sannders
7	Mrs. C. E. Shea	1	R. Ballantine
7	Madame C. Molin	1	J. P. Kendall
7	L'Isere	1	Silver King
7	Mdme. Ad. Chatin	1	Princess May
7	Inter Ocean	1	Duchess of Devonshire
6	Golden Gate	1	Viscountess Hambledon
6	Col. Chase	1	Wyndmoor
6	Richard Dean	1	Madame Ad. Moulin
6	Pallanza	1	Madame Calvat
6	Philadelphia	1	C. H. Curtis
6	T. Wilkins	1	Dr. Hull
6	Mrs. Dr. Ward	1	Mdlle. Thérèse Rey
6	Directeur Tisserand	1	Secretary Farson
6	Sir Edwin T. Smith	1	E. L. Jamieson
6	Madame Rozain	1	Le Rhône
5	The Queen	1	Tribune
5	Miss Rita Schroeter	1	A. T. Ewing
5	Mrs. E. G. Hill	1	W. H. Atkinson
5	President Borel	1	Le Grandson
5	Lilly Love	1	Edith Rowbottom
4	Challenge	1	No'cutt's Seedling Yellow
4	Pride of Swanley	1	Le Verseau
4	Mrs. E. G. Whittle	1	Baronne de Buffières
4	Dulcie Schroeter	1	International
4	Mons. Ad. Giroud	1	Exmouth White
4	Violetta	1	Mons. P. Dewolfs
4	La Meije	1	Thomas Davidson
4	Mons. Charles Molin	1	Madame Octavie Mirbeau
3	Frank Wells	1	Guirlande
3	Prefet Robert	1	Madame Isaac
3	Duke of York	1	Desdemona
3	Mrs. C. Cox	1	Th. Denis
3	Welton Beauty	1	Mr. D. Airdrie
3	Mrs. G. J. Beer	1	F. Waterton
3	Mdme. Cambon	1	Mdme. Auguste de Lacvievier
3	C. Harman Payne	1	Mrs. Walter Cutting
3	Eugène Dailedouze	1	Pearl Beauty
3	Lady Ridgeway	1	Undine
3	President Armand	1	Excelsior
3	W. H. Fowler	1	Maud Dean
2	Sarah Hill	1	Deuil de Jules Ferry
2	Captain Torrens	1	Chenon de Leché
2	Mrs. R. J. Hamill	1	Mons. Hoste
2	Mrs. George Gordon	1	James Lynch
2	Robert Owen	1	Dorothy Frankland
2	Charles Blick	1	Madame Ricoud
2	Mdme. Charles Capi'ant	1	Anna Broom
2	John Machar	1	Vice-President Calvat
2	Miss Goschen	1	Madame Edouard Rey

#### GRAPE GROWING IN KENT.

I HAVE been much pleased by reading very temperate letters on the above subject. During a twelve years' residence in Kent I saw many good examples of Grape culture, and in my opinion neither north nor south can claim a monopoly of good growers of horticultural produce. Those who saw Mr. Kirk's Grapes at the Crystal Palace last

year would not wish to begrudge the praise he received for such a fine exhibit, particularly the bunches of Madresfield Court and Mrs. Pearson; and further, the fine condition in which they arrived after such a long journey was very notable; but, given the convenience, there is no reason why equally good Grapes should not be grown in Kent. I think the finest young Vines in fruiting condition I ever saw were at Lambton Castle, about the year 1872, under the care of Mr. Hunter—the same Vines which a few years after produced the record bunch of Black Hamburgh Grapes. A year or two later I paid a visit to Mr. Johnson of Bayham Abbey, where Kent and Sussex join, and his Vines were equally good as at Lambton. I am pleased to record that both those gardeners are still in the same charge. They are both kind and genial men, given to hospitality. I did not ask them from which side of the Tweed they came from, but both are alike good representatives of British gardeners.—R. M., *Newbury*.

### ZONAL PELARGONIUMS IN THE WINTER.

MOST growers experience some difficulty with Zonal Pelargoniums in the depth of the winter, for there are obstacles in the way neither few nor insignificant; the want of a suitable house, for instance, is often a great source of trouble and anxiety, and even when that is at command it is in request for so many other purposes that the Zonals fail to secure the necessary attention and special treatment they require.

Provided there is a house where the plants can be kept near the glass, and where the other occupants do not require a moist atmosphere, for that the Zonal Pelargonium dislikes extremely, where the night temperature ranges from 60° to 65°, and air can be freely admitted on bright days, these will flourish and nothing will surpass them for brightness and beauty during the dull time through which we are now passing.

There are many excellent single varieties, but they are not so useful for cutting, nor do they last so long as the double and semi-double forms. Perhaps they are more floriferous, but of that I will say a few words later. I prefer to grow both, but the semi-doubles in the greater proportion.

For a really first-class variety, that is to say the one that combines utility with beauty, and a vigorous habit with floriferousness and dazzling colour, there are not many to choose from. I can well remember when Wonderful held the place of honour, but it was ousted by a rival with which it could not compete, and gave place to E. V. Raspail. For winter-flowering this Pelargonium is specially adapted, as also is it for bouquet making. The colour is a vivid crimson-scarlet, and when bunching for market the dazzling effect on the eyes of the operator is very marked. The trusses of bloom are borne on strong stalks, and the pips are a fair size, and in a suitable temperature it is perpetually in flower. The market growers have selected it as their principal, and in a majority of cases their only variety for winter flowering. Since they find it profitable there is little need for apology in calling attention to its merits and pushing its claims on the private grower.

To keep Zonal Pelargoniums at their best in severe weather is a formidable task. Fog, I find, is their worst enemy, as it covers the glass with a dirty film which must be washed off continually, or the effect is quickly seen on the blooms. I water the plants about three times a week, once with liquid manure, and ventilate whenever I have a chance, if only for half an hour, to dispel the dampness in the house. But the superb display of E. V. Raspail in 10-inch pots a mass of bloom is worth an even greater amount of trouble, for it is the brightest gem we possess to illumine the dark days after Christmas.—ENFIELDIAN.

### LIME.

I AM most grateful to "W. D." for his information, and am also looking eagerly forward for the promised article on this subject. But though your correspondent is so ready to correct my suggestion that slaked lime and chalk are, to all intents and purposes, one and the same thing, he virtually admits this fact later on his letter. Indeed, it is well known to be so, and in confirmation I may just quote "Miller's Elements of Chemistry," part II., p. 507, where is the following:—"Lime when exposed to air slowly attracts both water and carbonic anhydride, and as the result of this action it falls to powder and becomes what is termed air-slaked; in this case a compound is gradually formed, which is by some chemists regarded as a combination of a molecule of calcic carbonate with one of hydrate ( $\text{CaCO}_3, \text{CaH}_2\text{O}_2$ )."

"Watts' Dictionary of Chemistry," 1892 edition, also says of calcium carbonate (chalk):—"Formed when hydrated or anhydrous CaO (lime) is exposed to moist air, but not by the action of  $\text{CO}_2$ " (carbonic dioxide) on dry CaO. Thus we see the difference between atmospherically slaked lime and chalk is so slight as to be observable only in the laboratory, if even there.

I must, however, plead guilty to loose writing when I called the nitrifying bacteria "insects," though my argument is not affected thereby, as the former must be quite as delicate as the latter, and therefore likely to be exterminated by the use of lime, my view being that what is commonly spoken of as the "burning of the soil," is really sterilisation.

If calcium monoxide "decomposes the organic matter" in the soil as "W. D." assumes, is that a desirable result? I doubt it. Let us take for example a Strawberry bed at the present time. Would a dressing of lime between the rows be beneficial? because according to

"W. D." that application could not effect the destruction of the slugs and other vermin which will undoubtedly infest the buds later on.

I may here just remark on the silence of many writers who have constantly urged in the gardening Press the use of lime as an insecticide. Even "W. I.," whose note on "Garden Refuse" called forth my original inquiry, is dumb! This rather tends to confirm my suspicions that advocates of lime are not practical men, for I have never yet succeeded in discovering one garden or farm where lime is regularly or even casually applied to the soil.

"W. D." thinks my reading "has not been of a very scientific nature," as I do not seem well versed in the dictums of most writers and teachers of agriculture. I must admit the soft impeachment. I have something else to do—the *ex cathedra* utterances of these aforesaid teachers and writers having hitherto failed to command the respect and confidence of agriculturists and horticulturists, because their dogmas and theories are usually too academic to stand the test of trial by practical men.—INQUIRER.

[Most of the best practical gardeners and successful cultivators in the kingdom use lime. We hope to publish a communication from "W. D." next week.]

THE WEATHER IN LONDON.—After a week or more of mild dry, spring-like weather, a sudden change occurred, and nearly 3 inches of snow fell on Tuesday morning—the heaviest fall of the winter—but it soon commenced disappearing. On Wednesday morning there was for a short time a combination of lightning, thunder, hail, rain, snow, and fog, making everybody miserable for the time, but the weather improved as the day advanced.

— WEATHER IN THE NORTH.—An imperfect thaw has prevailed during great part of the week ending the 22nd inst. The snow disappeared from the low grounds; occasional showers, fog, and cold easterly winds made an unwelcome change, even from the severe weather that preceded. On the morning of the 19th 5° of frost, which gave way early, were registered; on those of the 21st and 22nd, 8° and 5° respectively; but Tuesday morning looked as if thaw were again impending.—B. D., *S. Perthshire*.

— HORTICULTURAL CLUB.—At the last monthly dinner and conversazione there was a good attendance of members. The chair was occupied by Mr. Harry J. Veitch, and there were present the Rev. W. Wilks, Rev. J. H. Pemberton, Messrs. H. J. Pearson, C. E. Shea, Selge-Leonard, Cockett, Mawley, C. E. Pearson, Monro, Webber, and others. The subject for discussion was rules for judging, which was opened by the Secretary, and a long and very interesting discussion followed, in which nearly all those present took part.

— THE Earl of Annesley, Hon. Walter Rothschild, and Mr. C. J. Lucas retire from the Council of the Royal Horticultural Society. The Fellows recommended by the Council to fill the vacancies caused by their retirement are Mr. Sydney Courtauld, Mr. Henry Williams, and Mr. Thomas Statter.

— THE HOLLYHOCK'S DISEASE.—I should like to try and dispel an erroneous idea in relation to seedling Hollyhocks withstanding attacks of the disease better than named sorts. As a successful grower of named Hollyhocks for the last fifteen years I say emphatically that in my experience the named sorts withstand the attacks of disease in exactly the same degree that seedlings do; if the fungus comes in contact with either they will take the contagion, if not they will keep clean.—GEO. FINLAY, *East Layton Hall, Darlington*.

— AMERICAN APPLES.—The Baldwin is the great commercial Apple grown in southern New England, with the Rhode Island Greening and Northern Spy following at a considerable distance. In some parts of Maine, however, especially near the banks of the rivers, the Yellow Bellflower, according to the "Vermont Farmers' Advocate," is a great success. The fruit from a Bellflower orchard at South Gardiner, Maine, rarely brings less than 5 dollars a barrel for the first quality, which is scarcely less than prices for extra Newtown Pippins. Large, highly coloured Baldwins from the same region bring much smaller prices.

— LAST YEAR'S RAINFALL IN KILDARE.—Mr. Bedford writes from Straffan Gardens that December gave 2.09 inches of rain, bringing up the total for the year of 33.56 inches, as against 23.10 for 1893.—E. K.

— VEGETABLES AND FRUIT IN COVENT GARDEN.—New Potatoes have been selling during the past few days at 1s. per lb. Home-grown Asparagus realised 1s. 3d. per small bundle, and foreign supplies fetched 9d. per bundle. Cape Apricots, Canadian Apples and Pears, and Florida Oranges have been abundant and found a ready sale.

— LEE, BLACKHEATH, AND LEWISHAM HORTICULTURAL SOCIETY.—The annual meeting of this Society was held at the Lee Institute on the 14th inst., Mr. M. N. Buttanshaw in the chair. There was a good attendance of members and the report was adopted. The balance sheet shows a deficiency of just over £2, but such does not exist, as £50 is invested as a reserve fund.

— FORCED LILIES OF THE VALLEY.—Mr. W. Iceton has sent us from Roehampton a pot of Lilies of the Valley which he forces so extensively. It is a 6-inch pot containing twenty-one plants bearing good foliage and fine spikes. Most of these contain fifteen large flowers, and are 14 inches high from the surface of the soil. Forcers of these delightful flowers may compare their own with this market sample.

— FLOWERS AND THE GARDENERS' CHARITIES.—On the 16th inst. Messrs. James Crispin & Sons provided an exhibition of Orchids and other plants in their show room at Bristol. A charge for admission was made on two evenings. The amount realised was £11 13s., to be divided between the Royal Gardeners' Orphan Fund and the Gardeners' Royal Benevolent Institution. This is a form in which the inhabitants in populous towns may be afforded a treat, and great good be done at the same time.

— LIVERPOOL HORTICULTURAL ASSOCIATION.—On Saturday evening last the third paper of the season, entitled "Horticulture in France," was given by Mr. Frank Ker, of the Aigburth Nursery. Mr. Ker related in an interesting manner his impressions and experiences of gardening as carried out in the neighbourhood of Versailles, at which place he served a portion of his apprenticeship. He spoke of what appeared to him a scarcity of private gardens, and described nursery routine. Mention was also made of the great Riviera trade. The great taste displayed by the Parisian florists in decorating their shops, and the bold and graceful way in which the plants at flower shows are arranged, he considered a long way ahead of our own. He said very little fruit is grown under glass, Grapes, Apricots, Peaches, Nectarines, Pears, and others ripening well outside. Altogether he thought that we were quite able to hold our own in the matter of plant-growing. A vote of thanks was accorded to Mr. Ker for his admirable paper.

— WAKEFIELD PAXTON SOCIETY.—Considering the inclement state of the weather at the last meeting there was a good attendance of the members of the Paxton Society. Mr. B. Whiteley presided. The essayist was Mr. W. H. Vere, gardener to Mr. W. H. Stewart, J.P., of Milnthorp House. Mr. Vere, who has thrice previously delivered essays before his fellow Paxtonians, took as his subject on the present occasion "The Fernery." After remarking that no garden, large or small, was complete without a house devoted to Ferns, Mr. Vere proceeded to describe their usefulness, their beauty, and the pleasure to be derived from their cultivation, which is very easy. In the first place he said that the best kind of a house for the growth of Ferns is a lean-to erection with a north aspect. Ferns could not grow freely under strong sunshine, but they require a good amount of light to bring them to their proper colour. In ventilating there should be no direct draught on the Ferns; air boxes should be fixed in the front wall of the house. The stage ought to have a flag or stone bottom covered with about 3 inches of ashes; the Ferns should have a moist atmosphere, and the heating must be carefully attended to. Cleanliness was another chief point to success in a fernery. In the middle of February or the first week in March all dead fronds should be cut away, and the plants repotted in a compost of loam, peat, leaf mould, silver sand, and charcoal. The pots should be perfectly clean, properly crocked so as to insure good drainage, and a little dried moss might with advantage be placed over the crocks. If the pots were new they ought to be soaked in water and dried before being used, and no cracked pots should be used. Overpotting was a mistake with Ferns; they succeed best when the pot is full of roots. Firm potting was necessary, and space should be left at the top of the pot for water. The only plants he would recommend to grow in a fernery were a few cool Orchids. An interesting discussion ensued, and a very hearty vote of thanks was accorded to Mr. Vere for his excellent paper:

— RAINFALL IN SHROPSHIRE.—Mr. C. A. Pearse, Oteley Park, Ellesmere, informs us that the total rainfall there in 1894 was 29.76½ inches. August was the wettest month with 3.81 inches, September the driest with 0.70 inch. Rain fell on 219 days during the year. We are unable to publish tabulated records.

— GROWTH OF BLACK WALNUT TREES.—Mr. Robert Douglas writes that Black Walnut trees, when planted thinly in a plantation of *Catalpa speciosa*, made as rapid upright growth as the *Catalpas* until they reached a height of 30 feet, while in a small block planted of Black Walnut exclusively the trees at the same age were not 20 feet high.

— "THE GARDEN ORACLE."—The publishers of this useful annual publication have favoured us with a copy for 1895. It is as well printed and bound as usual, and contains, besides calendrical matter, a number of excellent illustrations and practical articles on Fruit Culture, Insects, and other subjects. It may be obtained from Messrs. W. H. & L. Collingridge, 148, Aldersgate Street, London.

— VERBENAS.—"H. T. M." desires to know the names of the largest growers and exhibitors of Verbenas, going on to say that named collections of these plants are not seen in gardens now, as used to be the case in past years. The reason of this is that Verbenas as florists' flowers have gone out of fashion, and Begonias have come in. Most of the Verbenas now grown in gardens are, like Petunias, raised from seeds annually, but a few bedding varieties are grown under names.

— SHIRLEY GARDENERS' IMPROVEMENT ASSOCIATION.—The monthly meeting was held at the Parish Room, Shirley, Southampton, on the 21st inst., Mr. B. Ladhams, F.R.H.S., presiding over a good attendance of members. The lecture was under the auspices of the Hants County Council, the subject, "Hardy Fruit Culture, with Special Reference to Diseases," being especially well dealt with by their lecturer, Mr. C. W. Herbert Greaves, F.R.H.S. A discussion followed, especially with reference to the lecturer's remark that canker is caused by the fungus, *Nectria ditissima*. A vote of thanks was accorded the lecturer on the proposition of Mr. E. Molyneux. Some excellent Orchids were exhibited by Mr. W. Peel, gardener to Miss Todd, Shirley.

— THE ENGLISH CLIMATE.—"What compensations," says a writer in "The Country Month by Month," "we find everywhere! When in the tropics, surrounded by such luxuriance of vegetable life, and such a wealth of colouring that when, for instance, my eyes first rested on the Orange groves of Tahiti, and the Palm-clothed heights, their beautiful greens contrasted with the bright red tones of the soil, I felt my imagination had failed to ever picture such a scene as this; but I missed and longed for the song of the blackbird and thrush, and the bracing air of our moorlands and hills. I have lived for five years in New Zealand, and nearly four in the Hawaiian Islands; have visited the beautiful State of California at four different periods, spent some little time in Colorado, been through the West Indies, across Panama, and have touched at some points on the Mexican coast. Yet, in spite of our cold, foggy climate, I say, give me England, with its woods, which, if less luxuriant than the forests of the tropics, are far more enjoyable. Even those days which we call 'grey' are more favourable to thought and mental effort than is that glaring, unbroken sunshine on which other nations pride themselves so much."

— KINGSTON GARDENERS' ASSOCIATION.—The first ordinary meeting of the second half of the winter session was held at the Albany Hall on Wednesday evening. Mr. Plumb of the Normansfield Gardens presided. Mr. A. Dean gave the opening address on "Plant Life," taking the seed in its dormant form, showing how committal to warmth and moisture softened the epidermis and caused the lobes or cotyledons to swell and open, thus liberating the germ or dormant plant. Then ensued root and stem growth, the root becoming at once the anchor to the plant, also its mouth or feeder. The uses of the seed lobes or cotyledons in furnishing food for the infant plant were shown, until it could find its own means of subsistence. The gradual evolution of stem, branches, leaves, and flowers in the form of cellular tissue was also pointed out, and specially the purposes leaves serve as breathing organs to the plant. Flowers, their forms and uses, also their fecundatory organs, were described, also the various methods of securing fertilisation through the agency of the proto-plasmic grains found in the anthers, called pollen. Some references to the influence of light, both natural and artificial, on plant growth were also made. A most interesting discussion followed, taken part in by the Chairman and Messrs. Cushon, Martin, Pitcher, and others, and at the close a very hearty vote of thanks was accorded to the lecturer.

— DEATH OF MR. JOHN MORRIS OF BIRMINGHAM.—This well known horticulturist, who for nearly thirty years was the manager of Messrs. Pope & Sons' Nurseries, King's Norton, Birmingham, died on the 18th inst., after a very brief illness.

— A USEFUL PLANT SUPPORT.—We have received from the maker and patentee—Mr. W. C. Key, Walton-on-Thames—samples of a new form of flower stake. It has been made with a view of obviating the damage to the roots of bulbs, and has two prongs, so shaped as to entirely avoid any interference with the roots of the plant or the bulb, whilst the wire support to which the flowers are tied is stronger and presents a neater appearance than a stick. The supports are made of tinned wire, do not rust, and are practically imperishable. We presume some are made longer than the samples before us.

— EUPHORBIA JACQUINIÆFLORA.—Mr. A. G. Hookings, The Gardens, Olddown House, Almondsbury, writes:—"Seeing an article in the *Journal of Horticulture*, January 17th, page 59, by 'C. H. H.,' I beg to enclose three racemes for your inspection. They are cut from plants grown in 48-size pots from cuttings rooted the first week in May. I have cut some racemes 23 inches long as good as the enclosed. I grow about 100 plants." [The specimens are as good both in foliage and floriferousness as we could desire to see, and represent excellent cultivation. Details of the methods adopted in their production could not fail being acceptable to many of our readers.]

— MIDDLESBROUGH PARK—DEATH OF THE CURATOR.—A correspondent informs us with regret of the death which occurred early on Sunday morning of Mr. Charles Anderson, Curator of the Albert Park, Middlesbrough. Mr. Anderson, who was appointed to the Curatorship in 1888, was held in high esteem by the members of the Corporation, and by a large circle of friends. He managed the Park well, and kept its bedding arrangements up to date, though he worked under the disadvantages of smoke from the steel and chemical works, for which this town is famous. Mr. Anderson was an old Drumlanrig man, and leaves a wife and family to mourn his loss.

— SUMMARY OF METEOROLOGICAL OBSERVATIONS FOR THE YEAR, 1894.—The year was remarkable for unusually bright and dry weather during March and April, a cool showery summer, and mild weather during November and December. The prevailing wind came from a westerly direction on 103 days. The total rainfall was 27.02 inches, which fell on 249 days, the greatest daily fall being 1.04 inch on August 10th. Barometer (after May 31st only) highest 30.41 at 10 P.M. December 27th, lowest 28.736 at 4.10 P.M. November 14th. Thermometer, highest in shade 84° on July 6th, lowest 10° on January 6th. Mean daily maximum 55.89°; mean daily minimum 41.14°. Mean temperature of the year 48.5°. Lowest on the grass 0° on January 6th; highest in the sun 139° on June 29th. Mean temperature of the earth at 3 feet in depth 48.55°. Total sunshine 1356 hours 41 minutes. There were thirty-seven sunless days. The rainfall is 1.36 inch above the average of forty years.—W. H. DIVERS, *Belvoir Castle Gardens, Grantham.*

— THE VIRTUES OF WOOD ASHES.—Mr. J. M. Stahl, Illinois, has much to say in the "American Agriculturist" about the virtues of wood ashes. Speaking of them as a medicine for farm animals, he says he has found them of great value. He has raised swine rather extensively for more than twenty years without cholera or swine plague, and has not lost 1 per cent. of his hogs from disease. He keeps wood ashes and charcoal mixed with salt constantly before his swine in a large covered box with holes 2 by 6 inches near the bottom. The hogs will work the mixture out through these holes as fast as they want it. He selects ashes rich in charcoal, and mixes three parts of ashes to one of salt. There is no danger of the swine eating too much of this mixture, or of pure salt, if it is kept constantly before them, and they are provided with water. The beneficial effects of the mixture are quite marked, especially when the hogs are fattened on fresh Maize. A little wood ashes given to horses is also, he maintains, very beneficial. In thirty-seven years' experience upon the farm he has lost but one horse, and this was overheated in the horse power of a threshing machine during his absence, and the only "condition powder" he has ever used has been clean wood ashes. The ashes may be given by putting an even teaspoonful on the Oats twice a week, but he prefers to keep the ashes and salt mixture constantly before the horses, and has made for it a little compartment in one corner of the feed box. His experience is that the best condition powder is a mixture of three parts wood ashes to one of salt; and that when it is given regularly, and reasonable care and intelligence are used in handling the horse, no other medicines are necessary. Mr. Stahl has also great faith in the efficacy of wood ashes as a fertiliser.

— ROYAL METEOROLOGICAL SOCIETY.—The annual meeting of this Society was held on the 16th, Mr. R. Inwards, F.R.A.S., President, in the chair. The Council, in the report, reviewed the work done by the Society during the past year, and also stated that additional accommodation had been provided to meet the growing needs of the library. Forty-five new Fellows had been elected during the year. Mr. Inwards, in his presidential address, dealt with the subject of "Weather Fallacies," which he treated under the heads of Saints' day fallacies, sun and moon fallacies, and those concerning animals and plants. He also referred to the almanac makers, weather prophets and impostors who have from time to time furnished the world with fit materials for its credence or its ridicule.

— WIND VELOCITY.—At the above meeting Mr. C. Harding read a paper on "The Gale of December 21st, 22nd, 1894, over the British Isles." This storm, he said, was one of exceptional severity, especially over the northern portions of England and Ireland, and in the south of Scotland. It developed energy very quickly, and travelled with great rapidity. The self-recording anemometers show that the greatest violence of the wind occurred at Fleetwood, where the velocity was 107 miles in the hour between 8.30 and 9.30 A.M. on the 22nd, and for four consecutive hours the velocity exceeded 100 miles. This is the greatest force of wind ever recorded in the British Isles, and is 10 miles an hour in excess of the highest wind velocity in the great storm of November 16th—20th, 1893. At Holyhead the wind in squalls attained the hourly velocity of 150 miles between 10 A.M. and noon on the 22nd. The strongest force was mostly from the north-westward. Much destruction was wrought both on sea and land, and there was a heavy loss of life.

— ANBURY, OR FINGER AND TOE.—The disease of anbury, or finger and toe, is met with wherever the Turnip crop is cultivated, but it is probably nowhere more destructive than in the north of England. An experiment bearing on the disease, briefly described in the *Journal of the Royal Agricultural Society*, by Professor W. Somerville, will therefore interest all agriculturists. The experimenter emphasises the fact that the disease is extremely infectious, and may be easily induced by inoculating a soil perfectly sound with soil from a diseased field. Such diseased soil, however, may be easily disinfected by lime, a fact which points to the pathological phenomena being due to an organism—presumably *Plasmodiophora brassicæ*. This being so, too great care cannot be taken to prevent soil or diseased roots being conveyed from a field which is diseased to another which is sound.

— APPLE SCAB IN AMERICAN ORCHARDS.—The so-called Apple scab is one of the serious pests of American orchards, not only because it causes mis-shapen and undeveloped fruit, but because the affected trees suffer from defective foliage. When it is remembered that the fruit buds of one year are all started the year before, the necessity for healthy foliage every year is apparent, and it is plain that the fungus should be kept from trees on the off years as well as on the bearing years. We have often, says the "Garden and Forest," given accounts of the effectiveness of the Bordeaux mixture against this disease, but it is a matter which everyone ought to understand. Some late experiments made at the Agricultural College of Missouri seem to show that the weaker solutions were about as effective as the stronger ones, and that the first spraying should be given very early, and be followed by at least three others. The second crop of scab, which appears on late Apples seems in this case to have been entirely prevented by spraying.

— BIRMINGHAM AMATEUR GARDENERS' ASSOCIATION.—In their second annual report the Committee of the Birmingham and District Amateur Gardeners' Association congratulate the members "on the splendid progress the Association has made during the year." There has been a large accession of new members—ninety-four having joined during the year. Several members have left from various causes, and the total membership (excluding sixty-nine whose subscriptions are not yet paid) is now 185, as against 152 in 1893. In addition to this eight have already been elected for 1895. The number of meetings held during the year was twenty-three, compared with seventeen in 1893; the average attendance being thirty-eight, compared with thirty-two. Should it be found practicable the Committee have in view the idea of organising a show in the autumn, to comprise Chrysanthemums and other flowering plants and vegetables; but the achievement of this project must depend on the assistance which the members generally are prepared to give. The statement of accounts submitted with the report shows a balance in hand of £4 8s. 8d. The Committee feel it is their imperative duty to record how greatly the interests of the Association have been promoted by the untiring energy and self-sacrifice of the Hon. Secretary (Mr. Griffin) and the Hon. Treasurer (Mr. Rees).

— THE HESSLE GARDENERS' MUTUAL IMPROVEMENT SOCIETY.

—At a meeting of the above Society held on January 15th an essay entitled "The Reason Why," was given by a blind member—Mr. Lyon. On commencing his essay Mr. Lyon produced a common red flower pot, and most ably explained "The reason why" a pot of that kind is used in preference to an ornamental glazed one; also, why a red pot is more beneficial to the growth of plants than one of any other colour. Red, he said, was the emblem of strength, energy, and growth. Mr. Lyon was unfortunately deprived of his sight a few years ago, but he still takes a great interest in horticultural matters. His essay was based on scientific principles.—F. L. T.

— ESSEX OAKS.—Mr. J. C. Shenstone has taken a census of remarkable Oak trees in Essex, and he gives, in the "Essex Naturalist," descriptions and illustrations of noteworthy specimens found by him, together with notes on a few Oak trees outside the county. The five trees with the largest trunks in Great Britain, stated in "Loudon's Arboretum," are Cowthorpe Oak, Yorkshire, 78 feet; Merton Oak, Norfolk, 63 feet; Hempstead Oak, Essex, 53 feet; Grimstone Oak, Surrey, 48 feet; Salsey Oak, Northampton, 46 feet. Among trees having the widest stretch of boughs, are the Worksop Oak, 180 feet; and the Oakley Oak, 110 feet. All these trees are not, however, standing at the present time. The Hempstead Oak fell about twenty-five years ago, and a mutilated and decayed trunk is all that remains of this forest giant. A fine tree, 31 feet in circumference, exists in the park at Danbury Palace. The inside of the bole was completely burnt out more than sixty years ago, but the tree has continued to grow, and will probably yet survive many years. Several of the trees mentioned are said to be from 500 to 1000 years old, but there is not sufficient evidence to decide the point at all accurately.

— ROYAL HORTICULTURAL SOCIETY OF IRELAND.—At the last meeting of the Council of the Royal Horticultural Society of Ireland, held at 15, Lower Sackville Street, Dublin. Present: Charles Strong King, Esq. (in the chair); also Messrs. F. W. Moore, Henry Vincent Jackson, Captain Lewis Riall, Hugh Crawford, John Cumming, F. W. Burbidge, Hamilton Drummond, George Carson, and George M. Ross, Secretary. Arrangements were made for the annual general meeting of the Society, which is to be held on Thursday, 17th inst., at the Central Lecture Hall, 12, Westmoreland Street, at one o'clock. Auditors were appointed to audit the accounts for 1894. Mr. Joseph Sweeny, The Gardens, Leopardstown, and Mr. George Sayers, The Gardens, Obelisk Park, Blackrock, were admitted practical members of the Society. The dates for the Society's shows for 1895 were provisionally fixed. Prizes have been presented by the Right Hon. Ion Trant Hamilton, Mr. John Cumming, and by the Council. Extra prizes for Tomatoes, open to nurserymen, were added to the list.

— THE ROYAL HORTICULTURAL SOCIETY.—The meetings of this Society for the present year are fixed as follows; the subject of the afternoon lecture at the Drill Hall is given in each case. The Temple Show opens on May 21st, and the Crystal Palace Show on Sept. 26th. February 12th.—Show in the Drill Hall, and annual general meeting, at 117, Victoria Street, S.W., at 3 P.M. March 12th.—"The Diseases of Tomatoes and Vines," by Mr. Collenette. March 26th.—"Lifting Large Trees and Shrubs," by Mr. T. H. Crasp. April 9th.—"Campanulas from a Garden Point of View," by Mr. J. Wood. April 23rd.—Primula and Auricula Conference. "New Primulas," by Mr. J. G. Baker, F.R.S. "Culture and Classification of Primulas," by Mr. H. Selfe-Leonard. "The Auricula," by Mr. James Douglas. Special Show of Auriculas, Primulas, and Narcissi. May 14th.—"Plants and Gardens of the Canary Islands," by Dr. Morris. May 21st, 22nd, 23rd.—Great Flower Show in the Inner Temple Gardens, Thames Embankment. June 11th.—"Rose Culture under Glass," by Mr. Frank Cant. June 25th.—"The Uses and Organisation of National Botanical and Horticultural Gardens," by Mr. W. T. Thiselton Dyer, C.M.G., F.R.S. Special Show of Hardy Perennials and Cactaceous Plants. July 9th.—"The Effect of Darkness on the Form of Plants," by Mr. Francis Darwin. Great Show of Roses. July 23rd.—"The Carnation in Scotland," by Mr. R. P. Brotherston. August 13th.—"Hardy Bamboos," by Mr. A. B. Freeman-Mitford. August 27th.—"Crotons and Dracenas," by Mr. C. F. Bause. September 26th, 27th, 28th.—Great Show of British-grown Fruit at the Crystal Palace. October 15th.—"Nut Culture in England," by Mr. S. Omer Cooper. Special Show of Vegetables. October 29th.—"Potatoes," by Mr. A. W. Sutton. November 12th.—"Substitutes for Larch," by Dr. Maxwell T. Masters, F.R.S. November 26th.—"Asparagus Culture," by Mr. James Mason. December 17th.—Show in the Drill Hall, and meeting for the election of Fellows.

— THE FEEDING VALUE OF THE LEAVES OF TREES. — This, says a contemporary, was the subject of considerable inquiry in 1893, more particularly on the Continent, where the drought was as severely felt as in this country. Mons. Courmouls-Houlès, of Faillade, Tarn, France, was the first to attempt the ensilage of leaves and twigs of trees on an extensive scale, and in his report he states that the ensiled shoots of the Beech were eaten with avidity by his cows. The animals received from 9 lbs. to 17 lbs. each daily, and the value of the fodder per acre of plantation was found very great, and notwithstanding the drought the cattle were provided with plenty of food, and did well. Mons. Grandeau, as the result of his analysis of the silage, estimates the nutritive elements of the ensilaged Beech twigs to be equal to those of good hay. These facts are of interest, but we do not regard them of much practical importance, or, indeed, in the light of a new discovery. We have long had proof in parks and enclosures that cattle will eat the tender twigs of various timber trees, more particularly when there is a deficiency in the herbage, and we certainly do not share in Mons. Courmouls-Houlès' views that our woodlands should be utilised for feeding stock.

— A NEW ENEMY OF THE BLACK CURRANT.—Mr. CECIL WARBURTON, Zoologist to the Royal Agricultural Society, reports on a new Black Currant enemy. Early in May specimens were sent to him of a weevil which was said to be doing considerable damage to Black Currant bushes near Bewdley. They proved to be *Phyllobius calcaratus*, a species closely allied to the handsome green weevil *P. Alneti*, which is so commonly to be seen on Nettles. The life history of this species is as yet unknown, but it is probable that it lives in the larval and pupal condition at the roots of the Currant bushes. If this should be found to be the case, the chance of the pest recurring would be materially lessened by the removal of the surface soil during the winter, and either burying it to a depth of not less than 12 inches or mixing with it a liberal proportion of quicklime. Possibly forking in a good dressing of quicklime during the winter season would prove useful. It is suggested that when the bushes are attacked the weevils may be caught by shaking the branches over cloths or boards smeared with tar, this operation being most successful early in the morning and on dull days. It is possible that no great importance is to be attached to the occasional occurrence of this pest, but it is sufficiently destructive to justify strenuous efforts in waging war against it when it makes its appearance.

— BRIGHTON AND SUSSEX "NEW" HORTICULTURAL AND MUTUAL IMPROVEMENT SOCIETY.—The large number who attended the annual general meeting of the above Society on the evening of the 17th inst. is sufficient proof that the new life infused into horticultural matters by its establishment does not wane, but gathers strength as the years roll on. G. M. Kidd, Esq., President of the Society, presided on the occasion. Mr. T. Billing, Hon. Treasurer, presented the balance sheet, which was of a most satisfactory character. From the statement of accounts it was seen that the Society paid prizes to the amount of £372, for music £165, and to the Brighton Corporation close on £78 for the use of the Dome and Corn Exchange for their three shows. The total receipts for the year, including £91 19s. balance from the previous year, was £1158 17s. 5d., the total expenditure £996 16s. 7d., leaving a balance in hand of £162 0s. 10d. Mr. Billing proposed that £100 of this sum be invested. The Chairman remarked that it was in a great measure due to the success of their shows that they were able to add £70 to their balance this year. This is borne out by the fact that £706 19s. was taken at the doors. The balance sheet having been adopted, Mr. Balchin, jun., submitted some alteration of rules, namely, that the word "New" should in future be omitted from the title of the Society, not now being necessary; that ladies be admitted as members, and that instead of a "Secretary" there be an Hon. Secretary and an Assistant Secretary. He took that opportunity of stating, with regret, that Mr. Longhurst had, owing to the demands on his time, resigned the position as Secretary. Mr. Longhurst had been the pioneer of the Society, and they owed him very hearty thanks for all he had done for it. In putting the vote of thanks to the meeting it was suggested by the Chairman and carried unanimously, that Mr. Longhurst be made an hon. member. The latter gentleman in returning thanks expressed his gratification at being able to leave the Society in so prosperous a position. Though unable to continue as Secretary he hoped to be with them as much as ever. After some good humoured remarks about the admission of lady members, the motion was carried. Mr. Kidd was re-elected President, Mr. Balchin, jun., Chairman of the Committee; Mr. Cheal, Vice-Chairman; Mr. Billing, Treasurer; Mr. Johnson, Hon. Secretary; and Mr. Rupert Miller, Assistant Secretary. Mr. Longhurst was elected on the Committee in the room of Mr. Miller. Votes of thanks terminated an enthusiastic meeting.—R. I.

## THE PORTSMOUTH SETTLEMENT.

MR. CHARLES J. GRAHAME writes to say he is sorry we think that the decision of the Committee of the National Rose Society in endorsing the action of the Honorary Secretaries relative to the show fixtures in 1895 "settles the matter" in dispute. But it does settle it all the same, as no one expects the members of the N.R.S. are going to turn out the Committee forthwith and elect a new one to alter the present arrangements. As that seems to us the only way in which the decision arrived at can be altered, "settled" it must be, however much some persons may be disappointed. Mr. Grahame says he shall not write to the *Journal of Horticulture* any more. He has had a short term

Melliar's own heart, who shares with his helpers the work—the real and actual work—of budding and growing the plants, and staging the blooms. In one photo we see "acres of Roses," including 299 cut-backs of Mrs. J. Laing. Only a true amateur rosarian would be so exact in the counting. To this field is added a new strip, 170 yards long by 11 yards wide, and other slices may be expected to follow, for there appears to be plenty of room, earnestness, and zeal.

In another photo—a sort of snug corner of Roses—we see the work going on, for it is budding time. There stands the master "taking out," two men inserting, two tying, and the young "Master Chambers," head gardener of the future, looking on. Then follows the showing time, and at Gateford it seems to take five strong men to stage a box of Teas. Here they are all in a row, life-like photos. On the left Mr. J. Grant, rosarian, cutting the blooms. Mr. T. Clifton, under gardener, receives them and hands them to Mr. F. E. Chambers, head gardener, who trims them, passing them to the head over all for "boxing;" Mr. C. Stubbings, the gamekeeper, appropriately acting as trapper—*i.e.*, managing the lid as the box stands on the Rose barrow. The coachman, stud groom, and footman are not visible, but the assertion may be ventured that if they were wanted among the Roses

FIG. 13.—MR. MACHIN'S ROSE GARDEN.

and a lively one, and in allusion to what has transpired gives as a finale "*de gustibus non est disputandum.*" Quite so, and there the matter may well rest at present.

## MR. MACHIN'S GARDEN AND ROSES.

VERY much to the fore of late has been the name of the great amateur rosarian Mr. Henry V. Machin of Gateford Hill. Possibly this may have suggested the sending to us of a set of photographs by a gentleman into whose hands they fell some time ago. We have had the pleasure of seeing Mr. Machin's Rose field, his drying-ground rosery, his nursery, and interesting old garden. The latter is quaintly picturesque with its trimmed shrubs and bowery-like character, relieved by stately trees and brightened with old-fashioned flowers, some of which seem to have been very much let alone for generations. There is a charm in such old gardens as this, in which things appear to have established a right to be just where they are by long possession, and they are also living memorials of those who loved them in past years. The young squire of Gateford does not attempt to modernise this old garden and end, as many have done in dealing with similar examples, in spoiling instead of improving. Mr. Machin does his modernising elsewhere. He takes to the fields, and displaces Turnips with Roses.

That the owner of this much-cared-for and fertile Nottinghamshire estate is a very real and ardent rosarian, the photographs before us demonstrate. We should take him to be a man after Mr. Foster

they would have to be there, or—no, we will not suggest an unpleasant alternative, for Mr. Machin is one of the kindest of masters, considerate to all, loved by all, and who therefore give him willing and faithful service. He is known as a "thoroughbred who runs straight," esteemed alike by his exalted associates on the magisterial bench, by his tenants, and his workers. He is in a word an English gentleman, and unquestionably a leading amateur in the Rose world. No doubt honours are in store for him, and he will deserve all he wins. We are obliged to the sender of these photos, and reproduce one as the most characteristic of Old Gateford.

## MR. FOSTER-MELLIAR'S BOOK.

I HAVE just read with very great interest and profit Mr. Foster-Melliar's "The Book of the Rose," and have found therein many little side lights and observations on the Rose which I thought were known only to myself and a few particular friends, and which prove the author to be a close observer and a clever fellow! Now I am not going to praise the book further just now—it can make its own way; but I wish to point out one or two shortcomings. We, the rank and file of the nation, look to the Church, the Bar, and the Stage for the Queen's English. It is their privilege to uphold its purity, and to be looked on as its champions.

On what authority, may I ask, does Mr. Foster-Melliar use the phrase "different to?" Not Thackeray, for he withdrew it. Then, on pages

262 and 286 we get the word "aggravating" where "irritating" or "provoking" is meant. This is a common error, but only common folk may be excused making it.

The author must be congratulated on the selection generally, and the publishers on the excellence of the illustrations. Only photographers and printers know the technical difficulties in the way of producing such. Plates facing pages 263 and 292 could have been improved by the reduction of the straggling high lights which draw the eye to their contemplation.—ARCANUM.

#### ROSA BORRERI.

I AM looking into the history of Rose-growing in the classics, and I feel sure I may make your interest in it an excuse for troubling you with a few questions.

The *biferi rosaria Pæsti* have always been a puzzle. In Murray's *S. Italy*, I., p. 182, it says, "These Roses have disappeared, though a few plants may be found near the ruins of the temples, flowering regularly in May, which Mr. (Dr.) Hogg states agree best with the *Rosa Borreri*"—(Linn. Tr., vol. xii.). I have no access to the *Linnean Transactions*, and I do not know what the *Rosa Borreri* is. When I was at Pæstum, twelve years ago, it was winter, and I made nothing out of the Roses. Can you tell me whether the Roses differ here at all from the ordinary wild Rose of the South of Europe?—G. E. J.

[*Rosa Borreri* is a native species, so named by Mr. Woods in compliment to Mr. Borrer of Henfield. It is scarcely distinguishable from *R. micrantha*, and is identical with *R. inodora* of Agardh. We do not know what the Rose of Pæstum of Virgil's *Georgics*, book iv., ver. 119, is, further than it is one of those mythical subjects which from time to time give rise to some discussion.]

#### ROSA RUGOSA.

THIS grand single and very distinct Rose has been nearly a hundred years in England, but never, I believe, until lately taken in hand for improvement. I rejoice to say this has now been done by Suttons of Reading. Mr. Martin, their famous hybridiser, has been three years at work on it, and has lately favoured me with some short notes of his operations. He has every facility. A grand hedge 40 yards long, and about 4 feet high, divides a certain portion of the Portland Road Nurseries. Heps on this have been fertilised, with the following results. I should add that Mr. Martin is enthusiastically in its favour. He writes of it:—"Seven months of the year it is clothed in a mantle of beautiful and profusely serrated foliage, which for cutting and arranging with other flowers for indoor decoration can scarcely in any way be equalled. The display of the handsome heps, glittering in the autumn, fine rosy scarlet to a clear yellow, with others of a bronzy terra-cotta bordering on the edge of the beautiful foliage, causes everyone to admire it. For table decoration it has a charm of its own. In the woods, as a covert for game, it is useful and attractive when once established." This is a digression, but due to Mr. Martin. He has passed over *rugosa alba* as too feeble a stock, and is seeking for his new colours and character in *R. rubra*. Blooms on the great hedge were fertilised in 1890, "as soon as the buds were formed, early in the morning, to prevent the action of insects or the wind performing the act of fertilisation from its own or foreign pollen." There will be the less danger of this, as, I grieve to say, *rugosa* is the only Rose now tolerated at the Portland Nurseries. This has been crossed with the old York and Lancaster.

It is to be regretted that Lord Penzance's wider and more liberal selection of parent pollen was not adopted. This, however, is not the business of the public. We shall be thankful even for a new striped variety. It is an interesting matter of comparison "we gathered pods of *R. rugosa* crossed naturally," Mr. Martin says; in respect of which, "on opening the seed apples we found the crossed pods contained only a very few seeds, and of only half the size of those from the naturally crossed pods." And now for results. "We sowed in heat early in 1891, and at midsummer, 1892, we found the naturally fertilised seed germinating fruit; later on we found the crossed seedlings appearing, very much shorter in growth, with smaller leaves and more spiny." They had a narrow escape from a severe-minded boy who was on the point of throwing them away as being so inferior in size to the others. They have had every care, but have not bloomed even yet. "In 1893," says Mr. Martin, "we placed plants of each section in heat, but no flowers were produced on either of the six plants, though the wood was well ripened." I have just seen them all planted out, well fed, and protected, twenty-six plants "from the artificially and naturally crossed plants." They can hardly be so unreasonable as to refuse to bloom again this year; and when the N.R.S. visits Reading in 1896 will no doubt be in full force; rivals then of Lord Penzance, and repaying Mr. Martin for his paternal pains.—A. C.

#### MEDALS FOR TROPHY CLASSES.

I AM glad to find that the above subject is again being brought before your readers, and think that the suggestion for gold medals (on page 35) to accompany the trophies is a most excellent one. It is certainly very hard on an exhibitor who may have fought hard and won the National Rose Society's trophy (one of the most valuable prizes ever offered at a Rose or horticultural exhibition) to have no memento of the honour after the year has expired.

I have known more than one of our first rank exhibitors decline to compete with his best Roses for the championship, and "go in" for a piece of plate that would become the winner's absolute property, so that to some of our exhibitors to "have and to hold" a small prize in kind for a lifetime is preferable to holding even the champion cup for

one brief year. It would appear from this that something more than the mere honour is needed to secure the best Roses in the premier class.

The expense of the suggested medals might be met by dropping the two classes that were added in 1887 to the provincial exhibitions, and allow the Jubilee trophy to be offered in the largest amateur and open classes, as is done at the metropolitan exhibition. Such an arrangement would effect a saving of £12, which would more than provide the five medals that would be necessary. This suggestion is, I think, better than either "J. B.'s" (page 35) or "W. R. Raillem's" (page 50). Should none of the suggestions meet with approval, how would it act to impose an entrance fee in the special classes of, say 5s., which could go towards supplying the medals?

Any of the above arrangements, except "W. R. R.'s" (which I suppose would not be compulsory) would still leave past winners unrecognised, which is not desirable, for they have been, and many still are, liberal supporters of the Society, and any act of liberality (such as medals for past successes) on the part of the Society would in all probability be repaid twofold in increased subscriptions and offers of special prizes by the recipients. The medals would prove a source of great pleasure to every winner, more especially to the one who from ill health or any other cause may have had to give up exhibiting.—A NORTHERN MEMBER.

#### PEELING AND CLEANING VINE RODS.

WHILE not advocating the entire removal of the outer bark from the rods of Vines I do not think as much harm accrues from so doing as Mr. Craven (page 6) would have us believe. It is well known that Vines which are denuded of the greater part of their bark are quickly covered again with more. Neither do I think that the Vines so peeled increase so slowly in the diameter of their stems as some persons imagine. I have taken a few measurements from the stems of Vines growing not far from where I write, and the barking they have many times undergone does not appear to have prevented their making good progress during the fourteen years they have been growing.

One house is devoted to Muscat of Alexandria entirely. One Vine at 6 inches from the ground is  $8\frac{1}{4}$  inches in circumference, at 2 feet 6 inches from the same point it measures the same. Another rod 4 feet from the top of the border is  $5\frac{1}{2}$  inches around the rod, at 9 feet from the base it is still  $5\frac{1}{2}$  inches, a third rod at 3 feet measures exactly 7 inches. In an adjoining house Gros Guillaume at 6 inches above ground measures 9 inches, and at 3 feet it is the same size. Lady Downe's at 2 feet measures  $6\frac{1}{4}$  inches, and a Black Hamburgh at 1 foot girth 6 inches, at 6 feet it is  $5\frac{1}{4}$  inches round. In all cases the measurements were taken between the spurs. The Vines have yearly borne heavy crops of fruit, and produced bunches good enough to win premier awards at shows, and the crop of Muscats borne last year was the best yet produced by these Vines. I am not an adviser of the close peeling process, but should not hesitate to peel off the bark if circumstances necessitated its removal.

In my opinion it is the only way to cleanse Vines from that insidious pest mealy bug, and that alone will not do it. Mr. Craven may think himself extremely fortunate in not having had to deal with Vines much infested—if at all—with this pest. If his experience had been the other way perhaps he would have resorted to more extreme measures than simple washing with soapy water. Mr. Craven has produced very fine Grapes from Vines that I am well acquainted with, and has just cause to adhere to his present system of treatment, but whether readers generally will accept his dictum that the removal of the bark hinders the expansion of the rods and stems to the extent he would have us believe is another question; personally I think otherwise.—E. MOLYNEUX.

I HAVE been pleased by reading the interview with a noted Grape grower. I think the remarks have been full of common sense from beginning to end—a great thing in gardening. With regard to stripping Vines of their bark, and scraping into the skin with a knife, I do not think there is any common sense in that. I go over the Vines with my hands, and remove any loose bark for appearance sake. I have had 247 bunches of Black Hamburgh and Foster's Seedling on four Vines, two each, in a quarter-span house, 27 feet by 18. I have both sorts hanging now. I cut eight bunches last week. When I had finished limewashing the walls, with paraffin in the mixture, I painted the Vines all over with the same compound. I was troubled a little with the berries of Foster's Seedling splitting when they were swelling, but I attributed it to an extra dose of nitrate of soda which I have been using as a change for the Vines.—H. C., *Morefield*.

SOME correspondence having recently appeared in the *Journal of Horticulture* under the above heading, I venture to send a few lines; and although some of the remarks which I shall make will not coincide with some that have already appeared, I do not write with any disrespectful feeling towards anyone, and should a controversy follow let it be a friendly one. Cleaning Vines is the question at issue, which means cleansing them of some parasite with which they are infested. If it be mealy bug or red spider, I maintain that it is necessary to strip them of all loose bark in order to get at the insects, and no amount of washing or painting on the top of the bark will affect the life of the insects that are underneath it. This I have proved many times. I well remember a very bad case when employed as a subordinate in a gentleman's garden in Worcestershire some years ago. Being winter time, and

the Vines pruned, knowing they were badly infested with mealy bug, I began, as was my duty, cleaning them, and started stripping all the loose bark off them first. I had not proceeded far when the chief came in, and to my surprise sharply reprov'd me for my line of action, saying he did not like the plan of taking the bark off, and requested me to stop. After exchanging a few remarks about it, I asked him what harm it did taking it off. He answered, "I will show you what an old master of mine says about it," and he went into his cottage and returned with a book in his hand, which proved to be a work on the Grape Vine written by the late Mr. Meredith of Garston, of Grape-growing fame. The book was opened and a passage read to me to the effect that if the bark was stripped off the Vines the sun had a mischievous influence on the flow of the sap.

I was then told to paint the Vines with a strong insecticide, and keep a sharp look out for insects when the Vines were started. The houses were cleaned and painted, but soon after the heat was applied the enemy showed itself, and would not be subdued by the action of two camel's-hair brushes and insecticide daily applied by two men. True it was a bad case, and as the season went on became worse. The filthy pests got into the bunches of Grapes, and many of these instead of going to the table went to the rubbish heap. This case caused me to make a resolution that if ever I had to deal with mealy bug on Vines on my own responsibility, I should not hesitate to use drastic measures to eradicate the worst pest a gardener can be troubled with.

Notwithstanding what has been advanced in favour of keeping Vines clothed with bark, I am not yet a firm believer that it is so much needed as some gardeners think it is. The bark has performed all the functions which is required of it when it becomes loose. It does not adhere to the stem after the new skin is matured, and I have seen Vines carry good crops of Grapes suitable for home consumption and exhibition year after year that have had all loose bark taken off at the winter cleaning. Take another instance. Young Vines newly planted are cut back to the bottom wire on the roof of a vinery to induce them to make good fruiting canes for the next year. The Vines will ripen from four to six good bunches of Grapes, yet they have but one thin skin, and the sun does not appear to work any evil influence on the flow of sap; why then should it on older Vines with a thicker skin on them after the loose bark is taken off?—R. MORSE.

I CAN with confidence say, through years of observation, that peeling Vines is detrimental to their well-doing, though I have a case here under my notice where Vines have done remarkably well after severe peeling.

When the Vines under my charge are free from the much-dreaded mealy bug I simply take away the loose hanging bark, and give the rods a thorough washing, or rather scrubbing, using a new scrubbing-brush with warm water and 1 oz. of softsoap to the gallon. I make a practice of doing this in all my fruit houses at the close of every season, as prevention is better than cure; but in an extreme case I had five years ago I carefully stripped off all the bark I possibly could, then gave a thorough scrubbing with warm water and softsoap, repeating three times at intervals of a fortnight after the Vines were started. I also saturated every inch of wood and iron with neat petroleum, well working it into every crevice. Afterwards I gave a good scrubbing with hot water and softsoap, and with careful watching after this treatment I have been very little troubled with the pest.

Probably Mr. Craven will remember the Muscat of Alexandria shown at Liverpool by me in 1892, which gained first honours, the bunches weighing 5 lbs. each. These Grapes were cut from the Vines in question. At the same time my belief is that Vines are much better not stripped. I have never made a practice of using strong insecticides, nor do I believe there is any need of them, neither of the old-fashioned fad of coating Vine rods with a thick substance, such as clay, soot, and other mixtures. In my opinion these coatings only benefit insects, as affording them shelter during the resting season, the pigment cracking just at the right time in the spring to liberate them. Scrubbing with softsoap and warm water is, I am sure, the safest way of cleaning Vines. There is nothing I like to see in Vines better than the natural colour, with abundance of bark.

In the case of the Vines I found in such a bad state I not only dealt with the rods and houses, but with the roots also. I first examined the border; scarcely a root could be found within 9 inches of the surface. I took out what soil I could about 15 inches deep, and found the drainage was good; the roots were also better at the bottom, so I made a mixture with eight loads of good turf, cut 4 inches thick, from a very old pasture, one load of old mortar rubbish, 4 bushels of soot, three barrowloads of burnt refuse, and 2 cwts. of Thomson's manure. When filling up the border I laid all the roots I possibly could about 6 inches below the surface, at the same time notching them at various lengths. During the growing season I gave a good watering with sewage. The next year the border was so full of fibrous roots that I could not remove any soil for further dressing. I am pleased to say the Vines are still in good condition.—W. COATES, *Darnhall Hall*.

I AM very interested in this question, and would like to understand a few points suggested by Mr. William Taylor still better than his letter to you on the subject conveys (page 55), as I am free to confess I yearly peel off all loose bark that might harbour spider or bug in my vinery, and then wash with a strong creamy preparation of boiling water, sulphur, and a fractional part of petroleum, of course allowed to cool.

1, What objection is there to the "peeling" off of the loose bark

so long as the inner bark and the sap circulation is not interfered with? I ask this, as although an admirer of Mr. Taylor's writings in the Journal for nearly a score years, I cannot recollect the discussion of the point.

2, To what does Mr. Taylor attribute the "flagging" and "smallness" of the berries in connection with the peeling? Is it from evaporation from the stems or leaves? and if from the latter, how does that arise from the above operation?—W. J. MURPHY, *Clonmel*.

Mr. W. TAYLOR'S (page 55) interesting article on the above subject exactly coincides with my opinions. He objects to peeling the bark from Vines on principle, only resorts to it when absolutely forced by circumstances, and trusts he may never have to do it again. Evidence is given as to its ill effects on the Vines by the unusual manner in which they behaved with their jackets off. It is my belief that stripping off the bark causes excessive transpiration, consequently impaired vigour. I shall feel interested to know how these same Vines shape themselves for the next year or two, and no doubt your correspondent will be kind enough to give the information at the proper time.

Mr. Taylor seems to be fixed similarly to myself in respect to light soil. I, too, have had to incorporate clay to give more body. I think red spider is always more prevalent where such soils exist, especially when resting on sandstone or gravel. Under the best management Vines usually become more or less infested with red spider, notably under the above conditions, with perhaps borders all inside and sharp-pitched houses. Where localities favour red spider, as in Mr. Taylor's case, and I might say my own, does it not make its entrance through the ventilators and the laps of the glass? Other places again are remarkably free from this pest, and I recollect the Vines at Wycombe were rarely attacked to a great extent, owing, I presume, to the humidity of the valley, but then mildew was a foe to beware of. I note the fine proportions of the Bath Vines, and the pang it seems to have caused the good man to be compelled to undo what it had taken him years to achieve.

Probably in excellent Grape soils Vines would stand the barking process for a short time while they were at their best, but would it last? Would they continue to produce first-class examples? I should like to hear the experience of someone who has followed this practice for a long time, as it would be instructive. The efforts required to secure high-class Grapes renders it necessary to husband the strength of the Vine at all times, for I am of opinion that the most trivial matters often mar perfect finish. Every exhibitor knows the great difficulty of finding such samples in quantity for meeting powerful competitors. Most of the Vines here are over twenty years of age, and had been subjected to stripping. Young canes trained from old rods a few years ago, and also young Vines planted about the same time, and not peeled, will soon overtake them.—J. J. CRAVEN.

PEELED Vines always give me an uncomfortable feeling. It is obvious that such extreme measures would not be resorted to unless prompted by urgency to eradicate an insect pest. Yet it savours of the barbarous. The happy medium appears preferable—viz., to remove loose bark, rubbing off the shelly particles from around the spurs, where bugs do most abound. The more drastic measures of close peeling, as practically illustrated by Mr. Taylor (page 55), appear, as he hints, to be sufficient for once in a lifetime. The tar dressing, as advocated by me in a short article (page 303 of the volume ending June last year), has given me the best results. My recipe is, to a gallon and half of water, in which about 2 lbs. of softsoap has been dissolved, add sufficient clay to make it of a creamy consistency. To this add half a pint of gas tar, thoroughly mixing, and giving an occasional stir when using. I am aware that some recipes include more gas tar, but its nature emphasises caution. The mixture as prescribed I believe to be well within the bounds of safety, and efficient. To complete the thorough cleaning of a vinery I would strongly urge (as I have done previously) a coat of white lead paint being given to all wood, ironwork, and wires, with a limewashing to the brick or stonework where practicable, using freshly slaked lime for the purpose. Happily, the humid atmosphere of Ireland is in some measure inimical to red spider, which, as an insidious foe, is perhaps to be more dreaded than mealy bug.—E. K.

#### KENTIAS.

THESE indispensable Palms may truly be called the friends of gardeners, for among the numerous species and varieties of Palms which now find a place in British nurseries and gardens none is so thoroughly adapted for house decoration as the several varieties of Kentias. Since their introduction they have been the great rivals of *Seaforthia elegans*, and I think are now steadily driving the latter out of the field, simply because they will last so much longer in the heated atmosphere of dwelling rooms in the winter without showing signs of disfigurement than will the most sturdily grown plants of *Seaforthia elegans*, whose fronds lack the great substance necessary for the purpose.

Where only small plants are employed for room embellishment this matter may not appear to be of much moment, but the custom of using large plants for this purpose is largely on the increase, so much so in fact that specimens from 6 to 8 feet in height, growing in comparatively small pots or tubs, are in great request, and trade growers sometimes find a difficulty in supplying the demand. This I think will make it clear that when plants of this description are used the species which

suffer the least when subjected to such conditions should be obtained, because if much disfigured by the loss of leaves it takes two or three seasons to bring them into a presentable condition again.

*Chamærops excelsa* and *Latania borbonica* are both good lasting Palms, and answer for some positions, but they are too heavy in appearance to be used freely, and, moreover, it is necessary, in many instances for the fronds to have a fine arching habit, and stand clear for passing under. In this respect *Seaforthia elegans* bears the palm, as the long straight stems allow plenty of head room before the plants have become sufficiently bulky to require inconveniently large tubs.

Against this advantage we have, however, to set the fatal drawback of deficient lasting qualities. This allows *Kentias* to come in an "easy first," as they are but slightly less elegant in appearance or deficient in length of stem, while their lasting qualities stand unrivalled. *Fosteriana* is the best variety for use in a large state, and I would strongly advise all who require large Palms for the above purpose to obtain that variety.—H. DUNKIN, *Castle Gardens, Warwick.*

### THE LATE MR. THOMSON OF CLOVENFORDS.

A CORRESPONDENT writes:—On Wednesday, the 16th last, in Caddonfoot churchyard, on the banks of the Tweed, and amidst a multitude of mourners from all parts of Scotland, and of many professions, the grave closed over the remains of the late Mr. William Thomson of Clovenfords. And, though a good deal of interesting matter has been, and will be, written in gardening and other papers about one who was so widely and well known, and so much respected, as I knew Mr. Thomson for many years, and had ample opportunities—professional and otherwise—of judging of his abilities and opinions, I should like to add a few brief notes regarding him.

Mr. Thomson was known—personally or by repute—not only to those interested in horticulture, but also to many who have no personal connection either with amateur or professional gardening. His book on the Grape Vine, written when he was gardener at Dalkeith Palace, contains merely the nucleus of the encyclopædic knowledge of that subject, which, by long and careful study and experience, he afterwards acquired. By those competent to judge he was considered the most eminent authority on the Grape Vine. His complete and accurate knowledge of the physiology and of the analysis of this plant, and his acquaintance with chemistry, enabled him to produce a manure which, in addition to being suitable for other plants, contains all the elements that the Grape Vine requires; hence the enormous crops of finely finished Grapes which are year after year produced by the Vines at Clovenfords, where many young gardeners, not only from all parts of Britain, but from France, Germany, and other continental countries, go to perfect their knowledge of Grape growing.

For more than half a century preceding Mr. Thomson's death a large number of young gardeners were constantly either under his authority or in his employment, and to such men he was ever ready with wise and kindly counsel and encouragement. Many a young man has been stimulated to study and self-improvement by Mr. Thomson, who never failed to help a deserving man to better his position. There are men all over Britain and abroad who hold responsible and lucrative posts which, in a great measure, they owe to Mr. Thomson's recommendation. His firmness, kindness, and justice made him respected as a master, and his willingness and ability to give sound and sufficient reasons for every plan he adopted induced the asking of questions, the answers to which set others thinking for themselves. Apart from his professional skill, his gentlemanly and agreeable manner made his society and advice much sought after by those engaged or interested in horticulture.

His knowledge of and interest in chemistry, meteorology, agriculture, forestry, and other subjects brought him into contact with many who had no interest in gardening. In advocating his views in gardening periodicals, in newspapers, and elsewhere, argument rather than force of language characterised his statements. This, I believe, resulted from his liberal mindedness, and his careful consideration of every subject on which he expressed an opinion. He will, therefore, be greatly missed by many outside his own family circle, and large numbers of his gardening friends. Take him all in all, Mr. Thomson of Clovenfords was one of the ablest men that the horticultural world has yet produced.

### JUDGING—A COURT OF APPEAL.

"C. K." (page 34) speaks presumably from personal experience on this vexed question, and apparently that experience has not been a happy one. There is much in his able article that I can endorse from my own experience on this side of the channel, but there are also inferences to be drawn from it that one would fain believe exist only in his imagination. He says, "Some people affect to believe that there is no such thing as favouritism or partiality with judges, but it is one of the worst features of our show system." Well, I am one of those people who not only affect but do believe that this does exist and does not exist. It exists in the judicial mind so far as the individual ideal of form, colour, or variety in the exhibits is concerned, and other points which need not be mentioned here. To settle this matter the need of a court of appeal has been frequently urged—viz., clearly defined rules drawn up by competent authorities in those sections where controversy most arises, and confused ideas prevail. Ever and anon this question

crops up, and sound logic is advanced urging the need of something definite, but like the old farmer with the squire's claret at the audit dinner, "Its wery good, but we don't seem to get no forrader."

In looking at the other view, in which "C. K." tacks on those hard adjectives of "dishonest and incompetent," I may say that my observation is taken from neutral ground. In the past as a judge I have had some years' experience, as an exhibitor not less, and at the present being neither, the position appears to be one of vantage to judge the judges and the grumblers. Exhibitors who have not been behind the scenes—who have not at any time acted in the judicial capacity—are prone to think something in the nature of a dark séance is enacted when they are "belled" out of the tent. Their mind is already made up as to where the prize ticket should go, and if it gets on the wrong stand they then go for the secretary, and he, poor man, has a bad quarter of an hour. Supposing the court of appeal existed, may I ask what would be its elements? Experts of course. How many? Three say. Would not their super-excellent knowledge be better employed in the first hand judging? And how few societies could afford this luxurious litigation, even supposing it would or could give satisfaction? Some cases might not be settled there. If the verdict of those good men and true was reversed on appeal they might ask for a higher court, and between the whole land the society in the Bankruptcy Court.

Something is needed I admit, and some things will never be attained whilst human nature is human nature, but many of the difficulties might be met by the combined wisdom of a Society's ruling powers embodied in their schedule. If societies enveloped in the thick hide of self-satisfaction persistently ignore the duties they owe to themselves, to judges, and to exhibitors, the Nemesis of internecine litigation may be desirable from some points of view, but can hardly add to their dignity.

To return to "C. K.'s" unhappy experience, which fortunately has not been mine, I should think that "rotteness in the state of Denmark" (or wherever he alludes to), must sooner or later bring its own punishment, and that will be death. If Societies employ at least one expert in each section to act in concert with the gentleman amateur and the practical gardener, and time and arrangements permit of the onerous duties receiving justice at their hands, much of the present grievance would disappear. If the judges are curtailed in time, and feel that the necessary cool deliberation with attention to fine points cannot be given, they would be justified in declining to act—even at the last moment—rather than to incur the risk of having favouritism and partiality coupled with their names, not to mention more unpleasant suggestions. The subject is one in which I have, as a judge and exhibitor, given some thought to, but it must be understood my field of observation is limited to Irish soil, in which I can honestly affirm neither partiality nor favouritism are known, although there is room for improvement.—E. K., *Dublin.*

[Since the above article was in type we have received the following P.S. from our correspondent:—"May I suggest a footnote that my remarks were penned previous to 'A. D.'s' letter being printed? Our views are so nearly identical that it might be inferred I had stolen his ideas." The evident fertility of mental resources possessed by "E. K." forbids the suggestion.]

### ROYAL HORTICULTURAL SOCIETY.

JANUARY 15TH.

SCIENTIFIC COMMITTEE.—Present: Mr. Michael (in the chair); Rev. W. Wilks, Dr. Bonavia, Rev. G. Henslow, Hon. Sec.

*Primula obconica* and *P. sinensis* Causing Eczema.—Further observations were made upon this subject brought before the last meeting. The fact that the Chinese Primrose occasionally produces the same effect as *P. obconica* has been discovered by Messrs. Sutton of Reading; but the ill effects appear to be only in the case of very few persons who handle the plants. It was the variety known as *P. s. alba plena* which had the property. As a contrary case, it was observed that with regard to the very poisonous Neilgherry Nettle, none at Kew could touch it except one person, to whom it was innocuous. Mr. Michael added that very similar differences occur when hairy caterpillars are handled.

*Fertilisation of the Chrysanthemum.*—An interesting communication was received from Mr. H. Briscoe-Ironside of Burgess Hill on this subject. It had been thought by some writers, following Darwin a little too implicitly perhaps, that "the anthers of the *Chrysanthemum* . . . as of all members of the *Compositæ* . . . are proterandrous . . . and naturally adapted for cross-fertilisation."—(Burbidge.) The writer, quoting this passage, observes that from his own observations in Italy that the *Chrysanthemum* is quite, if not more, readily self-fertilised than naturally crossed. He finds, too, that the seed resulting from the self-fertilisation of the disk-florets gives very poor results from a horticultural point of view, and he thinks it to be "most probable that this is the seed which is advertised and sold, and which, as we learn, gives such poor results." It has now been generally recognised that the *Compositæ* trust quite as much to self-fertilisation in Nature as to intercrossing, and although the florets are seemingly adapted to the latter process, the former is quite as likely to take place, many inconspicuously flowering species, as Wormwood and Groundsel, being in all probability never visited at all. With reference to the "inferiority" of the flowers resulting from self-fertilisation, this is the rule; hence arises the importance of intercrossing for floral improvements; but the difficulties involved in trying to avoid self-fertilisation in the *Compositæ* are very great, in consequence of the minuteness and proximity to each

other of the florets. The writer proceeds to quote the following observation of Mr. Burbidge:—"The Chrysanthemum had ages ago become naturally adapted for cross-fertilisation, and to that fact, no doubt, is due its variability in Nature and our own gardens." Mr. Ironside thereupon asks:—"Why does history refer conspicuously to the varieties raised by their comparatively few raisers? Surely if cross-fertilisation were natural the raising of new varieties would seem a common event not worth chronicling?" This question might be asked of all other plants as well. The reply is that Mr. Burbidge here refers to *one* cause of variability, *intercrossing*, and omits the commoner one, *a change of environment*, which may give rise to it as well. With regard to the former there is always the antagonistic process of self-fertilisation to overcome. This fixes, or tends to fix, characters, while the other tends to alter them. Self-fertilisation, however, is the *rule* in Nature, notwithstanding the numerous contrivances for intercrossing. Mr. Ironside adds the further question:—"Do our English authorities, when describing the seeding or fertilisation of flowers not indigenous to the soil of Great Britain, give their opinions of experiences based on their having seen them in their native state, or otherwise?" Perhaps some author will reply to this question.

#### CLEOME HEPTAPHYLLA.

A CORRESPONDENT has had seeds of *Cleome heptaphylla* sent to him, and desires a description of the flower and a little information as to the culture essential. With regard to the form of the blooms, the illustration (fig. 14) shows it admirably, while the colour is white with long purplish stamens. The plant is of moderate height with seven-lobed leaves. It can be treated similarly to many other annuals from warm climates—namely, the seeds are sown in heat, and the young plants grown in light soil in the stove, or placed during the summer in the conservatory. It flowers late in the summer and autumn, and lasts some weeks in good condition with ordinary care.

#### TABLE DECORATIONS.

I AM sure this is a subject which concerns every practical gardener. I am interested in and should like to learn something new about it. Circumstances alter cases, and what is tolerated in one place is not allowed in another; for instance, I have been obliged to change my plan of decorations from what I had learned at Trentham under those accomplished decorators, the late Mr. L. Stevens and the present Mr. P. Blair.

I have lively recollections of the decorations of the large dinner table there. It was fashionable in those days to have groups of plants on the table, consisting of Orchids, Ferns, *Panicum variegatum* and others; also by way of change Grapes and dwarf Apple trees in pots, while suitable branches to make groups were employed during the autumn and winter months. On one or two occasions I remember an uncommon but unique arrangement being worked out there called the snowstorm, but I would not advise anyone to attempt it only on a large scale. It consists of light and graceful branches of Birch as specimens for each end of the table, to be surrounded by suitable branches and twigs of hardy shrubs. In the centre we used a plateau of glass, around which we arranged points of Conifer branches inserted in balls of clay mossed up, which represented specimen trees around a lake. The whole of the branches were wetted and dusted with common whiting before being arranged, and at the finish were "jack-frosted" over with a material obtained in town. Such an arrangement caused quite a furore at Trentham on several occasions when there were special visitors there.

I am in favour of using one or two colours only for the same occasion, and where Orchids are grown in quantity we have an abundance of material at hand for table work. During the autumn and early winter months I make use of variegated leaves such as Maples, *Ampelopsis*, and Vines; they work in well with Chrysanthemums, and so do long trailing pieces of variegated Ivy. I always aim at using material which will blend harmoniously; for instance, Orchids, Maidenhair Fern, and *Asparagus plumosus* are inseparable. Roses with their own foliage seem to me to be the proper dressing for a display of these flowers. I could describe more minutely several designs suitable for round and square tables if necessary. I believe it was the fashion in London a year ago to have table decoration carried out in the way of sprays laid on the tablecloth with an abundance of *Myrsiphyllum* trailing about in vacant places. I shall be pleased to hear from some of our able gardeners who are up to date in the work in question.—HERBERT MAY, *Markree Castle Gardens, Sligo*.

#### GARDENERS' ROYAL BENEVOLENT INSTITUTION.

ON Thursday, January 17th, the fifty-sixth annual general meeting of this gardening charity took place at Simpson's Hotel, 101, Strand, W.C. Mr. Harry J. Veitch presided over a fair attendance, and among those present we noticed Dr. Masters, F.R.S., Mr. J. H. Veitch, Mr. H. Williams, Mr. J. Laing and Mr. J. Laing, jun., Mr. R. Hogg, Mr. R. Dean, Mr. Watkins, Mr. Hudson, Mr. Wythes, Mr. H. Turner, Mr. Thomas Manning, Mr. Munro, Mr. A. F. Barron, and other influential gentlemen well known in horticultural circles.

After reading the minutes of the previous annual meeting, the

Secretary (Mr. G. J. Ingram) read the report and balance-sheet of the Institution for 1894. We append these in full.

#### COMMITTEE'S REPORT.

In submitting the fifty-sixth report of the Gardeners' Royal Benevolent Institution, the Committee have the satisfaction of again congratulating the members and subscribers on the continued prosperity of the work which has now been carried on with such signal success for the past fifty-six years, and has been the means of conferring year by year an increasing amount of benefit upon a most worthy class of

FIG. 14.—CLEOME HEPTAPHYLLA.

society who have been compelled to seek aid from the funds of the charity.

The Committee have much pleasure in stating that the annual festival dinner, held in June last, was most successful. They desire to acknowledge their great indebtedness to Sir Julian Goldsmid, Bart., M.P., who presided on that occasion, and whose able advocacy of the claims of the Institution and personal liberality conducted in a very large measure to the financial result which was attained. The Committee also desire to tender their hearty thanks to those gentlemen who acted as stewards, as well as to those friends who, either by gifts of flowers and fruit or in other ways, contributed to make the festival a success.

During the past year fifteen pensioners have passed away. The Committee have therefore decided to recommend an addition of fourteen pensioners to those now on the books, eight of whom they ask the subscribers to place on the funds without the trouble and expense of an election, they having fulfilled the conditions of Rule III., 5, the remaining six to be elected in the usual manner. It is with much regret that the Committee feel themselves unable to assist a larger number of candidates, the more so as the list of those seeking election is the largest on record in the history of the Institution. They deeply deplore the fact that there must be at least thirty-six unsuccessful applicants whose claims, urgent though they are, cannot be met. If "hope deferred

maketh the heart sick," then there must necessarily be a number of heart-sick ones who will be compelled to wait on before that aid which they so much need can be afforded. The Committee therefore very earnestly appeal for more support and increased effort on the part of their friends, and they would specially plead with those for whose benefit the Institution was founded to do all they can, not only to help the Institution themselves, but to urge its claims upon all those with whom they come into contact, and who are interested in horticultural pursuits.

The Committee believe that the Institution and its aims are becoming more widely known and better appreciated, and they have noted with much satisfaction that a keener interest appears to be taken in its work than heretofore, as indicated by the recent correspondence in the columns of the horticultural Press. They take this opportunity of thanking their well-wishers, and trust that all who have the well-being of the Institution at heart will redouble their exertions on its behalf.

With the full sanction of the Committee, and in order to increase the resources of the Institution, the Trustees decided to sell out the sum of £20,000, forming part of the invested funds of the Institution, and re-invest it in guaranteed securities bearing a higher rate of interest. They have, therefore, taken up the above amount in London and North-Western Railway Three per Cent. Debentures, Midland Railway Three per Cent. Debentures, Great Indian Peninsula Five per Cent. Guaranteed Stock, and Manchester Corporation Three per Cent. Stock. This will give an increased income from dividends of about £50 a year.

At the last annual meeting the Committee had the satisfaction of announcement that an auxiliary had been formed at Bristol for Bristol, Bath, and neighbourhood, with the view of making the objects and claims of the Institution better known. They now have much pleasure in stating that similar auxiliaries have been started at Birmingham, under the presidency of the Right Hon. the Earl of Dudley; and at Wolverhampton, under that of C. T. Mander, Esq. (Mayor). At both towns successful inaugural meetings have been held, which were addressed by the Treasurer of the Institution and the Secretary. Very heartily do the Committee thank those gentlemen to whose efforts the formation of these branches are due, and they cordially invite communications from friends in other parts of the country who are willing to help in establishing these local adjuncts to the Institution, which they believe will tend to promote its interests.

Like other charities, the Committee feel the effects of the commercial depression under which the country is passing, and the consequent cessation of many annual subscriptions which had been regularly remitted for many years. Then again, they have to deplore the loss of several warm friends and supporters by death, foremost among whom may be mentioned the late Earl Grey, who had been for a long period a contributor to the funds of the Institution. It is difficult to fill the places of these friends, but it is matter of much congratulation that a number of new annual subscribers have been obtained during the past year, which will in some degree compensate for the financial loss sustained.

The Committee have also to express their deep regret that, in consequence of advancing years, their revered and esteemed Chairman of Committee has been compelled to resign that important office. Mr. John Lee has fittingly been described as the father of the Institution. For upwards of fifty years he has taken the warmest interest in its welfare. He has been indefatigable in his exertions on its behalf, and he has had the satisfaction of witnessing its progress and prosperity year by year.

At a General Committee held December 21st last, the following resolution was unanimously adopted: "That the Committee sincerely regret the necessity for Mr. Lee's resignation, and they desire unanimously to place on record their grateful acknowledgement of the very great services rendered by him to the Institution during more than fifty years, but more especially during the long time he has acted as Chairman of the Committee, and they express the sincere hope that Mr. Lee may yet be spared many years to continue a member of the Committee and to give them the benefit of his mature judgment."

It was naturally a task of much difficulty to obtain a successor to Mr. Lee. The Committee, however, after much consideration decided to approach Sir Alexander Arbuthnot with a request that he would join their body and accept the position vacated by Mr. Lee. They now have the pleasure to announce that Sir Alexander Arbuthnot has very kindly consented to join the Committee and occupy the post of Chairman.

The Committee would add that the Gardeners' Royal Benevolent Institution is the only charity of its kind in the United Kingdom, and that, though its centre is in London, the benefits it dispenses are not limited merely to the area of the metropolis, but are extended to and embrace all parts—England, Scotland, Ireland, and Wales. They do not, therefore, put forward the claims of a charity the usefulness and importance of which have decreased, but for an institution which, after a period of fifty-six years' existence, is more than ever regarded as an inestimable boon by those assisted from its funds upon whom old age, sorrow, and misfortune have fallen.

The balance-sheet showed that the income during the year was, with the sum of £936 16s. 4d. balance from 1893, £4399 4s. 11d., the subscriptions amounting to £1302 19s. 4d., donations and proceeds of collecting cards to £1321 18s. 7d., and the dividends on investments and interest on deposits to £792 11s. 2d. The payments included £2710 2s. 5d., distributed in pensions and gratuities; £686 2s. 8d. for general expenses; and £100 placed on deposit.

We have audited the accounts for the past year, and are pleased to report that we found the books in perfect order, and well kept.

(Signed) { THOMAS MANNING.  
J. WILLARD.  
T. SWIFT.

The Chairman, who is also Treasurer of the Institution, briefly referred to the reinvestment of the funds, which would now bring in an increased dividend of £50, and stated the stock purchased by the Committee had risen considerably in value since the reinvestment. Mr. Veitch also referred to Mr. Lee's enforced absence through illness, and drew attention to the illuminated and handsomely framed address which the Institution intended to present to Mr. Lee as a small token of affection and respect for one who had for fifty years been Chairman of its Committee.

Dr. Masters moved that the report of the Committee and the balance sheet be adopted, and that the meeting give its best thanks to the Committee for their able management of the affairs of the Institution. Mr. Richard Dean having seconded the motion, the resolution was passed without dissent.

On the motion of Mr. B. Wynne, seconded by Mr. G. Wythes, Mr. H. J. Veitch was unanimously re-elected Treasurer, and the thanks of the meeting was tendered to him for the able manner in which he assisted the management and for the trouble he had taken to advance the interests of the Institution. It was then proposed by Mr. B. Wynne, "That Messrs. Cutbush, Williams, Watkins, and Sexby, who retire by rotation, be re-elected members of Committee for the next four years; and that Sir Alexander Arbuthnot and Mr. George Norman be elected members of Committee in the places of Messrs. Arnold Moss and George Woodgate." This was seconded by Mr. Osborn and passed.

Mr. H. J. Veitch then moved, and Mr. Munro seconded, "That Messrs. James S. Buck, W. Crane, R. Gold, H. Higgins, and R. A. Jack be reappointed Arbitrators for the ensuing year."

The proposal, "That Mr. George J. Ingram be re-elected Secretary," was carried unanimously, and Mr. Ingram thanked the meeting for his re-election.

Mr. Munro's proposal, "That, in accordance with Rule III., 5, and upon the recommendation of the Committee, who have investigated each case, the following eight candidates—viz., R. Vertegans of Birmingham, aged sixty-eight, nurseryman, annual subscriber of £1 ls. for twenty-five years, and a contributor of £7 7s.; J. Lemmon of Chichester, aged sixty-seven, gardener, annual subscriber of £1 ls. for eighteen years, and a contributor of £21; C. H. Fearenside of Boutham, aged sixty-eight, gardener, annual subscriber of £1 ls. for twenty-five years; Charles

Harris of Manchester, aged sixty-seven, gardener, life member for fifteen years; H. Parsons of Foot's Cray, aged sixty-five, gardener, annual subscriber of £1 ls. for eighteen years; M. Reed of Abbots Langley, aged sixty-nine, gardener, annual subscriber of £1 ls. for fifteen years; Susan Ridout of Reigate, aged sixty-one, widow of John Ridout, gardener, who was an annual subscriber of £1 ls. for twenty-two years, and a contributor of £63; and Eliza Burrell of Esher, aged seventy-eight, widow of Edward Burrell, a gardener, who was an annual subscriber of £1 ls. for twenty years, be placed on the list of pensioners without election from December 31st last," was unanimously adopted.

Messrs. B. Wynne, John A. Laing, George Munro, and James Webber were then elected Scrutineers, and it was agreed that all questions arising out of the voting be referred to them. The meeting was then adjourned until the polling, which closed at 4.30, could be declared.

#### RESULT OF THE POLL.

About a quarter past five the poll was declared. It was an exceedingly heavy one, and only those candidates who gained over 2000 votes were successful; the six names with an asterisk affixed will be duly placed upon the Institution's list of pensioners.

The following is a list of the candidates, with the number of votes gained; those with asterisks affixed were successful:—Clara E. Brown, 2188\*; John Collier, 769; Henry Fielder, 2261\*; Thomas Thomas, 2735\*; Thomas Bundy, 711; James Clarren, 2824\*; David Cornell, 356; Hester Falconer, 1608; Ambrose Minty, 364; John Percy, 1569; Robert Pettitt, 2024\*; Eliza Webb, 1033; Thomas Bannister, 1765; Robert Begbie, 519; Thomas Cawley, 1463; William Croshier, 1200; Samuel Hicks, 109; Emma A. Ivery, 2500\*; Joseph Monk, 513; Joseph Shearn, 1130; Charles Smith, 1213; J. Akehurst, 70; H. C. Allman, 10; George Ashby, 542; W. Bishop, 1139; S. Chinery, 1506; W. Dean, 864; F. W. Durrant, 1006; J. Field, 1142; George Fletcher, 1033; Eliza Gardner, 95; Elizabeth Hepburn, 514; Rachel Jefferson, 560; William Lee, 1022; James Lonsdale, 855; S. Pickstone, 1004; W. Rose, 369; Anne Smith, 23; John Thomas, 28; Caroline Wood, 492; Henry Wood, 1560; and W. Wood, 596.

Votes of thanks to the Chairman for presiding, and to the Scrutineers for their help, were, on the motion of Mr. Melady, unanimously tendered. The meeting then closed.

#### ANNUAL FRIENDLY SUPPER.

After the general meeting the members and friends of the Institution, to the number of about 130, gathered under the presidency of Mr. George Dickson of Chester, to a supper at Simpsons'. On former occasions this gathering has been known as "The Lark Pudding Dinner," and the dainty dish which gave rise to that title will doubtless figure in the *menu* on future occasions, as it did on this one. The Chairman was supported by Mr. H. J. Veitch and Mr. N. N. Sherwood. Other horticultural notabilities present were:—Messrs. H. Turner, H. Williams, J. Webber, P. Kay, P. Barr, G. Bunyard, J. H. Veitch, P. C. Veitch, A. Moss, Cutbush, Outram, Assbee, Watkins, J. Laing, and A. F. Barron.

The supper having concluded, and the usual loyal toasts honoured, Mr. George Dickson proposed, "Continued Prosperity to the Gardeners' Royal Benevolent Institution." The Institution, he said, was now doing more to alleviate the sufferings of distressed gardeners or their widows than it had previously done, while the reinvestment of the funds would bring in sufficient extra money to maintain two more pensioners. Mr. Dickson spoke highly of the auxiliary branches formed and forming, and hinted that if the Institution saw fit to open an auxiliary farther north than it yet had done, it would doubtless meet with approval and support. The Chairman regretted, as did the meeting, the enforced absence through ill health of Mr. J. Lee, who had for so many years been Chairman of Committee. The Chairman appealed to the friends to re-double their efforts for obtaining subscriptions, and so enable the Institution to extend its usefulness and bring relief to many more of those who were candidates for pensions. Mr. Dickson's speech was humorous yet forcible, and well received; the name of Mr. H. J. Veitch was coupled with the toast.

Mr. H. J. Veitch said he was pleased to respond, for as its Treasurer he could state the Institution was in a sound financial condition, and had a solid basis of well invested funds. Mr. Veitch referred to Mr. Lee's absence, and deeply lamented the recent decease of Mr. W. Thomson of Clovenfords, whose interest in the Institution had been unflagging during the past forty-seven years. When alluding to the auxiliaries, from which he expected much, Mr. Veitch took up the hint dropped by Mr. G. Dickson, and thanked him for what he considered was an invitation to Chester. There were three good reasons why gardeners should subscribe to the Institution; these, said Mr. Veitch, were self-interest, duty, and human sympathy, and no better arguments in its favour could be raised. In concluding his vigorous speech Mr. Veitch warmly thanked Mr. Dickson for coming to preside at a meeting so far from his home.

When proposing the health of officers and Committee Mr. P. C. Veitch said the Institution was well managed in every way, and its officers deserved the heartiest thanks. He could not understand why so few gardeners subscribed, and he hoped to see the day when almost all the gardeners in the kingdom would recognise in a practical manner the value of the Institution. Mr. George Wythes responded to this toast.

The health of the Chairman was given by Mr. N. N. Sherwood, who proposed that the heartiest thanks of the meeting be presented to Mr. Dickson for his presence at a gathering so far from his business, and for the ready help and support he had ever given to the Institution. Mr. George Dickson responded briefly, thanking the members for their good wishes and compliments. He concluded by proposing the health

of Mr. George J. Ingram, the Secretary of the Institution, than whom they could not find a man more suited to the position or better able to further the interests of the Institution. Mr. Ingram, who was greeted with applause, responded to the toast, and expressed his thanks for the good wishes tendered him.

During the evening toasts and speeches were interspersed with vocal and instrumental music, Mr. H. Turner giving several solos on the English concertina and Mr. Munro on the cornet. The meeting closed at a comparatively early hour.

#### MR. BLACKMORE'S CRITICS.

I WAS very pleased at seeing the remarks of "A. D.," pages 34 and 35, and hope that more light may be thrown on profitable fruit growing, which Mr. Blackmore has denounced as being a "fatal fad." Nothing, however, has been advanced to enable us to trace the cause of his failure; there must be something to account for it since so many persons succeed in the work. In the first place, no man can expect to succeed with a "muck rake in each hand."

Anyone who has read Mr. Blackmore's novels will agree at once that only a man thoroughly conversant with horticulture could write those beautiful descriptions so true to nature; and if Pomona has not presented Mr. Blackmore with golden fruit, she has been a healthy inspiration to his literature.

"A. D." is not quite correct with regard to his description of Teddington. I have known Teddington between thirty and forty years, and have no hesitation in saying that as good Pears have been grown there as at any place in England. I have been gardening in eight counties in England and Wales, and I never met with better soil for Pear culture than at Teddington; and the site of Mr. Blackmore's garden is perfect, in the eye of the sun, and part of the town shelters it from the worst winds. I never had the pleasure of being in Mr. Blackmore's garden, and I am speaking of the natural soil of Teddington a quarter of a mile to the north of it. There was 3 feet of good light loam on gravel.

Mr. Blackmore's failure is not in soil and situation. My opinion is that his first expenses for walls, trellises, buildings, and labour was one cause; he was too heavily handicapped at the start by his preparations on a very valuable site. And then I expect he has been a victim of the middleman. His fruit was well grown and good, but not well sold; but as he is a gardener and a gentleman I hope he will let us know the real cause of his failure to make fruit growing a pleasant and profitable undertaking, as it should be.—R. M., *Newbury*.

I DO not propose to prolong farther than needful this very undesirable controversy. A hasty rush into print *re* "Profitable Fruit Culture" has evolved unanticipated criticisms. These would never have arisen but for the literary position of the writer, thus giving to his utterances an unduly authoritative character. Had the complaints originally sent to the press come (as they did not come) from professional growers of fruit for market, they would have been entitled to the fullest consideration, but they would not have evoked one tithe the attention, simply because they would not have been surrounded by any literary halo. I have written absolutely in the interests of fruit culture, and as deeply biassed in favour of fruit culture as a national industry as is clearly a biassed friend of Mr. Blackmore's. Any reader can thus discern whose advocacy or criticism is most entitled to respect. What matters it whether the ground under Pear culture at Teddington be 700 acres, the experience remains of the same value; but if from out of the 10 acres he subtracted the ground occupied by houses, sheds, pleasure grounds, and paths, how much more than 7 acres under fruit actually remains? It is no argument to quote Mr. Blackmore's long position on the R.H.S. Fruit Committee. Did I not say that the Teddington fruit garden had been an experimental one, and, so far as Pears were concerned, calculated to give wide experience as to sorts, but it was impossible to expect with that market profits? Such knowledge, and the knowledge obtained by practical market culture and sale, are wide asunder. Desiring "H." to do the same, I append my name in full.—ALEX. DEAN.

#### HARDY FRUIT GARDEN.

**Wall Trees.**—If the pruning, cleansing, and regulating of Apples, Pears, Plums, and Cherries on walls have not yet been completed, the work ought to be pushed on at every favourable opportunity. After these hardier trees have been dealt with, Peaches, Nectarines, Apricots, and Figs claim attention.

**Apples and Pears.**—*Branch Pruning.*—If horizontally trained trees are allowed to retain too many branches the result is a crowded state of the trees in the summer. Young trees in the course of formation need special attention so as to avoid originating the pairs of branches too closely together. Apples, as a rule, require more room than

Pears, the individual leaves of some varieties of the former being large, and if the branches are thickly placed the consequence is that the foliage and the spurs will be unduly shaded. Leaves deprived of light never attain their full size nor assume the proper texture indicative of health and the elaboration of the sap. There is nothing eventually lost by well opening out a crowded tree. Removing every other branch is not too much in many cases, those retained not being less than a foot apart, 15 inches being more applicable to some. It is even better to have the branches thinly placed and fruitful at 16 or 18 inches apart than at 9 or 10 inches asunder and fruitless.

**Spur Pruning.**—When spurs are crowded as well as branches it will be necessary to reduce their number, though severe thinning of these following close on branch reduction is not always desirable, and it is better to proceed gradually. The upper tier of branches in neglected trees becomes the strongest, therefore the thinning of the spur clumps is imperative, and where they project conspicuously shortening them is essential. This is best done at once, so that the spurs on the branches below may receive the benefit of increased light. Foreright shoots, whether shortened in the summer or not, should be pruned back to the lowest bud above the point they originated from. If numerous some of the worst placed may be cut out entirely.

**Cordons.**—The various forms of this style of training are simply managed after the branches have been formed in the proper position. To cover the space provided the leader may extend without being shortened, the side shoots being pinched in the summer to five or six leaves, and shortened at the winter pruning to one bud. Old-established cordons may require the spurs thinning or cutting back to obviate unsightly projections as well as to induce the best fruiting spurs to form near the wall. Young cordons growing too vigorously may have their energy subdued by careful lifting and replanting, but with those longer established cutting away the strong roots that extend beyond 3 feet will suffice.

**Plums and Cherries.**—Plums and sweet Cherries are grown on walls in fan-shaped, horizontal, and cordon forms. Fan-training admits of a judicious combination of spurs and training in young wood for fruiting the second year. It also provides a ready means of refurnishing trees with a fresh supply of wood originating from the base, cutting the old worn out branches away. The distance between the branches of horizontally trained trees, and those of cordons too, should be not less than a foot. This is ample, and admits light and air in abundance. The young growth, which in the summer was shortened to 3 inches, may now be reduced to half that length, fruit buds forming freely on the part left. Very severe reductions of old wood ought not to be carried out at one time, as gumming is induced.

Cordon and horizontal trees are best trained to wires arranged closely to the wall. Fan-shaped trees are frequently nailed to the surface of the wall, using clean strong shreds and properly pointed nails according to the strength of the branches or shoots. The ordinary cast iron wall nail, having a flexible lead strip attached, will be found very useful for the smaller shoots. No shreds are needed where these are used, as they can easily be bent to enclose the shoot securely, and they give way to the swelling growth. Medicated shreds are neat and durable, and much superior to cloth shreds in damp positions.

**Pruning Gooseberries.**—The main object to keep in view in managing Gooseberry bushes is to maintain them as shapely as possible in outline, well furnished with healthy branches and young wood thinly disposed, and the trees standing separate from each other. Fruit is produced freely on young wood of the previous year as well as on spurs on the old branches. Some growers spur in all the branches, while others rely on the young wood to produce the crop of fruit. Very few bushes, if healthy and vigorous, can accommodate, without crowding, all the young wood; therefore, after forming a bush into shape and thinning out all the obviously crowded and ill-placed branches, shoots that cross and bend inwards, or reach closely to the ground, cut out the weakest spray. Retain the best of the annual wood evenly distributed over the bushes, shortening it but little.

**Currants.**—The annual growth on Red and White Currants should be spurred-in to an inch, the leading growths at the end of the branches also being pruned if no further extension is required, but where they have not yet attained the desired length leave the growths 6 or 8 inches long. Worn out branches may be replaced by strong growths from the base, shortening them to 9 or 10 inches. Black Currants must have abundance of young wood, either strong growths issuing from the base of the principal branches or sucker-like extensions from the roots.

**Protecting Gooseberry and Currant Buds.**—Fine lime sprinkled over the trees when wet is a deterrent to birds attacking the buds. It is also beneficial as a cleanser of the trees and the ground below them.

#### FRUIT FORCING.

**Pines.**—*Fruiting Plants.*—Afford a mean temperature of 70°, varying it 5° according to external conditions, admitting air at 80°, with sunshine, but do not lower the temperature, allowing the heat to rise to 85°, closing at 80°, with a prospect of a slight advance from sun heat. Syringe the paths and walls twice every day, but do not syringe the hot-water pipes, or the surface of the bed between the plants, as the dense steam arising from the first is quickly condensed by the leaves of the plants or glass, and has a tendency to unduly enlarge the crowns of the fruit, while the steaming from the bed is prolific of the fruits becoming black in the centre. This is also accelerated by too free supplies of water and liquid nourishment at the roots, the first needing

to be sparingly given and the latter discontinued when the fruit is swelled and gives the slightest indications of ripening. An occasional syringing, however, will greatly benefit plants swelling the fruit, providing it is done early in the afternoon of fine days, but only when the axils of the leaves become dry.

**Plants for Successional Fruiting.**—At the beginning of February an additional number of Queens should be started to supplement the supply of fruit from those which are already introduced to afford fruit in May and June. Beds having hot-water pipes beneath them can soon be prepared for the plants, but it is not the case where fermenting materials alone are employed for bottom heat, hence it will be necessary in the latter case to see that material is duly provided and had in the proper condition for furnishing a heat of 85° to 90° by the time it is required. When plants which have been kept somewhat drier are to be started see that the balls are made thoroughly moist, so that when they are placed in the extra warmth root action may commence at once.

**Successional Plants.**—Maintain a night temperature of 60° to 65°, and 5° less in severe weather, with 5° to 10° advance in the daytime according to external conditions. Keep the plants rather dry at the roots, but not excessively so, and when water is needed give it thoroughly at a temperature of about 80°, and always with a little stimulating food in it, such as guano or liquid from manure tanks. Suckers should have a temperature of 55° to 60° at night, and 60° to 65° by day from fire heat, with 5° to 10° more from sun heat.

**Melons.**—As the seedlings grow add a little warmed soil as top-dressing to those in single pots, while those several in a pot should be potted off singly in moist and warmed soil, which is necessary at this early season, so that water may not be required at the time of potting, placing the plants near the glass and keeping a sharp look out for slugs, crickets, cockroaches, woodlice, and even springtails, where fermenting materials are used. Brewers' grains or moist bran are excellent traps for slugs; hollowed Mangold Wurtzel for woodlice, phosphor paste being the best remedy for crickets and cockroaches, and for springtails a little boiled Potato placed at the edges of the bed, where they can be treated with boiling water. Soil should be placed under cover, so as to become dried preparatory to forming into ridges or hillocks in the Melon house. Good loam, rather strong than light, is suitable for Melons, and if it has been laid up in ridges so as to reduce the turf, it will be in a fit state for the purpose. If deficient in grit add a fifth of road scrapings, and if not calcareous a sixth of old mortar rubbish. If there is need of manure nothing answers so well as horse droppings. The compost in that case would consist of three parts loam, and one part each of horse droppings, road scrapings, and lime rubbish. This well mixed and made firm in the ridges or hillocks will grow Melons to perfection, other conditions being favourable. The only possible deficiency will be in mineral matter, such as phosphoric acid, potash, and soda, which can be supplied by an addition of wood ashes, using a peck to a good barrowload of soil. For frame culture seeds should be sown early in next month. This is quite early enough to begin when reliance for artificial heat has to be placed on fermenting material, as Melons do best when growth is maintained and there is ample of light and sun to perfect the fruit. The fruit of plants from this sowing will be ripe early in June, or at the close of May in the south. The bed for raising the seedlings should be made forthwith, unless one be made for Cucumbers, which will answer for raising Melon plants.

**Cucumbers.**—*Raising Plants in Frames.*—The beginning of February is a good time for raising plants from seeds to produce fruit fit to eat at Easter or the second or third week in April. The greatest mistake is made by commencing too early. The materials for making up the bed for raising the seedlings being in a fit state for turning over and mixing, so as to induce a sweet regular heat, a site for a bed should be chosen having a full southern exposure, with shelter to the north, as that of a wall or hedge, and if the ground be rather higher than the surrounding level all the better. In forming the bed, which should be about 6 inches larger than the frame all round, the sweetened manure and leaves, in the proportion of one of the former to two of the latter, must be beaten well down with the fork as the work proceeds, making the bed about 5 feet high at the back, and 4 feet 6 inches in front, which will allow for settling, as it will do, about one-third. A few Pea sticks placed across and along the bed at intervals not only prevent overheating, but admits the heat from linings to be conveyed to the interior of the bed. For early work frames with double sides are preferable, three-eighths-inch boards 9 inches less in depth than the box at the back, and 6 inches in front, with the boards at the ends sloping, and all the boards secured to the inside by nailing strips of wood an inch wide and thick vertically to the box, then the boards which form a cavity an inch wide all round the lower part of the inside of the box, which is essential to get ample heat from the linings. In about a week from making the bed the heat will be up, then level the surface, or rather make it evenly sloping to the front, replace the box, apply sufficient sweetened material to raise the inside within 2 or 3 inches of the top of the inner frame or cavity, placing rather dry, partially decayed leaves or spent tan for plunging the pots in. This bed will afford a mild and regular bottom heat, and the top heat will more accord with it than is the case without the cavity. Such a bed is valuable for raising many other plants from seeds and cuttings besides seedling Melons and Cucumbers. To raise the plants, half fill 3-inch pots with rich light loam, placing one seed in the centre of each pot, covering with fine soil in a moist state, so that watering will not be required to insure the germination of the seeds. Space is thus left in the pot for top-dressing,

which is preferable to potting the plants. Cover the pots with a pane of glass, which hastens germination, but remove it as soon as the plants appear. The plants, whether Cucumbers or Melons, from a sowing made early in February will be ready to plant out early in March.

**Cucumbers in Houses.**—Secure a night temperature of 65°, 5° more in mild weather, whilst it may fall to 60° on very cold nights, 70° to 75° by day from fire heat, and 80° to 85° or 90° with sun heat. When the external air is mild a little ventilation may be given at 80°, closing before the temperature is reduced below that degree, and so as to raise it to 90° to 95° or 100° in the early part of the afternoon. If, on the other hand, the external air is cold, although the sun shines, it is better to allow the temperature to advance a little beyond the limits named than to admit air, which cripples the foliage and causes the fruit to become stunted. Plants in bearing will require to be attended to about twice a week for the removal of all weakly and exhausted growths, reserving sufficient young bearing wood for filling the allotted space without crowding, stopping the shoots at one or two joints beyond the fruit. Young plants coming into bearing should not be allowed to bear too soon, and by no means be overcropped. They are greatly assisted by removing tendrils and superfluous flowers as they appear. Let the root moisture be governed by the condition of the soil and requirements of the plants. Avoid overwatering, as it is moisture in an aerified state that is needed for healthy growth, a sodden soil producing nothing but evil. When vigour is needed supply liquid manure in a tepid state, top-dressing with a little fresh loam and an approved fertiliser to accelerate surface rooting and an abundance of active feeders. Except on fine days syringing should not be practised over the foliage, a light sprinkling on bright afternoons being beneficial. Damping the floor and similar surfaces in the morning, afternoon, and evening—about 8 A.M., 2 and 5 P.M.—will give all the moisture necessary in ordinary weather. Keep a sharp look out for aphides, and fumigate moderately and carefully on two consecutive evenings, or preferably late at night and in the early morning. If mildew appears apply flowers of sulphur promptly, brushing a little on the hot-water pipes in case of attack from white fly or red spider, and rub quicklime well into any parts affected with canker.

#### THE FLOWER GARDEN.

**Hotbeds for Propagating Purposes.**—Propagating cases over hot-water pipes have largely superseded the old-fashioned hotbeds for propagating purposes, but it is doubtful if the results are generally so satisfactory. The moist, genial heat of a hotbed of well prepared manure and leaves is yet unsurpassed for raising plants from seeds or cuttings in glass-covered boxes. When the bottom heat is in the form of a tank set on hot-water pipes a moist heat is generated, while if the pipes pass through a brick and cement tank still more vapour arises. In each and every case the glass should be wiped dry every morning, the drip from this, if allowed to take place, proving fatal to either cuttings or seedlings.

**Tuberous-rooted Begonias.**—It is a mistake to start old tubers very early if cuttings are wanted for raising plants for bedding out. Keep them dry and cool. There should be no delay, however, in sowing seed of the best bedding strains. They can be had in separate colours as well as in mixtures. The seed is very minute, and more than ordinary pains have to be taken with it in order to be sure of germination. Six-inch pots or pans should be well drained and filled with fine sandy loam rather than peat or leaf soil, in which insects abound; make it firm, and level, giving a gentle watering a short time prior to sowing the seed. On no account surface over the soil with silver sand, as this does not afford the necessary foothold for the tiny seedlings. Sow the seed evenly, and do not cover with either soil or sand. Plunge the pots in a gentle bottom heat, cover with squares of glass, and darken with a covering of moss. The moist heat will obviate the necessity for frequent waterings; in fact, there ought to be no sprinklings after sowing, as these are almost certain to disturb the seed. At the same time the soil must not be allowed to become dry, and when approaching dryness the pans or pots should be partially immersed in a bucket or tank of warm water, the moisture soaking upwards. Worms ought to be kept out of the soil. When the seeds are bursting is a very critical time, a few minutes' exposure to bright sunshine or dry heat spoiling them. The removal of the shading ought, therefore, to be gradual, and some of it to be returned on bright mornings. By good culture seedlings raised now or early in February should be large enough for the flower beds early in June.

**Fibrous-rooted Begonias.**—The white and pink flowering forms of *B. semperflorens* are suitable for bedding, but the crimson variety is even more so; the bronzed foliage is also effective. These all come true from seed, and are more easily raised than the tuberous-rooted section. *B. Carrieri*, a neat-growing, very floriferous white variety, is well adapted for bedding, raising the stock from cuttings made from young shoots, and the same may be said of the old *B. weltoniensis*, both the foliage and flowers finding many admirers.

**Bedding Lobelias.**—The dwarf kinds, notably well-selected strains of *L. speciosa*, are still indispensable as edging plants, and should be raised by hundreds or thousands, according to circumstances. They may be depended on to come true from seed, and this should be sown at once, very much as advised in the case of tuberous Begonias. Avoid sowing very thickly, as when crowded the seedlings are liable to damp off. Where the seed was sown in the autumn, and many thousands of plants are raised thus early, the seedlings ought soon to be pricked out other boxes being filled with them later on. Stock plants of named in pans or boxes of fine soil, especially should there be any signs

of damping. They may be pricked out rather thickly, frames or varieties that are to be propagated from by either cuttings or division ought never to be exposed to much dry heat, as this dries up the young roots that form above the soil, spoiling the plants for division, also hardening the young growths, rendering them unfit for making into cuttings, as it causes them to flower early. Every little piece with a few roots attached will, if dibbled in boxes or pans of good soil and placed in a moderately brisk heat, soon become established, and by bedding out time have developed into good stocky plants. Quite soft tops will root freely in propagating or other frames over a fairly brisk bottom heat. *Lobelias cardinalis* and *Victoria* are perennials, and tall growing. These also may be raised from seed sown now, but they are best raised in June or July. Store plants, whether in pots or lifted from the beds, ought not to be subjected to much fire heat. Kept in a greenhouse or a pit they will duly push up numerous suckers, and it is then when division should take place.

**Verbenas.**—Seedlings are stronger growing than cutting-raised plants, and as a rule are only suitable for planting in beds by themselves, a packet of seed giving many excellent varieties. Sow at once in sandy loam in heat. Occasionally the seed germinates quickly, while at other times it is slow in moving, and the pots or pans ought not, therefore, to be hastily emptied under the impression that the seed has failed. Verbenas are among the first to suffer from too much fire heat. In by-gone days they were kept in better condition, and gave great numbers of succulent clean cuttings when wintered in pits and frames than has been the case since the store plants have been kept in heated houses through the winter. If good stocks of the long fleshy roots of *V. venosa* have been stored these may be cut into short lengths of two joints and dibbled thickly in boxes of light soil. The greater portion of these will form serviceable plants in due time.

**Hollyhocks.**—If old clumps have been kept through the winter, these if started in gentle heat will soon push up numbers of shoots, all of which could be taken off with a heel when about 4 inches long and rooted in heat. Where, however, disease ruins the old plants or any raised from cuttings, seedlings should be tried. If the seed is sown now in pans and placed in heat it will quickly germinate, and the seedlings being first pricked out in pans and boxes, then placed singly in 3-inch pots, and from these finally shifted into 6-inch, using a rich loamy compost, fine healthy plants will be ready for the borders by the middle of May. All may not throw up flower spikes the same summer, but the greater portion will do so, and some good varieties be had among them.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### CONSUMPTION OF STORES.

MANY inquiries have reached me concerning the safety of hives. Some point to a few dead bees on the alighting boards; others to bees flying and losing themselves in the snow; and in one instance the entrance is choked with dead bees.

Since Christmas my bees have never been observed on the wing. Although I have been outside very little I have had reliable information conveyed to me as to external appearances, and can see from the window the fronts of a few of my hives. Most of them have from one to a dozen dead bees on their alighting board. I regard these as a sure proof that the bees within are alive and healthy, due to internal dryness, which gives comfort and health to the bees.

The absence of dead bees on the floors or closing the entrances is entirely due to the ventilating metal floor being free from damp, unlike the solid floors, which are often damp and fatal to bees when they come into contact with them during cold weather. Hives so constructed have generally much moisture on the sides, and combs soon become mouldy. The temperature of a damp hive being much lower than a dry one the bees consume more food, consequently become restless and fly in an enfeebled condition when they ought to be resting in comfort within their hives. All my hives, except one that was diseased in the autumn, have ample stores to tide them over till honey can be gathered. The weak hive began to breed and feed a week before Christmas, and I am hoping to bring it through by close attention. Still, although I left my hives extra heavy, and some with their surplus untouched, they consumed more honey in the mild November and December than they would had the temperature in these months been lower.

Other bee-keepers have done the same, and those hives having under 15 lbs. of food at the start may be on the verge of starvation. In all cases where a shortness of stores is suspected, feed liberally the first night after the bees have had a flight. If weak, nurse rather than feed, and keep the crown of the hive over the bees well covered with porous material, and give them no inducement to fly until the flowers invite them forth.

#### REPAIRS AND IMPROVEMENTS.

Note every defect, and make arrangements to have them remedied before another winter, as well as to have any improvement

desirable which tends to economy, and having healthy and profitable hives. I especially advise those who have hives smaller than Nature demands to try larger ones, and see if the change is not a good one. If any difficulty arises an appeal to these columns will set them right, or advice will be given that will tend to clear the way to pursue their hobby with pleasure and profit.—A LANARKSHIRE BEE-KEEPER.

#### NOTES ON BEES.

A READER of the Journal writes, "What am I to do with one of my hives? It is a strong stock, and the queen will be three years old next June. I did not have more than 6 lbs. of honey from it last summer. It has eleven frames, and I am not certain if I ought to reduce the number, as I think the bees will go on storing in the frames instead of in the supers."

The colony should be headed by a young fertile queen, as only in exceptional cases is the queen of much use when in her fourth year. In my apiary I have several queens the same age as the above, but as they have been very prolific I delayed requeening those stocks until next summer. In the case of old queens they often do not make much headway early in the year, consequently it is late in the summer before the hive is full of bees, and, as stated above, very little honey will be stored. Queens of this age, too, will often die during a severe winter. If the stock is well provided with stores leave the whole of the frames in the hive until May, and if the weather has been favourable they will by this time be crowded with bees.

The proper time to rear queens is at their natural swarming season, and this should be done and the young queen laying before the old one is destroyed. It will take upwards of three weeks from the laying of the eggs till the queen is hatched and laying; and if during that time the old queen can be kept laying, at a very low estimate it will result in at least 20,000 young bees (a young fertile queen will at that time of the year lay at least 3000 eggs daily). These, if an increase of stocks is not required, will make an extra strong colony, which will reap the full benefit of the honey flow from the white Clover, if in a Clover district, or later in the season from the Heather.

On the morning of a fine day, when the bees are well on the wing, take two or three frames of well advanced brood, with all the adhering bees and the queen from the original hive, and place them in a new hive, adding two or three frames of fully drawn out combs or full sheets of foundation, closing with a division board, placing the hive on the original stand. The parent hive to be moved a few yards away, all the bees that are on the wing will return to their original stand, also many of the old bees from the parent stock, which will enable the new made colony to make progress. The frames in the parent stock should be closed up with the division board. Queen cells will at once be started.

If only one queen is required, these may all be cut out but one, delaying the operation until the tenth day. The best cell can then be selected. It is always advisable to rear an extra queen or two in case of loss. The queen will hatch out in about sixteen days, and, if the weather be favourable, should be fertilised and laying in six or eight days. In the meantime the brood will have been rapidly hatching out. All the empty cells in the new stock will soon be filled with brood, a frame of which should be taken out every few days and given to the queenless stock, and an empty frame should be put in its place. This will keep the nurse bees fully employed.

The hives should be moved a yard nearer each other every day until they are close together. As soon as the young queen is laying kill the old one, and put all the bees and frames of brood into one hive. If there is any danger of fighting sprinkle them with a little flour or thin syrup; but at that time of the year when honey is coming in freely the operation may take place without the loss of a single bee, and will result in an extra strong colony, and, being headed by a young fertile queen, will at once store a surplus in the supers.—AN ENGLISH BEE-KEEPER.

## TO CORRESPONDENTS

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Barked Fruit Trees (K. J. F.).**—We do not know what more can be done in addition to making smooth the torn edges of the bark and plastering, except carefully planting two seedling Crab or Apple stocks close to each tree, inarching these to the trees by slicing from the ground upwards to a length of 6 inches of the stem above the gnarled parts. In this way young fruit trees have been restored which would otherwise have been destroyed in consequence of the stems being deeply eaten all round by rabbits. The sliced portions of the stems must be absolutely clean for their union to be effected. When secured they must be clayed in the usual manner adopted in grafting, and no fissures allowed in the pigment to admit the air. Thin coverings which quickly become dry are of little use.

**Chimonanthus fragrans in Pots (C. H. C.).**—To flower the *Chimonanthus* successfully in a pot, it requires a very large one, good loam, with a little peat, plenty of water in summer, and a warm sunny place in the autumn, and the water to be reduced then to harden the wood. It requires much the same culture as a spurred Currant tree would do, only that the young stubby shoots are what must be looked after and prepared for winter. If the shoots produced are of the size of from a crowquill to a goosequill they will be quite strong enough, and if these side shoots grow longer than from 8 to 10 inches nip out the points. If the shoots are too thick to obtain light enough thin them out. Give all the heat possible out of doors in autumn, and as much dryness as the plants will stand, to ripen the shoots. As the soil becomes damp and the weather is mild the buds will expand.

**Cockchafer Grub (D. M. R.).**—The larva you send is not the caterpillar of the Goat Moth, which lives and feeds in the internal parts of trees; but the grub of the cockchafer (*Melolontha vulgaris*), that feeds on the roots of various shrubs and trees for about three years, when it becomes pupa, from which it emerges in the spring in perfect form—the familiar May bug or cockchafer. The larva is very destructive of tender roots and partial to vegetable matter, such as that of the decayed parts of manure and the roots of grasses, and the perfect insects feed on a great variety of trees, sometimes wholly denuding Hawthorn, Hazel, Elm, and Willow of foliage. It also attacks Oaks, and a great variety of other trees and shrubs. The grubs are stupefied, if not destroyed, by a dressing of nitrate of soda, 1½ lb. being used per rod, it being best applied after the ground has been dug level, so that the nitrate gets washed into the soil evenly. It is best applied in the late winter or early spring, alike for acting on the grubs and benefiting the land as manure. Soot, at the rate of 1 peck per rod, is also distasteful to the grubs and benefits the plants.

**Cordon Pears under Glass (A. B.).**—Pear trees succeed admirably as cordons in cool houses, but the fruit does not acquire so high a flavour, nor is so juicy, melting, or buttery as that perfected in the open air. Both early, midseason, or autumn and late Pears are eligible for this mode of culture, the fruit attaining large size under good management and feeding, and it generally carries plenty of colour, being very beautiful in appearance. The trees should be on the Quince, or if requisite double grafted. The following are excellent varieties:—Summer (July-September)—Beacon, Jargonelle, Souvenir du Congrès, Williams' Bon Chrétien, Triomphe de Vienne, Madame Treyve, and Fondante d'Automne. Autumn (October and November)—Louise Bonne of Jersey, Durondeau, Marie Louise, Madame André Leroy, Pitmaston Duchess, Beurré Superfin, Emile d'Heyst, Doyenné du Comice, and Comte de Lamy. Winter (December onwards)—Beurré Diel, Beurré Baltet Père, Maréchal de Cour, Beurré d'Anjou, Winter Nelis, Knight's Monarch, Beurré de Jonghe, Duchesse de Bordeaux, Nouvelle Fulvie, Josephine de Malines, Marie Benoist, Beurré Rance, Easter Beurré, Bergamot Esperen, and Doyenné d'Alençon. Cherries thrive excellently under glass as cordons. Some of the best for a succession of fruit are Belle d'Orleans, Banmann's May, Purple Guigne, Early Rivers, Governor Wood, May Duke, Belle de Choisy, Waterloo, Elton, Bigarreau de Mezel, Black Eagle, Black Tartarian, Emperor Francis, and Florence. Both the Pears and Cherries may be grown in pots, the Pears being placed in the house when the buds commence swelling in the spring and kept under glass till the fruit is set and the

weather has become settled, or in June, placing them outdoors, the Cherries being placed in the house in spring and continued therein until the fruit is gathered, then the trees may be taken outside. This is better practice in the south of England than keeping the plants constantly under glass.

**Pruning an Apple Tree (M. G. T.).**—Do not wait till next year before pruning the growths from the scions, as obviously that would necessitate cutting back into two-year-old wood. Shorten them now, but if the production of fruit is of greater consideration to you than the form and outline of the tree, perhaps the less they are shortened the better. If you particularly want a formal pyramid, pruning must be resorted to for producing it, but the closer you prune the more you will retard the bearing of the tree. Apple trees do not make good and productive pyramids, their natural habit of growth differing from Pears. If early fruitfulness is your chief object you had better limit the pruning to the removal of any soft unripe tips from the shoots.

**Dressing Vines with Lime and Sulphur (Nemo).**—An excellent insecticide and fungicide of proved efficacy is given herewith, and will doubtless be what you are in need of. Take 7 lbs. of flowers of sulphur and 7 lbs. of quicklime, boil together for fifteen minutes in 3 gallons of water, then add 2 lbs. of softsoap and 1 lb. of strongest shag tobacco, boiling all together for half an hour, adding 9 gallons of water, keeping it well stirred. Allow it to cool, then strain, and when settled take off the clear liquid, place in earthenware bottles, keeping them closely corked. In its pure state it may be used for dressing Vines and other fruit trees when at rest, applying it with a brush, taking care not to injure or dislocate the buds. For syringing Peach and other fruit trees during growth 1 pint to 3 gallons of water is a suitable quantity, and efficacious against insects and mildew. It must not be applied over Vines in growth, as it is apt to leave a deposit on the berries similar to stain marks occasioned by using hard or lime water. If used over Cucumbers or Melons, as well as plants with hairy leaves, half a pint is a full quantity to add to 3 gallons of water.

**Decomposed Seaweed (Seaside).**—The constituents vary according to the different plants or Seaweeds. Fucus digitatus contains 20.66 per cent. of potash, 7.65 soda, 6.86 magnesia, 10.94 lime, 2.36 phosphoric acid, 12.33 sulphuric acid, 1.44 silica, 0.57 peroxide of iron, and 26.18 chloride of sodium. Fucus serratus contains 3.98 per cent. potash, 18.67 soda, 10.29 magnesia, 14.41 lime, 3.89 phosphoric acid, 18.59 sulphuric acid, 0.38 silica, 0.30 peroxide of iron, 16.56 chloride of sodium. In the green state Seaweeds supply chiefly nitrogen and potash to a soil, decomposing rapidly, and are excellent manure, but a quantity is needed—viz., 20 to 30 tons per acre. They should be used as a potash-nitrogenous manure. Reduced to mould their value is similar in furthering plant growth to leaf soil, differing only in the enlarged amounts of potash and soda, and may be used in the same way. Dried and burnt the constituents would be as given above, but the value of the soil would be gone, the mineral only remaining, and chiefly valuable for its potash, soda, and phosphoric acid. In the mould state the organic matter would contribute considerably to plant growth, mainly from the humus, though the carbonic and nitrogenous elements would act beneficially. It may be used for the plants you name to the extent of one-third of loam, or if the loam be turfy a fourth would be sufficient, as its action would be directed to increase foliage, and in plenty of light to improve the colour of foliage and flowers.

**Tomato and Cucumber Fertilisers (Cross).**—The compound advised for Tomatoes on December 27th, 1894, should be used every fortnight or three weeks, or, if that is likely to impart too much vigour, at more distant intervals, say four or six weeks. Instead of the hoof and horn dust we should use nitrate of soda, which is a better form of nitrogen than that generated or evolved from animal matter, and is inimical to, while the other favours eelworm. The thing is to avoid clubbing altogether, upon which our advice was founded. Chlorophyll is stated to be mainly due to the presence of iron, but that is mere conjecture in many cases, as ammonia or nitric acid puts more green into plants than any other element. Iron is, however, absolutely essential to the formation of chlorophyll, but its activity, or the power of assimilation, depends on the extent of its nitrogenisation. The superphosphate advised is that of dissolved bones, not fermented, but treated with sulphuric acid. Mineral superphosphate is safer to use, as regards eelworm, than fermented bone compound, which often favours visible larvæ as well as micro-organisms. For the Cucumbers you may add a half part of sulphate of iron to the mixture, and apply as before advised. A slight sprinkling of soot would give you both the iron and ammonia, so essential for colour in the foliage and fruit of Cucumbers, using it alternately with the mixture recommended without the sulphate of iron, for the soil can hardly be deficient of iron; or it may be secured by using some of the gravelly subsoil with the compost as opening material.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (T. R. S.).—*Euonymus radicans variegata*. (*Erica*).—1, *Trichomanes reniforme*; 2, *T. radicans*; 3, *T. tricoideum*. (*S. M. R.*).—1, *Gleichenia flabellata*; 2, *Hermitelia horrida*; 3, *Dictyogramma japonica*; 4, *Gleichenia Speluncae*. (*Orchidist*).—1, *Cypripedium Harrisianum*; 2, *C. villosum*; 3, *Lælia anceps*, very fine form. (*L. E. C.*).—1, *Cattleya Percivalliana*; 2, *Lælia anceps*.

THE DAIRY IN WINTER.

A DRY building and an even temperature of 55° are now regarded by dairy experts as fundamentals on which successful butter-making depends in a high degree. The dry building is much more common than the even temperature. A thatched roof, north aspect, and good ventilation answer perfectly in the summer; but during the winter the proper temperature can only be maintained by means of a furnace and flue, or a couple of hot-water pipes running round the dairy. In good modern dairies attention is given to this, as well as to convenience for ripening cream—a matter of the first importance, because when well done the churning is more certain and more expeditious; the butter is of superior flavour and better texture, and there is at least 7 per cent more of it. If, as a prelude to skilful ripening, a separator is used we obtain a maximum result in quantity, as it is claimed for the separator that with it milk yields from 15 to 20 per cent. more butter than when it is set in pans.

A little consideration should bring conviction to the mind of every sensible dairy manager that the separator does much more than this. That it does extract more cream from the milk than is possible by using milk pans is certain; but in addition to this, if the milk is separated immediately after the milking the

risk of taint from exposure in pans is avoided, the trouble, expense, and anxiety of heating a large dairy in winter is avoided, and the cream, being in close compass can readily be prepared for churning.

Close attention to temperature is always important; it is even more so in winter than in summer. The cream should be kept in a room where there is a steady temperature of 55°; it can then be ripened readily for churning. By ripening the cream a slight thickening and sourness in it is meant. This comes naturally under a temperature of 55°, and with the whole of the cream slightly sour the greatest possible quantity of butter will be made. If the cream become too sour there will be less butter; it will not keep well, it will be of bad flavour, it may even be rancid, it will be practically worthless. Evenness of ripening is essential. Without it there will be some loss, simply because the butter grains come first from the sour cream, and those in the sweet or unripened cream will be lost in the buttermilk. That is why cream is stirred in the cream crock five or six times a day, and also when fresh cream is poured in. No fresh cream should be mixed with it for ten or twelve hours before the churning. When there is a large quantity of cream to deal with churning is more frequent, and recourse is had to artificial ripening. This is done by raising the temperature of the cream to 70°, adding and well stirring in 4 per cent. of sour milk or buttermilk, and keeping it covered and warm. It is then ready for churning in about eighteen hours; in some dairy schools four or five hours longer is allowed.

In the churning temperature is again an important factor. The best temperature of the cream for churning in winter is 58°; if it is at about 60° just before it is put in the churn it will be at the right temperature when churning begins. Before the cream is put in, scald the churn with boiling water to close the pores of the wood, follow immediately with a dash of cold water, then put in the cream, which has been brought to the right temperature, if necessary, by placing the cream crock in a larger one containing hot water. With the churn not more than half full of cream the churning is best done. Brisk churning is desirable in winter, but it is best to go slowly for the first ten minutes at all seasons of the year, so as to avoid frothing the cream, and the ventilator should be pressed down frequently so long as air rushes out. Then the rate of speed is increased to sixty turns a minute for end-over-end churns, and forty-five for churns with a dasher. Avoid over churning. Never suffer the butter to be churned into a mass, or buttermilk will be so mixed with it that it cannot be washed out; the butter will then be streaky, of bad flavour, and will not keep well.

If the churn is stopped when the grains are well visible the butter is then of one distinct colour, because the grains are unbroken, the buttermilk is clear, and is easily removed by about three washings, each lot of water being run off from the churn through a hair sieve. Flavour in winter is considered to be improved by leaving in a slight quantity of buttermilk. This and brining or salting is entirely a matter of taste, requiring careful study and management to suit special requirements.

#### WORK ON THE HOME FARM.

Carting of every kind is being pushed on now so as to have the horses at liberty for work on the land when required a little later on. We never like missing an opportunity of sowing spring corn early, and therefore always endeavour to get through as much estate work at mid-winter as can be managed. Such demands on the home farm for horses and men are often very inconvenient, and are not easily met without some hindrance to farm work. They are, however, inevitable, and the best plan for the home farmer, in view of avoiding friction and hindrance to his own work at a critical time, is to grapple with estate work now as full-handed as may be, and to get well forward—if possible, to finish—all carting of gravel, timber, and similar things. While at the gravel pit bear in mind any blemishes in yard-bottoms, roads, gateways, and drinking places, and if it can be managed, get material carted for all such purposes during the winter.

We have seen threshing machines at work on a few farms, and again recommend caution in threshing after so much wet weather. The exceptionally high winds in December may have done something to drive moisture out of the ricks, but we still say, Be cautious. Damp corn is not readily sold, nor is it ground or crushed without much difficulty.

As calving goes on throughout the winter the number of calves mounts up, and due care must be exercised in their management. Snug warm quarters, clean dry litter always, wholesome nourishing food frequently, are the main points. Let them have milk or gruel at the least three times daily. The older method of suckling calves morning and evening only had nothing but custom to induce anyone to follow it. It is certain that under it calves became terribly exhausted; that the effect of going so long without food, and then loading the stomach hastily, was so trying as to cause much sickness and loss among them. Teach them to eat some of the best meadow hay early. Once get them to do this and they have always something to turn to; then with abundance of gruel they thrive apace and afford pleasing evidence of the effect of really good management.

#### HOW TO MAKE GOOD BUTTER.

I HAVE found a very simple method by which butter can be made with no difficulty whatever and in a remarkably short space of time, however hot the weather may be. It becomes, too, perfectly hard, while its keeping qualities are very greatly improved. I think, therefore, it may be worth while calling attention to it. Experienced butter-makers, to whom it has been mentioned, have tried it, and were astonished at the result. It is simply to surcharge the cream with salt by adding a great excess above the usual amount which is, of course, always put into it.

My plan is to put 3 lbs. of salt into a bowl, and mix it thoroughly with the first day's cream. I then keep on adding the cream of each day's supply, stirring it and thoroughly mixing it, until about 4 to 4½ quarts of cream have been mixed and thoroughly combined with the 3 lbs. of salt. This being then churned the butter "comes" in a surprisingly short space of time, even in the hottest weather, and turns out perfectly hard and firm.

The interpretation of the process is that, in the first place, the excess of salt forms a more complete union with the whey than a smaller amount can effect. Secondly, it dissolves the nitrogenous matter (casein) more thoroughly; consequently the butter, by the more perfect elimination of the latter highly decomposable substance, is less liable to become rancid, and so keeps a much longer time than it does by the ordinary method of making it.

The advantage of adding a superabundance of salt is more pronounced in the summer than in autumn and winter. Thus—*e.g.*, there was no difference in time in churning between fresh and highly salted cream on December 10th; but when the temperature of the air itself becomes cool as the season advances the usual method of warming the churn will be found advisable. The other advantages, however, of rendering the butter firm and less liable to rancidity remain the same.

As a practical illustration of the advantage of this method to professional butter-makers, I will add that a farmer in Gloucestershire to whom it was mentioned last summer informs me that his butter is so greatly improved in quality, both in firmness and sweetness, that the demand for it by his customers has much increased in consequence.—GEO. HENSLOW.

#### OUR LETTER BOX.

**Chemical Manure for Meadow Land (Pasture).**—The mixture recommended in our Farm article of the 10th inst. (page 42) will answer your purpose well. Apply early in February, and if the land is of a dry nature follow in a month or less with 2 cwt. of salt and 1 cwt. of nitrate of soda per acre, both crushed into fine powder.

#### REMARKS.

- 13th.—Snow from about 2.30 to 7.30 A.M.; a little sun in morning; spots of rain about 1 P.M.; fair afternoon, clear evening.  
 14th.—Dull, with drizzle and slight showers from 6 A.M. to 1 P.M.; sunshine from 1.30 P.M.  
 15th.—Overcast and slightly foggy throughout.  
 16th.—Overcast with frequent drizzle and showers till 2 P.M.; gleams of sun at 3.30 P.M.; showers again in evening and night.  
 17th.—Rain from 3.30 A.M. to 6 A.M., and dull and showery later; generally sunny in afternoon.  
 18th.—Sunny throughout and cooler.  
 19th.—Overcast morning; rain from 3 P.M., and steady, heavy rain from 5 P.M. to midnight.  
 Remarkably low mean barometric pressure, but not much wind. Rain above the average, temperature near it.—G. J. SYMONS.

# VEITCH'S SUPERB CELERIES.

## VEITCH'S EARLY ROSE.

A beautiful rose-coloured selection of robust, compact growth, forming very solid hearts, which are crisp and of a fine flavour. Per Packet, 1s. 6d.

## VEITCH'S SUPERB WHITE.

The most perfect type of White Celery for table use, being a pure white counterpart of the well-known Major Clarke's Solid Red. Per Packet, 1s. 6d.

## VEITCH'S DWARF RED.

A distinct variety of dwarf growth and fine colour, very solid and crisp. Per Packet, 1s. 6d.

For full description of the above, and many other CHOICE NOVELTIES & SPECIALITIES, see SEED CATALOGUE, forwarded gratis and post free on application.

### LIME.

THIS being a good time of the year for the application of lime, it cannot be out of place to study a little about its value, first as a plant food, and secondly its functions and uses when applied to soils.

If any kind of vegetable matter be burnt, and the ash which is left analysed, it will be found that a large proportion of this ash consists of lime. It has been proved by experiments that lime is essential for the development and growth of plants. The following plants are taken as examples, and show the quantity of lime present in their ash—In the Grape Vine, 36 per cent.; fruit of Tomatoes, 12 per cent.; roots and stem of Dianthus, 45 per cent.; Chrysanthemum, 26 per cent.; Turnips, 50 per cent.; Potatoes, 20 per cent. This would show that in time a considerable amount of lime will be removed by growing crops. Another important loss of lime to soils is by drainage; Professor Way found on analysing different samples of drainage water, that they contained from 2 to 14 grains of lime per gallon. On an average about 20 inches of rain falls annually upon an acre of land; about one-third of this passes away by filtration, which must necessarily carry with it from 21 to 147 lbs. of lime per annum. It must be clear from the above that lime is an essential constituent of soils, and that it is constantly being removed, hence the necessity of fresh supplies.

When we speak of applying lime to the soil, it is not clearly understood whether it is the caustic, or mild form that we are going to use; we must know something of its chemical nature to understand of what the different compounds of calcium consist, and the changes which take place within the soil. Caustic lime (CaO) is composed of two elements—calcium (Ca), a metal, and oxygen (O), a gas; it is prepared by burning carbonate of lime (CaCO<sub>2</sub>) in kilns, when carbonic acid gas (CO<sub>2</sub>) is given off, and caustic lime (CaO) is left behind. If caustic lime be put into a heap, and water poured upon it, a considerable amount of heat will be generated, owing to the union of the water (H<sub>2</sub>O) with the lime, a hydrate (CaOH<sub>2</sub>O) being produced. But if the lime be allowed to slake

In sealed packets, price 2/- per pint.

in the air a large quantity will go back into the carbonate form, owing to its union with carbon dioxide from the atmosphere. Lime is also found in nature as a sulphate ( $\text{CaSO}_4$ ), and phosphate ( $\text{Ca}_3\text{P}_2\text{O}_8$ ); the former being the chief constituent of such minerals as gypsum and selenite; while the latter is found in bones, and also in the minerals phosphorite and apatite.

As slaked lime, it can be best applied to clayey and peaty soils; for it is able in this state to decompose the silicates, of which a clay mainly consists, liberating the alkalies, which are soon taken up by plants. It also acts mechanically in modifying the physical properties of clayey soils, the silicates of lime which are formed being more sand-like in their properties. This lessens the tenacity of clays and makes them more porous, which allows the air to enter freely to perform its useful function of preparing food for plants. Soluble salts of iron are injurious as such to vegetation; but lime has the power of rendering these salts insoluble. Slaked lime is the form to be used upon peaty, or soils containing much organic matter (as old garden soils), for it is able to neutralise any vegetable acids which may be formed owing to the decay of the organic matter, forming salts which are harmless, and which may even be of use to plants as food; by decomposing the vegetable matter the inorganic constituents are made available for plant nutrition, and are readily taken up by them.

When slaked lime decomposes the organic matter it unites with the carbonic acid gas to form carbonate of lime; this carbonate keeps the soil in a basic condition, which is of the greatest importance to nitrification, for the activity of the nitrifying bacteria may be hindered by the absence of sufficient lime salts, as may be proved by the beneficial results which have been obtained after an application of chalk. If quick or slaked lime be added to soils in excess it arrests their (the bacterias) activity, and can only be remedied by the application of some green manure. What takes place in the soil by the action of the nitrifying organisms is not clearly understood, but they ultimately produce under suitable conditions nitric acid, which, being a stronger acid than carbonic acid, drives the latter off from lime, and unites to form a nitrate of lime, this being one of the most valuable plant foods present in the soil.

The chief and most abundant supply of lime is the carbonate, examples of which are seen as limestone, chalk, shell sand, and marls, some of the beds of limestone being 6000 feet through them. In applying lime to a light sandy soil it should always be used as a carbonate or sulphate, for in these forms it will make the soil more retentive and better able to hold plant foods. Carbonate of lime from its slow action on organic matter is sometimes called mild lime; this slow action is an advantage in sandy soils, for it is chiefly owing to the humus that sands are able to retain plant foods. If quick, or hydrated lime, be applied to sandy soils it destroys the organic matter; but if it were put on the land and allowed to slake, it would then take from the atmosphere a considerable quantity of carbonic acid gas, much of it passing back into the carbonate form, and might be used if chalk, or some other carbonate of lime could not be procured.

Gypsum, or sulphate of lime, is used on light soils; it supplies sulphuric acid as well as lime to the plant. It can be used with organic manures where a loss due to the escape of ammonia might occur, for it has the power to fix this gas until it can be utilised by the plant.

Gas lime is slaked lime, and contains when fresh from the works calcium sulphide and sulphite. These are injurious to vegetation, but after being exposed for some time to the air they are oxidised and form sulphate of lime. Gas lime is useful for mixing with rubbish heaps, to hasten their decay. Many manures contain a large percentage of lime, so when any of these are used there will be less need to apply lime. Basic slag contains 50 per cent. of lime, mineral superphosphates 30 per cent., bones 25 per cent., guano about 15 per cent., farmyard manure 10 to 20 lbs. per ton. In superphosphate it exists as a sulphate, and in bones and guanos as a

phosphate. The quantity of quicklime to use per acre should be from 2 to 9 tons; twice the amount of carbonate could be used for the same extent of land, and of sulphate from 5 to 10 cwt. per acre.—W. D., *Turnford*.

## THE TOMATO SUPPLY.

TOMATO growing is a very important industry, and likely to remain so. In spite of the enormous output of fruit the demand has more than kept pace with the supply, every year seeing a very great increase in the number of consumers. Whether there would not be a glut during August and September if all who have entered on the culture of Tomatoes under glass could succeed in producing a good average crop, remains to be seen. During the early part of last season the prospect was decidedly good, as the plants very rarely set such heavy crops at the commencement. Unfortunately the later bunches of flower failed to set, a scarcity of pollen it was thought having something to do with this failure. In some instances I believe those in charge of plants on which extra heavy lower clusters of fruit set failed to realise that this must mean a greater strain than usual, and did not, therefore, feed them sufficiently.

We have become so frightened of diseases that one remedy, or rather preventive measure—viz., dryness of house and atmosphere, is apt to be overdone. Tomatoes in full bearing require abundance of water and food at the roots, otherwise they are liable to collapse, and we may easily err in the direction of keeping them too dry. Not only do plants insufficiently fed at the roots fail to go on setting clusters of fruit up to any required height above 3 feet, but they are also the first to collapse if attacked by eelworms or fungoid diseases. So plainly apparent was this latter fact that intelligent growers did not hesitate to lighten the crops where they were very heavy, and had good reason to feel convinced they had acted wisely by so doing.

Overcropping, however, was not the sole cause of so many partial failures. The season of 1894 was most favourable to the spread of fungoid diseases. The disease known as "black stripe" seems to be fast on the increase, and was the worst enemy Tomato growers had to contend with last season. It usually first shows itself on the most sappy plants in the form of striped stems, the leafstalks following suit. Sometimes the leaves also become black, while in others they do not. I strongly advise all who have this evil to contend with to adopt preventive measures at the roots. What makes me confident that the cause of the stripes is traceable to the roots is the fact that it is frequently only the upper portion of vigorous plants that show signs of the disease, the lower half being perfectly free. Strong plants failed at the points, but weakly ones collapsed altogether, owing probably to the disease completely encircling the stems underground. Wherever this form of disease has to be combated very little solid manure should be dug into the ground, a firmer more disease-resisting growth resulting from the use of chemicals, as frequently advised in the inquiry columns of this Journal. There is a strong probability that some of these manures are disinfectants, and, according to Professor Griffiths, sulphate of iron is both a fertiliser and a germicide, and I intend using it largely as such this season with a view to thoroughly testing its value. An excess of iron sulphate might probably prove injurious, and for this reason I shall be content to use it at the rate of 10 ozs. to the square rod, mixing it with ashes so as to be able to distribute it evenly and washing it down gradually.

Those who have suffered most from this disease, as well as eelworm attacks, would appear to have grown varieties principally that set the heaviest crops without much trouble being taken with them. If these free setters possessed extra strong constitutions then the selections would have been more justifiable. As it happens Early Ruby, selections made from Large Red or crosses which the latter has helped to bring about, are far from being robust, and are incapable of making much headway under difficulties accordingly. Added to this they are most of them corrugated more or less, and do not therefore sell so well in the markets as do the more smooth round forms. Then, again, corrugated or ribbed fruit are always very full of seed, and seed takes far more out of the plant than does the pulp and core of the more solid smooth round fruit. Ruby is a good early variety, and well worthy of being grown as such; but for succession and main crops give me Challenger, A1, Ham Green Favourite, Duke of York, and such like. Judging from appearances, and the character given by most trustworthy men to the Frogmore Selected, this should prove a great acquisition, and to be recommended to all classes of growers. There is just enough of the old Large Red or some other corrugated form in it to make it a very free setter nearly or quite

all the year round, and yet not enough to spoil either the form of the fruit or the constitution of the plant.

When commencing this paper it was my intention to give the greatest prominence to a matter that I have been frequently consulted on of late, and that is whether or not Tomato growing is an industry in which gentlemen's sons, or others with a moderate amount of capital and little or no experience in Tomato culture, may safely invest, but can only briefly allude to it now. I cannot honestly recommend any inexperienced person, male or female (for the latter are also "on the war path"), to commence Tomato growing for the markets, and have done my best to dissuade several from starting. It seems, however, that the more I argue against their starting the more determined are my interrogators to have a try. Some of them will regret not having taken my advice. Tomato growing is really a great lottery. Some there are who have succeeded well, but there are many others who would gladly take less money than their land and buildings cost, so doubtful is the prospect of gain becoming. Just merely getting a living is not enough, and he must be a smart man who can do that unless something over £800 is invested almost at the outset. Remember cheap glass structures depreciate in value rapidly, and this has to be taken into account when the profit and loss balance comes to be struck. Wood ready prepared and glass ready cut can be bought so cheaply that there is every inducement for the inexperienced to commence building on a fairly large scale, only to find that the heating and other ironwork, labour, water arrangements, and a variety of other expenses have also to be reckoned with. If these can be met all well and good; but in many cases, notably in the Channel Islands, accounts have to be held over and a heavy interest paid to those who have to wait for their money.

Several establishments in Guernsey are in the market. If experts find a difficulty in growing Tomatoes profitably, how much more so will those who know next to nothing about the work? Even private gardeners who have grown a sufficiency or an abundance for their employers find they have much to learn when they commence their culture on a large scale and in a different class of houses. I would not advise any of the latter to resign a comfortable situation in order to commence Tomato growing for the markets; but if they have a family largely consisting of strong boys, and find these regarded as an incumbrance, then if they have the wherewithal by all means strike out a new line—that is to say, Tomato and Cucumber growing. They must be prepared for much hard work and some disappointments; but there is "money in it" if only rightly sought after.—W. IGGULDEN.

PHALÆNOPSIS MARLÆ.

A CORRESPONDENT, "J. T. B.," writes for information on *Phalænopsis Mariæ*, and we may say that though one of the small flowered and small growing species of *Phalænopsis*, this elegant Orchid has found favour with the cultivators who have tried it. The plant was found by Mr. F. W. Burbidge in the Sunda Isles, when he was travelling for Messrs. J. Veitch & Sons, and bears the name of the discoverer's wife. An admirable coloured representation of it appeared in the second volume of the "Orchid Album," and Mr. B. S. Williams thus describes the habit and flowers of the plant:—"The leaves are deflexed, distichous, ligulate, acute, glossy, and obscurely striate. The flowers grow in a lateral, drooping raceme, and are about 1½ inch across; the oblong bluntish sepals and the somewhat broader petals are white, each marked with about six transverse bars of chestnut brown, the basal blotches being amethyst; the lip, which has the middle lobe obovate oblong apiculate, convex, and plane, not pilose, is of a rich deep magenta-purple margined with white."

#### CALANTHES FAILING.

FOR fifteen years I have been a successful grower of *Calanthes*, but for the last two years the *vestita* section have deteriorated in size, and this year have failed to flower. The buds decayed when about half an inch high. *Veitchi* is as strong as ever, and has had a flower spike fully a yard long, and both have been treated alike in soil and temperature. Could you give me a little advice on the subject?—M.

[It is difficult to account for these occasional failures with *Calanthes*, which often puzzle experienced growers. As you have been successful for so long, we venture to predict that

with carefully considered treatment the plants will soon come round. Perhaps the best way to help will be to mention a few causes of failure, and you will be the best judge as to which will meet your case. One of the most frequent is wintering this Orchid in too low a temperature, and from the fact of *C. Veitchi*, which is a better grower than *C. vestita*, doing well, it is possible that herein lies the mischief.

Deciduous *Calanthes* should be wintered in the pots in which they have been grown in a temperature of not less than 55°, and if 5° higher so much the better. They should not be repotted until the growths are starting from the base, when the roots will at once commence to take hold of the new compost. Where no fire heat is afforded during late summer the night temperature often falls much lower than is advisable, and causes a good deal of mischief among Orchids. The condensed moisture, which settles on the leaves in the form of dew, is all very well during warm summer nights; but as the days shorten and the nights get colder, fire

FIG. 15.—PHALÆNOPSIS MARLÆ.

heat must be turned on to dissipate this and create a more buoyant atmosphere.

*Calanthes* are also subject to a kind of black spot, to which many failures are attributable. Although this may be primarily caused by inattention to details in the matter of temperature and moisture, when once it obtains a hold on the plants no amount of care will rid them of it entirely, and in bad cases it is much better to obtain a fresh stock than to attempt it. Arrange the plants while growing so that they obtain all the light available, and only shade sufficiently to prevent injury to the foliage. Avoid wetting the pseudo-bulbs unduly after the foliage has fallen, and from that time onward maintain a free circulation of warm dry air about the plants.]

#### CALANTHE VEITCHI.

AS W. Penton (page 67) so ably describes this charming winter flowering Orchid under the management of Mr. Friend of Rooks' Nest Gardens, I am confident a few remarks on the management of *Calanthes* from Mr. Friend would prove an invaluable aid to myself and many other readers of the *Journal of Horticulture*. Seldom do we see examples producing exceptional long spikes of 5 feet 8 and 5 feet 9 inches in length, which must be indicative of first-class culture.—D. PHILLIPS, *Lindley Hall Gardens*.

#### ODONTOGLOSSUM TRIPUDIANS.

THIS *Odontoglossum* has not found so much favour with growers as some others, nor can it be classed as a first-rate species. I have, however, lately seen several very good varieties, these being imported along with and as *O. Pescatorei*, which fine species it closely resembles in habit. The flowers of the best varieties are nearly as large as those of *O. triumphans*. The sepals and petals are yellow, more or less blotched with chocolate brown; the lip narrow in the middle and rounded in front, yellowish white with violet purple markings. The plant comes from Peru, and thrives in company with the coolest section of the genus.

## ADA AURANTIACA.

The individual flowers of this species are not large or in themselves attractive, but as they are very bright in colour and plentifully produced on the gracefully arching racemes they are very welcome just now. This plant needs to be associated with other Orchids to produce the best effect, the bright orange red contrasting well with the quieter tints of various other kinds. It is easily grown under the same conditions of culture as *Odontoglossum crispum*. *Ada aurantiaca* is a native of New Grenada, and is the only member of the genus in general cultivation.

## VANDA COERULESCENS.

This is one of the most charming of the smaller flowered Vandas, which section seems to be rapidly growing in favour. The blossoms are produced on erect simple spikes, each bearing from eight to twelve. They are about  $1\frac{1}{2}$  inch across, the sepals and petals mauve, the lip violet. The plant grows from 1 foot to 18 inches high, the leaves being about 6 inches in length, and like *V. coerulea* peculiarly notched at the apices. This species thrives well in baskets suspended from the roof in the Cattleya house.

The basis of the compost should be formed of sphagnum moss, and some rough pieces of charcoal must be placed in the bottom of the basket. The plants may have new compost if this is needed immediately after flowering. Great care is necessary in removing plants of this description from the baskets in which they have been growing, especially if they are thriving and the roots are much entwined about the rods of the basket. In such a case these latter must be carefully sawn through just inside the corners, when all that the roots are not clinging to may easily be removed, and those that the roots cannot be separated from without injury left and placed in the new baskets.

Cut off all dead roots before replacing in the baskets, and if the lower part of the stem is decayed remove this also with a sharp knife. When returned to the house only sufficient water must be given to keep the sphagnum fresh until the roots are seen to be actively taking to this. Give more as growth proceeds, and on fine days sprinkle the foliage freely.

The plants must be kept free of insects, especially the small brown scale which clings so tenaciously to this class of Orchid. Cockroaches are also very fond of the roots of this and kindred plants and frequently do much mischief. These must be sought for at night with a lantern and killed, or when they are in strong force they may be poisoned with arsenic. The best way to do this is to make a stiff paste of white sugar, flour, and lard, and mix pure arsenic with it in the proportion of one to four. Lay this about near the plants that have been attacked in the evening, and the effect of it will be seen next morning. If they are not all killed the first time, lay a second lot of poison down in about a week's time.

*V. coerulescens* has been known to botanists since 1837, when it was discovered in Burmah. It was not, however, introduced to this country until 1869. The variety *Boxalli* is a still more recent introduction, having flowers much lighter than those of the type.—H. R. R.

## ONION CULTURE.

LAST year for the first time I raised the entire supply of Onions under glass. The seeds were sown in ordinary cutting boxes, and transplanted into the open garden. My reason for doing this was, that seeds sown in the open in the usual way seldom provided bulbs, and some years maggot cleared off whole rows.

Of course, methods of deterring the Onion fly from laying eggs were tried, and means were taken to destroy the maggots, but in no single instance with any material success. Now, however, by the simple plan of raising the seedlings early in the year the difficulty has been overcome. Not only was the maggot evaded, but the crop of Onions in 1894 was the heaviest I have ever grown. I had in previous years raised in this manner a few hundred plants in order to secure extra large bulbs, and consequently had no fear of the result other than as regarded the keeping qualities of the bulbs. Even in this respect it would appear that early sowing has a distinctly beneficial effect.

The present is a suitable time to sow the seeds. Last year some were not sown until the beginning of March, and though they grew as well as the others there was the greatest difficulty in ripening them off. On this account I would not delay sowing later than the first week in February. After the seeds have germinated the plants must be kept just on the move. There is a danger in forcing the plants, and in my experience they grow with enough speed when in a cool structure. The ideal would be a mild hotbed, where the seeds could be sown on a bed of soil under the protection

of a frame. Nothing is gained by transplanting the seedlings into other boxes or frames. I had been accustomed to do so, but the number grown last year rendered it unadvisable to attempt it. The seedlings, therefore, were transplanted direct from the boxes to the quarters set apart for them, and if anything I think we gained by this simpler method. The plants were very small when set out towards the end of April, but they overtook and in the end surpassed autumn-sown plants.

Onions, like Leeks and Celery, must have vast supplies of manure. A fair quantity of manure for either crop is a thickness of 6 inches over all the ground. What I prefer is a mixture of horse droppings and cow manure. I do not bury any of it deeply, and it is a moot point whether the manure should be laid in a layer at an equal depth below the surface, or incorporated with the soil. I prefer the latter method myself. Soot, superphosphates, and nitrates are good stimulants for Onions. I may add that it is very important that the soil should have been thoroughly well worked by means of light surface forkings, previous to setting out the young plants.

What about the extra labour? someone may ask. In reply, when the time taken to sow out of doors, the thinning of the plants, and hand-weeding, is set against simply transplanting a certain number of plants, it will be found there is the least labour involved in raising the plants inside and afterwards transplanting.—R. P. BROTHERSTON.

## OVERGROWN TREES AND SHRUBS.

FROM various causes these often become too large for their places, and encroach on paths, making them impassable without curtailment of the branches. The proper time to operate on trees or shrubs that have become aggressive is in advance of their annual growth, deciduous trees requiring to be cut sooner than evergreens, as they are more liable to bleed from their possessing vascular tissue far more abundantly than do evergreens. Deciduous trees or shrubs should always be acted on by severe pruning while quite dormant, or preferably in the early autumn months when the sap (so-called) is receding, which insures the speedy healing of the wounds by the then comparative solidity of the fluids and the retrocession of them from the external parts. Of course, the term "circulation" does not apply to plants; indeed, there is no analogy whatever between plants and animals in this respect, for it is not a matter with the former of circulation, but of diffusion. But there is what is known as the rise and fall of the sap, which must be recognised for purposes of pruning.

The manipulation of deciduous trees should be carried out while there is little movement of watery matter from the roots, and then the substances in the cells adjacent to the severed parts have time to solidify and form a new epidermis at the points around where the bark joins the wood by the energy of the protoplasm of the cambial layer, the cells of the bark or cortex being oxidised, or rather their contents implanted on the walls, and made more or less impermeable by fluids. A similar process insures the closing of the exposed cells of the wood, the contents of which retreat more or less, and they become filled with air. Thus pruning when the sap is receding allows of a barrier being interposed between the living and the exposed cells, and they are consequently unaffected by external influences. When the pruning is performed in the spring there is danger of bleeding in some cases, as in that of the Walnut; but the Oak bleeds very little, yet several bleed profusely, and this materially affects the pushing of fresh growth, for until the forces are concentrated on the latent buds no growth can take place, and this cannot be effected until the dissevered cells or those adjoining cease to transmit sap by osmose. This can be prevented to a great extent by an antiseptic applied to the wounds, but it is better to prune so that the sap recedes, and then close the pores by an adhering substance, otherwise they only form receptacles for fungus spores, that may or may not germinate and pierce the internal tissues.

When pruning is done late and no bleeding occurs the wounds heal over quickly by the growth of cellular matter from the cambial layer, but as no growth takes place of this nature from the wood cells they indurate, and can only be covered with fresh bark and growing cells from the cellular tissues last named, which is effected by growth over the wound by the process of occlusion. But growth from late pruning is not nearly so strong, nor the buds started so numerous, as from late summer, or early autumn, or even early spring pruning. By the latter is meant no apparent activity in the buds, and that is the latest time at which deciduous trees or shrubs should be pruned, then the non-bleeding kinds concentrate the energies on the latent buds, and they start into growth at the natural season, pushing vigorous shoots, which have time to develop and become thoroughly matured in wood and buds before autumn. On the other hand, trees or shrubs liable to

bleed, or even to gum, from the wounds should be pruned with the declining sap, say as soon as the leaves give indications of maturing, which is generally at the early part of October. Mr. Rivers advises this period for the pruning of Cherry trees, which are liable to gum from late spring pruning; and Mr. Bunyard goes farther than that, advising all pruning to be done in the autumn, or while the leaves are on the trees; this, of course, has reference to fruit trees, but what is good thing for them must be suitable for others of a similar nature. It is certainly desirable to so prune deciduous trees and shrubs that the buds to be started may have some little time to prepare themselves for the effort they are expected to put forth, so as to be able to profit by the flush of sap in the spring, and utilise the matter which passes from ripened wood by diffusion to wherever growth is proceeding. Remember that the latent buds are at a great disadvantage as compared with those that are in a visible state, and that they require all the benefit of a preparatory period, in order to profit by the nutrient elements, and all the time that can be given for their development and perfecting of the resultant growth.

Most deciduous trees and shrubs in a healthy state may be cut back to any extent with a certainty of their pushing fresh growths freely. Old trees, of course, push less vigorously than young, but there is no reason why most should not be pruned to the extent the proposer wishes, and top-heavy or even dangerous, or overshadowing trees near dwellings be pollarded, and new heads secured that will better serve the purposes of ornament, shelter, and seclusion. The thing to do is to effect it thoroughly at the right time, and when the wounds are dry dress them with a substance that will exclude wet from the wood and prevent the spores of fungi settling, growing, and entering the tissues. For large limbs I know of nothing better than gas tar, which should be used in a careful manner with a stiffish brush, confining the painting to the wound and not smearing it on the live bark. Stockholm tar thinned to the proper consistence with boiled linseed oil also forms a good antiseptic dressing for large wounds, and it excludes fungal germs from the pores. Either is better than paint, for no paint acts so effectively as the tar dressing. For small wounds on shrubs shellac dissolved in alcohol answers, and French polish will prevent bleeding even after the flow of sap has commenced.

Limes bear cutting better than, perhaps, any other tree, and the pollards that are seen in towns, even in the "hearts" of some old cities, attest their value as shade and screen trees. Elms and Oaks also bear the saw well, pushing growths from almost any part of the stem desired. Maples likewise bear topping, but the Beech rebels against the process, and Horse Chestnut must be begun with young or it will make a poor effort at forming a head. Willows are sure to put forth a second head better than the first, and it may be renewed as required from time to time with profit. These stand the sea breezes well, and have an appropriate association with water.

Overgrown Lilacs in shrubberies only require the old heads cut away to insure fresh growth and better form from the root, if care be taken to thin the sprouts and so treat the growths by timely manipulation as to secure an evenly balanced head. Lilacs make fine standards, and ornaments they are in town gardens when they have clear stems of about 6 feet height and the heads the shape of a half-ball about 8 feet in diameter. The wealth of colour and fragrance these bear in early summer is enormous.

Straggling Mock Oranges and nearly every deciduous shrub yields good returns for cutting clean down and beginning afresh. Of course there is a loss of flowers for a time, but there is the pleasure of seeing the garden in a thriving state instead of encumbered with gaunt "specimens," which shut out light and air from themselves and everything else. There is no radical remedy for overgrown shrubberies but a thorough overhaul. In extensive ones the back or interior part should be commenced with first, leaving sufficient of the best trees or shrubs here and there to give an appearance of height gradation from the outside, cutting the others well back to obtain fresh growths near the base, and low enough in all cases to form a good foundation. All the rubbish can be cleared away, and nothing further will be required than keeping down coarse weeds and shortening irregular growths in July to secure representative specimens. After three years the front line can be cut away—that is, treated similarly—and this will disclose a flourishing shrubbery behind, which will be enhanced in effect by the greenery in front. This will advance quickly, and thus a neglected shrubbery may be rejuvenated and even made pleasing.

Evergreens may be treated in a similar manner. Evergreen Oaks bear any amount of cutting for producing compact forms, but the work must be done as early as the weather becomes fairly mild in spring. If deferred till the buds are moving in May, the growths are late, and they are sometimes cut by the frost after a damp mild autumn.

Hollies, no matter how unshapely, may be transformed into handsome specimens by the use of the saw and tree pruner. I have operated on many trees, ungainly in habit and overgrown for their places, with the most satisfactory results. April is, perhaps, the best time to start old Hollies afresh, mild weather being chosen, and it is important to cut far enough back so as to give opportunity for shaping afterwards and allow for increased growth. If pruned late, slight bleeding occurs, and there is danger of the retarded growths not ripening sufficiently to stand the winter without discolouration from frost; the bleeding shows that evergreens have some vascular tissue, but that is not material.

Overgrown and poor-foliaged Portugal Laurels become quite charming in leafage and colour after a cutting down. They may be cut to the barest stumps, and will push growth which in a couple of years will form symmetrical heads, but it is essential to reduce the number of growths when they come in clusters, leaving the best in place and vigour, and shorten irregularities just before growth starts in the spring, or after the summer growth is ended.

Common Laurels always grow to a certain height and then become uncouth, whole limbs often dying off. The best plan is to cut them all down and begin afresh. The inside of the shrubbery can be done first, and in three years afterwards the outside, the place being made as notable for thriving shrubs as it previously was for decrepit. It should be remembered that the success of the pruning depends on its thoroughness. Half measures are of small use in neglected shrubberies, or even with hoped-for specimens on lawns. The cutting of the trees or shrubs on these will most likely leave bare ground. That, I find, is best treated with liquid manure, which can be made to sink into the ground by drawing rings of dry soil around the stem outwards about a foot apart, and into these pouring the liquid, giving a few good soakings after rain. The soil can then be levelled, and the ground sown with lawn seeds, and the specimens will be displayed to the best advantage.

—G. ABBEY.

## VIOLET CULTURE.

As the time for the division of the old plants for next year's stock is drawing nigh, perhaps a few remarks on the method that was adopted here last season may prove useful to some readers of the *Journal of Horticulture*.

We have for several years past, for want of room, been in the habit of doing away with a five-light pit of Marie Louise, so I determined to divide the plants there and then, which was the middle of February, instead of waiting for those in the cold frames, which had hitherto been the case, dividing them as late as the middle of April.

After filling a two-light frame with fermenting material, and covering with about 4 inches of fine soil, the crowns were inserted 4 inches apart, watered, and on fine days occasionally syringed. They were found well rooted by the first week in April, when they were planted in a border previously prepared, having been deeply dug, and a sprinkling of soot with equal parts of leaf soil and Mushroom bed refuse worked in.

The plants were disposed 10 inches apart each way, and so well did they thrive that by the middle of August they were touching each other. I am not speaking of plants with a single crown and five or six straggling runners, but bold clumps, 6 inches high and a foot in diameter. More space will be allowed them this year. About the beginning of August they commenced flowering profusely; this led me to think that such early division might be a mistake, but it is not so, as has been proved by the enormous number of large, well-coloured flowers which we have been able to gather this winter. At the present time the plants are smothered with buds and partly expanded blooms.

Strict attention was paid to the removal of all runners, syringing, and frequent stirring of the surface soil, two sprinklings of soot being also given between the rows. The plants were placed in their winter quarters by the end of September, and voted by several practical men to be the finest they had ever seen; certainly they were the finest ever grown here. As is generally the case, after filling the usual frames there were several good plants left over. These were potted, and they amply repaid us for the trouble. They were stood on shelves in the Peach house, the genial atmosphere and gentle syringing necessary to start the trees seemed to suit them admirably, as they gave a profusion of flowers during December.

Doubtless there are some amongst the many readers of this valuable Journal who have adopted the plan described; but to those who have not, I say try it. I am sure they will be more than satisfied with the result, and I think twelve months hence will be forced to admit that it is a step in the right direction.—WM. POTTS, *The Grove Gardens*.

WEATHER IN LONDON.—The weather during the past week has been most unfavourable for gardening, frost and snow having been prevalent the whole time. On Sunday evening and Monday morning about 2 inches of snow fell. There has been from 12° to 15° of frost nightly, and considerably more in some of the suburbs. Snow fell on Wednesday morning. Last week we referred to the peculiar nature of the weather on the day prior to publication. One of the daily papers summarised the matter as follows:—9.30 A.M., raining; 9.35, intense darkness; 9.40, thunder and lightning; 9.50, terrific hailstorm; 10.0, heavy snowstorm; 10.30, sunshine.

— WEATHER IN THE NORTH.—On Friday and Saturday last another severe snowstorm blocked railways and roads in the North of Scotland. Slight falls occurred in the middle of the country on Saturday night and Tuesday morning, when fully an inch lay on the low grounds. The frost has been almost continuous for a week, from 3° on the 24th to 18° on Monday. There was an appearance of more snow on Tuesday morning with 9° of frost recorded.—B. D., *S. Perthshire*.

— THE ROYAL GARDENERS' ORPHAN FUND.—The usual monthly meeting of the Committee took place at the Horticultural Club on the 25th inst., Mr. William Marshall presiding. The following special subscriptions were announced by Mr. Barron:—Mr. M. Todd, seedsman, Edinburgh, sale of flowers, £13 10s.; Mr. H. J. Jones, nurseryman, Lewisham, boxes in his Chrysanthemum houses, £9; the Midland Carnation and Picotee Society, per Mr. R. Sydenham, £5; Mr. J. Kipling, The Gardens, Knebworth, for skating on Knebworth lake, £2; Mr. H. Herbst, Richmond Road, Kew, £1 1s.; and Mr. W. H. Divers, The Gardens, Belvoir Castle, 8s. 4d. From boxes the following sums:—Mr. William Marshall, Auchinraith, Bexley, £1 7s. 10d.; Mr. J. Hughes, Harborne, Birmingham, £1 3s. 3d.; Mr. George Fry, Lewisham, £1 1s. 10d.; Mr. H. Perkins, The Gardens, Green Lanes, Henley-on-Thames, 10s.; and a number of smaller sums from boxes, all of which were most acceptable. The Secretary submitted a draft report and balance-sheet, both of which were approved and adopted, for presentation at the annual general meeting at the Cannon Street Hotel on February 8th.

— MAKING WREATHS.—The article by "H. D." (page 65) would be welcome to a large number of readers, as the subject of wreath-making is not often written about; nevertheless, it is often a part of a gardener's duty. "H. D." only recommends two rings being used for wreaths of 3 feet or upwards in diameter. I have always found it better to have two even in small wreaths of 1 foot or 18 inches in diameter, as when only one is used there is a danger of the material of which the wreath is made slipping round. It cannot do this when two are used, and a much firmer base may be made. For beginners and those who only have this kind of work to do occasionally, the latter, I think, will be found the better way.—J. S. UPEX.

— HERBACEOUS CALCEOLARIAS.—I had the pleasure of seeing a very fine collection of these plants the other day, many of them already in flower. The seeds may be sown at intervals from June to August, and care should be taken to sow as evenly as possible, but it is not advisable to cover them with soil. When the plants are large enough to handle, prick out about 2 inches asunder in pans or boxes, still keeping them in a close shaded situation. As they attain size they must be placed singly in 3-inch pots, keeping them as near the glass as possible. When necessary they can be shifted into 5-inch pots, in which they may be wintered—a frost-proof pit or shelf in the greenhouse are the best positions—just allowing enough water to prevent the plants flagging. Remove all dead leaves, and immediately green fly appears fumigate mildly two evenings in succession. By the end of January the plants will require another move into 7 or 8-inch pots, with abundance of drainage, and a compost consisting of two parts light fibrous loam, one of sheep's droppings sifted, and one of leaf soil with a good dash of sand. At the middle of April the plants will commence flowering, and will continue for a couple of months, providing air and water are given when necessary. The flower stems should be supported with a neat stick, and for seed purposes the best blooms only ought to be fertilised.—G. BURROWS, *Warwick*.

— GARDENING APPOINTMENTS.—Mr. J. W. Sigeo has been appointed head gardener to Capt. Drummond, Enderby Hall, Leicester. Mr. E. C. Cook, formerly under Mr. Fyfe, at Lockinge Gardens, as head gardener to the Rev. H. A. Berners, Harkstead Rectory, Ipswich.

— TADCASTER PAXTON SOCIETY.—At a meeting of this Society on January 17th, a paper was read by Mr. John Snell of The Gardens, Grimston Park, on Begonias and Gloxinias. It was highly appreciated, and an interesting discussion followed. A vote of thanks to the essayist closed the meeting.

— I SHALL be greatly obliged if any readers of the *Journal of Horticulture* can inform me how I may properly CURE PODS OF VANILLA. Through information given in the *Journal* of April 5th, 1888, I fertilised a few flowers; the pods resulting are now 8 and 9 inches long. I want to know when to cut them, and how to treat them afterwards.—J. CRISPIN, F.R.H.S.

— EXETER GARDENERS' MUTUAL IMPROVEMENT SOCIETY.—A meeting of this Society was held on the 23rd inst., when Mr. Edwards, gardener to Mr. James Hare of Honeylands, Whipton, read a paper on "Melons and Cucumbers, and their Culture." The essay was in every way a praiseworthy one, all the salient points in the culture of these plants receiving attention, and thus much practical information was conveyed.

— MR. BLACKMORE'S FRUIT.—Our correspondent "H." writes again on this subject, stating that the prices Mr. Blackmore obtained, and these alone, prevented his undertaking being profitable. Our correspondent, we are sorry to say, informs us that Mr. Blackmore is very ill, and therefore we refrain from inserting any more controversial matter on the subject that has been under discussion—at least for the present. We think, however, our correspondent can say something on the disposal of fruit generally that would be useful if he has time to devote attention to the subject.

— AMERICAN BUTTERNUTS.—Now that a growing interest is manifest in the subject of Nut culture, Dr. Hoskins observes that too little is said about the Butternut, especially for growing in the cold north. In quality the Butternut is rich, and, to some people, it is more agreeable than that of the English Walnut, but its rough outside is not attractive and its shell is hard. We have never heard, says the "Garden and Forest," of any attempt at growing select varieties, although the wild trees differ very much in the quality of their nuts. Perhaps some varieties of value could be secured by crossing our native Butternuts with the foreign species, and a seedling Butternut will bear when it is quite young. Dr. Hoskins planted a few Butternuts in rows sixteen years ago, and the trees from this seed have been bearing good nuts for several years, and he finds that the best varieties can readily be grafted on trees bearing inferior nuts.

— RAISING PEAS UNDER GLASS.—Whilst some gardeners prefer to have Peas sown thinly in pots to plant outdoors later, and others employ strips of inverted turf, not many, I think, use long, narrow wooden troughs for the purpose. These may be made 2 feet long, 3 inches wide inside, and 4 inches deep. One side and the bottom should be nailed to the ends, whilst the other side should be merely kept in place by ties of stout string or flexible wire. Filled two-thirds with good soil, the seeds sown thinly, then covered nearly to the top with fine soil, well watered, and stood in a frame or house in gentle warmth, growth soon ensues. From twenty to thirty of these troughs sown in this way will give a good early planting, and will under glass occupy a very limited space. When the plants are a few inches in height and hardened they may be easily transplanted in bulk into deep drills by merely removing the loose sides of the troughs.—A. D.

— FLORIDA ORANGES.—The latest news from Florida shows that the Orange crop will not be a total loss in some of the groves in the central part of the State and along the south-western coast. Although heavy frosts prevailed in these parts and the thermometer fell to 28°, there was no long-continued cold, as throughout other sections, where the freezing weather lasted for three days, and the Oranges were frozen solid on the trees. Later on these Oranges dropped, and the ground was thickly covered with useless fruit, and in many instances the leaves also fell, while the bark burst the entire length of the trunks. Besides the supplies of Mediterranean fruit under way to supply the deficiency, the New York market is, says a transatlantic contemporary, ready to take the supply from Jamaica, Porto Rico, and Cuba, so that, although there will not be as many Oranges of the first quality as was expected, there will be no scarcity of fairly good fruit at reasonable prices.

— BRANCHES of Tangerine Oranges, each bearing a dozen fruits in a setting of dark glossy foliage, now make one of the most attractive features in the fruit stores of New York. The best of them come from glass houses in southern New Jersey, and sell at the rate of 25 cents for each Orange.

— THE AMERICAN FORESTRY ASSOCIATION.—In the report of the Executive Committee of this Association, at its recent meeting in Washington, it was proposed to introduce into Congress Bills to provide for obligatory courses of instruction in forestry at the agricultural colleges, as well as a course of lectures at West Point, a post-graduate course at the Department of Agriculture, and scholarships for students in forestry to be sent abroad.

— CHEMICAL MANURE FOR ALPINE PLANTS.—Dr. Hugo Müller has concocted a mixture which he applies to all his rock plants with, he says, beneficial results. According to the "Garden and Forest," it is composed as follows:—40 gallons of water, 2½ ozs. potassium phosphate, 1½ oz. potassium nitrate (nitre), 1½ oz. magnesium sulphate (Epsom salts), 1½ oz. calcium nitrate. The calcium nitrate is prepared by taking 100 ozs. or less of chalk, dissolving it in dilute nitric acid until it ceases to give off carbonic acid. This leaves a solution of 1½ oz. of calcium nitrate for each oz. of chalk. This is mixed in a paraffin cask, and the plants are watered with it about once a fortnight during the growing season.

— LIQUORICE IN AMERICA.—As an instance of the increase in the importation of Licorice root into America, where it is stated to be largely used in the tobacco manufacture, it may be mentioned that out of the total quantity of root and paste shipped from Batoum in 1893, 16,720 tons were forwarded to the United States, the balance of 1196 tons being shipped to England and France; out of the latter-mentioned amount only about 300 tons were paste, and the rest pressed roots. Over-production has, says a contemporary, brought about more or less a crisis in this trade, and about 14s. 7d. was being paid, towards the end of last year, to the peasantry for every ton of root delivered at the factories in the Governments of Baku and Elizavetpol. The result was that little or no root was being collected by the natives, and it is said that in consequence of the large numbers of pressed roots in stock two out of the three root-pressing works of the Caucasus remained inactive during a portion of the past year.

— THE NATURAL HISTORY OF PLANTS.—We have to acknowledge the receipt of Nos. 8 and 9 of this standard publication. The subject has now reached the interesting stage of fructification and fertilisation. In the realm of organised tissue, whether vegetable or animal, the questions of impregnation and reproduction have always been those of absorbing interest to mankind. In the customs of savages and in the religious systems of all peoples we see the emblems, theories, and ceremonies (often grotesque and startling to the ordinary sense) which seek to explain these phenomena. With the advent of modern science the question of reproduction assumed an additional importance, and culminated when Darwin published his conclusions regarding the origin of species. These conclusions were to a great extent based on his investigations into what his grandfather poetically designated "The Loves of the Plants," but which he more materialistically named "Cross and Self Fertilisation of Plants." The results of his labours, together with those of his enthusiastic followers, are embodied in the pages now under notice, and persons desirous of obtaining the latest information on this question will do wisely to purchase the work.

— BACTERIA.—Most of the diseases that afflict plants and animals are now attributed to small minute organisms called bacteria, and yet the manner in which the work is performed is something of a mystery. Many believe that in animals the injury which bacteria do comes from their power to introduce nitric acid in injurious quantities. One singular feature about them is that different kinds do not seem to be able to live in harmony together. Vinegar, for instance, is the result of the action of a species of bacterium, and yet it is able to destroy almost all, or perhaps all, other species with which it comes in contact. It is bacteria which first by their presence turn sweet Apple juice into cider. After this has been accomplished they disappear, and a new set takes their place, which changes the cider into vinegar. It is on account of this peculiarity of a bacterium of insisting on having the whole field to itself in disease, that vinegar is so useful in various disorders of animals, as this bacterium is found to destroy others of its family. In cases of cholera or similar diseases in animals, vinegar has been found to easily destroy the other bacteria which cause so much trouble.—("Meehans' Monthly.")

— THE MISSOURI BOTANIC GARDEN.—Six years ago, under the will of the late Henry Shaw, this garden was formed at St. Louis. The fifth annual report received from Mr. W. Trelease, the accomplished director, forms a substantial volume, and contains, in addition to the record of the year's work, the annual flower sermon, the proceedings at the annual banquet of the trustees of the garden, and several scientific papers of much value.

— DISEASE IN THE LOMBARDY POPLAR.—According to "Meehans' Monthly" few trees have been so persistently cleared away by disease in America as the Lombardy Poplar. It is extremely rare to find any in Eastern Pennsylvania that have not been nearly destroyed out of the many thousands that have been planted at various times. It does not seem to attack the tree in its younger years, but after it has grown to some 20 or 30 feet in height the trouble begins, until the tree gradually becomes little more than a huge stump.

— LIVERPOOL HORTICULTURAL ASSOCIATION.—The sixteenth annual general meeting of the above Association was held in the lecture room of the Free Library, William Brown Street, Liverpool, on Saturday, January 26th, when there were present about seventy members. Mr. T. White presided, and called on the Sub-Treasurer (Mr. G. Blackmore) to read his report, which showed a loss on the summer show of £226 5s. 4d., and on the autumn show of £95 10s. 6d., or a total of £321 15s. 10d. In the bank and from other sources there is still left a balance to the good of about £140. A sum of 3 and 2 guineas was given respectively to the Gardeners' Royal Benevolent and Royal Gardeners' Orphan Fund.—R. P. R.

— THE STUDENT PARSNIP.—I was fortunate enough to meet with a true stock of this very excellent Parsnip the other day. The skin and flesh is very white, the form of a handsome tapering character, roots never unduly large, long, or coarse, indeed in form more closely resembling that of a good new Intermediate Carrot. The top or shoulder is very much of the Carrot nature, being rather elevated than flat, and is much the reverse of that of the Hollow Crown. An attendant at one of the Surrey vegetable lectures kindly brought me a sample of the true Hollow Crown also, with its deep crown set in a round ridge of white flesh, to show the distinct characteristics of the two varieties. Student was reputedly raised by Dr. Buchanan from a cross between the garden and wild Parsnip, and when first introduced seemed very distinct. Of late Student stocks seem to have resolved themselves in many directions into older varieties.—D.

— QUASSIA AS AN INSECTICIDE.—The original Quassia wood was derived from *Quassia amara*, L., a small tree of Surinam. The supply, however, fell short, and the Quassia of commerce is now almost entirely derived from the tree known as Jamaica Quassia or Bitter Wood (*Picræna excelsa*, Lindl.). This is a large tree 40 to 60 feet high, with a trunk sometimes attaining a diameter of 1 to 2 feet. It has pinnate leaves not unlike an Ash, hence one of its colonial names, Bitter Ash. The flowers are small, yellowish-green in colour, followed by small black berries. Quassia is imported into this country in billets or logs. Usually the smoothish grey bark has been removed. The wood is of a pale yellowish colour; it has no odour, but is of an intensely bitter taste. Quassia chips are officinal in the Pharmacopœias of Britain, India, and the United States. They possess tonic and stomachic properties, and are valuable in dyspepsia and debility. Bitter cups (in which water allowed to stand acquires a different flavour) are made from Quassia wood. The active principle is Quassin or Quassite, which appears in small white crystals, very bitter and inodorous. It is present in the proportions of about one-tenth per cent. Although an infusion of Quassia is harmless to human beings, it is remarkable that the drug acts as a narcotic poison to animals. It is used in what is known as *pâpier mourî* to destroy flies, and fruit and Hop growers also use large quantities at certain times of the year to destroy aphides and so-called "blights." To prepare an extract of Quassia on a large scale it is recommended to use very fine chips and boil them in water with soft-soap. A simple infusion without soap is, however, quite as effective, and for use in greenhouses the latter is preferred. Quassia water is odourless, and perfectly safe to use. In these respects it is preferable to both kerosine emulsions and to tobacco water. There is always a certain amount of risk in using kerosine emulsion even in the most careful hands, and besides, the smell is specially objectionable. If more widely known, it is probable that Quassia extract, for delicate plants in houses, would almost entirely take the place of tobacco water and largely also of kerosine emulsion. If sprayed regularly over the plants it would keep them entirely free from insect pests.—("Kew Bulletin.")

— **FLOWERS IN THE SCILLY ISLANDS.**—The delightful labour of flower-farming is steadily on the increase among the people of the Scilly Isles, the astonishing quantity of 40 tons of cut flowers, chiefly Narcissi, being sent over to England weekly during the winter season. The farms, which employ many hands and much capital, are excessively interesting, and the sight of them in February or March is worth even the risk of a rough voyage. Literally millions of white and yellow blooms, richly fragrant, nestle between tall hedges of *Euonymus* and *Veronicas*, and form a fragrant picture—as exquisite as it is unique.

— **THE METROPOLITAN PUBLIC GARDENS ASSOCIATION.**—The twelfth annual report and financial statement was placed before this association at the last meeting, and both were adopted. The statement of accounts for the year 1894 showed that the income was £4300, against £6600 in 1893, and the expenditure £5400, necessitating a considerable call upon the reserve fund to make good the deficit. It was announced that grants of £20 and £10 10s. had been received from the Grocers' and Salters' Companies, and that a lady had sent £25 for a drinking fountain; that trees had been planted, at the suggestion of the Association, in Exhibition road; and that the Association was in negotiation for the purchase of a site for a playground in Deptford. It was agreed to give £160 towards the laying out of Bartholomew Square, E.C., and to lay out the eastern end of the churchyard of Allhallows, London Wall, if the rector would maintain it as a public garden.

— **WOKING AND DISTRICT HORTICULTURAL, COTTAGE GARDENERS' AND FANCIERS' ASSOCIATION.**—The above young but flourishing Association held its first annual dinner at the Assembly Room, Railway Hotel, Woking, on Wednesday evening, 23rd inst. The chair was occupied by J. Orlando Law, Esq. (President of the Association), and the vice-chair by Dr. T. C. Eager. The tables were well decorated with plants kindly lent by E. H. Drake, Esq., one of the vice-presidents, and Messrs. Geo. Jackman & Sons. After the loyal toast the Chairman gave "The Woking and District Horticultural Association," drawing attention to the excellent work performed during the first year of its existence, having held two capital shows, one in the summer and one principally devoted to Chrysanthemums in November, whilst most interesting meetings had taken place on the third Thursday in each month, at which very instructive lectures had been given. In referring to this portion of the Association's work the Chairman wished to take the opportunity of publicly thanking the Surrey County Council for the valuable assistance they had rendered the executive in providing them at some of their meetings with such an admirable lecturer, whose visits were anxiously looked forward to by all the members, and to whom personally he also wanted to tender their heartiest thanks. The toast having been very heartily drunk, Mr. H. J. Bidwell proposed "The President of the Association," remarking on the good work Mr. Law had done to insure the success attained. The toast was received with musical honours, and appropriately responded to by the President.

— **THE "BOTANICAL MAGAZINE."**—The following are the subjects of the January number of the above-named periodical:—*Talauma Hodgsoni* (Magnoliaceæ).—This was discovered by Sir Joseph Hooker in 1848, at an elevation of some 6000 feet, in the Himalayas. Sir Joseph describes it as being one of the handsomest of the Magnolias. There is a specimen some twenty years old in the temperate house at Kew. The sepals are a deep purple without, and the petals cohere so as to resemble hen's eggs. *Acidanthera æquinoctialis* (Iridaceæ).—This genus of seventeen species is intermediate between those of the *Gladiolus* and *Ixia*. The corms were sent from Sierra Leone to Kew in 1893, where they have been successfully grown. The perianth-tube is white with six-pointed segments, and each marked with a purple line at the centre. *Lonicera Alberti* (Caprifoliaceæ).—This member of the *Xylosteum* section of the Honeysuckles was discovered by Dr. Albert Regel in Turkestan, who sent a specimen to Kew, where it flourishes as a hardy plant. It is very pretty, and has rose-coloured flowers. *Acacia spadicigera* (Leguminosæ).—This is one of the Horned Acacias, and is a native of Central America and Cuba. The Horned Acacias are mentioned as being grown at Hampton Court in the time of William and Mary, two centuries ago. The peculiar characteristic of the plant is its spinous, horny stipules like thorns. The most curious feature of the Horned Acacias is that these stipular thorns serve as the homes of a certain tribe of ants, which keep off other tribes of leaf-cutting ants which would otherwise make an end of the plants. *Cyrtopodium virescens* (Orchidaceæ).—This species was discovered at Lagoa Santa in Brazil. The flowers are about an inch broad, of a yellow colour splashed with dark red, and at their base are bracts some three-quarters of an inch in length speckled with red-brown.

— **TREES AND SHRUBS OF THE BOMBAY PRESIDENCY.**—Mr. W. A. Talbot, F.L.S., Deputy Conservator of Forests, has, says the "Kew Bulletin," compiled what he modestly entitles a systematic list of the trees and shrubs and woody climbers of the Bombay Presidency. Sind and North Kanara are included, and are referred to separately by name throughout the book. It is, however, very much more than a list, as it contains brief descriptions of the orders, genera, and species, together with references to Hooker's "Flora of British India," to Brandis's "Forest Flora," and to other important works. There are also keys to the orders, genera, and species. Of course, the real merits or defects of such a book are discovered by using it; but from a cursory examination it appears to have been prepared very carefully, and it is certainly singularly free from typographical errors. The arrangement, paper, and typography are good; and the book is certain to prove useful, and will probably promote the study of botany by forest officers. The author expresses a hope that it may form the framework of a future Forest Flora of the Bombay Presidency.

— **SWAINSONIAS IN AMERICA.**—The planting of *Swainsonia* for cut flowers in this country began, says the "Florists' Exchange," in Philadelphia, and is still more largely grown near that city than elsewhere. It is said that a florist of Germantown has a house 90 feet long by 16 wide, with centre and side benches, filled with these plants. These benches were filled with soil without any manure, and the plants put in about 18 inches apart last May. They are now about 3 feet high, very bushy, and covered with flowers. As *Swainsonia* has a habit of climbing, some method must be devised for keeping it dwarf. To bring this about the surface of the soil is not loosened, but allowed to become hard under constant watering. The plants thus treated are short-jointed, and they flower freely at every joint. The flowers are cut and put in water in a cool place ten or twelve hours before shipping, and they have been shipped 120 miles and were in good condition for use four days later. Single flowers sell at the prices of Carnations, and Mr. Cliffe's house contained 500 sprays for Christmas week. No manure water or any other feeding has been resorted to, as the plants seem to flower better in poor soil than otherwise.

— **PUBLIC PARKS AND GARDENS, PAST AND PRESENT.**—This was the title of a paper read before a recent meeting of the Exeter Gardeners' Improvement Society by Mr. F. W. Meyer. In the first part of his paper, so we learn from a local contemporary, Mr. Meyer gave an interesting history of celebrated gardens generally, showing the gradual development of the art of laying out beautiful grounds. He described the most ancient gardens on record—namely, those of the early Egyptians, the Persians, and the Chinese, and quoted extracts from the Greek writers Herodotus and Diodorus, dealing with the ancient hanging gardens of Babylon, which existed many years before the Christian era. The first public gardens in Europe were those of the Greeks, and the so-called "Akademy" gardens in the suburbs of Athens, with their "Philosopher's walks," the favourite haunts of Socrates, Plato, and their disciples were mentioned. Roman gardens were also described, and, after a brief reference to the mediæval period, the lecturer described the gardens of the Renaissance, and the subsequent Italian and French styles, giving as an example the enormous formal gardens at Versailles, with their miles of clipped trees and stupendous terraces and fountains, which, in spite of all their pomp and splendour, were so depressing and monotonous that even Louis XIV., who had them constructed, soon tired of their formality, and retreated to the more modest and secluded Trianon. Dealing next with modern gardens in the irregular style, Mr. Meyer said the present generation had learnt to appreciate the beauty of form in nature, and the modern landscape gardeners therefore tried their best to develop in their works a style of natural beauty, which could be practised successfully only by those who had closely studied the subject. The cradle of this natural style was China, and it was a remarkable fact that a country generally considered to be several centuries behind the times should in this respect be so far advanced. The first European country to adopt the natural style was England, and from there it spread all over the Continent. Public parks and gardens should be places of enjoyment where the people could breathe pure air, where they could find repose and recreation after their daily toil, and where among tasteful arrangements of plants and flowers they could learn to appreciate the beautiful in nature, and educate their taste and refinement by studying the effect and development of plant life, and acquire in addition a most useful knowledge of plants generally. Modern public gardens on the Continent were dealt with at some length, including the public park and Botanical Gardens at Brussels and Antwerp, the Bois de Boulogne in Paris, the

new public grounds at Zurich, the phenomenal glacier garden in Lucerne, the Theiergarten and Humboldshain in Berlin, all of which Mr. Meyer was able to speak from personal experience. With regard to public parks and gardens in England, the lecturer considered that in London Battersea Park was the best, while as an educational field Kew Gardens far surpassed all others.

— FRUIT CULTURE IN NEW SOUTH WALES.—This industry is receiving the attention its importance to the colony demands, and its most recent development is the formation of an experimental farm at Wagga Wagga, a town about 309 miles from Sydney and nearly equidistant from that city and Melbourne. The farm of which Mr. George Valder is Superintendent has an area of 75 acres, 45 acres being apportioned to fruit trees, 25 acres to Grape Vines, and 5 acres to agricultural experiments. About 3000 fruit trees and 4000 Vines have been planted during the past season. The collection, says a contemporary, comprises 600 different Apples, 450 Pears, 250 Plums, 200 Cherries, 100 Peaches, 120 Apricots, seventy Olives, fifty Figs, and eighty Nectarines. In addition there are Gooseberries, Raspberries, Loquats, Strawberries, Date Plums, Quinces, Almonds, Chestnuts, Walnuts, Guavas, Dates, Prunes, Mandarin and other Oranges, Lemons, Currants, and a few odd trees of other fruits. It is intended to plant one acre each of Prunes, Figs, Apricots, Raisins, and Currants for drying. The experimental farm is situate on the side of a high hill, from the top of which magnificent views are obtained of the surrounding country, and about four miles from the town of Wagga Wagga, and the climate of the district is colder than Sydney in winter and hotter in summer. The district is favourable to the cultivation of the majority of fruits grown in the colony, and the farm will be of much value to growers in indicating the varieties to plant and which to avoid.

— A SCIENTIFIC DISCOVERY FROM JAPAN.—A Japanese savant, Jokichi Takamine, who has studied at Glasgow and Tokio Universities, has, according to the "Times," discovered a novel method of preparing diastase and some other substances, of which we recently received specimens. He has been cultivating Eurotium Oryzæ, a mycelial plant of the Aspergillus family, on Wheat bran, and has found that at an early stage of its growth it bears upon its roots minute crystals of diastase, while the unripe spores contain a very powerful ferment. By washing the bran in percolators and crystallising the solution, he claims to be able to obtain diastase of considerable purity as a commercial product. Diastase is, of course, a familiar enough substance, though our chemical knowledge respecting it is at present far from complete. Its property, however, of transforming starch into sugars is made use of every day by brewers and distillers, whose object in performing the troublesome operation of malting is the production of diastase. But it has never hitherto been produced in such a form as the present. Takamine claims that a mixture of equal parts of this diastase (or "Taka-koji" as he calls it) and crude Wheat-bran, when added in the proportion of 10 per cent. to the quantity of grain mashed, will effect a more perfect conversion than the use of 10 per cent. of the best malt. The ferment is a very remarkable substance. It is said to be three times as powerful as yeast—that is, it will continue to produce fermentation in a sugar solution till there is 20 per cent. of alcohol present, whereas the action of ordinary yeast stops when the percentage of alcohol reaches 7. This one fungus, therefore, appears to produce in itself the converting agents required in two of the most important processes in the manufacture of beer and spirits. Besides this, the Wheat-bran, after two or three cultivations have been grown upon it, is said to form a good food for cattle, containing some 20 per cent. of protein, or flesh-forming substance.

— VEGETABLES IN NEW YORK —The supply of vegetables to the New York markets is, at the present time, says the "Garden and Forest," remarkably varied, comprising the ordinary autumn root crops, both home, Canadian, and European, as well as the more perishable green crops kept in cold storage, new vegetables from the Gulf States and from the Pacific coast, and choice hothouse products from adjoining States. The principal supplies of Potatoes in our markets now come from Long Island and interior sections of New York State, and from New Jersey, Maine and Michigan. Cargoes have recently arrived from Scotland, England, Germany and Belgium, and new Potatoes from Bermuda are already here. The best Sweet Potatoes come from Vine-land, and West India Yams, weighing from 5 to 8 lbs. apiece, are occasionally seen. These are cut in quantity to suit the purchaser, and sell for 15 cents a pound. Winter Turnips, from New Jersey and from Canada, are abundant and cheap, while small and tender hothouse Turnips cost 5 cents each. Carrots grown under glass may be had for

20 cents a dozen. Florida Cucumbers, small, and of irregular form, sell at the rate of four for 25 cents, the smooth and shapely hothouse product bringing 20 cents each. These have more than their appearance to account for the difference in price, since their crispness and delicate flavour is most marked. Tomatoes from the Southern States and from California cost 25 to 30 cents a pound, the firm flesh and rich colour of hothouse fruits making sales for them at 50 to 60 cents a pound. Small bunches of Asparagus from St. Louis are offered at 35 cents each, and slender stalks of the same vegetable from New Jersey greenhouses are luxuries which cost as much as 1.25 dollar for two dozen tips. New Okra, from Havana, costs 10 cents a dozen, Artichokes, from Louisiana, 25 cents each, and Florida Squashes, 10 cents. Other vegetables from Florida are Egg-plants, Brussels Sprouts, Leeks, Peas, string Beans, and Lettuce. Dandelion grown in cold frames on Long Island finds ready buyers at 20 cents a quart, and the best Mushrooms cost 1.25 dollar a pound.

THE "CHARLES COLLINS" FUND.

THE following (circular) appeal and list of subscriptions have been sent to us for publication:—

At a meeting of members of the Horticultural Press held at the Hotel Windsor, Victoria Street, S.W., on January 11th, the following resolution was unanimously passed:—

"In consideration of the services rendered to horticulture in his journalistic work by the late Charles Collins, of the high respect in which he was universally held, and of the fact that owing to the long-continued ill health of himself and his wife he was unable to make adequate provision for his family, who are in deep distress, a fund be opened for their benefit."

On the same occasion a General Committee, comprising a number of horticultural journalists, together with the following gentlemen who form the Executive Committee, were elected to carry the above resolution into effect—viz., Maxwell T. Masters M.D., F.R.S. (Chairman), 41, Wellington Street, Strand, W.C.; Brian Wynne, F.R.H.S. (Vice-Chairman), 1, Clement's Inn, Strand, W.C.; George Gordon, F.R.H.S. (Treasurer), Endsleigh, Priory Park, Kew; T. W. Sanders, F.R.H.S. (Hon. Secretary), 57, Cressingham Road, Lewisham, S.E.

For the information of those who are not fully acquainted with the facts of this sad case it may be briefly stated that the late Charles Collins was for some few years engaged on the Editorial staff of the "Journal of Horticulture," and prior to that filled similar positions on the "Gardeners' Chronicle" and "Amateur Gardening." He was returning on the evening of December 26th from a visit to some friends at Forest Gate, and just as he was about to enter the train was suddenly taken ill, and expired almost immediately. He leaves a widow and two little girls, aged three and four years respectively.

Mr. Collins, having only attained the age of thirty years, had been unable to make adequate provision for the support of his wife and family, and hence the Committee and Executive have resolved to make an earnest appeal to those who knew him to subscribe to the above fund, and thus enable them to alleviate in some measure the pressing needs of the widow and family.

Subscriptions may be sent to either of the gentlemen named above, or to the Editors of the various gardening journals. The amounts received will be duly acknowledged in the gardening Press.

[The "Journal of Horticulture" having been the means of enabling immediate wants being met during a sad and sorrowful time, warmly appreciates this effort on the part of press associates on behalf of the widow and children of a lamented coadjutor and estimable man. We shall be glad to forward any further sums that may reach us to the treasurer of the fund.]

## A WOMAN'S THOUGHTS ON WOMAN'S WORK.

It has often been a puzzle to me to see how little practical interest leisured women take in their gardens. True, they are fond of planning and of giving impossible orders, but when it comes to real work they are nowhere. There is a great tendency among women to prefer the house and household pursuits, and this is all very well in its way and very necessary too, but if only women would believe they have lungs which must materially benefit by fresh air, and muscles which would strengthen by use, we should see more of them abroad.

There is in this case no need of smart garments or useless "dressing up," which must be gone through for a walk in frequented neighbourhoods or for the making of a round of calls; also, odd minutes may be utilised, and at first this is the better plan, till the body becomes accustomed to the change of exercise. In this climate a pair of really strong boots are a necessity, a short skirt desirable, and a shady hat. To everything there is a beginning, but to the woman who means work a failure is only an incentive to greater care and diligence. In some cases they may have someone who will direct their first efforts, but as a rule a gardener dislikes a woman "messing" about. Some small flower gardens may be entirely managed by a woman; even grass cutting is made easy. An old lady friend, now too stiff for the machine, gets her strong, willing "general" to take that part of the work.

The paths come first, and no one can go far wrong in the weeding of them—only be true, and go to the root of the matter. No chopping weeds off by the head. It is so satisfactory to get a really big weed uprooted; to see its great fangs, and the hole it has left, that seems something done, and really as work nothing repays the willing novice much better. As the state of the doorstep is said to indicate the state of the house so the paths do that of the garden. In some places not only is gravel dear but bad to meet with. Cherish what you have, keep it well raked up towards the centre. You must have a good water shed, and then you have always a dry promenade whatever the weather may be. If you have Box edgings there is another outlet for energy; untrimmed, broken borderings look very bad, and has an old-fashioned formality about it. Nothing comes in more useful as a foundation for wreaths and crosses when other materials are not to be had. Beds have always a tendency to sink. My adviser says I have my beds too high; let that be as it will, they look better than my neighbour's, whose sometimes sink level with the border. It is a matter of taste what the beds are to be filled with, but it is not a matter of taste that the edges be kept neat. It is tedious to go down on your knees, and clip, clip, clip, but it is satisfactory in the end.

Then bear in mind if you give nothing you have nothing. Town people are perforce obliged to depend on that evil-smelling stuff in bags obtainable from your florist; you country people if possessors of hens, pigs, or pigeons, are rich beyond dreams of avarice. If without offence to your neighbour you can get some sheep droppings or cow manure do so. After a long dull winter one looks forward with such pleasure to the simplest spring flowers, and it seems a pity they should not be found in all gardens. Aconites do so well even under big trees, Snowdrops spring up everywhere, except on the strongest clay. A bed of seedling Polyanthus is delightful. These planted in autumn need no further care till they have flowered, been divided, replanted in a cool situation to await a second autumn. If you are of a generous disposition others will participate in your belongings, and you will have plenty to give and to spare. No spring garden is complete without Wallflowers, but see that the plants are short and sturdy. "Planting out" is an art. Visit some good garden, and use your eyes and observe the neat deft way in which the operation is carried out. A handy man will often pick up the knack directly, and so should a woman.

Pruning, too, is quite a woman's work, provided her heart is hard. A well-pruned Rose garden looks such a wilderness in March, as wheelbarrow after wheelbarrow of Rose wood goes away. No rule can be laid down for this work, practical observation is the only recipe and knowledge of the habit of the variety. Amateurs usually fail by doing too little, and leaving too much badly ripened wood and weak growths crowded together. A friend unused to Rose growing prayed her husband just to spare her one bed so that she might have a few early blooms. He was a silent man; smiled, and did her bidding. She got her early blooms, but oh! such frost-injured, insect-mangled specimens that she could not bear to look at them. Next year she used a sharp knife fearlessly, and then had "glorious Roses."

Pricking out requires careful fingers, careful preparation of soil, careful watering afterwards. A fidgety sick man bothering about his seedling Primulas, his wife suggested her assistance. It was

grudgingly received, and with special instructions she began her work. "Just see that the pan is moist enough for the plants to come out easily with little balls of earth." "Fill the pots (don't forget the crocks) with one part soil from which the turf has been removed, one part decayed leaf mould, one part that stuff in a bag we got from Primrose Hill. Mix it well and let me see it first. When repotted water from the bottom, and perhaps you had better bring one or two up for me to look at." "Yes, they will do," and they have done. That lesson was worth heaps of book learning.

A garden is not prized so much by a real lover for the actual money value of the plants as from the associations. A root of crimson Anemone, from the old garden at home; a yellow Crown Imperial, from a neighbour; a bit of Bergamot, because prized in a story book; Clove Pinks, the gift of an old servant; Mrs. Sinkin, from "Madam" at the Hall; Daffydownillies, from Sherwood Forest; Ferns and Wordsworth Poppies from the home of the Lake poets. All these, and a thousand others, go to make up the charm of one's own garden. The foot of a garden wall adjoining the public road was always an eyesore and continual source of irritation from the weeds that infested it. They were difficult to uproot on account of the stony foundation. A happy thought struck the owner. Why not overcome the strong man with a stronger? Get out as much weed as possible, then plant with the little frail and graceful Wordsworth Poppy, make a fringe of bright yellow and pale green. Once get that well established, and weeds may be defied. Then there is the care of the grass. A lawn infested with Plantain will always provide occupation. It is not a bad plan to drop a few grass seeds into the hole left by the removal of the root. Do not leave a fang if you can help it. Dandelions, too, may provide wholesome exercise, and the weeding of the Asparagus bed has dispelled ennui many a time. Often, too, there are creepers to train and tie, seeds to gather, dead Roses to remove, and always the earth's heritage of weeds.

In the days of long ago, when Gloire de Dijon and "Général Jacqueminot" reigned supreme, the most charming garden and most redolent of sweet flowers was entirely managed by its mistress, and filled with standards of her own budding and flowers of her own raising. She had nothing but an old-fashioned frame or pit, but she did wonders. Her Christmas Roses and her summer Roses were the surprise of the neighbourhood, and her herbaceous border was a glory. From her many imbibed their first love of gardening. She had a wonderful charm for children, and gathered her young nieces and friends, who were only nieces by courtesy, and made them, whether they would or not, love the country and take interest and delight in their garden work. She has moved to a town, but you need only know the name of the terrace; the house reveals itself.

A word as to garden visitors (female). You have all in trim—your best blooms in their glory—your lawn like velvet, and you, in a moment of weakness, ask your friends. Before they have been in ten minutes you are provoked beyond endurance. "How sweetly pretty! How lovely! Oh, where did you get that?" and then in the same breath, "Were you at the dance last night? Did you hear of So-and-so's engagement?" You show them a grand "Cleopatra." They say they prefer W. A. Richardson. You point out a "Victor Hugo," but they retort that for size give them Magna Charta or Paul Neyron. Such folk are incurable, and must be answered according to their folly.

In a village where the working people are born gardeners much pleasure is given and received by interchange of visits. There is always something to learn, and little gifts of plants and cuttings do more to cement real friendship than anything I know. A garden is common ground, and how our feet linger! Well, it is only nature. We are all sons of Adam, though some of us "favour" our father more than others. A garden gives an outlet for individual taste. A little eccentricity is always pleasing, and much Derbyshire spar. No two gardens will bear exactly the same treatment, soils, situation, and so many factors are at work. A few experiments tried at first will soon prove what is the most desirable kind of garden "stock." With a western exposure you must not look for glowing Rose beds, nor on strong clay will bulbs do well. Of course in the confines of a garden much may be done in the way of making soil, but there are often natural impediments that cannot be overcome.

Those who have children, teach them the proper use of a garden. If they see you respect your plants and treat them lovingly they will do the same; children are the grandest imitators. I cannot remember how young some children were when they borrowed their father's exhibition boxes and had flower shows of their own, and were cruelly critical about their father's productions. These children were never shut out of the garden for fear of the damage they might do. It never occurred to them to injure what their parents loved, and I am sure the eldest boy knew sooner than any-

one of the birth of a new bloom, and would tell the points of a Rose as well as many an old judge.

Just one word in conclusion. In all the work clear up after yourself. Nothing is so aggravating to the powers that be than litter left after "Missus" has been gardening; it would not tire you much more, and then there is such a sense of "finish." Tools, too, have a place, and they are easier to find when next wanted, if only put away carefully. An old friend who complained that sermon writing made his back ache, never complained after the hardest day's gardening, and he did put some work into that; and I fancy my lady readers, if they try the experiment, will find that outdoor exercise and work will do more to take "backache"

Rhododendrons, and should become very popular. It was exhibited by Messrs. J. Veitch & Sons, Chelsea, at the Drill Hall, Westminster, in April last, when it was deservedly accorded a first-class certificate.

#### APPEAL JUDGES.

ALLOW me to thank "Shooter" (page 56) for the kind assistance he has given me in ventilating a subject in which I have taken a very deep interest for some time, but I cannot agree with his suggestion to allow an appellant to ask that a class be rejudged by another judge because it might lead to many appeals. A number of competitors in any class where the competition was very close might put forward an appellant on

FIG. 16.—RHODODENDRON PRINCESS WILLIAM OF WURTEMBERG.

out of their mental worries than any other remedy that can be suggested. "Watch and pray" is the apostolic admonition; Work and weed, is mine.—H. G. F.

#### RHODODENDRON PRINCESS WILLIAM OF WURTEMBERG.

ONE of the finest of the spotted Rhododendrons is that depicted in the illustration (fig. 16). The variety, which belongs to the ponticum section, is of very robust habit and remarkably free flowering. The trusses, comprising upwards of a dozen blooms each, are very compact. The flowers are about 2 inches across, creamy white in colour, charmingly tinted rose-pink on the lower segments, while the upper are spotted with crimson. It is a splendid addition to our hardy

the mere chance of getting their exhibits advanced a point. "A. D." (page 78) appears indignant by the supposed inference that judges are not always what they should be. He entirely overlooks the gist of my letter. There is no such proposal in it; all that was suggested was the appointment of appeal judges by our show-promoting societies, and to allow competitors who might have reasons to believe that their exhibits have been overlooked to appeal to the judgment of the gentlemen appointed for the purpose. There is nothing novel in the proposal; the system is in operation in our law courts, and although "A. D." clearly shows us how ridiculous it is having so many courts reversing and reversing one another's decisions, he does not say what he would put in place of this very stupid arrangement, and we can only infer that it would be a single tribunal. "A. D." then, on his own showing, is bound to admit that my idea of an appeal court for horticultural shows is not quite so ridiculous as that bewildering labyrinth of endless appeals to which he refers.

If some society would try the experiment I think it would be

neither found impracticable nor impossible. If one good all-round man, with a wide experience in judging such as "A. D." has had, were appointed appeal judge, given a comfortable room convenient to the exhibition, with the daily papers on the table before him and a choice of teetotal drinks, he could pass a pleasant hour or two, and the dread of his appellate jurisdiction would make the judges so careful that he would very often have a maiden court. Not even a grumble would be heard, and instead of having his decisions supervised by other judges he himself would be the head of all. Would this not be worth his fighting for?—C. K., *Garguncock*.

#### NATIONAL ROSE SOCIETY.—THE TROPHY CLASSES.

NEITHER your correspondent, "J. B.," or others who have taken up this subject, seem to be aware how their wishes have been more than anticipated by the Committee. At the November meeting two resolutions were brought forward on this subject, one that the winner of the amateurs' trophy should become a Vice-President for the year, and the other, that a large gold medal, the same size as the silver medal, should be substituted for the money prize. The cost of this will be £7 10s., and its intrinsic value, I suppose, about £6. Possibly this may be extended, as I think it ought to be, to the amateur jubilee class also. The nurserymen present at the meeting who had been winners of the trophy in their own class thought it ought not to be extended to them, and the Committee decided on confining it to the amateurs.—D., *Deal*.

#### THE QUEEN'S ENGLISH.

HAVING had occasion to write to Mr. Foster-Melliar on the subject of his book I have received from him a reply in which I find the following slight reference to the little critique of a correspondent on page 75:—"Arcanum" is right in his criticisms of my English; but what of 'may be excused making it,' and 'way of producing such' in his own communication? I had rather not discuss my own book in print."

Of course, as Mr. Foster-Melliar knows, I did not request him to do so, and hope he will not object to the small citation from his letter. The best of writers make occasional "slips" in the Queen's English, which they know so well.—A READER.

#### ROSA RUGOSA.

I CAN fully endorse all "A. C." (page 76) says in praise of these Roses, for surely we have no flowering shrub of more constant beauty. The deep green leafage, remarkable freedom from insect enemies, a constant show of bloom through the whole summer and autumn, and, by no means the least, a crop of particularly showy hips. But when your correspondent claims for Mr. Martin seeming priority in the attempt to improve these I cannot quite follow him. Monsieur Bruant of Poitiers is doing considerable work in this direction, and has been for some time. In 1887 Monsieur Bruant gave us that beautiful semi-double hybrid named Madame Georges Bruant. I understand this to be a cross between *Rosa rugosa* and *Sombreuil*, and the plant, bloom, and whole habit seem to confirm this. It is one of the first to bloom and the last to cease. I have used the white *rugosa* and this semi-double form very frequently in large wreaths and crosses. Nothing works up better, as the beautiful foliage is so well in keeping, and the pointed buds retain their shape and boldness for a long time. Within the past few days I have had a letter from M. Bruant, and also plants of his two new rugosas of this spring. Several good hybrid rugosas are now on the market, notably those from the raiser named, Cochet and Dr. E. Kaufmann.

I have grown a few seedlings of *rugosa alba* and *rubra* for a long time, and find they vary considerably; so much so that few will purchase seedling plants in preference to those worked from a good type of either variety. We might do worse than grow a few of these in pots on a north border, then house them with our Chrysanthemums and so secure a lasting show of handsome foliage, a few blooms and many berries up to and beyond Christmas. That they are capable of this I know from experience. Nor can we possibly find a Rose more suited to town and suburban gardens, seeming entirely unaffected by fogs and smoke, while all soils appear congenial. I hope to visit Reading with the N.R.S. and shall certainly look out for Mr. Martin's hybrids. I may say that I, also, have found hybrids longer in flowering than naturally crossed hips.—PRACTICE.

#### BURR-KNOT APPLE.

THIS is a very useful, free-bearing, culinary Apple, in use during October and November. It is also called "Bide's Walking-stick." The following description is taken from Dr. Hogg's "Fruit Manual," fourth edition. "Fruit round; skin shining of a clear lemon-yellow colour with a blush of red on the side next the sun; eye closed; stalk half an inch long; flesh white, tender, juicy, and of an agreeable acid flavour. The tree is a close and compact grower, and a profusion of burrs are

produced on the branches which emit incipient roots. If a branch furnished with these burrs is inserted in the ground it will take root and become a tree." The name of Bide's Walking-stick originated from a person of that name having cut a branch for a walking-stick in Cheshire, and brought it to his place near Hertford, and inserting it in the ground it took root and became a tree.

There are a number of trees of this variety in the gardens here, and it is also to be found in some of the cottage gardens in the neighbourhood, several of which trees I have been informed have been grown from cuttings. My first knowledge of it was on taking charge of these gardens four years ago. Every year all the trees, some of which are very small, have produced good crops of fruit, and though last year was a bad Apple year, and most varieties were badly infested with insect pests and made but little growth, all my Burr-knot trees fruited well, and also made good clean growth.

This, I believe, is quite a local Apple, or at any rate a north of England Apple. I have looked through the catalogues of several of our fruit tree growers and books on fruit culture, but do not find it mentioned in any of these. A few weeks ago one of our greatest authorities on fruit culture told me he had known this Apple for fifty years, but had never seen it in the south of England, and a reader of the *Journal of Horticulture* has procured trees from several different nurserymen under the above name, but in no case did he obtain the true variety. My reason for penning these notes is to gain information, and I shall be glad if any correspondents of the *Journal* can tell me when this Apple was raised and who was the raiser.—J. S. UPEX, *Wigganthurpe*.

#### THE HISTORY OF THE VIOLA.

IN the *Journal* I have on two or three occasions referred somewhat fully to the introduction into notice of the *Viola cornuta* by Mr. John Willis, and of the work followed by others, but as the *Viola* has now become so very popular both as an outdoor decorative plant and at our exhibitions, I feel that a more complete history would be of much interest to those interested in the cultivation of this plant.

The honour of being the first person to hybridise the various species of *Viola* belongs to Mr. James Grieve, the manager of Messrs. Dicksons and Co., Pilrig Park Nurseries, Edinburgh, who in the year 1861 collected plants of *Viola lutea* on the Pentland Hills, and *V. amœna* from Moffatdale, and went to work hybridising and raising seedlings, using the pollen of various Pansies. From *Viola lutea* he obtained Dicksons' Golden Gem, Grievei, and others of that type. *V. amœna* was the parent of all the Blue Bell type, and *V. stricta* of all the rayless type of the earlier period of the *Viola*. Mr. Grieve having raised rayless varieties for twenty years writes, "Of late years size has been the first point aimed at by so many, which is an error."

The credit, however, of first bringing the *Viola* into notice as a bedding plant must be given to Mr. John Willis, who, in 1862, was gardener to Sir Philip de Grey Egerton, Bart. When in London the same year he saw half a dozen plants in bloom of *Viola cornuta*, and tried to buy them, ultimately purchasing three of the plants. This was in the summer, and by propagation he obtained a large stock. In 1864 Mr. Willis obtained plants of *Viola lutea* for the purpose of testing it as a spring decorative plant, using it extensively at Huntroyde Park, Burnley, whilst gardener there. This fine old species produced *Lutea grandiflora* or *Lutea major*, a variety still grown, and of which I saw a grand bed in the Birmingham Botanical Gardens during the past year.

It was about the year 1870 that Mr. Grieve went thoroughly into the work of hybridising *Violas* and raising seedlings, using *Violas lutea*, *stricta*, *montana*, *cornuta*, and others. His earliest seedlings were Vanguard, Celestial, Polly, Oculata, The Fairy, *Lutea major*, Golden Gem, Grievei, and Pallida. Finding a great demand for *Violas*, he worked assiduously, and in 1872 twelve of his new varieties were figured in the "Floral Magazine" for that year—viz., Eyebright, White Perfection, Canary, Advancer, In Memoriam, Regina, Dickson's King, Snowflake, Tory, Favourite, Claret, and Scotia. Of these Tory and Snowflake are still frequently to be met with in gardens. In the same year the firm exhibited at the Crystal Palace a collection of 100 varieties of seedlings and others, chiefly their own raising. Like the Fancy Pansy when I introduced it, our Scottish florists at that time gave the cold shoulder to the *Viola*, and when the firm exhibited collections as they did at the Edinburgh shows, "Here comes Grieve with his weeds," was the common salute he received.

Other growers also began to take up the *Viola*, for in 1870 Mr. B. S. Williams, of Holloway, sent out *Viola Perfection*, followed by Sensation and Admiration, varieties raised at Rotherfield Park Gardens, in Hampshire. In 1872 Mr. R. Dean, of Ealing, introduced Blue Bell, which soon became a very popular variety. Some little time after he sent out Corisande, Lothair, and Princess of Teck, raised in his seed grounds at Bedfont. Some Tom Thumb varieties of *Violas* or miniature Pansies were raised there from seed, having a very compact dwarf growth and small flowers, resembling the *Violetta* section of the present day, but florists did not seem to care for them.

In 1874 Messrs. Dicksons & Co. sent out Sovereign and Alpha, and in their catalogue of that year twenty-five varieties of *Violas* are named. In 1875 Mr. R. Dean sent out Crown Jewel, Royal Blue, Lilacina, Mulberry, and White Swan, Mr. B. S. Williams introducing a good white variety Mrs. Gray, raised at Eglinton Castle Gardens. About the year 1878 the writer of these notes raised True Blue, and subsequently other sorts such as Queen of Lilacs, Golden Queen of

Spring, followed later on by Mrs. Charles Turner, Sir Joseph Terry, Golden Gem, Bridesmaid, Master of Arts, and others.

It is not my intention to trace the "sendings out" of every year, but just to refer to some of the leading raisers and introducers of new varieties. In a catalogue of Messrs. Dicksons & Co. for 1880 now before me seven new varieties of their own raising are then being introduced. Year after year they have gone on, and in their catalogue for 1894 and 1895 four new sorts are introduced, and nearly fifty varieties of their own raising, including Bullion, a very fine yellow; Acme, a rich rosy purple; Dorothy Tennant, H. M. Stanley, two fine varieties, and Mary Gilbert, a fine yellow, are to be found.

In their 1880 catalogue Mr. Grieve laid down the following "qualities that go to constitute a good bedding Viola"—viz.,

1, A dwarf dense habit of growth, with the flowers thrown well above the foliage.

2, That they bloom freely and continuously either during the spring and summer, or during the summer and autumn.

3, That the flowers be of good size, but especially of good texture, in order that they may bear well extremes of drought or wet.

4, The most desirable shades of colour are those that are clear and well defined, so that they may come out well at a distance. Mixed or fancy colours, though they may be dotted individually in a miscellaneous border, are worthless for massing.

I think it will be freely admitted that the necessary qualities of the Viola in 1880 hold good now.

Messrs. Dobbie & Co., Rothesay, must also be closely identified with the progress of the Viola, especially since Mr. William Cuthbertson took this plant in hand about ten years since. The firm has on many occasions, in London and elsewhere, exhibited superb displays of Violas arranged in artistic style. They introduced in 1888 Mr. John Baxter's superb collection, which included Spotted Gem, Ethel Baxter, York and Lancaster, and Mrs. Baxter, and subsequently such fine varieties as Duchess of Fife, Ravenswood, Gipsy Queen, Ada Adair, Blue Cloud, and others. Messrs. Dobbie & Co. have also sent out new varieties raised by Mr. J. D. Stuart of Belfast, Dr. Dickson, Mr. Biggar, Mr. George McLeod of London, Capt. King of Lennoxton, and others. Amongst sorts of their own raising which have taken a high position are Lemon Queen, Iona, and Edina, three very first-class varieties; also Mrs. Bellamy, Minnie, Duchess of Rothesay, and others.

Dr. Stuart of Chirnside, N.B., claims notice as a successful hybridiser and raiser, especially of the Violetta or Miniatum type. He is also the raiser of "Sylvia," a rayless white large-flowered variety which has become popular. I wrote to Dr. Stuart recently asking for full information as to his commencement with the Viola, and in a letter just received from him he writes: "I send you a few facts relative to the origin of the rayless strain of Violas." (It seems evident that Dr. Stuart was unaware of Mr. Grieve's work in the same direction previously, as already recorded.) He adds, "In 1872 I crossed *V. cornuta* with the Imperial Blue Pansy and twelve seedling plants resulted, identical in habit, and of a blue colour, still distinct from any other yet raised. I then crossed these flowers with the pollen of various coloured Pansies, and a considerable quantity of seed was saved. The plants raised from this flowered the following season, and exhibited a great variety of colours, all showing the *V. cornuta* keel or horn, proving their parentage, but they still resembled the Pansy more than I wished. I then determined to take the pollen from these hybrids and carefully crossed the *V. cornuta*. I was, however, disappointed with the result, for very few of the crosses took, and where the seed pod did swell the seed failed to vegetate. This is exactly what we may expect from in-and-in breeding, and I had only two plants from this cross, carefully saving seed from them when they flowered. The first to bloom was like *V. cornuta* in habit, with a fibrous tufted root habit, not in the least like a Pansy, the flowers being like *V. cornuta*, but three times the size and equally floriferous. In 1875 all raisers of Violas were invited by the Royal Horticultural Society of London to send plants for trial at Chiswick, and the chief growers responded. I sent up six plants each of the following seedlings:—Lady Susan Suttie, Hillside Beauty, Georgia, Ormiston, Dr. Stuart, and William. At the blooming time Mr. Barron wrote to know how I had procured the cross, as they flowered more continuously than most of the varieties under trial. The Floral Committee of the R.H.S. awarded a first-class certificate for each variety. Plants of these were afterwards distributed, renamed, and sent out from another source.

"In those days Violas were not rayless, and I endeavoured to get a good white self without rays, but some years elapsed before I succeeded. In the year 1887 my attention was attracted by a pure white variety, which I named 'Violetta,' remarkable for its dwarf habit, floriferousness, perfume, and for its small, well-formed flowers. 'Violetta' has been the mother of many other good varieties, and with pollen from Violetta the beautiful rayless white variety 'Sylvia' was raised."

Still it must not be forgotten that before we had Sylvia we possessed a grand old rayless white, the "Countess of Hopetoun," which will take some beating as an all-round Al white bedding Viola. Dr. Stuart has been a most successful raiser in such as Blue Gown, Gold Crest, Old Gold, Ophir, Marginata, Summer Cloud, Sweet Lavender, and others. Blue Gown is destined to be a very popular bedding variety, and Mr. Grieve, in one of his letters to me, writes, "Sylvia is a grand variety of the real type of a bedding Viola."

Other growers in Scotland also raised seedling Violas, amongst them the late Mr. John Downie, who sent out about six years since amongst others The Mearns and Lady Amory, two fine varieties, and more

recently Mr. Andrew Irvine of Tighnabruaich has formed an extensive collection, and is raising seedlings, and has already sent out such good sorts as Lady Borthwick, Miss Alexander, Wm. Dean, Duke of Clarence, Maggie Todd, and others. Mr. J. Smellie, florist, Glasgow, obtained a certificate at the recent Viola Conference for a seedling Lizzie Thornley, and Messrs. Dobbie & Co., Rothesay, obtained one for a charming yellow named "Gem," and Capt. King of Lennoxton was awarded certificates for two fine seedlings, "Mrs. Palmer," and "Verona." Mr. Frater, Messrs. Paul & Co., Bridge of Weir, Mr. D. Fergusson, Mr. Hamilton, and others are also raisers of new varieties.

Ireland is also furnishing a good contingent of raisers in Mr. J. D. Stuart and Mr. Samuel McKee, both of Belfast. The former has been the more successful as a raiser, and has sent out, through others, such fine sorts as Golden Flake, Laverack, H. W. Stuart, Blue Garter, Carissima, Erin, Diva, Hibernia, Mary Stuart, Acushla, Colleen Bawn, Charm, and others. Mr. McKee grows a much lesser number of plants, but has already raised such fine sorts as Reliance, Comet, Magnet, Duchess, Countess, Mars, and others, and was also awarded a certificate at the Viola Conference for Charmer, a lovely variety. Mr. George Steel, Etal, Cornhill-on-Tweed, is now devoting his attention very much to the Violetta or miniature section, and has some fine varieties yet to be sent out, most of which I have seen. Amongst varieties he has already introduced are Mrs. Joseph Oliver, Maggie Steel, Mrs. George Finlay, Mrs. Stevens, and others.

Mr. Septimus Pye of Catterall is also earnest in Viola work, and the introducer of many new varieties raised by himself, Mr. J. D. Stuart, and others.

Several amateur florists in the neighbourhood of London are also raisers, Mr. George McLeod of Chingford being one of the first to take the Viola in hand close to London, and obtained at the Viola Conference a certificate for a seedling pink-tinted variety named Rose Queen, as well as having previously raised other varieties. Mr. A. J. Rowberry, Woodford, near London, also obtained a certificate at the Conference for a beautiful almost blue miniature variety named Olivetta, really a gem, and Mr. D. B. Crane, Highgate, London, also obtained a certificate for Ethel Hancock, a charming white of the Sylvia type.

Much more could be written on the Viola, but I must now draw these remarks to a close. I rejoice in its popularity, and in the certainty of its being universally used in gardens for a number of years until superseded by some other plant, but that time is yet far distant.—  
WILLIAM DEAN.

#### THE LATE MR. WILLIAM THOMSON.

IT would be with a sad sense of a great personal loss that many of your readers looked on the portrait given in your issue of the 17th inst. of the practical horticulturist and good man, whose noble qualities of mind and heart had justly endeared him to a wide circle of friends not exclusively confined to horticulture, and many pleasant hours would again be brought to mind of time spent in his company listening to some practical advice, or enjoying some of his pleasant reminiscences of which his mind seemed to be a veritable storehouse.

Who that has been present at some of our horticultural functions when he has presided that has not felt proud of having such a grand old man as chairman, and have gone away from the meeting instinctively feeling better men, and with a higher sense of the duties and responsibilities of his calling after listening to a speech on some gardening subject from him? and who, again, that has been privileged to spend a day at Clovenfords has not been struck with the masterly mind that has been at work in all the detailed arrangements of the place? The marvellous crops of Grapes taken off the Vines there for years in succession might entitle Clovenfords to be called the home of Gros Colman and Lady Downe's Grapes for market purposes. Perhaps one of the finest houses of "Duke's" to be seen was growing here a few years ago, pruned on the long spur system. The writer was told by the late Mr. Wm. Thomson the roots had a free run of the natural soil outside (which is very poor), the only attention given being an occasional dressing of their Vine manure.

But the most interesting feature of all to visitors at Clovenfords was found in the personality of Mr. Thomson himself, the charm of whose manner and gentlemanly bearing made old and young alike welcome, and he was ever ready to give advice and encouragement to both; especially was this so with the young, whose welfare he had thoroughly at heart, and perhaps in his day did more than any other man in seeking to improve the position and raising the standard of young gardeners.

For one, I hope that in any attempt which may in the future be made to raise a fund for the perpetuation of Mr. Thomson's memory, that this admirable trait in his noble and many-sided character will be kept well in view.—N. F. BARNES, *Eaton*.

#### A REMINISCENCE.

IT was with sorrow that I read of the death of Mr. William Thomson. It was rather singular that a discussion should be going on in the *Journal of Horticulture* over his favourite subject just at that time. I once had the pleasure of a shake of his hand when on a visit to Clovenfords, although the name of this famous pioneer in Grape-growing was familiarly known to me long ago. My young days were spent close to the scene of his early triumphs, almost in touch with that lasting monument of his old friend, the late Mr. Peter Kay, that fine example of extension Vine training at Finchley.

Then there was Mr. David Thomson, now of Drumlanrig, who lived at Dyrham Park, near Barnet, about the same period his brother was at Wrotham. I believe at that time, amongst other good things, Strawberries in pots and Pelargoniums were particularly well grown at Dyrham. In close proximity to the latter place about this time lived Mr. Thrower at High Canons, another excellent Grape grower. I have heard it remarked of him that once he had a foreman who stripped the Vines of their bark, and so annoyed was Mr. Thrower that he made him tie it on again. The late Mr. John Davis of Oak Hill, East Barnet, another grand Grape grower, was well known to me in my youth. I can picture Oak Hill as I write here, which I could see daily from my father's doorstep. My father was at that time foreman to the late Mr. William Davis, at the Whetstone Nurseries, now owned by Mr. Sweet.

Another notable man who used to visit there was Mr. Forsyth; he, too, has left his mark concerning Grapes in his table of the temperatures of the early vineries at Oak Hill, as detailed in the "Gardeners' Assistant." Both he and William Davis served together at Oak Hill under the elder brother of the latter. I have heard how Grapes from there in those days were carried to London on the head of one Harry Mills, who was afterwards many years sexton at Whetstone Church. I think he is gone too. In the same radius, somewhere about that period, lived also another noted fruit grower in the person of the late Mr. Tillyard, who then lived at Stanmore Priory, Middlesex.

I heard much in my earlier days of the work of these good men, and I must have caught on that enthusiasm for Grape-growing that has never left me. The fine Lady Downe's grown at Whetstone some years ago I shall ever recollect. Many a time have I carried them on my head from King's Cross to the West End, when they were worth something like 20s. per lb. Things are different now. Then almost adjoining Oak Hill at one time lived Mr. Thos. Baines, growing his grand specimen plants. Now, only a short distance from there we have Mr. W. H. Lees of Trent Park Gardens making fame with Chrysanthemums.—  
J. J. CRAVEN.

I WOULD like to thank many members of the horticultural community for their kind sympathy in our recent sore bereavement. My sisters and myself have been much comforted by the many kind letters received from all quarters. We shall not, I fear, be able to answer them all personally, and therefore I hope those who do not receive a direct reply will accept this public acknowledgment of their kindness.—  
JOHN THOMSON, *Clovenfords, N.B.*

#### SEASONABLE NOTES.

IN these days of keen competition it behoves everyone who would advance with the times to be on the alert to embrace every favourable opportunity which presents itself that will in any way supply additional knowledge or assist them in the race and struggle of life. With the advent of the New Year the various duties of a gardener commence. The trade catalogues remind us that it is high time that we began to prepare our lists for another season, and in making up our seed lists year after year I think we are apt to adhere too closely to the old order of things instead of exchanging some of the varieties of the past and supplementing them with those of more recent date.

These remarks are not so much intended for vegetable as flower seeds, for of course where a fair trial has been given, and the most suitable varieties of the former have been selected, I should say by all means do not despise a good thing till you have found a better; but in the case of flowers I think a great deal more interest would be evinced if we were to diverge somewhat from the beaten track. Of the old-fashioned flowers what can be more beautiful during the summer evenings than the Night-scented Stock (*Matthiola bicornis*), filling the air with its delicious perfume? The *Hesperis* or *Rockets* are good plants, and although they are getting a little more popular, they are not nearly so often met with as their merits deserve. They are equal in every way to the Stock, blooming twice as long, and are perfectly hardy. For supplying cut flowers they are excellent. *Nemophila insignis* is one of the most charming of our garden flowers, attaining a height of about 6 inches it is suitable for edging or bordering purposes.

Another subject which I think needs our attention is in reference to the tool shed. How often do we see tools laying about, some in one place and some in another; and though this state of things shows a state of carelessness on the part of the men, it also shows loose management on the part of the head gardener. I remember during my early days the rigorous accuracy exercised by one head gardener in this matter. The plan adopted by him was as follows:—Each man on his entry into the garden was presented with a set of tools necessary, and was also given space in the tool shed to keep them in. No man was allowed to use another's tools. In addition to the ordinary garden tools each man was presented with a good pruning knife every two years or thereabouts.

A matter too often overlooked was also strictly enforced—thoroughly cleaning the boots before coming off the garden on to the walks. This is a very important matter, the neglect of which not only tends to the production of weeds, but also causes the walks to present a dirty and untidy appearance. On each quarter of the garden was placed a scraper and a partly worn-out broom. Five minutes were allowed at leaving time for thoroughly cleaning boots and tools, and for placing the latter in their respective places in the tool shed. In short the motto, "A place for everything, and everything in its place," which was hung up in the most conspicuous place in the shed, was always carried out,

with the result that no time was lost in looking up the tools, as is the case in so many gardens.

At this season of the year many changes are usually taking place, and it is for the benefit of those who are relinquishing the duties of foreman, and taking the duties of head gardener, that I am prompted to make these few remarks, and I am confident that where the foregoing hints are strictly enforced the result will be in every way satisfactory. The change may cause a little murmuring amongst the men at first, but this will be quickly overcome, and the routine will eventually become a pleasure to the workmen.—GEO. PARRANT, *Ashby Lodge, Rugby.*

#### NATIONAL CHRYSANTHEMUM SOCIETY'S EXHIBITIONS.

IN addition to the three exhibitions announced to take place at the Royal Aquarium in October, November and December, the usual show of early Chrysanthemums, Dahlias and Gladioli will be held on September 3rd, 4th and 5th, the National Chrysanthemum Society giving £20 in prizes for early Chrysanthemums and £10 towards the Dahlia and Gladioli classes, supplemented by a grant of £50 from the Royal Aquarium Society. The schedule of prizes will be issued, as heretofore, with those of the National Chrysanthemum Society.

#### M. DE REY-DELLET'S CHRYSANTHEMUMS.

THIS French amateur raiser was better known a few years ago than he is to-day, for unfortunately a long time has elapsed since he sent us anything of great merit, *La Triomphante*, *L'Ebouriffée*, and *Marsa* being the last. During this season I have only met with two from this grower which have struck me as worthy of note. Vice-President *Boulreux*, a fimbriated Japanese, a fair sized, roundly built flower, colour rosy mauve, and *Mlle. Antoinette Truelle*, a globular Japanese, medium size, colour a rich scarlet crimson and golden reverse. Very solid and compact are the ones referred to.—P

#### SHEFFIELD CHRYSANTHEMUM SOCIETY.

THE annual dinner of the above was held in the Masonic Hall, Sheffield, on the 28th inst., under the chairmanship of Mr. C. E. Jeffcock, President of the Society. Delegates were sent from the Wakefield and Leeds Paxton Societies, Rotherham Gardening Society, and the Sheffield and Walkley Amateur Floral Societies. Mr. Housley, Secretary, in reply to the toast of the Society, said it was a credit to its patrons. They commenced the year with the sum of 9s. in hand; but the Committee worked hard, and at the end of the year they had a balance of £63 5s. 9d. In addition to this the sum of £9 13s. 6d. had been contributed to the provident fund established in connection with the Society, which had to its credit £37 0s. 4½d. This spoke volumes for the efficiency of the Committee. Monthly meetings are held, when papers and essays are read and discussed on general horticultural topics, and small prizes are offered for exhibits of cut blooms and plants. A library has also been formed in connection with the Society, consisting of the principal works published on horticulture. After the usual round of speeches, toasts, and songs the proceedings closed, a most enjoyable evening having been spent.

#### PRINCESS VICTORIA.

I SHOULD like to advise gardeners who have to meet a large demand for white flowers at Christmas to give Princess Victoria a trial, for it is the best late white that I know. At the present time it is quite equal to the best blooms of *Avalanche* that I have seen at any of the shows during the last season, with very much more substance in the petal, and altogether a heavier flower. I am sure a few dozen blooms of the above would be appreciated by many employers, and admired by visitors at this time of year. It is a splendid keeper, and blooms that have been cut ten days and kept in a room with fire daily look as if they would keep for as long again.—W. F. SMITH.

I CAN fully endorse all Mr. G. Inglefield says on page 69 in favour of the above as a decorative variety. I bought three plants last winter which, however, were not delivered until March, 1894, and then only moderately rooted; consequently, the crown bud was late in formation. On this account I ceased to take out side growths. The plants were housed with the general collection in September, and allowed to extend side shoots at will. To my surprise in December it produced the most beautiful display I ever beheld in any one Chrysanthemum. The stem is very erect, and the creamy-white flowers from side shoots are carried on thin, erect stems requiring no support. Having a heavy demand for flowers at the time, I introduced this variety for room decoration, and I need scarcely say the name was soon inquired after, and everyone who has seen it admit it to be the best. I intend growing a large number of it in the same way this season, and would strongly advise others to grow it. *Eda Prass* was treated precisely the same, but the result was not so encouraging.

In the list of twelve decorative varieties sent by me to Mr. Molyneux, and which appears in the *Journal of Horticulture*, January 24th, I gave it a vote, the only one it appears to have received.—J. DOUGHTY, *Cranbrook*.

#### A CRITIQUE.

THERE is no doubt that the elections of the Chrysanthemum for all purposes is a step in the right direction, to enable one to choose what to grow out of the number of varieties we now have, especially when plants are limited to small numbers.

If these elections are to be continued it is hoped that it will be possible to increase the number of decorative varieties to thirty-six, twelve is not sufficient to cover the flowering season, and to divide these into three sections, taking Madame Desgrange, James Salter, and Lady Selborne, in the first section; Source d'Or, Mons. Astorg, and Cullingfordi, in the second; Meg Merrilies, Ralph Brocklebank, Grandiflora, and Mrs. Cannell in the last. My idea of decorative Chrysanthemums is that they should be a decided colour, good constitution, carry their heads erect, and be free flowering, whether for furnishing or cut flowers. When discussing this subject in a company of gardeners it was generally admitted that the incurved and Anemones did not find favour, nothing but the Japanese would please the ladies.

Looking down the list Mrs. G. Rundle is admitted to the charmed circle of twelve. *Soeur Melanie*, *Avalanche*, and *James Salter* just miss places, three of the best for decorative purposes, while others could be mentioned equally as useful. *Mrs. C. Harman Payne*, *Moonlight*, *Mrs. Dixon*, *Stanstead White*, *Stanstead Surprise*, *Barbara*, *Nonpareil*, *Princess of Teck*, *Jardin des Plantes*, *Chevalier Damage*, *Thorpe, jun.*, *Fleur de Marie*, *Nelly Rainford*, the *Christines*, and several others in the lists sent in, are not good decorative varieties. If a certain variety is liked there is nothing else to do but to grow it.

My motive for writing this critique is to point out to those who kindly sent in their votes that other varieties might be substituted with advantage to persons who are forming collections or in search of new sorts.—F. G.

#### GREYIA SUTHERLANDI.

THOUGH this plant has been considered chiefly interesting to botanists it is by no means devoid of horticultural merit, for the bright red flowers are produced in dense terminal clusters, and have a rich appearance. (See woodcut, fig. 17). In this country specimens, which are not very numerous, seldom exceed a few feet in height, but in its native habitats, the rocks at Port Natal, it is said to attain the dimensions of a small tree, which when in flower has a very brilliant appearance. The leaves are somewhat fleshy and crenated at the margin. Some are quite smooth, and others densely pubescent, a peculiarity that has been repeatedly noted by several observers. It blooms early in the year.

#### PEELING AND CLEANING VINES.

As has been so graphically described by Mr. Taylor, extreme cases of insect attacks on Vines require extreme methods of eradication. As all Grape growers are aware, both red spider and mealy bug are serious pests to deal with in the routine of culture of the Vine, and in obstinate cases desperate measures have to be undertaken if the foe is to be successfully combated. But to carry out the practice of peeling away the bark of Vines year after year as a safeguard against insect attacks is, besides being an unnecessary proceeding, not in my opinion likely to add either to the general health or longevity of the Vines.

During the past nine years I have not had a particle of bark removed from the Vines under my charge, although during earlier years both red spider and thrips were very much in evidence. Of these latter not any has been seen for the past seven years, but of red spider we have had a little occasionally, according to the season. The hot and dry season of 1893 brought the worst attack of late years, but last season none was seen, in fact I never saw Vines clearer from this pest.

My practice is to give the rods two thorough washings with warm soapy water, following immediately before the bark is dry with another washing, this time using a decoction of Gishurst compound. These washings cannot be too thorough, in fact the bark should be saturated. For this work of washing we use new painters' brushes. It is of little use if red spider has been in evidence to use half worn out brushes, or worse still those home-made toys of matting so often seen. By using brushes in good condition, if there is the "will" behind the brush, the wash can be thoroughly worked in, especially about the old spurs. If the above practice of washing annually is carried out, whether red spider is present or not, I do not think other details of culture being carefully carried out that red spider will prove very troublesome.

Attacks of spider are very often aggravated by faulty ventilation as much as anything. I have been in vineries, and could see at a glance by the appearance of the foliage that the structure was not properly ventilated. On feeling the foliage it has been quite hot, and just in the right condition for inviting an attack of spider.—A. YOUNG.

I THINK I have used the tar mixture as freely as most men have, but not with very satisfactory results. However, "D. R." (page 55) will find the following formula (Austin) quite safe. Take some stiff clay and work up with water to the consistency of cream, 4 quarts; then add

three-quarters of a pint of coal tar and mix well. Paint the rods alone but not the eyes. After careful scraping and the application of the tar mixture, on careful examination "D. R." may perhaps find on bright sunny days the pests taking their walks abroad, and he will be justified in resorting to drastic methods of destruction.—W. POTTS.

I HAVE read with great interest the various opinions expressed in the *Journal of Horticulture* on the peeling of Vines, and wish to express mine on the subject. By what I understand peeling Vines is taking off all the bark that can be torn or scraped away, for the purpose of facilitating the destruction of insects. The dead tissue formed on the stems of Vines and other trees is certainly not without its use. Its purpose is to protect them from external injury, and probably also from sudden changes of temperature, as the dried tissue is a bad conductor of

FIG. 17.—GREYIA SUTHERLANDI.

heat. Vines grown under glass may not need protection against injury or sudden changes of temperature, and in this case there can be little or no detrimental effect to them, although the vital tissues are deprived of the natural protection. Yet neither can there be any direct benefit to the Vines from such an unnatural operation, but there may be indirectly benefit in their being more easily kept clear of insect pests.

Mr. Taylor (page 55) attributes his light crop of Grapes in 1894 to the scraping of his Vines the previous year. He may be right, but it is to be noted that he also tells us that previous to his cleaning the Vines many of the leaves were rendered useless, owing to severe havoc by red spider. Was not that alone sufficient to cause the crop to be lighter this past year than usual? I am at a loss to understand why Vines should have a tendency to flag after being deprived of their dead bark. Surely this has little to do with transpiration and absorption of water. The direct rays of the sun on the stems might to a slight extent cause evaporation from them, but is not the loss infinitesimal, especially when the stems are painted with clay?—B. S.

I CANNOT refrain from saying a few words in the present discussion. Like other questions, the dressing of Vines has two sides—a right and a wrong one. The right one Mr. Craven has evidently pursued in his case, but I cannot agree with Mr. Craven when he says

no dressing should be done beyond washing with some approved insecticide, as circumstances alter cases, and Mr. Craven would do something more if his Vines were badly infested with mealy bug. But the words "peeling Vines" grate on my ear. To peel them is one thing, but to take off loose bark is another. The Vine throws off its bark as new is made, and that is the bark to pull off which we find hanging from the rods or in any way loose; but the inner bark must be let alone.

If vineries are looked after as they ought to be no bug ought to be found in them, but I advise those who are troubled with it to paint the houses with two coats of white lead, or rub all woodwork and iron with a cloth wrung out with petroleum before any washing down is done; then wash the Vines and paint with coal tar, mixed as follows, though I have not to use it here:—One 5-inch potful of coal tar to five 5-inch potfuls of water; mix with clay to form a smooth paint. The above mixture with a watchful eye will banish the enemy.—MAY FLOWER.

THE subject under discussion being of great importance to gardeners, I should like to give a definition of what bark is, taken from an old educational work by Chambers. "The bark of exogenous trees, consisting of three, and sometimes four parts—namely, the cuticle, or outer skin; the cortical integument, or solid part; and the liber, or inner bark. Of these the cuticle, or outer skin, soon cracks, and partially peels off, as from the closeness of its texture it cannot dilate, so as to give space for the bark beneath it when that increases in thickness. The cortical integument is what is properly called bark, and this in some trees attains a considerable thickness, as, for example, in the Cork tree, which is a variety of the Spanish Oak, and in several kinds of Elm. This bark, or cortical integument, is occasionally in two layers, the inner one of which increases so rapidly in diameter, that the outer often cracks, and in some trees, as, for example, in the Oriental Plane, it falls off in large plates as the part below it expands. The liber, or inner bark, which is quite distinct from the two layers of cortical integument, is very thin, though a layer is deposited of it every year within that of the preceding year. It is generally very elastic, and dilates as the stem of the tree increases in thickness, but in a few ligneous plants, such as the Vine and the Honeysuckle, a portion even of the liber is thrown off annually."

The words "peeling" or skinning appear to mean taking off the entire skin down to the wood. I prefer the word barking, as there are several layers of bark. Who is more able to give advice to young gardeners than those who have had practice? I have heard of Mr. Craven's success as a Grape grower; but I fear from his own admissions he has not had the chance of proving his ability as a bug exterminator—at all events, on Vines, as he said in one of his articles that he only had connection with it in one instance, and that as a subordinate.

It is my firm opinion that where mealy bug and red spider abound on Vines the only sure way of reaching them is by assisting Nature in the removal of all superfluous bark. Even with this method their eradication is not an easy matter. To my mind, trying to clear bug out of a vinery without removing the loose bark from the Vines, and that somewhat closely, would be like trying to wash filth off the body with the clothes on.

A practical question we have to consider is this: Would the health of the Vines be as much impaired by barking as a house of Grapes would be injured were the bark and insects under it to remain undisturbed? I think the old motto fits in here very well—"What is worth doing at all is worth doing well."

My advice to those who have either bug or red spider on Vines is to remove as much of the loose bark as can be done without penetrating the skin of the Vine. I should not be an advocate for this practice were it not that I feel convinced that it is next door to impossible to exterminate these pests without taking this course. Barking Vines in a rational manner has been resorted to for many years by good growers, who, as "Erica" states, are not allowed to figure in the show tent. By this means, whatever insecticide is used, it has a fair chance of producing the desired effect. Those who have no insects on their Vines have cause to rejoice, and certainly have no need whatever to remove any bark during the whole life of the Vine. I have heard people say they like to see the rods made smooth, though I think they look much better if the bark is only partially removed. I cannot see how this loose material can be of any benefit to the rod; it can hardly be necessary to keep it warm in a heated house. I hope we shall be enabled to get the best information possible on the subject from practitioners.—J. S. G.

I AM not acquainted with Mr. W. Taylor personally, nevertheless I admire the man for recording his experience in peeling Vine rods. He has made it plain that they were denuded of every particle of bark. I strongly disapprove of the practice, and hope W. Taylor will tell us how his Vines have behaved at the end of the next season.

Your correspondent, W. M. Potts (page 55), has remarked on the merits of the Grapes grown by Mr. Nash. I have seen his very excellent Grapes at exhibitions, and the grower of them, too, on one occasion, and thought him a less pompous man than some I have met. I feel sure he would be ready to show anyone interested, the peeled Vines at Badminton. As regards the garden labourers taking part in the operation of peeling Vines, I think Mr. Potts casts a mild slur on them. Many of them are thoroughly observant and careful. I was a garden labourer once, taking part in all outdoor rough and smooth operations, and often taken indoors to assist in peeling and cleaning

Vines. I well remember the caution I had at the commencement against scaling the buds.

I have two vineries planted with young Vines, unfortunately infested with red spider, and also a small trace of mealy bug. I am painting all wood and ironwork, and dressing the Vines with their "jackets on" with the tar mixture in about the same proportions as stated by your correspondent "E. K." (page 77). I have used this mixture on other occasions, and can thoroughly rely on its efficiency in eradicating these pests. I am not in a position to say how the Vines in question became infested, as I had not charge of them, but I will gladly send a few lines at the end of the season, giving the effects of the dressing.—D. P., *Lindley Hall Gardens.*

DURING the last few weeks several letters have appeared in the *Journal of Horticulture* on peeling Vines, some writers condemning the practice, while others advocate the system when properly carried out. If Vines have been more or less attacked with red spider, thrips, or mealy bug during the summer the cultivator may rest assured that with the fall of the leaf the pests will take up their winter quarters in and under the loose bark, especially that in the crevices surrounding the spurs, and there quietly wait the advent of favourable conditions to appear in greatly increased numbers as soon as young leaves are developed. This being so, what is to be done? To attempt to destroy the insects by means of softsoapy water applied with a brush without first removing the loose bark would be simply a farce—labour wasted. There is a great difference in removing all loose bark from affected Vines, even to the extent of carefully scraping the bark off the spurs with a blunt knife, and in laying the inner (green) bark bare. The former treatment is sound in the circumstances indicated, and the latter method of procedure simply barbarous.

Our Vines are barked in the reasonable way, washed with a softsoap solution, then dressed with a mixture of 3 lbs. each of softsoap and sulphur, a 6-inch potful of soot, and half a pint of paraffin in eight of water, clay being added to form a paint. This is applied to fruit trees also, and answers the intended purpose well. One year the Vines were not so dressed, and the next were attacked with red spider from a few of the preceding season having rested under the bark.

In reading Mr. Taylor's interesting and useful article on page 55, it occurred to my mind that the flagging of the leaves of his Vines might in a great measure be attributed to the check which they had sustained through partial loss of foliage the previous summer and autumn. Mr. Taylor's testimony is favourable to the barking of Vines under certain conditions. "I think under the circumstances," writes Mr. Taylor, "it was best to take the bark off." The operation was performed on the principle of bad cases requiring the application of strong remedies, otherwise such an able cultivator as Mr. Taylor would not have "peeled" his Vines to the extent he appears to have done.

I can fully endorse Mr. Potts' remarks on the excellent examples of Grapes annually staged at Bath and other shows by Mr. Nash of Badminton, and who, Mr. Potts says, "takes every particle of bark off" his Vines every year in the process of cleaning preparatory to forcing them the following year, a fact which goes to show that Grapes of the highest order can and are annually produced by "barked" Vines, notwithstanding statements to the contrary.—H. W. WARD.

#### SPAWNING MUSHROOM BEDS.

IT could not fail to be instructive to many gardeners and others if your readers would state the temperatures for spawning Mushrooms which they have found the most satisfactory. I have a bed in which at the end of last week the thermometer rose to 120°, so I took the bed out partly, well turned the material with other manure, and now I have put all in again, as I did not intend it to be dried by overheating. I do not think it will rise much more than 110°. The material smells sweet, and I could not press any moisture out of it. Am I right in pulling the bed out, or how high might the temperature of a new bed be expected to rise, and how deep should the thermometer be plunged in the bed?

The Mushroom crop is so important, and the disappointment so great when beds fail, that I am sure there are gardeners both able and willing to try and help the less successful to reduce failures to a minimum. I have unfortunately had two partial failures. I send a portion of "spawn."—MUSHROOM.

[The corner of a brick sent contained only the smallest particle of mycelium, but this is not infrequently the case with "corners," whereas the bulk may be fertile. Still, if the whole brick was like the sample sent it would not be capable of affording good produce. We shall be glad to publish the experience of Mushroom growers as suggested by our correspondent.]

#### THE FRUITERS' COMPANY AND ST. PAUL'S DAY.

THE Master and Wardens of the Fruiters' Company for each year are annually chosen on the 25th January, the Feast Day of the Conversion of St. Paul, the Patron Saint of London.

This festival day has a celebrity peculiar to itself. During the Middle Ages, and even down to our time, it was an article of constant belief that the whole character of the coming year is prognosticated by the condition of the weather on this day. The special knowledge of the future which might be derived from it was arranged under four heads in

four monkish Latin verses. Several old translations of the lines are met with; the following is one of the English versions:—

"If Saint Paul's Day be fair and clear,  
It doth betide a happy year;  
But if it chance to snow or rain,  
Then will be dear all kinds of grain;  
If clouds or mists do dark the sky,  
Great store of birds and beasts shall die,  
And if the winds do fly aloft,  
Then war shall vex the kingdom oft."

St. Paul's Day last year was miserably wet and cold; this year it was made unpleasant by rain and sleety showers. Still, we will hope for a happy year, and, at least, we do not expect that abnormally high prices will rule in our grain markets. At the meeting of the Court of Fruiterers last Friday, the Lord Mayor (Sir Joseph Renals) was unanimously elected Master of the Company, and Mr. W. E. Brooks and Mr. T. Platt, Wardens. The Lord Mayor was unable to attend the banquet that followed in consequence of impaired health. Mr. W. Garland Soper, the Senior Past Master of the Guild present, was chosen to preside, and he displayed marked ability in the position. The company numbered about 150. After the Chairman, the chief speakers were Sir Donald Curric, Sir Stuart Knill, Mr. Alderman and Sheriff Samuel Alderman Pound, and Mr. John Eagleton. Among horticulturists present were Messrs. G. Bunyard, Peter Kay, George Monro, T. Francis Rivers, and J. Wright.

### WINTER-SPRAYING FRUIT TREES.

THE fruit trees here are washed regularly every year as soon as they are pruned with soft soap and water, and the branches thoroughly scrubbed with a brush, such as is used for cleaning carriage wheels, to remove insect pests, smut, and any cryptogamic growth that may be on the bark. After this is done the trees are syringed all over with solution of a wineglassful of petroleum to a gallon of water to destroy any insects that may still be left harbouring in the crevices of the bark and branches.

Hitherto this operation was performed by two men. One was employed in churning and mixing the oil and water with the syringe in a pail, while the other was applying it to the tree. It was a tedious process in getting over the work where there were a number of trees to be done, and I often thought it would be a great advantage and saving of labour if a garden engine could be constructed so as to mix the petroleum and water just as it left the nozzle of the engine. About two years since a member of the firm of the Stott Fertiliser and Insecticide Company, Ltd., called on me, and I mentioned the circumstance to him, pointing out the great advantages to be derived from such an engine. He said that the firm had been working for some time trying to perfect an engine of this kind, and they had succeeded, with the exception of some minor details, in adjusting the quantity of petroleum the engine can deliver per gallon of liquid, which could be easily got over.

After this assurance I ordered a 30-gallon engine to be sent on as soon as possible after it was perfected. It took longer to do this than they expected, and I did not receive it till last autumn, and this is the first season I have used it in spraying the trees. It does its work well. It is a great saving of time, as we can do six trees in the time we used to take to do one with the syringes, and it is much cleaner and easier for the men. The petroleum is put into a square box with a perforated lid, which is level with the top of the engine, and by means of a valve attached to it, it can be regulated and adjusted to distribute from a quarter of a glass to two wineglassfuls to the gallon of water.

For summer or winter spraying of fruit trees I consider the engine is perfect, and a great improvement on the old method of using the syringe when applying petroleum as an insecticide to trees.—  
A. PETTIGREW, *Castle Gardens, Cardiff.*

### UPWARDS AND ONWARDS.

PROBABLY at no other time of the year are flowers so greatly appreciated as at present. They brighten the wintry days; cheer us when we feel downcast; provide us with food for thought and for work, and moreover prove to us that at all seasons of the year flowers may be had by proper attention to the essential details of culture and of kinds. During the past decade the advance made in the improvement of winter flowering plants has been unprecedented, as will readily be admitted when the Chrysanthemums, the Primulas, the Cyclamens, and numerous others of to-day are mentally compared to those of days gone by. For quality of flower, richness, and diversity of colouration, and exquisite symmetry of form in either of the examples above named there can be little, if any, comparison. Yet we must not despise those that were really pioneers to the present greatness, for did they not act as an incentive, if such was needed, to those true florists, who, in their unremitting endeavours to find something better, have earned for themselves the gratitude and respect of all classes of the gardening community of the present day? Upwards and Onwards was their motto, and it must be ours. Let us strive as our predecessors have striven, that our successors may say the same of us as we are saying of those good men who have gone before. The reward is worth the winning, and it can only be had by honest labour. Who will not enter the lists?

Though mention has been made in the above lines of Chrysanthemums it is not proposed to refer again to them, but to the other two mentioned—Primulas and Cyclamens. Taking them in their order, let us look in on a collection now at the summit of its beauty, and see what

a wealth is afforded. But perhaps it would be as well before going farther to say that the display may be seen by any readers who care to journey as far as Reading and inquire for the nurseries of Messrs. Sutton and Sons, and whenever it is possible to go the opportunity should be taken, for there is much to see, to interest, and to instruct, as everyone who has been will be only too ready to testify. Let the guide be Mr. Leonard Sutton (as in the present case) or Mr. J. Martin (as on a previous visit) the result can but be the same, and that is the visitor departs with the glory of the flowers ever before his eyes; the thought of the courtesy and geniality, combined with an unusually deep practical knowledge of his guide, and the determination that should ever kind fate place Reading in his way again he would not fail to avail himself of another look, and mayhap another talk.

The strides that have been made in Primulas by the great Reading firm have been referred to many times, and it is consequently the more difficult to say anything fresh, and yet did we not place the latest introductions on record year by year we should not be doing justice either to the introducers, to our readers, or to ourselves, and it is simple justice that is aimed at by the writer, and surely that is all that is desired by anyone. Thousands of plants are to be seen, representing many varieties, and it is obviously impossible for anyone to mention the whole, so reference will only be made to those that are possessed of more than ordinary merit either in colour, freedom of flowering, or shape.

Though it has been pointed out many times before, the fact of the Chinese Primulas having been raised from one species will bear repetition. To the cultured mind of the florist this conveys a world of meaning, for does it not show that instead of hybrids the magnificent kinds seen to-day are cross-breeds? At Reading the original form may be seen alongside the best varieties, and the latter certainly lose nothing in the comparison. The plants are of course models of health and good culture, and as examples of the latter could not be overpraised. The chief points may be briefly stated. The plants are compact, the foliage stout and broad, and the handsome flower trusses are carried well above the leafage. There are thousands of plants in 5-inch pots, all raised from seeds sown in June; but let us now glance at a few of the varieties, for time presses, and they must not be missed.

As representing one of the first of the firm's introductions, and one that continues to maintain a very high position in the public estimation despite the fact of its having been sent out in 1879, mention may be made of Ruby King, while another introduced in the same year—namely, The Pearl, still holds its own. The truss of this chastely beautiful white variety are shapely and strong, while the individual flowers are as near perfect as possible. Of the first named nothing need be said; it has its reputation, and in upholding that it proves its merit in a most convincing manner. Brilliant Ruby is exceedingly floriferous and sturdy in habit. The colour, while resembling Ruby King, is richer and more intense, and is of a distinct and pleasing shade. The flowers of Reading Pink are of a particularly delicate tint that commands instant attention and admiration. The blooms are large in size, stout in texture, and of splendid shape, while they are in addition borne in great numbers. Rosy Queen speaks for itself in regard to colour, as indeed do most of the Primulas seen at Reading. The soft shade of rose is peculiarly pleasing, the trusses being large and shapely. It is a Fern-leaved form, and this characteristic not a little enhances its beauty. Reading Blue is a blue indeed. The drab shade that predominated in many of the earlier "blues" has almost disappeared in this, and it probably stands unrivalled for depth and purity of colour, combined with freedom of blooming and compactness of growth.

One of the most useful of the Fern-leaved section is Snowdrift, which is exceptionally early and very free flowering. The blooms do not fall from the plants so readily as do some of the varieties, and this may be taken as a distinct point in its favour for decorative purposes. Grenadier is very brilliant in colour, of splendid habit, and is certain to attain popularity in a very short time. Gipsy Queen everyone knows. The heads of flowers, pure white in colour, stand prominently over the deep green leaves, which have red stalks. It belongs to the Fern-leaved section, and is one of the most distinct, and at the same time charming, of the whole collection. A word for the Giants, and then we must glance for a few moments at the doubles. They have been well named, for they are giants indeed. The blooms are of immense size, extraordinary substance, and carried in a manner that leaves nothing to be desired. Though of such size, there is no semblance of coarseness either in foliage or flower. White, pink, and crimson are each represented in perfect condition, while a superb Fern-leaved white lends variety and makes a splendid fourth.

The structures devoted to the double kinds were hands of colour on each side, the colours being arranged in groups, each numbering some dozens of plants. In this manner the best possible effect is insured, and the eye of the visitor can thoroughly grasp and retain the one ere it passes to the next. As a whole the display is wonderful. The intensity of colour, the contour of the flowers, combined with the sturdy, erect habit of growth, demonstrate very conclusively the quality of the strain and the care with which it has been selected. It has been said that with a double blue Primula there is a lack of substance of petal and compactness of habit, and no doubt that was the case a little time ago, but it is not so now. The growth is very robust, and the blue shade is most decided. Both Sutton's Double Blue and Imperial Blue are of the first quality, and will long hold a foremost position. The blooms of Double Heliotrope are excellent in every way, being particularly refined both in shade and build.

The popularity and utility of the double Primula for cutting

purposes is unquestioned, and the double white seen at Reading, with crimson, carmine, and scarlet, must be accorded the most prominent position for this purpose. There are, however, other varieties that may well be added, such for instance as Fern-leaved double white, which is of the greatest beauty. Then we have Carnation flaked, appropriately named from its resemblance to a flaked Carnation. The semi-double Gem, with its pink flowers set in finely cut leafage, must not be forgotten, neither must double alba magnifica, which, with its charmingly fringed flowers, is undoubtedly one of the very best.

One of the most interesting houses at these nurseries is the one devoted to the trials. Here twelve plants of every sort are grown for comparison, and a glance suffices to show the quality of any particular stock. Though the plants are smaller than in the houses previously inspected there is no lack of health observable, and as a whole the trial is probably unique. It is in every way complete, and the firm is to be congratulated on the thoroughness with which it is carried out, as were it in any but this manner it would, instead of being valuable in all ways, be worse than useless.

Marked as is the advance in the Primulas it is scarcely less so in the Cyclamens, and to go to Reading in the winter without seeing the latter would be an error always to be regretted. More perfect examples of proper methods of cultivation could scarcely be found anywhere. The plants, which are almost all in 48-sized pots, are dwarf and sturdy, with marbled leafage, and flowers standing on stout footstalks well above. It is not possible to mention all the varieties, but one cannot stop without reference to a few of the best. Vulcan, with its rich maroon coloured flowers, at once attracts the eye, and commands admiration; as does the Salmon Queen, for the strain of which Messrs. Sutton & Sons received an award of merit at the last meeting of the Royal Horticultural Society. Its colour may be best gathered from its name; Butterfly, pure white, is a general favourite, and is certain to continue so, while for the giant section only words of praise can be found. But time flies, and the end must be reached. Let all who read this take the advice previously conveyed, and go to Reading to judge for themselves.—H.

#### FRUIT FORCING.

**Peaches and Nectarines.**—*Earliest Forced Trees.*—Although good setting of the fruit often attends the mere shaking of the trellis or trees, it is desirable to fertilise the blossoms as they expand and the pollen becomes ripe, distributing it over the stigmas with a camel-hair brush, feather, or rabbit tail mounted on a stick. Syringing may be resorted to both morning and afternoon, when the fruit is well set and the weather bright, but in dull periods damping the floors and borders will be sufficient, and the afternoon syringing should take place early to allow the foliage to become fairly dry before nightfall. This is important, for excessive moisture encourages soft woody growths, weakens the tissues, and interrupts the elaboration and assimilation of the juices, which are essential to the development of the fruit and the sound construction of the wood. The water used for damping and syringing must be of the same temperature as the house, also that supplied to the roots. Avoid a sodden condition of the soil, which frequently induces the casting of the fruit, and the growth of the long-jointed useless wood. Disbudding must be done very carefully at this early season, removing a few growths from a tree at a time, and continuing the process daily. This is preferable to removing many young sprouts at distant intervals, as it gives a check to the roots, interferes with the diffusion of the nutrient matter, and promotes wood growth at the expense of the fruit. The night temperature will need to be maintained at 55° to insure steady progress, or even 60° on mild nights may be allowed, while on cold it may fall to 50°, for safety is on the side of the low degree, 60° to 65° by day artificially, 5° less on these figures when the weather is severe and dull. Ventilate early, admitting a little air at 65°, not allowing an advance over 70° without free or full ventilation, closing at 65°, always excepting a small opening at the top of the house constantly. This prevents a stagnant atmosphere, secures a healthy condition in the foliage, and it is enabled to act fully in the presence of light.

*Second Early House.*—Trees started at the new year are expanding their flowers, and are singularly free from aphides. Great care must be exercised in fumigating with tobacco or even vapourising with nicotine, as the organs of fructification are easily destroyed, therefore fumigation on two or three consecutive evenings moderately must be had recourse to if necessary in order to keep the insects in check, but vapourising is the safest process. Solutions sometimes injure the blossoms, and ought to be avoided. With an excess of blossom buds the trees may fail to set the fruit well, but by removing those on the under side of the shoots the remainder are correspondingly invigorated and the setting satisfactory. Syringing is best discontinued from the time the buds show colour and until the fruit is set, but the house may be sprinkled in the morning and afternoon, which will afford quite enough moisture for steady progress, a stagnant atmosphere being avoided by leaving a little

air on constantly at the top of the house and increasing the ventilation from 50°, which should be the minimum day temperature, and 65° the maximum from sun heat with full ventilation. Regard, however, must be had to cold air, it not being advisable to admit too much, but vary the ventilation according to external conditions. Inside borders should be thoroughly moistened to the drainage, avoiding needless watering.

*Trees to Afford Fruit in July.*—The house should be closed at the beginning of February, when such varieties as Dymond, Royal George, Grosse Mignonne, Noblesse, and Bellegarde Peaches, with Elruge, Dryden, and Pineapple Nectarine, will give a supply of the choicest fruit, while the earlier varieties, if any are grown, will come in about three weeks earlier. The very early varieties, however, are not worth growing beside these midseason sorts, but the second early, as Hale's Early, A Bec, Dr. Hogg, and Rivers' Early York Peaches, with Rivers' Early, Goldoni, and Lord Napier Nectarines, are excellent for preceding the midseason varieties. The trees should be syringed in the morning and afternoon during bright weather, occasionally only in dull, and the border must be brought into a thoroughly moist condition. Employ fire heat to raise and maintain the temperature at 50° by day, above which ventilate freely, and allow to fall to 45° or 40° at night.

*Succession and Late Houses.*—Finish pruning the trees at once, dressing them with an insecticide, after washing with softsoapy water, 3 or 4 ozs. to a gallon, taking care not to dislocate the buds, not using the dressing at winter strength if the buds are advanced in swelling, but employ a weaker solution and applying with a syringe. Secure the trees to the trellis, allowing ample space for the swelling of the branches, and leave room between them for laying in young wood for future bearing. Loosen the surface of the border lightly, not disturbing the roots materially, removing any loose soil or old mulching, and supplying fresh loam, with a dressing of bone superphosphate three parts, sulphate of potash two parts, and one part sulphate of lime, mixed, applying a good handful per square yard; the waterings will wash it in fast enough. If the borders are at all dry afford a thorough watering.

**Vines.**—*Early Forced in Pots.*—Thin the berries somewhat freely, so as to secure large ones, yet not to the extent of making the bunch loose and unshapely. Maintain the night temperature at 65°, falling to 60° on cold mornings, but raise the heat early to 65° or 70°, keeping at 70° to 75° by day, increasing to 80° or 85° with sun heat, and closing at 80°, with a prospect of an advance to 85° or 90°. Ventilate very carefully, always early, and closing in good time, then damping the house. Damping is also necessary early in the day. Afford copious supplies of tepid liquid manure.

*Early Forced House.*—Duplicate and surplus bunches should be removed, and the berries thinned as soon as they become well formed, not deferring it beyond the distinguishing of the fertilised from the unfertilised. The inside border may be covered about an inch thick with sweetened short stable litter, which should be turned several times before it is introduced, otherwise the ammonia evolved may prove disastrous to the foliage. Attention will be required in tying the shoots and in stopping the laterals. Where space is restricted the shoots may be stopped closely, say one joint beyond the bunch, and the laterals be pinched at every joint as made. In other cases more growth may be allowed, but in all it is important that the principal leaves have full exposure to light and air.

*Vines in Flower.*—When coming into bloom maintain the night temperature at 65°, 70° to 75° by day, and 5° to 10° more from sun heat. Muscat of Alexandria must have 5° more, and as these are liable to set indifferently the bunches should have all the light possible and their ends facing the sun, then, when in flower, they can be rapped on the stem gently, or better have the pollen disposed on the stigmas by using a camel's-hair brush charged with pollen from free-setting varieties. A constant circulation of warm, rather dry air is conducive of a good set, and it is advisable not to stop the growth closely during the setting period.

*Vines Started at the New Year.*—Continue syringing the rods twice a day, but do not keep them constantly wet, as this induces aerial roots from them, and interferes with soil-root formation. Syringing may continue until the bunches show, but damping the borders and paths two or three times a day will be necessary to maintain a genial condition of the atmosphere. Do not be in a hurry to disbud, letting the growths advance until the bunches appear in the points of the shoots, then the weakest and otherwise least desirable can be removed, but it should be done gradually so as not to cause an appreciable check.

*Vines to Afford Ripe Grapes in July.*—The beginning of February is the latest time for starting midseason varieties to finish after mid-summer. Outside borders need not be covered with fermenting material, but a covering of leaves with a little litter over them to prevent their blowing about is all that is necessary to prevent the soil becoming frozen. The stems of the Vines, if outside, must also be thoroughly wrapped in haybands. Maintain a minimum temperature of 50°, and allow an advance to 65° from sun heat, 55° being the maximum from fire heat in the daytime. This will cause the sap to rise steadily, and a light damping occasionally assists in promoting the osmotic action of the cells, and the transference of stored matter from the wood to the growing parts. Due moisture at the roots is also imperative, for though the moisture may not be excessive some is necessary, therefore moisten the border through to the drainage, using water slightly in advance of that of the house in temperature, and if the Vines are weakly and the border in good order afford liquid manure after the moistening of the soil, which will to some extent displace the water and afford nutriment in due time.

## THE KITCHEN GARDEN.

**Cauliflowers.**—If late Broccoli has been much injured by frosts, or to the same extent as some of the midseason varieties, another sharp frost will about finish them. If it be thought advisable to forward a few dozen Cauliflowers so as to have them fit for use in advance of any wintered or started in band-lights, make a hotbed about 2 feet in depth and quite firm, spreading a little manure over this for the roots to lay hold of, and on this 9 inches of good loamy compost. When the soil is warmed through plant Early Snowball or one of the small forcing varieties, 15 inches apart. Protect with glazed lights and mats, but avoid undue coddling. Keep them well supplied with water, and use liquid manure freely directly the plants give signs of forming hearts. Autumn-raised plants wintered in frames should have abundance of air whenever the weather is not frosty, as they transplant badly after having grown strongly. If very small place singly in 2½-inch pots, and keep rather warmer than formerly. Hardened and planted under hand-lights or at the foot of warm walls before they become much root-bound there is a possibility of their surpassing larger plants not given a start in pots. In order to have a succession to autumn-raised plants sow seeds thinly in pans or boxes and place in gentle heat. If plants of Autumn Giant were not raised last autumn sow a few seeds at once, and the plants, if grown to their full size without experiencing a severe check, will give fine hearts about the middle of August, those kept through the winter being a fortnight ahead of them.

**Celery.**—The time has arrived for sowing seeds of early Celery. Give the preference to a good white variety, those which attain the largest size gaining most favour with exhibitors. Sow in well drained pans filled with fine loamy soil, making the surface quite level. Give a gentle watering, and after the water has drained away sow the seeds, covering very lightly with fine soil. Plunge in brisk bottom heat, cover with squares of glass, and shade heavily. The soil ought to be kept uniformly moist, and a light shading afforded whenever bright sunshine prevails after the seedlings appear. Before the plants become drawn transfer the pans to shelves near to the glass, but not in a cool house. After the first rough leaf is well developed prick out the requisite number of plants into boxes of rich loamy soil and keep in heat near the glass, or prick them out in a frame over a gentle hotbed.

**Onions.**—Those who are anxious to grow extra fine Onions should sow seeds of choice varieties in heat. It will be found that every fairly sound seed will germinate in heat far more surely than in the open ground, and every plant raised and duly planted on good ground will soon recommence active growth and surpass any that have been raised in the open in the usual way. Those small but expensive packets of fine varieties can thus be utilised to their fullest extent. There is no good reason why gardeners who are not exhibitors should not adopt the practice of raising Onions extensively under glass and planting out. Several thousand plants may easily be raised in boxes, and when about 4 inches high they can be dibbled out where they are to grow with trifling losses. The seeds will germinate quickly if the boxes are placed on a hotbed in an early started vinery, but bottom heat is not absolutely necessary.

**Leeks.**—In order to have fully grown well blanched Leeks fit for exhibition in August plants must be raised in heat, sowing the seeds not later than the first week in February. One of the larger exhibition varieties should be preferred. Leeks are excellent served as a vegetable, while if Onions keep badly a good supply of Leeks will prove very acceptable as a substitute.

**Early Peas.**—Very few gardeners can afford time and space for Peas in pots, but if extra early dishes are desired they might yet attempt their production by means of shallow mild hotheds and rough frames, or such as may be at present in use for protecting Endive. Chelsea Gem or William Hurst are the best for frame culture, and in order to lose no time sow from a pint to one quart of seeds at once, either in pots or boxes of light soil. Germination will quickly take place in a Peach house or vinery, being forced, and the plants should be hardened off and planted where they are to crop before they have a chance of becoming stunted. In the meantime prepare the frame for the plants, surfacing over a shallow solid hotbed with short manure, on this placing 6 inches of rich loamy soil. When this is warmed through plant the Peas rather thickly in lines 15 inches apart. Those raised in boxes ought to have their roots shaken clear of soil, and be planted Box edge fashion in deep drills and pressed with a spade. If there is sufficient height in the frame place short stakes to the rows at once, and in any case dibble out a row of either Early Paris Market or Golden Queen Cabbage Lettuce between them. The latter will more than repay for the work done. Protect from frosts and cold winds. This class of dwarf early Peas may be raised in a similar manner for planting in lines at the foot of sunny walls, and a little later on south borders generally. William I., Exonian, or other popular early round-seeded varieties ought also to be raised in pots or boxes ready for planting out as soon as the state of the ground will permit—earlier though not quite so heavy crops being had in this way than by sowing in the open. During the first fortnight in February seeds of early round-seeded varieties may be sown in the open, but if the ground is in had working order or saturated with moisture, delay sowing till it is in a better state, otherwise much of the seed may perish in the ground.

**Broad Beans.**—Should these be wanted extra early sow seeds singly in 2½-inch pots and place in heat to germinate, planting on a warm border after hardening. The remarks as to sowing in the open apply to these equally with Peas. Early Longpod and Beck's Dwarf Green Gem are very suitable for sowing early.

## PLANT HOUSES.

**Carnation Miss Jolliffe.**—Young plants raised from layers late last autumn and placed in small pots will be well rooted. They are useful for autumn and winter flowering, saving the time and trouble of rooting cuttings in the spring. These plants may be placed in 2½-inch pots, and then stood in any cool house or frame where frost can be kept from them. Under these conditions they will continue to grow slowly and be ready for a good start when genial weather arrives. The point of the plants may be removed if they do not branch freely. Where sufficient have not been rooted cuttings may be inserted at once, and for this purpose young growing shoots should be taken from plants in a cool house. These must be cut close to a joint with a sharp knife, and two or three inserted round the side of thumb pots in sandy soil. When watered place the pots under a bell-glass in a house where the temperature ranges at night about 65°. If other varieties are needed they may be treated in the same way.

**Asparagus plumosus.**—Cuttings may be inserted singly in thumb pots in sandy soil. A portion of the main stem should be attached to each frond, say about half an inch in all on each side of the joint. These must be well watered and placed under bell-glasses in the temperature advised for Carnations. From cuttings inserted now good plants for decoration in 4 and 5-inch pots will be produced by the autumn.

**Caladiums.**—A few of these may be shook out of the old soil and started into growth. If a propagating box with a good bottom heat exists the tubers may be plunged into it amongst cocoa-nut fibre refuse until they commence to grow, when they can be potted. Failing this provision place them in a pan or box, and arrange them over a hot-water pipe.

**Crotons.**—Where a brisk moist heat can be maintained young healthy plants may be potted at once. Be careful that the soil in which they are to be potted has been thoroughly warmed, or a severe check may result. The plants should be potted in the house in which they are to grow. Careful watering is necessary after repotting at this period of the year. Plants that have become bare at the base may be notched near the top and mossed. As soon as growing conditions are favourable they will form roots, and may be taken off. Cuttings of these plants if inserted while the wood is firm and the plants at a standstill, the foliage is certain to fall, and the cuttings will be a long time before they root. Plants intended to do duty for some time longer in small pots may have a little chemical manure applied to the surface to keep them in good condition.

**Gardenias.**—Those with prominent flower buds may be placed in brisk heat; do not overwater, and if infested with insects do not use strong stimulants, or the flower buds will become deformed. Young stock, if brisk bottom heat can be given, may be placed in larger pots and plunged.

**Ixoras.**—Autumn-rooted plants in small pots may, where abundance of heat can be maintained, be placed in 4-inch pots. These make capital decorative plants, 9 inches or a foot high, according to the variety. Water carefully and do not syringe the plants, or their foliage is liable to become spotted. Very frequent spotting is due to too low a temperature. Do not pot these plants until their shoots have started again into growth.

**Marantas.**—Plants that have enjoyed a period of rest and need repotting should be attended to at once. They start freely if brisk bottom heat can be given; in fact, much better than if potting is delayed until the sun has gained power. Strong, robust growing kinds do well in fibrous loam, one-seventh of manure, a liberal addition of sand and charcoal. If the pots are large enough carefully remove the old compost from about their roots, reducing the old ball about one-third. Some varieties do best with a good proportion of peat used in lumps in the compost.

**Anthurium Scherzerianum.**—Plants that have been removed for some weeks from the stove to a temperature 5° or 10° lower may again be introduced into the stove. With increased heat and moisture the plants soon commence to grow and flower. Where a good number are grown the plants may be flowered in succession.

**Dracaenas.**—Plants of various kinds that have been used for decoration and have become shabby may be stood on one side in a fairly warm house, and dried to harden their stems. If cut up while moderately soft at this early period of the year they are liable to decay. When dried for a few weeks the stems may safely be cut into lengths, and if placed in brisk heat nearly every one will start into growth. The root portion of old plants always do best.

**Cannas.**—The newer varieties are very useful for various decorative purposes. Plants that have enjoyed a rest may be divided and placed singly in pots according to their size. If placed in fairly brisk heat they will soon start into growth, when they can be removed to somewhat cooler quarters. If kept in heat they will soon push strong growths and flower.

# THE BEE-KEEPER.

## APIARIAN NOTES.

### FOUL BROOD.

"WILL you kindly inform me through the medium of the Journal if the bees (a sample of whose comb is sent by this post), died from the dreaded disease foul brood? Three expensive frame hives stocked with bees were purchased last spring. All have died in the same manner. I should be glad of definite information."

The comb sent is very badly affected with foul brood. Steps should at once be taken to eradicate this pest, as this disease is often propagated from one colony to another by robber bees entering affected hives and carrying off foul brood honey. No half measures will be of any permanent use. All combs and frames should be burnt, also the quilt, coverings, and any débris there may be about the hives. This should be carefully done so that not a particle escapes, and if burned in the open air the whole should be afterwards buried.

I am reminded of the care necessary in carrying out this operation, as when calling on a bee-keeper in a foul-broody district last autumn I saw combs from some stocks that had been condemned as a very bad case of foul brood. These were supposed to have been burned the previous week, a fire having been made in the open, and the frames and comb of the worst stocks had been consigned to the flames. They had only been partially destroyed, and I saw the bees from other stocks busily employed among the débris in clearing up any honey that remained. No wonder that foul brood was rampant in that district, and careful bee-keepers in the neighbourhood will doubtless suffer from the carelessness of this negligent bee-keeper.

If there are a number of good frames they may be preserved for future use by boiling them, as this will kill the germs of foul brood. They may then be used again, but as frames can now be made and bought so cheaply it is probably not worth the trouble. If the hives are in good condition they need not be destroyed, if some sulphur is burned in them after covering the hive as closely as it is possible. This will destroy all the germs, and afterwards the hive should be well washed inside and out with boiling water, and painted with carbolic acid, working it well into every crevice. Leave the hive empty for a month or two to allow the smell from the acid to pass away. The hives may then be used again with impunity, and there will be no further danger from foul brood unless brought from other stocks.

Procure some native black bees from a healthy neighbourhood, and if in straw skeps early in the spring early swarms may be put into the frame hives. If foul brood exists in the neighbourhood, and bee-keepers will combine among themselves, this disease may be eradicated. I find foul brood is much more prevalent in the south and west of England than it is in the northern and midland counties. Why it should be so I do not know. I do not think there is a single case of foul brood within many miles of my apiary. I hope it will continue so.

If there are still any stocks in which there is the least suspicion of foul brood I would recommend the Canadian plan of dealing with this disease. This is done by removing all the bees from an affected colony, and placing them in a clean hive with frames having a strip of guide comb to act as starter. On the evening of the fourth day remove the frames and any work the bees may have done, and insert new ones into the same hive with whole sheets of foundation. This, according to the American bee journals, is successful in curing this disease. The experiment would be worth trying in this country, but should be deferred until the weather is warmer in the spring.—AN ENGLISH BEE-KEEPER.

## TO CORRESPONDENTS

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Book (A. J.).**—You did not do what you observed we asked of another correspondent—namely, send us a postcard addressed to yourself. Your other question would have been answered this week had it been written on a separate sheet. It will have attention.

**Lifting Salsafy (Gaddur).**—It is always advisable to lift Salsafy and store it in sand in a cool place, but safe from frost, in a cellar or root-house. It keeps excellently in such places, provided the sand be just moist enough to prevent the roots shrivelling. The tops should not be cut off too close to the crown or root, but about an inch of the leaf-stalks left. As the season is so far advanced you may lay the plants in under a north wall, burying them up to the crowns and covering in severe weather.

**Chinese Sacred Lilies (R. S. O.).**—We do not see why they should not succeed outside equally as well as other of the Polyanthus section of Narcissus; but these ordinary forms after forcing do not flourish outside in cold localities. You would not lose much by planting the bulbs after the leaves have ripened, and you would at least gain experience.

**Fast-spreading Water Plants (G. W.).**—Two of the plants which spread quickly in water are the common Bulrush and the yellow Water Lily—*Nuphar lutea*. How these plants or any others are to prevent moisture or damp from your pond, even your doctor would find some difficulty in explaining. Plant the Bulrush near the margin, and the Nuphar in deeper water.

**Narcissus Poeticus Ornatus (Sussex).**—From your letter we should say the Narcissi were hurried too much in their early stages. For a time the plants are most impatient of heat, and if hurried many come "blind." If you had given the date of boxing the bulbs we could have formed a better idea, but judging from our own the plants ought to have remained in cool or semi-cool quarters for some time longer. Further notes will appear on the subject.

**Seedling Dracaenas (C. B.).**—Grow the plants in the best possible way for displaying their characteristic beauty, and when they are in the best condition in which you can show them send a few of the more promising for examination by the Floral Committee of the Royal Horticultural Society. Certificates granted by this Committee have greater weight, and invest plants with greater value than do certificates granted elsewhere. If you write to Mr. A. F. Barron, Royal Horticultural Society's Gardens, Chiswick, London, some time prior to sending the plants he will give you all necessary information for that purpose.

**Chrysanthemum Madame Desgrange (A. E.).**—This variety will grow and flower year after year in the same spot undisturbed, provided the plants are liberally supplied with water and liquid manure during the season of growth, and the growths thinned. They succeed best when lifted in spring, the ground dug and manured, the plants divided and replanted. If this is done they need very little attention afterwards. Mulching with good manure is beneficial during dry weather, and a little chemical manure applied to the surface and washed in certainly assists the plants. In well dug and liberally enriched soil they seldom need other attention beyond watering.

**Laelia anceps (A. H. E.).**—The white material on your Laelias is scale. Imported Orchids are nearly always infested with this pest. They should have been thoroughly cleaned when they arrived, and if properly attended to afterwards would not have got into their present lamentable condition. If neglected much longer the plants will be ruined. Your only chance is to sponge them carefully and remove all the offensive matter with a weak solution of softsoap. One ounce of the soap will be ample dissolved in a gallon of warm water. A weak solution of Fir tree oil or other good and safe insecticide will answer the same purpose. Watchfulness is needed afterwards, and directly scale makes its appearance, which it will for some time, the plants must be sponged again. It is only by constant care and frequent cleaning of the plants that the pests can be eradicated. The better the work is done each time the longer the plants will remain clean, and the more certain you will be of getting rid of the insects.

# VEITCH'S NEW MELONS OF SUPERB QUALITY.

## HERO of ISLEWORTH

Award of Merit, Royal Hort. Soc., Aug. 8, 1893.

A green-fleshed Seedling, of exceptional merit, free setter, and superior quality. Per Packet, 2s. 6d.

## INGESTRE HYBRID.

Award of Merit, Royal Hort. Soc.

A high-class Seedling, of robust constitution, flesh white, of great depth, and superb flavour. Per Packet, 2s. 6d.

## BEAUTY OF SION.

A scarlet-flesh Seedling of great merit. Fruit of medium size, with a bright golden-yellow netted skin, and of exquisite flavour. Highly recommended. Per Packet, 1s. 6d.

### PATIENCE.

THE hard weather and the snow are both compelling and educating us in patience. The commonest fault of all gardeners is anxiety to catch the early worm. The result is, not infrequently, getting caught themselves. Those who make haste to be rich are with those who are in great haste to "garden"—often found in the same category, and realise the force of the old saying, "There's many a slip," etc. The fact is Nature will not make seasons to gratify people in a hurry. We must wait on her moods and variations. What prospect could there be for seeds committed to the ground prior to the most recent hard weather? If in the south there has not been any heavy fall of snow, at least there has been enough in its lying and melting to render the soil very cold and wet. Frost, too, has been severe enough to penetrate several inches into the soil; and, therefore, in all cases out in the open, seeds—especially if they had commenced swelling—must have been seriously crippled. Even when a thaw ensues it leaves the soil in a very cold, wet, ungenerous condition for some time, so that seeds and infant plants suffer material check. I have yet to learn that any gain is found in such exceedingly early sowing. Soils must naturally be somewhat dry and seeds well protected to enable them to germinate healthily. Seedsmen suffer in reputation in this way just as those who will sow unduly early suffer loss, yet the fault lies with the gardener. Those who, having patience, wait until the hard frost and snow have gone, and the ground has become normally warm and dry, will find they have everything to gain for being prudent. That we shall have presently a splendid seed-sowing season there can be no doubt, and those who wait for it will doubtless later reap a rich reward."

Thus writes a gardener of great experience, and his remarks are as opportune as they are, generally speaking, true. One expression is possibly a trifle too comprehensive—namely, that "all" gardeners are so anxious to catch the early worm that they are habitually too far in advance with their work, or are up too soon in the morning. If all we hear is true, there are

## IF YOU WANT REALLY GOOD SEEDS

At MODERATE PRICES, apply to  
**MR. ROBERT SYDENHAM,**  
Tenby Street, North, BIRMINGHAM.

NO NURSERYMAN WILL SERVE YOU BETTER IN QUALITY,  
QUANTITY, OR PRICE.

### THE SIX BEST TOMATOES

In cultivation, often sold under other names to get fancy prices. Each packet contains nearly 200 seeds. Perfection, 3d.; Ham Green Favourite, 3d.; Hackwood Park Prolific, 3d.; Challenger, 3d.; Roseleigh Gem, a grand new large smooth selection, 3d.; Golden Perfection, the best yellow, 3d. Collection, 1s. 8d., post free; singly, 1d. each extra for postage.

### THE FOUR BEST CUCUMBERS.

Each packet contains 10 seeds, Lockie's Perfection, Rollisson's Selected Telegraph, Epicurean, and Covent Garden Favourite, 6d. each; or the Collection, 2s., post free; singly, 1d. extra for postage.

### SWEET PEAS—A SPECIALITY.

ECKFORD'S and other choice varieties at a third or a fourth usual prices.

Nothing gives so much cut bloom at so small a cost, or so little trouble. To get best results SOW AT ONCE, as directions sent with each Collection.

### SPECIAL VERY CHEAP OFFER.

8 Really Good Varieties—Queen of England, white; Blanche Ferry, pink and white; Princess Beatrice, pale pink; Apple Blossom, apple blossom tint; Orange Prince, orange pink; Splendour, rich deep rose; Cardinal, bright cardinal; Countess of Radnor, pale heliotrope, 25 seeds of each, 1s. 3d.

7 Extra Choice and Newer Varieties—Emily Henderson, fine large white; Venus, pale lemon flushed with pink; Mrs. Gladstone delicate pink; Her Majesty, soft rosy pink; Lady Penzance, bright pale rose; Firefly, bright glowing crimson; Monarch, large bronzy purple, 25 seeds of each, 1s. 6d.

The Two Collections, 2s. 6d.—Postage 2d. each Collection extra; or the two 3d. extra.

EXTRA CHOICE MIXTURE, 3d. per 100 seeds; postage 1d. extra.

### ALL OTHER SEEDS EQUALLY MODERATE.

see this unique Stock.

GEORGE BUNYARD & CO.,  
PRACTICAL POMOLOGISTS,

MAIDSTONE. Established 1796.

GRAPE VINES.—Well ripened, short-jointed  
canes of all the popular kinds, established in pots, extra  
strong for fruiting this year in pots, 6s. to 10s. 6d. each; for  
planting, 2s. 6d. to 5s. each; extra strong, 6s. to 10s. 6d.  
WM. PAUL & SON, Waltham Cross, Herts.

men who are rather prone to be somewhat behindhand in their operations, and to let the early worm very much alone. The majority, however, are animated with admirable zeal, and display commendable energy often in the face of great obstacles, to be well abreast of the work they are expected to do. These are the men who, as a rule, succeed the best, especially if with their zeal they possess knowledge; and they have certainly more right to consideration with the view to promotion or the filling of good positions than have those who strive less assiduously.

If the lives and habits of men who have won prominent, and to many, enviable positions in the gardening world could be made known, it would be seen that nine out of ten of such have forced their way upwards by their own merits—their devotion to their work, strenuous search for knowledge, persevering endeavour to excel in the multifarious duties of their calling, willingness to lend a hand wherever they could help in a needed object, and especially in habituating themselves to being up and in search of the worm early in the morning.

It would be seen, too, that they sought unceasingly not only for supremacy in the performance of material work, but had devoted more time to study than to sport in cultivating their intelligence and strengthening their reasoning powers—in acquiring theoretical as well as practical knowledge on various subjects, and thus preparing themselves—or, in other words, making themselves ready to undertake with credit anything likely to come within the wide domain of an accomplished gardener's varied duties. Most of the men of mark in gardening are not only those who have worked the hardest in their calling, doing that for which they were paid, but who have, with not less diligence, worked out their own education. They have not only brightened their spades by good and honest work, but brightened their minds. They have not been content to learn how and in what manner certain operations should be carried out, and no more, but have desired to know the reason for every particular action in each case, and not been satisfied till they have attained the object in view. Nor is this all. The very efforts they have made to that end, by research and by reading, have convinced them that to be able to take a distinct lead as gardeners they must possess much more than cultural ability. The great truth gradually dawns on them that they have to speak and to write in a manner which commands the approval of persons who are the best able to judge on matters of education and discretion.

How many young men who are being trained as gardeners are there per hundred who can, with credit to themselves and satisfaction to others, share in the art of public discussion on any subject connected with their calling? What is the percentage of probationers who can write a letter faultless in orthography and grammar, also couched in terms the most appropriate to the subject and occasion? What is the proportion to the total number, not only of those who can write an article on subjects with which they are well acquainted, that the public will have pleasure in reading in print, but who are seriously trying to do so? These are questions that our young men who hope to succeed the old in gardens which they have done so much to make famous should think about, and after thinking act—just as the writer of the note at the head of this column thought and acted when he was young.

Wholly by self-effort and devoid of "schooling," except of the most rudimentary kind, yet now, as the result of continued endeavour, not a mere hurried start and fainting by the way, he is in a position to hold his own as a worker in the garden, a debater at meetings, or as a writer in the press with most contemporary gardeners, and it is certain he could have filled a page of the *Journal of Horticulture* on the theme he has introduced if he had chosen to do so as easily as he penned his short note.

Once during his career he never thought he could do what he can now accomplish with so little effort, and this to his own

advantage in a form, and to an extent of which he never dreamt in bygone days. This is said to his credit. He prepared himself for a possible opportunity, and the opportunity came, and just because he had so prepared himself, not through any "influence" or personal favour, was he chosen to do what he does so well for others and for himself.

It was the work of patience—years of patient striving and of forethought—the same patience and forethought that form the keynote of his timely remarks. They embody sound, simple, common sense. Anyone can see that who comprehends the position. They suggest the value of forethought, imply the danger of precipitate action, indicate the value of calm consideration, yet engender hope. Let the best be made of them, for there is something in them, and then will be attained the object—the good object—for which they were, as is apparent, hurriedly penned. It is not often that a mere "dash off" provides a wider field for thought than does the note on "Patience."

### AZALEA INDICA.

AN occasional visit to gardens, exhibitions, or even other countries certainly does good, and hints thus acquired add considerably to the store of knowledge. I especially remember my visit to Belgium, relating to which I have not written anything, nevertheless I consider my expenses have been saved by information gained on the treatment of certain plants, and in the material used for potting the same.

Some readers may wonder what this has to do with *Azalea indica* and its varieties. It, however, has a good deal to do with them. Previous to the visit to which reference has been made, peat was regarded as being essential for the potting of these plants. This is strictly adhered to by a large number of cultivators at the present time, and where good peat is available nothing need be said against its use, but the plants can be grown equally as well without it. My visit to Belgium convinced me that peat is not necessary in the cultivation of *Azaleas*. When the plants were examined and their treatment carefully noted, it was palpable that peat was not indispensable any more than is the firm potting to which these plants are often in this country subjected.

The leaf mould used in Belgium is gathered from the woods where it has broken up by natural exposure. Before use it is passed through a kind of circular sieve of about half-inch mesh. This forms the staple of the composts used for almost all kinds of plants.

The plants are grown during the summer in beds about 4 feet wide, consisting of leaf mould, and there appears to be no attempt made to consolidate the material about the roots to any great extent. The younger stock are simply protected during the winter by lifting them and placing their roots in leaf mould under glass. From the time the stocks are raised until their arrival in this country they are never potted. There are many places in this country where leaf mould, equal to that used in Belgium, can be obtained, and since my visit to that country no peat has been used for the plants under my charge, and I find they grow more profusely than hitherto. Our compost consists of leaf mould and good fibry loam in equal proportions, with a liberal dash of coarse silver sand. Good drainage is necessary and firm potting.

The plants should be purchased early, potted at once, and placed on some moisture-holding base, such as ashes. They require careful watering at the roots and frequent syringing. It is a great mistake to water the plants directly after potting. The compost used should be in an intermediate state for moisture, and if the material on which the pots are placed is kept moist and the plants well syringed, little or no water will be needed for a week. The house in which the plants are grown should be kept somewhat close to induce growth. In about a fortnight under these conditions they become partially established, and their white silk-like roots are visible on the surface. These plants once started into root activity are in much better condition to produce good flowers with substance than those partially established before winter, and then exhausted by flowering profusely, as they are a long time before they recover and grow satisfactorily afterwards. It is the rough treatment to which these plants are subjected that has led to the preconceived idea that imported plants rarely thrive well.

We are not just now going to enter into the summer treatment of these plants. It will, therefore, suffice for the present to say they should be encouraged to make free growth, which must be kept clean. This ought to be accomplished without resorting too

much to insecticides or fumigation, as these plants have a great antipathy to the latter. If kept clean, instead of being practically leafless when introduced into the forcing house, they should be covered with dark green foliage, proving that the plants have been properly treated and are in good health. If kept in a dry atmosphere after the completion of growth they are almost certain to be attacked by thrips. They require a cool treatment, and should be fully exposed to sunshine and the syringe freely used. The Azalea does not like fire heat, although it is often subjected to it, but rather cool, airy treatment, until the use of artificial heat is necessary. If the temperature of the structure in which they are placed can be kept 33°, that is ample, and it is better to allow it even to go a few degrees lower than dry the atmosphere in which they are grown. These plants being hardy should not be subjected during the resting period to hothouse treatment. The nearer an intermediate state for moisture, throughout the year, the soil can be kept, the more luxuriantly they grow. In Belgium a system of sprinkling with water is practised, and the leaf soil in which they are grown is never saturated, or, on the other hand, allowed to become dry.

It is a well-known fact that Standen's manure has been for years recommended for these plants. Many growers, however, have condemned it on the ground that it will eventually kill the plants if persisted in, but this is by no means the case, if used with care and judgment. Old root-bound plants with a few puny leaves only nestling round their flower buds can with two applications be restored to health next season. They will produce dark foliage, and the character of the plants in a single season become completely changed. One or two applications annually are necessary for plants in the condition described.—WM. BARDNEY.

#### CYPRIPEDIUM MRS. FRED HARDY.

AMONGST the many handsome *Cypripediums* that have been introduced of late, the one depicted in the woodcut (fig. 18) must be accorded a prominent position. It was obtained from a cross between *C. superbians* and *C. bellatulum* and evidences of both parents are readily observable. The petals are very striking and of much substance, with purplish spots on an almost pure white ground. The lip is somewhat small, and is of a dull white flushed with rose colour, darkening towards the mouth. The dorsal sepal is white faintly tinged with green, and having rows of dark maroon spots. It was exhibited by Messrs. F. Sander & Co., St. Albans, at the Drill Hall, on January 15th, when it received an award of merit.

#### CALANTHE CULTURE.

I AM interested in, and should like to learn something new about growing *Calanthe Veitchi*. For some years I have been, as I thought, a successful grower of these plants, and have had spikes measuring 4 feet 6 inches and 4 feet 8 inches in length. This is considerably behind Mr. Friend's 5 feet 9 inch spikes (page 67), and I feel sure a few remarks from him as to his method of culture would be useful and interesting to many readers.—JOHN BATES, *Stone*.

#### PHALÆNOPSES AT HARNHAM CLIFFE.

SOME very fine *Phalænopses* are now flowering with Captain Greenwood at Harnham Cliffe near Salisbury, the strong flower spikes and vigorous growth of the plants betokening the care that is bestowed on their culture. The plants are growing in wood baskets suspended about 18 inches from the roof in a small lean-to pit. A fine piece of *P. Stuartiana* has four large leaves and a spike bearing twenty-four flowers; these are upwards of 2 inches across, the sepals and petals white, the former spotted about the base with brown; the lip is also white in ground colour, with many bright red spots on the side lobes. Several fine plants of *P. Schilleriana* deserve note, with spikes bearing from fifteen to twenty large, brightly coloured flowers, as also does a very fine form of *P. grandiflora* with blossoms of extra size and substance.

#### DENDROBIUM CRASSINODE BARBERIANUM.

Although closely allied to the well known *D. Wardianum*, this fine *Dendrobe* is distinct whether in or out of flower. The stems or pseudo-bulbs are, on the strongest plants, nearly a yard in length, and easily distinguishable by the much swollen nodes and depressions between. If these are well ripened they produce a great number of flowers, which are probably the most showy in the genus. It makes a fine display in wood baskets suspended from the roof, allowing the pseudo-bulbs to assume their natural pendent habit.

A strong moist heat is essential while growing, and during this period the plants must have an abundant supply of water at the roots, a light sunny position, and be frequently sprinkled with tepid water. Like all the deciduous species it requires little or no water after the leaves have fallen until showing signs of life early in the new year, a minimum temperature of 45° suiting it well during this period. Small plants of this *Orchid* are

FIG. 18.—CYPRIPEDIUM MRS. FRED HARDY.

apt to die off at the base of the pseudo-bulbs, a habit they generally lose after attaining a large size. Although to a certain extent this is a natural defect in the species, it may occasionally be caused by injudicious watering when the young growths are pushing.

At this stage a certain amount of water is needed, as the flowers are a great drain on the resources of the plants, but this is in all cases better applied by immersing the plants in water just deep enough to cover the roots without wetting the young shoots. As the season advances and the sunlight increases this caution is unnecessary, but care must still be taken that the water does not collect in the apex of the young growths.

#### ODONTOGLOSSUM LUTEO-PURPUREUM.

This well known and very variable species is much stronger growing than *O. crispum*, which it somewhat resembles in habit. Hardly two plants have flowers exactly alike, and although varieties innumerable have been named and described, not half of these are

entitled to rank as distinct. A good typical flower would be  $3\frac{1}{2}$  inches to 4 inches across. The sepals and petals are yellow, streaked and blotched with brown and purple, the latter being in many forms deeply serrated at the margin. The lip is white or yellow with blotches and spots of brown. This is sometimes also deeply fringed.

Being a native of New Grenada and found at a great elevation, *O. luteo-purpureum* must be grown in the cool house, and the treatment advised recently for *O. crispum* will suit it admirably. This Orchid is supposed to be one of the parents of many fine natural hybrids, as for instance *O. lyroglossum*, *O. mulus*, and the beautiful *O. Wilckeanum*.

#### ONCIDIUM SPHACELATUM.

Although this species cannot compare with such as *O. Marshallianum* and others of that section for size or brilliance of colouring, its free-blooming qualities, combined with the fact of its being so easily grown, will recommend it to many. The spikes are frequently 6 feet in length, and the small side branches of these are well adapted for cutting for various purposes, and especially for buttonholes and sprays. The flowers are yellow, the sepals and petals transversely barred with chocolate brown. The spikes are a long time in opening, as they usually grow to the full length before branching. Should they be wanted earlier than they are likely to grow naturally, they may be pinched when about 30 inches high to hasten their opening. This of course reduces the number of flowers produced, but it prolongs the flowering season by several weeks if some are left to open naturally.

*O. sphacelatum* is one of the freest rooting Orchids in existence, and for this reason seldom gets out of health. The plants may be potted in three parts of sphagnum moss to one of charcoal; the best time for this operation being directly after flowering. While growing it requires the heat of the *Cattleya* house with a copious supply of moisture both at the roots and in the atmosphere; but after the pseudo-bulbs are fully matured it should be rested by withholding water but keeping the plants in the same house. As soon as the spikes can be seen in the axils of the leaves the plants must be again watered, or shrivelling of the pseudo-bulbs will be the result. *O. sphacelatum* is a native of Mexico and other parts of Central America.

#### DENDROBIUM AGGREGATUM.

This pretty little species is not so much grown as formerly, in fact it is not often met with. The pseudo-bulbs are clustered about 2 inches high, angular, and becoming furrowed with age; each bears a single leaf. The short, arching, many-flowered racemes are produced from the side of the pseudo-bulbs near the top during the present month. The flowers are of two shades of yellow, the lip being darker than the sepals and petals; they last about a fortnight in good condition.

A peculiarity of this species is the short time the pseudo-bulbs are growing, usually not more than five or six weeks. It succeeds well as a block plant if given a little sphagnum about the roots when established, or it may be grown in small shallow pans in peat and moss suspended near the roof. In either case it must not suffer for want of water while growing, and must have plenty of heat and moisture during this period. In winter it does best in the *Cattleya* house, and should not be dried sufficiently to cause shrivelling of the pseudo-bulbs.

The best plants of this Orchid I have seen were grown on bare blocks of teak wood with one end in a specially made pot, containing 2 or 3 inches of water. These were kept filled during the summer and empty in winter. This very desirable little species is a native of Northern India, and first flowered in this country in 1834.—H. R. R.

### THE MULBERRY.

The Mulberry is generally considered a biblical tree, but the original term *baca* seems to have puzzled the translators, and scholars agree that it is hard to say what tree is meant by the word rendered Mulberry tree. Parkhurst gives it as his opinion that *baca* means a kind of large shrub, from which is distilled an odoriferous gum; and, singularly, the Arabs have a shrub corresponding to the description which they call *baca*. Hasselquist states that the Mulberry scarcely ever grows in Judæa, very little in Galilee, though abounding in Syria and in the mountains of Lebanon.

Ovid's "Metamorphoses" upsets our evolutionary notions as regards the origin of species. In it appears the story of Pyramus and Thisbe, and reads something like this:—Pyramus, who lived in Babylon, became enamoured of Thisbe, a very beautiful virgin of that city. The flame was mutual, but their parents forbade their

marriage, so that the lovers interchanged their sentiments through an aperture in a wall which separated their houses. They agreed to meet at the tomb of Ninus, which was overshadowed by a white Mulberry tree, and without the walls of Babylon. Thisbe was first there, but the unlooked-for arrival of a lioness frightened her away, and as she fled she dropped her veil, which the lioness found and left covered with blood, having immediately before killed an ox. Meanwhile Pyramus appears on the scene, and having found Thisbe's blood-besmeared robe, concluded "she was no more," he took his own life. Thisbe, returning soon afterwards and finding the body of her lover, she fell upon the sword with which Pyramus had destroyed himself. The Mulberry tree was stained with the blood of the swains, and ever afterwards bore fruit of that colour. Shakespeare caricatures this story in "Midsummer Night's Dream."

The white Mulberry (*Morus alba*) is the most interesting on account of the leaves being used for food by silkworms. It is a native of China, and the Chinese claim the art of rearing silkworms and manufacturing silk stuffs from a remote period. This art was introduced from China into India and Persia, and though long practised, there silk was not known to the Greeks at the time of Alexander, or to the Romans until the end of the republic, and for many ages bore an enormous price at Rome. At the middle of the sixth century, during the reign of Justinian, two monks arrived at Constantinople from India, bringing with them the white Mulberry and the eggs of the silkworm. From Constantinople the white Mulberry was introduced into Greece, and in or about the year 1130 it was introduced into Sicily and Italy. About forty years later the white Mulberry was brought into France. Some records state that the white Mulberry was not brought into Italy till 1440, nor into France till 1480, and it is stated to have been little known in that country till 1564. The first Mulberry tree that was planted in France was living in 1802.

The date of the introduction of the white Mulberry into England is given at 1596, or forty-eight years later than that of the black Mulberry (*Morus nigra*). If so, there is no wonder that silkworm farming never flourished in this country, for the leaves of the white are a much better food for the "worms," and a superior quality of silk is produced than when the black Mulberry is the food-plant. Early in the seventeenth century James I. made an attempt at Mulberry tree and silk culture, and got a French nurseryman, Sieur de la Forest, to travel the eastern and midland counties of England, and in that way disposed of 100,000 Mulberry trees in 1609. Mulberry gardens were common in the neighbourhood of London at the latter part of the sixteenth and beginning of the seventeenth centuries, when it is recorded that "either from the climate, or the prejudices of the people, the growth of silk never prospered."

The black Mulberry (*Morus nigra*) is said to be a native of Persia, and has been cultivated in Europe from a very remote period. The Romans preferred its produce to every foreign fruit. The black Mulberry, according to Loudon, was introduced from Italy into England in 1548, and the first trees are stated to have been planted in the gardens at Syon House. Shakespeare's Mulberry tree is supposed to have been planted in 1609 in his garden at New Place, Stratford-on-Avon. It was cut down in 1750. Other notable Mulberry trees are Milton's in the gardens of Christ's Church College, Cambridge; two in the gardens of Pembroke College, Oxford, which, it is supposed, were planted at the foundation of the College in 1624. Stanmore Priory gardens were also famed for an old Mulberry tree. But the most antique English Mulberry tree was, and may be now, that in the old abbey gardens at Canterbury, the original stem being prostrate, but there springs from it several trunks of great size and age.

Many other old Mulberry trees in and around London are, like Thisbe, "no more," for the builder spares nothing old, and it is similar in and about most other cities and towns. Even in the country few old Mulberry trees are left to link the past with the present, which indicates the small esteem in which this very handsome foliage tree was held for ornamental and useful purposes. Nevertheless, there are several Mulberry trees in the southern parts of the country that have attained large proportions and bear enormous crops of fruit, which is greedily devoured by blackbirds, these preferring Mulberries, like the Romans, to any foreign fruit of its season.

Nearly all the Mulberry trees I have seen of any age and size worth mention were of the black variety, or rather species. This may or may not indicate that the white Mulberry requires a warmer climate. It certainly suggests its being less esteemed than the black as a fruit-bearing tree, therefore it was but little planted. It also produces fruit less freely than the black Mulberry, and on that account it would be in less request. Yet the white Mulberry forms a handsome standard, being quite hardy in warm situations

and on gravelly loams incumbent on a well-drained substratum. On deep and moist loam it grows more freely, but the growths, especially late, are liable to be damaged by severe frosts. The leaves of the hardily grown tree, that on gravelly well-drained soil, are far better food for silkworms—that is, the worms are healthier, have sturdier bodies, better coloured parts, and produce finer cocoons of the substance called silk, than caterpillars fed on the leaves of the white Mulberry tree growing in deep loam and a somewhat damp situation. This is a point worth knowing in connection with vegetable pathology, and it is still further worth recording that the worms prefer the sappier leaves to the drier foliage as food. Such phenomenon are little noted, but the importance of such items are far reaching and of consequence to cultivators.

The black Mulberry is not only the hardiest in deep somewhat moist soil, but really requires such, and a favoured situation to produce full crops of the finest fruit. It succeeds admirably in Huntingdonshire on the oolite—a light gravelly loam, 2 or 3 feet deep, with a gravelly or sandy substratum and water therein, often within 6 feet of the surface. The black Mulberry also thrives on the old red sandstone, as in Herefordshire and Worcestershire's fruit-growing, cider, and perry-making districts. Similar remarks apply to Gloucestershire, Somersetshire, and Devonshire. It also thrives on the new red sandstone, some fine trees existing at one time in the environs of York, also within that city. This is about its northern limit as a free and certain fruit-bearing tree.

On the calcario-silicious loams, incumbent on chalk, in Hertfordshire, it produces enormous crops of fruit. In the neighbourhood of London, on the free loams overlying the London clay, it succeeds and ripens its fruit well as a standard. Similar remarks apply to all the more favourable parts of the midland counties and to Wales. In Kent and the southern counties the black Mulberry thrives in all but elevated and cold situations and soils. But in the north of England and in Scotland a warm aspect and a wall is necessary to secure satisfactory crops of fruit. In certain favoured places in these parts it, however, succeeds fairly well as a standard, and is well worth growing as a shrubbery or lawn tree. It is the latest of all trees in putting forth its ample and distinct foliage; and it parts with them early in autumn, not in a littery mess prolonged over many weeks, but in a hearty manner quickly, and is as distinct in wood as in leaf from other trees.

The black Mulberry, commonly called the "Large Black," can be procured of all the principal nurserymen, especially those making a speciality of fruit trees, in the form of pyramids for gardens, dwarf fan-trained for walls, and standards for orchards, lawns, or select spots in parks. Trees of bearing size are sometimes comatable. These are of course more costly than younger ones, but they are most profitable from a fruit-growing point of view, as young trees often continue sterile for years. Once the trees commence bearing they continue fertile. The older the trees, as a rule, the finer and higher flavoured the fruit.

In the matter of pruning, standard trees need little after the crown is formed. Of course, an excessive number of limbs is undesirable; this should be guarded against by timely attention to thinning the growths. The branches will only need shortening to secure an evenly balanced crown, which is important, as the Mulberry, left to itself in its early years, pushes a few growths that take the lead and become limbs, and these become so ponderous in time that they cannot support their own weight, hence fall without apparent cause as regards wind and weather. The Mulberry, however, is more apt to be wrecked by wind than perhaps any other tree; therefore it should be carefully trained in its early years, and be given a sheltered situation.

Pyramids can be treated similarly to Red Currants, for though the fruit is produced from young shoots as well as spurs they seem to acquire the habit of bearing on spurs or short stubby shoots, and a mere shortening and thinning of the growths in summer, with the needful adjustment of them when the leaves commence falling, is all the pruning required. By cutting out overgrown spurs, or shortening so as to keep the trees fairly open and compact, pyramid Mulberry trees are singularly tractable. The chief point is to induce them to bear, which is, perhaps, best effected by lifting, firm and not over-rich soil.

Fan-trained trees on walls may be treated similarly to Plums, both of which are better for reducing the old wood frequently and encouraging young and sturdy spurs. It must not, however, be overdone, or sappy, irrepressible shoots will be the result, and it is then farewell to health and good-bye fertility. This may, to some extent, be counteracted by lifting and root-pruning; but the better way is to provide a firm soil and so prune as to maintain health and fruitfulness.

In cold localities the Mulberry is best grown under glass. It succeeds admirably in pots, producing much finer and better flavoured fruit than outdoor trees, except in the case of highly

favouring sites. The trees may be grown in either pyramid or standard form; the latter is best, as the heads are nearer the light, and the more they have of that the better.

Mulberries may also be forced. Mr. T. A. Knight was the first to show the way in this country. Established trees in pots, started with Vines in January, ripen their fruit about the same time—that is, in June. He says, "A tree . . . when fully loaded with fruit presents at least as agreeable an object to the eye as many plants which are cultivated for ornament only." Thus, Mulberries may be had by forcing, culture in orchard houses and outdoors from June to October or November; but the fruit does not keep long, requiring to be used without delay, for an apparently white fungus fastens on it soon after it is gathered. The fruit, however, ripens in succession, maintaining a supply for a month or more.

The fruit falls when ripe, and on grass plats there is little needed for its protection. But it is this bruising that gives the fungus such a ready grip of the fruit as to cause it to become white with mould in a few hours. On bare ground, which is better, perhaps, for the trees bearing after that habit is established, as manure, both in solid and liquid form, can be readily supplied as the crop and season require; a clean cloth must be spread on the ground to receive the fruit as it falls, but it is better to use small mesh netting suspended a few inches from the ground to prevent the fruit being blemished.

The tree, as before stated, is liable, as a standard, to accidents from high winds, and to lose limbs from sheer weight of leaves and fruit. Too much care cannot be bestowed on shaping the crown, so as to balance its boughs as evenly as possible. Timely attention must also be given to propping up overweighted limbs, but these are very unsightly and intolerable on lawns. It is best, therefore, to use chains. These should be attached before an accident occurs, taking the chain round the main boughs, and so that one cannot become detached without bringing away in an upward direction its opposite, which is just the thing that does not happen, therefore neither come to grief, as the one helps the other. There is no need to trouble about the chain hurting the tree, for the more it is allowed to grow into the wood the sturdier the tree becomes, and the more and finer fruit it produces. As the tree advances in growth more chain support must be provided, each time higher up the limbs, and the chains being galvanised there will be no wreckage; but as the years roll round, and generations come and go, the tree will improve, gladdening by its bounteous produce and associations.

The choicest and ripest "berries" are esteemed by some for dessert. Only the blackest fruit answer for table use, as the semi-ripe are too sharp in flavour for most palates. It should be served on its own leaves, and has a pleasing effect at dessert, as the fruit contrasts well with the yellowish leaves. The black Mulberry makes first-rate puddings, excellent pies, high-class jam, and capital syrup. The fruit is esteemed very wholesome by the medical profession. Its juice, diluted with water, is sometimes used as a beverage in fevers, from its cooling and laxative properties. The juice is used to give a dark tinge and a pleasant vinous flavour to liquors and confections. When properly fermented and prepared the fruit yields a pleasant vinous liquor, known under the name of Mulberry wine. This, however, does not keep long, but that depends upon the manufacture and the amount of spirit added. In the cider counties Mulberries are sometimes mixed with Apples to form a beverage known as Mulberry cider.

The wood of the tree is yellow, tolerably hard, and may be applied to a variety of purposes in turning and carving. It is, however, necessary to steep it in water before it is worked, in order to remove the tough and fibrous bark, which is capable of being converted into strong cordage, ropes, and brown paper. Finally, the bark of the root has an acrid, bitter taste, and is a powerful cathartic—hence it has been successfully used as a vermifuge in doses of a scruple in powder.—G. ABBEY.

## THE FLORISTS' TULIP.

[By JAMES W. BENTLEY, Hon. Secretary to the Royal National Tulip Society.]

### CHAPTER IV.

(Continued from page 557.)

WHEN the petals are falling and the beauty of the bloom is over all the canvas and calico screens should be removed, so that light and air can have free access to the plants. The glass-lights should, however, be allowed to remain over the beds until the bulbs are taken up. Most growers, as soon as the flowers fade, remove all protective appliances and allow the beds to have all the weather that comes, under the idea that by so doing the bulbs will be strengthened and improved. In my opinion there is no good

reason for supposing that any benefit accrues at all, for the bulbs are matured and have attained to their maximum size as soon as the plants go out of bloom; consequently the exposure is at the best useless, and if long-continued rains fall positively injurious. Such rains soak the beds, delay the operation of lifting the bulbs, and probably cause the outer skins to be cracked and decayed.

All the old writers are unanimous on the necessity of removing all seed pods, except those that have been artificially cross-fertilised by the grower, when they begin to swell, lest their growing should weaken the bulbs. Mr. Horner, I believe, was the first to point out that this idea is quite a mistaken one, as the new bulb that has been growing as the plant grew has nothing whatever to do with the nourishing of the seed pod, that office being performed by the old roots. This can be proved by digging carefully down to the roots of a seed-bearing plant, when it will be found that the bulb can easily be detached and taken away without disturbing either roots or stem, which will go on growing and ripening the seed without feeling the removal of the bulb. It is, in reality, quite immaterial whether the seed pods be removed or not as far as the bulbs are concerned; but if they are suffered to remain the plants keep alive longer, and have the labour of producing something that is not required.

The bulbs are ready for being taken up when the leaves become pale and yellowish, and the stem will bend double without snapping off; this occurs from three to four weeks after the bloom is over, which is generally at the latter part of June. It is far better to lift the bulbs at this time than to wait until later, when the leaves and stems have become dry and withered. If the taking up be done soon, the bulbs and offsets being at that time pale in colour, are readily seen amongst the darker soil as they are lifted by the hand-fork or trowel, and the stem still firmly attached to the roots and bulbs is of much assistance, for being grasped in the left hand while the fork is being carefully forced underneath the roots by the right, the whole plant with bulbs and offshoots attached, is by its means easily lifted away. The earth is then shaken from the roots, the stem broken or cut off just above the top of the bulb, leaving an inch or two adhering, and the bulb placed in its compartment in the drawer or box. Care must be taken not to tear away the old roots and stems at this time, as serious injuries are sure to ensue to the tender bulbs so treated. If the lifting be deferred until late the outer skins of the bulbs and offsets will be found to have become much darker in shade, and are so near the colour of the soil that finding them is much more difficult than at an earlier period, and from this cause probably some of the smaller ones will be overlooked altogether, and the stems, being decayed, break away at a touch, and are of no assistance. The outer skins of bulbs that have been taken up early are perfect and without cracks; they clothe the bulbs, preventing loss of moisture by evaporation, whilst those of bulbs lifted too late are always cracked, and in some cases almost entirely wanting.

Cloudy days are best for taking up, both for the bulbs and the operator; if, perforce, hot sunny weather has to be put up with it is wise to cover the bulbs as they are placed in their compartments with something cool, such as Rhubarb leaves, and if the glass has been kept over the beds that may be covered with shading also.

The bulbs, being lifted and placed in their boxes or drawers, should be allowed to dry in a moderately warm place in which currents of fresh air freely circulate. The boxes must not be piled one on another, but be spread out in such a way that the air has free access to every bulb. The rays of the sun must not be allowed to fall directly on the bulbs whilst they are drying, or indeed at any other time, or great mischief will ensue. A splendid collection was once almost totally destroyed by sun heat. The bulbs were laid out to dry in what were called cold frames. It was the summer of 1893; one day early in July was phenomenally hot, the cold frames became close ovens, and nine-tenths of the bulbs were completely destroyed, although the frames had been shaded to some extent, and air could gain admittance. When the bulbs are completely dry the drawers containing them may be returned to the cabinet, when no further attention is needed until they are cleaned previous to planting again.

Having now completed the cycle of the year I have arrived again at my starting point, with the bulbs at rest previous to planting, and have little further to add on the subject of culture. The methods of procedure recommended are such as I use myself and have every reason to be satisfied with, and although I do not pretend that what I have written on this subject of culture will make the reader a full-blown Tulip grower, still I think I may claim that it will help the earnest inquirer along in the right direction, and if carefully followed save much trouble and disappointment in his early efforts.

It is much to be regretted that no one has as yet thought the Tulip worthy of study from a scientific standpoint. A series of careful chemical analyses of bulbs and plants in various conditions of health and growth would be most useful as tending to a more thorough understanding of the character and proportions of the various chemical elements required in the soil for the highest development of the bulbs and flowers. At the same time, considering the delicate balance that has to be attained and kept in the matter of marking, I do not hope for such good results from chemical research as would be obtained in the case of Turnips, say, where the main consideration is an increase in the size of the root. Still, the analyses referred to could not fail to be of value.

I have known chemical manures such as nitrate of soda and sulphate of ammonia used for Tulips, but only in limited amounts, and so rarely that no reliable statement of their effects can be given. I certainly do not advise their use in the present state of the chemical knowledge of the subject. There is a good opening for an enthusiastic grower of a scientific turn of mind to experiment with various chemical manures and report progress from time to time to his brother growers. He would deserve their cordial sympathy and gratitude, and would no doubt readily obtain them. Some self-sacrifice would have to be shown, as his stock of bulbs would be a continually vanishing quantity, and all would have to pay an annual toll of bulbs for the good of the cause.

(To be continued.)

#### FORCING NARCISSI.

NOTHING is more detrimental to the forcing of *Narcissus* than trying to hurry them in the early stages of growth. By the time the plants have made  $1\frac{1}{2}$  inch of growth under ashes outside they should be removed to cold frames until they have turned green and display signs of growing. Up to this stage, after removing them from the ashes, they appear to be at a standstill, but they are making roots freely.

Once signs of movement are visible in the cold frames, or if severe frost compel their removal, they should be placed in a cool house where frost can be excluded. They must then be removed to a temperature  $5^{\circ}$  higher—say  $45^{\circ}$  to  $50^{\circ}$ —for ten days or a fortnight, where the atmosphere is fairly moist and the plants can be well syringed. Under these conditions they quickly display signs of growth, and they would flourish in a temperature of  $50^{\circ}$  to  $60^{\circ}$ , or even more in their last stages if wanted out as early as possible. We have been forcing the old common Daffodil in a temperature of  $65^{\circ}$  to  $70^{\circ}$ . But they should never be subjected to this heat until the flower buds are well developed. Strong heat is only advised in cases of real need,  $60^{\circ}$  being ample.

It is very easy to overforce *Narcissi* in the early stages of their growth. More bulbs of various kinds are ruined by injudicious forcing than from any other cause. Many growers err in giving liquid manure when the plants have practically no growth to absorb these soluble foods. About half an inch of decayed manure at the bottom of the boxes is the course we pursue, and never attempt at feeding afterwards, and we rarely water beyond syringing until the plants are growing vigorously.—O. M.

#### MELON BEAUTY OF SION.

I HAVE pleasure in forwarding a photograph of the above Melon grown here this summer. There were two plants grown side by side in a box 4 feet in length, 2 feet 6 inches in width, and 1 foot 6 inches in depth, half the latter being drainage, and the remaining portion good fresh maiden loam, to which was added a little clay and wood ash. One of these two plants had its point taken out as soon as it reached the trellis, taking three shoots on the cordon principle.

The reason this plan was adopted was to secure four or more flowers, if possible, ready for fertilisation on the same day (a difficulty often experienced on the single cordon system). This plant ripened its fruit at the same time as the plant which was allowed to grow unstopped, owing to the fact that the lateral growth in the latter case was more than that of the other. This mode of procedure seems to be effectual, there being twenty fruits set on these two plants, of which eighteen were allowed to remain, and were very handsome though not large, weighing 36 lbs., or an average of 2 lbs. each. These plants were grown with their foliage over a tank of water, which would doubtless have been much against them had the weather been very dull during the period of flowering.

It would be interesting to know from others who may have grown this variety if it is susceptible of cracking. We have grown all our Melons this year in boxes of wood and slate with excellent results, having proved that good crops of Melons may be obtained from a much less amount of soil and bottom heat than was formerly supposed. It is needless to add that careful and diligent attention must be given to watering and feeding when the roots are confined. Through this I feel satisfied that the fear and risk of canker is greatly reduced.—J. SNELL, *Grimston Gardens*.

[The photograph sent represents a crop such as could only have been produced by thorough cultivation, but the picture was not sharp enough to permit of successful reproduction.]

**EVENTS OF THE WEEK.**—Events of horticultural interest have not been very numerous in the metropolis during the past few weeks, but there will soon be an awakening. On Friday next the annual meeting of the Royal Gardeners' Orphan Fund will be held at the Cannon Street Hotel. The Committees of the Royal Horticultural Society meet on Tuesday, 12th inst., at the Drill Hall, and the general meeting of the Society will take place on the same day at 3 P.M., in the Society's rooms at 117, Victoria Street.

— **THE WEATHER IN LONDON.**—Pronounced wintry weather has prevailed in the metropolitan area during the past week. Snow has fallen on several days, while the frost has been very severe. This morning (Wednesday) the thermometer in Fleet Street registered 10° of frost at one o'clock, and in the northern suburbs at eight o'clock there were 15°, while at the time of going to press in the afternoon our thermometer showed 6° of frost.

— **WEATHER IN THE NORTH.**—Frosts of from 9° to 17° continued last week up to Friday, when a partial thaw took place in the afternoon. This continued throughout Saturday and Sunday, with occasional sleety showers; but little effect was made on the snow, even on the lower grounds. On the morning of Monday 5° of frost, and on that of Tuesday 6° were registered, and Winter seems again to be tightening his hold.—B. D., *S. Perthshire*.

— **THE TOMATO—FRUIT OR VEGETABLE.**—I have read with interest correspondence on this subject. It would be a good thing if the matter was decided one way or the other. At the Plymouth Chrysanthemum show last November a local exhibitor had in his six dishes of fruit one of Tomatoes, also one of Nuts, and was adjudged the first prize, though he had no competitor in the above class. It would be interesting to learn what other exhibitors have to say on this point. I consider the Tomato should be classed as a vegetable.—JAMES MAYNE, *Bicton*.

— **BROWN LINNETS.**—The rapidity in which a flock of these birds will strip the foliage from a bed of green vegetables is simply amazing. During severe weather when food is scarce they leave their moorland haunts in flocks, and woe unto a bed of spring Cabbages that happens to lie in their path. In a few hours, if unnoticed, not a leaf will be left whole, and so tame do they become by hunger, that if a gun is fired in their midst many of them will not rise, and in case of so doing will be back again to their plunder almost immediately.—G.

— **THE GARDENERS' ROYAL BENEVOLENT AND ROYAL ORPHANAGE INSTITUTIONS.**—The gardeners of Worcestershire are bestirring themselves in a novel and praiseworthy manner on behalf of the above excellent institutions. A thoroughly representative and well attended meeting of the gardeners and nurserymen of the county was held at Worcester on Saturday last. The claims and advantages of these charities were pointed out and discussed, also the fact that these Institutions paid in the shape of pensions considerably more money than was subscribed annually in the county taken by itself. It was shown also that the sum of 6d. per week contributed by any person constituted full membership to both societies—viz., 1 guinea per annum to the Benevolent, and 5s. annually to the Orphanage Fund, with the result that many subscribers' names were promised forthwith. Furthermore, the meeting resolved itself into a general committee, undertaking to canvass every individual gardener and nurseryman in the county. Directories were produced and a roll call instituted, each person present undertaking to bring personal influence and acquaintanceship to bear on those residing in his district. It was also proposed and carried that each individual gardener should respectfully call the attention of his employer and other patrons of horticulture to the movement. Progress to be reported that day month. General details were completed, and great enthusiasm and unanimity prevailed. The meeting separated after expressing the wish to merit the ejaculation, "Well done, Worcestershire!" Will other counties do likewise?—W. C. [This county co-operation on behalf of our gardening charities is a splendid idea, and the action taken is highly commendatory.]

— **MR. S. DEADMAN**, for many years head gardener to the late J. Whitborne, Esq., J.P., Gorway, Teignmouth, S. Devon, has been appointed instructor on horticulture at the South-Eastern Agricultural College, Wye, Ashford, Kent.

— **CURTIS, SANFORD & Co., LIMITED.**—We have received the prospectus of this company, which has been formed for the purpose of acquiring and further developing the well-known business of Rose growers, nurserymen, and florists of Messrs. Curtis, Sanford & Co. of the Devon Rosery, Torquay (established by the late Mr. Henry Curtis in 1844), and the business of fruit and vegetable growers established by the South Devon Fruit Farm Syndicate at Cockington, near Torquay.

— **ST. PAUL'S DAY.**—I am rather puzzled by the article on page 102, of January 31st. I had always understood that Candlemas Day (February 2nd) was the weather criterion day, and the Latin seems to confirm this.

"Si sol splendescat Mariâ purificante,  
Major erit glacies post festum quam fuit ante."

If Candlemas Day be fair and bright,  
Winter will have another fight;  
If Candlemas Day be cloud and rain,  
Winter is gone and will not come again.

The two days are so near that probably the same has been predicted of both of them.—A. C.

— **PRESENTATION TO MR. R. FRISBY.**—A meeting of the members of the Preston and Fulwood Horticultural Society was held recently with the object of presenting a silver-mounted ebony walking stick and tobacco pipe and pouch to Mr. R. Frisby, gardener at Worden Hall, Leyland, who is about to leave the neighbourhood owing to the death of his employer. There was a good attendance, and the Mayor (Councillor W. H. Woods), in making the presentation, said Mr. Frisby had done much to bring about the success of the Society, and no doubt he would be very sorry to leave them. Mr. Frisby briefly responded and wished the Society every success.

— **THE HESSLE AND DISTRICT GARDENERS' AND AMATEURS MUTUAL IMPROVEMENT SOCIETY.**—The above Society held their fortnightly meeting in the Parish Schoolroom on Tuesday, January 29th, when Mr. Thurston, of Hesslewood Gardens, read a very instructive essay on the cultivation of the Carnation. The essayist remarked that the Carnation succeeded best in a light porous soil; he also mentioned the different pests that the Carnation is subject to the attacks of and the best remedies for their eradication. A hearty vote of thanks to the Chairman, Mr. J. P. Leadbetter of Tranby Croft, and the essayist brought to a close a very pleasant evening.—S. R. C.

— **DEATH OF MR. M. T. BROOMHEAD.**—Another blank has been made in the office staff at 171, Fleet Street, by the lamented death of the above gentleman. The older among our readers will remember that a few pages of this Journal were devoted to poultry some years ago. These did not suffice for the bird fanciers, and to meet their wishes the first penny weekly paper devoted to their interests was established and entitled "Poultry." It speedily became a pronounced success. Of this paper Mr. Broomhead was the editor until his death last Thursday, but he had not been able to attend the office for some months, his son, Mr. F. Broomhead, ably discharging his father's duty there. By the zeal, ability, and industry of our departed friend "Poultry" became the influential and popular organ it is to-day. An eloquent tribute to the memory of Mr. Broomhead is recorded in the following words by the staff artist of the paper, Mr. Harrison Weir:—"Another light has gone out, another good, true, and honest man has gone to his rest, who when with us was deeply, sincerely, and deservedly respected, and worthily regarded, and so thus it is that his loss cuts the more keenly into our sorrowing hearts. It seems but the other day, though it is years, so quickly flies the time, yes! but the other day that he, bright, hearty, strong, full of life, vigour, and hope, accepted the editorship of the then almost new paper, "Poultry," and that with the full intention of making it successful. This he has done, and has left it to his editorial credit with a large and increasing circulation and a world-wide reputation as being conducted with full ability, and on honest, straight, and truthful lines. This alone is, and will be, a lasting and honourable testimony of the uprightness of the man, and no mean monument to his memory." We can only add to these well-merited words that we mourn the loss of a faithful friend, a good, true, and genuine man, and share largely in the deep and widespread sympathy that is felt for his widow and family in their great bereavement. Mr. Broomhead's death was brought about by a chill following an attack of influenza. He was only forty-eight years of age.

— THE annual general meeting of the ROYAL GARDENERS' ORPHAN FUND will be held at the Cannon Street Hotel on Friday, February 8th, at two o'clock, P.M. It has been arranged (after the annual meeting at the Cannon Street Hotel on Friday, February 8th) for the Committee to have a friendly dinner together at Anderton's Hotel, Fleet Street. Mr. John Harrison, of Leicester, will preside.

— PRESENTATION.—Mr. Hollingworth, who for the last five years has held the position of general foreman at Alton Towers, at the time of his retirement a few weeks ago was presented with a handsome case, containing a set of gold cuff-links and studs, by the young gardeners employed in the establishment, as a token of the good fellowship which had existed during the period he had been amongst them, prior to his obtaining a position on the office staff of the *Journal of Horticulture*.—J. C.

— THORNBURY HORTICULTURAL SOCIETY.—A meeting of the members of this Society took place on January 28th. Mr. George Nixon presided, and there were also present the Rev. G. B. Browne (Iron Acton), the Rev. H. R. Wilkins (Oldbury-upon-Severn), Messrs. H. P. Thurston, C. Fry, C. Pitcher, W. O. Chambers, J. Bruton, F. Williams, and E. J. Underhill, Secretary. The accounts, which showed a balance in the bank of £37 15s., were examined and approved, and it was decided to hold the next annual exhibition in August.

— THE MIDLAND CARNATION AND PICOTEE SOCIETY.—The fourth annual report of this Society, together with the schedule of prizes and rules for the present is to hand, and contains much valuable information. Financially the Society is in good condition, the balance-sheet showing cash in hand of upwards of £46, exclusive of unpaid subscriptions and other sums, estimated to amount to about £12 10s. The prizes offered for competition at the show on July 31st and August 1st are liberal, and should be provocative of good exhibits. The lists of the best varieties in the various sections cannot fail to be of the greatest utility, and the Committee is to be congratulated on their production. We wish the Society continued success, and trust that Mr. Wm. Dean may be spared many more years to hold the hon. secretaryship, than which none other is better able to fill.

— READING HORTICULTURAL SOCIETY.—The thirty-eighth annual meeting of this Society was held, by permission of Messrs. Sutton & Sons, at the Abbey Hall. Mr. J. F. Ferguson presided. Mr. W. L. Walker read the annual report, which stated that the result of the year's work was satisfactory generally, and would justify the holding of two exhibitions during the current year. It would be remembered that the 1893 report stated "That it was in contemplation to hold a bulb or Rose show in 1895," and it had now been settled to hold an exhibition of Hyacinths and other flowers in the Queen's Hall on March 19th next, and should it prove a success a spring and autumn show will probably be held each year. Messrs. Sutton & Sons, with their usual liberality, have again provided the whole of the prizes in the fruit division of the schedule for the coming August show. The statement of accounts showed that the sum of £122 was carried forward as balance in hand. A discussion ensued as to the advisability of amalgamating the horticultural and Chrysanthemum societies, but no definite action was taken. Mr. W. L. Walker was re-elected Hon. Secretary.

— WAKEFIELD PAXTON SOCIETY.—At the usual weekly meeting of the members of the Paxton Society, Saturday evening, Jan. 26th, Mr. Brown of the Outwood Cemetery presided, and Mr. B. Whiteley occupied the vice-chair. There was a good attendance of Paxtonians, most of whom had come direct from the Town Hall, where they had been listening to the first of a series of lectures on horticulture by Dr. Clark of the Yorkshire College, Leeds. The essayist was Mr. George Hudson, head gardener at Woolley Park, and his subject was "The Cultivation of Flowering Plants." Mr. Hudson illustrated a thoroughly practical essay by a grand collection of flowers of many varieties which were greatly admired. He remarked at the outset that his subject covered a wide field, and could not be exhausted in one paper, and he intimated that his essay was intended for amateur gardeners, who deserved every encouragement. Wherever they saw a small greenhouse in connection with a little house they might generally depend on finding "love at home." Mr. Hudson then proceeded to mention a number of flowering plants which he recommended amateurs to grow, prefacing his remarks on his variety by impressing upon his hearers not to keep their greenhouses too warm, not to neglect ventilation, not to "coddle" their plants, and not to crowd them. A vote of thanks to the essayist closed the meeting.

— THE WEATHER IN HERTS.—The weather during the past month has been very wintry in character, rain, frost, and snow being very abundant. On the 19th, 0.91 inch of rainfall was registered, and on the 27th as much as 23° of frost was experienced. I have registered 2.29 inches of rainfall against 2.00 during January, 1894.—E. WALLIS, *The Gardens, Hamels Park, Buntingford*.

— THE WEATHER IN DERBYSHIRE.—We are a good foot deep in snow, with tremendous drifts; some of the roads are not cut through yet for traffic; our rural postman had to give up getting near one part of his district. Nothing seems to have suffered with the severe weather outside above the snow line. Ivy and creeper-clad walls look fresh; Tea and Noisette Roses on the same are plump. We have bright sunshine and an Italian sky most days. The sun is quite hot now, 9 A.M.—GEORGE BOLAS, *Hopton Hall*.

— RAINFALL AT ABBOTS LEIGH, HAYWARDS HEATH, SUSSEX.—The total rainfall during January was 2.37 inches, being 0.24 inches above the average. The heaviest fall was 0.58 inch on the 19th. Rain or snow fell on sixteen days. The maximum temperature was 52° on the 20th, the minimum 17° on the 27th. Mean maximum, 37.26°; mean minimum, 28.09°; mean temperature, 32.67°, which is 2.82° below the average. There has been continued frost and more or less snow since 22nd, and on the 1st February no signs of it breaking up.—R. I.

— JANUARY WEATHER AT STIRLING.—The rainfall for the last month was 1.410 inch, which fell on fifteen days; the greatest fall on any day was 0.410 inch on the 16th. The mean maximum was 36.3°, and the mean minimum 23.6°. Highest maximum, 45.4° on the 22nd; highest minimum, 35.3° on the 15th. Lowest maximum, 18° on the 10th; lowest minimum, 7.3° on the 10th and 7.2° on the 11th. Frost was recorded on twenty-nine nights. The 15th was the coldest day, with a mean of 17.4° of frost for the twenty-four hours. Altogether a very cold month, but the snowfall has been very light in comparison to other parts of the country; not over 4 inches fell for the whole month.—G. M'D.

— JANUARY WEATHER IN SOUTH WALES.—The following is a summary of the weather here for the past month. The number of days on which rain fell was twenty-one, and the total depth 6.40 inches. The maximum was 1.00 inch on the 12th, and the minimum 0.02 on the 26th. Snow fell on twelve days; and the sun shone on twenty-five days. Total for the month, seventy-four hours twenty minutes, the maximum being seven hours on the 28th, and the minimum five minutes on the 14th. There was frost on twenty-six days, and rain, hail, snow, and lightning on the 24th. It has been a very cold month throughout: snow has been on the ground since December 29th, and no signs of going now. The wind has been from the north and east for twenty-eight days.—W. MABBOTT, *The Gardens, Gwernllwyn House, Dowlais, Glamorgan*.

— THE WEATHER AT BELVOIR LAST MONTH.—We had snow on the ground the whole of the month, with the exception of 19th and 20th; heavy fogs on 15th and 16th; and a thunderstorm on 23rd. The wind was in a northerly direction fifteen days. Total rainfall 3.23 inches, which fell on twenty-five days, the greatest daily fall being 0.99 inch on 20th. Barometer—highest reading 30.310, at 1 P.M., on 30th; lowest, 28.716, at 1 P.M., on 14th. Thermometer—highest in shade 42°, on 18th and 19th; lowest, 10°, on 11th and 12th. Mean daily maximum, 35.22°; mean daily minimum, 25.48°. Mean temperature of the month, 30.35°; lowest on grass 5°, on 12th. Highest sun temperature 86°, on 26th. Mean temperature of the earth at 3 feet deep, 38.25°. Total sunshine, 58 hours 50 minutes. There were ten sunless days.—W. H. DIVERS, *Belvoir Castle Gardens, Grantham*.

— WOODBRIDGE HORTICULTURAL SOCIETY.—Though the last show day of this enterprising Suffolk Society was very wet, the report shows a balance in favour of the Society of £11 9s. 5d. The Committee refer approvingly to the fact that the £25 challenge cup for Roses was won last year by one of the leading nurserymen of the eastern counties. The Committee are now contemplating making arrangements for a much more interesting exhibition of table decorations, decorated fireplaces, mantel borders, also centre epergnes and specimen glasses. Several ladies have promised their assistance by offering special prizes, and the Committee hope that by providing a special tent for this department only it will meet with general approval; they have also arranged to leave this department on view till eight o'clock in the evening. Mr. John Andrews is the Honorary Secretary.

— THE ACADEMY OF SCIENCES.—Mons. Cornu, the Director of the Botanical Garden at the Jardin des Plantes, Paris, has been elected a Vice-President of the Academy.

— THE WOLVERHAMPTON SCHEDULE has just come to hand for the next exhibition in July, and is a very generous one. For 116 stove and greenhouse plants, £20, £15, and £10 are given. For groups, £20, £15, £10, and £5. Roses have liberal encouragement, and this year a new Rose class is added for "the most decorative arrangement of Roses," in a given space. Mr. Paul Lutz of Wolverhampton gives handsome prizes for "the most tasteful arrangement of Pansies and Violas," and the Society has greatly increased their fruit prizes for this year. It is altogether a very liberal schedule, and the Messrs. Green, senior and junior, who work so energetically, deserve the cordial support of all horticulturists.

— SOWING ONIONS UNDER GLASS.—After reading the excellent remarks by R. P. Brotherston in last week's issue (page 90), I may say I thoroughly agree with all he says on this subject. For many years now the Onion maggot has almost run riot through different parts of the country, and various remedies have been propounded. In large gardens experiments may readily be made, but to those who have only a limited space they become almost dangerous; hence I hold that any remedy calculated to throw light on this question of the Onion maggot ought to be ungrudgingly given. If to some the system of sowing under glass does not commend itself entirely, they may at least give it a trial, however small; and, with Mr. Brotherston, I can safely say that the results, either in combating the maggot or in insuring fine bulbs, will not be disappointing. The sorts we grew last season to very fine dimensions were Sutton's A1 and Exhibition, Cranston's Excelsior, Ailsa Craig, and Cocoa Nut—all fine keeping varieties.—R. P. R.

— THE BIRMINGHAM GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—On the 28th ult. the fortnightly meeting of this Society was held at the Athletic Institute, Birmingham, under the chairmanship of Mr. W. B. Latham, when Mr. A. W. Wills, F.C.S. (the President) of Wyld Green, Erdington, delivered an interesting and instructive lecture on "Welcome and Unwelcome Guests." Mr. Wills prefaced his subject by observing that on a former occasion he called attention to some of the mutual relations of plants and insects, pointing out how the perpetuation of most species of flowering plants depend on their effectual fertilisation, how this is accomplished by insects, and how Nature usually favours allogamy and discourages autogamy, or fecundation of the flower by its own pollen. He then proposed to draw attention to a kindred subject—namely, the manner in which the structure and disposition of these parts of the plant are arranged for the protection of the flowers, and in which the structure of the flowers themselves conduces to the encouragement of the visits of insects whose access is desirable, and to the discouragement of those whose access is disadvantageous; his remarks, as he himself desired to intimate, being chiefly based on a charming book by Dr. Kerner, Professor of Botany at Innsbruck, entitled "Flowers and their Unbidden Guests." We hope to publish a digest of Mr. Wills' lecture in a future issue.

— THE SHREWSBURY SCHEDULE.—This is now being issued, and is truly a liberal one, the prizes being so heavy generally. In Class 1, for a group of plants, £62 is offered in four prizes, and £45 in Class 2 for twenty stove and greenhouse plants, in two prizes. The display of floral arrangements, in a space 12 feet by 5½ feet, has always been a great feature here, and in the new schedule the prizes are considerably augmented to £12 10s., £10, £7 10s., and £5, a total of £35. The Society celebrates its coming of age this year, and a new class for fruit has been specially added in honour of the occasion. It is for a decorative arrangement of fruit, "A collection of twenty-four varieties to be staged in a space 10 feet by 4½ feet. Lycopodiums and other trailing plants, Ferns, and foliage may be used for effect; tasteful arrangement being considered by the judges in addition to the quality of the fruit." First prize, £20; second prize, £15; third prize, £10; fourth prize, £6; a total of £51. Instructions to guide exhibitors in this class are given, and the Committee hopes that this class may meet with the approbation of our leading fruit growers and lead to some good exhibits. In addition to this class there are two other classes for collections of fruits, besides the very liberal prizes for Grapes and other fruits as usual. Nearly £800 are given in money and medals as prizes, and no wonder the Shrewsbury Executive deserve such grand displays, especially with two such experienced Hon. Secretaries as Messrs. Adnitt and Naunton, to whom the work of the show days seems to be so easy, so excellent are their arrangements.

— KINGSTON GARDENERS' ASSOCIATION.—The members of this body met on January 30th for the purpose of taking part in a discussion arising out of a series of eight questions on flower gardening, to which Messrs. Pitcher and Plumb undertook to furnish replies. This course was thought desirable, as there seems to be much objection on the part of the members to the having too many papers and to the preparing of them. The above named members dealt with the questions so fully and furnished such complete replies, that with the discussion which ensued the evening was fully occupied. Mr. Morton, Maple Lodge Gardens, presided. At the next meeting, should no complete paper be furnished, a similar discussion arising from answers to questions will be promoted.

— THE SALE OF NOVELTIES.—A novelty in flowers, fruits, or vegetables may be a new species, or a new variety, or it may be an improved selection of an already popular sort, and in many cases it is something that was in cultivation long ago, but only in a limited way. By booming an "old" but little known plant as a novelty, says an American contemporary, is the only way to make it popular quickly; if it is a good thing it will sell better the second year than it did the first, and still more of it will be sold the third year, and so on. It sometimes happens that the dealers themselves have to drop a sterling novelty simply because they cannot get up a stock of it quick enough or cheap enough to supply the demand created by advertising it prominently at paying rates.

— BIRKENHEAD GARDENERS' IMPROVEMENT SOCIETY.—We are about to start a reading-room in connection with our newly inaugurated Gardeners' Mutual Improvement Association for Birkenhead and district, the room to be open each evening (Sunday excepted), from 6 to 10 P.M. for the use of members only. A botany class is to be held one evening each week, and another evening will be set aside to coach any willing to study for the examinations of the Royal Horticultural Society for their certificates of efficiency. One of the primary objects of the association is to secure a library of good standard works on horticultural subjects. This, of course, will take time, though doubtless many of the gentry of the district who employ gardeners will be willing to assist when they are assured that the gardeners themselves are really in earnest, and are not above making some little efforts among themselves for their own mutual improvement.—T. D. SMITH.

— THE GERMINATION OF MUMMY WHEAT.—In January "Nature Notes," Mr. W. Carruthers, F.R.S., has again confuted the ridiculous statement concerning the germination of seeds which have laid dormant for thousands of years—one that still appears in books and magazines, though its erroneousness has been pointed out. In some instances the notion has arisen from the germination of seeds which have been accidentally attached to mummies or mummy cases in transit. Other instances are explained by the roguery of natives, playing on English credulity. The absolute impossibility of it is proved by the fact that all seeds and fruits that are found in ancient coffins of Egypt appear to have passed through the fire. Besides careful experiments have been made upon seeds, and few retain their vitality more than two score or three score years. In one exceptional instance a seed of a Nelumbium germinated which had been kept for 150 years in a museum, but this has a specially hard covering.

### THE CHARLES COLLINS' FUND.

We have great pleasure in announcing the following subscriptions received during the past week towards this very deserving case:—

### THE CULTIVATION OF THE MELON.

THE Melon has been with us about 400 years, and well may the present staff of gardeners look with interest on the increased cultivation of the last fifty years. I well remember when I first learnt the way to obtain the highest awards for Melons; it was at the Reading Horticultural Show in 1886. I was once fortunate enough to have a few words of advice from one of our most noted growers, Mr. T. Lockie, who remarked—"What a mistake gardeners make in drying off Melons for improving the flavour of the fruit."

It would be useless to deny that for general market work the Melon has not the same advantage as the Tomato, as we are not all lovers of Melons, but with the increased demand they can, with good cultivation, be made very profitable, provided a suitable one for market work is obtainable. For market purposes we must have size with quality. For this purpose it would be advisable to cross a large Melon with one of a better flavour; for instance, Conqueror crossed with Hero of Lockinge should be good, and only these two should be grown together at the time, or the cross might throw several varieties the next season. Great care should be taken to choose a healthy staminate flower on the parent plant, and a strong pistillate flower, inserting the pollen and allowing it to remain.

We will now take the method of cultivation in houses. Having selected a variety suitable for our purpose, propagation next demands attention. The seeds may be sown at different dates, according to heat at command, commencing from the shortest day until the end of June. Where we have a good supply of heat the first-named date would be most suitable for those who require early fruits. Clean, small, 3-inch pots are most suitable to raise the young plants in. The crocks used for drainage should also be clean and sweet; insert a large one over the hole so that it allows the water to pass through freely, then cover over with smaller pieces in two layers. The pots should be filled with soil consisting of three parts of good loam, one of sand and leaf mould, no manure at this stage being used. Press down moderately firm, make a small hole half an inch in depth, fill with sand, then insert a good sound seed. The next object is to induce the seed to germinate quickly. The pots may be plunged in some moist material, then placed on the pipes. In a few days the seedlings will appear, and from this time to the ripening stage no plant requires more attention.

The preparation of the soil for planting in should now be proceeded with, and the bed must be made up so that by the time the plants are ready to put out the soil will be of the same temperature as the house. The material for this purpose should consist of fresh loam, broken up to the size of a hen's egg. To this add a small quantity of lime rubble, leaf mould, and road grit in proportion to the texture of the soil. We do not recommend any farmyard manure being added, as it often induces too free a growth. What we much prefer is bonedust, using about 1 gallon to two barrowloads of soil. In making the bed, good drainage should not be lost sight of. One of the best plans is to have about 2 feet of long manure pressed down firmly; on the top turves placed grass downwards, or faggots may be used in the place of straw, or, what is better still, strong boards raised on pots or boxes, with crocks or brick rubbish spread on the surface, then the turves. On the top of this should be placed some feeding material, such as half-inch bones or hoof parings, then the soil. The compost must be firm, as this encourages the firm wood so desirable in Melon cultivation.

When the plants have attained the third leaf is the best time to plant out, and this should always be done with great care, never giving the Melons a check. The best time to plant is just before closing the house in the afternoon, as the plants then rarely if ever flag in the leaves. Growers differ greatly as to the depth of planting, but if the plants are stocky we prefer to plant them up to the seed leaf. If they are leggy the plants should not be put in deeply, but the ball should be placed a little way off the place where the plant is required, and the stem laid in about 2 inches in depth. Place a stake by the side of the plant and make fast to the nearest wire, then secure the stem to the stake, allowing room for swelling.

Watering may be considered one of the most important points in Melon culture. It has been said, and rightly so, that Melons are lovers of water, but more failures in cultivation may be traced to giving water at the wrong time than to any other cause. Only by careful attention can this part of the work be successful. Never water Melons until convinced the plants require it, and then let it be in the morning, in wet or dull weather withholding it altogether. The water, too, should always be of the same temperature as the house, as cold water is very injurious to the roots. When the Melons are first planted little or no water is required, syringing the plants being sufficient unless the soil in the bed is dry, when a little may be afforded, and it should last for several days. When the plants have covered the trellis, and the fruit begins swelling, they will require more water than at any other time, giving it only sparingly when the fruits are netting, and when the ripening stage is reached only sufficient to keep the foliage green.

Syringing is another important matter. Young plants should be syringed freely every morning, and on bright afternoons. As growth extends syringing should decrease, withholding it when the fruits commence netting, relying then on damping the house to keep insects in check. Airing is also an essential point, and no favourable occasion

should be missed to admit as much air as can be given without causing a draught, especially in the morning before syringing, closing the house for a few hours early in the afternoon after having first syringed or damped down, and if the evening will allow give a little more air for an hour to let all moisture escape. The temperature, too, is another point that must not be neglected, and must be regulated according to the external air. If a temperature of 55° to 60° can be maintained at night, and from 65° to 70° through the day during January and February, this is quite sufficient, raising it according to the season later on. Feeding Melons is often carried to excess, as if the material they are planted in is good this is generally sufficient, although weak liquid manures are of great service in the swelling stage to plants carrying a heavy crop.

In training, the growths should never be allowed to become crowded, and the main stems must be given ample room, as unless the wood properly matures only poor results may be expected. We practise the method of growing three plants to a light, running up five leaders in all. The main leader may be allowed to grow without check, starting the side shoots from the first wire; all laterals showing fruit are stopped at the first leaf beyond the fruit, removing all others entirely, rubbing a little quicklime over the place so as to heal it quickly and prevent decay. When the leader reaches to within a foot of the top wire pinch out the point, and as soon as sufficient fruits commence swelling for a crop cut away all the spare laterals and fruit. The best time for setting the fruit is the middle of the day, as then the pollen is drier than at any other time. Some growers keep the house very dry at this stage of the work, but it is bad practice, as it encourages the increase of red spider, and rather hinders than helps the fruits to set.

In selecting the crop it is always advisable not to leave too many fruits on the plant, eight to a light being a fair average, but in this we must be guided by the plants. When the fruits are selected always choose them as nearly of a size as you can, then remove all the other growths as before stated. Tie secure the fruits with good strong bass to the wire, and when in the netting stage place four bands of bass crossed underneath the Melons and make firm to the trellis, then place one piece around the fruit, seeing that there is room for the Melons to swell. When the fruits approach the ripening stage expose them to the sun by tying the foliage back, as this with abundance of air is of great assistance in producing good flavour, a point so essential in Melons. Melons at this stage should be examined often, as when the fruit has cracked around the stem it should be removed to a cool place. Some people allow the fruits to be placed on shelves in the greenhouse, but this is wrong, as unless the flavour is grown in a Melon no sun after it is cut will put it there, whereas when stored in a cool place fruits will keep a much longer time. Never hurry Melons that are intended for show through the ripening stage, and endeavour to keep the plants healthy with good foliage. Choose a fruit that finishes on the plant, and is ready to cut just two days before the show unless it is Hero of Lockinge, which requires four days, as some Melons are ready before others, and we can only gain this knowledge by experience. I remember on two occasions taking first prize for Triumph straight from the plant. If very early Melons are required they should be grown in pots under similar conditions, as by this method fruits may be had several days earlier.

I will now draw attention to Melons grown in a cool house, and for this purpose seeds should not be sown until the beginning of March, in fact my best results have been obtained from seeds sown in April. It is very important that the young plants are not forced on too quickly. Make a small hotbed in one corner of the house with short hot manure pressed firmly down; cover with 4 inches of soil. Plunge the pots, but remove them to the surface as soon as the seeds have germinated, and if the weather is bright and warm the next day place them on the shelf near the glass, doing this at night, and giving a little shade next day. The soil recommended previously would also be the best to use for this purpose, but we would recommend a good hotbed being made, say 3 feet wide and 3 feet high of short manure, and made quite firm. Then place on turves and soil as before. The plants must receive careful attention for at least a short time every day, and an experienced eye will quickly detect anything going wrong with the Melons. Good crops can be grown under these conditions, as the photo (fig. 19) taken in 1892 of my house at Andover will testify. It was taken when the fruits were just beginning to net, and no less than 150 were grown and ripened, the house only measuring 20 feet by 10 feet. We prefer the wires about 9 inches from the glass, and the same distance apart. Watering and syringing must be done with great care, and only when the weather is suitable; from four to five good waterings will be found sufficient to carry the crop.

To those who have only frames to grow Melons in, and have not even a cool house at command, I would advise great care being taken in the preparation of the hotbed, as this is the most important part of the work. Procure, if possible, some good manure, throw it into a heap, which turn over every other day for a week, adding water if the manure is at all dry. Then make up the bed a foot wider on all sides than the frame, treading well at every layer, and leaving a few barrowloads to fill in the frame. Then insert the turves as before, placing about 9 inches of soil on this, and tread firmly down, especially at the corners and sides, and when this is done the surface should be about 6 inches from the glass. This is very important, as failure often results through the plants being too far from the glass. Two small mounds may be formed at equal distances in the middle of the light,

in which the plants should be set. The training of Melons grown on this method is of great importance, and should never be neglected, removing all laterals at once that do not show fruit, and pinch the leader when it gets to within a foot of the side of the frame, and never allow the growths to become crowded. Eight to ten fruits to a light will be a fair crop, although we have seen even more than this grown with good cultivation. When the fruits commence swelling they should be raised near the glass on some substance that will allow the moisture to escape. When brick frames are in use we would advise

Hero of Lockinge; Blenheim Orange, Al, Read's Scarlet, Scarlet Premier, County Councillor, and for market work Conqueror and Triumph.

Insects and diseases are not numerous, although all are very destructive if not kept in check. First of all we have canker, a disease which to some growers is very troublesome. Should it appear the best remedy is to cut away with a sharp knife all the diseased parts, dry with a cloth, then rub on a little quicklime. To prevent canker, when planting out place a mound of earth 3 inches high around the stem, and

FIG. 19.—MELON TRIUMPH, GROWN BY MR. W. PALMER.

the bed made as for indoor cultivation, with wires under the glass to train the plants to, as with care they can be grown equal to those in a house; in fact, the fruit of Sutton's Triumph, which gained the first-class certificate at the Crystal Palace fruit show, was grown by me under these conditions.

It is somewhat difficult to make a selection of varieties, but a few may be mentioned for home use and exhibition purposes. Hero of Lockinge should be grown by all. Eastnor Castle is one of the best flavoured Melons, but unfortunately not always of the best shape; William Tillery, Windsor Castle, Amberwood Beauty, Royal Prince, Sutton's Triumph, which I consider a good scarlet-fleshed companion to

keep this dry, only watering on very favourable occasions. Decay of the stems may be prevented by always rubbing in quicklime when cutting away any portion from the plant. Red spider is the result of neglecting to syringe the plants when they are young. If plants are infested they should be well syringed on fine mornings, thoroughly drenching the foliage. Care should be taken, however, not to damage the leaves by using too much force. Black fly is another troublesome pest, but for this there is a very simple and certain cure—that is, to add more leaf mould to the soil, as it is only on stiff heavy loams that this insect is troublesome.—WILLIAM PALMER, F.R.H.S., *Horticultural Instructor to the Hants County Council.*

## RUGBY CHRYSANTHEMUM SHOW.

THE annual show of the Rugby and District Chrysanthemum Society will, this year, be held on Wednesday and Thursday, November the 13th and 14th.

## CHRYSANTHEMUM SHOW AT COVENTRY.

AT a meeting recently held at the Craven Arms Hotel it was unanimously resolved to hold a Chrysanthemum, Fruit, and Flower show in the Corn Exchange, Coventry, in November next, and a Committee was appointed to solicit subscriptions to start the show on a firm basis. Mr. F. Curtis of 9, Cross Cheaping, Coventry, was appointed Secretary.

## A PLEA FOR ANEMONE-FLOWERED CHRYSANTHEMUMS.

YOUR correspondent, "F. G." (page 101) thinks the blooms in this section do not please the ladies. Did he attend the last Crystal Palace show? If so, did he notice the crowds of ladies and others round the tables containing the twelve fine stands of eighteen varieties of Anemones and Japanese Anemones, and hear the remarks made about them? If not, I can tell him that those stands were acknowledged to form one of the most striking features of that fine show, the crowds lingering round them made it very difficult to get a second look at the beautiful blooms. The general verdict was unanimous in their favour.—H. HARRIS.

## THE N.C.S. YEAR BOOK.

I HAVE an idea that this book will be considered by many readers to be disappointing. With very few exceptions the articles are behind the times. One chapter I am particularly struck with—viz., the "List of Japanese Novelties for 1895." This is by a trade grower, a very prominent member of the Floral Committee, and almost every other Committee of the N.C.S. The writer of the article begins by informing us that he has tried a large number of novelties in his nursery, besides 1000 selected seedlings of his own.

The list of novelties for 1895 contains varieties introduced in 1892-93-94-95, some of which were certificated by the N.C.S. in 1894. To show how very apt some of us are to consider our geese swans, I would point out the fact that out of the twenty-seven varieties mentioned, and which were raised or introduced by seven of the English trade growers, no less than sixteen were or are being sent out by the writer, four varieties by another, two each to two other growers, and the remainder one each. The exhibition Japanese illustrated throughout the book are five, the whole of which were, or will be, sent out by the writer.

Again, although nine of the sixteen varieties, and three others mentioned which are only catalogued by the trade grower in question, have not been certificated by the N.C.S., some varieties which have been certificated by that Society, but were introduced by other growers, are not mentioned. If Niveus, Th. Dennis, Souvenir de Petit Ami are novelties of 1895 so are Louise, Duke of York, Cecil Wray, and others, and should not be excluded because they are popular and plentiful. Philadelphia, which has caused such a sensation here and in America, is described in such a meagre manner that would lead many to suppose it a second-rater only. If the book is to be of substantial value it must be written by those who are above trade interests.—FAIRPLAY.

## THE CHRYSANTHEMUM ELECTION.—DECORATIVE VARIETIES: PRINCESS BLANCHE.

I HAVE been much interested in the elections of Chrysanthemums, as recently published in the *Journal of Horticulture*, and the latest for decorative varieties (page 70) shows a wide difference of opinion. I think a variety to be classed as decorative should be not only free flowering, of good quality, and decided colour, but the habit of the plant should be considered. Had this been done, a great many of the varieties enumerated would have been left out altogether, as pointed out by "F. G." (page 101). The list should be divided into early, midseason, late, and the first twelve are all early and midseason varieties. There is one late white variety—viz., Princess Blanche—that I see only received three votes, but which deserves a much higher place. I have grown and tried scores of varieties for a late white, but have for five or six years past discarded all others for this.

I have heard it said it has not a good constitution, and some have discarded it. I have no hesitation in saying the fault is not with the variety. I grow yearly from five to six dozen plants in 7 and 8-inch pots, each plant producing from three to five dozen blooms, the plants seldom exceeding 3 feet 6 inches high, and from 2 to 3 feet through. As regards cuttings, soil, and potting they are treated the same as other varieties. I never pinch or stop them, but thin the growths and let them grow as they will until the third terminal bud. They make the first break when about 9 to 12 inches high, the second and last from 12 to 15 inches.

As the shoots grow they are looped up to a stake in the centre of each plant, this being all and the only support they require. The plants are fed liberally until the bloom commences to expand. The

peculiarity of this variety is that about the time it makes the last break occasionally a kind of rust attacks the points of the shoots. All I do in any case is to turn the plant over and dust the under side and top of foliage with sulphur. This is done about three times—in August and September, and again when housing the plants. This prevents both rust and mildew. I commence cutting blooms from this variety a few days before Christmas, and on February 2nd I cut down the plants. The blooms were required, or they would have kept at least ten days longer. There is in existence a sport from Princess Blanche, which, excepting colour, is the counterpart of its parent. It opens a bright yellow, and with age changes to a deep primrose. It is named Jannette Sheaham, and received an award of merit from the F.C. of R.H.S. on 15th January last. When this can be obtained I would advise all who require a quantity of white and yellow flowers during the latter part of December and January to give a trial to these two varieties, and if treated as I have described I feel sure they will not be disappointed with results.—J. LYNE.

## CHRYSANTHEMUM VISCOUNTESS HAMBLEDON.

THIS comparatively new Japanese incurved variety is a welcome addition. The fine ivory-like substance of the florets stands out and forms a striking contrast to the more feathery varieties. It is a grand keeper when cut. I had some blooms quite fresh for more than a month in a vase in a living room. It is most peculiar in the growth, being very floriferous, and may be rightly called a perpetual flowering variety, resembling in this respect Miss Anna Hartshorn, to which I should think it is closely related. It is a very difficult one to get stock from, so no wonder the majority of the trade announce plants only, no cuttings. What cuttings or side shoots are produced have a bud about every third leaf? and one of my objects in writing is, whatever objections one might have to inserting bud or stem cuttings of other varieties, not to be deterred from this one, but take advantage of what pieces you can procure, though of course suckers would be preferred. Pot them firmly near the side of a small thumb pot in light sandy soil, and as soon as the cutting is well callused or has commenced rooting nip out the top flower bud, when it will produce side shoots from the base of the other leaves. These in their turn will produce other buds, some more than others, and they also must be removed. The laterals produced should also be cut out, leaving three or four main stems. The buds showing about the first or second week in August should be taken, as on account of the great substance of the flower it takes a long time to develop.—C. ORCHARD, Bembridge, I.W.

## SHEFFIELD CHRYSANTHEMUM SOCIETY.

PERHAPS nothing has done more to further the interests of horticulture in this country than the formation of such societies as the above. It is at the meetings of these that growers congregate for the purpose of comparing notes and discussing knotty questions relating to the cultivation of various plants, by which all are benefited. In addition to this they are the means of establishing exhibitions of fruits, flowers, and vegetables, where prizes and diplomas of merit are offered, and in many cases keenly contested for. Thus the standard of cultivation in these localities is raised considerably. An excellent illustration of the success of such societies was the annual dinner of the Sheffield Chrysanthemum Society, held at the Masonic Hall on January 28th.

Smoky Sheffield itself had anything but a prepossessing appearance. However, any dull forebodings that might have arisen were instantly dispelled on arrival at the hall, where a hearty welcome was accorded by more than one hundred members and friends, all interested in horticulture. Amongst the guests were E. G. Jeffcock, Esq., President; and Mr. H. Broomhead, Hon. Treasurer; Mr. Housley, Secretary; and Mr. Haigh, Accountant to the Society.

The Midland Railway Company was represented by Mr. A. S. Jarvis, and Mr. Jones of Ryecroft Nurseries, Lewisham, was also welcomed. The kindred societies in the locality were well represented by delegates from Wakefield and Leeds Paxton Societies, the Rotherham Gardening Society, and the Sheffield and Walkley Floral Societies, each of which are doing good work to further the interests of gardening in their several localities.

Mr. Jones, when proposing the toast of the Society, said that of Sheffield was recognised as being one of the best in the country, their shows being well arranged and conducted on the best principles, though he had a few suggestions to make which he thought might be acted on with advantage at the next exhibition. The Chrysanthemum show, instead of the dull sameness of row after row of blooms on boards, might be varied by the introduction of such classes as mixed groups of flowers; vases of Chrysanthemum blooms arranged for effect, with a limited number of blooms in each. The seconder also presented medals for premier blooms at the recent show to Mr. Broomhead of Sheffield, and Mr. Alderman, gardener to J. D. Ellis, Esq., Sparken House, Worksop, each of which were acknowledged by the recipients.

Mr. Housley, Secretary, in responding said he was glad to be able to present such a satisfactory balance-sheet. They had commenced the season with only the small sum of 9s. in hand, owing chiefly to the inclement weather on the day when the show was held in 1893. This year, however, things were in much better form, as they had now a balance in hand of £63 5s. 9d. This capital result had been brought about by the amicable and energetic manner in which the Committee had worked, and by which efforts an excellent show had been established, resulting in such good financial returns. Mr. Housley's declaration was received with loud applause.

A worthy branch of this Society is the provident fund, to which the sum of £9 13s. 6d. has been appropriated. A library has also been instituted, mainly through the benevolence of Mr. H. Broomhead, who has presented the bulk of the volumes; thus the members have at their command a mine of information, which many of them, judging by the standard of their exhibits, turn to good account.

The Society is deserving of congratulation on its most satisfactory condition, and it is hoped that under the present able and business-like management it will continue to flourish, and thus be enabled to extend the limits of its shows and usefulness.

#### FERTILISATION OF THE CHRYSANTHEMUM.

UNDER the above heading (page 78), you refer to a communication upon this subject made by Mr. H. Briscoe-Ironside to the Scientific Committee of the R.H.S., and read at its meeting of the 15th inst.

I infer from the references and quotations made that Mr. Briscoe-Ironside suggests a doubt whether florets of the Chrysanthemum are proterandrous, and therefore naturally adapted for cross-fertilisation, a statement of Burbidge to this effect being apparently challenged. I think that a close examination of the life history of the floret of the Chrysanthemum will show to demonstration that the florets are clearly proterandrous, the lengthening of the style, with its stigma surfaces closed, and therefore not susceptible of fertilisation, serving to clear away from the tube of the anthers the pollen which has been already for some time set free by the dehiscence of the anthers.

The correctness of this view I have found to be absolutely established in practice, for, notwithstanding the "minuteness and proximity to each other of the florets" which is alluded to, I have never known, in the practical work of artificial fertilisation, as distinguished from that effected by insect agency or by wind, a single case of fertilisation of the ovary by the pollen of the same flower; and this means the experience of some hundreds of seedlings—over 250 in the year 1894 alone.

It is obvious that the mechanical application, by the camel's hair brush, of foreign pollen, however carefully effected, would occasionally bring about the fertilisation of the ovary by the home pollen, were such abundantly, or even appreciably, present on immediately adjacent anthers. I conclude, therefore, that for the purpose of artificial fertilisation, whatever may be the case where insects and wind have access to the capitulum, the florets of the Chrysanthemum are sufficiently and distinctly proterandrous.

Whether, under the conditions prevailing in Italy, the Chrysanthemum is more, or less, susceptible of self-fertilisation than of cross-fertilisation I am not prepared to definitely state, but it must be remembered that while it is undoubtedly the fact that the stigmas of the ray florets, and of the outer florets of the disc, are ready for the reception of the pollen before the inner florets of the disc have shed the pollen which they produce, it is also a fairly established conclusion, which has, I believe, the acceptance of Sir John Lubbock, that insects visit the capitulum centripetally, and are therefore less likely to convey the pollen from the inner to the stigmas of the outer florets.

Mr. Briscoe-Ironside tells us that the seed resulting from the "self-fertilisation" of the disc florets gives poor results from the horticultural point of view, and that he thinks it to be "most probable that this is the seed which is advertised and sold, and which, as we learn, gives such poor results." That artificial fertilisation of the florets of the disc—the outer rows only being used—gives the very best results experience has proved, and the result of your recent "audits" has confirmed; but undoubtedly if the seed be but the result of "self-fertilisation," then, whether it be from ray or disc floret, we can understand its comparative poorness of quality, a point upon which I should not be disposed to differ from Mr. Briscoe-Ironside. But the American florists, from whom the bulk of the seed of commerce comes, profess, at least, to use only the ray florets for fertilisation, cutting out the disc altogether, and to carefully fertilise by hand. I fancy that the charge of leaving their flowers to "self-fertilisation" would rather astonish them.

That because "history conspicuously refers to the varieties raised by their comparatively few raisers," we are to infer that cross-fertilisation is not natural or is infrequent, I confess is not very apparent. You have already given two answers to the suggestion, and I may add a third. History "refers conspicuously" to the productions of man, whether they be improvements in the breed of horses, cattle, or of flowers, not because these members of the natural world find it "unnatural" to breed on their own account, but because the intelligence of man directing the selection provides a more certain and immediate road to higher results than are furnished by the unaided and unguided action of "natural selection" or haphazard insect agency.

Suggestions aimed at the acquirement of a more accurate appreciation of the laws of Nature are always to be welcomed, but in the interest of exact science we are bound to examine and test the character and sufficiency of the observations which are the cause and authority for the suggestions, so that we may assure ourselves that inferences are not too hastily drawn from insufficient premises. In the present instance Mr. Briscoe-Ironside gives us an insight into his data in an interesting article upon "The Chrysanthemum in Italy," contributed by him to the N.C.S.'s "Year Book for 1895." Referring those interested in the matter to this article in question, I fear I must say that the range of ascertained fact must be somewhat extended before we can safely modify our opinions adversely to those of the authorities by whom we are accustomed to be guided, for we learn that from two flowers of C. Florence Davis Mr. Briscoe-Ironside obtained three seeds only, and that from three flowers supposed to be fertilised after removal from the plant—I say

"supposed," for there is nothing whatever to show that these few seeds were not the result of insect fertilisation prior to removal—only seven seeds resulted. And Mr. Briscoe-Ironside candidly admits, "but the amount of seed I obtained in crossing was always very small." Whether we have, therefore, yet premises sufficient to found any acceptable theory of fertilisation must be at least a question for consideration.

I trust, however, that Mr. Briscoe-Ironside will continue in this country the observations which he has commenced in Italy, and that data will eventually be amassed sufficient to add to the stock of knowledge which we possess upon a very interesting section of Nature's handiwork.—CHARLES E. SHEA.

#### PEELING AND CLEANING VINES.

"IN the multitude of counsellors there is wisdom," and it is certain that your correspondent who asked for advice cannot complain of inattention on that score.

It appears there are one or two points on which a few more remarks are expected from me, and I am quite willing to make myself as useful as possible. So far the majority of correspondents favour the removal of at least some of the bark, but still I am unconverted. I like to see it in all its rough and ragged beauty. True, if a piece half a yard long hung in my way I would not hesitate to shorten it, otherwise let it remain or fall as happens to suit it best.

I do not say that there can be any great harm in pulling off the loose bark, but does anyone ever stop at that which is really loose? You take hold of the end which has parted from the stem and pull it gently. It tears along easily a yard, perhaps 2 yards, and you think you are only pulling off the loose bark; but examine the stem at the two extremes from which the bark came, and you will find them very different in appearance. The first part has provided itself for the loss, and the other has not. Mr. Molyneux (page 76), who is very temperate in his remarks, and who, I think, would not, any more than myself, peel Vines if there were no necessity for it, yet gives some measurements to prove that no very bad results follow the practice.

His figures for fourteen-year-old Vines are 9 inches circumference for the largest, and 5½ inches for the smallest. These measurements are, I believe, considerably above the average for Vines of that age, but they do not "beat the record." If he will turn to the *Journal of Horticulture* for December 21st, 1876, he will see that of the Longleaf Muscats planted at midsummer, 1870, "the circumference of the largest is 13 inches, and that of the smallest 10½ inches, measured just above the ground. At 2 feet 6 inches from the ground the largest measures 8½ inches, and the smallest 7½ inches." In one of the numbers for 1882, that is twelve years after planting, it is recorded that the smallest Vine then measured 18 inches in circumference. These Vines are, I am happy to say, still in good hands, and are doing remarkably well.

Mr. Murphy (page 72) is too flattering. He evidently expects me to be not only a practical grower but a cyclopædia of physiology. Now I have no difficulty in stating facts as they appear before my eyes; but when I commence with theory I am not on such sure ground. Nevertheless, I will do my best even in that line.

First, we must consider what bark really is, and here let me say that the definition given by "J. S. G." (page 102) from Chambers' is out of date, and that there is no such thing as a "solid part" in bark at all. In Prantl's "Text-book of Botany," second English edition, revised by Dr. Vines, at page 65 is given a highly magnified section of the bark of *Ailantus glandulosa*, and this shows a series "of tabular cells arranged in rows perpendicularly to the circumference of the organ, their walls are converted into cork, and are scarcely permeable to water. They usually contain nothing but air." Between the outer skin and the cortex these cells are to be counted to the number of eight or ten, one above another, besides two or three near the inner bark, which are not empty. At page 66 we read, "A formation of cork is wholly absent from only a very few woody plants, such as the Mistletoe and a species of Maple (*Acer pennsylvanicum*). . . . In consequence of the impenetrability of water, which is characteristic of the cork cells, all the tissues outside the periderm necessarily dry up, and these dried tissues, which may belong to different tissue-systems and include the most various forms of cells, constitute what is known as *bark*." And at page 84, "Every part of a plant which is exposed to the air and which is not covered by a layer of cork or of cuticle is constantly losing water by evaporation into the atmosphere. . . . The stems of most woody plants and trees are almost entirely prevented from transpiring by thick layers of cork."

We see then what a perfect covering the bark forms, and if the flow of sap, as believed in by our forefathers, upward and downward, as regular as the water in our heating apparatuses, was not a myth, all the rest would be easily explained. But modern science, that cruel destroyer of the poetry and simplicity of our youthful beliefs, says there is no such thing as sap in the old acceptance of the term to flow like blood from the human heart and back again. That plants were heartless we have long found out, or they would oftener reciprocate our tender love, and that there is no continuous channel even for half an inch for a fluid of any kind.

We have only, then, water and air as far as I know to look to for solving the problem. I take it that if all this non-conducting material was necessary to prevent transpiration, which is certain to take place on its removal, and also that the exposure would interfere with the current of water necessary to keep the leaves rigid.

I cannot say for certain, but should imagine that the bark on my

older Vines was nearly, if not quite, a quarter of an inch thick, and of course they would suffer more than those from which the bark is removed annually. One or two correspondents suggest that the flagging might be the effect of the ravages of the spider during the previous year, but the fact is some of the Vines which were not badly injured in that way flagged just as much as those which were injured the most.

One house of Vines only three years old was barked like the rest, and here out of eight or nine varieties the Black Hamburgs only flagged, and these very badly. Gros Colman here, perhaps a dozen in number, showed no sign of drooping, and yet in the older house it exhibited more signs of distress than any other sort.

Mr. Coates (page 77), is quite correct in saying that clay dressings harbour the insects. If the dressing could be made and continue airtight everywhere it might do some good, but that is impossible, and wherever there is a crack there is a harbour for the enemy. There is no use in putting it on during the winter, but although I certainly could not see any benefit from applying it in the summer, I must think the shade it afforded to the stem should count for something, and I shall try it again.—WM. TAYLOR.

I WAS much interested in reading Mr. Taylor's graphic account of his experiment in peeling Vines (page 5, January 17th). His was an extreme case, no doubt, and a desperate remedy had to be applied. I am quite sure it would not have been undertaken by such a skilful Grape grower had it not been a case of necessity. I believe his article has conclusively proved that close peeling is injurious to the health of the Vine, and such extreme cases of treatment ought not to be lightly indulged in. What a pity it is that this pointed and decisive letter of his could not be made to fit in at the end of those articles on Grape growing which were written by him and published in the Journal some years ago. Could not those articles be reprinted with such additions as Mr. Taylor's experience might warrant? Many a young gardener at the present day would profit by them.

I should like to hear what is the aspect of his vinery, and if it is glazed with large panes of clear glass. If it is, and has a southern aspect, there is no wonder that the leaves flagged and the crop was light, for there must have been intense heat beating down on the exposed tender green bark, with some amount of transpiration. I think more harm is sometimes done to the tender tissues of the inner bark of Vines and fruit trees under glass than is often imagined, this intense dry heat acting injuriously in checking the proper action and circulation of the sap, and encouraging insect life, more especially on Vines which have been ruthlessly deprived of their natural protection. I regret to say I have had to resort to this skinning process, and know the ill effects, but will never again willingly attempt it.

I believe there is no better cleansing dressing than the following for battling against these insidious pests:—Softsoapy water at a temperature of 100° to 120°, brushing it well into the bark, particularly around the spurs, but being careful of the eyes; wash well with this until the bark is quite saturated, then before it dries go over them with a wash made of a pint of Lemon oil to 6 quarts of water at the same temperature, working this well into the bark, particularly around the spurs. I have a great liking for this insecticide, as I have never seen any ill effects from its use.

In chemistry nothing now seems impossible; surely it could not be very difficult for chemists to produce a substance that would penetrate the porous bark of Vines without injury, and at the same time prove fatal to insect life.—J. EASTER, *Nostell Priory Gardens*.

#### PEAT MOSS LITTER.

As there has been some discussion on this subject in the Journal, I venture to send a few remarks representing my experience. A few years since I had charge of extensive gardens where peat moss was used as bedding for a large stud of hunters. The manure was used for all kinds of kitchen garden crops, mulching fruit trees, growing Mushrooms, in fact everything that it was wanted for. The effect on most crops the first year was about the same as if manure from straw-bedded stables had been used. The second year the effect of the moss litter was ruinous. After all the manurial elements were used up the decayed refuse caused the ground to be filled with fungus, which destroyed all the fibres of every plant that it touched.

I mulched fruit trees against walls through the summer, leaving it on all the winter to decay the following spring. The whole border underneath the litter was white with mycelium very difficult to destroy, and only got rid of by several dressings of half-slaked lime forked in. The same effect occurred in a Peach house where it was used. I mixed some with loam for filling pots for layering Strawberries in. The runners took to it very quickly, and soon filled the pots with roots. They were planted in well prepared ground in August, and all went well until the following spring. Just after the fruit had set one plant after another commenced flagging, and the whole quarter became a pitiable sight. I suspected the cause, and on examination found every ball filled with this fungus. With Asparagus the effect was very different. I dressed beds heavily with it, but no fungus occurred. This immunity I attributed to the use of salt, a few handfuls of which were scattered on the beds every week all through the growing season. This destroyed the fungus germs, and finer Asparagus I have never seen.

I used the moss litter largely for growing Mushrooms, and for such purpose I think it has no equal, but it should be kept under the horses for some time until every particle is saturated with urine, and

then thrown into a heap and turned two or three times to sweeten; it is then ready for use, and fine Mushrooms may be expected. It is well to add a few wheelbarrowfuls of good loam when making up the bed, as it helps to give firmness and durability. Thus we find that though it has its drawbacks it also has its good qualities, and should be used with care. It has a wonderful effect on grass land, especially clay soils, and should be used as it comes from the stable, as the manure is soon washed out by rain when laying in heaps, and consequently lost.—S. D.

#### FARNINGHAM ROSE SHOW.

THE annual show of the Farningham Rose and Horticultural Society will be held at Farningham on Wednesday the 3rd July.—STANLEY EDWARDS, *Hon. Sec.*

#### ROSA RUGOSA.

I HAVE been much interested in "Practice's" correction (page 98) of my statements respecting *R. rugosa*. I evidently was not up to date, and am glad to be introduced to Madame George Bruant, and to hear of other new plants coming on. Unless I am wrong again "Macartney" is now the one Rose race that has not been as yet improved on. The foliage is magnificent, but the flower unsatisfactory. "Maria Leonida," says Rivers, "planted in an orchard house and fertilised might give some curious hybrids."—A. C.

#### HARDY NOISSETTES AND TEAS.

I PRESUME there are few lovers of Roses who have not remarked their winter characteristics. Some of these, for example, will be found to be much hardier in constitution than others, and it is rather remarkable that among the Noisettes two of the hardiest should be perhaps the most beautiful of all—viz, L'Idéal and William Allen Richardson. This, at least, is the teaching of my own experience. During the past month, the most exacting January in the matter of frost we have had in Scotland for many years, these superb Roses have yielded much less to its influence in my own garden than even the greatly lauded Aimée Vibert, which, like them, is growing on a sheltered south wall.

Up to the present period, though perfectly unprotected either by Fern or Fir branches (the latter of which I keep for the more tender Teas) the Noisettes to which I have alluded in such complimentary terms have not lost half an inch of their wood. I have another William Allen Richardson on a wall exposed to the south-east wind which is very frequently strongly touched with frost. Having been transferred to that exposed position from a conservatory, I expected that in such a season as this it would, metaphorically as well as literally, "go to the wall;" but I find to my gratification that it is perfectly intact. An utterly unprotected L'Idéal, planted in one of the most central and exposed borders of the garden, has with equal tenacity of existence, survived.

The most vigorous of all Roses, and the strongest in constitution, is undoubtedly the redoubtable Gloire de Dijon. I can well understand the Dean of Rochester's enthusiasm for this remarkable Rose. My grandest specimen (or rather my youngest sister's) received during the memorable storm of December last a very severe and unexpected pruning by the sudden collapse of that portion of the north wall on which it was placed. All its leading branches were broken off, and the giant Rose tree hurled to the ground. But Gloire de Dijon is famous for its capability of producing strong laterals, and I doubt not that in virtue of its vigorous character the amputated limbs will be completely recovered by the end of next summer.

During a crucial season like this the Roses that chiefly require protection from frost are the more delicate Teas; nevertheless, I find that many of these are much hardier than I had anticipated, and one that I have found very admirable in this and other respects is Princess of Wales, one of the most attractive varieties within the range of my acquaintance. I have also been much gratified by the vigour and endurance under extremely exacting atmospheric conditions of Madame Elie Lambert, a valuable new Tea Rose not yet widely known. Comtesse de Nadaillac, also Madame Pierre Cochet, are exquisitely beautiful and free-flowering Noisettes, recently introduced; Maréchal Niel, which can tolerate winter frost with more equanimity than summer rain; Corinna, Medea, Clara Watson, Miss Ethel Brownlow; Marguerite, a pure white variation from Mrs. James Wilson; Catherine Mermet and her two fascinating American daughters, Waban and The Bride; Madame de Watteville, and Marie Van Houtte. All these Roses have distinctive attributes, but none more valuable than the special qualification to which I have referred.—DAVID R. WILLIAMSON.

#### THE ROSE AND MILDEW.

WITH the present season of young growth among our indoor Roses I would like to give a few hints on the above disastrous disease. We can kill mildew, it is true, but when once its germs have put in an appearance on old or young leafage it is very difficult indeed to eradicate them without risk of serious injury. Noting this fact, it

surely behoves us to keep the disease away as far as we possibly can. This is so simple if we but take precautions from the first; but if we let it secure a hold, as I have already said, it is the worst of all Rose pests. Changes of temperature, chilly draughts, and drought are the chief causes. In fact I may say that a serious check from any cause will oftener than not result in an attack of mildew.

I recently visited a set of Rose houses, and the majority of them already had serious attacks from mildew. I was much surprised to find this, and also to see nothing but dusting with flowers of sulphur used as an antidote. When sulphur is used as a dry dust we have to use much more than I like, it also chokes up the pores of the foliage and has a very unsightly appearance. Drought was the cause of mildew in the estimation of my friend, but I feel certain that it was the severe check to root growth quite as much as the former. Climbing Roses were grown in low, span-roofed houses, and the roots turned into borders on the same system as Vines. Of course many of these were outside, and the severe frost affected them. Some few varieties are affected more than others, nevertheless the first cause is the same.

The outside roots of these Roses were protected slightly, but by no means sufficiently for the present severe frost. I think my readers will agree with me that as the young growth of these Roses was in most cases showing the flower bud there is little doubt the whole of their roots, both inside and outside, were active. My own experience tends to prove that we should never force Roses that have their roots in outside soil so liable to fluctuations. Either let them be confined to the inside border, or else treat them in as steady and cool a manner as possible.

I have traced the cause of mildew on pot plants to the use of very chilly water, too a strong stimulant, and to a wide fluctuation of temperature. Is it not exactly the same among our summer Roses in the open? We find this disease prevalent immediately on any sudden change or artificial means that may have resulted in a check. We cannot entirely avoid mildew in the open, but I contend there is very little excuse for it under glass, and especially in the case of a house devoted entirely to Roses. If the temperature rises unduly, and, as is so often the case at this season, a bright sun is accompanied by a keen wind, we had far better temper the atmosphere with moisture and immediately lower the fire than to admit ever so little of the outside air. If we also syringe with some very weak insecticide containing rather more sulphur than usual we shall have a delicate and not unsightly dusting all over our Rose growth, and it is surely far better to have the remedy already on the plant than to wait until the enemy has taken possession.

Such is my practice, and from the result I should require considerable persuasion to alter. In the next syringing with ordinary solutions the sulphur will be removed. Even if it is not we avoid any unsightliness, and also the use of sufficient to do harm. Petroleum, again, is a grand addition to any insecticide when fighting mildew, and a very little has a wonderful effect, besides being perfectly safe.—PRACTICE.

#### CAMPANULA GRANDIFLORA PUMILA.

THE stately perennial which is variously known as Platycodon or Campanula grandiflora is a favourite occupant of many gardens, its large, open, deep blue flowers being produced most freely. This and some of its varieties reach the height of 2 or 3 feet, and therefore either require permanent corners and similar sites, or they must be placed behind other dwarf-growing border plants. A variety possessing all the good qualities of the ordinary *C. grandiflora*, but with a considerably dwarfer habit, is that represented in the woodcut (fig. 20), *C. grandiflora pumila*. This grows 9 to 12 inches high, producing flowers similar to the type in size and colour, and forms a beautiful specimen, as it soon becomes covered with flowers. The plant is well adapted for culture in pots also, and is readily increased by seed. Any ordinary garden soil that is not excessively heavy or wet suits it.

#### APPEAL JUDGES.

WITHOUT doubt "C. K." was disposed to be satirical when proposing me as an excellent appeal judge. Realising the complete absurdity and incongruity of such a post I respectfully decline. I have no disposition to gratify the humours of a few dissatisfied exhibitors. On matters of taste or opinion I have no faith in courts of appeal. The utter impropriety of such a thing was well demonstrated at that Edinburgh show, when an "expert" was invited to act as such a court. The position of judge of appeal would entitle the person or persons undertaking such an office to treble fees, suits of armour, and stout cudgels lest he or they should meet with the reception sometimes awarded to referees at football matches.

If there be a disputed award made the proper court of appeal in every case is found in the ordinary judges, and if they choose to ask in such case for the assistance of a member of the Committee or other suitable person as assessor no exception can be taken to such course. That other persons of equal knowledge, or perhaps less knowledge, should be called on to review the decisions of other two or three capable judges on matters of taste or of opinion is a proposal that can scarcely be entitled to serious consideration.

Obviously, as I have said before, it is the duty of committees to secure the best men they can as judges. To admit of an appeal is to admit the Committee were remiss in not obtaining the best available judging talent, and that farther they regarded their judges as after all incapable. It need hardly be said that such a thing would be intolerable; in fact, nothing would so surely tend to drive the best, most capable, and honourable men out of the judging arena.

My intimation that the only fitting court of appeal is found in the judges themselves applies only to questions of fact, interpretation of conditions, or of disqualifications, which can only be based on matters of fact. In these matters committees who prepare schedules are generally most to blame, because conditions and requirements in competitions are so obscurely drawn. Why do not exhibitors who have reason to complain of troubles arising from this cause communicate with committees,

FIG. 20.—CAMPANULA GRANDIFLORA PUMILA.

and point out how, by different wording, similar troubles may in future be avoided? If exhibitors misread, or do not read prescribed conditions affixed to classes, they have themselves to blame. Seeing, however, how comparatively few the *bona fide* complaints are (I use that term with complete emphasis), arising from the hundreds of shows held during the year, it does seem after all as if molehills were being converted into mountains.

As a member of the Royal Horticultural Society's Code of Judging Committee, I am not at liberty to disclose what that hard-working body is doing, but I may say at least that this very subject is not lost sight of, and have reason to hope that proposals will be formulated which may, so far as matters of fact are concerned, satisfy all practical requirements.—A. D.

ARE they necessary, when so many competent judges, both gardeners and amateurs, are to be found throughout the country? If societies select the most competent men that their means afford, and assign each set to adjudicate on the classes for which they are the most qualified, there would be fewer complaints about the verdicts. If one judge is an expert on fruit, does that make him as good a judge of florists' flowers or of plants? I have accompanied judges in their work, and have not found them to err knowingly in their verdicts. We do not all see objects with the same eyes, and the owner of an exhibit close in merit

to a rival thinks his own the more meritorious. I have always found judges most willing to review their own decisions, but with a very bad grace would they undertake to review the awards of others, because they were not looking through the same spectacles.

I do not see how "C. K.'s" proposal of "appeal judges" would work. I will appeal to his own sensibility, and ask him if he would cheerfully undertake to judge a Pansy show, knowing that his near neighbour was sitting in a room anxiously waiting until "C. K." had finished, then to sally forth and perhaps reverse some of his decisions. Whose decision, then, would be the correct one, seeing that the appeal judges are as qualified as he is himself? Let "C. K." answer.—G. MCD.

### VIOLA NOTES.

AS an ardent admirer of the Viola I have read with interest the notes from your able correspondent, Mr. W. Dean (page 98). The history of our favourite flowers is always a point lost, more or less, to every new or young cultivator of the flower, unless, as in this case, an old fancier steps into the breach and supplies the need. I have from time to time collected from various sources scraps of Viola history, but I was quite unaware that Mr. Jas. Grieve had experimented in Viola crossing on the same lines as Dr. Stuart; thus it is a case of "honour where honour is due," at the same time it does not detract from the doctor's work.

Looking through the list of varieties as given on page 98, it is surprising to notice how few of them are generally grown at the present day. Tory, Snowflake, Blue Bell, Truc Blue, and Golden Queen of Spring appear to be all the old varieties noted that have any claim to popular favour now, though some of the others are met with occasionally. I wish all raisers of Violas would accept the necessary properties as laid down by Mr. Grieve in 1880, and I heartily agree with Mr. Dean on this point, but what do we find? Simply this. We are now getting all kinds of rubbish year after year; the only *sine qua non* followed by introducers is "Something that will sell," no matter what its value as a bedding plant may be, or in fact any other of its essential characters.

I hold it to be a very important point that every new Viola should possess the dwarf dense habit of growth so desirable for bedding purposes, but I can recall, only last season, a case where a prominent exhibitor had one of the new varieties staked as though it were a Carnation. Surely such as these do not come up to our ideal of a Viola. The second point in Mr. Grieve's standard is also being lost sight of—viz., "That they bloom freely and continuously during the spring and summer, or summer and autumn." I am sure any Viola grower who has a modern collection can point out many varieties which do nothing of the kind. They may produce a few flowers which are very attractive on the exhibition boards but are utterly worthless for other purposes.

I am quite willing to acknowledge that the majority of our new varieties do possess the necessary stout texture in petal, because if lacking in this particular point exhibitors would not recognise them, knowing full well if put on the show stand they would collapse before the judges examined them. The Fancy, or parti-coloured flowers, are certainly the most popular for exhibition purposes, and I do not wish to decry their merits in the garden, for many of them are particularly beautiful; they may not be so useful for massing as the self colours. Duchess of Fife, White Duchess, and Goldfinch, are excellent examples of this type, and worthy of a place in every collection. Their growth is also admirably adapted for carpeting the ground, if the flowers, instead of looking downwards would turn their faces upwards, they would form an almost ideal type. Then, again, we have a parti-coloured type of a different habit in Skylark, Blue Cloud, Acushla, and Laverock that are always the first to produce their flowers in the spring, which they do to perfection. Later in the season they do not maintain their "belting" very well, and this fact alone makes them so unpopular with the modern exhibitor.

The Violetta type, about which we have heard so much lately, is essentially one for the flower gardener, as it is not adapted for exhibition purposes unless classes are formed for it, and even then it is not striking. Its place is certainly in the garden, and its failing there is it blooms very late. If raisers of this new section will turn their attention to creating an early flowering class of the type, they will be conferring a benefit on all lovers of this flower.—JAS. B. RIDING, *Chingford*.

### HARDY FRUIT GARDEN.

**Pruning Peaches, Nectarines, and Apricots.**—As the buds will be swelling shortly, the requisite attention necessary at this season must be given to wall trees, so that the work may be completed before they are advancing rapidly into bloom. As a rule it is advantageous to defer the training, if not the pruning, until the middle of February or

even a little later, because the branches and shoots, being away from the influence of a warm wall, the buds are retarded. This is the object of loosening the branches from the walls in the winter. The practice also fully tends to ripen the wood, and it is necessary when the trees require extra overhauling, together with a general regulation of all the principal branches.

**Pruning.**—When due attention is given to all the details of management occurring in their various seasons, the amount of pruning required at any one time is not large. Neglected trees, however, will need considerable manipulation, first in removing any crowded main branches, the proper disposal of the subsidiary branches, and then the thinning out of the bearing wood. Severe pruning is an evil with most stone fruit trees, as it interferes with the balancing power of growth; but overcrowding must be avoided, or the crops will be influenced unfavourably. With such trees the main object should be to obtain a fair amount of vigorous, yet not too luxuriant, wood, discarding the old as much as possible, and with due attention to providing successional growths from the base of each fruit-bearing shoot, as well as in other suitable parts, if necessary, to furnish bare places, the trees will be renovated gradually. Trees pruned in the autumn to the extent of having all the old bearing wood cut out will need but little now. Thin out the future bearing wood, leaving the shoots so that they can be laid in 4 to 6 inches apart. The unripe points may in most cases be shortened to triple buds, in order that that wood growth can be continued to attract sap to the fruit. Shortening to a point where a wood bud exists is important, and if a triple bud is not selected prune to a single wood bud.

**Character of Buds.**—The difference between wood and blossom buds is easily seen, the former being thin and pointed, the latter plump and round. Shoots vary in the number of particular buds they carry; some may contain nothing but blossom buds, the end bud or terminal, however, will be a wood bud. Such shoots ought not to be shortened at all. Others may have nothing but wood buds; these, of course, are useless to retain for fruiting, and being usually weak may be cut back to basal buds, providing a number of shoots for furnishing are not wanted near that point. On other shoots the buds vary greatly, triple buds predominating on some, a wood bud and two blossom buds. Double buds may also be present, both sometimes being bloom buds, at others one of each; while frequently a wood or blossom bud occurs singly. Invariably the best shoots are those that have a wood bud adjoining the blossom bud or buds. All shoots contain growth buds at the base, from which successional shoots are secured each season.

**Lateral Shoots.**—Some vigorous trees have growths that during the previous growing season formed laterals. These ought to be checked by pinching to the first joint, and afterwards to one leaf, shortening at the winter pruning to the buds at the base, which by pinching the growths have become plump. Shorten the point of the main shoot to a ripe portion where there is a wood bud. Those shoots with laterals are not quite so desirable as clear young wood, and generally indicate that a little curtailment of strong roots would be beneficial.

**Spur Growths.**—Fan-shaped unrestricted trees are not freely furnished with spurs, either natural or artificial, except in the case of Apricots, which produce spurs readily, as well as long annual shoots. Natural spurs are those short clustering growths borne on the branches without any inducement by pruning. Artificial spurs are formed by shortening surplus growths in the summer, and cutting them back in the winter. A fair number of each may be admitted, or the trees may be kept wholly to producing fruit on young annual wood.

**Cleaning the Trees.**—After pruning, and before training-in the branches, a fresh and effective dressing should be applied carefully to every part of the trees, in order to destroy mildew, insects, or hlight. Any of the advertised insecticides are good, also a solution consisting of 4 ozs. of softsoap to the gallon of water; to this, form into a paste and mix in 1 oz. of sulphur. Apply with a brush to the trunk, branches, and shoots, working the brush upwards from the base of the latter, so that the buds are not injured. The solution may be thickened like paint by adding enough soot and clay. It is well to cleanse the walls by brushing or syringing with the solution or very hot water, filling-in all old nail holes, crevices, and had joints with mortar.

**Training.**—Dispose the main shoots over the wall as equally as possible, using strong shreds and stout nails; follow with the subsidiary branches, and finally the young wood. Use no more ties or shreds than are necessary, and train as straight as practicable.

**Top-dressing.**—The top layer of soil immediately over the roots is usually poor and inert material. If this is removed down to the roots, fresh material—consisting of loam, wood ashes, and a little partly decayed manure, adding to every hushel about 1 lb. of chemical manure—may be advantageously applied. Make the addition fairly firm, and roots will soon lay hold of it.

### FRUIT FORCING.

**Pines.**—*Fruiting Plants.*—The plants placed in heat at the New Year are showing fruit, and should have a mean temperature of 70°, varying 5° according to the weather, admitting air at 80° with sunshine, but do not lower the temperature, nor allow a current of cold air to act directly on the plants. Allow the heat to rise to 85°, close between that and 80°, and if it rises somewhat after closing that will be advantageous rather than otherwise. The plants now pushing fruit will, if in good condition at the roots, produce strong suckers. When these are large enough to handle, all except one to each plant must be removed or have the growth checked by screwing out the centre.

*Supplementary Plants.*—To supplement the autumn-potted plants

select others from the nursing department which have been wintered in 7 or 8-inch pots, choosing the most vigorous. Those remaining may be reserved until the general spring potting, when they can be shaken out and treated similarly to suckers. Good fibrous loam, with the turf well reduced, placed under cover to become dried, is a suitable compost. It should be torn up roughly, rejecting the small particles. Drain the pots well, dust dry soot or wood ashes over the crocks to exclude worms, and ram the soil firmly round the plants, keeping them well down in the pots to admit of copious supplies of water being given when necessary; 10-inch pots are suitable for Queens, and 11 or 12-inch for those of more robust growth. A temperature of 60° to 65° will be sufficient for these plants, also those potted last autumn, and about 85° bottom heat.

**Starting Plants into Fruit.**—The beds in which these are placed must not be more at the base of the pots than 90° to 95°, or the roots of the plants will be injured. If sufficient fruits be started to meet the requirements later successional plants that have not been subjected to a high temperature may be advanced slowly, they with autumn-rooted suckers requiring careful watering, especially when the heat at the roots is supplied by fermenting materials.

**Figs.**—*Earliest Trees in Pots.*—The trees started in November or early in December to afford fruit at the close of April and early in May will be forming fresh roots, the bottom heat being kept steady at about 70° to 75°. Raise the fermenting material to the rims of the pots, and instead of allowing the roots to come over them place pieces of turf round the rims to keep the roots near home and induce a sturdier growth. Maintain a genial atmosphere by syringing twice a day and damping as may be required in bright weather. Admit a little air at 70°, increasing it with the temperature; close at 75°, and if the heat rises to 80° or 85° from sun heat it will be an advantage. The drainage being good, and the trees in proper condition, there is little danger of giving Figs too much water, many crops being lost by the soil being allowed to become too dry. The temperature in dull weather may be kept at 60° to 65° by day, 55° to 60° at night when the external air is cold, but 5° higher when the weather is mild. Disbudding must have attention as growth advances, and gross shoots be stopped; but it is better to keep the growths rather thin and secure sturdy, short-jointed wood than practise close pinching, as the finest fruits are borne on extensions.

*Early Forced Planted-out Fig Trees.*—The trees planted in narrow inside borders and started early in the year are commencing growth, and may have the night temperature raised to 55°, 60° to 65° by day from fire heat, with an advance from sun heat and free ventilation to 70° or even 75°. Syringe twice a day, and see that the borders are thoroughly moistened. If the trees are weak a drenching with liquid manure, not too strong, at a temperature equal to that of the house, will assist the growth.

**Cherry House.**—Ventilate early, for no fruit tree dislikes a close and moist atmosphere more than the Cherry. Maintain a night temperature of 40° to 45° as the trees come into blossom, 45° to 50° in dull cold weather, 50° in mild, increasing the ventilation from 50°, allowing a rise of 10° to 15° from sun heat, with full ventilation, closing at 55°. Syringe the trees and house in the morning and afternoon till the blossoms are somewhat advanced, but cease it before they expand, damping the paths and borders occasionally to maintain a genial condition of the atmosphere. Allow a little ventilation constantly at the top of the house. Trees in pots must have the necessary care in watering.

**Strawberries in Pots.**—The earliest plants have set the fruit fairly well, and being thinned to about half a dozen berries to each plant are swelling freely. The December plants have, however, been brought on slowly, and are commencing to flower strongly. These will give a far better crop of fruit than those started very early, providing air be freely admitted, the weaker flowers removed, and when the pollen is ripe each flower is lightly brushed over with a feather charged with the fertilising farina. After the fruit is set thin them to the number the plant is likely to swell perfectly, this being a matter for judgment, and must be regulated by the condition of the plant and variety. Whilst the fruit is setting 50° to 55° will be sufficient heat artificially, advancing to 60° or 65° with sun heat; but after the setting is effected remove the plants to a house with a temperature of 60° to 65° artificially, and 70° to 75° by day, supplying liquid manure until ripening commences, then employ water only and sparingly. Whilst swelling they require a moist genial atmosphere.

Successional plants must not lack water, but needless watering is highly prejudicial, therefore examine each plant and afford a supply only when required. The plants succeed best when brought on gently, a temperature of 50° artificially being ample. Examine the plants carefully for aphides, and if there be any trace fumigate moderately, taking care to have the plants perfectly clean before they come into flower.

**Cucumbers.**—Avoid overcrowding, keep the foliage thin, remove bad leaves and exhausted growths, stopping one or two joints beyond the fruit. Crop lightly, and secure clean growths as essential to free successional bearing. Keep the night temperature at 65° to 70°, and 75° by day, with 80° to 90° from sun heat, closing early in the afternoon, with abundance of moisture on bright sunny afternoons; this, with judicious applications of liquid manure in a tepid state will insure due nourishment and free growth in the plants and fruit.

Young plants may be transferred to the hillocks or ridges in the structure prepared for their reception, and soil having been in a few days to warm it should be pressed firmly about each plant, placing a stick to each, and securing to the lower or such wire as suits for training the

plants when grown on trellises. Shade for a few days from bright sun at planting, but not more than is absolutely necessary to prevent flagging.

**Melons.**—When the plants from seeds sown at the new year are sufficiently strong they may be planted in their fruiting quarters. The ridges or hillocks of soil should be made quite firm and had insufficiently long to become warmed through, then turn out the plants carefully, firmly pressing the soil about the roots, and keeping the collar slightly elevated. Place a stick to each plant and secure to the trellis, rubbing off all laterals appearing on the stem whilst quite small until the trellis is reached. Maintain a genial condition of the atmosphere by syringing surfaces other than the plants in the morning and afternoon. A night temperature of 65° to 70°, falling 5° on cold nights, 70° to 75° by day artificially, and 85° or 90° from sun heat will insure steady progress. Ventilation must be given very carefully, always in the early part of the day, closing so as to secure a good advance from sun heat in the early part of the afternoon. Seeds should be sown without delay for raising plants to be placed in frames, also for successional planting in houses.

**Vines.**—*Eyes and Cut-backs.*—Eyes may now be inserted, using pots, pans, or square pieces of turf. Select plump buds on firm, well-ripened wood, filling the pot or pan with rich friable loam; insert the eyes with a pinch of silver sand and about half an inch beneath the surface; plunge the pots in a bottom heat of 80°. Cut-backs should be placed in a house where they will have a temperature of 60° to 65° at night, and 70° to 75° by day. When they have started into growth shake them out and return to the same size of pot, using good friable loam, and give a rather close and moist atmosphere until re-established, when they should have a position near the glass, so as to insure sturdy, short-jointed, thoroughly solidified growth.

#### PLANT HOUSES.

**Cyclamens.**—Where a number of young plants have not been raised from seed for another season no time should be lost in sowing. The seed should be sown in pans of moderately light soil and just covered, the pan or pot containing the seed being watered, and then covered with a square of glass. Place the seed in a temperature of 65°, and germination will soon take place. When the young plants are up air must be admitted gradually, and the pot or pan should be put close to the glass on a shelf, which will prevent the seedlings becoming drawn.

**Clivias.**—Seedlings of last year that have been in a cool house may be repotted into larger pots, using a compost of good loam, leaf mould, decayed manure, and sand. The young plants may then be placed where they can enjoy a temperature of 55°, when they will soon start into growth, and before the end of the season should make strong plants. Established plants that have been kept cool and on the dry side may be gently forced into bloom. Where a good stock of these plants is grown a few may be introduced at a time, in order to form a succession. Well grown single plants in 6 or 7-inch pots when in flower are most useful for room decoration, where they will stand without the slightest injury.

**Azaleas.**—The varieties of *A. amœna* and *A. indica* as they finish blooming should be placed in a vinery having a warm moist atmosphere. If placed again in the greenhouse the plants are seriously checked and make their growth late, rendering them unfit for early forcing another season. When placed in warmth they soon commence active growth, and if they need more root room should be potted directly the roots display signs of activity. If the plants are in pots large enough when their roots are active give them a little chemical manure on the surface of the soil. Two dressings during the growing season will be ample.

**Lantanas.**—These should have enjoyed a good rest, and may be started again into growth. Prune the shoots well back, and place the plants where they can be syringed once or twice daily, and where the temperature ranges 50° to 55°. The plants under these conditions will soon start, when they may be repotted. The old balls should be reduced by one-half and the plants placed again in the same sized pots in loam. Very little water is needed until the plants are growing and rooting freely.

**Freesias.**—As these cease blooming, if the bulbs are needed for another year they should not be cast on one side in any out-of-the-way place. The pots ought to be arranged on a shelf where the temperature ranges at least 45°, and the plants supplied with water when they need it. A little chemical manure applied to the surface of the soil will assist in developing the bulbs for another season. These plants increase rapidly, and even the small bulbs soon develop into a flowering size.

**Grevilleas.**—Plants that have done duty and have become shabby may be cut close back. Some growers throw them away, but this is a mistake, as they make even better plants the second season than the first. If two or three shoots are needed these can be retained, and for some purposes are to be preferred to those with a single one. If plants with a single stem only are needed disbudding must be practised.

**Zonal Pelargoniums.**—Plants that have flowered and have been kept dry may now be pruned close back and placed in gentle warmth to break again into growth. If increased stock is needed cuttings may be inserted singly in thumb pots, and will root freely on a shelf if a temperature of 65° can be maintained. Young stock in 2½ and 3-inch pots may be placed in 5-inch. Press the soil firmly in the pots, and place the plants on a shelf where the temperature ranges about 50°; they will soon start into growth and flower.

**Daffodils.**—Plants that have bloomed in boxes should, after the flowers have been removed, be stood in a light place in a cool house. If

watered until the weather is sufficiently genial for placing them outside they will mature fair bulbs for planting outside. It is surprising how rapidly they increase in numbers. If the soil in which they were boxed was good no feeding is necessary. Nearly all the varieties of Narcissus that were potted or boxed fairly early will now flower freely enough. Do not give them too much heat at first, but when fairly on the move they may be placed into the forcing house.

**Prunus sinensis fl.-pl.**—As these go out of flower they should be cut close back and arranged in any house where an intermediate temperature can be maintained. These plants grow freely, and are very easily forced into bloom. *P. triloba* does not force so freely, and when forced loses to a very large extent that beautiful pink colour which renders it so attractive when flowered in a cold house.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### THE WEATHER.

THE weather last month has been the most severe I ever experienced in January. During the past month the thermometer here never rose above 32°, while the night temperatures ran between 5° and 10°, and only once so low as the latter.

#### QUEEN REARING.

The good qualities of queens depend entirely on their ovaries being capable of bringing forward the full number of eggs, and a large-sized sperm sac well filled with spermatheca. These properties exist in very small as in very large queens. I advise bee-keepers to raise all queens intended for stock in hives in good condition, having ample honey, pollen, and bees, at any time between the months of May and August, when drones are numerous. I may say, however, some of the most prolific and long-lived queens I ever possessed were raised in poor-conditioned hives.

The course I pursue in selecting or rejecting queens is to select queen cells on which a large quantity of wax has been expended, and that is prettily indented, rejecting those approaching to smoothness. From smooth cells I have had queen cells which commenced laying in less than an hour after creeping out of the cell, and as a matter of course such queens remain drone-breeders for life. I do not hesitate to keep queens which were raised from foul-broody stocks, and never had a recurrence of the disease; but it is different with those affected with chloric dropsical fever.

Bee-keepers who are prepared to make the most of their bees by raising queens early should set about doing so at once by getting ready nuclei boxes and other things required to make them miniature hives. My boxes hold four frames—one containing a queen or queen's cell, well covered with bees and filled with brood placed in one of these boxes, and the three other frames filled with foundation make capital nuclei; but two or more frames are better. Small as these nuclei are, when more than one queen is present they are liable to swarm, therefore it is advisable not to have more than one queen or one queen cell.—A LANARKSHIRE BEE-KEEPER.

#### MARKETING HONEY.

OWING to a variety of causes there has been a much greater difficulty in finding a ready market for really good samples of English honey than has previously been experienced, and from the many inquiries I have had from bee-keepers in different parts of the country I find the complaint is pretty general that there is still a quantity of honey on hand for which customers cannot be found except at ruinous prices.

The past season was not a good one; indeed, in some districts it was very bad, so that it cannot be owing to the glut of English honey that is on the market. It therefore behoves bee-keepers to seek the cause and, if possible, the cure for this state of things. One of the chief is the great quantity of foreign honey that is brought into this country, very little of which is retailed as foreign. One large dealer lately told me he was buying it at 35s. per cwt., which left a good profit even when sold at store prices. The public will buy because it is cheap; they do not mind about the quality, he said.

Bee-keepers should endeavour to create a local trade in their own neighbourhood among the consumers, as this is much better than sending it a long distance to a tradesman at a low price. It is surprising the quantity that can be disposed of in this way if put up neatly in saleable form, and made attractive. The 1 lb. screw-top glass jars are recommended; they are rather more expensive than the others, but are much more serviceable.

The different qualities of honey should always be graded, as there is a marked contrast in the colour and flavour of honey obtained from field Beans, white Clover, and Limes. These are the sources from which I obtain the chief of my honey harvest. The former is brown, and of strong flavour. White Clover is of splendid flavour and perfect in colour, whereas that obtained from the Limes is of a pale yellow tinge, which gives it a pleasing appearance. These if bottled separately are much more useful, as some people prefer the stronger-flavoured brown honey, and *vice versa*. Very few people will buy from the shops if they know a genuine article can be procured from a neighbouring bee-keeper.

For larger quantities wide-mouthed brown pot-jars are useful. These are made with a cover, to hold from 7 lbs. to 9 lbs. Comb honey in 1 lb. sections, if well sealed, will find a ready sale among the consumers, particularly in the late summer and early autumn; but few tradespeople care to stock them, owing to their liability to damage. If they are glazed it is a great protection, but it would add to their price. Bad trade, too, affects the sale of honey very considerably. It is, however, better to keep a stock in hand unless a fair price can be obtained, as there may be a scarcity another season.

A few years ago there was no difficulty in obtaining 1s. per lb., and even more, for honey that was very inferior to what is now obtained under the modern system, for with the exception of Heather honey such prices are a thing of the past.—AN ENGLISH BEE-KEEPER.

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Dressing Vine Rods (Kidderminster).**—The ingredients recommended by Mr. H. W. Ward in the second paragraph of his letter on page 102 last week are sufficient for mixing in eight gallons of water. The word "eight" was inadvertently omitted by the printers.

**Temperature for Dendrobium densiflorum (Books).**—The Dendrobium mentioned will be quite safe if the temperature does not go below 40° during the winter, but 50° as a minimum is much better for these evergreen kinds. Their natural flowering season is about April or May.

**Steam from Zinc Plate (W. L.).**—The steam from a heated zinc plate is more or less injurious to vegetation. This mainly arises from the generation of the water vapour at a high temperature, and the fineness of its particles, which become rapidly diffused, and coming in contact with the foliage of plants has a more or less scalding effect. The leaves and other parts of plants being also much colder than that of steam rapidly condense the moisture, which interferes with their respiration, and has a weakening tendency. It is bad practice, therefore, to syringe highly heated surfaces. Zinc, so far as we are aware, does not give off any fumes injurious to plants, but it is not a desirable substance to use for heating purposes, as certain decomposition takes place under the influence of moisture, and such moisture may contain deleterious matter under steaming.

### PROFITABLE LIVE STOCK—SCOTCH CATTLE.

THE superiority of Scotch beef has obtained such general recognition that it has a special quotation on the London markets, the price always being higher than that of any other beef. This is an outcome of good management, affording proof of the profit of really intelligent breeding and feeding. It has reference to the prime Scotch beasts sent regularly to Smithfield, and not to just a few extra choice beasts specially fed for exhibition. This is the fact, but results at cattle shows in recent years, where the leading breeds are brought into competition, tend to emphasise the cattle dealers' opinion by placing Scotch beasts before all others.

To take an example we may point to the remarkable success of Mr. Clement Stephenson, who in 1893 and 1894 won the champion prize at Birmingham, with Bridesmaid of Benton in 1893, and Benton Bride last Christmas, both out of the same Aberdeen Angus cow—the famous Bride 13,343. Since the last cattle show it has been announced that Bride has another calf, "a most promising one, just as fine as could be. Bride is certainly a grand cow for a breeder to own. She is very short-legged and wide-bodied, milks like a good dairy cow, never gives any trouble, settles to the first service, and produces a good calf every year. She was calved December 7th, 1886, and this is her seventh calf."

Such a description causes us to regret that every heifer from such a cow has not been saved for breeding. But when it is remembered that Mr. Stephenson must have received about £1000 in prizes, and for this and the sale of Benton Bride alone, it must be admitted that he has a grand incentive to try again in the same direction. It was the general opinion that Benton Bride was superior to those other prizewinners of Mr. Stephenson's—Bridesmaid of Benton, Achievement, and Luxury. Her form was as near perfection as we shall ever see, flesh well and evenly laid on, fine bone, short legs, frame wide and deep, a model of symmetry, and yet so massive that there seemed more of her than the reserve beast, the Queen's shorthorn steer Masterpiece. Her age was about thirty-four months, and she weighed 16 cwts., 2 qrs., 21 lbs.

It is certain that the exhibition of such magnificent examples of this breed has done much to induce more general attention to its high value. The sales of Aberdeen Angus last year were remarkably successful, many being purchased to form the nucleus of fresh herds both in England and Ireland, where an association has been formed for the extension of this excellent type of the polled breeds in that country. Quality and merit have been kept well in view in the development of the Aberdeen Angus in Scotland; it will rest with breeders in the sister countries to maintain the high standard of excellence to which they have been brought.

That older type of polled breeds, the Galloways, is well known to repay one for all the care that can be bestowed on it. In no breed does selection and breeding tell better, or prove more profitable. These are remarkable for the long silky black hair—in such striking contrast to the short coats of the Aberdeen Angus, for points of excellence all over them—long sides, well-sprung ribs, well-rounded hips, straight and broad backs, width of chine, deep prominent chests, and short legs. Many of them are good milkers. For hundreds of years have they been sent over the border into England in very large numbers. On the rich pasture of the midlands they answer so well that they become larger and heavier than in Scotland.

They are very hardy, bearing exposure better than short-coated cattle; but even they with their long shaggy coats are the better for shelter. So kindly are they that a Galloway cow is said to cost £2 or £3 a year less to keep than a shorthorn.

In 1892 a remarkable feat was achieved at the Smithfield Cattle show in the winning of the champion prize by a cross-bred, a blue-grey from a Galloway cow by a shorthorn bull. Blue greys are in high favour on the border for the early maturity, choice quality, and heavy weight of cattle from this cross. A brisk demand for blue greys sprang up after the show of 1892, affording one more instance of how prompt graziers are to adopt and turn real improvements in breeding to account. We have no doubt that if only really well-bred cattle on which profit is a certainty could be had in sufficient numbers there would be an end of the sale of mongrel breeds on our markets. Ample materials have we for breeding with for such a purpose, let us turn them to full account and so have really profitable live stock, to the exclusion of all that is inferior.

### WORK ON THE HOME FARM.

Very trying has the weather been for all live stock. As we are writing there is snow lying everywhere several inches in depth, and a bitter east wind, with 6° of frost, at midday. Animals exposed out in the open in such weather, if at all low in condition, have a severe struggle for bare life. Every scrap of food they can get goes to support vital heat—the heat on the maintenance of which life itself depends. What wonder, then, if many of them die outright, under such insane exposure, such reckless mismanagement, such shameful cruelty. To those having and using proper means of shelter, we advise making a close inspection now of every enclosure, in order to ascertain if the yards and hovels are really snug. It is not an uncommon thing to see yards with nothing but posts and rails; such yards are wind-swept, the cattle would find more shelter in pasture with a thick hedge to break the force of the wind. Or hovel shelter may be very inadequate. We have actually seen at a so-called model home farm hovels for stall-fed fattening beasts so narrow that the hind quarters of the beasts were barely covered by the eaves, and they must have frequently suffered from wind-driven rain and snow, one side of the hovel being left open.

Now is the time to look into all such matters, while the yards are full and faults are readily detected. It is the yards shut in by buildings or enclosed by walls, boarding, or corrugated iron sheeting that are worthy of the term "snug," which afford cattle real shelter. Make the shelter of buildings equally efficient, keep out wet and cold cutting draughts, keep the floors dry and the litter clean, then indeed will the food be turned to best account. This may be repetition of advice often given before, but so long as we see so much negligence and evidence of so little thought in the management of live stock, we are bound to persist in calling attention to the fault and its consequences. It is a good plan during such cold weather to improve the quality of the dietary by using more crushed Oats or mixed corn. This is always eaten greedily, and it can be followed by straw, hay, chaff, roots, only make sure of the more nutritious food being eaten first. A free hand with food now is true economy; it keeps the store beasts steadily improving, and in the dairy cows keeps up a full flow of milk.

### REMARKS.

- 27th.—Sun shining through fog all day; snow showers from 7.30 P.M.  
 28th.—Snow showers early and till 9 A.M.; unbroken sunshine from about 11 A.M.; clear night.  
 29th.—Fog all morning, but very little in afternoon and evening.  
 30th.—Alternate sunshine and sprinkles of snow in morning; cloudy afternoon.  
 31st.—Fine early with solar halo at 10 A.M.; heavy snow shower at 11.15, sun again at 11.30, snow and soft hail from 11.55 to 0.45 P.M., and frequent slight snow showers during the rest of the day and night.  
 1st.—Snow in small hours; overcast all day, with occasional sprinkles of snow.  
 2nd.—Snowing more or less from 1 A.M. and at intervals all morning; overcast afternoon and evening.  
 A very cold week, owing chiefly to uniform low temperature, and not to any one excessively low reading, the lowest 17.2° having often been exceeded at this station.  
 —G. J. SYMONS.

# WEBBS' NOVELTIES

OF STERLING MERIT.

(Now Offered for the First Time.)

## Webbs' New Broccoli, SNOWDRIFT

Firm white heads of good size and quality, and well protected.

1s. 6d. and 2s. 6d. per Packet, post free.

## Webbs' New Brussels Sprouts, PRIZETAKER

For exhibition purposes, or for culinary use, this new variety is unexcelled.

1s. per Packet, post free.

## Webbs' New Onion, MASTERPIECE

A handsome new variety, of globular shape, growing to a large size, and a good keeper.

1s. 6d. per Packet, post free.

## Webbs' New Pea, ENTERPRISE

Its dark green pods are produced abundantly, and contain from eight to nine large Peas of the finest quality when cooked. Height 2½ to 3 feet.

5s. per Pint, post free.

## Webbs' New Potato, GOLD-FINDER

A most handsome, round, white-skinned, main crop variety, very productive, and of unsurpassed quality when cooked.

6s. per Peck of 14 lbs.; 21s. per Bushel of 56 lbs.

## Webbs' New Potato, PROGRESS

This new main crop kidney Potato is exceedingly prolific, and most valuable for either table or exhibition use.

6s. per Peck of 14 lbs.; 21s. per Bushel of 56 lbs.

## WEBBS' SPRING CATALOGUE,

POST FREE, 1s.

ABRIDGED EDITION, *Gratis and Post Free.*

## WEBBS' Wordsley, Stourbridge

# ANT. ROOZEN & SON'S CHOICE VEGETABLE & FLOWER SEEDS

FOR PRESENT SOWING, AND

## BULBS AND PLANTS, FOR SPRING PLANTING.

## COLLECTIONS of VEGETABLE and FLOWER SEEDS,

Made up of the most popular Varieties, and to suit all requirements, from 2s. and upwards.

DESCRIPTIVE CATALOGUE of the above, with CULTURAL DIRECTIONS, will be sent post free on application to our Offices at OVERVEEN, near HAARLEM HOLLAND, or to our General Agents—

Messrs. MERTENS & CO.,  
3, CROSS LANE, LONDON, E.C.

## IF YOU WANT REALLY GOOD SEEDS

At MODERATE PRICES, apply to MR. ROBERT SYDENHAM, Tenby Street, North, BIRMINGHAM.

NO NURSERYMAN WILL SERVE YOU BETTER IN QUALITY, QUANTITY, OR PRICE.

### THE SIX BEST TOMATOES

In cultivation, often sold under other names to get fancy prices. Each packet contains nearly 200 seeds. Perfection, 3d.; Ham Green Favourite, 3d.; Hackwood Park Prolific, 3d.; Challenger, 3d.; Roseleigh Gem, a grand new large smooth selection, 3d.; Golden Perfection, the best yellow, 3d. Collection, 1s. 3d., post free; singly, 1d. each extra for postage.

### THE FOUR BEST CUCUMBERS.

Each packet contains 10 seeds, Lockie's Perfection, Rollison's Selected Telegraph, Epicurean, and Covent Garden Favourite, 6d. each; or the Collection, 2s., post free; singly, 1d. extra for postage.

### SWEET PEAS—A SPECIALITY.

ECKFORD'S and other choice varieties at a third or a fourth usual prices.

Nothing gives so much cut bloom at so small a cost, or so little trouble. To get best results SOW AT ONCE, as directions sent with each Collection.

### SPECIAL VERY CHEAP OFFER.

8 Really Good Varieties—Queen of England, white; Blanche Ferry, pink and white; Princess Beatrice, pale pink; Apple Blossom, apple blossom tint; Orange Prince, orange pink; Splendour, rich deep rose; Cardinal, bright cardinal; Countess of Radnor, pale heliotrope, 25 seeds of each, 1s. 3d.

7 Extra Choice and Newer Varieties—Emily Henderson, fine large white; Venus, pale lemon flushed with pink; Mrs. Gladstone delicate pink; Her Majesty, soft rosy pink; Lady Penzance, bright pale rose; Firefly, bright glowing crimson; Monarch, large bronzy purple, 25 seeds of each, 1s. 6d.

The Two Collections, 2s. 6d.—Postage 2d. each Collection extra; or the two 3d. extra.

EXTRA CHOICE MIXTURE, 3d. per 100 seeds; postage 1d. extra.

ALL OTHER SEEDS EQUALLY MODERATE.

FULL LISTS POST FREE ON APPLICATION.

## Journal of Horticulture.

THURSDAY, FEBRUARY 14, 1895.

### THE FROST AND THE FUTURE.

AT the moment of writing frost is king and rules with unwonted severity. Zero! zero! zero! is what we have seen recorded day by day, varied by indications of still greater intensity of few or many degrees below zero, according to the locality, the position of thermometers, and their individual peculiarities. Yet making full allowances for the disturbing influences of the nature suggested, and which preclude the returns in the majority of cases being regarded as strictly accurate, the frost of February, 1895, will still rank among the most severe that have been experienced for several years. Coming after an autumn of abnormal mildness, in which vegetation did not seem able to go to rest, the extreme cold has, perhaps, been felt the more keenly. Its area has also been wide, whilst its continuance, depart when it may, has been long enough to satisfy most persons except skaters and coal dealers. If rime and fog may be regarded as the precursors of a change we may hope to have seen the beginning of the end, for we have had the blackness of night in London (on the 9th inst.), whilst in the suburbs every twig and spray was laden with chaste crystals.

For the full effects of the arctic severity to be appreciated we must wait, though its inconveniences are only too apparent. In towns the freezing of water in supply pipes and gas in the mains cause discomfort to thousands, yet it is still more saddening to feel that thousands more have been to a serious extent deprived of warmth and food, and some even of life. It is on such occasions as these, when work is practically at a standstill, that the evil is seen in all its magnitude of the crowding of our working-class population in cities and towns; but how to avert this is a problem yet unsolved, and a serious problem, as we shall probably see in the not far distant future.

To return to the frost, though in London it has been less severe than in the midlands and the north, thermometers have registered 28° of frost, and in the suburbs the cold has fallen to zero. The Thames has been covered with ice floes, slabs piled on slabs stopping traffic and presenting a veritable arctic scene. Seagulls have come in thousands in search of food, and

where birds have been fed in suburban gardens they have come in shoals—thrushes, fieldfares, blackbirds, with others—and fought for the scraps and the crumbs scattered far from their haunts and where in the ordinary course of things such birds are never seen. It is somewhat of a mystery how so many ascertain so quickly where the food is spread; yet, by whatever means the news may be conveyed, it is a pity the birds should die, for even if they do take a few Strawberries from gardens in the summer, do they not take Strawberry and other enemies too in the form of snails and various depredators hidden from human eyes?

But though the frost in London has been unusually keen we have to take a wider survey to comprehend its full intensity. In Scotland records are published of the cold reaching 12°, and in some cases more, below zero, and it seems to have been much the same in Derbyshire, Leicestershire, Lincolnshire, and Yorkshire. Many are the trees, shrubs, plants, and garden crops that must suffer by the extreme visitation, but they will not show it fully till the time for sap movement in the spring. In some districts the snow will have proved its protective value, for there appears to have been abundance in some localities, and indeed too much from an obstructive point of view, for we read of blocked roads and railways and snowed-up villages, for the inhabitants of which food could not be conveyed. In the vicinity of London there have been no such obstacles, the greatest snowfall being in many places about 2½ inches, and accumulations not exceeding 3 inches. It is therefore possible that the damage to many plants and vegetables may be even greater in the south than the more northerly parts of the kingdom.

Great, too, must have been the difficulties of gardeners and amateurs innumerable, in maintaining the requisite temperature in glass structures, or indeed excluding frost from many of them, and there are doubtless many disasters to be deplored. These may in most cases be attributed to inadequate provision either in the size of boilers or too limited areas of heating surface, known as "short of piping"—a misfortune too commonly experienced. As the strength of the chain is determined by the weakest link, so should the provision made for the warming of glass structures be based on the severest frosts which are likely to occur in this country. The last great frost, in the beginning of the year 1881, brought many disasters, and taught significant lessons, heeded by many owners of glass structures, but not by all. History is now repeating itself, and those who are induced to make good all defects of the nature indicated will be gainers in the end—gainers in the fuller, more certain, and better supply of what they need, as well as gainers financially by the saving in fuel which would otherwise be blazed away by the roaring fires which have to be kept up all night long by constant attendance, whereas with sufficient boiler power and piping not half the consumption of fuel would be necessary. There is no lack of choice in boilers suitable for all positions and kinds of fuel, while the increased cost involved in providing piping exceeding the "absolutely necessary" limit, as based on average temperatures, is the reverse of formidable. It is unwise because unsafe, and may be most costly, to base calculations in this work on averages at all, as this amounts to spending money for a breakdown, which is only a question of time when the frost king comes his rounds again and makes his power felt, as in the case of the present February winter. All defective means of heating should be made good as soon as circumstances permit, and new structures be sufficiently equipped for doing the work that is expected of them when the next strain comes.

Also, too, would we venture to suggest the advantage of timely equipment for the most effective discharge of seasonable routine operations. A period of rest is the time for making ready for best meeting coming demands. Much work is planned, such as in planting, that remains undone, and there may be a disposition to let a considerable amount of this stand over till another year. That may be far from being the better plan, and if what is

required be ordered in readiness for arrival when the favourable time comes, the results may be even very much better than if the work had been completed just before the frost. When and where much spring planting has failed, the cause of it can in most instances be traced to leaving the dispatch of orders till the last moment, and thus letting favourable opportunities come and go before what is required can arrive at its destination. This apparently small mistake has in many instances led to great disappointment and loss that might have been averted.

Severe and protracted frost of necessity brings much work to a standstill, and some for which there is not the least need. It is a pity this should be so, but so it is. Take, for instance, the ordering of seeds of various kinds. They must be had if flowers and vegetables are to be produced in due season, yet through want of thought, or of knowledge as to the facts of the case, hundreds of men in seed-supply establishments are kept in semi-idleness during periods of frost, and then when the weather changes, and the seeds are wanted, are compelled to work nearly all night long under the unhealthy conditions of a gas-impregnated atmosphere, while gardeners are being prejudiced because they cannot lay hands on the seeds at the most favourable moment for making the best of them. Seeds cost not one penny more through being ordered early, and are as safely and soundly kept in the drawers of the purchaser as the vendor, while the workers in warehouses and shops are benefited by steady action—the result of timely orders, while gardeners and amateurs are advantaged by having possession of seeds well in advance of the time of sowing.

Though a check has perforce been given to progress in gardening by the frost that will be memorable, activity will be all the greater when it goes and spring-time comes to cheer us on—to incite new hopes and stimulate to fresh endeavours. Never was greater interest manifested in gardening, both in its useful and ornamental aspects than now, and never were so many persons engaging in the pleasant, wholesome, mind-inspiring, and health-giving occupation. We would wish for all, now that "winter lingers on the lap of spring," a season teeming with an abundance of what they desire to produce; and one way of bringing about the realisation is to file the present issue of the *Journal of Horticulture*, as we take the liberty of thinking it is full of good things, both in advertisements and literary matter, and we have reason to believe there are others equally good to follow for meeting the varied tastes of readers all over the kingdom and beyond its shores. May 1895, after this rest at the beginning, prove in the end a good year to them all.

LÆLIO-CATTLEYA DECIA.

MANY charming hybrids have emanated from the nurseries of Messrs. J. Veitch & Sons, Chelsea, and among these may be included the beautiful Lælio-Cattleya Decia, a bloom of which is depicted in the illustration (fig. 21). This is the result of a cross between Cattleya Dowiana aurea and Lælia Perrini, the first named being the pollen parent. In many respects the flower resembles a Lælia more than a Cattleya, except in size. The sepals and petals are very pale rose, the lip at the base being rosy mauve, with a deep purplish crimson lobe. This fine hybrid was exhibited by Messrs. J. Veitch & Sons at the Drill Hall, Westminster, last year, and a first-class certificate was awarded for it by the Orchid Committee of the Royal Horticultural Society

CŒLOGYNE FLACCIDA.

THE specific name of this Cœlogyne refers to the drooping character of the inflorescence. The racemes are many-flowered

and of considerable length, the flowers being set rather widely apart. The flowers are white, except the lip, which has the yellow blotch common to most *Cœlogynes*. The pseudo-bulbs are 4 to 5 inches in length, the dark green lanceolate leaves which are produced in pairs are from 8 to 10 inches long. The plant has an erect habit of growth, and when in flower is very attractive. The flowers are produced very freely in winter and early spring, and last a long time in full beauty. *C. flaccida* requires an intermediate temperature—the *Cattleya* house suits it very well—and should be well rested. It was introduced from Nepal by Dr. Wallich, and first flowered at Wentworth in 1833. A handsome plant carrying ten spikes is now in flower at Messrs. J. Veitch & Sons, Chelsea.—A.

#### MASDEVALLIAS.

THERE is probably no more interesting or fascinating genus of Orchids in cultivation than *Masdevallias*, and certainly no other

The roots then, and how to conserve them, must be the grower's first care. Anyone who has had a little experience with Orchids will have noticed how these delight in rambling about over the hard porous surface of the pots where they are fully exposed, often quite dry, and have nothing of a close nature about them. Here then is the cue for root preservation, and in preparing the compost for these beautiful plants growers must keep in mind the necessity of providing for a constant supply of air to the roots, at the same time checking too rapid evaporation, and providing the necessary nutriment. The plants must not be dried at the roots at any season, but no stagnant moisture must be allowed to collect about them. They all thrive in a cool house during the summer, and must have a light airy position shaded from bright sunshine.

The winter temperature must not be allowed to fall much below 50° for the *Chimæra* group, while 45° is quite low enough for the

FIG. 21.—LÆLIO-CATTLEYA DECIA.

contains such a wondrous variety of form or beautiful combinations of colouring.

The lover of the grotesque will delight in such exquisite little gems as *M. Estradæ* and *M. trochilus*, or the wonderful *M. Chimæra*, while those who look for brilliant colour and simple form will find ample to please them among the *Harryana* and *Lindeni* section. *Masdevallias* as a genus are not difficult to cultivate, but they show the results of indifferent treatment sooner than many others. For instance, an *Odontoglossum*, or even a *Cattleya*, may not have a sound root in the pot in which it is growing, and yet an inexperienced person would not for a time detect anything wrong by the appearance of the pseudo-bulbs or leaves, because the stored-up nutriment in the former keeps the plant going for a time without much assistance from the roots, and may perhaps produce a few flowers. *Masdevallias*, on the other hand, if once the roots get in a bad way, show the effect almost at once, as they have no pseudo-bulbs to sustain them, and are naturally more sensitive to atmospheric changes.

*Harryana* and *Veitchi* sections, and in fact for any cool house Orchid. The chief insect enemy to *Masdevallias* is the yellow thrip, and unless constant war is waged against these they soon get the upper hand, ruining the appearance of foliage and flowers. *M. amabilis*, *M. Harryana*, *M. Chelsoni*, *M. Veitchi*, *M. ignea*, *M. coccinea*, and *M. Lindeni* will be found a good selection of the showy flowered types. These are natives of Peru and New Granada except *Chelsoni*, which is a hybrid raised by Messrs. Veitch & Sons from *M. Veitchi* and *M. amabilis*. *M. tovarensis* is the only well known white flowering kind, and was recently described in the *Journal of Horticulture*.

*M. Chimæra*, *M. Backhouseana*, *M. Bella*, and *M. Wallisi* are amongst the most marvellous productions of the whole Orchid family, and I hope to refer to the culture of these more fully in the near future. Of the small flowered section *M. triaristella* and *M. triangularis*, as well as those named above, are free flowering, elegant, and very interesting species.—H. R. R.

WEATHER IN LONDON.—Severe wintry weather still prevails in the Metropolis, though there have been no further falls of snow during the past week. This morning (Wednesday) the thermometer in the southern suburbs registered 16° of frost. On Saturday last a thick fog hung over the Metropolis, and at time of going to press a raw, dull atmosphere prevails.

— WEATHER IN THE NORTH. — Intensely severe weather has marked the past week. On the 5th inst. another snowstorm raged furiously along the east coast, and blocked the northern railway lines for the third time. The frost of 6° on that day increased to 27° on the 10th, 26° and 22° being recorded on Monday and Tuesday mornings, but from various parts of the country readings below zero are reported. The days have been brilliantly clear and bright, and no change was indicated on Tuesday.—B. D., *S. Perthshire*.

— EXTRAORDINARY FROST.—Mr. David Thomson sends us from Drumlanrig the following readings from a meteorological society's thermometer in a sparred box 4 feet from the ground:—

February	8th	..	..	..	..	8°	below zero.
"	9th	..	..	..	..	9°	"
"	10th	..	..	..	..	12°	"
"	11th	..	..	..	..	4°	"

At twelve o'clock at noon, with bright sun, the instrument registered 22° below freezing. Mr. Thomson states that the lowest previous reading was 5° below zero in 1860, and further observes he has never seen on four successive nights such low readings as those quoted, and doubts if such have occurred in the century. We have received many notes of the weather, but as we have to prepare for press sooner than usual this week they arrived too late for insertion. At Aldin Grange, Durham, Mr. W. A. Jenkins mentions 5° below zero as the lowest reading there on the morning of the 8th inst. Messrs. Fell & Co., Hexham, registered 2° below zero last Friday and Saturday. Mr. A. Bartley, Eshwood Hall Gardens, Durham, has registered 3°, 7°, and 8° below zero. Mr. Forbes mentions 2° and 3° below zero as low readings at Hawick; and Mr. A. Keith, gardener to Sir G. O. Trevelyan, 10° below zero at Wallington, Northumberland.

— ENGLAND IN THE ANTIPODES.—The suburbs of Christchurch, New Zealand, are English villages, the streets are English lanes, the paddocks English meadows, the parks and gardens are likewise English. The river that flows through the city is the Avon. It runs bright and clear, Willows overhanging the banks, and English trout glide up and down the stream. How green and beautiful are the English trees that grow there—Oaks, Elms, Larches and Beeches, Willows, Poplars, and Elders. The town is surrounded with rich meadows, divided by Briar and Hawthorn hedges, all adding their share to the truly English character of this far-off country.

— ROYAL CALEDONIAN HORTICULTURAL SOCIETY AND THE LATE MR. WILLIAM THOMSON.—Mr. Charles Stewart, W.S., 4, Albyn Place, Edinburgh, writes:—"At the last meeting of members of the above Society, held in Edinburgh, it was agreed that a fund should be instituted and the interest thereof applied in providing prizes in memory of the late Mr. William Thomson, Clovenfords, such prizes to take the form of medals and sums of money to be awarded for exhibits at various shows in the United Kingdom in the same manner as the Memorial prizes already in existence, and Mr. Thomson's family have expressed their approval of the proposal. To carry out this scheme it is proposed that a General Committee should be formed to collect subscriptions, and circulars are being sent out inviting gentlemen to join such Committee. When this Committee is formed the members will send out circulars and collect subscriptions from their various districts, but as no doubt there may be many who would be willing to subscribe and who may be overlooked by the Committee, or not known to them, and who can only be reached by public announcements in the Press, it has been suggested that the gardening papers should be asked to insert a paragraph relating to the proposed object. I have been appointed interim Secretary for the Committee, and shall be glad to receive subscriptions or intimations."

— NATIONAL VEGETABLE SHOW.—At a meeting at the Royal Aquarium on Tuesday last the following resolution was proposed by Mr. R. Dean, seconded by Mr. Cummins, "That as the prospect of holding a National Vegetable Show at the Royal Aquarium in September next is by no means of an assuring character, the holding of such an exhibition be postponed to another year."

— CHINESE PLANTS.—China has yet many charming ornamental plants in store for us, as was evident from an exhibition of dried specimens at the Linnæan Society on Thursday last by Mr. W. B. Hemsley, on behalf of the Director of Kew Gardens. A new *Jasminum* in the way of *J. nudiflorum*, but having flowers nearly three times as large, was much admired, and would certainly be a great acquisition to our gardens. It was collected in the western province of Yunnan by Mr. W. Hancock, but too early in the season to secure seed. A new species of *Brandisia* from the same region is a highly ornamental rambling shrub with crimson flowers, reminding one of the Mexican genus *Lamourouxia*, belonging to the same natural order—namely, the *Scrophulariaceæ*.

— EUCHARIS BLOOMS FROZEN IN WATER.—Many people are under the impression that if delicate flowers are exposed to the cold they will immediately perish. That such is not the case can be proved in the fact that recently a quantity of *Eucharis* blooms were gathered and placed in a shallow dish of water and placed on a fruit-room shelf. During the night a severe frost set in, and the next morning the flowers were frozen stiff in the water. No steps were taken to extricate them, nor were they touched in any way, but the dish was left until the water thawed slowly. The blooms were then taken out and used, apparently none the worse for their starving. It would be interesting to learn, by experiment, how long such flowers would remain fresh in a frozen condition.—G.

— GLASGOW FRUIT TRADE.—At the first annual soirée of the Glasgow and District Fruit Merchants' Association, held recently in the City Hall, the Chairman, Bailie James Ferguson, remarked that the fruit trade of the city has been one of tremendous growth. Not so many years ago the quantity of Grapes brought into the city consisted of some 500 barrels, which supplied the city and surrounding districts. Last year one broker sold alone 104,000 barrels. This growth in Grapes also applies to every other kind of fruit. The trade has grown to such an extent that the bulk of the business is conducted outside the bazaar altogether, and he thought the time had now come when the Council should increase the accommodation they required. As regards the brokers they were a smart class of men; but he considered that the conduct of the business was in many respects more favourable to them than to the merchants.

— VANILLA PODS.—In reply to Mr. J. Crispin, F.R.H.S., January 31st (page 92), I may say that the Vanilla pods of commerce—not the *V. aromatica* as long believed, but shown by the investigations of Morren and Schiede in Mexico to be those of *Vanilla planifolia*—are gathered as soon as they become yellow, and are carefully dried by exposure to the sun's rays until they are made warm, in which state they are wrapped in woollen cloths, to promote evaporation and absorb the vapours. By this process the Vanilla acquires a black hue, often silvered over with glistening white prisms. The slender pods, 8 to 12 inches in length, are seldom of good quality when grown in this country, and dried in the ordinary way by exposure to natural or artificial warmth, but when prepared in the manner described they are considered in some respects better than the commercial article.—G. A.

— THE HORTICULTURAL CLUB.—The twentieth anniversary of the Horticultural Club was held at the Hotel Windsor, Victoria Street, London, on the evening of Tuesday, the 12th inst. The chair was taken by Sir J. D. Llewelyn, Bart. There was present a very large proportion of members considering the inclement state of the weather. The table was beautifully decorated with flowers and fruit generously provided by Messrs. Harry Veitch, T. Francis Rivers, and George Paul. Some half a dozen toasts were given, including that of the Horticultural Society, and in the course of the evening kindly reference was made to the presence of the Rev. W. Wilks, now convalescent, and to the long and excellent services of the Rev. H. H. D'Ombrian, the Secretary of the Horticultural Club. The evening was most agreeably diversified by a musical programme executed by the Maidstone Quartette, under the direction of Mr. George Bunyard, and two delightful solos on the English concertina were performed by Mr. Harry Turner.

— FLORIDA'S CROP OF PINE APPLES last year is estimated to reach 50,000 crates, or fully 2,300,000 Pine Apples.

— MR. JOHN R. WARD, an old Kewite, who for the past twelve months has occupied the position of Superintendent of the Nagpur Botanic Gardens, India, died, we much regret to hear, quite recently.

— THE extensive and valuable BOTANICAL LIBRARY OF THE LATE PROF. N. PRINGSHEIM has been presented to the German Botanical Society, of which he was President, together with a sum of 25,000 marks for its maintenance.

— PHOSPHORUS IN APPLES.—Mr. G. Searles recommends the eating of Apples just previous to going to bed. Its use at such a period of the day is said to assist the digestive organs, absorb any excess of acid in the stomach, and insure calm sleep to the eater. The Apple he contends contains more phosphorus than any other fruit or vegetable, and, after the fruits of the Citrus family, it is the best natural disinfectant of the mouth.

— ROSES FROM AUSTRALIA.—A bunch of frozen Roses from the garden of the Editor of the New Zealand "Truth," St. Albans, Christchurch, has recently been an object of some interest at the Royal Aquarium. The bunch was of good size, and appeared to consist of blossoms of rose and red Bourbon varieties, mingled with which were blooms of Gloire de Dijon. The flowers had retained their colours in a very satisfactory manner, but of course soon fell to pieces after the block of ice in which they had been frozen thawed down to the edges of the petals.

— WAKEFIELD PAXTON SOCIETY.—At the meeting of this Society, held on Saturday, 2nd inst., there was scarcely so large an attendance as usual. Alderman Milnes presided, and Mr. J. G. Brown was in the vice-chair. The lecturer was Mr. Haigh of Sheffield, who has previously appeared in the same capacity before the Society, and who on this occasion dealt with "The Sporting Character of Flowers" in a very lucid and interesting manner. He spoke of the means that were adopted to obtain a superior form of plant, and pointed out that in the cultivation of plants we reversed the order of Nature, both the strong and the delicate being sacrificed to the weakly seedling. If we followed Nature, he said, we should have very few of our most chaste flowers. Mr. Haigh dealt also with cross-fertilisation and the variation of plant life, remarking that unless attended to plants would revert to their original type. The strongest would survive, but only in a degenerate form. A discussion followed, and at the close a vote of thanks was passed to the essayist.

— CHICKWEED AND RHEUMATISM.—I enclose slip on rheumatism, distributed for the public good by our octogenarian rector, Begonia raiser and gardener. He tells me of many cases that his remedy has cured. If you could find space for the same I expect there are many suffering gardening friends who would soon put it to the test.—G. BOLAS. [We find the space below.]

A CURE FOR RHEUMATISM WITHIN REACH OF ALL—I need not say how prevalent this ailment (RHEUMATISM) is, or how great is often the suffering from it—a ready and effectual cure for this ill, from which no one can claim to be always exempt, is a thing much to be desired. And having discovered such a remedy, or rather having led to the discovery of it, I wish to make it known as widely as possible. The remedy is very simple, and abounds almost everywhere where a garden is to be found; and I now proceed to name it and to describe the way in which it is to be prepared. Almost everyone knows the common weed called CHICKWEED. To prepare the remedy in question fill a bottle pretty closely with this plant, and then pour in spirits of wine sufficient to cover the whole. Cork the bottle, and let it stand any length of time. It will be ready for use in two or three days. To use the remedy, moisten the tips of your fingers with this tincture and gently rub it on the parts affected. Rheumatic pains will often take flight at the first application, as I have myself experienced more than once, and severe cases, whether recent or of long standing, will be effectually relieved by a few repeated applications—of this I have had abundant and satisfactory testimony. It will relieve also pains that often recur in old healed wounds upon change of weather, and the severe pains that many suffer from in hands with swollen joints, or chalk stones. Let no one despise this remedy because it is so common a thing, but if a sufferer, let him put it to the test, and I can assure him he will not be disappointed. Our commonest weeds, I doubt not, abound in valuable remedies, if we only knew how to discover them, not indeed by haphazard trial, but by scientific proving.—F. H. BRETT, *Carsington Rectory, Derbyshire.*

— DEATH OF MR. GEORGE TABER.—We much regret to hear that Mr. George Taber of Rivenhill, Essex, died on Saturday last at the age of 76. Mr. Taber was a Director of the well known seed firm of Cooper, Taber & Co., Limited. He was widely known in the trade, and highly respected.

— BEAUTIFUL CYCLAMENS.—Messrs. Sutton & Sons have sent us from Reading a sample of Cyclamens, and having regard to their size, form and variety of colours, these ranging from pure white to ruby crimson, we have seen no blooms to surpass and few to equal them. The accompanying stout marbled leaves are also ornamental and indicate superior cultivation.

— INK FOR ZINC LABELS.—Various kinds of ink are used for writing upon large labels. A continental contemporary says that here is one of the best:—"Dissolve one part of sulphate of copper and one part of chloride of calcium in thirty-six times their volume of pure water. Allow the writing to dry for two minutes, then wash with a good quantity of water, dry it, and wipe with a piece of cloth soaked in oil."

— THE "GREAT" CLASS AT WOLVERHAMPTON.—Our correspondent who favoured with the note on the Wolverhampton show (page 117, last week) was "quite shocked" when he saw it in print, but says he found consolation in the intelligence of his readers, who would be quick to perceive that the class is to consist of sixteen plants, not 116, as he wrote without his spectacles. He presumes also that London was under a fog, or his little accident would have been discovered in Fleet Street. The delicacy of the reference is appreciated.

— AFRICAN MAHOGANY.—Mahogany logs from the east coast of Africa have got as far west as Louisville, Kentucky, and an American contemporary says that it is much cheaper than the mahogany from Central America and Cuba. From these Mahogany forests in Africa it is said that 12,000,000 feet of lumber have already been cut and exported, and they promise to yield an immense revenue to the British and French colonists who have the territory. The wood has a tinge of pink in contrast with the somewhat reddish colour of the American variety, and some of the squared logs which have been imported are 2 by 3½ feet in size.

— EARLY CAULIFLOWERS.—We may well expect to learn when a thaw comes that great injury has been done to white Broccoli. It seems impossible that the plants can have successfully resisted the intensely severe frosts without great harm being done them. That fact renders it all the more imperative that sowings of the Snowball section of dwarf Cauliflowers should be made at once, especially where not previously done. I always made a first sowing of Snowball in January, but in a cold house. Where there is some warmth, growth is rapid, and it is surprising how soon plants can be had several inches in height, and strong enough to plant on a warm border early. Those hard pressed for heads because of the loss of Broccoli should try and grow some plants in 24-sized pots, or even plant a foot apart in a large frame. Heads so obtained would be of the greatest value. To get them early, however, sowings must be made immediately.—D.

— WEIGHTS AND MEASURES OF FRUITS.—In looking over the notes written, presumably by the late Mr. Collins, reference is made to Apples, "profit and loss." It affords me an opportunity of offering a few remarks respecting the present confusing system in different localities of weights and measures as applied to fruits and vegetables. Nothing seems to me more expedient than an Act of Parliament giving a scale of weights and measures to be used throughout the land. I must be pardoned if I am misleading in any of my quotations as applicable to Lincolnshire. There are 14 lbs. of Strawberries to the stone, 15 lbs. of Gooseberries, 16 lbs. of Currants, Cherries, and Plums; 16 lbs. of Apples to the peck, 18 lbs. of Pears, 20 lbs. of Potatoes; and in other vegetables sold there must be—Cucumbers thirteen to the dozen, bunches of Radishes thirteen, Cauliflowers thirteen, and Lettuces fourteen. Young plants of Cabbages, Cauliflowers, and Brussels Sprouts are sold at six scores to the hundred. In almost everything produced from the garden there is some excess above the actual number, weight, or measure, according to produce sold. It is impossible to put 20 lbs. of Potatoes into a peck basket, white a bushel of such in a corn measure of that size would weigh 56 lbs. without the vessel. An Act of Parliament showing a definite scale of weights and measures, to be used compulsorily throughout the country, would prove beneficial to those dealing in such articles, by putting to an end much of the confusion which now exists. I shall be very glad if any one of your readers will give their opinions on this important subject.—GEO. DYKE, *Stubton Hall Gardens.*

— **EUONYMUS JAPONICUS.**—Mr. Charles Leslie Melville has sent us from Messrs. Bush & Judd's Gardens at the Royal Marine Hotel, Ventnor, Isle of Wight, a fruiting spray of this plant, it being the first that has been received at this office. Mr. C. Orchard, Bembridge, writes:—"The *Euonymus japonicus* (green variety) is fruiting here in many places. It is much like the deciduous *Euonymus europæus*, but the berries are not quite so large."

— **ROYAL METEOROLOGICAL SOCIETY.**—At the ordinary meeting of the Society to be held at 25, Great George Street, Westminster, on Wednesday, the 20th inst., at 7.30 P.M., the following papers will be read:—"Report on the Phenological Observations for 1894," by Edward Mawley, F.R.Met.Soc.; "The Thunderstorm and Squall of January 23rd, 1895," by William Marriott, F.R.Met.Soc.; "On Some Gradual Weather Changes in Certain Months at Greenwich and Geneva," by Alexander B. MacDowall, M.A., F.R.Met.Soc.

— **WEATHER IN THE RIVIERA.**—The weather at the Riviera has not been so severe since 1865. The western part has suffered mostly, although the temperature is far below the average over the whole. At Cannes 3 inches of snow fell on January 6th, and was succeeded by severe frosts, 14° Fahr. having been registered. On the 28th from 10 to 12 inches of snow fell, and again in the early morning of February 1st from 6 to 8 inches. At the time of writing it was freezing hard, and every sign of its continuing. The Palms have been broken about by the weight of the snow, and everywhere great damage has been done.

— **WREATH MAKING.**—A simple and inexpensive wreath frame may be made with the young wood of Willows. Take two pieces about the thickness of the little finger, one for the inner circle, the other, and larger of the two, for the centre. Bend carefully and place about 2 inches apart, then with small twigs of Willow tie or weave together. When done the frame is substantial yet light. In arranging flowers I always lay the greater part of them in at once, leaving a few choice wired ones to fill up any vacant space. We must bear in mind that it is not the quantity of flowers so much as the taste and lightness in arranging that is so essential in wreath-making.—W. T.

— **THE GREAT YORK GALA.**—Thirty-seven years ago a few of the tradesmen and others of York met with a view of seeing whether a horticultural exhibition could be arranged for, and those present formed a guarantee fund, each to the extent of £10. Officers and committee were appointed, and the first exhibition in June of 1858 was held. The Society has gone on gradually progressing in influence, size, and funds, and a very large sum of money has during the thirty-seven years been handed to the York charities. The schedule for their next exhibition in June is a most liberal one, with fully £675 in money and medals and a silver cup. Excellent prizes are offered for stove and greenhouse plants and for groups. £10 as a first prize for a group of Carnation plants; £15 as first prize for a collection of Roses in pots. Prizes are offered for Orchids, including the "Veitch Memorial" medal and £5 for Orchids by amateurs. Great prizes, including the "Turner Memorial" silver cup and £5 for Pelargoniums. Splendid prizes are likewise offered for cut Roses and fruits.

— **TOMATOES IN FRUIT COLLECTIONS.**—It has been a disputed point for some time as to the admission of Tomatoes in fruit collections, and in large collections especially. I think it should be allowed, since the Tomato has been acknowledged as a fruit on the dessert table. The Shrewsbury Committee in their schedule for this year, in wording of this class for twenty-four varieties of fruit, say that three distinct varieties (or less) of Tomatoes, eight fruits of each, will be allowed, so this is plain enough. Mr. Mayne (page 115) refers to a case at the November show at Plymouth, where a local exhibitor had in his collection of six dishes of fruit, one of Tomatoes and one of Nuts. In such a case, and with no competitor against him, as was the case, I should have hesitated about giving him the first prize unless exceptional quality marked the whole. This object most societies have in view in offering prizes for six or eight varieties in the open class, so as to induce exhibitors to stage the higher class fruits obtainable at that season of the year, and the Nuts must have shown that the exhibitor was rather "hard up" unless they were very fine Cobs or Filberts. "A. D." (page 123) hits the nail by saying that, "In this matter committees who prepare schedules are generally most to blame, because conditions and requirements in competitions are so obscurely drawn." As to "C. K.'s" proposal of "appeal judges," it is a sort of nightmare dream. What man with any self-respect would act as a judge under such conditions?—W. D. [The Shrewsbury class might have been drawn better.]

— **DAPHNE INDICA.**—In far-off Australia this sweet-smelling shrub flourishes profusely, and in many parts of Victoria long stretches of hedgerows are composed of it. To dwellers in that country it is much appreciated, owing to the fact that there, as in many other tropical climes, the flowers have not the sweet fragrance they have in more genial countries. The hot north wind plays havoc with vegetation out there, causing the foliage to droop and wither in the same manner as frost does in England.

— **POST-CARDS FOR THE CONTINENT.**—M. Ernst Benary, Erfurt, requests us to state that—"Since people have been allowed in England to use post-cards of their own with an adhesive stamp affixed, large numbers of them furnished with a penny stamp have found their way over here. Now, if the words 'Post-card. The address only to be written on this side,' are printed on the address side, our post-office authorities will pass them, but if not, they are treated as insufficiently prepaid letters, and a fine of 3d. is inflicted. It is hardly necessary to say that this is a great annoyance and loss to firms who have a large correspondence with Great Britain."

— **IVY FOR WREATHS.**—Where Ivy is grown under certain conditions, especially when the soil is of a barren, stony nature, the leaves during the severe days of winter change colour to a rich reddish brown. In this state they are very useful for making up into wreaths and crosses, and if mixed with a little silver Holly look simple and very pretty without any addition of flowers. If used as a groundwork, or tastefully mixed to stand above the flowers, they also make a charming effect, as the pretty contrast between the rich red foliage and the flowers is very attractive. Many wreaths and crosses are made up of leaves alone at a trifling cost, and find ready sale in the markets.

— **HORDEUM JUBATUM.**—From a note in the "Botanical Gazette" we learn that the Fox-tail Grass or Squirrel-tail Grass, *Hordeum jubatum*, is a serious pest to stock in the Western States of America. The barbed awns break up into pieces, penetrate the gums especially near the teeth, producing swelling, and ultimately suppuration, of the gums, and ulceration of the jaw-bones and teeth, the latter being so loosened as to drop out. If the animal continues to eat hay containing this Grass, the disease progresses till the bony tissue of the jaws is disarranged, the ulcers extend to all parts of the jaw-bone, and it becomes distorted and enlarged. The marrow-filled interior is changed into great cavities filled with the broken awns. This condition may continue till the cavities extend entirely through the jaw, and the tightly packed awns protrude till they may be pulled out with forceps or fingers.

— **THE BOARD OF AGRICULTURE AND MARKET PRODUCE.**—The Board of Agriculture has met the farmers and the fruit growers more than halfway in a circular just issued on the subject of frauds in the marking of market produce. The British dealers in commodities of this sort have long complained that they are heavily handicapped by the absolute freedom of imposture in the mode of describing fruits and vegetables which dealers now enjoy. Honestly described, British goods are thus often thrust out of the market by the mere magic of a name which does not properly belong to the articles in competition with them. The Board now offers to institute prosecutions under the Merchandise Marks Act, 1894, for offences of this sort, and it has drawn up a set of regulations for this purpose with the concurrence of the Lord Chancellor. The Board has no doubt that frauds of the kind complained of, including those based on misrepresentations of the place of origin, may be dealt with under the Act. Agriculturists and others concerned in finding a remedy must, however, co-operate heartily with the authorities in furnishing all needful particulars, and for this reason the circular is to be widely disseminated throughout the country.

#### THE CHARLES COLLINS' FUND.

WE have pleasure in announcing the following subscriptions received during the past week towards this very deserving case:—

## ASPARAGUS.

ALTHOUGH so well known and so commonly cultivated it may not be amiss to direct attention to this most important esculent at this season of the year. I say this season of the year, because to anyone intending to plant new beds this is the time to make the necessary provision for the work. The Asparagus has been written on and discussed so frequently and so well in the past that to some it may appear presumption to enter on the consideration of the subject again at this time. However, I have a conviction that all has not yet been said in its favour that its value and importance as a useful and remunerative garden crop entitles it to.

No one will, I think, dispute the statement that of all vegetables grown this is as much, if not more sought after and appreciated when in season than any other, and I think it may also be stated with equal truth that in the midst of depression and ruinous prices for many crops of the garden this article is in the unique and happy position of always being in demand and always returning fairly remunerative prices.

It is acknowledged on all sides that our home growers of produce for sale, in consequence of the immense and increasing importation of fruit and flowers which are placed on our markets from abroad almost daily throughout the year, are at their wits' end to know what to grow at a profit. We have not been, and are not now, without advisers as to what to grow and what not to grow, and more particularly with reference to British hardy fruit, and I am hopeful that much good to horticulture and to the country will follow the recent discussion in the general and gardening Press, and more especially from the recent exhibitions and conferences held by the Royal Horticultural Society. But after all that has been done, doubts will still exist in the minds of many whether we shall ever be able to oust the foreigner from our hardy fruit market at home. But there should be no doubt whatever as to our power (if we care to use it) to render it unnecessary for him to share so largely in the Asparagus supply.

Better climate favours growers on the continent and handicaps us in the production of many fruits; but not so with Asparagus. Here we stand together on more equal terms, as our soil and climate are as suitable for the growth of this vegetable as any to be found abroad. How comes it, then, that the humiliating fact must be acknowledged that more Asparagus is imported, both forced and naturally grown, into this country than we grow ourselves?

Different people will be ready with different answers to this very important question. My impression of the cause, and which I respectfully submit, is to be found in the apathy and indifference of our growers, and also perhaps to the want of inspiration and organisation. Before giving a few details as to the mode of cultivating the plant adopted here, I may be allowed to point out one or two ways in which I think it would be possible to advantageously increase very considerably the growth of Asparagus. We hear on all sides of the desirability of supplying our rural population with allotment land for the cultivation of garden crops for home use, and also if possible for sale. Now, what a little gold mine a quarter of an acre, more or less, would be under Asparagus in a labourer's allotment properly tended and cared for; and this would follow very soon after it was discovered that the Asparagus bed vied with the cow, the pig, and even the orchard in the golden return it is capable of bringing to its owner.

Oh, but many will exclaim, Look at the cost of making an Asparagus bed, and look besides at the time we shall have to wait before we have any return for our labour and money! Just so. Look also, my friends, at the fact that when you buy a calf how long it is before you receive any milk and butter, or if you plant an orchard how long deferred your returns often are. The one may last you ten years or so and the other fifty, but the Asparagus bed will go on for ever for anything we know to the contrary if it is tended with care and intelligence. I know of one in Bakewell, Derbyshire, the property of the late Mr. William Greaves, which is known to be upwards of 100 years old, and when I saw it a few years ago it was in splendid condition.

As to the cost of forming Asparagus beds and the time it takes before returns are obtained, exaggerated and erroneous ideas are held by the inexperienced. No doubt the cost in the first instance is more than for an ordinary crop, but once let it be practically demonstrated to the workman that there is more money in his Asparagus bed than in anything else he can produce, depend on it that the little trouble and extra labour necessary to grow this esteemed vegetable will soon be overcome, and after all the extra expense is chiefly represented by labour, which the workman has in his own hands to provide. If this idea, which I hold to be quite practicable, could be carried out throughout the country among our rural population the increase in the supply of

Asparagus would be enormous, with a corresponding gain to our workmen and their families.

There is another aspect of this question on which I would briefly touch, and which, I think, will appeal with greater force to gardeners, and I cannot illustrate what I mean in a better way than by referring to the large increase which has taken place of late years in the number of small growers throughout the country who centre their energy and labour on the growth of specialities for market—some Roses, some Carnations; others Tomatoes, others Cucumbers, and so on, and who, I believe, are fairly prosperous. Now I trust that there is an equally promising field open in the future to the gardener who may decide on making Asparagus culture the chief object of his study and industry.

An industrious man with 4 or 5 acres under Asparagus, well cultivated, could make a most comfortable living for himself and his family, and that without heavy and laborious toil, for once the beds are formed the labour of cultivating and looking after them afterwards is light and agreeable work, and is such, indeed, that the wife and children, if they were so disposed, could easily perform. If in addition to the open beds he could afford to provide some heated frames in which the vegetable could be forced then the value of his business would be much increased, as he could be cutting from October to July, and in winter there is always a sale for Asparagus roots for forcing.

It may be argued that if grown or multiplied in the wholesale way proposed that the supply would soon exceed the demand. I do not think so. At present Asparagus is an article of luxury, and seldom, if ever, within the reach of the artisan and working population, but once let it be offered at a price within their reach, the demand would be so great that no supply could satisfy; and, moreover, the article being so portable, and not too perishable, I can see no reason why we should not turn exporters of this article instead of importers.

The plant flourishes best in deep rich loam of rather a heavy than a light texture, but it will succeed with good cultivation on any ordinary well-drained soil. Our beds here are 6 feet wide, with a path or an alley between of 2 feet. I endeavour to have the beds dug out (one spit deep only) in winter, so that all the garden refuse which is collected from day to day, such as Cabbage and Broccoli stalks, are carted and wheeled into the trenches. This forms an excellent basis to start the beds with, as it answers the double purpose of draining and keeping the soil aerated and warm for the first year, thus affording the exact conditions necessary for the successful growth of the young plants, and afterwards, when the vegetable matter is decayed, it affords nourishing food for the voracious roots of the fully grown plants.

The next step to take is to place a layer of manure of the best quality procurable (either horse or cow) 4 to 6 inches deep when trodden down, on the top of the refuse, and this will bring the surface of the bed on a level with the ground; on the manure should be placed from 5 to 6 inches of the soil from the alley, and this afterwards raked level and gently pressed down with the feet when in fairly dry condition; the rake should then be drawn over it again, and the surface made ready to receive the plants.

For forming permanent beds we plant four rows, 15 inches between the rows, and the same from plant to plant. The line is stretched down and the plants laid on the surface (not planted) by one man, and another follows with a barrowload of friable soil and leaf mould. A little of this is dropped on each plant, and another man follows, gently treading the soil over the roots, at the same time carefully avoiding touching the crowns. This operation finished, about 4 inches more soil from the alley is placed on the beds, gently trodden down, and levelled afterwards with the rake, then all that remains to be done at the time is to edge down the side of the beds and finish them in "a workmanlike manner."

For the first summer after planting we usually sow some Lettuce seed thinly broadcast over the beds, and from which we obtain most excellent samples; a crop of Beans or Cauliflower is also taken from the alleys the first year. I do not think any harm is done by this light cropping the first season, but of course after the first year no other crop is taken.

If the work, which should be carried out during the last week in March or the first week in April, has been carefully executed as directed, and if the plants used are healthy and strong, they will make good progress during the summer. In the autumn when the foliage dies down and is cut off, it should be noted whether any plants have died or refused to grow, and a stick placed wherever there may be a blank, so that it may be filled up the following spring. The next season the plants will make splendid progress, and the following year, that is two years after planting, and three years from seed, a small cutting of grass may be made. The next year, the third year after planting, the beds

will be in full bearing, and will remain so if they are well attended to and not cut too hard for any length of time.

The plant is impatient of too much moisture, and it will be noted that I have advised the bed to be a little elevated above the surrounding ground. The beds are benefited with a moderately light dressing of good short manure each winter, and when the spring comes round again the rough and spent part of it is drawn in the alley and dug in, at the same time a sprinkling of soil being thrown over the beds, and at a later date, about the middle of April, a dressing of chemical manure is recommended.—OWEN THOMAS, *The Royal Gardens*.

### CONFUSION IN GARDENS.

CONFUSION reigns supreme in far too many gardens. In some instances the gardeners in charge are not allowed to make any alterations which might safely be regarded as improvements, in others they appear to be content with matters as they find them. Much of the confusion prevailing is largely due to the indiscriminate distribution of fruit trees and bushes. When these are dotted anywhere and everywhere there is no possibility of systematically

FIG. 22.—TOMATOES AND MUSHROOMS.

cropping the rest of the space with vegetables, nor is it possible to cultivate the ground properly. If the trees and bushes were arranged in straight lines with spaces of from 30 feet to 50 feet between them then an orderly appearance would be presented and much better provision made for growing good vegetables. It ought now to be a very well known fact that digging and cropping with vegetables close up to or even within several feet of the stems of trees is a great mistake. We want to find abundance of fibrous roots near the surface, as without these there is but little likelihood of the trees or bushes proving really profitable. Long naked roots, or such as strike downwards into a clayey subsoil, favour the production of rank fruitless top growth, whereas a good surface action means the formation of abundance of root fibres, which collect food of the right description for the production of short-jointed fruitful branches. This is an oft-told tale, but, judging from what I have seen going on, still unheeded by many men who ought to have long since realised the fact that they are so many muddlers.

It is very much the fashion to form fruit borders alongside the garden walks, only in this case Apples, Pears, and Plums are grown as low standards, pyramids, bushes, or horizontally trained cordons, bush fruits occupying the rest of the space. This plan has its good as well as bad sides. I like it for the simple reason that it affords the best opportunities for the owners and others interested in fruit culture observing closely and readily all that is going on, and does not altogether prevent vegetable culture being carried out in good style. It ought, however, to mean an inner path between the fruit borders and vegetable quarters, not only because such paths are actually wanted, but also, owing to what ought to be regarded as the necessity for keeping either a spade or deep digging forks well away from the trees and bushes. More often than not the ground is dug and cropped close up to the latter—a great mistake. A mixture of fruit trees and flowers is common enough and not wholly to be condemned, but when we meet with

instances of huge clumps of *Pyrethrum uliginosum*, herbaceous Sunflowers, *Harpalium*s, Japanese Anemones, and such like plants growing into horizontally trained Apples and Pears, then it is time to plead for the fruit trees. Either keep those great hungry rooted herbaceous plants well away from the fruit trees or root out the latter altogether.

Opinions may vary as to the best methods of arranging fruit trees and bushes, but all things considered it is doubtful if the plan of growing them all in one or more quarters is not the best in the end. If standards are grown, and it is these from which the heaviest crops may be expected when they have attained a productive state, then I would most certainly advocate keeping all together. When standards are dotted about garden ground they rarely have fair play. The attempt is nearly always made to crop with vegetables close up to the stems, and what chance have the roots under such conditions? They would be far more likely to do well if arranged market growers' fashion, that is to say in rows from 24 feet to 30 feet apart each way, the greater distances being given to the stronger growers. Between the lines of these may be planted bush or pyramid trees of Apples and Pears on dwarfing stocks, and between these again can be arranged bushes of Gooseberries, Currants, and single rows of Raspberries. Half-standard Plums could be planted midway between the lines of standards.

Thus arranged it is many years before the standards materially interfere with the usefulness of the rest of the trees and bushes, especially if timely shortening some of the more straggling branches to better placed back growths is resorted to. It will also be found that, thanks to the avoidance of deep digging, and the applications of manure to the surface, the top spit is largely occupied by roots, this rendering the work of shifting trees and bushes overshadowed by the standards to a more open position a comparatively safe and easy matter. When all are kept in quarters proper attention can be given for keeping both roots and branches in the best order for the object in view—a good supply of fruit.

The question has yet to be faced of the possibility of reducing the confusion existing in numerous gardens. If the trees and bushes are not too old, or the varieties are not of a worthless character, they may be transplanted, but many are not worthy of retention, either in their present or new positions. The simplest plan is to clear one quarter at once of the garden of trees and bushes, reserving only the very best, and laying them in till they can be properly replanted. This admits of the cleared space being deeply dug or bastard-trenched, if need be, preparatory to forming into a regular fruit plot on the lines already laid down. In the spring, just as the buds are on the point of bursting, the lifted trees or bushes may be replanted with every likelihood of their doing well, and that, or November, is also a good time for planting the rest of the prepared ground with young trees and bushes.—W. IGGULDEN.

### DEAR OLD JOURNAL.

MUCH have I to thank you and your able contributors for during the last twenty years, and I must confess to having a certain amount of bias whenever I take up a fresh number, for I always look at the end of each article before I read it to see the name or initials placed there; and those articles with such old-standing signs as W. Iggulden, W. Bardney, J. Wright, and other old Journal fogies, including "D., *Deai*"—though put last not least—stand well in my estimation. However, I wish to convey my thanks to all for the useful advice I have obtained from your pages. After following the advice of "W. I." in his excellent little work on the Tomato, and finding it good, I should like to suggest to our good Editor that he reprints "W. I.'s" article on "Dwarf Tomatoes," of January 14th, 1886, for it is as good to-day as when it was written.

This and other articles in the Journal from time to time have at last ended in an attack of Tomato disease. It may be called, if you like, the

"Tomato Growing Craze." But to be serious, I have to say that to thoroughly test the question of Tomato growing for profit, my employer has found the means to erect a large range of twelve houses specially for growing the crops, and we have some thousands of plants ready for planting.

So far so good. We are trusting to succeed; but now I want to give your able correspondents a nut to crack. What shall we grow from the end of October to the end of February in order to reap a profit from our Tomato houses? Chrysanthemums seem to be overdone, if I may take the following paragraph from a contemporary to be correct—viz., "The competition is now so severe that the ordinary price for blooms grown without thinning has at the holiday season (Christmas) dropped to about 2s. 6d. the dozen bunches, twelve blooms to a bunch. It is evident there is no golden harvest to be reaped from Chrysanthemum growing at the present time." Now, will some reader try to throw a ray of light across the path of a—PERPLEXED ONE?

P.S.—Arum Lilies, Freesias, Tuberoses, cool house Orchids, &c., dance

#### A WONDERFUL ROSE GARDEN.

WHEN in the neighbourhood of Bath, before the Flood—I mean the flood which submerged the lower parts of the city and valleys round about last autumn—I had the pleasure of calling on Mr. Alexander Hill Gray and inspecting his Rose garden. Surely this is the most wonderful garden of its kind in Britain, and it affords such evidence of its owner's devotion to his favourite Teas, and of his determination to provide generously for them and to deal liberally with them, that is not elsewhere to be found.

FIG. 23.—MR. HILL GRAY'S ROSE GARDEN.

before one's eyes; but I leave all these, and wait to see the verdict on what to use our Tomato houses for in winter with a view to profit.—P. O.

[We permit our racy correspondent to write under the heading of his choice, as we should not like to hurt his feelings. We shall be glad if readers will try their teeth in cracking the nut submitted, and to he who does so in the best manner and shows the most kernel we will give a handsome silver medal if in the opinions of independent examiners such an award is merited. The subject indicated is an important one, and those who think they can deal with it usefully had better in the first instance communicate with the Editor. In the meantime our "perplexed" correspondent will have the satisfaction of finding in the present issue something to read from every writer he mentions, and it may therefore be expected he will consider the issue a good one; and further, as his letter suggests that he has not read the last and best edition (the fourth) of his favourite author, we advise him and others in a similar position to procure a copy of "Up-to-date Directions" on the cultivation of the Tomato; and to show that the point advanced by our correspondent has not been overlooked we reproduce an illustration of a profitable combination—Tomatoes and Mushrooms in the same house (fig. 22). They need not, however, necessarily be both bearing together, but Tomatoes during the summer and Mushroom production throughout the winter, and if both yields are as abundant as they ought to be, and may be, both crops are profitable. We may add that no one on the office staff of any gardening journal will be eligible to receive the offered medal, but all outside contributors and non-contributors to our columns are free to do so, and we shall be ready with his sanction to publish the portrait of the winner. Mr. Iggulden's "Up-to-date" *Tomato Manual* can be had post free from our office for 1s. 2d.]

Beaulieu, Mr. Gray's residence, is situated a mile or two from Bath, on the Weston Road, from which we look down on the chimney tops of the residence, and before entrance can be had to the great traveller's sanctum, ornated with the spoils of the chase in India and Africa, we have to descend some forty or fifty steps; then when we go out again to see the Roses have to descend many more, and before we see all we have to go down and still down, and then we are perhaps a hundred feet, and perhaps more, above the far-stretching meads, with the river meandering through them, bounded by distant tree-clad hills. It is a delightful outlook, placid in character and suggestive of repose. It will be perceived that the home of the great rosarian is half way up a steep hillside. The house and the prospect pleased him, and therefore he purchased the property, determining to make it suit the Roses he intended to grow. The task must have been herculean, and it may be presumed the greater the difficulties the greater the zest to overcome them.

Fancy a rugged and in places almost precipitous slope some half a mile long, or it may be more, with rocks jutting out and little soil among them, and an idea may be formed of the position in the concrete. See it now, or in the summer, when between 7000 and 8000 Teas are in bloom; note the three far-stretching terrace gardens of Roses, and the long, strong supporting walls, and you can but marvel at what has been accomplished. Every man able and willing to work at stone-digging and levelling down was set on there, till a small army collected, working all day long month after month, and one would think year after year, till the whole great undertaking was completed. Many thousands of loads of soil must have been brought for mixing with the thousand loads of manure for filling these huge beds some 3 feet deep. In forming these terrace gardens for his Roses and building the walls Mr. Hill Gray built himself a monument of an enduring character, for

all the king's soldiers and all the king's men could not build up the ancient precipice again.

And what is the return for all the labour and wealth invested in the work that has been accomplished? Roses, Tea Roses, nothing more, and nothing more is wanted, for these give the owner happiness. They are his delight, and his pleasure is to attend to their wants and make friends happy with baskets of blooms. See how the plants are cared for. Summer shoots tied out each to its separate stake, lest they should brush against each other and injure their precious leaves; half a dozen men walking abreast moving the soil, searching for suckers and a stray weed, lest it should abstract a trifle of the abounding food that has been provided for the Roses. Of the blooms their owner is entitled to the best, and grand are many of them. Now and then he takes same to the shows, bringing home his share of the prizes, but his labour of love is not directed to showing alone, but mainly for home pleasure, and it must be a pleasure for him to feel that his son, his only son, inherits the parental love for Roses and flowers generally, enjoying himself in raising many. Both of them, father and son, were preparing for a journey to the Azores on a hunting tour—for Rose seed, and whatever they could find to bring home to Beaulieu in the spring. Some seedling Roses have been raised of wonderfully rampant growth against walls, and one of these is, I think, being distributed by Mr. George Paul.

Of the varieties grown by Mr. Gray, Maréchal Niel is the first favourite, and he cuts magnificent blooms from admirably grown standards. About 500 plants of this famous Rose are grown, and about 400 each of The Bride, Catherine Mermet, Comtesse de Nadaillac, and Souvenir d'Elise Vardon. Next in order of merit, and grown in lesser number accordingly, are Innocente Pirola, Edith Gifford, Madame Cusin, Anna Ollivier, and Marie Van Houtte. Then follow Souvenir d'un Ami, Souvenir de S. A. Prince, Francisca Krüger, Alba Rosea, and Princess of Wales. Next in order of numbers at Beaulieu are Caroline Kuster, Madame Lambard, Ernest Metz, and Ethel Brownlow. Cleopatra comes within the charmed circle, but as being comparatively new is not yet so largely represented as the others. Mr. Hill Gray, however, regards Maréchal Niel as the queen of Roses, and may he not be regarded as the king of Teas among amateur growers?

Mr. Foster-Melliard gives a view of part of this wonderful Rose garden in his beautiful book which has been previously referred to, and I have the permission of Messrs. Macmillan to use the illustration (fig. 23), in which the master is seen standing among his plants, evidently discussing the merits of the blooms he has cut and handed to his assistant for the tray held by a servitor, women as well as men having to help "among the Roses" at Beaulieu.—J. WRIGHT.

#### WORKSOP ROSE AND HORTICULTURAL SOCIETY.

THE annual general meeting of this Society was held at the Lion Hotel, Worksop, on Friday last, the 8th inst., Mr. H. V. Machin in the chair. In spite of the bad weather some of the members of this Society came several miles over the snow (some on foot) to attend. Amongst others present were Messrs. J. S. Whall (Treasurer), George Baxter (Hon. Secretary), A. Baxter (Assistant Hon. Secretary), C. Slade (head gardener to Duke of Newcastle at Clumber), S. A. Woods from Osberton, and F. E. Chambers (Gateford), John Dougall, F. Sissons, and others. The following officers were unanimously elected:—Patrons, His Grace the Duke of Portland, His Grace the Duke of Newcastle; President, Mr. H. V. Machin; Vice-President, Mr. J. S. Whall; and an active and influential Committee, composed of twenty-five members, was elected; Hon. Treasurer, Mr. J. S. Whall; Hon. Secretary, Mr. George Bailey (subject to his consent to act).

The much-esteemed late Hon. Secretary of this Society (Mr. George Baxter) finds himself unable to undertake the hon. secretaryship for 1895 owing to the increased demand on his time from other sources. He will, however, act in his old capacity until a new Hon. Secretary comes into office. It is hoped that Mr. Bailey, who is very highly thought of in Worksop, will succeed Mr. Baxter, who was heartily thanked for his past services. Mr. Baxter has for a long time been connected with horticultural shows at Worksop. He was Hon. Secretary of the old Worksop Horticultural Society, which was broken up some eighteen years ago. The present President, who may justly be called the founder of the new Rose and Horticultural Society, which came into existence in 1889, is eldest surviving son of the late Mr. J. V. Machin of Gateford Hill, who in his turn was President of the original Society for upwards of twenty years. The next Rose and Horticultural show will be held on Thursday, 11th July.

#### WHITE AND YELLOW RICHARDIAS.

AMONGST the crazes that have been ventilated of late years has been that of giving English instead of botanical names to plants, such, for instance, as when we are told that a Tiarella should be called Foam Flower, a practice which, it is hoped, will never be popular, and which in the instance of the Richardias is singularly incorrect. This is sometimes called the White Arum, and at other times the Lily of the Nile, but in truth the plant is a native of South Africa, and does not occur within a thousand miles of the Nile. It has been more than 200 years in our gardens, and is often the ornament of a cottager's window as well as a gentleman's con-

servatory, but never during its history has it been so largely cultivated as at the present time; the demand for cut flowers, which has so greatly increased of late, and the custom of placing wreaths on the graves of departed friends, have both largely influenced this culture.

Tens of thousands of plants are now grown near the Metropolis and in various parts of the country for supplying this demand, and the facility with which the plant increases by offsets has greatly assisted in this matter; in fact, it is one of the easiest plants in cultivation where a cool greenhouse can be relied on. It is essentially a water-loving plant. The plan which I have found succeed best with it is, after it has flowered, and all fear of frost is over, to take the plants out of the pots and plant them in a cool, moist part of the garden. Here they may remain during the summer, and then in September they may be lifted and repotted, brought into the greenhouse, liberally supplied with water, and kept clear of aphid, which are very fond of getting into the spathes, and if they do nothing worse disfigure the purity of the flower. I do not think it is at all particular as to soil, but a good retentive loam seems to suit it best.

During the past few years considerable interest has been excited by the appearance of dwarf forms, and also of bright yellow flowered varieties. With regard to the former there seem to be two forms at least, very different indeed from each other; one of these is called *compacta nana*. This plant has a very curious habit. The leaves are about one-third the size of the normal form, and so indeed are the flowers. These are formed at the base of each leaf, so that every leaf has a flower attached to it; it also comes into bloom in the winter months without any forcing whatever. The other "Little Gem" is entirely different in character; its foliage is much smaller—indeed, the leaves, which are only a few inches long, are flaccid instead of being stiff, more like the Lords and Ladies of our hedges. The flowers also are very small, about 3 inches in length, so that the whole plant deserves the name which has been appropriately given to it, "Little Gem."

It has been doubted by some whether it will retain its miniature character under higher cultivation. All I can say is I have now grown it for three years, and have not found it alter in the least. I know, however, that in some cases the previous variety has been supplied instead of this. I received last year two plants from a well-known nurseryman as "Little Gem," which turned out to be "*compacta nana*;" they had been supplied to him under the former name, and as such he had grown and distributed them. I have no idea as to how this plant originated, but it is so unlike the type that I have heard some people call it a distinct species.

Perhaps the greatest interest which this flower has aroused has been the introduction of two beautiful yellow flowering forms which have been exhibited during the past two years, R. Elliottiana and R. Pentlandi, one introduced by Capt. Elliott of Farnborough Park, Hampshire, and the other by Mr. R. Whyte, Pentland House, Lee; the latter of these, I think, the more beautiful of the two. I happened last year to meet at the Hotel Windsor a gentleman who evidently took some interest in flowers, and who told me that he was home from the Transvaal. This led me of course to inquire about the yellow Richardia, which I had just seen at the Drill Hall. I asked him whether he had seen this flower. "Oh, yes!" was his reply, and then he told me that in the Cape Territory he had seen whole gullies and ravines full of the white variety in flower, and that it is a most beautiful sight; while in the Orange Free States there was a variety with yellowish flowers, which gave place in the Transvaal to the fine yellow varieties named. On leaving he gave me his card, and I found that he was a Mr. Montague White, but I did not think of asking him whether he was related to the introducer of Pentlandi. He told me that he had brought home some bulbs of it, and that they could be had in any number in their native habitat.

Both of these are peculiar in their habit, being deciduous; they form tubers something like a Caladium, and as all the small pieces of tuber will grow it is likely that they will soon be widely distributed. The nurseryman from whom I obtained my plant seems inclined to think that it will not be so easy of cultivation as some imagine, and I think it is just possible that it may require more heat than the ordinary varieties. He said that he was going to shake out his early in the year, take off the small tubers, and repot the plants. As during the winter months it is at rest it will require only a little water, but must not be allowed to become perfectly dry. I am treating my plant in the same way, and shall look forward with some anxiety to the result.

There are, I believe, other varieties or species in cultivation, but as far as I am aware they are not of great horticultural interest, while those that I have enumerated above are, I think, the general favourites. I should add that the yellow of these two varieties is not a washy but a brilliant colour, and a number of them will probably be seen in the coming season.—D., Deal.

#### FERTILISATION OF THE CHRYSANTHEMUM.

ALLOW me a few lines to say that your correspondent, Mr. Chas. E. Shea, in his criticism of the report of the Scientific Committee of the Royal Horticultural Society, pages 78 and 79 of your Journal, has missed the point. As to whether the Chrysanthemum is protandrous was not in question, but whether the Chrysanthemum is by Nature self-fertilised or cross-fertilised. My experience is that the Chrysanthemum is self-fertilised by Nature, and this the Scientific Committee have confirmed. I hope on the first opportunity that arises to practically illustrate the experiments to which I resorted that warranted my arriving at that conclusion.—HENRY BRISCOE-IRONSIDE.

#### A PLEA FOR ANEMONE-FLOWERED CHRYSANTHEMUMS.

IN answer to "H. Harris" (page 120) I may tell him I was not at the Crystal Palace show, and that the admiring crowd of ladies round the stands of Anemones does not alter in the least what I wrote respecting the Anemone as a decorative flower. I gave my experience and the experience of other gardeners with whom I have discussed the subject. The Anemone and Japanese Anemone will always find a place and a host of admirers at our autumn shows, and justly so, and amongst them will certainly be—F. G.

#### NEW CHRYSANTHEMUMS.

HAVING taken a deep interest in the election, I should like to see the names of the electors who placed their favourites in high position. The variety at the head of the poll I have no doubt is good, but what opportunity has the general cultivator had of testing it? It may be a sturdy grower, or it may be a weak grower. The same may be said of eighteen or twenty others. No variety should be elected unless it has been thoroughly tested by the general cultivator one year. Mrs. E. S. Trafford (fourteen votes) is a sport from William Tricker (seven votes), and placed with the decorative varieties. This is a strange position for the poor parent. In the election for thirty-six Japanese poor Tricker only gets one solitary vote, and Hairy Wonder the same; in the new varieties it has thirteen votes. Mrs. R. C. Kingston is placed among the new Japanese with one vote. This variety is not yet in commerce; besides, it is a Chinese incurved, and should not be placed in the list. There are several others with votes not placed in commerce, and some of them, I think, never will be. Again, there are varieties two or three years in commerce. J. P. Kendall, I think, is four years old, taken out of commerce by the raiser, and now brought forward as a new variety. Verily, the election has brought out strange results, and some of the electors appear to have curious notions.—SPECTATOR.

#### CHRYSANTHEMUM L. CANNING.

SEVERAL varieties of Chrysanthemums have been recommended for producing white flowers for the festive season, but this year I have been fully convinced that the best of all is L. Canning. Calling on a florist on December 15th I saw such a sight that I had never seen before—viz., over 1000 plants of this variety developing their charming blooms. The majority had been disbudded, and each plant carried an average of ten blooms, of large size and of snowy whiteness. The plants were about 3 feet high, and clothed with foliage to the pots. They were very clean, pictures of health, and as arranged on each side of the paths of four long span-roofed houses, they looked like beds of snow. Cutting had just commenced, and the demand for flowers kept the packers busy, and the stock was soon cleared off at a good price.

L. Canning has been grown for three seasons in the establishment with equally good results. Before that time Pelican, Miss Marchaux, and Mrs. H. Cannell were found useful, but now only a few of these are grown by way of comparison, and the superiority of the favourite is at once apparent. The shape, build, and pureness of the flower is just what is wanted in the market. Another point in its favour is its freedom in producing cuttings, so much so, that already over 10,000 cuttings have been disposed of from these plants, and still they come, so do orders for them, and by the time these lines are printed thousands more of the cuttings will be sent away.

I see that Mr. O. Thomas of Windsor obtained an award of merit for L. Canning at the Royal Horticultural Society's meeting on January 15th, so probably its merits will soon be appreciated. My advice to all who desire white Chrysanthemums later in the season is to try this useful variety.—H. HARRIS, *Denne Gardens, Horsham.*

#### LOOKING AHEAD.

IN Chrysanthemum culture, as with everything else nowadays, the successful growers and exhibitors are those who look some distance ahead in the matter of cultural details. Now is the period when many arrangements for the future development of the plants and blooms should be made, and one of the most important is the final selection of

varieties and the number of each to be grown for the present year's requirements.

I think it is the accepted method of all cultivators to insert many more cuttings than are really required for final growth, and then to make a selection of the most promising plants. Although I am now alluding mainly to plants cultivated for large blooms for exhibition and home use, it is necessary to use the same discretion when dealing with plants grown for decoration only. It is a mistake to give space to varieties of indifferent merit, or to those that are difficult of cultivation. In the case of exhibition blooms, cultivators would do well to include all those possessing high merit combined with peculiarities of constitution, because in competition such points weigh heavily with qualified judges. Not only are these of considerable importance in the matter of prizewinning, but the fact of one cultivator being able to produce blooms of varieties that others fail with, stamps the former as possessing superior knowledge of the details required. With the vast array of names embraced in nearly all Chrysanthemum catalogues there can be no reasonable excuse for the inclusion of inferior varieties. I would impress on all, especially those who have had but a limited experience, the necessity of rigidly excluding all doubtful varieties, bearing in mind that variety may have charms but not always use. It is also a mistake to overcrowd the number of plants. All are more or less spoilt for want of the desirable space. Far better grow 100 really well than spoil double that number.

The bulk of the early rooted plants are now well furnished with roots and awaiting their first transfer, and this affords a good opportunity to make the final selection, rejecting those that exhibit the slightest sign of weakly growth, premature bud formation, insect pests, mildew, or other parasites, in favour of those free from the ills named. A stocky habit of growth ought to be encouraged; a good foundation is most desirable, and abundant space is the chief necessity for obtaining these. As long as the leaves of one plant do not overlap those of its neighbour no complaint in this direction can be made. Directly the plants are a few inches high and the weather favourable the best position is in cold frames or pits, choosing a position where any advantage from the sun is gained, sheltered also from north and east winds. The glass must be well cleaned, and the frame made watertight. A thick bed of coal ashes should be provided, as too much moisture at the roots is certain to create a paleness in the colour of the leaves.

Some thought must shortly be paid to the manner in which the bush or purely decorative plants are to be trained. Many persons prefer the continual topping of the plants as fast as 2 or 3 inches of growth are made with a view to obtaining large plants. No doubt that aim is readily accomplished, but I venture to assert that plants grown under the method I will name will be much more satisfactory. The larger plants will occupy more space, but not give better results. Plants of this kind produce blooms with weak peduncles and generally short stems, therefore are not nearly so useful for the decoration of vases. Top the plants twice—once when 4 inches high and again when 5 more inches of growth has been made, afterwards allowing them to grow uninterruptedly. From such plants spikes of bloom from 1 to 2 feet can be obtained, and which, furnished with numerous side shoots, will be distinctly useful and meritorious.

After writing so much and so long in favour of the extension of single flowering varieties, it is pleasing to me to note there is a greater tendency to favour this section. Cultivators have come to realise the value of these flowers for decorative purposes. At the time I write, February 8th, I have just been enabled to cut charming blooms of this type, and which are distinctly useful at this season of the year. No complaint can now be fairly lodged against the want of colour or variety in single flowering Chrysanthemums; most brilliant in colouring are many now obtainable. For instance, *Souvenir de Londres* and *Mdme. Le Mouet*. Then we have almost all neutral shades of colouring, and what is more, the blooms possess a fragrance not obtainable in any other section.

Cultivators, I find, appreciate much more than formerly the early flowering type of Japanese for outdoor growth. For providing a display of cut bloom in September and October before the regular indoor Chrysanthemum season commences, I can strongly recommend the early flowering race of Japanese varieties, like *Ryecroft Glory* and *Comte Fouchier de Caria*, the former yellow with a slight trace of bronze, and the latter distinctly bronze. Specimen trained plants, such as pyramids, standards, and those of convex form must have unstinted attention to space, cleansing from insect pests, and otherwise encouraging a free and vigorous growth.

The preparation of the compost for potting the plants, no matter for what purpose they are grown, must receive early attention. Where the necessity arises of employing chemical manures the preparation of the soil is too long deferred. It is useless to mix the compost on the same day it is required, with the idea of obtaining full benefit from the manures thus employed. All phosphatic manures—such as bones, horn, and hoofs—require a longer period for assimilation of their virtues by the soil before the plants derive benefit. Basic slag is much thought of by some cultivators for Chrysanthemums, and should be mixed with the loam for at least a couple of months before required. In preparing the compost for the final potting, and this is the most important, the loam, which is the chief ingredient, should be stacked with layers of manure between, so that the whole will be thoroughly incorporated when used at potting time.

Stakes of various sizes, posts and rails for making the framework to

which the plants that are cultivated for the production of cut blooms are made secure, should be prepared, so that when the time comes for their use no trouble will be experienced or delay occur. Pots of all sizes requisite for the various phases of culture ought to be clean if already in stock, and all other minor details facilitated, and then will be the advantage proved of "looking ahead."—E. MOLYNEUX.

#### MR. CHARLES E. SHEA.

FROM time to time portraits of men of mark in the horticultural world, and of those who have achieved success in some particular department, have appeared in our columns. We have now pleasure in giving an excellent photographic representation of the gentleman under notice, whose name is so familiar to readers of garden literature. Mr. Shea may be fairly described as both a scientific and practical horticulturist. His article on the fertilisation of Chrysanthemums (page 121, last week), shows that in raising new varieties of these flowers he does not resort to easy, haphazard or empirical methods, but follows strictly scientific lines as suggested by botanical knowledge, and to this may be attributed his quickly won success, but we only regard this as a beginning of greater triumphs to follow. He has good reason to persevere in the work in which he has proved himself an adept, and we shall be both surprised and disappointed if he does not share largely in placing England on a level with France or any other nation in the raising of new and meritorious Chrysanthemums.

Mr. Shea, as is well known, was a successful exhibitor of Chrysanthemums during some four or five years, and though he limited his culture to

350 plants, met the best growers in open classes and won many prizes at the shows of the N.C.S. at the Crystal Palace and the Kent County exhibitions, and it will be remembered that in 1891 he succeeded in securing first prizes in the forty-eight Japanese classes at the National and "cighteen Japs" at the Palace. After this Mr. Shea appears to have become tired of the monotony of exhibiting, and turned his attention to the raising of new forms, guided into being by his own judgment in the selection of varieties for manipulation in the production of ideals that he has in view, and of which he seeks the realisation. He has thus entered the domain of infinite variety and practically inexhaustible.

We believe that of his first batch of seedlings he saved thirty-six

(from the foliage mainly) and threw the rest away. The best of these thirty-six were Miss Dorothea Shea and Silver King. Next year he kept thirty-six more, and sent out Miss Maggie Blenkiron and Miss Sylvia Shea, the latter rather a weak variety and difficult, it seems, to grow. The late audit shows the position of these. Of the 1894 seedlings the best so far is Mrs. C. E. Shea. Miss Rita Schroeter obtained a F.C.C. from the F.C. of the N.C.S., and Miss Dulcie Schroeter an award of merit at the Drill Hall last November. Miss Elsie Teichmann and Miss Bronna Foster are also 1894 seedlings, but have not yet been submitted to the Committee, and there are still more yet unproved. Mr. Shea, it is hoped, will continue in this work, though he does not pretend to give

it his whole thought, devoting attention also to Roses, herbaceous plants and fruit culture; but will he be satisfied with cultivating, even in these departments? We suspect not; but sooner or later he will be tempted to see what can be accomplished by the art of pollination, which has already given him such encouraging results.

Then he has other calls on his time, and is always ready to help where he can possibly do so. His ability as a chairman was fully recognised at the recent annual meeting of the National Rose Society, and he was admittedly of assistance there. He is chairman of, to coin a term, the court of judges now trying to reduce order out of chaos. His legal training (though he has retired from practice) fits him admirably for sifting the wheat from the chaff, and he is helpful there. Mr. Shea also occupies a seat at the Council table of the Royal Horticultural Society, and he must be admirably qualified for such a distinguished position. For these reasons we are glad to have the opportunity of adorn-

ing our pages with the portrait of a gentleman who works so willingly and well in the advancement of horticulture.

FIG. 24.—MR. C. E. SHEA.

#### IMPRESSIONS OF EATON.

EATON HALL, the magnificent home of the Duke of Westminster, is so well known in the gardening world that it is scarcely necessary to explain its whereabouts. After a long railway journey in the early morning I arrived at the quaint old city of Chester. Gladly would I have lingered for a few hours and examined more closely its old-fashioned houses with their timber-studded gables of the Elizabethan period, or wandered round the crumbling remnants of the old city wall. Stern duty, however, forbade this, and a rapid drive through pleasant

country scenery brought me to the park entrance, through which a long sweep of carriage drive led between an avenue of giant Oaks and Elms to the main entrance of the mansion itself.

On arriving at the gardens I was welcomed by the genial and

coupled with an ardent love for his garden on the part of his employer, the whole place has been completely renovated since he (Mr. Barnes) took charge of it three years ago. Old houses have been swept away and replaced by imposing looking structures, the whole being heated by

FIG. 25.—THE CORRIDOR AT EATON. (From a Photograph by Mr. G. Walmough Webster, Chester.)

accomplished head of this department, Mr. Barnes, who at once proceeded to bring before my notice all the interesting points connected with his responsible charge. Eaton Hall is one of those establishments where everything is done well, and gardening is carried on to a high state of excellence. Owing to the great energy of Mr. Barnes,

seven new Trentham boilers, and in fact everything, so far as the buildings are concerned, put into the best possible order.

The houses are grouped in a compact area surrounded by a high brick wall, the enclosed space being again intersected by walls, against which are erected the vineries and Peach houses, and all built on

modern principles. Most of the Vine borders are on the outside only. Mr. Barnes, however, is gradually introducing inside borders, and since his taking charge has made seven new ones, his principle being shallow borders on a firm concrete bottom. The remaining walls are covered mainly with Pears and Plums, from which during the past season good crops have been gathered, though the Apples, as in many other places, were a failure.

A range of lean-to fruit houses occupy a south wall, the first planted entirely with Coe's Golden Drop and other Plums, followed by cool Peach houses, in which Barrington and Sea Eagle Peach and Lord Napier Nectarine predominate. Following these is a range of late vineries, four in number, the first planted with Lady Downe's and Alicante, followed by Muscats; the third with young canes of Lady Downe's planted last spring, and fourth with Black Hamburgs. We next glance through a succession of pits containing winter crops of Cucumbers and Tomatoes, to be followed by supplies of Melons and additional crops of the above for summer use.

The Orchid houses are substantially built of teak wood. Like everything else at Eaton, Orchids are well grown, and consist of fine collections of Cattleyas, Cypripediums, Odontoglossums, Coelogynes, and Dendrobiums. As the different species come into flower they are effectively staged in one large exhibition house, now particularly gay. Conspicuous amongst others are some fine pieces of Dendrobium Wardianum and Lælia Sanderiana and L. anceps. Angraecum sesquipedale, too, is quite at home here, there being several fine specimens producing twelve and fourteen blooms each. A superb collection of Calanthes gives evidence that their cultivation is thoroughly understood, the chief varieties being Veitchi, lutea, and vestita rubra.

Another range of lean-to houses contains Figs, which are extensively grown at Eaton, and Vines, mainly Black Hamburg, Lady Downe's, Muscat of Alexandria, and Madresfield Court; early vineries just now showing fruit, and Peaches in bloom, claim special attention.

Perhaps the chief feature of interest at Eaton is the handsome corridor. It is a structure about 150 yards long, 15 feet wide, with a height of about 20 feet. The roof is covered from one end to the other with creepers of many kinds, which by their trailing habits give the whole an elegant appearance. As there is no conservatory attached to the mansion the corridor takes its place, and is at all seasons kept gay with flowers, chiefly with Fuchsias and Campanulas during the summer months and with Chrysanthemums in the autumn and winter. It is now adorned from end to end with Arum Lilies and Liliun Harrisii, intermingled with elegant Ferns and foliage plants, the effect of which can be easily imagined from the illustration (fig. 25), which is reproduced from a photograph taken by Mr. G. Watmough Webster, Chester. The view, looking from one end to the other, can scarcely be surpassed, as it is a long continuation of floral beauty. For the furnishing of this, it is needless to say, a large number of plants are required, and for this purpose alone 1600 bulbs of Liliun Harrisii are potted annually.

Leading from the corridor are a series of houses, conspicuous amongst which is the spring house tastefully adorned with forced plants, such as Hyacinths, Lily of the Valley, Deutzia gracilis, Lilac, and Freesias, and another staged with well bloomed plants of Cyclamen persicum. In addition to these there are several, containing Palms, Azaleas, Camellias, and Imantophyllums. A splendid collection of Carnations, of which Mr. Barnes may feel justly proud, must be passed with but a cursory glance. Malmaisons are strongly in evidence, as about 2500 plants in different stages of growth are cultivated. After the recent controversies in the *Journal of Horticulture* respecting the growing of Malmaisons it may be interesting to know that Mr. Barnes is a strong advocate of the non-syringing principle, and believes in maintaining a gentle current of air to avoid a murky atmosphere, and dusting the plants very lightly about once a fortnight with flowers of sulphur. No sign or spot of disease is to be seen, and the success of this method is apparent in the healthy condition of the plants themselves. About 2000 plants of border varieties are also grown, amongst which I noticed Miss Jolliffe, Miss Mary Godfrey, Lady Nina Balfour, and Uriah Pike.

The capacious orchard house, used during the season for the exhibition of Chrysanthemums, for which purpose it is admirably adapted, is substantially built. It is now filled with Pears in pots, chiefly Easter Beurré, Pitmaston Duchess, and Glou Morceau; Plums, Coe's Golden Drop and Jefferson; besides a number of Peaches and Nectarines. Strawberries for forcing are to be found everywhere, 4000 plants being needed to keep up the supply, consisting mainly of Keens' Seedling, Sir Harry, and Vicomtesse Hericart de Thury. To meet the constant demand for cut flowers, about 2000 Poinsettias and a like number of Euphorbia jacquiniæflora are annually grown, and, in addition to these, about 500 Roses are forced, while the number of bulbs of all descriptions amounts to many thousands.

The spacious vegetable garden, from which the kitchen supply is produced, is situated about a mile away from the mansion, so that time would not allow an inspection of this department. At this dull time of the year, however, little can be said of these, and the flower gardens, the latter of which—now planted with Wallflowers, bulbs, and other spring-bedding plants—are tastefully laid out in Italian style in front of the mansion. An interesting feature in the grounds is that here and there, through the masses of shrubbery, can be seen pretty landscape views of the winding River Dee and the country beyond.

No description of Eaton could be considered complete without special mention of the bothy, built in 1893, for the accommodation of the

young gardeners, under the supervision of Mr. Barnes. It is an imposing building, commanding a pleasant outlook, and built on the latest sanitary style, being furnished with kitchens, dining and sitting rooms, bath room, and lavatories, and the whole thoroughly ventilated and heated by a system of hot air. It is gratifying to know that the proprietor takes such an interest in the comfort of those in his employ, as in many establishments the comforts of young gardeners are sadly neglected. The air of neatness and order which prevails throughout the establishment is ample proof that the whole is under the care of a master hand, to whom great credit is due.

After partaking of the kind hospitality of Mr. and Mrs. Barnes, I again proceeded homewards, with notebook well stocked with useful information and mind full of pleasant recollections of my visit to Eaton.—G. H.

## PROBLEMS IN VINE CULTURE.

I CANNOT say that I have ever feared attacks of red spider on Vines. Some cultivators dread this pest, and have long since come to the conclusion that it is next to impossible to grow Vines without an attack of it. Looking back over several years I cannot help concluding that some cultural defect is the cause of an attack by this enemy. When Vines are arranged directly over a number of hot-water pipes and hard forcing is resorted to red spider will appear, but even under these circumstances if timely action is taken its progress may be readily arrested. When the insects appear I have always found sponging the leaves with a weak solution of softsoap and a little sulphur added ample for destroying it. It should be taken in hand in time and not allowed to spread over the vinery before an effort is made to subdue it.

In May, 1890, when I came here, one of the vineries had the leaves at that early period of the year nearly yellow with an attack of red spider. The house was a late one, and the Vines just coming into flower. They flagged daily when there was a little bright sunshine. On examination the border was found to be saturated, and fully 1 foot of material was removed from the surface. The border was pointed over with a fork and dried, no water being given during the season nor sprinkled in the house. "A good method of increasing red spider," some will exclaim. Under some circumstances it might have been, but as the border became dry the Vines commenced growing and the spider disappeared. I do not remember having seen any in the house since. My experience leads me to the conclusion that a check to Vines from any cause whatever may predispose them to an attack of red spider.

Unfortunately, it has been my lot to practise nearly all through my gardening career where the Vines have been infested with mealy bug, and consequently the rods were peeled annually. I do not admire the system; it seems unnatural, and I never practise it where it can be avoided. While at Norris Green I barked some Vines annually for thirteen seasons, the rods swelled, and the Vines very much improved. I do not think this annual barking does much harm provided strong insecticides are not used afterwards. It is impossible to remove the bark closely without cutting into the inner bark more or less, and strong insecticides are then certain to prove injurious.

When Vines, through barking and dressing, assume a bright polished appearance like the wood of Plum trees something is radically wrong, and injury results. They do not appear to form fresh layers of bark, but seem to be hide-bound. This is caused by strong insecticides after barking. After a moderate barking, and a good washing with softsoap and water, also thoroughly cleaning the house, I have every faith that mealy bug may be eradicated from our vineries by the use of nicotine vapourised in the atmosphere. One fact is certain—it will destroy all bug in an active condition, and does not appear to injure the fronds of the most tender Ferns.

I well remember Mr. W. Taylor's writings on the barking of Vines, and do not regard his last contribution in any way inconsistent with his previous practice. Exceptional cases often require exceptional remedies. His article is welcome as pointing out injury that he thinks results from the practice of barking.

From my experience, however, I think Mr. Taylor must look to some other cause than mere barking for his Vines not doing so well. The roof being covered or partly covered with foliage would protect the stems to a very large extent. The Vines appear to have lengthened out their growth satisfactorily, thus exhausting the reserve material that had been stored up for them. The roots should then have been in an active state, bringing up fresh supplies. Vines that are not barked sometimes flag for a few days after the reserve stores of food have been exhausted, and before root action has commenced. Especially is this the case when the roots are outside and the sun is bright. Under these circumstances we damp the house more frequently, and are careful to allow the Vines to move gently, in fact we never hurry them until signs of root activity are apparent.

The established Vine, to my mind, makes much of its growth by the aid of the food stored in the stems the previous season. Then the food taken up by the roots is mainly devoted to the development of the growth, and for filling the reserve organs with nutriment for the following season.

Firm, well-matured wood, the reserve organs abundantly stored with food, the main foliage stout, clean, fully exposed to the sun, and retained until it naturally turns yellow or assumes other colours, with well-matured roots near the surface, are the essential conditions for insuring success, or in other words healthy Vines and excellent Grapes.—W. BARDNEY, *Osmaston Manor*.

## POTATOES.

WHILST gardeners generally are almost driven to their wits' end to keep up heat in forcing and greenhouses during the present intensely severe weather, it is feared that there are numbers of cases where less thought is bestowed on the safety of Potatoes both for consumption and seed. In how many cases are these stored where under ordinary conditions they are perfectly safe, but are not at all protected in such a way as to resist repeated frosts of such intense severity as from 20° to 30°? It need hardly be said that the protection required in such cases usually exceeds not only what is held requisite, but what often can be afforded. Hence it will be no matter for surprise later to learn that in all directions seed tubers especially have been frosted and spoiled. Whatsoever may be the nature of the temperature when this is read, it is certain that advice to afford the tubers more protection will come far too late. The horse will have already been stolen.

I have charge of a considerable quantity of seed Potatoes in numerous varieties. Most of them are in shallow boxes, and all of the later ones are safe in a cellar, where there is ample air in circulation, and a fairly equable temperature. Some others in larger quantities I have in hampers at the coolest part of my kitchen, chiefly Magnum Bonums, safe and keeping well, whilst early sorts in boxes that have already made growth are kept securely covered in a top room, where in open weather they can get abundance of light and air. As I have thus stored some five or six bushels in all, I mention it to show how possible it is with absolutely no outdoor appliances or room to house Potatoes safely during very hard weather, if to that end very special efforts be made. The possession of medium sized flat deal boxes in which Potatoes can be stored for winter preservation, is an advantage that cannot be over-estimated. Thousands of persons who may have a few bushels of seed stored in pits outdoors, or in heaps in sheds, or in large boxes or tubs or on shelves, and are in a condition of grave anxiety respecting the safety of their seed tubers, would, if they had them in such boxes as I have, and for lack of other room placed two or three deep even under the bed, would sleep far sounder at night in consequence than they do now. I shall expect to learn that farmers, market gardeners, and cottage gardeners have suffered very heavily indeed, unless they have taken precautions far in excess of what are usually deemed sufficient.

The disaster which happened to Potato breadths at the end of May last gave a warning that it would be folly to ignore. Without doubt, breadths that had, as was so general, the tops cut to the ground had to suffer also an average tuber loss of fully one-third of the crop. That was a matter of such serious moment no one should fail to remember. I fear few will regard the warning any the more. No doubt there will soon be seen the same haste to plant, and to get the tender tops above ground some time before the season of late frost is over. To have specially early sorts thus early above ground is all very proper where some kind of protection can be afforded, but to have the main crop breadth thus exposed to danger is, after previous experience, so manifestly unwise that those who do suffer loss have only themselves to blame.

I venture to suggest, in view of a possible recurrence of such a disaster again this year, that general planting be deferred to the end of April, and if in the meantime the sets have been properly prepared by exposure to light and air in shallow boxes, they will at planting time be so far advanced in growth that practically they will be equal in precocity to other and similar sets that were planted some three or four weeks earlier. Long experience has satisfied me in respect to securing both early and abundant crops that the condition of the sets when planted has as much bearing upon the results as almost any other element in Potato cultivation. As a matter of ordinary security, I would far sooner see Potato tops just showing through the ground, if they be as they should be—stout and robust, on May 25th, than twenty days earlier. Of course, I except those very early sorts that can have some kind of protection afforded. I have no doubt, having regard to the prolonged intensity of the frost we are now experiencing, it

will largely be concluded that the winter cold will have expended its forces, and that we shall have a comparatively safe mild spring. That is a more comforting than safe doctrine. It is best to take nothing for granted, and if there be any error at all in the later planting of Potatoes, and I cannot admit there is, then will it be an error on the safe side.

I am often asked to state what new kinds of Potatoes there are being put into commerce. Really in connection with Potatoes we move very slowly now. There is a very narrow field open for improvement; as evidence of that we see comparatively few new varieties being put into commerce, a sign of undoubted wisdom on the part of the trade. There never will be again seed Potato booms. The days of 2s. 6d. per lb. once paid are past; indeed, it is hard now to get 6d. per lb. for novelties, and they should be superlatively good to be worth so much. Unless I had before me the whole of the Potato lists in issue I could not state how many new sorts are being sent out, and even if I could I should still be haunted by the fear lest some of these should be mere seedling reproductions of old varieties. That not a few of the Magnum Bonum strain now so numerous are just that and no more is certain; that even in such case they do bring to us some moderate access of strength and energy over others some time in commerce there can be no doubt. Still, I have always found that where tubers for such purposes be saved from the best kinds, and stored under proper conditions, that there is practically no loss of robustness of productiveness, even after many years of growth.

We see very interesting seedling trials conducted every year at the Royal Horticultural Gardens, Chiswick, and as last year it usually happens that some half dozen sorts seem to exhibit very remarkable productiveness; but then the value of the trials is much minimised because there is so little of available space for the growing also the older standard sorts for comparison, so that relative merits could be fairly tested. It does not follow that there may not be just a few each year that show some small advances. To find out such merits growers generally should purchase annually a few pounds' weight of new kinds and test them, and specially so from own-saved seed a second year, as I have usually found that to be the best test trial after all. The initial outlay is small, and the result with Potatoes always profitable.

It is most difficult to furnish a good selection suitable for all purposes and soils. It is so common for a variety which succeeds admirably in one place to be unsatisfactory in another. Still there are many varieties that are generally reliable. Thus as first earlies Ringleader and Laxton's Early are good; then come Early Puritan, Duke of Albany, Early Regent, Snowdrop; and for later crops of white kidneys, Chancellor, The Bruce, Main Crop, Reading Giant, and Magnum Bonum are first-rate; whilst of Rounds, Triumph, Supreme, Windsor Castle, Prime Minister, Quantity and Quality, and Sirius, are equally excellent.—A. D.

## WELCOME AND UNWELCOME GUESTS.

IN his interesting lecture at the Birmingham Gardeners' Mutual Improvement Society last week (referred to on page 117) Mr. Wills designated as "unwelcome" guests such insects or animals as would attack the flower itself or abstract its nectar without assisting fertilisation, and "welcome" guests those that assisted fertilisation. Of these, wingless or crouching animals are specially disadvantageous, because in passing from flower to flower they would generally steal the nectar, which is at once the inducement and the reward of those winged insects which are chiefly concerned in the processes of fertilisation, and would remove the pollen without transferring it in due order to the stigma; also because, unlike those "welcome" guests, they are rovers, not confining their visits to one species at a time. Of all those wingless creatures perhaps ants are the worst and most dangerous enemies.

Mention was made as to the almost innumerable protective appliances, corresponding to the endless variety of possible visitors, great or small, soft or hard, winged or wingless; also that one flower is guarded by several distinct means, which fall into definite types of defence, either direct or indirect in their action, and of which such as hairs, prickles, and viscid secretions form a large proportion. Special reference was made to water as an impediment of access of insects and creeping animals to some flowers, as in some of the Bromeliads, Dipsacus, the alpine Gentians, and others; whilst plants which grow in water, such as Water Lilies, Butomus, Sagittaria, and Alisma are absolutely protected, and for this reason the stems of these are freed from hairs, bristles, or opposing processes of any kind.

In connection with this matter it was pointed out as a remarkable fact that at least one water plant—the common Polygonum amphibium, which, as its name implies, continues to live when the water is drained from around it—adapts itself to its new environment by developing, as soon as the necessity of protection has arisen, innumerable glandular hairs on the leaves and stem, from which a sticky substance is exuded, on which if a creeping insect steps he is at once effectually bird-limed. This plant will flourish for years on dried-up ground, but if this becomes

again flooded the glandular hairs at once disappear, being of no longer use to the plant, and by alternate floodings and drying up the two conditions of stem and leaves may be reproduced in turn over and over again on the same plant.

This mode of protection is especially frequent, and is an excellent defence to the nectar; the viscid matter being secreted either from the ordinary cells of the stem or from glandular hairs. Conspicuous examples are afforded by the extensive order Caryophyllaceæ—*e.g.*, *Silene muscipula*, *Silene viscosa*, and *Holostium glutinosum*, the inflorescence of *Lychnis viscaria* being especially provided with viscid matter, thereby affording a most efficient death trap. In *Pinguicula* (Butternut), and in some Primulaceæ there are radical rosettes of leaves spread out on the ground, coated over with tenacious viscid slime, secreted by small glandular hairs, of which 2500 are crowded into each square inch in some species. No small animal which ever came into contact with this ever escapes alive, but its body is dissolved by the secretions, and the dissolved nitrogenous constituents digested by the plants.

Many plants which secrete a milky juice are protected by this secretion—*e.g.*, several species of *Lactuca* for ants and other small animals having their feet terminating in sharp hooks lacerate the tissue, producing a flow of juice, and in their efforts to extricate themselves they struggle and bite, their position becomes worse every moment, and as the viscous secretion is more and more effectually exposed to the air, so it hardens the more rapidly, until their movements become weaker and weaker, and they speedily die. Regarding flowers which possess hairs or prickles in their interior, and which act as barriers to the ingress of some insects, and especially to such as bees and larger flies, they act as path-finders, as in some of the Labiates; and in the genus *Cypripedium* there is a special contrivance, the mode of access and escape of the insect being humorously described by the lecturer, and who also remarked that this arrangement seems to have escaped the notice of Dr. Kerner.

Having adverted at considerable length to the conformation of certain flowers and their nectary organisation, and especially that remarkably long caudate nectar-containing appendage of the beautiful Orchid *Angraecum sesquipedale*, and which can be reached only by the correspondingly long proboscis of certain moths, natives of this Orchid's habitat, Madagascar. Reference was made to day-closing and night-closing flowers, in association with day-flying and night-flying insects; also to the odours and colours of flowers, which serve as attractions to invited guests. The lecture was listened to with rapt attention, and it was rendered further instructive by the display of a series of large pencil diagrams, beautifully executed for the occasion by Mr. Wills himself.

Mr. W. Gardiner afterwards alluded to the processes of fertilisation effected by insects in such flowers as those of the Ivy and Aucuba, as the sexual differences of such organised plants render insects or other artificial agency necessary for their fecundation.

### THE TOMATO SUPPLY.

MR. IGGULDEN'S able communication (page 88) on this subject has been read with great interest by many practical growers, and also by many who were under the impression that Tomato growing was very profitable. Many men have embarked on this enterprise through the fact that they have grown good crops in their small greenhouses, and consequently think they can do the same in large houses. I fully agree with Mr. Iggulden that there is "money in it" if properly sought after; but to suppose a person can invest a few hundred pounds without a knowledge of market growing and reap a fine income is sheer folly. Throughout the Lea Valley hundreds of glass houses are annually erected solely for market growing, the principal crops being Cucumbers and Tomatoes, and many of the growers appear to be flourishing, but there is a "large seamy side" also to be found.

Your correspondent seems to be under the impression there might be a glut of fruit during August and September if all the crops were a success. As a matter of fact such a glut does take place often during these months, but not in such seasons as last year. And again, it should be remembered that the Tomatoes that usually come into the markets at that date are not considered main crops. In reality they form a kind of catch crop, and generally speaking are from houses that have been filled with plants, such as Ferns, pot or bedding plants, which are usually cleared out in May, and the Tomatoes taken from 5-inch pots to plant in their places. Last season my Tomato crops were the most profitable I have ever obtained, prices being very satisfactory. I never remember seeing the plants so heavily laden near the ground; I did not experience the difficulty mentioned by your correspondent, viz., bad setting of the later trusses. In cases of a similar character I should undoubtedly conclude the scarcity of pollen was due to impoverished plants. Once we can secure a good set of the lower trusses there should be no difficulty with those following later. I fear in cold seasons, such as last, growers are afraid to ventilate, under the impression that the crops will be late, but it is better to have a good crop, if a few weeks later, than half a crop which produces 2d. or 3d. per lb. more.

The disease which Mr. Iggulden so ably describes as "black stripe" was the only one that gave me any trouble last season. In a light buoyant atmosphere it develops very slowly, but under a warm moist condition it grows rapidly. There can be no doubt whatever this disease is traceable directly to the roots. If a stem so affected is cut across the brown lines can be seen quite clearly. Directly it was

discovered the plant was pulled out and burnt, while the gap was refilled by plants growing in No. 16 pots, so the house was always kept full. In cases where cultivators hesitated to remove the plants because they had a few good bunches of fruit on them it appeared to lead to a further spread of the pest. I have also resolved to adopt the sulphate of iron remedy, or rather preventive, so strongly recommended by Dr. Griffiths, his figures showing clearly it was beneficial. A great number of market growers are now largely adopting chemical manures for Tomatoes, and numbers have already worked in their potash in the form of kainit ready for next season; but in some soils decayed farmyard manure is preferable, because it renders it more porous, and consequently warmer.

I am surprised to find Mr. Iggulden makes no mention whatever of the most popular market Tomato, *Chemin Rouge*, as quite 75 per cent. grow no other variety. Challenger I have found to be a good one, and the Duke of York is likely to prove very valuable in this respect, as where well grown last year it turned out splendidly. Many growers who have seen *Frogmore Selected* in the flesh will be giving it a trial, for it was always good whenever Mr. Owen Thomas staged it. My own packet will be sown by the time these notes appear.—JAS. B. RIDING.

### HYACINTHS CASTING FLOWER SPIKES.

THESE popular bulbs frequently, during the throwing up of their flower spikes, cause much disappointment. In several cases

FIG. 26.—HYACINTH CASTING ITS FLOWER SPIKE.

20 per cent. of them cast their spikes just when they appeared from the apex of their respective bulbs.

The cause of the flower spike being cast is the forcing forward of the embryonic flower spike (fig. 26, A) by the growth of foliage from the base B, the flower spike appearing before the leaf growth, and it manages to push its way through the bulb scales, which are drawn together for protection at the apex. The growths from the leaf bud are equally anxious to reach daylight and strive to push through the apical orifice, and being below the flower-spike pips and the thicker part of its stem the neck of the bulb becomes choked. Something must give way, and the matter is soon settled by the part containing the most vigour—the leaf growth. If the bulb scales give way, well and good for the flower spike; if not the leaf growth pushes its way through the aperture, throttling the stem of the flower spike and forces it out of its way, snapping its connection with the bulb at the point C. Presently, the lower part of the stem (D) shrivels and the leaf growths are the better able to push the flower spike forward in their growth, and almost, if not, clean out of the bulb as shown in the spike at E.

Thus Nature maintains the "survival of the fittest" in the struggle for existence by mastery, and is not by any means a new thing, nor confined to cultivated plants, yet it is far less common in natural grown. It may be seen in the wild Hyacinth (*Scilla nutans*), the flower spikes shrivelling in their sockets, and it is a strange thing that it occurs more seldom in shady and damp places than in those that are open, sunny, and dry. But this really is the key to the situation, and we are bound to take cognisance of the fact that bulbs are ripened much too quickly and kept out of the ground far too long, for the predisposition is over-

maturity of bud formation through dryness of season, too quickly facilitated by early lifting or bulb induration. The harder a bulb is grown the firmer its scales and the tighter they grasp the embryonic flower and growth buds in their interior to protect them from external influences. Of course growers of bulbs act on that principle to harden them and render them less susceptible of attack by fungal and insect pests, for the more compact the bulbs the less are they amenable to invasion by *Polyactis cinerea* and to mites, which are generally associated in the same diseased bulbs.

The only remedy, so far as I know, is to cut the bulb through the outer scales vertically downward from F to G at planting, taking care not to injure the part containing the flower spike and growth. By that means the apex of the bulb opens and the flower spike has room to emerge and develop without being forced off by the leaf growths.—G. ABBEY.

### SPRAYED POTATOES.

THE accompanying block (fig. 27) for the use of which I am indebted to the kindness of the Editor of the "Irish Farmer's Gazette,"

FIG. 27.—POTATO SPRAYING.

exhibits at a glance the effect of a sulphate of copper application to a crop of Champion Potatoes grown by Lord Clonbrock on his home farm at Clonbrock, Co. Galway.

The original photograph was taken at the end of last September, and shows the disparity in the condition of separate sections of the same crop at that date, the whole of which was grown under identical conditions, but of course, with the addition in the one case of the dressing.

The land is medium clay loam, well cultivated and manured, and kept properly cleaned. The growth of the crop was even until the appearance of the blight, before which occurrence, however, the part of the field shown had received its first dressing, and was treated three times in all. Some parts dressed only once showed little, if any, superiority to the undressed drills. The composition was that ordinarily used, that is 20 lbs. sulphate of copper and 10 lbs. of lime to 100 gallons of water. The calculated cost of the three applications in this instance was, I think, excessive; taking it, however, as it stands and without entering into what might prove misleading details, I find that a series of small plots of land of a given area, when treated exactly as an acre in bulk would be treated, required each an additional outlay of 7d., which is in the same ratio as the total cost of the dressing per acre. For this they individually showed an increase of from 3 to 6 stoncs of sound marketable Potatoes over and above the production of similar and contiguous plots that had not been so treated. This at 3d. or 4d. a stone works out a substantial balance on the right side.

It may interest some of your readers who are not farmers to know that the fungicide was also used by one of the farm hands on his own "lazy beds," with the result that his enterprise was rewarded in that, while one unsprayed "lazy bed" only produced 28 stoncs of good Potatoes, the adjoining one which had been sprayed returned 50 stoncs of sound tubers—nearly double!

In the first of the above instances there was, I must add, considerably over an Irish acre, which was treated in the bulk, but divided into plots for the purpose of obtaining reliable data, so that it was not altogether experimental.

For the rest, the photograph which was taken by Lord Clonbrock speaks for itself.—J. S. KERR, *Roscommon*.

### PEELING AND CLEANING VINES.

So much has been written on the barking of Vines that I think much can be learned from the opinions of such practical men whose names appear in the current controversy. In answer to "J. S. G.'s" practical question, I say thoroughly clean the loose bark off, but do not scrape the Vines.

I have taken a small range of vineries, which are badly infested with mealy bug. The Vines have not been barked for years. To attempt to eradicate the pest, as "D. P." informs us he is trying to do, I should consider it simply waste of time, for it is well known that as the temperature of the house is lowered to ripen the wood, so does the bug find its way closer to the rod. Even when the bark is perfectly smooth they are found hidden so secure that no mixture would reach them without their being first exposed by removal of outer bark.

As "B. S." suggests, and not other reasons, barking to some extent accounts for the lighter crop of Mr. Taylor's Grapes, and should he obtain a crop up to his usual average this coming season, will it not be as much from the improved health and cleanliness of the Vines as from the additional bark they will have made?

Often has my attention been called to the magnificent and highly finished bunches of Grapes staged at Bath and Bristol shows by Mr. Nash. Though ignorant of his mode of treatment, I was fully aware that such good results could only be produced by a practical man fully acquainted with the requirements of the Vines. I trust Mr. Nash will favour us with his opinions through the medium of your valuable paper.—W.

AFTER Mr. Taylor's conclusive testimony (page 121) as to the advantages of retaining the bark on Vines, there remains but little to be said in further support of it. As he so pointedly observes, when one begins to pull off loose bark there is no telling where one will stop. Loose bark that is fairly clear of the Vine is of no further use, and, as I

remarked in my first article, I think it is all that is necessary to remove. If Vines were so badly infested with mealy bug that it was imperative to strip them to eradicate the pest, I should do so. In the first place I should make strenuous efforts to prevent the foe making such strides as to necessitate such harsh treatment.

Some of your correspondents remark that Vines under glass do not require such coatings of bark. I think they are in particular need of it to preserve them against the paralysing effects of a scorching sun, particularly under large squares of glass. Who has not noticed the distressed look of Vines on hot days, especially in light soils? They have not the same cooling advantages as plants growing in the open in a larger body of air. The internal tissues of Vines, too, are much safer than in most fruit trees, hence it seems that Nature had provided them with thicker coating to protect them.

The readiness and force with which the sap flows in Vines, as may be observed in the manner in which they bleed if late pruned, for instance, points to their liability to loss from evaporation if their functions are in any way disturbed.—J. J. CRAVEN.

### ROYAL GARDENERS' ORPHAN FUND.

#### ANNUAL MEETING.

THE members of this excellent Charity met at the Cannon Street Hotel on Friday last to receive the report and balance-sheet for the past

have earned the hearty thanks of the Committee. Grateful mention must on this occasion be made of the contribution of £50 10s.—proceeds of a concert given by the Altrincham Gardeners' Society, and to whom the special thanks of the Committee are hereby tendered.

"For last year's annual festival dinner the Committee were fortunate in securing as Chairman the Right Honourable Sir Robert Tyler, Bart. (the Lord Mayor of London), to whom the warmest thanks of the Committee are due for his able advocacy of the claims of the charity.

"The Committee have the greatest pleasure in announcing that Mr. Harry J. Veitch, Vice-President of the Fund, and one of its most munificent patrons, has consented to preside at the next festival dinner, which is fixed to take place on April 5th, 1895, when it is hoped that horticulturists and gardeners will attend and give Mr. Veitch their hearty support.

"The members of the Committee who retire by rotation are Messrs. Assbee, Ballantine, Cannell, Cummins, Gordon, Lane, Roupell, and Wynne, who being eligible all offer themselves for re-election, with the exception of Mr. Lane, who retires. Mr. McLeod of Dover House Gardens, Roehampton, is nominated for election in the place of Mr. Lane. Mr. George Bunyard and Mr. J. Wright having resigned, Messrs. H. B. May, Edmonton, and H. J. Jones, Lewisham, are recommended for election to fill the vacancies thus created. The retiring Auditor (Mr. Fraser) is again nominated, with Mr. M. Rowan, of Clapham, in the place of Mr. Sharp, who retires. The Treasurer (Mr. T. B. Haywood) and the Hon. Secretary (Mr. A. F. Barron) are again nominated by the Committee for re-election."

Having inspected the Securities, and examined the Books and Vouchers supplied to us, we hereby certify the above account to be correct.  
(Signed) JOHN FRASER, *Leyton* } Auditors.  
M. ROWAN, *Clapham*

Dated, January 28th, 1895.

twelve months. There were about twenty-five persons present. Mr. Harrison of Leicester, presided and proved a very genial Chairman. The minutes of the last annual meeting having been read and confirmed the Chairman called on Mr. W. Marshall to read the report and balance-sheet for the past year, which are printed hereunder :—

"The Executive Committee, in presenting their seventh annual report, again have to congratulate the subscribers to the Royal Gardeners' Orphan Fund on the continued prosperity of the charity. Notwithstanding the intensity of the commercial depression of the country, which so greatly affects all that pertains to gardening pursuits and the cultivation of the soil, it is extremely gratifying to be able to record a success, and to feel that so far as this institution is concerned the tide of charity and benevolence flows on as freely and as fully as ever.

"The receipts during the past year are somewhat higher than in 1893, while the ordinary working expenses remain about the same—two decidedly gratifying facts.

"During the past year the Committee have been able to assist in the maintenance of sixty-one orphan children, at a cost of £787 10s., and the Committee recommend the election of six this day, thus raising the number of beneficiaries for 1895 to sixty-four.

"Of the number of orphans elected since the establishment of the Fund in 1887, five having attained the age of fourteen years are no longer chargeable to it, two of these ceased to be recipients during the past year.

"The Committee regret their inability to recommend that more than six of the thirteen applicants be elected at the annual meeting, the remaining cases—all of urgent necessity—have to be deferred for another year.

"The Committee would again draw the attention of the gardeners themselves to the excellence and importance of this charity, and to solicit from them more help and assistance, which are urgently needed, as the whole object of the Fund is for their exclusive benefit.

"Among the Local Secretaries and others who are foremost in supporting the Fund are many who, by reason of earnest and successful work,

In proposing the adoption of the report Mr. Harrison referred in eulogistic terms of the manner in which the Society was managed, and thought the report a highly satisfactory one in every way. He referred with pleasure to the fact that Mr. Harry J. Veitch had consented to preside at the next festival dinner of the Fund to be held in April, and was of the opinion that a gentleman, so greatly respected and so much looked up to in the gardening world, would prove in every way a model Chairman. He wished the Fund continued success, and hoped gardeners would give it even more support in the future than in the past.

The retiring members of the Committee were each re-elected, while Messrs. McLeod, Dover House ; H. B. May, Edmonton ; and H. J. Jones, Lewisham, were elected to the places of three members who did not seek re-election. Mr. T. B. Haywood was elected Treasurer, Messrs. J. Fraser and Rowan Auditors, and Mr. A. F. Barron Honorary Secretary.

Mr. B. Wynne moved that the words, "provided they have attended three meetings during the year," be added after the word "re-election" in Rule 4. This was seconded by Mr. W. Marshall, and after slight discussion carried unanimously. Mr. Brown, Chertsey, wished to propose that the system of canvassing for votes for applicants to the Fund be abolished, and considered the practice in every way a bad one. He also desired the Committee to discuss the question as to whether it would not be practicable for the Committee to give the widow of a gardener who had been a subscriber a number of votes, and thought that more would subscribe if some such inducement was held out. The question will be brought up at some future Committee meeting.

The following is a list of the candidates for whom application had been made to be placed on the funds of the Society. Those to whose names an asterisk is prefixed were elected:—\*Rosa Emily King Ward \*Felicia Barber, \*Alfred Alexander Crafter, Amy Farrant, Frank Leslie Haycock, \*Isabella Elizabeth Pratt, Andrina Brown Litchie, Seymour Small, Reuben Charles Stevens, Fred Barson, William Clark, \*Frederick Smith Parker, and \*Leonard Taylor.

A friendly dinner of the Committee was held in the evening at Anderton's Hotel, Fleet Street, when an enjoyable time was spent.

## SPAWNING MUSHROOM BEDS.

IN reply to "Mushroom" (page 102) I should say that if the manure had been properly prepared it was unnecessary to take the bed out and mix it with other manure, as a temperature of 120° a few days after making the bed is quite common, and at this time of the year would not have become too dry by overheating. There is a great danger in spawning beds at too high a temperature, and from my own experience more beds are ruined from this cause than any other. If the heat is declining 80° to 85° is a safe temperature at which to insert spawn in the beds, but it would be better to do so at 70° or even less. In testing the heat of a bed the thermometer should be placed in the manure at the same depth as the spawn is put.

Having now for several years past grown Mushrooms on open air ridges on commercial lines perhaps a few words on the subject may be of interest. I have been indebted for many useful hints to the book "Mushrooms for the Million," also to Mr. J. F. Barter, the well-known manufacturer of Mushroom spawn, and although we had some partial failures we have had our share of success. We now very nearly dispense with the Mushroom house, as much better crops can be grown in the open air. The house is useful, however, to make up a small bed or two to come in at midwinter, to gather daily for home consumption, as during severe weather like the present, with the thermometer down to within a few degrees of zero, it would not be advisable to uncover the beds out of doors each day. Although we have had over six weeks of continuous frost, the thermometer this morning, February 6th, registering 27° of frost, the outdoor Mushrooms are not injured. They do not grow much during such weather, but directly there is a change in the temperature the beds will bear freely again. The ridges are well covered with litter, and over this is several inches of snow keeping the beds frost-proof.

The present is a good time to collect the manure as it comes from the stables, and put it in a heap in the open. The long litter should be shaken out, and put in a dry place, as this will be required to cover the beds after they are made up. When several cartloads have been collected the whole heap should be turned over, and if dry well watered. It must then be turned three times a week, and it will take about three weeks to prepare. The ridges should be 2 feet 6 inches wide at the bottom, the same in height, and about 6 inches wide at the top, though beds made at midwinter will hold the heat better if made 3 feet wide at the bottom. When all is finished off the whole must be made firm. Start by putting a foot of manure at the bottom, make it firm by treading, and as it increases in height stand on the ridge and well beat the sides with the back of an ordinary digging fork. When the desired height is reached finish off neatly, then cover the whole with about 6 inches of long litter that had previously been shaken out of the manure, except about 6 inches on the top of the ridge, where it may be about 3 inches deep, to allow the moisture to escape, and in a few days the heat will probably go up to about 120°. When it has fallen to 85°, which will be in about ten days, spawn may be inserted.

This is done by dividing an ordinary brick of spawn into eight parts, inserting each lump about 9 inches apart over the whole surface of the bed, and about 2 inches in depth. The bed must then be covered with about 1½ inch of good, fairly moist garden soil, and be well smoothed over with the back of a spade. It will depend on the heat of the bed, and the outside temperature what thickness of litter is required. In warm weather 6 inches will be sufficient, but in cold weather 1 foot or more will be needed. Keep the surface of the bed as near 60° as possible for a month or six weeks after spawning, and afterwards a lower temperature will suffice. Mushrooms will appear in about six or eight weeks from the time of spawning, but should the weather be very cold they may be longer. Spring and early autumn are the best times for making the beds.—GEO. SUMMERS, Sandbeck Park.

## ROYAL HORTICULTURAL SOCIETY.

FEBRUARY 12TH.  
THE COMMITTEES.

AS might have been expected, owing to the severity of the weather, the meeting at the Drill Hall was a very small one, and comprised Orchids principally, though a few fruits and flowers, including Rhododendrons, were shown.

FRUIT COMMITTEE.—Present: Philip Crowley, Esq. (in the chair); with Rev. W. Wilks, Messrs. Geo. Bunyard, P. C. Veitch, G. Goldsmith, J. H. Veitch, J. Cheal, W. Pope, Alex. Dean, T. Glen, J. A. Laing, W. Bates, W. Farr, C. Herrin, J. Hudson, F. Q. Lane, A. H. Pearson, and G. H. Sage.

Mr. G. Harvey, gardener to Major Thornhill, Bakewell, Derby, sent a handsome collection of Oranges, for which a silver Banksian medal was recommended. Mr. A. G. Nicholls, Nuneham Park, Abergavenny, staged Onion Nicholls' Favourite.

Messrs. T. Rivers & Son, Sawbridgeworth, received a silver-gilt Knightian medal for a collection of Oranges, including Silver Egg, Bitten Court, Dom Louis, and Maltese amongst others, all in splendid condition. A small collection of Apples was sent by Messrs. J. Peed and Sons, Norwood.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. J. Fraser, Owen Thomas, John Laing, H. Herbst, Richard Dean, E. Molyneux, George Stevens, H. Briscoe-Ironsides, H. B. May,

J. Jennings, J. H. Fitt, J. W. Barr, W. Bain, W. J. Grant, Chas. T. Druery, J. D. Pawll, Robt. Owen, Chas. E. Shea, H. J. Jones, C. Blick, H. Turner, Geo. Paul, Ed. Mawley, and Chas. Jeffreys.

Messrs. Veitch & Sons, Chelsea, staged a collection of Javanico-jasminiflorum hybrid Rhododendrons, comprising several of the best varieties, such as Ne Plus Ultra, Rose Perfection, Primrose, Purity, Star of India, Imogene, Luteo-roseum, Monarch, Conqueror, and Empress. Considering the present inclement weather, and the many difficulties arising from such, the collection was well worthy of merit, as also was the smaller exhibit of multicolor hybrid Rhododendrons, conspicuous amongst which were, Ruby, Mrs. Heal, and Neptune.

Messrs. Paul & Son, Cheshunt, staged a bunch of Azalea mollis blooms cut from English-grown plants. A vote of thanks was given to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, for a well bloomed plant of Thysacanthus rutilans. Mr. J. E. Burton, gardener to Sir G. Paul, Bart., Cambridge House, Twickenham, staged a collection of plants of single Primula, Bouquet, obtained from seeds sown in June, 1894. The blooms were fine, of good substance, and the plants well grown.

A group of new single Primulas, Lady Evans, was exhibited by Mr. G. Einton, gardener to Sir David Evans, Ewell Grove, by whom they were raised; the flowers are pure white, and of good substance. Flower spikes of Hæmanthus Kalbreyeri were staged by Messrs. Sander of St. Albans.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); with Messrs. James O'Brien, F. Hardy, W. H. White, E. Hill, Jas. Douglas, H. J. Chapman, H. Ballantine, E. Ashworth, W. Thompson, Walter Cobb, and H. M. Pollett.

From Messrs. J. Veitch & Sons came Calanthe Masuco-tricarinata, said to be a new garden hybrid, and Cymbidium eburneo-Lowianum superbum. From Mr. E. Hill, gardener to Lord Rothschild, Tring Park, came a fine spike of Lælia superbiens, and also one of Phalænopsis intermedia Portei, for which a first-class certificate was awarded.

Mr. Fred Hardy, Ashton-on-Mersey, staged a collection of Orchid blooms, including some good Cattleyas, Dendrobiums, and Phalænopses. Messrs. F. Sander & Co., St. Albans, also showed a group of cut Orchid blooms, including Dendrobium luteolum, D. Statterianum, D. Eger-toniæ, Odontoglossum Humeum, O. coradinei albanense, Lælia anceps Schröderiana, The Dell variety, and a few others. Mr. W. H. Young, gardener to Sir F. Wigan, Clare Lawn, East Sheen, exhibited some Cypripediums, including Lathomeum, Wiganianum, Rothschildianum, and Stauropsis (Vanda) gigantea. Mr. H. J. Chapman, Cambridge Lodge, Camberwell, showed a handsome collection of dried Orchid flowers, in which the natural colours had been retained to an exceptional degree (silver Banksian medal).

A splendid spike of Odontoglossum coronarium var. miniatum was staged by Sir Trevor Lawrence, Bart., Burford Lodge, Dorking. Mr. G. Cragg, gardener to W. C. Walker, Esq., Percy Lodge, Winchmore Hill, arranged a few blooms of various Orchids, comprising some good forms. W. Thompson, Esq., Stone, Staffs, also showed a collection of blooms. Baron Schröder, The Dell, Egham, showed a small but choice collection of Orchids, of which Phalænopsis Youngi received a first-class certificate (silver Banksian medal).

## CERTIFICATES AND AWARDS OF MERIT.

*Anthurium Perfection* (Sir Trevor Lawrence).—This is a fine Anthurium, with a large, brilliant scarlet spathe (award of merit).

*Calanthe Masuco-tricarinata* (J. Veitch & Sons).—This is a garden hybrid with very delicately rose shaded flowers, this colour pervading the whole of the bloom (award of merit).

*Cymbidium eburneo-Lowianum superbum* (J. Veitch & Sons).—This is a handsome and rare hybrid, between eburneo and Lowianum, and carries four flowers on the spike. The prevailing colour is creamy white, the lip being heavily marked velvety crimson (first-class certificate).

*Phalænopsis intermedia Portei* (E. Hill).—This is a very floriferous form with white sepals and petals and lip with purplish rose tip and crimson base. The spike shown was exceptionally good (first-class certificate).

*Phalænopsis Youngiana* (Baron Schröder).—This is a splendid form with broad dull white petals, slightly tinged rose at the base. The upper sepal is of the same colour, while the lower are very pale rose spotted maroon. The ground colour of the lip is pure white, heavily spotted deep rose (first-class certificate).

## ANNUAL MEETING.

The annual general meeting was held during the afternoon, a moderate attendance of members being present. Sir Trevor Lawrence, Bart., President, took the chair. Mr. McLachlan proposed a vote of thanks for the services of the retiring members of the Council. The Chairman, in the course of his remarks prior to moving the adoption of the report, said he was glad to say the general condition of the Society had made decided improvement, the fortnightly meetings had been much better attended than in previous years, and with regard to the Temple Show it was looked on as being as great a pleasure to the authorities of the Temple as it was to the Society, and it proved beneficial to the show, the plants being allowed to remain the whole three days.

The Crystal Palace show was also a marked success, as the returns showed a small profit. He was glad to say some gentlemen had subscribed generously towards supplying the prize money, and he hoped

that many more interested in fruit culture would do all in their power in this respect; he also wished to make special reference to the benefits derived from the different papers which were read at the show. He was pleased that steps had been taken towards placing judging at shows on a more general footing. It was very difficult to form any hard and fast rule, but great improvements might be made. He was sorry that, owing to the inclemency of the weather at the time, the conference on trees and shrubs held at Chiswick was altogether an unfortunate affair, though the papers read at that occasion were of a high order. In spite of this, however, the finances of the Society were in a very satisfactory condition, and he was sure all interested in the Society were pleased to see that it had emerged from the financial difficulties that once prevented its progress, and was now on a firm basis. In concluding his remarks he wished to add a few words of thanks to Mr. Wilks, the Secretary. He was sure that all present were delighted to see him in improved health, and he hoped he would soon be quite recovered. He also wished to thank Mr. Weathers, the Assistant Secretary, Mr. P. Crowley, and Mr. Barron of Chiswick for their able services.

In some discussion that followed, in which Mr. F. Barker, Mr. Ranger Johnson, Mr. Peter Finch, and the Rev. G. Henslow took part, suggestions were made that the Fruit and Floral Committees that were called together to go through the gardens at Chiswick and make awards should present their reports at the fortnightly meetings held at the Drill Hall, as these meetings were doing much to benefit horticulture.

The adoption of the report was then seconded and carried unanimously. Mr. Wilks, in a few brief words, thanked the Chairman for the kind words spoken about him; and Mr. H. J. Veitch proposed a vote of thanks to the Chairman, which was carried with applause, after which the proceedings closed.

#### REPORT OF THE COUNCIL FOR THE YEAR 1894-95.

THE year 1894 has again been one of steady work and progress for our Society.

Nineteen fruit and floral meetings have been held in the Drill Hall, James Street, Victoria Street, Westminster, besides the more extended shows at the Temple Gardens on May 23rd, 24th, and 25th; at Chiswick Gardens on September 25th; and at the Crystal Palace on September 29th, and October 1st and 2nd; and lectures have been delivered at fourteen of the meetings, exclusive of those given at the conferences. The number of awards has been as follows:—On the recommendation of the Floral Committee, 71 first-class certificates against 64 in 1893, 225 awards of merit against 201, and 3 botanical certificates against 6. On the recommendation of the Orchid Committee, 68 first-class certificates against 39 last year, 134 awards of merit against 86, 21 botanical certificates against 25. On the recommendation of the Fruit and Vegetable Committee, 15 first-class certificates against 16, and 12 awards of merit against 23 last year.

The Society's great show held (by the continued kindness of the Treasurer and Benchers) in the Inner Temple Gardens, and graciously opened by H.R.H. the Duke of York, was a greater success than ever, and it is a matter of satisfaction to the Council to find that this meeting is now universally acknowledged to be the leading horticultural exhibition of this country. The best thanks of the Society are due to all who kindly brought their plants for exhibition, or otherwise contributed to the success of this show.

The great show of British-grown fruit held by the Society at the Crystal Palace on September 29th and October 1st and 2nd was of national importance, and as an object lesson in British fruit culture it stands out unrivalled. It is needless to enter into further details, as full particulars will be found in volume xviii. of the Journal, issued at the same time as this report.

To one point, however, connected with the fruit show, the Council desire to draw the special attention of the Fellows and of the general public interested in fruit cultivation. The Society may well be proud of this show, but it must not be forgotten that the holding of the show was due to a very small number of gentlemen, who subscribed the £100 asked by the Council towards the prize money before they would consent to embark on the scheme. This year (1895) the Council have made arrangements with the Directors of the Crystal Palace to again hold a similar show, and they will be glad to receive offers of special prizes from any who are interested in British fruit culture. Donations towards this fund should be sent at once to the Secretary, the Rev. W. Wilks.

The Council have decided to devote the meeting of October 15th, 1895, entirely to an exhibition of vegetables. A special schedule of the show will be issued in April, together with one for the Crystal Palace fruit show.

The Conference on trees, held at Chiswick on September 25th, abounded in interesting material and in papers of the greatest use to landowners interested in woods and plantations, but unfortunately the weather was such as to make it exceedingly difficult to examine the multitude of specimens so kindly sent by contributors, to whom the best thanks of the Society are specially due.

The Society's general work of scientific experiment and investigation, and of the practical trial of various plants, has been going on steadily at Chiswick, under the superintendence of Mr. Barron. Trial has been made of 40 varieties of Cauliflowers, 86 of Peas, 116 of Strawberries, 55 of new varieties of Potatoes, and 67 of Tomatoes. In the floral department 400 varieties of Carnations and Picotees, 70 of Pinks, 78 of Cannas, 60 of Sweet Peas, as well as many Clematis, Campanulas, and Mignonette have been tried.

The following table will show the Society's progress in regard to numerical strength during the past year:—

The Journal of the Society has been continued so as to enable Fellows at a distance to enter more fully into and reap the benefits of the study and work of those actively engaged at headquarters. Vol. xvi., parts 2 and 3, and parts 1 and 2 of vol. xvii., were issued during the year, and vol. xviii., containing the reports of the conferences on trees at Chiswick and on British fruits at the Crystal Palace, is now ready for issue. The Council would like to remind Fellows of two very valuable volumes published in 1893, of which a few copies are left, viz., (i) a monograph on bulbous Irises, by Professor Michael Foster, Joint Secretary of the Royal Society; and (ii) a complete list of certificates to plants, flowers, Ferns, Orchids, fruits, vegetables, &c., granted by the Society from the year 1859 to January, 1893.

An examination in the principles and practice of horticulture was held on May 1st concurrently in different parts of the United Kingdom, a centre being established wherever a magistrate, or clergyman, or schoolmaster, or other responsible person accustomed to examinations would consent to superintend one on the Society's behalf, and in accordance with the rules laid down for its conduct. No limit as to the age, position, or previous training of the candidates was imposed, and the examination was open to both sexes. 126 candidates presented themselves for examination, and were divided into three classes. Eleven of the candidates gained 200 marks and more out of a possible 300 in the first class, 37 gained between 150 and 200 marks in the second class, 40 gained between 100 and 150 marks in the third class, and 33, having failed to obtain 100 marks, were not classed. The names and addresses of the successful candidates, together with the number of marks assigned to each, will be found in the Society's Journal, vol. xvii., 1894, page 67.

In connection with this examination it is satisfactory to record that Mr. W. N. Sands and Mr. G. F. Tinley were appointed to the two scholarships, value £39 a year, and tenable for two years, kindly given to the Society by Baron Schröder, Sir Trevor Lawrence, Bart., and the Worshipful Company of Gardeners.

It is proposed to hold a similar examination in May, 1895, and candidates intending to sit for it should apply to the Secretary, 117, Victoria Street, Westminster, during March.

In round numbers £1900 has been expended at Chiswick this year on the general work, and repairs and keeping up of the Gardens. The receipts from the Gardens by sale of surplus produce amount to £400, making the net cost of the Gardens £1500.

The Council, acting in conjunction with the Lindley Trustees, have devoted considerable attention to the Library. All serial publications have been kept up to date, a large number of valuable volumes have been bound, and the following new books, amongst others, added to the library—viz., "The Natural History of Plants," "The Forester" (sixth edition), "The Diseases of Trees," "The Genus Masdevallia," "Flowers of the Engadine," "The Gardens of the Sun," "Les Orchidées Exotiques," "Schneider's Book of Choice Ferns," "European Ferns," "Index Kewensis," (part 3), &c.

At the last annual meeting of the Society a wish was expressed that a Catalogue of the Library should be published. A fund to meet the expense was accordingly opened, and a sum of £80 has been received up to the present. The Catalogue is already partly advanced, although this sum will not be sufficient, but it is hoped that many Fellows, seeing that the matter is actually in hand, will now come forward with donations however small they may be.

The hearty thanks of the Society are due to the Chiswick Board and to all the members of the Standing Committees—viz., the Scientific, the Fruit and Vegetable, the Floral, the Orchid, and the Narcissus Committees, for the kind and patient attention which they have severally given to their departments.

The Council are of opinion that the special work for which the Narcissus Committee was originally appointed has, thanks to their labours, been so far accomplished that it will not be necessary to call together a separate Committee this year, but that this work may now be carried on by the Floral Committee, to which one or two Narcissus experts have been added.

The best thanks of the Society are due to all those who, either at

home or abroad, have so kindly and liberally presented books to the Library or plants or seeds to the gardens. A list of the donors has been prepared, and will be found in the Society's Journal, vol. xvii., parts 3 and 4, 1895. The Council also wish to express, in their own name and in that of all Fellows of the Society, their great indebtedness to all who have so kindly contributed, either by the exhibition of plants, fruits, flowers, or vegetables, or by the reading of papers, to the success of the fortnightly meetings in the Drill Hall.

A scheme for the affiliation of local horticultural societies was put forward in 1890, and sixty-five local societies have availed themselves of it. The Council express the hope that Fellows will promote the affiliation of local horticultural and cottage garden societies in their own immediate neighbourhood.

A special general meeting of the Society was held on July 24th, 1894, when the following addition to the bye-laws was adopted:—Bye-law 11A.—Any Fellow wishing to commute his annual subscription may do so by making one payment of 40 guineas in lieu of a £4 4s. annual subscription; of 25 guineas in lieu of a £2 2s. annual subscription; or of 15 guineas in lieu of a £1 ls. annual subscription; such commutation entitling the Fellow for life to all the privileges of the corresponding annual subscription.

The Council wishing to recognise in any way in their power the fact that Fellows residing at a distance from London are at some disadvantage in not being able so easily and regularly to attend the Society's meetings, have decided that in future all Fellows residing outside of a radius of thirty-five miles from London shall, in the annual distribution of plants, receive twice the number allotted to those who live within the said radius. The Council are conscious that this may

create a slight feeling of grievance with those who live only just within the boundary fixed, but this is inevitable whatever the radius may be, and they hope that Fellows, seeing the reasonableness of the principle involved, will gladly see it adopted, although they themselves may not benefit from it.

In order to meet a suggestion made by the Fruit Committee, the Council have decided to limit the number of dishes or baskets of fruit shown in any collection to 100 dishes or baskets of distinct varieties.

At the request of many secretaries of local societies, and of some of the most prominent judges at shows, the Council have consented to appoint a Committee to draw up a code of suggested rules and regulations for judging at fruit and flower shows, in order to secure, if possible, some sort of uniformity underlying the principles on which judging is conducted at shows all over the kingdom. The Committee have already begun their work, and will be glad to receive any suggestions, or information concerning cases of difficulty or doubt which have actually occurred within the experience of any.

The Council would like to draw the attention of all Fellows of the Society to the more extended use which the Scientific Committee might be to them if they availed themselves more freely of their privileges in submitting instances of diseases of or injuries to plants caused by insects or otherwise. The Scientific Committee is composed of gentlemen qualified to give the very best advice on all such subjects, either in respect to the prevention or cure of disease. The Committee is also glad to receive specimens of malformation or other subjects of horticultural or botanical interest.

Subjoined is the usual revenue and expenditure account, with the balance-sheet for the year ending December 31st, 1894.

## FRUIT FORCING.

**Vines.**—*Early House.*—The Vines in flower should have a temperature of 60° to 65° at night, and 70° to 75° by day artificially, but Muscats require 5° more both day and night. A somewhat drier atmosphere, secured by freer ventilation rather than withholding moisture, favours the development of the organs of fructification. Care, however, must be taken in ventilating during severe and sharp weather, avoiding an inrush of cold air, which chills and stagnates the growths, producing rust in the berries and crumpled foliage. A genial atmosphere must be insured by keeping the floors sprinkled two or three times a day in bright weather, but occasionally only in dull periods. Any shy-setting kinds, such as Muscats and Buckland Sweetwater, may have the pollen distributed by a camel's-hair brush, first brushing the bunches over lightly so as to dislodge the "caps," and then follow with a brush surcharged with pollen from the free-setting varieties, such as Black Hamburgh. Stop the laterals below the fruit at the first leaf, and keep those stopped to one joint throughout the season, but those above the bunch may be allowed to make two or more joints, provided there is space for the full exposure of the foliage to light and air. Heavily cropped Vines make correspondingly little growth, and the Grapes frequently do not colour, because there is not sufficient chlorophyll developed, and matter stored for conversion at the time of ripening into the purple, black or amber colour. When Vines make little growth it is a good plan to reduce the Grapes early, so as to secure some growth in the laterals, and so keep the roots active, thus maintaining a good supply of nutriment. This is better than relying exclusively on stimulants, for the assimilative power depends on the amount of foliage exposed to the influences of light and air, and a moderate nourishing diet is far better than forcing and excessive amounts of rich food.

*Vines Started at the New Year.*—The Vines are in leaf and showing the fruit in the points of the shoots. Do not hasten disbudding, but perform the operation gradually, removing the weak and least promising growths in the first instance, then give further attention when it is seen which shoots are likely to afford the best bunches. One bunch on a spur is as much as is likely to finish properly, but that is a very unsatisfactory estimate of the producing capabilities of the Vines, as the bunches are of different sizes; therefore judgment must be exercised, leaving no more than what is calculated to amount to a pound of Grapes when ripe per foot run of rod. Where the spurs are widely distant along the rod two shoots may be left on each spur, but one only must be allowed to bear fruit, the duplicate bunch only remaining until choice can be made of the better, and it is desirable to have the non-bearing growth nearest the rod, so that when the crop is cleared the most distant growth can be cut away, thus keeping the spur as short as possible, and the future crop produced by wood not previously decreased in vigour by heavy cropping. Weak Vines may be allowed more space so as to secure stouter wood, larger and plumper buds, and better bunches in the following season. When the growths are advanced about two or three joints beyond the bunches their points may be pinched off, this being effected when the leaf at the stopping joint is about the size of a halfpenny. Give the needful protection to outside borders, keeping the soil from becoming frozen.

*Vines to Afford Ripe Grapes in July and August.*—The Vines must now be started, and as they break more evenly and strongly when assured a moist, genial atmosphere, damp the rods two or three times a day in bright weather and sprinkle other surfaces. Occasional damping will only be necessary in dull weather, avoiding such syringing as keeps the rods constantly dripping with moisture, for the tendency in that case is to promote the emission of aerial roots, which certainly appropriate stored-up food and hinder the formation of roots in the border. A temperature of 50° at night, 55° by day, and 65° from sun heat is suitable until the buds begin to move. Bring the inside border into a thoroughly moist but not saturated condition by repeated waterings with tepid water, and if the Vines are weak and the soil open afford a supply of liquid manure after it is watered sufficiently for healthy growth. The soil will then retain most of the manurial elements, and they will pass into an assimilable form, or such as is available for taking in by the roots, and will accelerate root activity as well as supply nourishment. The outside borders should have sufficient protection to prevent chill, a little stable litter being all that is required. Avoid thick coverings of manure, particularly when likely to settle into a close mass to the exclusion of light, air, and warmth. Give preference to rather lumpy, partially decayed material, which will admit of the free access of air.

*Late Houses.*—The Vines being cleared of the Grapes early in January, then pruned, dressed, and the structures thoroughly cleaned, afterwards removing the loose surface soil and supplying a top-dressing of fresh loam with an admixture of fertilising ingredients, they will be ready for starting whenever desired, as they will have the wounds made in pruning so healed as to prevent bleeding and derive benefit from the complete rest. The varieties taking a long time to grow and mature

perfectly, such as Gros Colman, Gros Guillaume, Trebbiano, and Mrs. Pince, must be started in good time, so as to give them the benefit of the summer for developing and maturing their crops. A start should therefore be made without further delay, as it is essential to the perfecting of the Grapes, especially those subjected to the highest cultivation, that the Vines be started so as to be perfectly finished by the middle of September. Strong rods should be brought into a horizontal position or lower, and a good break secured by maintaining a genial condition of the atmosphere, and syringing the Vines occasionally in dull, or two or three times a day in bright weather. A temperature of 50° to 55° at night and on dull days, with 10° advance from sun heat, will be sufficient until the buds break, then allow 5° to 10° more by day, husbanding the sun heat by early closing, but losing no opportunity of ventilating freely in the early part of the day, so as to secure sturdy growth and well developed stout foliage. Nevertheless, avoid chills and sudden depressions or fluctuations of temperature, which by alternating tendencies of crippling and provoking growth seriously impair the health of the Vines, and it is seen later in the indifferent doing of the crop.

*Ripe Grapes.*—Avoid fire heat as much as possible in the Grape room, but the severe weather has necessitated recourse to constant firing, and moisture is apt to be drawn out and deposited on the cooler surfaces of the Grapes. This sometimes results in "spot," both with and without fungal growth, for it is certain that without the moisture the fungoid germs could not develop, and their germinal tubes not enter the tissues of the Grapes until the cuticles were weakened, if not actually ruptured, by the contact and continued presence of the moisture. A little air will prevent such accumulation of water on the berries, and the Grapes will not shrivel unless the evaporation be excessive and the temperature high. An equal temperature of about 45° is most suitable, and the less light the Grapes receive the longer they will retain their colour. As the water in the bottles diminishes it should be replenished with clear soft water, taking care to avoid spilling any or allowing drops to fall on the Grapes.

## THE FLOWER GARDEN.

**Acacia lophantha.**—Young plants of this graceful Acacia will be found of the greatest service for dotting among tuberous Begonias, Verbenas, Violas, and such like, and also for large mixed beds. The seed is very hard, and in order to hasten germination soak it in a bottle or jar of water till it has softened and swollen considerably, when it should be placed singly in 2-inch pots and peaty soil, previously warmed through, and plunged in a brisk bottom heat. Thus treated the seed is not slow in germination, and if the seedlings are given one good shift before they become badly root-bound they will be ready for cooler quarters towards the end of April, and for bedding out early in June.

**Antirrhinums and Pentstemons.**—These may well receive identical treatment. Both well deserve to be more generally bedded out, especially where they are kept in separate colours. Cuttings may be rooted by hundreds or thousands in the autumn, and kept through the winter in frames, selected stocks of Pentstemons being similarly treated. Seeds should be sown at once, and it will then be possible to have strong plants ready for bedding out in May.

**Alpine Auriculas.**—A packet of seed obtained from a reliable source should give a number of good varieties, and in order to have strong plants for flowering next season no time should be lost in sowing in well-drained pans filled with sandy loam, given a gentle watering, and allowed to drain two or three hours. The gentle moist heat of a mild hotbed best favours early germination. Sometimes the seedlings appear in the course of three weeks, and with some show of regularity; but more often than not they come up singly, and at long intervals apart, the last showing six or more months from the date of sowing. The strongest may be placed singly in thumb pots. Avoid coddling the young plants. They succeed best under frame culture till they are strong enough for the open.

**Cannas.**—A packet of seed of Crozy's hybrids will give several superior flowering varieties, but a collection of well established plants of named varieties would prove a feature if grouped in a large bed next summer. They flower finely in the open, and if carefully lifted and repotted will continue flowering in a warm conservatory during the rest of the year. Pot plants after receiving a rest of a few weeks will when started in gentle heat push several suckers, all of which can usually be detached with a few strong roots attached. Potted singly into sizes that comfortably hold the roots and kept in heat, serviceable plants would be ready for the beds early in June. The seed is remarkably hard, and must be softened as advised in the case of *Acacia lophantha* prior to sowing it in pans of warm peaty soil. From small pots the young plants may be shifted into 5-inch, and if kept growing in heat will be quite large enough for the beds in June.

**Dahlias.**—Newly rooted plants with a single stem and turned out of a 5-inch pot are greatly to be preferred to divided old roots with three or four shoots apiece. Start a few old roots of the best varieties in gentle heat, and abundance of young shoots will soon be produced. When about 4 inches or rather less in length take each off with a thin heel of old bark and place singly in thumb pots, a little sand being placed at the base of each. Set them in frames or hand-lights over a rather dry bottom heat and there will be few failures, removing to cooler quarters before the plants become drawn, and repotting early in larger pots. Dahlia seed germinates readily when sown in pans and placed in a brisk heat. If pricked out thinly in boxes the plants would move very well out of these, or the seedlings may be placed singly in 2½-inch pots.

**Grevillea robusta.**—This is an elegant, serviceable, but by no means showy plant, and can only be raised from seed. Sow at once in pans of peaty soil. Bury the seed point uppermost, and it may then germinate quickly. Place the seedlings as they become large enough to handle singly into thumb pots, and keep in gentle heat till well established.

**Chamaepeuce and Centaurea.**—A good stock of strong young plants of these are of the greatest assistance. Sow the seeds at once in pans of sandy soil, plunge in a hotbed, cover with squares of glass, shade heavily, and keep the soil uniformly moist. The seedlings must be carefully lifted out of the pan and placed singly in small pots as they attain size.

#### THE KITCHEN GARDEN.

**Kidney Beans.**—There is every likelihood of outdoor vegetables proving scarce this spring, and for this reason, and also because Kidney Beans are always acceptable, as many as possible should be grown under glass. Those grown on the back shelves, fronts, and walls of forcing houses are the quickest to come into full bearing, while those who can afford to devote a well heated house principally to Beans may venture to cover the roof thinly with the new climbing Kidney Bean. The latter, if not unduly crowded and well fed at the roots, will produce fine succulent pods in abundance and in a fairly long succession. Do not sow dwarf varieties in small pots with a view to shifting them into larger ones unless house room is very scarce, as this makes extra work without compensating advantages. Nor when the seed is sown in 8-inch or larger pots ought space to be left for top-dressings, as the latter are rarely taken possession of by the roots. Fill the pots to within 3 inches of the rim with rich loamy soil, sow eight or nine sound seeds on this, and cover with 2 inches of soil. If wanted quickly stand the pots on the hot-water pipes, and if the soil is kept moist the seed will germinate in a few days. Reduce to about six plants in a pot if Ne Plus Ultra, Sion House, or other comparatively small varieties are grown, while three plants of Canadian Wonder are enough for a 9-inch pot. Keep the plants growing in a warm, light position, support them early with Birch or Hazel spray, using stakes and strips of raffia by way of a substitute. They must never become dry at the roots, should have liquid manure freely directly they commence cropping, and the pods ought to be gathered as fast as they are fit. Sow every ten days. Kidney Beans succeed well in boxes, such, for instance, as herrings are largely packed in, and require less water in these than they do in pots.

**Cabbage.**—In many places only quite the earliest Cabbage finds its way into the dining-room, and if it can be cut at Easter or thereabouts it invariably meets with favour. Severe frosts will have seriously checked the growth of the plants, the more forward probably coming to grief. Directly the state of the ground permits hoe lightly among the plants, and either apply soot freely or nitrate of soda if the soil is somewhat light, sulphate of ammonia on the heavier soils, at the rate in the two last cases of about 2 ozs. per square yard. Cabbages can be forwarded as easily as Cauliflowers, and pay for the trouble. Where possible cover patches of four or five plants with hand-lights, give a little air on bright warm days, and apply liquid manure freely whenever the soil approaches dryness. If there is a scarcity of autumn-raised plants, or if the latter give early signs of bolting, sow a pinch of seed of a quick-hearting variety in a frame or box over a gentle hotbed. Giving the whole of a light up to this purpose answers best, as then by sowing thinly the plants may eventually be transplanted direct to where they are to grow. These early raised plants make very rapid progress on rich ground.

#### PLANT HOUSES.

**Adiantum cuneatum.**—Plants from which all the fronds have been removed and display signs of growth should be potted at once. If larger plants are needed do not disturb the old ball beyond the removal of the drainage. By this method the plants quickly establish themselves. The soil should be placed in the house to warm before potting is done, and may consist of three parts of good loam and one of leaf mould, to which a liberal quantity of coarse sand should be added. Press the soil firmly into the pots and water carefully until root action has well commenced. The plants soon commence growth if placed after potting in a temperature of 60°.

**Microlepia hirta cristata.**—This is a most useful Fern, and makes a splendid basket plant for the conservatory. It is a good Fern for rooms, and is admirable for dinner table decorations. The best method of keeping a good stock is to constantly divide a few plants. For our smallest plants we cut over, at this season of the year, two or three plants and then divide them into small pieces. These are planted thickly in boxes and placed in brisk moist heat. In a very short time the plants commence growing, and are then potted singly in sizes varying from thumbs to 2½ inches. In from 5 to 7 inch pots, for the embellishment of the conservatory, they will be found most useful. This variety does well in the compost advised for *Adiantum cuneatum*.

**Pteris serrulata.**—This and its many crested forms are amongst the most useful Ferns for furnishing purposes, and are so easily raised that any plants seriously damaged may be thrown away. If the fronds only have been injured the plants may be cut down and started into growth in any house where an intermediate temperature can be maintained. Those that have been confined in small pots may be placed in larger, while seedlings from pans and boxes may be potted singly or in little bunches as opportunity offers.

**Pteris tremula.**—This is also useful and nearly hardy. Plants are so easily raised from spores and grow so rapidly that once they

are damaged it is best to throw them out. For nearly all furnishing purposes this variety is best when little bunches of seedlings are potted together.

**Polystichum proliferum.**—This is exceedingly useful in small pots for edging purposes, and will stand in rooms exceedingly well. It is a good plan to plant in a fairly warm place about two well-established specimens. These will produce plantlets freely and even rapidly. These fronds should be pegged down on light sandy soil, and when well rooted the fronds can be cut off and the young plants placed in boxes and grown in any position where a little warmth can be maintained. From the boxes the young plants should be placed in 2½-inch pots, and the second season beautiful plants in 4 and 5-inch pots are produced. Plants well established in small pots may be placed in 4-inch at once, and if put in warmth new fronds will quickly follow. Where a good stock has been wintered in a cool place they can be potted and introduced as required.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### THE WEATHER.

FOR several mornings previous to, and including the 9th, the thermometer stood at zero, continuing at that low temperature during the night, and in some places it was 10° lower. It is when high or low temperatures are protracted that we feel the effects of them most. How the bees will come through the rigorous time remains to be seen, but we may make up our minds that some will have succumbed. I had occasion to move my bees about fifty yards a few days since, and was surprised to find many of them much lighter than I anticipated. The moment a thaw sets in they will be attended to with food, as the temperature at present does not justify the slightest interference with them.

#### FOUL BROOD.

The question of foul brood being so much before the country at present, the Blantyre No. 1 Bee Club and Vale of Clyde Bee-keepers' Association at a meeting on the 7th inst. resolved, "In order to keep the enemy at bay, as it has been amongst some of its members' hives, to adopt similar hives to those used by some bee-keepers so successfully for so long a period." It was also decided that the Club should have full power to inspect members' apiaries, and overhaul suspicious cases should any symptoms appear. All the members agreed to report to the Secretary from time to time the state and health of their stocks. One of the rules of the Club makes these measures imperative on its members.

It was also unanimously agreed to, in order to prevent any measure becoming law, or in any way inimical to privacy, success, or profit in and from the apiary, that the President of the Board of Trade and member of Parliament be written to, detailing several facts concerning foul brood, and suggesting likely measures which would be agreeable and satisfactory to all concerned.

The Blantyre Bee Club and Vale of Clyde Bee-keepers' Association intend holding a honey show, open to all comers, in October, when prizes will be given for honey pressers, and technical instructions given from time to time on bee-keeping generally. The President of the Association, Mr. Pearson, Rutherglen, gave a handsome donation, with the promise of more towards making the show a success, while silver medals and other prizes have been promised from other sources.—A LANARKSHIRE BEE-KEEPER.

#### SEASONABLE NOTES—LOOKING FORWARD.

THE severe frost and heavy fall of snow which appear to have been general throughout the country will be the means of keeping the bees snugly clustered in their hives, and if previous instructions have been carried out they will be dry, warm, and ready to take advantage of the fine weather when it comes. Spring-flowering plants are well protected under a warm covering of snow. The Winter Aconite (one of the earliest bee flowers) and the Snowdrops were ready to burst into bloom when the frost came in all its severity. When the frost and snow disappear, and a higher temperature prevails, the merry hum of the busy workers on these and other spring flowers will remind bee-keepers that spring has indeed come. Every day will bring its work, and the negligent bee-keeper will regret the time lost during the quiet winter months in not making preparation for another season.

Now is a good time to have a general stock-taking, as necessary to the cottager with his solitary hive as to the bee-keeper who counts his stocks by the dozen. All spare hives should have a coat of paint; roofs should be examined to see that no leaks occur;

any frames or sections that have been previously used should be cleaned and got in readiness; extractors should be examined to see that all is in working order, and notes made of what is likely to be required for another season. If the stock is to be increased, new hives, frames, sections, and comb foundation must be ordered at once, and there will be no difficulty in obtaining a good discount on all money so expended in the slack season. During the busy time of the year, however, the majority of dealers will only supply goods for net cash, besides often keeping their customers waiting, which is very annoying, but by ordering now everything is ready to hand when required.

As some of my readers may be beginners, and are anxious to invest in their first frame hive, but are in doubt as to the best one to select from those advertised by different dealers. For many years past I have had business relations with a firm of high repute among bee-keepers, and their goods have always been most satisfactory; I refer to Messrs. Geo. Neighbour & Sons, 127, High Holborn, London. I believe they were the first firm in this country to introduce the moveable frame hive, and since that time have always been to the fore with the best hives—from the humble straw skep to the Stewarton and the more elaborate bar-frame hive.

I will describe some of them that have come under my notice. One of the cheapest is the Cottage Frame Hive. It is made of three-quarter-inch boards, and has nine bar-frames and a dummy. These are of the standard size, and fitted with metal self-adjusting ends, which keep them the required distances apart, and rest on a ledge without notches, so that they are not liable to be fixed with propolis. The Sandringham Hive has taken numerous prizes as the best and most complete bar-frame hive. It is of a substantial character, with arrangements for summer and winter use capable of being used for doubling to obtain extracted honey, or of being storified with one or two crates of sections. Another good hive is the Double-cased Hive, with cork dust between the walls, which are nearly 3 inches thick. The floor-board is also packed with cork dust, and is moveable for cleansing purposes. The hive is provided with a dummy and twelve frames of the standard size fitted with metal self-adjusting ends. A double quilt forms the crown, provision being made for feeding.

The bees are thus kept snug and warm. Honey may be obtained from the stock hive by introducing a wide frame filled with sections, protected at the sides with perforated queen-excluder zinc, and a crate of sections may also be worked on the top. Two colonies may be packed in this hive for wintering, but for such a purpose another entrance must be made at the opposite end. This is a more expensive hive. The Buncefield hive is very similar to other frame hives, except that the walls are made of straw neatly bound with cane, and the rustic appearance of straw is always agreeable in a garden. The improved straw skep has a window through which the bees can be seen at work. A crate of sections or a glass may be worked on the top.—AN ENGLISH BEE-KEEPER.

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Manures** (*Cross*).—Our answer to your question is in the negative as to the use of the material you mention. It is desirable to write a little more fully in asking questions of this nature. Abbreviations are not helpful during moments of pressure.

**Banana Fruits Ripening** (*Banana*).—You do not name the variety or species, but if *Musa Cavendishii* the fruit requires about three months from the first "fingers" being fairly set to their ripening—that is, a plant showing fruit at the end of January will ripen it in May or thereabouts. We have recently seen some "fingers" or pods of this

variety that weighed over 1 lb. each, and the cluster over 100 lbs. without the barren end.

**Snow Plough** (*A. B. P.*).—You will find the plough depicted in the woodcut (fig. 28) suit admirably. It was made by Mr. Harrison of Knowsley, who wrote when sending a photo of it:—"The 'Knowsley' snow plough is, as will be seen by the illustration, an adjustable machine, and can be readily fixed to suit various widths of road, up to about 12 feet. There is a slight projecting plate of iron fixed to the bottom edge of each side piece, which act as 'shares' in cutting the snow loose from the ground, and a pair of iron 'skates' fixed in the line of draught, and secured to the shafts and front part prevent the possibility of the implement refusing to act when it happens to get into a deep drift. As a further aid to that end the power is applied, that is the horse is hooked on, not at the extreme end as is

FIG. 28.—THE KNOWSLEY SNOW PLOUGH.

usually done, but a little further back. The draught of the new implement is much lighter than that of the old pattern. The plough is shown here with one side extended and the other drawn in."

**Primula japonica** (*Leicester*).—If the seed had been good plants should have been raised under the treatment you adopted for *Polyanthus*, though the seed takes a little longer to germinate. With new seed we have no difficulty in raising plants. You may sow any time during the present month, placing the pan where the temperature ranges from 55° to 60°.

**Crotons** (*Derby*).—The Crotons, unless tall, should not be cut down to the pot; but if they are bare of leaves at the lower part it would be advisable to shorten them, so as to secure growths near the base, otherwise the plants are best left to themselves, and in plenty of light usually branch freely. If cut down the earlier it is done the better, so as to allow time for their making good growth, which, to develop and colour well, requires abundance of heat, moisture, and all the light possible, with thorough cleanliness and judicious feeding.

**Petroleum and Peach Trees** (*T. H. C.*).—The branches are killed where the petroleum has been used; even the thick part sent is saturated with the oil. In other respects there is no disease whatever, not even gum, to which the dying of the branches here and there in former years may have been due. The petroleum has simply penetrated the bark down to the wood and destroyed the cells. The young growths to which it has not been applied have both live bark and sound wood, even green growths, but the character is such as to be of no value for bearing, being soft, unripe, and mostly blossomless in character. The petroleum dressing would act more disastrously on such wood than on well ripened, but crude petroleum is dangerous to use on even thoroughly matured wood, and not infrequently fatal, as in your case.

**"Insects" in Soil** (*Henri*).—No. 1 is *Jules terrestris*, one of the Snake Millepedes, and feeds on decaying and living animal and vegetable substances. It preys on the roots of various plants, and is very fond of Strawberry fruit and Mangolds. The pests may be greatly reduced in numbers, if not entirely got rid of, by cutting Mangolds in slices and placing them in their haunts, or, preferably, cutting a Mangold in two transversely, scooping out the centre so as to form a cavity, making notches in the cut edge to admit the animals, and placing that side downwards. Examine the traps daily, and destroy the lurking creatures by brushing them into boiling water. No. 2 is not an insect, but a fungus, one of the low saprophytic forms, which may, or may not, be injurious to plants, as that depends upon its development, but, as a rule, such fungi are not prejudicial to plant growth.

**Tropæolums** (*An Old Subscriber*).—The varieties you name, as well as many others, do not pass the winter in very good condition unless great care is taken in their preparation and management. Strong well-established plants in pots generally succeed best when placed on a shelf not far from the glass, only keeping the soil sufficiently moist to prevent the leaves flagging. The atmosphere should also be fairly dry, and abundance of air given whenever the weather is favourable. When the plants are employed for bedding the cuttings are rooted in boxes outside, in the same way as Zonal Pelargoniums. The cuttings should be inserted fairly early in soil containing a free admixture of sand, so that they will be well established before it is necessary to house them. This should be done before they become saturated by heavy autumn rains. We find they keep very well in a vinery if placed close to the front ventilators. You may propagate your plants towards the end of the present month in a temperature of 60°. The cuttings will root best if not placed under hand-lights or bell-glasses. As soon as the plants are established they must be removed to cooler quarters, or they will be attacked by aphides. It is possible you have kept your plants a little too close, and the soil too moist as well.

### PROFITABLE LIVE STOCK—HEREFORDS.

No breed of cattle is so generally attractive as the Herefords; with their red coats, white faces, chests, and tail ends, they are most picturesque objects out on pasture, as they are certainly the most attractive class at cattle shows. Regarded from a more practical point of view they are in high favour. The breeder likes them for their robust hardy constitution, their thrifty condition, and early maturity; the butcher, for the smallness of offal, and the excellence of the meat, which always has a ready sale, the marbled beef with its admirable admixture of fat and lean being in high favour with the consumer. They are especially remarkable for the early maturity, which in a great measure has led to the rapid extension of this breed both at home and in the colonies. When it was found that the progeny of carefully selected parents developed this valuable paying property more and more, and that they fattened readily and cheaply, beef and beef only became the breeders' aim, and marvellously successful have they been. It is claimed for them that they are "good doers owing to a contented mind, placid disposition, and gentle manners," which reads like the description of an enthusiastic breeder. It is certain that the gentle kindly disposition of this breed does exercise a beneficial influence on growth and condition.

But the well formed beasts, with their rich mellow flesh of superior flavour, so well and evenly laid on over the whole carcase, would not come so early to maturity nor be so profitable without good management. The store beasts must be kept going well during the winter—condition keeping pace with growth—an easy matter when well-bred healthy beasts have perfect shelter and wholesome nourishing food. When turned out to grass they thrive so well that most of them go direct to the butcher off the pasture, and it is claimed for them that beasts of eighteen and twenty months readily realise £1 per month on their age. It may not perhaps hold good as to price just now, but that does not affect the general question, and there can be no doubt that Herefords rightly hold a high position among our profitable live stock. Their reputation has spread to the ends of the earth, and they have followed it breeders in North and South America and in Australia having eagerly sought after them.

There can be no doubt that agricultural societies have done very much to bring this, as well as all our best breeds, into prominence, and draw the attention of foreign breeders to them. At the summer meetings admirable examples are always to be met with in very considerable numbers, and at the Christmas cattle shows there are always select specimens, serving to illustrate the early maturity of the breed. The favourite age for the fat stock appears to be about twenty-two months, at which age the weight ranges from about 11 to nearly 14 cwt, which shows that they are no mean rivals of the shorthorns in the class under two years, as indeed they are in older classes. Herefords of a ton in weight are often to be seen at our shows now, but we regard such beasts as interesting curiosities, as showing what is possible with the older beasts, and not as examples of profitable management.

Taken for all in all, the kindly, hardy Hereford is one of our very best beef producers. We want more of them in the hands of graziers generally, instead of the mongrel stock which is so unprofitable, and is still so common. Of the whole of the

tenants of an estate of Leicestershire grass farms, not one of them has a single head of well-bred stock, yet some of them have herds of thirty cows. It is true enough that Hereford cows would not answer their purpose as dairy farmers, but the objectionable part—the weak point of their practice—is the purchase of such large numbers of mongrel store beasts, about which there is so frequently an outcry, that after "keeping" them a year they have been sold at a positive loss. Perhaps the less said about such doings the better.

We long for the day when asture will be really cultivated and brought under a system of sustained fertility, and when the stock on it will be well bred, and altogether so well managed as to realise the highest possible profit. In the neighbourhood of Market Harborough considerable herds of Herefords are to be seen on the summer grazing, but they are very seldom to be met with near Leicester or Melton Mowbray.

#### WORK ON THE HOME FARM.

Since writing our last farm note more snow has fallen, and the cold has continued growing in intensity; 38° of frost, or 6° below zero, has been registered in Leicestershire. There are snow wreaths of considerable depth in the midlands; farther north we hear of sheep buried in snow, and flocks inaccessible to the shepherds owing to deep snow. In such trying weather the full value of a lambing yard is realised, and the flock can be thoroughly cared for. We allow no frozen roots to be used for any sheep, only those which have been placed in well covered heaps and which can be cut up and used unfrozen. The flock can do very well if need be without roots, and there should be no difficulty with the abundant store of food we have. Give the ewes a pint of crushed Oats daily till the frost breaks, or even afterwards if thought necessary, keep abundance of Pea straw in the racks, mix with the Oats chaffed hay and straw to be given in the troughs, and see that these are kept clean. Feed so freely that the sheep are not driven to search for food under the snow, give a change when possible—some Peas or other corn with the Oats, and some silage in the racks.

Suffer no exposure of lambs to cold cutting winds, make an extra fold or two if necessary, keep up the store of food near the folds, and litter with long straw sufficiently often to insure a dry bed. Keep all small flocks near the homestead so that they may have proper attention, and run no risk whatever of loss from exposure. We make a point of seeing that all matters of detail have prompt and timely attention. The shepherd must not be taken from his flock to procure supplies of food of any sort; it is the master's affair to see that nothing is wanting for the flock, not to wait till complaints are made of negligence, and there is suffering and loss among the sheep. For shelter there are many contrivances, one of the best being hurdles thatched thickly with straw for roofs, and for sides to keep off wind two rows of hurdles about a foot apart, the space between being stuffed with litter or straw. Brushwood faggots, too, if bound together closely make a capital wind guard.

#### REMARKS.

3rd.—Overcast all day.

4th.—Fine, with frequent sunshine; a few flakes of snow about 1.30 P.M.

5th.—Bright sunshine all day; cold night.

6th.—Light snow from 7 A.M. to 8.30 A.M.; bright sunshine all day; cold night.

7th.—A few snowflakes in early morning and between 8 and 9 A.M.; sunshine almost a day; cold night.

8th.—Bright sunshine throughout; lunar halo in evening.

9th.—Slight fog till about 10 A.M., faint sunshine after; dense fog from 1 P.M. to 6 P.M. gradually clearing.

The duration of the intense frost is not merely unequalled in any February, but in any month since observations were commenced here in 1858. At present it appears to be remarkably similar to almost the corresponding days of February, 1855.—G. J. SYMONS.

# VEITCH'S

## GENUINE SEEDS.

### THE BEST TOMATO, FROGMORE SELECTED

First Class Certificate, R.H.S., April 24, 1894.

Exceedingly prolific, of medium size, very uniform and smooth in outline, firm and solid, the best Tomato of the season, either for early forcing or outdoor cultivation. Per Packet, 2/6.

### THE BEST MELON, HERO OF ISLEWORTH.

Award of Merit, Royal Hort. Soc., Aug. 8, 1893.

A green-fleshed seedling of exceptional merit, free setter, and superior quality. Per Packet, 2/6.

### THE BEST CUCUMBER, VEITCH'S PERFECTION

A distinct and superior variety of robust constitution. Strongly recommended for either spring or summer work. Per Packet, 2/6.

### THE BEST ONION, VEITCH'S MAIN CROP.

This is a most desirable and perfect strain for exhibition or table use, and though generally grown for a main crop, is also an excellent keeper. Per Ounce, 1/6.

For full descriptions of the above, and many other CHOICE NOVELTIES & SPECIALITIES, see SEED CATALOGUE for 1895, forwarded post free on application.

## JAMES VEITCH & SONS,

ROYAL EXOTIC NURSERY,

CHELSEA, LONDON, S.W.

## THE NEW MELON FOR 1895.

# SUTTON'S Royal Favourite.

We have the honour of offering a New Melon of singular beauty, originated by

Mr. OWEN THOMAS, of the Royal Gardens, Windsor, Who has placed the entire stock in our hands.

The fruits of this Melon are perfectly spherical and elegantly netted. The flesh is white, exceedingly deep, with a full and exquisite flavour. The plant is robust in constitution, sets freely, and is very productive.

Price of Seed, 3s. 6d. per Packet, Post Free.

GENUINE ONLY DIRECT FROM—

### MAKING VINE BORDERS AND PLANTING VINES.

THE soil or compost for new or renovating old Vine borders is best prepared and held in readiness some time prior to use, so that the work may be performed expeditiously when the weather is suitable and the material is in good working order. Some Grape-growers, however, prefer the material fresh, as it then contains a much larger amount of raw nitrogenous matter, which by slow decomposition gradually becomes available as food for the Vines. It then contains the live roots and herbage, and may or may not be alive with visible or microscopic organisms. The turf of most pastures contain the accumulated remains of preceding years' vegetation and dead lowly animals, which implies a store of plant food in the best possible form for another or different plant—to wit, fruit trees, Vines, and potted plants. It also contains the living representatives of the animals and low vegetables that feed on such herbage as compose the sward, which we are pleased to term parasites. These range in size from eelworms and mites that require a microscope for their detection in the egg, larva, pupa or adult stage, up to that of various grubs and insects that are visible to the naked eye. Beetles are amongst the latter, and to this family some of the most malignant Vine pests belong, such as those of the genus *Otiorynchus*.

It is not, however, the present intention to allude particularly to any special form of vegetable or animal organisms which have been detected in old pasture turf, or to draw any distinction between the so-called useful and injurious bodies found therein. Nevertheless, it may be stated that the microscopic forms alone are enough to make anyone wonder how vegetable life is able to exist when so many mouths are ready to devour it, and on which they depend for existence. Indeed, it would be inexplicable, but from the circumstance that the microscope reveals other bodies which feed on the malignant micro-organisms, and maintain a balance in favour of vegetation, also of themselves, for no living creature concerns itself about sentiment, but is bent on nothing but its own existence—feeding, growing, and reproducing. All bodies, visible or microscopic, like nothing

### KENT—THE GARDEN OF ENGLAND.

IF YOU CANNOT BUY FRUIT TREES TRUE TO NAME, Write to GEORGE BUNYARD & CO.

IF YOU WANT CHOICE NEW SORTS that Local Firms cannot supply, Write to GEORGE BUNYARD & CO.

FOR HEALTHY & VIGOROUS FRUIT TREES by the Dozen, Hundred, or Thousand, Pot Peaches, Nectarines, Short-jointed Vines, Figs, &c., Write to GEORGE BUNYARD & CO.

SEND TO MAIDSTONE, and get the FINEST TREES—No Starvelings, no Blight, at GEORGE BUNYARD & CO.'S.

THE LARGEST STOCK in the WORLD of developed Cordous, Pyramids, and Espalier Trees, bristling with fruit buds—saving years in time. The only Nursery where the Amateurs' Standard Apples can be bought to fruit first year, 2/6 and 3/6 each.

ILLUSTRATED CATALOGUES OF FRUIT TREES, 800 Kinds, Six Stamps. Strawberry List Free.

ROSE, BULB, CONIFER, and SHRUB LISTS Free. Two Hundred and Twenty Acres Nursery. Liberal Terms. Free Carriage and Discount.

GARDENERS are reminded that Fruit Trees from these Nurseries succeed grandly in all soils. (See Testimonials.) All lovers of Horticulture should come and see this unique Stock.

GRAPE VINES.—Well ripened, short-jointed canes of all the popular kinds, established in pots, extra strong for fruiting this year in pots, 6s. to 10s. 6d. each; for planting, 2s. 6d. to 5s. each; extra strong, 6s. to 10s. 6d.—WM. PAUL & SON, Waltham Cross, Herts.

## IF YOU WANT REALLY GOOD SEEDS

At MODERATE PRICES, apply to MR. ROBERT SYDENHAM, Tenby Street, North, BIRMINGHAM.

NO NURSERYMAN WILL SERVE YOU BETTER IN QUALITY, QUANTITY, OR PRICE.

### THE SIX BEST TOMATOES

In cultivation, often sold under other names to get fancy prices. Each packet contains nearly 200 seeds. Perfection, 3d.; Ham Green Favourite, 3d.; Hackwood Park Prolific, 3d.; Challenger, 3d.; Roseleigh Gem, a grand new large smooth selection, 3d.; Golden Perfection, the best yellow, 3d. Collection, 1s. 3d., post free; singly, 1d. each extra for postage.

### THE FOUR BEST CUCUMBERS.

Each packet contains 10 seeds, Lockie's Perfection, Rolliss's Selected Telegraph, Epicurean, and Covent Garden Favourite, 6d. each; or the Collection, 2s., post free; singly, 1d. extra for postage.

### SWEET PEAS—A SPECIALITY.

ECKFORD'S and other choice varieties at a third or a fourth usual prices.

Nothing gives so much cut bloom at so small a cost, or so little trouble. To get best results SOW AT ONCE, as directions sent with each Collection.

### SPECIAL VERY CHEAP OFFER.

8 Really Good Varieties—Queen of England, white; Blanche Ferry, pink and white; Princess Beatrice, pale pink; Apple Blossom, apple blossom tint; Orange Prince, orange pink; Splendour, rich deep rose; Cardinal, bright cardinal; Countess of Radnor, pale heliotrope, 25 seeds of each, 1s. 3d.

7 Extra Choice and Newer Varieties—Emily Henderson, fine large white; Venus, pale lemon flushed with pink; Mrs. Gladstone delicate pink; Her Majesty, soft rosy pink; Lady Penzance, bright pale rose; Firefly, bright glowing crimson; Monarch, large bronzy purple, 25 seeds of each, 1s. 6d.

The Two Collections, 2s. 6d.—Postage 2d. each Collection extra; or the two 3d. extra.

EXTRA CHOICE MIXTURE, 3d. per 100 seeds; postage 1d. extra.

ALL OTHER SEEDS EQUALLY MODERATE. FULL LISTS POST FREE ON APPLICATION. Please mention this Paper

better than to be let alone. Closely grazed turf, therefore, signifies few vegetable and animal parasites, as the treading and browsing of the animals diminishes their number proportionately. An abundance of herbage, on the other hand, implies numerous pests, as these correspond to the herbage and the harbour, or the amount of matter unchanged from the organic state—their food—into inorganic, the essential and sole food of most useful plants, always excepting the Mushroom and other edible fungi, which live like animals—that is, require organic matter for the maintenance of their existence.

Without bothering over these insignificant visible and micro-organisms, which are seldom recognised until housefuls of Cucumbers and Tomatoes succumb to eelworm or similar bodies, and till Vines will not grow satisfactorily, or only flourish for a time to later afford roots for grubs to feed on and foliage to fatten *Otiorynchus* beetles, we may pass on to suitable soils or compost for Vines. The turf of an old pasture may or may not contain all the inorganic and organic substances Vines require for their growth and the perfection of profitable crops. Such staple has proved pre-eminent in practice. What about the failures? Well, we hear nothing about them only under the cover of initials, and there are numbers of these recorded in the correspondents' column of the *Journal of Horticulture*. The turf, therefore, is not satisfactory, nor is it likely, as some turf contains little beyond decayed or decaying vegetable matter, and such decomposes still further into a close mass, impermeable to air, and holding water to soddenness. Then the growths of the Vines become sappy, long-jointed, and large-pithed; the foliage thin, large and flabby, the should-be bunches swirl, twist—do anything but become clusters of Grapes, or if they reach that stage are loose, uneven in berry, swell indifferently, colour anything but black or amber, and many shank. Of course such turf is not made use of by experts, but the majority of Grape growers are not prepared to distinguish at sight between a suitable and an unsuitable turf. They go in for the "fatted calf," the top 3 inches at most of the pasture that is famous for fattening oxen. It grows first-rate beef, and it is thought will grow high-class Grapes. So it will, but it is necessary to adhere to the conditions. The roots of the Vines must have the same substratum, or a similar, as the grass—that is, below the rich surface soil an intermingling with the soil of mineral matter, an abundance of stony particles that contain such elements of plant food as potash, lime, iron, and other essentials, and serve the purpose of keeping the soil open and sweet, while slowly but surely affording supplies of nutrient matter.

Loams from the old and new red sandstones grow the best Grapes. They are red by virtue of the iron they once contained in large per-centages, and they now contain 6 to 10 or more per cent., but a vast proportion of this is locked up in the ferruginous pebbles, and is only given off slowly. The "cornstones" of the "old red" give of their stores of lime and potash abundant food over long, in fact untold periods, and once the substratum is secured them it is only a question of feeding at the surface—the turf of the pasture—the nitrogenous matter for washing into the soil, and the conversion there into nitrates of the mineral constituents.

Calcareous loams also grow high-quality Grapes, such as the Frontignans and Muscats; but the coarser kinds, such as Alicante and Gros Colman, prefer the alluvial deposits, an admixture of earths, deep and free, with an abundance of both mineral and organic matter. Perhaps the site of sites and a soil of soils for the coarser Grapes is that of an old water-course, which is a mixture of almost everything, and contains the detritus of ages. Frontignans and even Muscats go out of cultivation under such conditions, for they grow too rankly, and the fruit shanks so decisively as to be unprofitable. The Sweetwater Grapes also like these alluvial soils, providing always that the substratum be loose, gravelly, rocky, or sandy, and water does not lodge within 6 feet of the surface.

The Vine, however, is not fastidious about soil, for any good garden soil will grow Grapes, and in many cases better than costly turf, which in most cases has to be "doctored" before even experts dare use it. Any soil, therefore, over a well-drained substratum, and in itself containing at least 75 per cent. of gritty matter, will produce as fine Grapes as need be. The question of crop is a matter of nutrition, and the quality a question of management. It is sheer folly to imagine that Vines require soil different to other fruit trees. A soil that will grow Nuts will grow Grapes. The point is to insure the sweetness of the soil by drainage and enough opening material for aëration. All the other ingredients can be supplied at the surface, such as potassic, phosphatic, and nitrogenic manures. Humus, even, can be imparted by dressings of organic matter. Nature does not bury manure 3 or 4 feet deep in order to attract the roots downwards, and the deep borders of turf and "muck" and rubbish are often mere pits for producing shanked Grapes. Gravelly subsoils, mixed with a moderate amount of fresh stable manure, are far better for Vines to grow in than rich turfy loam devoid of stony matter.

Where the subsoil is unsuitable and the soil itself unsatisfactory there is an excuse for making artificial Vine borders, not otherwise. It is money thrown away in most cases, and the value of the Grapes forestalled for years. But things that cost most are generally valued most, therefore it is useless saying anything about economy and the indulgence in expensive borders. The staple of these is turfy loam—the top 2 or 3 inches of a pasture, rich and friable, and in nature neither very light nor very heavy. It, however, is better rather strong than light. As that is not always procurable, light soil may have a sixth of clay marl, dried and pounded, added to it, and heavy loam, a similar proportion of old mortar rubbish. If the loam is obtained where it thinly overlies limestone, is of medium texture, and contains a large proportion of calcareous gravel, it could not be improved on by any admixture whatever for Frontignan and Muscat Grapes—the finest of all for quality.

An orthodox mixture consists of the following cartloads:—Twelve of good friable turfy loam, two of old mortar rubbish, one of charcoal "nuts," one of wood ashes, half of calcined oyster-shells, 2 cwt. of horn and hoof shavings, and 4 cwt. of crushed bones, thoroughly incorporated. Such mixture will, as it ought, grow anything in the way of Grapes. There are other mixtures equally costly and some far more nasty, such as those containing fish refuse, which, however, make Vine "jump" in their early years, and others contain about a fifth of horse droppings.

In preparing the border, which may be proceeded with as the weather permits, bear in mind that the Vine naturally is a hill-side plant, therefore is impatient of stagnant water. Hence thorough drainage must be provided, and in low sites it is better to elevate the border than waste money in concreting a pit-like excavation. Employ 3 or 4-inch drains, with proper fall and outlet to carry off the superfluous water. Provide a foot of drainage, placing the roughest at the bottom and the finest on the top, preferably finishing with old mortar rubbish to a depth of 3 inches. A width of 6 feet will be sufficient border space in the first instance, and it need not be more than 30 inches deep for the strong growing Vines. Put the materials together compactly, and not when in an unworkable condition. Where the Vine roots are to have the run of both inside and outside borders first confine them to the inside, not making the outside until the Vines are thoroughly established. This, and the additions of border from time to time, will secure to the Vines the full benefit of the loam and its nitrogenous and other readily available food elements in the freshest and best form. It entails a little more labour, but is better in the case of employing rich material, as the Vines are more under control and the food appropriated as it is required.

The proper time for planting Vines is when they are starting into growth, after having been pruned to the required length when at rest and early in the resting season, so as to allow time for the

wounds to heal, and so prevent bleeding. They may be kept in a cool house or pit, and allowed to start into growth naturally, then, when the shoots are an inch or two in length, they should be turned out of the pots, have the soil entirely removed or washed away, spreading the roots out carefully after disentangling them, pressing the soil firmly about the roots, not cover them more than 2 or 3 inches deep, and keeping the neck or collar somewhat high, as however firm the soil may be it will settle somewhat, and the keeping high affords facilities for top-dressing. This will encourage roots from the collar, and by judicious mulching and top-dressing they may be induced to spread on the surface of the border and appropriate any food that may be supplied in an available form. A moderate watering with tepid water will settle the soil about the roots, and with judicious treatment they will start rooting afresh, and push growths correspondingly.—G. ABBEY.

CYMBIDIUM EBURNEO-LOWIANUM SUPERBUM.

ONE of the most interesting Orchids shown at the Drill Hall, Westminster, on the 12th inst., was this Cymbidium, which is admirably portrayed in the woodcut (fig. 29). It was staged by Messrs. J. Veitch and Sons, Chelsea, and is a hybrid between eburneo and Lowianum, and the presence of both parents is readily perceptible. The plant exhibited had one spike carrying four handsome flowers, the colour of which was creamy white, the lip being heavily marked velvety crimson. This Orchid is very rare, and, as has been said, interesting. A first-class certificate was adjudged.

## CALANTHE VEITCHI.

MR. FRIEND, Rooksnest, Godstone, writes:—"I am forwarding you a specimen of Calanthe Veitchi as grown here, and shall be glad to furnish particulars of the culture followed as soon as my health—which has been bad of late—will permit me to do so."

[We greatly regret to hear of Mr. Friend's indisposition, and trust that he will soon recover his health. The specimen of C. Veitchi was a magnificent one, the flower spike measuring 5 feet 5 inches in length, and the pseudo-bulb 1 foot in length with a circumference, 1 inch from the base, of 7 inches. We shall be glad to publish Mr. Friend's notes, which will be read with much interest by many of our readers.]

## TRICHOSMA SUAVIS.

ALTHOUGH not a showy Orchid this is well worth growing on account of its distinct appearance. The plant grows from 5 to 8 inches in height, and consists of a cluster of stems, each bearing a couple of broad leaves. The short spikes issue from between these, and each carries five or six flowers about 1½ inch in diameter. The sepals and petals are creamy white; the lip is also white, crested, the centre lobe yellow, with short diverging lines of crimson. These, as the specific name implies, are sweetly scented. T. suavis thrives well with the warmest section of Odontoglossums, and if well grown seldom fails to flower. The pots must be clean and well drained, and the compost rough and open, good turfy peat with a little chopped sphagnum and potsherds suiting it well. Abundance of water must be given at all times, as the plants have no pseudo-bulbs to sustain them through a period of drought. It is the only species in the genus, and was introduced from the Khasia Mountains in 1840. It flowers at various times, but usually during the winter and early spring.

## ODONTOGLOSSUM PARDINUM.

The habit of this species is different from the majority of the genus, the pseudo-bulbs being large, ovate, light green, and bearing

several leaves of a similar colour. From the appearance of the flower spikes on newly imported plants this would be a truly grand kind if happy under cultivation, as these are sometimes nearly half an inch in diameter. The best plants I have seen were growing in wood baskets suspended from the roof with the coolest section of the genus, and this appears to be the most suitable treatment for it. The compost must be very open, as the roots are larger and not so persistent as those of some other kinds. The spikes on the plants referred to were from 2 to 2½ feet in length, and bore many of the pretty spotted flowers; individually these were 4 inches across, light yellow or straw-coloured profusely spotted with crimson. O. pardinum is a native of Peru, and first flowered at Rendlesham Hall, Woodbridge, in 1878.

## WATERING ORCHIDS.

At this season when many plants are beginning to grow, and others are still in a dormant condition, a good deal more care and judgment is necessary in this operation than when all are growing freely. Although mischief may occasionally be caused by a too limited supply of water, yet the greater danger lies in the opposite direction, especially among the pseudo-bulbous kinds.

If growers would only keep these well watered in the autumn when they need it to supply the nutriment for the swelling pseudo-bulbs, and wait until the new growths begin to root before increasing the supply very much, it would be a material advantage, causing less shrivelling during the winter, and saving many young growths from an untimely death in the spring. I am referring more especially to such as Cattleyas and Dendrobiums, and not to those that, like Cymbidiums and others, require a good deal of moisture all through the winter and have foliage of a harder texture, less likely to damp. These latter and Cypripediums require probably more water than any others at this season, healthy

FIG. 29.—CYMBIDIUM EBURNEO-LOWIANUM SUPERBUM.

plants with the pots full of roots needing attention daily. Disa grandiflora, too, if growing freely, must never be allowed to become dry at the roots, and is better for frequent sprinklings. Cattleya Mendelli, C. intermedia, Laelia grandis, L. purpurata, L. superbians, and others advancing into flower, must have an increased supply, the appearance of the roots being a safe guide to the cultivator.

When these are seen by the fresh growing points to be actively searching for moisture, it must be provided in adequate quantities to meet their demands, but when they are, on the contrary, quite dormant, the less water they have the better as long as the bulbs keep plump. Many of the distichous-leaved section, as Vandas, Phalaenopsis, and Saccolabiums, are still quiescent, and must be kept as dry as possible without killing the sphagnum moss about them. Others of this section, as for instance Angræcum sesquipedale and Vanda cœrulea, seem never entirely at rest, and the treatment must be varied accordingly.

Many other instances of different species in the same genus requiring varying treatment may be mentioned, but they can be seen by intelligent cultivators for themselves if they study their

plants, and experience gained this way will be much more useful than that imparted through the medium of these pages. The plants are the best teachers, and it is by observation of their peculiarities that proficiency in Orchid growing is to be gained. It must not be forgotten either that we are to a great extent the slaves of circumstances, and what is right in a properly heated, well appointed Orchid house might prove fatal in a badly arranged, ill-adapted structure. This being so, each grower must shape a course for himself, carefully noting the experience of others, but not accepting this in too literal a sense.

Have all water used of an equal or higher temperature than that of the house in which the plants are growing, and be careful that no water lodges in the growths or sheaths of Cattleyas and others advancing into flower.—H. R. R.

### THE PROSPECTS OF GARDENERS.

Now that the strong hand of frost and snow holds our native soil in its flint-like grasp it is well for gardeners as a body to look as far as human foresight can, to the requirements and probabilities of the future. Those among them of a thoughtful turn of mind who watch the slow revolutionary times through which we are now passing, must ponder deeply on the ultimate basis on which gardening as a profession will stand. Nay, alas! there are those who at the present moment have almost reached the point of despair, as day after day, week after week drags by without bringing for them the longed for situation. Yet while good men and true are patiently waiting for chances, which in many cases will never come, shoals of lads with the vigour and enthusiasm of youth are rushing into the same calling, which to only an extremely small percentage of them can ever bring adequate reward.

To many this may seem far too dismal a picture to paint of the prospects of a body of men whose lines, to those who only look on the surface, seem to be cast in truly pleasant places. There can be no doubt that it is this prospect of a pleasant career that induces so many in early life to join the ranks and compete for the prizes of the craft. The conditions are, however, very different now to what they were a quarter of a century ago, that those who have a fair share of ambition ought to consider the matter thoroughly before they take up gardening as a means of livelihood in which ability is likely to meet with a fair reward.

My own idea of the matter is that gardening must in the future be looked on in a totally different light from that in which it has been the custom to regard it in the past. To the great number who have at various times taken to gardening as an employment which offered the readiest means of raising them slightly above the drudgery of the lives of rural labourers around them, this changed condition of affairs will not appear to be a particularly serious matter, and the prospects for such are even now fairly good, because the aggregate wealth of the country steadily increases, and with it the number of individuals who can afford to keep one, two, or three gardeners. These establishments in many instances offer comfortable situations for men who have no great amount of ambition, and who are by Nature intended to be led rather than to lead. Those who belong to this category have no great cause for alarm at the prospects before them, as Nature has endowed them with a capacity for leading peaceful, happy lives, doing useful work without accomplishing any great results.

I have now a few remarks to make on a totally different class of men. I refer to those who take up gardening as a calling, who in their youthful days have regarded with profound respect the chief in some large and well-ordered garden. To win such a position themselves has seemed to be a crowning reward for strenuous endeavours and the realisation of their highest hopes. Youths of this calibre have a definite object in view, and with a fair share of the fortune of work will win. What I maintain, however, is that at the present time the percentage of gardeners who have the hopes, aspirations, and abilities enumerated above, are very largely in excess of the positions to be filled which would satisfy them, and the tendency of the present time goes to show that this disproportion will be much more pronounced in the future—though in truth it is bad enough now—unless a little more shrewdness is shown by parents and youths in the choice of a calling. The mere fact that our ancient calling at one time offered sufficiently lucrative posts for the sons of the comparatively well to do, often induces parents who have no definite knowledge of the present state of affairs, to start their sons on a race which is exceedingly like the proverbial one of pursuing a "phantom ship."

It may be that these lines will meet the eye of some who are at the present time seriously considering the knotty problem, "What shall we do with our boys?" Then, perchance, some

inward thought begotten of sentimentalism will appear like an inspiration, Make gardeners of them? To this I say yes. All men should be such, but to take up gardening as a living what a different matter! To me it seems that that pithy but famous piece of advice which "Punch" once volunteered comes again fresh to the rescue, "Don't."—A LOVER OF GARDENING.

### TIMELY SUGGESTIONS.

GARDENERS generally are in rather a happy frame of mind when unpacking their seed hamper, pocketing a new knife and donning a new apron. Yet it is a feeling which soon gives way to one of responsibility and anxiety. The leader (page 109) setting forth the virtues of patience has forestalled some thoughts on this subject. Most readers will readily admit that patience is as good for gardeners as it is reputed to be for the gout. Anyway, we need all we have of it, and doubtless, under some conditions, a little more. Not less can we endorse the wisdom of being early birds, and it behoves us to go for that worm, whether it takes the form of the earliest dish of Peas, new Potatoes, or other things so warmly welcomed after the monotony of the winter season. Yes, that worm is good value; and whether or not the early bird crows over his neighbours, the catch is soon published in the locality, and the go-ahead man is held up as an example to his easier-going brother.

Growers for market recognise the importance of being first in the field, with the reward of realising fancy prices for their smartness. In private establishments it is worth some effort, in spite of risk, to obtain a few early dishes, especially in a season like this we are passing through, with scarcity at present and dearth in prospect. Small patches, a few short drills sown at the earliest opportunity, to be followed at intervals until the main crops are sown, may be more or less speculative, but often result in little gains on time, which serve as peace offerings to the kitchen, and are duly appreciated. The main crops obviously claim most attention, and the chief anxiety is to get them in under the most favourable conditions. The exhaustive thrashing out of the Onion maggot subject last year, with the unanimous verdict of the benefits to be derived from early sowing, appear to be shelved by the weather for this season, but doubtless raising in heat is being extensively practised.

In localities favoured by open, generous, free-working soils, the importance of seizing on the first opportunity for the sowing of some particular crop is not so paramount as in those places where the reverse conditions obtain. With the latter an ungenial spring may yield but one opportunity as to a dozen in the former. Although "All things come to those who wait," even good weather, a great deal of vexation comes to those who, while waiting, know that an opportunity has been missed. The good day for a certain job may be a better one to-morrow, but that to-morrow may be deferred for weeks, thus taking far too large a slice out of what may prove to be but an indifferent season of growth.

Caprice of weather sets at defiance the wisest calenderial directions. It is a game of chance, and often those who court criticism by apparent undue haste succeed beyond even their own expectation. Later sowings may be, often are, caught by a bad spell in a critical stage that earlier-sown, stronger plants, are able to withstand. Yet the question of early sowing this season is to some extent nullified by the prevailing Arctic weather, which, whilst not only locking our seeds out of the ground may, by accumulating arrears of work, cause further delay when changed conditions present the opportunity, unless deliberate thought now leads to prompt action then.

What to sow? is a question annually raised when noting the numerous additions yearly increasing in our seed lists. There is a temptation to all in novelties which not a few, by various reasons, have to resist. New things come to us with exceedingly good characters; but we, prompted by prudence, can only take them on trial. Many are precluded by questions of space, time, or means from entering with a free hand into culture which is, to some extent, experimental; hence watch those who can afford to do so, and await their verdict in the gardening press. So a good thing is heard of again, and disappointment by the reverse is avoided by those who feel they must—

"Be not the first by whom the new are tried,  
Nor yet the last to lay the old aside."

I have observed that employers sufficiently interested to scan the seed catalogues are often attracted by a name. What's in a name? A good deal to some, for some names are attractive, and others there are which may be termed repellent. Amongst the former may be noted a novelty for this season, *Saintpaulia*

ionantha, and I venture to predict that whatever its merits may be as a stove plant—and they may be all that is said for it—it will for the above reason be in considerable demand. But whatever results obtain from inclination or ability to test the practically untried, we neither wish nor can afford to despise the old friends, often tried and seldom found wanting. Many of these have, too, approached so near perfection as to leave but little to be desired. Some of these there are in the vegetable department which have held a prominent position for years, and by merit may continue to do so for years to come. In the trial of some so-called new things one recognises now and again an old friend with a new face, across which is written pride or perfection, marking but the smallest, if any, advance. The vendors' names attached are at least a guarantee of quality with the incentive of keeping the stocks worthy of the name they bear. Progression is a feature of our plethoric seed lists, and time, which tries all things, promotes the survival of the fittest.

How to sow? The best methods to insure success is a matter of direct concern to ourselves, and of considerable import to the seedsman. There is, I think, but little to complain of in the quality of seeds obtained from firms of repute. The bulk of those complaints which do arise are the effects of a cause which, if sought for, may be found in methods of sowing and culture during the most critical period of vegetable life, or indeed of all life—viz., infancy. The fallacy of asserting that seeds are bad because "they do not come up" might frequently be demonstrated by the aid of a magnifying lens. They have, like some other infants, been ushered into a world of uncongenial surroundings, and as quickly perished.

There are, doubtless, gradations of vitality in seeds, traceable to age, indifferent harvesting, or even hereditary influences. Good nursing is required by delicate kinds. Investigation will often reveal the fact that germination has taken place, hence badness is out of the question. Seeds that are held over for some time previous to sowing should be stored in suitable quarters. Well ripened seeds are those in which germination is arrested until set in motion by atmospheric influence; and noting how quickly those influences excite the suspended functions, it is obvious that fluctuating temperature accompanied by varying degrees of moisture must have some bearing on the matter. This may be more or less remote. Yet, when seeds are held over for some time, perhaps for a season, Nature asserts her rights by embracing such opportunities as a damp seed cupboard affords in causing some excitement prejudicial to dormant life. True, this is but a side light on the matter, and may be a dim one to boot.

The question is, how to sow? and this with delicate plants raised under glass is how to germinate successfully, for here, though under direct control, the largest percentage of failures are recorded. It would be well if those heads who have to relegate this work to other hands could illustrate the delicate organism of the infant plant developing from the seed; to show how by inattention or carelessness failure ensues. Younger hands may carry out the work to the letter by rapping the pot or pan to evoke the signs of drought, but the method invokes not the spirit of success in the germination of small seeds. Spring days are often trying days to plant life under glass. Seeds in a right condition of moisture when the water-pot makes its morning call may by a burst of sunshine be parched at noon, and perished by the next day; hence frequent inspection is necessary. Here, too, soil should be regarded more as the medium for germination than as a support to the plant, which can be given when transplanting—pricking off—takes place. A free, open mixture, such as is afforded by a liberal use of leaf mould and coarse sand, is preferable to more tenacious soil, which the fine rose waterings tend to cake. Warmth, moisture, and darkness promote quick germination; with this accomplished, prompt removal to light airy quarters before attenuation sets in is of vital importance. Long legs are not conducive of sound constitutions, and overcrowding causes wholesale damping.

Turning to those plants, which with our best efforts are at the mercy of the weather, overcrowding from too liberal sowing is the prevailing evil. We sow 100 seeds to pull up, may be, ninety. A margin must perforce be allowed, but that margin is, as a rule, far too broad. Timely thinning is the remedy, but the operation is tedious, and however carefully and promptly done we rarely see such results as are obtained from a stray seed, forming a lusty plant out of bounds. Thinning should be regarded as a necessary evil, and the less of it required the better. Deep sowing of Peas as a protection from frost finds favour with some. My experience, obtained by means of a negligent workman, points to the contrary. Peas germinating practically on the surface will remain uninjured by severe frost, whilst those buried deeper decay. All phases of the subject point the moral that "As we sow so shall we reap."

—E. K., *Dublin*.

## THE FLORISTS' TULIP.

[By JAMES W. BENTLEY, Hon. Secretary to the Royal National Tulip Society.]

### CHAPTER IV.—CONCLUDED.

(Continued from page 114.)

IN concluding this portion of the subject, a few words regarding insect pests are necessary, as I have hitherto written little or nothing about them. Fortunately, the Tulip grower has not, like the Auricula and Carnation grower, to be constantly at war with green fly. The foliage of the Tulip may be said to be entirely free from the attacks of this troublesome nuisance. I have known green fly enter Tulip cabinets and feed upon the juices of the bulbs during their summer rest, a few having probably got amongst the bulbs whilst drying. Their amazing fecundity soon caused them to be numbered by thousands. In a few weeks the exposed portions of every bulb were thickly covered, and much trouble was experienced in getting rid of the pest. The bulbs should be examined from time to time in the cabinet, and any green fly destroyed. Wireworms in the soil have been alluded to; they should be carefully looked for and destroyed when the bed is being made. If evidences of their presence are noticed after the plants have come up they should be carefully searched for in the soil. Pieces of Potato or Turnip buried a few inches deep in likely places and examined daily will act as traps for them.

There is a kind of slug called locally "leather-back," which is sometimes very troublesome; it is small, of a dark grey colour, and yellowish underneath. It attacks the Tulips when very young, and will eat the young shoot right through at the surface of the ground, or even a little below the top of the soil. A friend of mine suffered very much a few years ago from these slugs. He found his Tulips in many cases begin to die as they were coming through the soil, others came up damaged and sickly, and very few were in their normal health. Upon searching for the cause he found that all the covering soil was infested with these slugs, and that they were the cause of the mischief. Slices of Potato and Turnip laid on, and just under the surface of the soil, lured them from the Tulips, and he had the melancholy satisfaction of catching some thousands of them in this manner. From the small size of most of the slugs it seemed probable that they had been introduced into the bed among the covering soil in the form of eggs. What gave corroboration to this idea was the fact that the soil had been stored during the summer against an old garden wall made of loose stones, and the inference was that the eggs had been deposited among the soil whilst it lay against the old wall, which was a likely retreat for the slugs. Three-quarters of the plants were destroyed, with much consequent loss amongst the bulbs as well, which were in many cases also found eaten. A visitation of this kind is happily unusual, but as it is so serious in its consequences it is wise to have its possible occurrence in memory.

### CHAPTER V.

#### ON EXHIBITING AND GROWING FOR EXHIBITION.

Although growing for exhibition and exhibiting may be considered by some persons to be rather mercenary, and altogether inferior to growing for the pure love of the flower, it is nevertheless true that but for the exhibitions of the Royal National Tulip Society and two or three smaller local societies the Tulip would have been almost extinct years ago as a florist's flower, so one cannot, no matter how one regards exhibiting, pass it by without mention.

As far as growing for exhibition is concerned, the chief objects of desire are to have the best exhibition varieties well grown, in the best of their bloom, on the day when the show is held. As the Tulip is a garden flower which can neither be retarded nor forced in its blooming time, it is, of course, a matter of impossibility to insure this desired result. Up to recently there have been only three Tulip shows held in this country for many years. They are all in the North of England, and the dates fixed were almost invariably too late for Midland and Southern growers. Last year, however, the Royal National Tulip Society, in addition to its chief exhibition held at York, tried the experiment of a show in London, in connection with one of the Royal Horticultural Society's exhibitions, held at a date which would suit early growers. The result was so encouraging to the promoters that the show will be held again this year in the hope that the culture of the Tulip will be stimulated in the South, and that the few growers already established there will be added to considerably. Facilities for exhibiting collections of florists' Tulips are also afforded in May and June at other meetings of the Royal Horticultural Society. I mention all these exhibitions to make it clear that, although one can have but little control over the period of blooming, yet the opportunities for showing are now so numerous that every grower

can, if he wishes, stage his blooms in good condition at one or more of them.

The best varieties for growing for exhibition are those kinds which combine constancy of marking with a good constitution. I advise the beginner to commence with the under-mentioned varieties which are fairly abundant, and to add rarer and more delicate sorts by degrees.

<i>Feathered Roses.</i>	<i>Feathered Byblæmens.</i>	<i>Feathered Bizarres.</i>
Modesty (Walker)	Bessie (Hepworth)	Masterpiece (Slater)
Mabel (Martin)	Adonis (Head'ey)	Sir Joseph Paxton (Wilson)
Heroine (Dutch)	Violet Amiable (Haigh)	Sulphur (Birtwistle)
Alice (Dymock)		
Comte de Vergennes (Dutch)		
<i>Flamed Roses.</i>	<i>Flamed Byblæmens.</i>	<i>Flamed Bizarres.</i>
Annie McGregor (Martin)	Adonis (Headley)	Sir Joseph Paxton (Wilson)
Mabel (Martin)	Talisman (Hardy)	Dr. Hardy (Storer)
Aglaia (Lawrence)	Chancellor (Battersby)	Masterpiece (Slater)
Triomphe Royale or Heroine (Dutch)	Duchess of Sutherland (Walker)	Sulphur (Birtwistle)
<i>Rose Breeders.</i>	<i>Byblæmen Breeders.</i>	<i>Bizarre Breeders.</i>
Annie M'Gregor (Martin)	Adonis (Headley)	Dr. Hardy (Storer)
Mabel (Martin)	Talisman (Hardy)	Sir Joseph Paxton (Wilson)
Mrs. Barlow (Hepworth)	George Hardwick (Hardwick)	Sulphur (Birtwistle)
Industry (Lea)	Queen of the May (Hepworth)	William Lea (Storer)
Queen of England (Parker)		Richard Yates (Lea)

Selves are little grown now. The best are Cygnet and White Nancy, whites; Buttercup and Goldfinch, yellows.

There are many other varieties that I should have liked to have included in this list, but as they are scarce I have omitted them. It does not follow that because a sort is scarce that it is good, and the list includes those kinds that form the backbone of almost every grower's collection. When opportunity offers the following scarcer kinds may be added. It is, of course, all-important to secure the best strains in both this and the preceding list.

*Feathered Roses.*—Mrs. Lea (Lea), Mrs. Thurstan (Thurstan), Industry (Lea), Rachel (Martin).

*Feathered Byblæmens.*—King of the Universe (Dymock), Elizabeth Pegg (Camp), Queen of the May (Hepworth), Bertha (Hiley), Mrs. Cooper (Boardman).

*Feathered Bizarres.*—Lord Frederick Cavendish (Hardwick), William Wilson (Hardy), Typo (Dymock), Commander (Marsden).

*Flamed Roses.*—Circe (Headley), Mary Jackson (Knowles).

*Flamed Byblæmens.*—Queen of the May (Hepworth), Salvator Rosa (Brown), Friar Tuck (Slater).

*Flamed Bizarres.*—Dr. Hutcheon (Storer), Lord Stanley (Storer), Ajax (Hardy), Lord Sidney (Haynes).

*Rose Breeders.*—Rose Hill (Oldfield), Tryphena (Thurstan), Dawn (Horner).

*Byblæmen Breeders.*—Glory of Stakebill (Ashmole), Alice Grey (Walker), William Park neon (Hepworth), Bridesmaid.

*Bizarre Breeders.*—Goldfinder (Hepworth), Lord Stanley (Storer).

The exhibiting grower will find plenty to do when the buds on his beds begin to "show colour," as the change from the green state is termed. All the buds of rectified flowers showing signs on the outside of refined marking should be at once carefully secured from the chance of injury from wet or bruising. This is easily done by means of neat-squared garden sticks about 3 feet 6 inches long, which are pushed into the soil near to the plants to be protected, care being taken not to injure any bulb in so doing. The stem of the plant is then fastened to the stick by means of 10-inch lengths of lead wire about one-eighth of an inch in diameter in the desired way. This is very easily done, as the lead wire is readily bent, and yet is sufficiently rigid when bent to keep the flower in the required position. One end of the wire is bent round the stem, but not pinching it, just under the flower, and the other end is wrapped round the stick several times, and there will be a straight length of wire between flower and stick sufficient for the former to expand freely without rubbing against the latter. Care must also be taken that the flower does not rub against any of its neighbours, or against any of the posts supporting the glass over the bed. If grown under glass the flower will not need much more attention, as the protection afforded by it, and the shading described in the previous chapter, will in most cases be ample. At the same time, it is well to have some shading boards for special cases. These boards are made of wood about half inch in thickness and 8 inches square, with a square hole near one edge through which the stick passes. They can be adjusted at any height over the flower by sliding up or down the stick, and are secured in the desired position by means of a small wedge or other simple device. These boards are useful in case the flower is in a position where drip is feared, or as an extra shade in very hot weather. If the Tulips are grown without glass in the old fashion these boards are quite indispensable, and have to be used in such numbers that the beds seem more devoted to timber than Tulips, and the effect of the display is utterly marred.

Some growers also take much pains, with a view to improve the faulty shapes of many of their growing flowers. They insert into the flower a kind of ring made of stout paper or stiff wood shaving, which prevents it from closing; then by winding carefully round some soft tying material, such as fine knitting wool, on the outside, they compel the petals to clip up close together into a cup. By so doing they contend that the petals will keep the close cup-like shape in which they have been confined when they are cut and freed from their bonds; or that, at all events, a great improvement in that direction is effected. I must admit that I never could see any material advantage gained by this troublesome process. The disadvantages are, however, very numerous. The labour is great, and notwithstanding every care, petals are often torn and bruised, neighbouring flowers damaged or broken off, and the delicate bloom observable on the untouched flower is gone. At the same time I own that the ring or "crinoline," as it is often termed, is useful occasionally on the bed, as, for instance, in the case of a flower that requires bleaching at the base. When the weather is dull and cold, and the flowers remain closed all day, such a flower cannot receive the bleaching influence of the light unless it is kept forcibly open by some such means.

If the weather at blooming time is very hot, or if the bloom is rather too forward, it will be an advantage to cut any flowers that would otherwise be over, as they can be preserved for a considerable time in water. They must be cut with long stems, be perfectly dry when cut, and should be kept in a cold, airy, dry situation. A dry, cool, well ventilated cellar lighted in a subdued manner from the north is an ideal place. The flowers should each have a separate bottle, and nothing but the stem in the water should be at all wet, or they soon begin to decay; the water in the bottles should be changed every two or three days, and the stems should be shortened a little by a clean cut with a sharp knife every day. Tulip stems must always be cut and never broken; when broken, and then put into water they frequently begin to split, and I have known the splitting spread and extend nearly up to the flower. A pinch of powdered charcoal may be added to the water with advantage. By careful attention to these details flowers cut reasonably young may be kept ten to fourteen days. I have heard that a little carbonate of soda is a fine addition to the water, and one grower having got rather mellow and consequently confidential revealed to me that a little dash of whiskey had quite as an invigorating effect on the flowers as on their owners, but these are matters of report merely, and not of my own knowledge.

It is an advantage sometimes, and especially in cold, ungenial weather, to cut, two or three days before the show, any flowers which are too young to get to perfection, in time, on the bed, and place them in a warmer climate, such as an ordinary greenhouse. In case this accommodation cannot be had, a warm living room with abundance of light is no bad substitute. Treated in this manner they make astonishing progress, and many are the stories told among the growers of success insured by such means as these.

When cutting flowers for exhibition, only those having reasonable claims to excellence should be gathered. It is a great mistake to encumber oneself with flowers which have no chance of doing their owner credit, and yet take up his time and attention. The flowers should all be cut the day previous to the show, placed in bottles in their respective classes, and carefully examined, those having fatal defects, such as being "quartered," having too many or too few petals or dead at the top of the petals being rejected, and those which are the best in each class noted in some way. Then the flowers destined for the show should be packed for the journey, and here the best use of the "crinoline" comes in, and is of great advantage.

#### PEAT MOSS LITTER.

I NOTICED "S. D.'s" remarks on page 122 respecting his experience with peat moss after coming from the stables. His letter was certainly rather alarming to those who, like myself, have not yet seen the effects of it on crops generally. I have a quantity of it on the ground, and some dug in ready for the coming season's crops. It is too late to alter some of it now. I hope there may be something different in its quality from that alluded to, and that it will not have the same unfortunate effect on our crops. I think the material must vary, as I have failed, like many others, in growing Mushrooms in it, whereas we always had plenty when straw was used with the manure. I should be much obliged if "S. D." would forward a few more particulars through your columns as to his treatment of it for growing Mushrooms. I have collected it as it came from the stables until we had enough for a bed, and made it quite firm. It heated freely at first, and the spawn ran well, but the heat was soon gone and the spawn died away. I have tried three or four beds in the same house, which is well heated, but they have all failed. I know many persons are trying to grow Mushrooms in the material, so that any hints from those who have been successful with it will be welcomed.—R. C. W.

**WEATHER IN LONDON.**—At the time of going to press the weather is considerably milder and shows signs of relaxation, as the thermometer in the southern suburbs this morning reads 30°. As the result of the rising temperature there is a marked improvement in the condition of the Thames. The ice floes have visibly diminished in both size and number, the stream during flow tide being now practically free. The gulls which have recently hovered over the river in quest of food are greatly reduced in numbers, showing signs that they can now feed elsewhere. Notwithstanding the tendency to thaw recent borings of ice on the Serpentine in Hyde Park showed a thickness of 7½ inches, while that of the Long Water was from 8 to 10 inches, the Round Pond 9¼ to 9¾, and St. James' Park 8¾ to 9 inches.

— **THE WEATHER IN THE NORTH.**—Winter shows little sign of relaxing. Again in the middle of last week our Highland lines have been blocked by snow. The frost has been rather less severe than in the previous week, ranging from 8° to 18° on Tuesday morning. From Saturday till Monday slight thawing took place for an hour or two each day, but from little else than sun heat. Tuesday morning was very cold with a thick frosty haze.—B. D., *S. Perthshire*.

— **THE KEW GUILD.**—The annual general meeting of this Association will be held in the Garden Library at Kew on Thursday evening, February 28th, at eight o'clock. Members who are unable to attend are requested to send any contributions for the Journal, to be published in May, or any suggestions they may desire to make with respect to the Guild, to the Secretary, Mr. J. Aikman, Whitestile Road, Brentford.

— **A NOTE OF WARNING.**—A timely caution comes from Messrs. Sutton of Reading, pointing out that as soon as the present prolonged frost breaks there will be a natural desire on the part of most gardeners to catch up the delayed outdoor work; but, as Messrs. Sutton say, in the matter of sowing it is better to be a fortnight behind the usual time than a week ahead. There is more wisdom in patient waiting for suitable conditions of soil and temperature than in undue haste, and the important essentials of light and warmth of soil should be considered rather than any fixed week of the month for sowing. Unfortunately it takes more than a few fine spring days to warm the ground, and when germination is accompanied by too low a temperature the seedlings and ultimate plants necessarily lack vigour.

— **ENGLISH ARBORICULTURAL SOCIETY.**—At present the English Arboricultural Society is more or less limited to the North of England. There is every prospect, however, of its extension southwards in the future, both on account of the attention now being given to forestry, and because the Society is making efforts to increase its membership by going further afield. The Transactions of the Society (vol. iii., part iv.) should materially assist towards this end, for the instructive papers contained therein appeal to all foresters. The information which Prof. Somerville has brought together and published forms a valuable summary of the present position of knowledge in regard to the Larch disease, and shows the various conditions and cultural methods which hold out some prospect of securing comparative immunity from attack.

— **STORING SEED POTATOES.**—Truly "A. D." (page 143) is an ingenious as well as a bold man. Has he no fear of wife or housemaid before his eyes? Boxes under the bed! After such audacity I shall expect to hear he has appropriated the space under the dining table. One friend and neighbour—a great Potato man—has his early sets in shallow boxes, and arranges them in the cart-horse stable above the standings. I am not sure whether he does not utilise his cow houses for the same purpose. He farms between 5 and 600 acres, so needs a good deal of storage room even for "earlies." As to the main stock of Potatoes, if the "pie" is really well made—*i.e.*, 7 feet across at the base, and yielding three-quarters of a ton to a yard (all sorts), lavishly covered with straw, well packed, and closely earched, surely they cannot take much harm. Of course, the "pie" must be made with its ends north and south, and care must be taken not to open it during the sunny hours of a frosty day. "Pie"-making is a gift, but it is a gift that can be acquired and cultivated.—**THE MISSUS.**

— **RUST IN CARNATIONS.**—For this purpose dissolve 1 lb. of sulphate of copper in two quarts of ammonia in a 2-gallon jar. When dissolved add another quart of ammonia and stir well. [The liquid can be kept in this form for some time and used as needed.] Add a pint of this solution to a barrel of water and spray the plants every two weeks, taking care to commence prior to the attacks of the fungus.

— **THE USE OF GAS TAR.**—In greenhouses this is a dangerous article to use, at least in the hands of the large majority of people, and should never be employed as a coating for the pipes. In the first place it gives off for a time noxious fumes when heat is let in which are certain to cause very severe damage to the plants; and in the second place, it does not maintain a good black colour. Lamp-black, mixed with linseed oil and turpentine, made into the consistency of an ordinary paint—rather err on the side of being too thin than otherwise—is about the best thing to use.

— **FLOWERS FROM THE RIVIERA.**—In fresh cut flowers from the Riviera there is now a brisk trade. The principal forwarding agency is at Calais, where the perfumes of spring flowers are strangely associated with surroundings of frost and snow. The consignments average 500 packages, containing Violets, Narcissus, Jonquils, Anemones, and Roses. They leave the Riviera every afternoon, reach Calais next evening, and are in Covent Garden the next morning in time for market. Many of the consignments go direct to Manchester and Liverpool, and even across the Irish Sea.

— **INK FOR ZINC LABELS.**—On page 133 appears a recommendation to use sulphate of copper and chloride of calcium. I do not know what the merits or demerits of this particular mixture may be, but I think it is necessary to suggest caution. Sulphate of copper I consider useless for the purpose. I recommend a solution of bichloride of platinum, 16 grains to the ounce of distilled water. This is much more expensive than sulphate of copper, but it is infinitely more satisfactory, and I can vouch for perfect legibility after an exposure of nearly fifteen years. For this recipe I was indebted, and still am indebted, to Mr. P. N. Fraser of Edinburgh.—**R. IRWIN LYNCH.**

— **VISITORS TO KEW GARDENS DURING 1894.**—The number of visitors was less by about 450,000 than those who entered the Gardens in 1893. This falling off is due to the marked difference in the summer of the two years. The "Kew Bulletin" shows the total does not differ materially from that of 1891, or depart widely from the average of the past ten years, which is 1,416,887. The attendance at Kew for a year now oscillates about a figure nearly approaching a million and a half. The total number of visitors to the Royal Gardens during 1894 was 1,377,588; the lowest number admitted in any one month was 18,184 in January, and the highest was 229,161 in May, the latter number closely followed by 218,514 in March and 211,192 in August.

— **GERMAN EAST AFRICAN VANILLA.**—The first sample consignment of Vanilla cultivated in German East Africa (Kitopeni plantation) has recently been received in Hamburg, and was, says the "Chemist and Druggist," very favourably commented on, both in regard to natural quality and to preparation. The pods, it is true, are not equal to the best Mauritius Vanilla, but the shipment was of thoroughly marketable quality, the pods being from 6½ to 10 inches in length, and well crystallised. The great drought of the last season has been very injurious to the development of the fruit, but shade trees have now been planted and irrigation works started, and it is expected that next year the output will be much in excess of the present. The present season's crop, however, which amounts to about 10,000 pods, is expected to cover the cost of production.

— **JANUARY WEATHER AT HODSOCK PRIORY, WORKSOP, NOTTS.**—Mean temperature of the month, 31.0°. Maximum on the 2nd, 42.6°; minimum on the 12th, 8.8°. Maximum in the sun on the 30th, 90.1°; minimum on the grass on the 29th, —0.6°. Mean temperature of the air at 9 A.M., 30.4°. Mean temperature of the soil 1 foot deep, 35.1°. Nights below 32°, in the shade twenty-two, on the grass twenty-nine. Total duration of sunshine in the month, forty-six hours, or 19 per cent. of possible duration. There were thirteen sunless days. Total rainfall in the month, 3.54 inches. Rain fell on twenty-four days. Approximate averages for January—Mean temperature, 37.1°; sunshine, thirty-five hours; rainfall, 1.69 inch. The coldest January since 1881, the wettest for at least twenty years. Most of the downfall was snow, but a good deal of rain fell between the 18th and 20th, though the thaw was never complete and the frost soon returned. We are passing through Arctic weather just now. On Friday morning the 8th inst. the thermometer on the snow registered 9° below zero.—**J. MALLENDER.**

— THE annual show of the LONDON PANSY AND VIOLET SOCIETY will be held at the Crystal Palace on Saturday, July 6th.

— BETWEEN January and September, 1894, Apples for which 2,500,000 dollars was paid were sent from America, and our cousins "on the other side" have concluded we are great Apple eaters.

— AN AMERICAN TOMATO.—Mr. T. R. Haines, Abbott, Nebraska, claims to be the raiser of the largest Tomato—3 lbs. 3½ ozs., and 8½ inches in diameter. The grower is no doubt proud of his feat, but such monstrosities are not popular in the "old country."

— DISTRIBUTION OF SEEDS.—According to an American contemporary Secretary Morton is doing good service by discouraging the free distribution of garden seeds by the Government. The best of all reasons is that there is no more reason why seeds should be sent away by the thousands of dollars worth, than that it should give away penknives or scrubbing brushes. Indeed, it would be more sensible to send these useful things, for not one package of seeds in a hundred is ever sown.

— BOURNEMOUTH GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—The annual meeting of the above Society was held recently, Mr. H. Elliott, Christchurch, presiding. The report and balance-sheet for the year was submitted and approved. The report showed the Society to be in a satisfactory condition, although there had been no increase in the number of members, some former members having left the neighbourhood, and others being unable to attend. Hearty votes of thanks were accorded to the President and officers of the Association for their past services. Dr. H. K. Hitchcock was again elected President, and the names of Mr. T. G. Rooper, Mr. C. A. D. George, and Mr. C. H. Mate were added to the list of Vice-Presidents.

— A SUBSTITUTE FOR SEAKALE.—The question of keeping up a continual supply of forced vegetables during the early spring is one of some concern to many gardeners, and as "Necessity is the mother of Invention," this problem has been the means of several substitutes being tried to take the place of Seakale. Perhaps the most suitable for this purpose are the tender forced growths of the ordinary Swede Turnips, which, if properly treated, form a very palatable dish. The best mode of procedure is to plant the Turnips in a warm dark position, as in the case of Seakale. The quicker they grow the better, as if the temperature be cool, and the growth made slowly, they will become tough and of a strong flavour, thus rendering them unfit for table. Care should be taken not to cover the crowns of the Turnips with soil, or this will probably cause the young growths to decay. After planting they require well soaking with lukewarm water, and the light totally excluded. In a few days the growths will be sufficiently long to cut, when, if cooked and served up in the same way as Seakale, they form an excellent substitute. The used roots may then be replaced by a fresh supply.—G.

— THE BOTANICAL MAGAZINE.—The current monthly number of this work comprises the following subjects:—*Richardia Pentlandi* (Aroideæ)—Of eight known species of *Richardia* this is one. It is a native of Basutoland in South Africa. The tubers were given to the Kew Gardens by Mr. Galpin of Barberton, South Africa, in 1892. The colour of the spathe is canary yellow without and bright gamboge within, while at the base below the spadix there is a dark purple ring. *Aphærema spicata* (Samydaceæ).—This is a slender, smooth, shrub-like plant, coming from the South of Brazil. The leaves are not unlike those of the *Fuchsia*, the midrib having a deep red colour. The yellow flowers are arranged in dense spicate racemes. *Aloe brachystachys* (Liliaceæ).—This was sent from Zanzibar by Sir John Kirk to Kew, where it flowered in 1894. The leaves have the usual character of the Aloes. The raceme consists of flowers having a pale pink perianth tipped with green, and arranged rather densely, so as to resemble an obtruncated *Tritoma* in outline. At the base of the pedicels are green bracts striped with brown. *Cephalanthus natalensis* (Rubiaceæ).—This plant, though discovered in the borders of Natal some forty years ago, has only recently been raised at Kew, from seed received in 1886. The flowers are arranged in dense globose heads, almost like those of a composite plant, and owing to the tube of the corollas being rose red, their lobes green, and the anthers yellow, present a curious admixture of colours. *Musa Hilli* (Scitamineæ).—This is one of four species of Plantain indigenous to Australia, and comes from Queensland. The seeds from which the present plant was raised arrived at Kew six years ago. The male flowers are exposed, and arranged in circles below the conical envelope which encloses the female flowers.

— MRS. PARKER returns her most grateful thanks to all subscribers to the Royal Gardeners' Orphan Fund who contributed by their votes towards the election of her son.

— AMERICAN FRUIT CROPS.—The Nova Scotia fruit crop is the best on record, and is valued at 10,000 dollars. Two hundred thousand barrels of Apples were exported to London. The total number of men employed in fruit culture amounts to 9000.

— THE NATURAL HISTORY OF PLANTS.—The tenth number of this work has appeared. In it the subject of fertilisation is continued, being illustrated by many interesting diagrams. The question of the Linnæan system of classification is discussed, and prefixed to the text is an excellent coloured illustration of *Victoria Regia*.

— THE HESSLE GARDENERS' MUTUAL IMPROVEMENT SOCIETY.—At a meeting of the above Society on February 12th a paper was read on "The Potato: its History, Cultivation, and Disease." After giving the history of the Potato from its first introduction to this country, Mr. Riley passed on to the cultivation. Potatoes, he said, may be grown in a wide range of soil and climates. The lighter class of soil produces the best qualities, especially for early use, the stronger and warp lands the heavier crops. Good crops are grown on peat and bog lands, notably in Ireland. Fair sized tubers of about 3½ ozs. uncut give the best results. For arresting disease a dressing of sulphate of copper and quicklime was recommended.—F. L. T.

— NEW YORK FLORISTS.—Just now the stores of the retail florists are bright with an unusual number of cut flowers of different kinds, which show a wide variety of colour. Single red Tulips sell for 1 dol. a dozen, the more popular pink and yellow sorts commanding as much as 1 dol. 25 cents, while the double yellows cost 1 dol. 50 cents a dozen, which is also the price asked for the few double pink Tulips that have appeared. Other flowers of bulbous plants are single Hyacinths at 75 cents a dozen, the limited supply of double Hyacinths bringing 35 cents a stalk. Poet's Narcissus are occasionally seen, and these sell for 1 dol. a dozen. Paper-white Narcissus, yellow Jonquils, and Freesias are seen in many collections. Well grown Lilacs, with luxuriant foliage, cost 1 dol. 50 cents to 2 dols. for a bunch of ten to twelve single sprays for the purple flowers, and the white Lilacs bring 2 dols. to 3 dols. The best Carnations, and a fair grade of Mignonette, cost 1 dol. 50 cents a dozen. A bunch of two dozen sprays of Forget-me-nots may be had for 1 dol., and half this quantity of Lily of the Valley costs 75 cents. Roses are in great abundance, and vary in price, according to the quality, a great many of them being of more than average excellence. Good flowers of Madame Cusin bring 2 dols. a dozen, while the same grade of Bride and Catherine Mermet sells for 2 dols. 50 cents to 3 dols., and the better grades of any of these Roses command 5 dols. and 6 dols. a dozen, and even more. Cattleyas sell for 9 dols. a dozen and upward, and white varieties bring twice as much. *Cypripediums* are scarce, and cost 4 dols. to 5 dols. a dozen.—("Garden and Forest.")

— WAKEFIELD PAXTON SOCIETY.—There was a good muster of members at their rooms on Saturday, the 9th. Mr. H. S. Goodyear presided, and Mr. H. Chapman was vice-chairman. A function unique in the annals of the Society was performed in the election of Dr. Clark, M.A., Ph.D., Yorkshire College, as an honorary member. In proposing a resolution to this effect Mr. G. W. Fallas stated that it was the unanimous desire of the Committee that something should be done to give expression to their gratitude and high appreciation of the many services Dr. Clark had rendered to the Society. He spoke in the highest terms of the Doctor's abilities as a horticulturist and agriculturist and as an eloquent exponent and teacher of these sciences. In electing Dr. Clark to this position the Society would be honouring itself and in some slight degree be showing its sense of the many favours it had received at the Doctor's hands. The lecture for the evening was on "The Art and Method of Grafting," Mr. T. Wilson reading an excellent and practical paper on the subject. In the course of his paper he showed the great importance of the process in the duplication of new varieties, and in the invigorating or restraining influence it exercises on various plants. Interesting reference was made to the peculiar affinities which various plants manifest when subjected to the operation, and to the ease with which plants could be multiplied which would otherwise be expensive and scarce, owing to the difficulty of increasing them in other ways. Mr. Wilson enumerated and fully explained all the principal modes of grafting, and illustrated his remarks by showing well-prepared specimens of each mode. A number of questions were answered, after which the essayist was thanked for his paper.

— SHIRLEY AND DISTRICT GARDENERS' AND AMATEURS' MUTUAL IMPROVEMENT ASSOCIATION.—An extra meeting was held at the School Room, Highfield, Southampton. Mr. E. Molyneux, Swanmore Park Gardens, gave a lecture on "The Salient Points in Vegetable Culture," more particularly addressed to the owners of allotments and cottage gardens. "The salient points," he said, "were proper preparation of the soil, manuring in abundance, thin sowing of seeds, and regular attention during the period of the growth of crops." He laid stress on the fact that the Potato, which is after all the mainstay of the cottager, should receive more attention than is sometimes given it. A hearty vote of thanks was accorded to the lecturer at the close of his remarks.

— THE WEATHER IN GUERNSEY.—After three weeks of as fierce a north-easter as could be wished for, with a share of King Frost, but no great weight of snow, a welcome change has come about since Saturday, the wind having abated and changed its quarter, but the nights are still more or less frosty. The full extent of the damage to outside crops can hardly be estimated till the frost is thoroughly out of the soil. This much, however, is certain, that all the early Radishes are spoiled, and the same to a great extent may be said of the Broccoli, though a portion of the most backward of this may recover. It is hoped Daffodils have not taken much harm, though the frost, having penetrated the soil to a depth of 4 inches or more, it is causing some anxiety. Those growers who have been raising Potatoes in cold houses have also had their crops much damaged. Tomato planting is now in full swing, and if we are spared any further checks may yet, though necessarily late, have a bountiful season. I should say that everything out of doors will be quite three weeks late.—X., *Guernsey*.

— TOMATO CHEMIN ROUGE.—On page 144 Mr. Jas. B. Riding expresses surprise at my having omitted all mention of Tomato Chemin Rouge in my article on the Tomato Supply (page 88), and further adds that this, according to his experience, is the most popular market variety. Why it was not mentioned is because with us it does not succeed so well as the others recommended. I was one of the first to grow Chemin Rouge in this country, Messrs. Vilmorin & Co., Paris, kindly forwarding the variety for trial. It proved to be a really good variety, and I was one of the consenting parties to its receiving special mention at the great Chiswick Vegetable Conference. At the same time, it is not very distinct from Ham Green, and for two seasons in succession it did not do so well as either that variety, Al (Sutton's), or Challenger. It was not a case of growing a few score, but several hundred plants were tried each time, and we found that the plants of Chemin were more liable to disease and the fruit more given to crack than in the case of the other varieties named; hence the reason of its being ignored this season. If I am rightly informed, very large growers near London find the Chemin Rouge less addicted to disease than other popular market varieties, but hearsay is doubtful evidence, and Mr. Riding, I feel certain, would rather have my own experience, whether it agrees with his or not.—W. IGGULDEN.

— THE ORPHAN FUND ELECTION.—Now that out of the thirteen candidates nominated, six are elected on the Fund, seven remaining over, it may be as well to take stock of the claims of the seven before new ones are added, or promises to vote be asked for. There are of the non-elected candidates three that many subscribers to the Fund will agree with me in thinking should be withdrawn, as it is too improper to ask of poor gardeners to subscribe to a fund to assist in such cases. To me it is a marvel that such cases should have been nominated or selected by the Committee. The first, a child eight years of age, in a family of seven, has six brothers and sisters of the ages now from fourteen to twenty-five, and will next year range from fifteen to twenty-six years. What are all these doing that they cannot support the other one next year, nine years of age? Can anyone conscientiously say that is a fit case for the Fund? Next comes a child three years of age, thirteen in family, of whom eight range in age now from thirteen to twenty-eight years, and all next year will be older. What are all these now comparatively able-bodied persons doing that they cannot help the younger to the extent of a few shillings a week? Surely so many could provide for all the rest well. There is still another case of a candidate eight years of age, twelve children, ages ranging from eight to twenty-six years; that means, though not shown, oddly enough, that at least eight of the number must be of working age, and well able to contribute largely towards the younger children's maintenance. I cannot see that the Orphan Fund is intended to help such cases as these.—ALEX. DEAN,

— THE HISTORY OF THE VIOLA.—The Rev. David R. Williamson writes:—"Like your Chingford correspondent, Mr. J. B. Riding (page 124), I read with much pleasure Mr. William Dean's recent contribution to the *Journal of Horticulture* (page 98). His history of the Viola, which was admirably condensed, was to me uniquely interesting, for there are few Violas of any conspicuous merit that I have not, for the most part successfully, cultivated in my garden. Yet I cling strenuously to certain of my favourite varieties, such as Violetta, Countess of Wharnccliffe, Duchess of Fife, Ardwell Gem, Ravenswood, H. M. Stanley, Edina, True Blue, Blue Gown, Countess of Hopetoun, and Countess of Kintore in preference to many more recent introductions (White Duchess, Iona, and Olivetta being excepted, as pre-eminently attractive) for the creation of artistic effects. I am glad to find that Mr. Dean appreciates so highly the productions of such raisers as Dr. Stuart, Mr. William Cuthbertson, Mr. Baxter, and Mr. James Grieve. I think it is possible that the last mentioned horticulturist, who has been especially successful as a Viola cultivator, has not by the majority of writers on this subject been adequately recognised. Many earnest cultivators, I doubt not, are perfectly familiar with Mr. Grieve's creations who have never heard his name."

— THE EFFECTS OF THE FROST.—It is perfectly correct to say that vegetation in the south may have been found to suffer more largely than in the north, because with us the snow cover has been so thin just recently. When over in the Middlesex market garden districts I heard the most lamentable accounts of the complete drying or wilting up of all vegetable greenery, the leafage and stems being frosted beyond possible recovery. Not only is there nothing worth marketing, but because of the water famine, dealers will not buy, neither will consumers. Even such small kinds as Primroses, Violets, Daisies, amongst hardy and close-growing plants, the mischief done is excessive, and the hardy plant growers who supply the dealers will find it hard to meet the demand till late in the spring, when the season for sale is practically over. Amongst shrubs and Roses the frost seems to have, even so far as appearances go, worked havoc. The real extent of the harm in this direction cannot yet be fully estimated. Tender plants in greenhouses and frames have been killed wholesale where heating powers were moderate, and there will be a large demand for bedding plants in the spring. From many directions I hear of Potatoes largely frosted in pits, so frosted that they are irrevocably destroyed. Clearly to make good deficiencies, seeds will have to be largely sown in many directions, and a busy time seems in store for seedsmen.—A. D.

— SCOTTISH HORTICULTURAL ASSOCIATION.—The first meeting of the session of the Scottish Horticultural Association was held in Edinburgh last week, the new President, Mr. R. W. E. Murray, presiding. Mr. Murray, in his opening address, dealt with the professional and amateur aspects of horticulture, and the advantages which young men now possessed as compared with those offered fifty years ago. As an amateur gardener, he said the class of horticulturists to which he belonged did not meet with the consideration they deserved at the hands of the general body of horticultural societies, but that charge of neglect could not be laid at the door of their Association, which provided classes for amateurs at its great exhibitions. One reason for the success of the amateur was that he was generally a specialist, devoting his energies to very few varieties of plants, and another was his great love for what he cultivated. When a man was drawn into the cultivation of flowers his life became better, purer, and worthier, for there was no pursuit more fascinating and no more elevating taste than the love of flowers. He advised young men desirous of becoming professional gardeners to be sure that it was the line of business for which they were best suited, and having once entered on that path of life to be prepared by energy and determination to overcome all difficulties, and not to give way before disappointments. On the motion of Mr. D. P. Laird, Mr. Murray was cordially thanked for his address.

THE CHARLES COLLINS' FUND.

WE have pleasure in announcing the following subscriptions received during the past week, and sent to the Treasurer, towards this very deserving case:—

## SEASONABLE NOTES.

THE great havoc which the past few weeks of intensely cold weather must inevitably make among the inmates of our gardens cannot be gauged with anything like accuracy until some weeks after the frost breaks up. It is therefore impossible in many instances to do anything at present to make good the losses we shall assuredly have to deplore. There is, however, one department in which we can do much to help to tide over difficulties which must occur later on. I refer to the kitchen garden. We may take it as a foregone conclusion that large breadths of Broccoli will be killed outright; none but the very hardiest will be able to withstand such a succession of severe frosts.

Under such circumstances it is questionable if even such sturdy and reliable kinds as Leamington and Late Queen will not show a percentage of losses. Large numbers of Cabbages intended for the spring crop, especially those not planted early, will certainly succumb. Lettuce, too, which in the early autumn months were pricked out rather closely together in sheltered positions, ready for transplanting in the spring, will, I fear, be totally destroyed, even where the protection of straw or bracken has been given.

Parsley is already extremely scarce in many gardens, for although these may have as large a stock as usual to begin the winter with, the suspension of growth for so long a time upsets all calculations as to supply and demand. Seeds should, of course, be sown at once in a brisk heat so as to get a stock of young plants as quickly as possible. But to tide over present difficulties, or rather those of the immediate future, plants may at once be carefully lifted from the open air, placed in boxes, and taken into heat. The work of lifting is not altogether easy, but it may be accomplished by the following method of procedure:—With the aid of a pick drill out a narrow channel on either side of a row of plants. Let this be 2 or 3 inches from the plants on either side, fill the channel with very hot water, and repeat the operation until it is possible to loosen and remove in large blocks the soil containing the Parsley roots. After placing these in heated structures to thaw, the additional operations necessary are simple enough.

A sowing of some early variety of Cabbage ought also to be made at once. Veitch's Earliest of All I find exceedingly useful for this purpose, as it grows and "hearts" very quickly, and is of the finest quality. I have already made a sowing of Golden Queen and Early Paris Market Cabbage Lettuces, and strongly advise those who have not done so not to delay longer, as the plants resulting from sowings made now cannot fail to be of great value. A moderate sowing of some well-trying variety of Cauliflower ought also to be made now. Extra Early Forcing is one of the best for the purpose. I find it is a good plan to sow seeds of the above description in shallow boxes, placing them in an intermediate temperature. When the young plants appear they should be kept near the glass, and as soon as the first rough leaf appears be pricked out 2 inches apart in other boxes, or in soil placed upon a hotbed. In either case they ought to be kept warm and rather close, and afterwards be gradually hardened till the weather is favourable for planting them in the open air, then they should be protected with spruce branches for a week or ten days.

This work of seed-sowing with a view to securing an early supply of vegetables ought this year to be done more extensively than usual, for a dearth of "green stuff" must follow such exceptionally severe weather. Bearing this in mind, I am making two sowings of such indispensable vegetables as those enumerated, one being placed in heat, as before stated, the other in a pit to which only sufficient heat to exclude frost is given. This will insure a succession of plants, and at the same time help forward future operations by getting these important details off hand before the "rush" of work following the frost.

During the prevalence of the present severe weather materials should be prepared, and hotbeds made up in every available pit. All spare frames ought also to have beds formed for placing them on. It is often necessary through force of circumstances to have these scattered about in various positions where shelter and sunshine can be obtained, but when it is possible to do otherwise it is a great advantage to have a proper frame ground, so that hotbeds for various purposes may be made up in ranges; the labour involved in giving them the necessary attention is then reduced to a minimum, and loss of heat from the fermenting materials is more gradual than in the case of isolated beds. If any old lights are at command time will be well spent in fitting up rough boards to form sides for them on some of the prepared hotbeds. These will be of great service in raising early crops of Carrots, Radishes, Lettuce, Potatoes, young plants of Leeks, Cauliflowers, Celery, early Borecole, and Parsley.

The winter and early spring of 1895 will in the future be

looked on as an exceptional one, and a scarcity of vegetables there must be for some time to come, but those who are the most energetic now in taking time by the forelock, so as to provide early supplies as quickly and abundantly as circumstances permit, will undoubtedly meet with due reward.—KITCHEN GARDENER.

## MR. GEORGE TABER.

MR. GEORGE TABER, whose death was recorded in our columns last week, was one of the most widely known and highly respected members of the English seed trade. In his early manhood he occupied the position of head gardener to the Du Cane family at Braxted Park, and during this time he was a frequent and successful exhibitor at the metropolitan and local exhibitions. The seed grounds of Essex being close at hand soon attracted his attention, and ultimately led him, about forty years ago, to rent a small field in Rivenhall, and start in business as a seed grower. The extensive botanical knowledge which he had acquired proved of the greatest service to him in his new venture, and, united with sound judgment and untiring zeal, enabled him to build up a large and successful business. He has been heard to say that he found it necessary to grow 80 acres of one variety of Mangold Wurtzel to meet the demand for seed.

With a view to obtaining some relief from the heavier burdens of this large and still increasing business, as well as the establishment of it on a permanent basis, Mr. Taber in 1887 joined with the executors of Mr. Robert Cooper in founding the business of Cooper, Taber & Co., Limited, of Southwark, and Witham, Essex. Although on the formation of this Company he may be said to have practically retired from business life, he held a position on the Board of Directors, where his wide experience and extensive knowledge were of the greatest possible value. He also paid occasional visits to some of his old customers, by whom his genial manners and wise counsels were highly appreciated. The leisure he now enjoyed gave him the opportunity to accept a position on the Fruit and Vegetable Committee of the Royal Horticultural Society. His extensive knowledge was of great value here, and he was quick to perceive the merits or shortcomings of anything brought under examination. He took great interest in the vegetable trials at Chiswick, and he was rarely at fault in his estimates of the value of the kinds and varieties of vegetables under examination. He attended the meeting of the Royal Horticultural Society at Westminster last month, but did not appear to be in his usual health.

In private life Mr. Taber was one of the most cheerful and estimable of men, an ardent supporter of the cause of temperance, and other good work. Many a struggling farmer, seed grower, and seedsman have been helped out of their difficulties by his generous aid, and one of the most pleasing acts of his closing years was the building of a number of cottages in the village of Rivenhall, in which the deserving poor might live rent free.

He leaves one son, Mr. James Taber of Little Braxted Hall, who is also a director of Cooper, Taber & Co., Limited. The funeral took place on Saturday, 16th February, at the Rivenhall Parish Church.

We give a portrait of Mr. George Taber, as a gardener who rose to affluence by his excellent work and business aptitude, and because he was a good and kind-hearted man.

## REMOVING INSECTS' EGGS IN FEBRUARY.

GARDENERS sometimes complain, not unreasonably, of the peculiarities of the British climate, its frequent ungenial summers, its cold springs, and stormy autumns, but then there is a compensation which is often forgotten. The warmer, more equable climate of other countries, not to go farther than the Continent, favours the increase of insect life as well as the growth of plants; thus, for example, there are various species of which we have only a yearly brood, though elsewhere there are two or even three. Severe, too, is the British winter on many broods of hibernating caterpillars. The author who made himself so pathetic over the sorrows of a broomstick might have found a better theme in the trials of a juvenile caterpillar, which, after some small allowance of food in the autumn, has to endure the cold of winter patiently expectant of spring leaves. Many thousands no doubt never live to taste them, killed by damp or rough winds more frequently than by frost (the subterranean ones come off the best), other thousands are devoured by birds, or destroyed by gardeners—when they can.

Also, just about this time it is very desirable to remove all eggs of insects that can be got rid of before the hatching season arrives.

Many are cleared off trees and plants by the processes of syringing and spraying, also by pruning and scraping, but if they are only carried to the ground a part of them may hatch afterwards. It is probable some eggs can pass the ordeal of our solutions without the germs being killed, and neither cold nor rain affects them, so that those insects which pass the winter in the egg state have a notable advantage. Fortunately for us, one check on them is the activity of tiny ichneumon flies, which puncture insects' eggs, depositing their own progeny, by which the contents are devoured.

to prevent its farther increase. Very fortunately, the gipsy moth caterpillar—once not uncommon in Britain—has become scarce, but the patches of eggs coated with furry down are easily discoverable on the bark; and on the Continent, where the insect still much infests orchards, it would seem the removal of these is not attended to.

The eggs of our well-known foe, the winter moth, are often laid in clusters, which, by their green colour, may be detected on the trunks and branches of fruit trees, but they are also placed on

FIG. 30.—MR. GEORGE TABER.

Our egg-killing proceeds usually in a more wholesale manner, but it is necessary to be also on the outlook for small patches of them which may come under our notice, or which we may search after because they may not be removed by washes. To take an instance, the curious rings or necklaces in which the lackey moth arranges its eggs resist the application of water, being covered with a sort of varnish; so they must be picked off the twigs and branches. As the caterpillars feed in companies on the Apple, occasionally on other fruit trees, and the species has been rather abundant the last few years, it is desirable

the twigs and buds, where they escape the eye, though spraying, even with water alone, removes them. Another species allied to this is the mottled amber (*Hybernia defoliaria*). The moth deposits eggs early in the winter on a variety of trees, and occasionally selects the Cherry, the caterpillars sometimes doing unsuspected mischief, from their feeding out of view. The accidental finding of this moth's eggs in lots of 200 or more on twigs high up in a tree suggests that here, as in the case of the winter moth, there may be assistance given by the male, enabling the wingless female to reach a height to which she would hardly

crawl. Solitary eggs are seldom noticed, especially if pale in colour, nor those in twos or threes, such as those of the figure-of-eight moth, which are laid in the autumn on the Apple bark, and the blue-headed caterpillar begins to feed while the leaves are expanding. Their eggs may be artfully hidden. I have searched in vain on the Gooseberry for those of the V moth (*Halia waryana*), which must be laid during the summer, which is the moth's season; and the caterpillar, a black-warted, variously coloured creature, joins that of the Gooseberry moth in attacking the early foliage. Probably it is lodged about the buds, and may be removed by syringing or spraying; this is also effective for the destruction of a much smaller insect, the scale, which much infested Gooseberries in 1893 and 1894. With this, as with the other species of scale or coccus, there is usually the dried body of the parent serving as a shield to the eggs, so that some force of application or else friction is necessary to dislodge them.

Miss Ormerod notes that the Gooseberry scale begins to be moving in February, its food being obtained by suction from the bark. No doubt, both indoors and out, the various scale insects are on the alert early; hence the need of energetic measures now, if such have been delayed. That able entomologist recommends as effectual a mixture of equal parts of kerosene and soft-soap, suitably diluted with water; also, the sulphuret of lime dressing has been recommended for the eggs of scale, and indeed for any kind. It is possible these and similar dressings, compounded of petroleum or of gas tar, may permeate many eggs, and kill the germ they contain, even should they not be dislodged from the bark, or some destroyers may act by closing any minute pores that admit air to the interior. This is probably the efficacy of oils, such as whale and lemon oil, which some strongly recommend for Apple and Pear scale, insects that are slow to stir, since they are seldom moving till the end of April.

Amongst the smaller moths of the Tortrix tribe we notice that the eggs of several injurious species are laid in the autumn on, or around the buds, and hatch during the spring. The species familiar to us as an early disfigurer of Rose leaves may be checked by syringing in the winter. If a petroleum liquor be used it should be of only half the strength that is employed for fruit trees, and washed off afterwards. Few gardeners take the trouble to spray that favourite shrub, the Lilac, yet this might be done to advantage about February, as the eggs would be removed of the troublesome little moth, *Gracillaria syringella*, which, in its larval stage, so greatly disfigures the Lilac by twisting and devouring the leaves. Even when they are of black hue it is seldom the eggs of aphides, which are placed singly, and of course minute, are noticeable to the eye, but they can be washed off trees and shrubs now. There is special reason for cleansing Plums and Damsons, since on them the first brood of the Hop aphid (*Phorodon Humuli*) generally feeds in the spring, performing a migration to the Lime at some date in early summer.—ENTOMOLOGIST.

### TOMATO HOUSES IN THE WINTER.

I DO not know why "A Perplexed One" should suggest the necessity of having something profitable to grow in Tomato houses in November, seeing that it is really not difficult to have June-sown plants fruiting more or less freely in gentle warmth up to Christmas, if only the blooms have been set up by the end of October. Of course no one would suggest that all houses should be so utilised, but at least some might be, and thus furnish Tomatoes for a much longer season. Then the earlier houses could be cleared of Tomatoes by the end of October as intimated, and having at hand a large extent of rough span stages that could be erected, on these could be stood as thickly as possible pots sown with some good early forcing dwarf Beans. If these stages would admit of access beneath them, such as is frequently seen in span Strawberry houses, a portion of the space below might be utilised for Mushroom beds, assuming that the drip from the Bean pots did no harm. Of course I am assuming that the houses are broad spans, as depicted in the illustration, but "A Perplexed One" gives no information.

If they be low narrow houses, and have stages fixed on each side, then no others would be needed. As the seedlings become strong the pots may be thinned out so far that two or more other houses may soon be filled, and if there be successional houses for other sowings then every house might be filled with dwarf Beans by Christmas, and once gatherings were started there would be good pickings all through the winter. Is it probable there can be found any other product that can be so easily and so cheaply raised, and so comparatively easily grown during the winter that would be more profitable than Dwarf French Beans?

"A Perplexed One" seems to regard flowers as a forlorn hope. I do not find that such is the case generally with the professional grower, but here, as in so many other things, very much depends on marketing methods. But if in this particular case flowers be out of the question, and it must be so when flower culture for market is not the regular vocation, there seems to remain no other course open than to utilise Tomato houses by growing French Beans. It is quite possible to have

young Tomato plants coming on in the months of February and March at the same time that Beans are podding, so that one crop in no case incommodes the other.

The necessity which seems to exist for the filling of the houses with Tomatoes again early in the spring of course materially handicaps their free winter use, and for that reason it is not practicable to grow many things that otherwise might be suggested. I shall be pleased to learn of some other crops which may be thought as advantageous, or more so, as are Dwarf French Beans.—INQUIRER.

NOWADAYS such an "one" as "Perplexed One" has a numerous kindred, who would only be too glad to know for a certainty what to grow at any time in order to reap some benefit. As he confines himself to what may be termed off-season, he has evidently no fault to find with the in-season. His query, "What to grow from the end of October to the end of February in order to reap a profit from Tomato houses?" is of an extremely interesting character, not only to the immediate parties concerned, but also to an ever-increasing and consuming public. We may all witness with delight the spread of horticultural knowledge, and we may safely say that that knowledge can never outstrip what lies hidden in the bosom of Flora; and though some may lament the intrusion of outsiders into the pleasantries of horticulture, they need not be down-hearted on that account, the source is as yet abundantly in a primeval state, and not likely to be exhausted.

It is quite true that last Christmas Chrysanthemums were a drug, but it must be remembered that was not the fault of the cultivator, nor yet of a purchasing public, but simply arose from the extraordinary mildness of the particular season, therefore "Perplexed One" would act wisely not to discard the Chrysanthemum, for with his facilities of house room let but a sharpish frost fall about September 20th, Chrysanthemums, unless under cover, would be scarce enough by Christmas, and instead of being quoted at 2s. 6d. per dozen bunches, would be more likely to be 12s. or 15s. for the same number. Anyone who has attended Covent Garden flower market for the twenty years must be cognisant of the wonderful increase of produce now displayed in that emporium for sale. As a feature of that expansion it may be stated that in the seventies there was but one solitary continental representative who brought into the market the cut flowers in a few boxes strapped to his shoulders, but now the increase is of such dimensions that the tonnage has to be computed almost daily. Even our own home trade has increased and will increase, and it may be truly observed with all the expansiveness, good produce in the season will always command fairly remunerative returns.

No doubt the prosperity of the profession is greatly influenced by the unhealthiness of commerce; people must have bread and cheese, but they need not have flowers, and thus, naturally, the beautiful administration of Flora is curtailed and markets rule somewhat dull. Nevertheless, cultivators must ever try to be ready with what is wanted. It is not business to bring good produce late into the market; be in time, and secure the best custom.—A. M.

[We shall be glad to publish any suggestions that may be possibly helpful on the subject under notice, apart from the offer we made last week of a silver medal for an essay that may be deemed worthy of the award, in accordance with stipulations that will in due time be furnished to intending competitors.]

### PLANT NOTES.

#### STATICE PROFUSA.

THIS useful plant does not appear to be nearly so much appreciated as it deserves, consequently a few notes respecting its general qualities will not be out of place. It requires a warm or intermediate temperature, and the purple and white flowers are produced on erect, branching spikes. The successful cultivation of *S. profusa* may be briefly summed up as follows. Young plants are by far the best for general decorative purposes. A stock of these should, therefore, be raised annually, either from seeds or cuttings.

If propagation be effected by means of cuttings they should be inserted singly in small pots, and placed under a hand-light till rooted. As soon as the roots have obtained full possession of the soil the plants must be removed to larger pots, as on no account should they be allowed to become root-bound, in case of which the plants would quickly present a sickly appearance. At all stages of their growth they are subject to the ravages of various insect pests, mealy bug and green fly being especially troublesome. Stringent measures should, therefore, be taken for their eradication, for if once allowed to become thoroughly established the plants rarely flourish. *S. profusa* delights in a rich loamy soil, with a little charcoal and sharp sand intermixed.

#### FARFUGIUM GRANDE.

This plant, which is synonymous with *Senecio Kämpferi aureo-maculata*, stands unique amongst fine-foliaged plants either for greenhouse, conservatory, or general decorative purposes, lasting a very long time in perfection, especially if placed in a light airy position. The leaves, which are similar in shape to those of *Peperomia resedæ-flora*, though much larger, are of a beautiful dark green colour, freely blotched with yellow.

Propagation may easily be effected by means of division of the roots, which can take place at almost any season, but where practicable I should recommend doing it some time during the present month, just

as the plants are commencing to make new growths. It is of comparatively easy cultivation, and delights in a good loamy soil with a fair amount of root room, for if stunted in this respect the foliage is not so fine either in size or colour.

#### CISSUS DISCOLOR.

In this we have one of the most showy and highly coloured foliage plants that can be found amongst our stove climbers. The bright velvety green foliage, spotted on the upper side with white, the under side being of a deep reddish purple, is very effective. It may be grown in a variety of ways, being equally at home either trained over a halloon or along the roof of the stove, but nowhere is it seen to better advantage than when trained over lofty roof girders, or arches, or up pillars in a warm conservatory, its long sprays of growth, when so employed, if allowed to hang in graceful festoons, presenting a pleasing and attractive appearance.

The best means of propagation is by layering, which may easily be effected as follows:—Prepare a sufficient number of small pots by filling them with a mixture of fibry peat and sharp sand. This being accomplished select a few of the strongest growths, and place every second or third joint on a pot, just covering it with soil and securing it with a small wooden or wire peg; do not cut the joints in any way, but keep the plants, layers and soil, moist to encourage them to emit roots, when in about three weeks they may be severed from the parent plant and grown in the ordinary way. This plan far surpasses that of taking cuttings. If given a temperature of from 65° to 70° the colour will be much better and richer than when grown in a cooler house. *C. discolor* delights in light, rich open soil; a mixture of good turfy peat, fibrous loam and leaf soil, together with a small amount of charcoal and silver sand, suiting them admirably. Great care should be taken to supply an adequate amount of drainage, for anything approaching stagnation about the roots is very detrimental to the well-being of this class of plants. When the plants are growing a little liquid manure will prove beneficial to them, but it must not be given too strong or it will do more harm than good.—GEO. PARRANT, *Ashby Lodge Gardens, Rugby.*

#### SPAWNING MUSHROOM BEDS.

UNDER this heading, "Mushroom" (on page 102) has asked for information as to the temperatures found most suitable for this, one of the important points in the culture of Mushrooms. Perhaps a few words as to the method we follow may be acceptable to others as well as "Mushroom," though if any inexperienced readers would provide themselves with "Wright's Mushrooms for the Million" there would be small necessity for anything I may be able to say on the subject.

In the first place good spawn is absolutely indispensable. I believe in many instances failures have been attributed to carelessness or ignorance on the part of the cultivator which were really nothing more or less than the result of had or feeble spawn. Now, as to the manure. Ours is saved in small quantities every day and spread about a foot in thickness in a large shed until it is thought enough has been obtained, but owing to being collected thus the usual practice of turning every other day is dispensed with, as it has been found that the spawn acts more quickly and the beds last longer under these circumstances; if, however, the manure could be obtained fresh at one or two gatherings I should certainly have it turned until quite sweet. All that is done, however, is to mix the later gathered droppings with those obtained earlier, and the whole is then turned once or twice before making up the bed.

The form of the beds may be such as seem most convenient under differing means of shelter, if any. Ours are made flat one above the other on shelves in a house at this season. The beds are about a foot in thickness, beaten firm, but not really hard. I believe it is quite possible to make Mushroom beds too hard. From what I have seen of spawn working in a loose dry heap of manure during the past summer, I have been led to the conclusion that failure may have occurred through making the beds just about as hard as a road. At the same time do not err in making them loose, let them be firm, but with an elastic firmness.

In the matter of spawning let us take as an instance a bed spawned on the 5th January. This bed was made up in the ordinary way, and sticks were inserted by which to judge the temperature, which rose rather high for a few days. I do not know how high, as a thermometer is never used by me for this purpose. At the first opportunity after the heat was found to be declining the spawn was inserted in pieces from 2 to 3 inches square, and about 9 inches apart all over the bed. In spawning a deeper or thicker bed, it would most likely be found wise to wait until the heat had declined to about 80°, but for shallow beds such as ours all the heat possible should be taken advantage of for "running" the spawn. In a fortnight after spawning the bed mentioned was full of white cloudy mycelium from end to end. The Mushrooms are now, February 4th, coming up in all directions, lifting the soil, and some of the earliest are almost ready for gathering.

I forgot to say that soil is placed on the beds from 1 to 2 inches thick after the spawn is put in. Where turf can be spared for the purpose the idea of turfing Mushroom beds, as mentioned in the Journal some week or two back, appears to me well worth carrying out. Our soil has generally grown a crop of Cucumbers or Melons before being used for Mushrooms.

My experience of peat moss litter for Mushrooms has been short, but certainly not sweet. A load of manure procured from a cab

proprietor in the town near was found on arrival to consist of the litter. It is not too much to say that after being at considerable trouble to, as it was thought, get the manure sweet, it grew us the finest lot of an unknown fungus (unknown to me at any rate) that I have ever seen grow on a proposed Mushroom bed.

It has been mentioned times enough perhaps that the manure from horses frequently under physic is of little or no value, that it is true I have proved to my own satisfaction a year or two ago. In a place where the horses were often the recipients of medicine in one form or other I tried to grow Mushrooms in every position I could think of. I should say that from all the beds made in the course of two years possibly half a dozen Mushrooms were procured.—J. W. K.

YOUR correspondent "Mushroom" (page 102) appears to have been unfortunate with his Mushroom beds. It is not unusual for a bed after being made up to reach 120°, and would afterwards do well if, as was the case with the bed mentioned by "Mushroom," the material was in a suitable condition. My practice after having the manure carted to a spot near where the bed will be made up, is to have it carefully turned over, at the same time shaking out all long straw, retaining only the short litter and manure, which is left in a ridge and lightly covered until the trial peg feels uncomfortably warm to the hand; it is then turned every second or third day until the rankness has left the manure, which will be in a fortnight from the time it is first thrown in a ridge.

For the summer supply they are grown on ridges 3 feet wide at the base, and 2½ feet high, length according to manure we have on hand. Trial sticks are placed at intervals the length of the bed, and examined daily. The heat will sometimes rise rapidly for a few days, and when it has reached its highest temperature and declined to about 95° it may be spawned. If a thermometer is used it should be plunged from 2 to 3 inches near where the spawn will be placed. Each brick of spawn should be broken into eight or ten pieces and put in the bed 8 inches or a foot apart, and 2 inches deep, when it must be covered with 2 inches of soil, good strong loam with the rough pieces riddled out will be most suitable. A light covering of litter is again thrown over the bed, this being added to from time to time if the temperature on the soil is likely to get below 80°, during the first month when the spawn will have permeated throughout the bed. I prefer covering the bed with soil at the time of spawning, to leaving it, as is sometimes done, until the mycelium is moving in the bed.

A bed may be spawned at any temperature from 80° to 95° if the heat is on the decline, but if spawned at the higher temperature the Mushrooms will appear in a shorter period, or from six to eight weeks; if at the lower, from eight to twelve weeks, except in the late autumn or winter, when they will not appear until the following spring. The finest Mushrooms are obtained from beds spawned at 80°, and they are produced over a longer time than if spawned at a higher temperature, not throwing so many at one time, which is sometimes an advantage where a continual supply is required, rather than a large number at a given time.

A couple of spare beds are spawned during September, and we find them very useful in the following summer, as they are more to be depended on from May onwards than beds spawned in March or April, and Mushrooms are in greater demand with us in the summer than winter.—J. D. S.

#### ORDERING SEEDS.

SOME years ago, when I was in the employ of one of our largest seed merchants, I remember the blessings that were called down on the head of many a British gardener because he allowed procrastination to overcome him, and refrained from ordering seeds during the prevalence of a somewhat severe frost. The seedsmen kicked their toes on the sacks, hammered their hands on the counters, and prayed for orders that they might have work and warmth. However, prayers availed but little, the orders did not come until the weather changed, then there was a rush, as everyone wanted them complied with at once. Still the seedsmen were not satisfied, and the prayer changed to one for fresh air and sleep. Midnight found them slaving, and at six o'clock in the morning they were at it again. They were weary and worn and sad, and the remarks on the gardeners were numerous, pointed, and moreover just.

As was the case in my younger days, so it is now; and if it is possible for anyone to call attention to a class of men generally underpaid, and mostly overworked, in such manner as to improve their position in either respect, he certainly ought to do so. A few days ago I was in the seed department of a well-known and highly respected firm, and asked how orders were coming in. I was met with the expected reply, "Very slowly; the gardeners will not send their orders until the frost gives way, and then we shall be worked to death." I have been through the mill, and heartily sympathise with the numerous seedsmen who are so situated at the present time.

Why will not the gardener order his seeds early? No substantial reason can be adduced for what has become with many a mistaken practice which may tell against himself. "There is frost in the air and snow on the ground, and I cannot sow my seeds if I procure them, so I may as well wait a while until the weather takes a change." Pause and think of the possible consequences of "putting off till to-morrow." Think of the men who have your order to execute. Bear in mind that they cannot have the inestimable benefits of fresh air such as you have to maintain the all-important health and strength. Remember the loss

of health means loss of situation to the man in the seed trade, and there is no chance of more work for six months at the least. Take the war into your own country if you like, and speculate on the possibility of having to wait two or three weeks after despatching the order ere the package comes to hand. What does this mean? Is it not equivalent to lost, and might I add wasted time?—  
VERBUM SAT SAPIENTI.

#### HAVANT CHRYSANTHEMUM SOCIETY.

THE annual show of this Society will be held on Tuesday and Wednesday, October 29th and 30th.

#### NATIONAL CHRYSANTHEMUM SOCIETY.

A MEETING of the General Committee of this Society was held on Monday evening last at Anderton's Hotel, when Mr. R. Ballantine presided. After the usual preliminary business of minutes and correspondence had been disposed of, the Secretary announced that all the judges nominated for the Society's three shows in October, November, and December next, had consented to act.

The report of the schedule sub-committee was then presented and passed. The draft report detailing the work of the Society, which will be more fully alluded to in our report of the annual meeting, was also submitted for approval, as well as the draft financial statement for the past year. Although the latter can scarcely be regarded as finally complete it is interesting to record that the total of the income for 1894 closely approaches the sum of £900, of which £246 1s. 9d. is members' subscriptions. Prize money paid to exhibitors, including the value of medals, was £413 6s. 6d.

Referring to the proposed alteration to rules as set forth in a circular distributed to the members, Mr. H. Briscoe-Ironside called attention to the suggested alteration in rule 3, line 6, which practically made the Vice-Presidents members of the Floral Committee. This was thought to be undesirable, as it might possibly have the effect of swamping the votes of the ordinary members who were experts, and after some discussion the meeting decided to withdraw the recommendation.

Some correspondence from New Zealand was read, showing the interest that is being taken in the Chrysanthemum there, and the opinion of the Committee was taken on the wording of one of the colonial schedules, in which the ambiguous term large-flowering varieties had caused some difficulty.

There were several new members elected, and the Windsor and Eton Society was admitted in affiliation.

The annual general meeting of the members of the above Society will take place at Anderton's Hotel, Fleet Street, E.C., on Monday, February 25th next, at 7 o'clock.

#### FERTILISATION OF THE CHRYSANTHEMUM.

MR. H. BRISCOE-IRONSIDE (page 79) tells us that the "point" of his communication to the Scientific Committee of the R.H.S. was not the question whether the Chrysanthemum is proterandrous or not, but "whether the Chrysanthemum is by nature self-fertilised or cross-fertilised." But surely there can exist no doubt whatever that the Chrysanthemum is, in nature, both self-fertilised and cross-fertilised, the comparative frequency of the two processes depending largely on the character of the insect life in the particular locality. It scarcely required the confirmation of a scientific committee to assure us of that.

I note that Mr. Ironside does not apparently contest the assertion that the Chrysanthemum is proterandrous, although the paragraph of the report which I quoted, and again append, seemed certainly to suggest a doubt on the subject. Page 78, "It had been thought by some writers, following Darwin a little too implicitly perhaps, that 'the anthers of the Chrysanthemum . . . as of all members of the Compositæ . . . are proterandrous . . . and naturally adapted for cross-fertilisation'—(Burbidge)." I think that those who aim at a scientific cross-fertilisation of the Chrysanthemum cannot follow Darwin and Burbidge too "implicitly" on the point referred to.—  
CHARLES E. SHEA.

#### NOMENCLATURE AT CHRYSANTHEMUM SHOWS.

I WONDER what "An Old Judge" would think (who wrote on nomenclature at shows some time ago) of the Chrysanthemum show of a leading society, where, in the matter of labelling cut blooms no system whatever prevails, and exhibitors finding themselves fancy free, make use and choice of material, from tiny slips hidden amongst the blooms to large square envelopes displayed at the front or back of their stands? About two seasons since I was honoured by an invitation to make any suggestions tending to improve the framing of this Society's schedule. Being duly affected by the incongruities presented by this heterogeneous labelling, I ventured, amongst other things, to call their attention to this point, suggesting that they (the Society) might provide

an adhesive label of a uniform pattern, supplying each intending exhibitor according to his requirements. The cost would be but trifling compared to the all-round benefit it would confer.

If such a label was neatly outlined, and the space ruled for text, but little margin for absurdities in this part of the question could exist, provided a society insisted on their use. Affixing on the front of the stands is doubtless the simplest way, but not practicable in all cases. For elevating on supports at the back pieces of cardboard, or, better still, zinc cut to the pattern of the label for adhering to it, would give equal facility, and the same pattern labels thus used should meet all the requirements of plants and fruits, as well as cut blooms.

I think those exhibitors who take pride in their stands are loth to place the names amongst the blooms, for it cannot escape their notice how much such stands suffer at the hands of an interested public in their endeavour to arrive at particulars they are anxious to know, and whose right it is to thus ferret out their information at the exhibitor's cost when he compels them to do so. Give the public the advantage of legibly written, conspicuously placed labels, then, and not till then, can societies and exhibitors join in the cry, "Hands off, visitors."

The want of a system also tends to confusion with the uninitiated taking notes amongst the florists' flowers, nor could it be otherwise with the diverse methods employed by exhibitors. I may add that my idea is an elastic one, and capable of stretching either way, provided that the necessity of a general system, protected by a rule in the schedule, is not lost sight of.—E. K.

#### ANEMONE-FLOWERED CHRYSANTHEMUMS.

I WAS pleased to hear the remarks in defence of this beautiful section of Chrysanthemums by H. Harris (page 120). Why they should be looked on with so little favour has always been a puzzle to me, for we have certainly nothing amongst the whole range of Chrysanthemums calculated to stir up more admiration than well-grown flowers of Anemone varieties. What can be more charming than the chaste Fleur de Marie, the light rose ray florets and sulphur-tipped disc of Enterprise, the primrose guard petals with deep yellow disc of John Bunyan, or the salmon-blush guard petals and golden rose-coloured disc of W. W. Astor?

As a grower and ardent admirer of them I feel certain that we must ere long see them figuring prominently in every schedule in the kingdom, as being equal to hold their own against Incurved, Japanese, or Reflexed, and I venture to say that with just as much—if not more—delight to those who visit our exhibitions. Damp seems to affect them to a slight degree, whilst for decorative purposes, associated with foliage or Maidenhair Fern, they form a pleasing break, not by their striking contrast alone, but by lasting qualities.

The present being a good time to order varieties, I can thoroughly recommend the following in addition to the above mentioned:—Ada Strickland, a rich chestnut-red colour with broad ray petals; Duchess of Westminster, silvery-blush guard petals with rosy bronze disc; Jeanne Marty, a large flower, blush-coloured petals with deeper disc; La Deuil, crimson-purple; Madame Charles Lebocqz, citron-yellow with carmine tint; Madame Robert Owen, pure white; Mons. Pancoucke, orange-red, very handsome; Mrs. Judge Benedict, white, changing to blush guard petals with high lemon centre; and Nelson, deep rosy violet. Judge Hoitt, Sir W. Raleigh, Queen Elizabeth, and several others of last year's introduction will have to be tried again before an opinion as to their merits can be expressed. The new varieties which are being sent out in the spring are Caledonia, Owen's Perfection, Junon, and Descartes, the three former being fully described in the Journal of November 8th, page 428.—R. P. R.

#### THE "CHRYSANTHEMUM YEAR BOOK."

AS the Editor of this new venture on the part of the N.C.S. may I be permitted to point out to your correspondent, "Fairplay" (p. 120), that the pseudonym under which he attempts to hide his identity is singularly inappropriate? The heading of his complaint and the first two lines seem to suggest a criticism of the book as a whole, but further acquaintance with his effusion very plainly shows that the object of "Fairplay" is to attack one contributor only.

It may be useful to point out to such of your readers as have not seen the "Year Book" that it contains twenty-four articles in all. Some of them necessarily refer to the work of the N.C.S. during the past season, others to the work of kindred societies that are doing good service in Chrysanthemum matters, while another class of contribution deals with the aspects of the flower in America, in Italy, and in Japan. This, I venture to assert, is a broader programme that has ever been adopted in any similar publication, and is a sufficient guarantee that the book, the joint work of fifteen or sixteen writers of acknowledged authority, has not been written by those who seek to advance trade interests.

In another class of article, which may be referred to as descriptive, is one by Mr. Jones of Lewisham, and it is this which "Fairplay" seems to have analysed so keenly, and as I shall show so unfairly. What a novelty is depends on individual opinion, but in the paper by Mr. Jones he mentions and describes fifty-four varieties of Japanese of recent introduction. These are the product of twenty-two different raisers, English, French, and American, and the following is the result:—Mons. Calvat, twelve varieties; Messrs. Pitcher & Manda, eight; Messrs. C. E. Shea and R. Owen, four; Messrs. Walz and Lacroix, three; Messrs. Spaulding, E. G. Hill & Son, Kelly, and H. J. Jones, two; and Messrs. Carruthers, Sautel, W. Wells, Délaux, Atkinson, Godfrey, Cox, Smith & Son, H. Briscoe-Ironside, Crozy, Graham, and unknown, one.

So, too, with the illustrations of flowers. These are five exhibition Japanese, one of Scotch origin, one of English, and three American, but in the place of one of the latter there would have been one French variety for completeness, only the photograph was such that the engraver could not use it.

"Fairplay" need be under no apprehension as to the "Year Book" not being of substantial value. The article on the Kingston challenge vases, the statistical information of the November show, the lists of certificated varieties and medals awarded, to say nothing of the others of a more varied nature, will insure its value for many years to come.—  
C. HARMAN PAYNE.

I THINK the same as "Fairplay," there is something very misleading in the article (page 67) headed "Japanese Novelties for 1895," for if the three continental varieties priced at 30fr. each, and which do not appear in any English catalogues are excluded, there are not a dozen 1895 varieties, all the rest being 1892, 3, and 4 varieties. So there are about forty varieties to misdirect the public, and this from one of the most prominent members of the N.C.S. The whole article is more like a trade advertisement than an article for a National Society's annual.—  
ANOTHER FAIRPLAY.

LIVERPOOL NOTES.

At the last meeting of the Liverpool Horticultural Association Mr. William Blomily, a noted cultivator, read a paper on greenhouse plants, devoting attention to the following among others:—

KALOSANTHES.

These were recommended to be raised from June to August, selecting shoots with three or more growths, and placing them in sandy soil in a cool frame kept somewhat close and shaded on very hot days. If large specimens are wanted in the shortest space of time five or six plants should be placed in each pot, using a compost of fibrous loam, leaf mould, charcoal, and sand, and kept up near the glass in a greenhouse. Pinch out the points when they have made 3 inches of growth. In February they should again be pinched and potting done as required, syringing and watering carefully during the summer, giving the last shift not later than August, still keeping the plants near the glass, with attention to having the shoots tied into position. After flowering they may be placed outside, the shoots being pruned back to about 2 inches in length, the same routine of treatment being recommended when they break into growth.

LACHENALIAS.

These were described as amongst the most useful of greenhouse flowering bulbous plants, but sadly neglected. For early work he advised potting in August and September, placing tea bulbs in a 6-inch pot in a compost of good loam, spent Mushroom bed refuse, and sand. After potting stand in a cold frame, where they may be left until severe weather is expected, then be removed to a greenhouse shelf, giving liberal supplies of weak liquid manure as the pots become filled with roots. After flowering remove again to a cool frame until the bulbs show signs of resting, when the pots may be placed on their sides for the season. Mr. Blomily specially mentioned the latter as being of great importance, many collections being lost by placing them outside exposed to all weathers.

STATICES.

These, he said, would not bear strong sunshine. Cuttings should be taken with a heel, inserted in sandy soil and sand, and placed in a propagating frame. When rooted pot in three parts loam and one of peat, with silver sand, placing them on a greenhouse shelf, the temperature of which should not fall below 45°. Potting should be done in March, and the plants syringed every afternoon all through the summer. Varieties mentioned as being the best were profusa, Holfordi, imbricata, and brassicæfolia.

An interesting discussion followed, Mr. Stoney remarking on the beauty of Lachenalias for growing in baskets, the variety Nelsoni being the best. A question was asked by Mr. R. Pinnington regarding the inability of Statice floribunda to open its flowers sufficiently, this being a great drawback to its ever becoming popular. Mr. Devanny, Botanic Gardens, stated that he had never seen a plant with flowers fully developed, all being in the state referred to by Mr. Pinnington.—R. P. R.

RAISING PEAS UNDER GLASS.

UNDER the above heading your correspondent, "A. D." (page 92), advocates boxes, and I fully agree with him, but I do not agree with the way he describes of making them. I enclose a sketch that I think will almost explain itself, and anyone thinking of making boxes would find a good deal of trouble saved in the operation of planting if they had them made as advised below. It will be seen that the bottom is loose, and is simply slid in and rested on the two strips of iron or wood. To plant a trench is made, a box is placed in the end, the bottom drawn out, and the box is lifted straight up. The bottom being wider than the top allows the mass of soil with the Peas in to drop out and remain intact in the trench. All that then remains to be done is to draw the soil up to them on both sides; this is repeated to the end of the trench.

A handy and useful size would be 2 feet long, 3 inches wide at the

top, 4 inches at the bottom, and the same in depth, inside measure. The ends should be made of wood 1 inch or  $\frac{3}{4}$  inch thick, and cut to the size named. The sides may be made of  $\frac{1}{2}$ -inch wood, and for the bottom  $\frac{1}{2}$  or  $\frac{3}{4}$  will be quite strong enough, and should answer without any additional support. The best support for the bottom would be irons  $\frac{3}{4}$  inch wide,  $\frac{1}{4}$  inch thick, and bent to shape with two or three holes for nails or screws, as shown in fig. 31. They would then go through the sides and into the thick wood of the ends. The bottom should be made 2 or 3 inches longer than the sides to enable anyone to draw it out from either end, and it should be made to slip in very easily, as in watering the Peas the wood will swell and make it difficult to draw out. A handy man would soon make a number out of old packing cases, which are usually to be had on a gentleman's place, and if taken care of they would last several seasons.

FIG. 31.

Fig. 32 shows a portion of the box at one end. A A are the sides of the box; B, the end; C, bottom partly drawn out; D, narrow strip of wood or iron, the same width as the thickness of wood in the end of the

FIG. 32.

FIG. 33.

box, one of these at each end supports the bottom; E, shows how extra support may be given to the bottom, if required, by two nails and a piece of string. Fig. 33 shows the box endways.—W. S. E.

APPEAL JUDGES.

It is said that there are none so blind as those who will not see. I thought that I had made it sufficiently plain, in my former letters, that what I proposed was only to allow exhibitors to appeal under well-defined conditions, that the reserve judge or judges were only to be called in if any of the decisions of the first set of judges were appealed against, to decide in these cases alone. "A. D." and "G. McD." (page 123) seem to think that my proposal is that the appeal judge or judges are to review or overlook all the decisions of the first set of judges. I cannot for the life of me see that my proposal can bring about such a dreadful state of matters as is conjured up.

"G. McD." says that he has always found judges willing to review their own judgment. This is a most objectionable practice. I know a society, and if I am not mistaken "G. McD." knows something about it also, where this is sometimes done. This society embraces a wide district, and as the meetings are always held at night in the county town, the members in the immediate neighbourhood get themselves appointed to assist the judges, and see if things are going on as they would like. A case happened a few years ago at one of these gatherings which shows what can be done. Prizes were offered for a special variety of Apples. After the prizes had been awarded the judges were told by an exhibitor that the Apples to which they had adjudged the first prize were not the variety specified in the schedule. The judges then reversed their decisions, giving the complaining exhibitor the first prize, and the dish which should have been disqualified, if his statement was true, the second.

"G. McD." asks me if I would be willing to act as one of the first set of judges. I say yes, and I cannot see why any person who gives his opinion honestly need care who comes after him. I have had experience in judging at cattle shows, flower shows, and ploughing matches, and sometimes have had very great difficulty in preventing my coadjutors making mistakes that they ought to have been ashamed of.—C. K.

[We insert the above letter, though we are unable to see what good can be done by further discussion on the present lines. In both the cases animadverted on by our correspondent the responsible managers were at fault. In the first instance in two respects: (a) by appointing judges who required to be looked after; (b) by allowing a person interested in the awards to be present during the adjudication. In the second instance, if "C. K." is correct, in appointing judges who were obviously unfit for the position they occupied. No horticultural societies in which such loose methods prevail are worthy of the name, and it is impossible that they can command the respect of the gardening community.

Judges must not only be men of unquestionable probity, but of admitted competency, and in our experience, which is not very limited, these are the very men who are the most ready to re-examine any class to which their attention may be directed by the officials on the possibility of some point having been accidentally overlooked; because the only object of independent and unbiassed judges is to do strict justice, and they never give a thought about the exhibitors whose products are in question.

The most flourishing societies and those which enjoy to the fullest

extent public confidence are those the responsible officials of which strive to procure the aid of the best judges obtainable for the different sections of their exhibitions, and if the "best" are secured, these being undeterred by any false pride or captious remarks from re-examining their own work if it should be thought desirable, where are appeal judges to come from? There can be no better than the best—judges of the first class, though there is no lack of others much less experienced who feel themselves competent to alter half the awards in one-quarter the time that it took their seniors to make them.

In the case of the great and varied exhibitions of our most successful societies complaints about the judging are extremely rare, and if made are still more rarely substantiated. The procedure is based on the principle of securing judges of irreproachable integrity and acknowledged competency, their decisions being final; and we are bound to say that in our opinion any departure from this principle would sooner or later lead to disquietude, distrust, and dissatisfaction, the certain precursors of loss of prestige and eventual collapse.]

#### ELTHAM ROSE SHOW.

THE annual show of this Society will be held on Thursday July 4th, 1895.

#### SOIL FOR YOUNG ROSES IN POTS.

AT this season we are more or less busy in potting our young Roses from the grafting case, and having lost, or at any rate checked a good many at different times through using too rich a soil, a few practical hints may be of some service. Our chief aim until the young plants are in 3-inch pots is to secure a number of healthy roots. If these grow freely the sap is abundant, and the graft not only unites firmly but pushes into promising growth at once. We need healthy roots later on also, but then they must be fed to a greater extent than in the younger stages.

Beginners are often too anxious to give their plants a rich and concentrated soil, but it is better to wait until the plant has greater need of this. Turfy loam with a dash of sand, or any good garden loam and leaf soil in equal proportions, is best for Roses at this stage. We find the new roots taking to this at once, and producing those thick and succulent rootlets that must result in healthy and rapid wood growth. A richer soil does not encourage these to the same extent, in fact rather the reverse. Breaking the compost up too finely is also a mistake. If we use it in a coarser condition the roots can pick and choose to a certain extent from the variety of food supplied, and a little observation will prove this, whether we take a pot plant or one growing in the open ground. On turning the former out of the pot, or carefully lifting the latter, we shall find the roots have thoroughly permeated one or other of the component portions of the compost, and, comparatively speaking, avoided the remainder. Much of the first strength of the latter will be imparted to the poorer soil, and as this is lessened, and our Rose roots become more eager or hungry for the richer food, they will take this in due course.

If potted firmly there is no fear of too rapid percolation of water and its consequent washing away of any valuable soluble constituents contained in the soil. In pots we cannot give our Roses enough room to allow of their roots searching for and choosing their food, but we may approach this nearer than many do. While in the open, and also in borders under glass, there is no drawback to follow this plan, and I am certain it is a good one from the results which have been derived from it.—PRACTICE.

#### SMILAX.

I AM acquainted with no plant that is more useful than this. It is equally well fitted for decorating dinner tables during every season of the year, and for lending added grace to arrangements of cut flowers in vases. For wreath-making it is also very useful; indeed, I have constructed wreaths of choice flowers and Smilax without using any other kind of foliage.

Fortunately the cultural requirements of this plant are easy to meet. It grows well under a shade of foliage where few other plants would succeed. The present time is most suitable to sow seeds, and if a high temperature can be given the seedlings are not long germinating. If a very sandy compost is used there will be no difficulty in securing fibrous roots by the time the plants have grown sufficiently large to transplant. I have tried them on the back wall of a stove, but the temperature was too hot. Close to the back wall of a late vinery seems to suit them better than houses in which there is more heat. As to soil, they are not at all particular. Two years ago a lad planted Smilax in one house among a layer of gravel. Strange to say the largest and finest foliage has been produced from these. Indeed, so robust did they grow that they were quite unfitted for using on a table, though for other purposes they proved most useful.

At the time of planting a piece of strong thread for each plant is

secured to the top wire of each vinery and fastened at the bottom to a strong peg driven into the soil close to the plant. Further than this no attention to training is called for, unless it may be in cases where single-stemmed plants are wanted, then it is necessary to nip out any twin shoots that may appear. Single stems, it may be noted, are superior for table or for vase-furnishing. At no season is this plant prettier than in the spring. Wreaths 15 feet in length are then covered with their pretty white blossoms, excelling in beauty the plants when adorned with nothing but leaves. I keep a supply to provide for the London season, and these always flower freely and set most abundant crops of seeds. There is thus no difficulty in securing from the same set of plants others to keep up a supply year after year. Two-year-old plants become bushy, and are, on that account, not so valuable as one-year seedlings. I have tried two-year-old plants in pots for decorating, but did not find them of so much use as those grown as noted above. R. P. BROTHERSTON.

#### REDUCTION OF THE VARIETIES OF APPLES AND PEARS.

CAN our varieties of Apples and Pears be reduced with advantage, and what is about the number of varieties we should grow? If you ask the first part of this question of any fruit grower or horticultural authority nine out of ten would answer "Yes." But this is a more difficult question than appears on the face of it. Each of these persons answers truthfully from his own view of the question, but there are so many standpoints from which you can look at it. There is the grower for market; there is the farmer who has various other agricultural pursuits; there is the grower who grows only for his own consumption; there is the grower who takes a pride in his fruit and likes to exhibit it occasionally; and there is also the one who makes a hobby of fruit growing. These growers are again subdivided into the growers of the north, the south, the west, and the east of Great Britain and Ireland, and to these I may add the nurseryman who supplies the trees, both the man who does a local trade chiefly and the one whose trade extends through all the localities. I believe if a general census was taken of the opinion of the growers named throughout the United Kingdom as to which are the best ten varieties of Apples or ten varieties of Pears a very large number, perhaps a hundred or more, would be named between them all. I propose to take each of the classes of growers I have named, and say a few words as to the position in which each grower stands in regard to number of varieties and about the quantity I think best cultivated by him.

I will first take the grower for market, whose sole object is to make fruit growing profitable. I say to this grower, Do not grow too many varieties; plant a good bulk of the few you select, so that it may pay you to pick and market each sort in bulk. Find out from your own or neighbours' experience what varieties do best on your soil and in your locality; find out what sorts sell best in your most convenient market, and plant these largely. On the other hand, you can confine your sorts too strictly; it is astonishing how varieties vary as to cropping in different seasons. The blooming time of different varieties of Apples and Pears varies greatly, some varieties blooming early, others late, and we sometimes have early frosts, sometimes late; the consequence is that a variety which crops heavily in one season does not do so in another, and you are sometimes astonished to find a usually shy cropper give a heavy yield in a scarce year; the crop greatly depends upon whether the variety is in blossom at the time the frost comes.

I believe there is another reason for having a little admixture of sorts, say in adjoining rows. Some varieties are not sufficiently self-fertilising to grow in a large block and crop well, but are benefited by being grown near other varieties. The Americans, I believe, have found this out and act on it largely. A grower for market should have a good bulk of early varieties, a few midseason varieties, and a quantity of late varieties. I think, as a rule, early and late varieties pay the best. Some years the early varieties will pay the best, in others the late varieties, but the midseason sorts being more numerous, and meeting more foreign competition, usually pay the worst. A grower for market does not often require to exceed eight to twelve varieties to grow in quantity; but he must not forget that there may be a new or little known variety suitable to his locality which may prove of great value. I say try these on a small scale first, and if you find they answer your requirements grow them more largely. In growing for market do not be guided entirely by what looks most attractive on the exhibition table; some of the best there are for one reason or another not the best to grow for market.

There is next the farmer who has various other agricultural pursuits; to him I again say, "Do not grow too many sorts," and the remarks I make in reference to the grower for market to a great extent apply to the farmer, but it does not follow that he should grow the same varieties. The average farmer has seldom the skill, aptitude, or time to devote to the cultivation of very choice varieties of fruit; he usually wants hardy, good growing, and heavy cropping sorts, suitable to grow as standards. He should grow about the same number of varieties as the market grower.

There is then the grower who grows for his own consumption. He can extend his list, because he wants both dessert and cooking varieties to extend over as long a season as possible; he does not care to have a

glut of one variety and then a scarcity. Tastes vary; some people like a soft spicy fleshed Apple, whilst others will prefer a brisk, crisp Apple. The cook for one purpose wants an Apple which cooks white and flaky, and for another one with highly coloured flesh which goes to a jelly when cooked. These requirements must be met. There is also the grower who likes to have an extra fine dish for exhibition, to show to his friends, or place on his table, and who takes a pride in growing extra fine fruit. He does not care so much about the cost of this fruit, so that he has something better than his neighbours; he wants large handsome fruit, new varieties of high reputation, or well-known sorts of high quality to be successful on the exhibition table, and, as I said before, some of the most suitable for his purpose are not the best for others.

I now come to the gentleman who makes a hobby of fruit growing. I believe there is such a thing as finding a pleasure in fruit growing independent of profit. Does the grower of flowers (Chrysanthemums, Roses, Dahlias, Carnations, and others) think of profit altogether? Such a grower takes a pleasure in testing the different varieties, noting their behaviour in different seasons and on different soils, watching their various colours and different styles of growth, and likes to test the new varieties or those unknown to him. I say to such a grower, who has his heart in the work, a trial fruit plantation is a fount of pleasure, where he will probably grow a large number of varieties, and I do not think he should be blamed, for, on the contrary, he may greatly benefit the neighbourhood, as he it is who usually introduces or brings into notice new or little known fruits of high merit, and his plantations are in a great degree educational. These growers are necessarily subdivided into those who grow collections of fruit in various parts of the United Kingdom. One particular variety may be popular in the north, but of little value in the south; one thought highly of in the midlands hardly heard of in the west.

To show how even the opinions of our best authorities can differ, one of our greatest fruit experts in the south (Mr. George Bunyard) lately read a paper on "New versus Old Apples," and amongst the old sorts he mentions which should be discarded is "Tom Putt" and "Catshead Codlin." We, with other growers in the west, consider "Tom Putt" one of the most useful and most popular of farmers' Apples; and as regards the old "Catshead," I know old standard trees of this variety which pay the growers better than any others they possess, and I have had more people ask for the fruit of this variety than any late Apple I grow except "Dumelow's Seedling." The value of Apples also varies greatly in different markets; for instance, the "Wyken Pippin" is one of the most popular and best selling Apples in Birmingham, but it would hardly be looked at in most other markets. Again, our best dessert Apple, "Cox's Orange Pippin," if sent to the Manchester and north of England markets (where it is not yet sufficiently known) would make a very much lower price than it does in Covent Garden Market, where its good qualities have become appreciated. Then, again, highly coloured Apples sell best in some markets; larger green Apples sell better in others.

The Americans have often been quoted as sending us a few sorts, and the general impression seems to be that they cultivate very few varieties, but this is a mistake. One of the chief fruit tree nursery firms in the United States, whose catalogue I have, enumerates over 130 varieties of Apples. I have also had a list sent me of the names of the varieties cultivated by a gentleman in the States who has established an experimental orchard, chiefly for educational purposes; he grows upwards of 900 varieties of Apples, and the greater part of these are not known in England. The Americans cultivate as many sorts as we do, but they send us only a few of them which they know suit our markets.

I will say a few words in reference to new varieties of fruits. We can in fruit growing improve our varieties, as well as the farmer can improve his breeds of live stock or his varieties of corn, and we are always looking out for the best. There is no doubt that some of the fruits lately introduced will prove of high merit and take a leading position in our lists. On the other hand, we as nurserymen cannot be too careful in introducing varieties which are not better for any purpose or are inferior to existing varieties. A new fruit as a rule does as well or better in the district of its origin than it does in any other district. Most nurserymen would welcome a reduction in the number of varieties they have to grow, with the attendant reduction of trouble and expense in keeping all these varieties separate and true to name, but as long as the growers ask for particular varieties we are bound to supply them. To the nurseryman who only does a local trade the answer is easy as to how many sorts he shall grow, for if he knows his business he knows those which are most in demand in his district; but a nurseryman who caters for a trade over a wide area and amongst all classes of growers is bound to cultivate a large number of varieties. A customer who cannot get the variety he wants at one nursery, will not only go to another nursery for this variety but will probably take more of his trade there also. I cultivate as many varieties as most nurserymen, but out of the large number I grow I am sometimes asked for one now and then which I do not possess. Nurserymen, then, must not be blamed for the large number of varieties they offer; when the growers stop asking for them the nurserymen will soon stop growing them. In conclusion, I will offer my own opinion as a nurseryman, as a grower for market, and as one who

perhaps makes a hobby of fruit growing. It is this: I think there are many varieties, superseded, of little value and which can be dispensed with, and I think our lists would be better cut down to a great extent, the limit of which rests with the growers, but I do not think the varieties of Apples and Pears grown will ever be reduced to the narrow limits which some people think they ought to be.—JOHN WATKINS, *Pomona Farm Nurseries, Herefordshire.*—(*Fruit Conference Paper.*)

### THE SEVERE WEATHER.

MANY reports have been recently sent to us from all parts of the country relating to the arctic weather by which we have been visited. In almost every shire the thermometer has fallen below zero. The disastrous results of this we have yet to learn, but former experience tells us that in many respects it must prove serious. For the interest of our readers we herewith insert a few of the reports that have reached us, by which it will be seen how general and severe the weather has been.

SUCH is the effect of the frost that several large Elm trees of 100 years' growth have split, the cleft in each case being from the ground to the height of from 10 to 15 feet, and fully 6 inches into the side of the tree.—JOHN J. EMERSON, *Easby Hall, Great Aytoun.*

WE have now had about seven weeks of severe weather, and the temperature on the 8th and 9th inst. fell 40° below freezing point; 10th, 37°; 11th, 32°; 12th, 20°; and 13th, 32°. In each case the thermometer was placed 18 inches from the ground, and the readings were taken from 8 to 9 A.M.—JOHN BROWN, *Delgaty Castle Gardens.*

ONLY on six nights since the new year has the thermometer stood above freezing point, and only on one occasion since the 1st February has the night temperature been higher than 30°, or 2° of frost. On the 7th the mercury was down to zero, and on the 8th 2° below zero; on the 9th and 10th, 28°; and on the 11th, 17°. There has been an average depth of 3 inches of snow for several days, and the ice on the lake is 8 inches thick.—G. R. ALLIS, *Old Warden Park, Biggleswade, Beds.*

WE have experienced an unusually cold week, the temperature being as follows:—February 5th, 24° of frost; 6th, 30°; 7th, 29°; 8th, 27°; 9th, 25°; or a total of 135° on five nights.—W. STANTON, *Caddington Hall Gardens, Bedford.*

THE greatest amount of frost registered in our gardens during the present month has been as follows:—6th, 27°; 7th, 32°; 8th, 34°; 9th, 30°; 12th, 23°; 13th, 26°.—ROBERT JORDAN, *Llanaway Gardens, Godalming, Surrey.*

THE frost here for the seven consecutive days, from February 7th to February 14th inclusive, was 257°, or within a fraction of 37° of frost for each day, the lowest being 40°, and the highest 25° below freezing. Do any of your correspondents know of any previous week that has given more frost in this country?—D. THOMSON, *Drumlanrig Gardens.*

THE reading of the thermometer here has been—February 5th, 11°; 6th, 18°; 7th, 13°; 8th, 34°; 9th, 27°; 10th, 34°; 11th, 30°.—WM. FELL AND CO., *Wentworth Nurseries, Hewham.*

THE thermometer registered here on the 8th inst. 10° below zero, or 42° of frost. The glass is 2 feet from the ground, and is placed 10 feet to the south of a brick wall.—ED. KEITH, *Wallington Gardens, Cambs, Northumberland.*

A FEW notes respecting the weather and the temperature taken here from the 6th inst. up to 13th:—6th, 24°; 7th, 22°; 8th, 45°; 9th, 32°; 10th, 40°; 11th, 28°; 12th, 20°; 13th, 31°. These temperatures have been taken in an exposed position, with the thermometer on a board close to the snow line. In two other positions wide apart from each other and very much sheltered, the thermometers at 4 feet from the ground, the readings have been just 5° above these figures, all taken from Negretti & Zambra's minimum thermometers. It is now rather more than six weeks from the 31st of December that the ground here has been quite covered with snow. At present it is about 7 inches deep, though none has fallen for a week.—H. E. GRIBBLE, *Wynyard Park Gardens, Stockton-on-Tees.*

ON the 7th inst. the thermometer registered 28° of frost, falling on Friday morning to 8° below zero. A great number of Oak trees are split with the intense frost from the ground upwards, the splits being all on the north and north-east side of the trees.—A. BENTLEY, *Eshwood Hall Gardens, Durham.*

THE amount of frost registered on February 2nd was 13°; 3rd, 22°; 4th, 17°; 5th, 24°; 6th, 27°; 7th, 23°; 8th, 22°; 9th, 20°.—R. BASSIL, *King's Ride, Aseot.*

THE weather here, as well as at other places more distant from London, has been exceptionally severe. On February 6th there were 19° of frost; 7th, 27°; 8th, 32°; 9th and 10th, 24°. Since 1889 we have only registered more than 20° of frost four times.—JAS. CARTER AND CO., *Nurseries, Perry Hill, S.E.*

## APPLE ROUNDWAY MAGNUM BONUM FOR DESSERT.

SOME time ago Mr. George Bunyard expressed his opinion on this Apple, and it was very laudatory. He described it as the best of all winter dessert Apples, having regard to its size, tenderness of flesh, sweetness, and flavour. Mr. Bunyard recently sent us a few fruits of this Apple, and though they are not handsome in appearance, we have none to equal them in quality at the present time. We append a description of the Roundway Magnum Bonum from the "Fruit Manual":—"Fruit, large; ovate, angular on the sides, having five prominent ribs, which extend into the basin of the eye and form ridges round the crown. Skin, lemon yellow, with a few broad broken streaks of pale crimson on one side; it is here and there marked with several russet patches. Eye, half open, with flat convergent segments that are reflexed at the tips, and set in a narrow basin. Stamens, basal; tube, conical. Stalk, about half an inch long, very stout, and inserted in a pretty deep cavity. Flesh, yellowish white, tender, crisp, very juicy, and with a fine aroma. Cells, obovate; axile. A first-rate culinary or dessert Apple, very solid and heavy for its size; in use till April without shrivelling. This was raised at Roundway Park, near Devizes, and was first exhibited at the Royal Horticultural Society in 1864, when it received a first-class certificate."

Mr. Bunyard at the same time sent a fruit of a new Australian Apple Duke of York—a tender-fleshed culinary Apple, of good size, faultless in symmetry, and very handsome. This variety, we believe, is being increased at Maidstone, as likely to become a popular favourite.

### HARDY FRUIT GARDEN.

**Pruning Cob Nuts and Filberts.—Young Plants.**—Suckers planted in the autumn having one strong stem only may have that reduced to a length of 18 inches. Six of the upper buds, if as many push strongly, should be selected and trained outwards to form a good preliminary groundwork for a well-shaped bush. Plants of more weakly habit may only have three shoots reserved, these being the strongest and best placed towards the upper part of the shortened stem. Train the shoots round a hoop placed in the centre, which will press them outwards and give the desirable cup-shaped form of bush, the growths being secured at equal distances apart. At the next winter pruning each shoot must be pruned back to a length of 4 inches, and two growths afterwards encouraged from each. In the case of plants starting with three shoots, the following year they will have six, the next twelve, enough to form main branches for an ordinary sized bush 5 or 6 feet in height. The pruning during the extension of the branches consists of annually shortening the leaders to strengthen the main branches and induce the formation of side shoots for fruiting.

**Pruning Established Bushes.**—When the branches have extended as far as desirable the leaders must be shortened closely each year at the winter pruning, and any that produce very strong leading shoots should have these topped in the summer. The side shoots are managed variously. Some may be cut back to two or three buds, these giving successional shoots which, if not growing too strongly, assume a fruitful character, blossom buds forming at the extremities both on these and shorter twiggy growths, also spurs. Shoots that produce numbers of catkins or male blossoms must be left freely distributed over the trees, but if such are not plentiful procure catkins from other Nut trees or the common Hazel, and hang them over the female blossoms to aid fertilisation.

**Time to Prune.**—The proper time to prune Cob Nuts and Filberts varies according to the season. If early the staminate blossom buds may appear prominent at the end of January and during February, but March is the proper month. Fruit buds are easily recognisable from wood buds by reason of their scaly character, and as they become fully developed the crimson styles protrude from the flowers. The blossoms or catkins are very conspicuous and develop first. They are pendulous in habit and brush-like in appearance, shedding when shaken a quantity of pale yellow pollen, which it is important should reach the fully formed fruit blossoms. This is the best time to prune, as no mistake can be made, and long side shoots or laterals may be pruned to blossom buds.

**General Pruning.**—Many Nut trees are not grown on the restrictive method, and with these it will be advisable to regulate the growth so as to admit light and air freely to every branch. Old, useless growth must be removed, weakly and crowded wood or spurs cut or thinned out. On severely pruned branches spurs often extend too far; these should be reduced in length, a few every year. The old bearing wood of the previous year may be freely shortened back. Old exhausted branches sometimes need renewing, and this can readily be accomplished by reserving a promising growth near the base, training and pruning this several years if necessary before cutting out the old one. Large overgrown bushes may be reduced in height when desired by shortening to well situated lower growths. Remove suckers where they appear between the bushes.

**Pruning Outdoor Fig Trees.**—Fig trees on outside walls, protected by mats or dry fern from the severity of the weather, may be gradually uncovered after the frost. Cut any decayed or injured wood away before training. Fasten the main branches to the wall or trellis, distributing them equally. Lay in all the best placed young growths of the previous summer's formation, leaving them unshortened. Those not well placed, and apparently superfluous, cut out entirely.

**Completing Pruning and Regulating Wall Trees.**—The conclusion of this work should be hastened, as buds will shortly be actively swelling. Worn out or useless branches are best cut out before fresh growth commences. Their removal causes a gap, or several bare spaces, which must be filled up by re-arranging the remaining branches. Take the opportunity of thinning out crowded wood at the same time. All wall trees are apparently thinly trained at this season, being leafless, but with many formally trained examples the branches are really too close. With espaliers, cordons, bush trees, and pyramids a good distance for the mains is a foot. For Gooseberries and Currants on walls 8 or 9 inches. As a rule it is better to have the branches too thinly disposed than the opposite.

**Training Young Trees.**—Wall trees planted in autumn and temporarily fastened to the wall to allow the newly moved soil to subside and the trees along with it, may now be permanently secured, the required pruning back of the branches being carried out as the buds swell.

**Disposal of Prunings.**—The end of the winter pruning season affords a good opportunity for clearing away and burning the accumulated trimmings from trees and bushes. The ashes and charcoal resulting are admirably suited for mixing with the compost for top-dressing borders, or they may be utilised when preparing the ground for a fresh plantation of fruit trees, and a quantity can be incorporated with the material used for spreading among the roots when laying them out in the process of planting. Roots take readily to wood ashes, and as they contain potash most fruit trees are benefited by the use of them in the soil.

### FRUIT FORCING.

**Peaches and Nectarines.—Earliest Forced House.**—This may be a structure containing trees of the second early or midseason varieties of Peaches and Nectarines, such as Hales' Early, Stirling Castle, and Royal George Peaches, Hunt's Tawny, Lord Napier, and Elruge Nectarines, which, started in December, will not ripen their fruit until May; or a house occupied by the very early varieties, such as Alexander, Waterloo, and Early Louise Peaches, Early Rivers and Advance Nectarines, that started at the same time will ripen their fruit in April. The trees must be syringed every morning and afternoon during sunny weather to check red spider. If, however, the weather be dull the syringing must be practised early in the afternoon, so that the trees may become fairly dry before night, or if that does not take place the afternoon syringing ought to be dispensed with, damping the paths and borders instead, as keeping the trees dripping with water through the night causes weak growth and thin foliage.

Water inside borders as required, using liquid manure, which will assist the trees in swelling the fruit, especially in the case of weakly trees long subjected to forcing. Healthy trees will not require any active stimulants, excessive vigour being unfavourable to the fruit safely passing the stoning process. Such trees will be assisted by a dressing of basic slag phosphate, using about 4 ozs. per square yard, and washing-in with water. When the fruit is about the size of small marbles thinning may proceed, the growths up to this not being overburdened by a superfluous number of fruits beyond those required for choice being made, as thinning should commence when the fruit is about the size of horse beans, then leaving two or three of the best in promise and place on a bearing shoot, in all cases removing a few fruits only at a time, and reserving the requisite number for the crop, with a margin for contingencies. Continue disbudding, taking care to leave a growth at the base of each bearing branch, and another at its extremity, or at least level with the fruit. The shoots retained for attracting the sap to and supporting the fruit should be stopped at the third leaf, but the basal shoots must be trained to take the place of those now bearing fruit. The shoots on extensions must be left at 12 to 15 inches distance apart to form the bearing wood of the future and for framing the trees. Crowding the growths is a great mistake, therefore permit only those to remain for which there is room, each having full exposure to light and air, seeking to maintain an equal balance of growth throughout the trees, and effecting its solidification by judicious ventilation. This must be carefully done in severe weather, avoiding currents of cold air, always ventilating early and closing in the afternoon, so as to enclose a moderate amount of sun heat.

**Second Early House.**—Trees started in January have the flowering somewhat prolonged in consequence of the severe weather, and fertilising may still be practised, brushing the flowers, or distributing the pollen by shaking the trellis. Admit air on favourable occasions, freely when the external air is mild, avoiding cold currents in severe weather, and provide a little ventilation constantly at the top of the house. The night temperature should be maintained at 50°, and 5° less on cold nights, 55° by day artificially, and 60° to 65° from sun heat, not allowing a rise to 65° without a free circulation of air. Syringe the trees when the flowers fade, but only moderately, as excessive moisture facilitates wood growth more than the development of the fruit. The moisture will assist the fruit to throw off the remains of the flowers. In dull weather a genial condition of the atmosphere may be secured by damping the surfaces rather than the trees in the morning and early afternoon, an occasional syringing early in the day sufficing to keep red spider in check.

*Houses Started Early in February.*—The trees are now coming into flower. Syringing over the trees must cease; indeed, it should be discontinued when the blossoms show colour. Nevertheless, maintain sufficient moisture by damping the paths and borders two or three times a day as weather may indicate as advisable, avoiding a close stagnant atmosphere. If the flowers are numerous thin them by rubbing the hand downwards on the under side or back of the growths, which will strengthen the remainder. Examine the trees closely, and if there are any aphides fumigate with tobacco or vapourise with nicotine, so as to destroy them before the flowers expand. Continue the temperature at 40° to 45° at night and 50° by day, above which ventilate freely. When the flowers expand raise the temperature to 50° at night, 55° by day artificially, and 60° to 65° from sun heat with free ventilation. On cold nights the temperature may fall to 45° or even to 40°, also 50° by day in dull cold weather, allowing a little ventilation constantly at the top of the house.

**Cherry House.**—The temperature having been maintained at 40° to 45° at night and about 50° in the daytime regularly, the trees started in December will be going out of flower, and the fruit having set may have the night temperature slightly advanced; while trees started early in the year and forced for the first time will be rapidly unfolding their buds. Before the flowers expand the house should be fumigated, as aphides are almost certain to be present, but the fumigations must be done carefully or the blossoms will be more or less injured. An application of rather strong quassia water (4 ozs. chips to a gallon of water boiled for a quarter of an hour) will answer the same purpose, repeating it at intervals of a day or two. The temperatures named above must not be exceeded, ventilation commencing at 50°, more freely at 55°, and an advance above 60° to 65° not allowed without the fullest amount of air. Keep water from the blossoms, but secure a genial atmosphere by damping the paths and borders occasionally. Maintain the soil in a thoroughly moist, but not sodden condition, and supply water to trees in pots as required.

**Cucumbers.**—Plants in bearing require looking over about twice a week, removing bad leaves, cutting out exhausted growths, thinning the shoots, stopping these one or two joints beyond the fruit, or leaving more growth where there is space, and removing old and deformed fruits. By thinning the old growths room will be provided for young successional bearing shoots, and keeping the growing parts fairly thin the plants will fruit better and be of much better quality. In securing the young shoots to the trellis do not tie them too tightly, but allow room for development. Plants that have been in bearing some time should have the surface soil removed, and previously warmed fresh soil added. Turfy loam, with a fourth of well-decayed manure and a little quicklime and soot mixed through the compost, is suitable. This will encourage abundance of surface roots, and then the plants can be fed to any extent by liquid applications, or preferably chemical manures washed in. The bottom heat should not be allowed to fall below 75°, nor exceed 90°; top heat 65° to 70° at night, 5° less in severe weather, 70° to 75° by day artificially, rising to 85° or 90° with sun, closing soon after midday, so as to secure and maintain for some time a temperature of 90° to 95°, or even 100°. Damp the pathways and walls in the morning, at closing time, or early in the afternoon, and again later. An occasional light syringing may be indulged in on bright mornings or at closing time. Keep the evaporation troughs filled with liquid manure, or damp the pathway with it at the time of closing the house, but take care to use it weak, or the ammonia evolved may do irreparable injury to the foliage.

**Melons.**—The young plants have made sturdy but not very free growth, being retarded by the severe weather. If not planted out this should be done before they become root-bound, forming a ridge the whole length of the bed and about 2 feet wide at the base, with the top flattened so as to give a depth of 10 to 12 inches. Hillocks may be formed with a similar base and depth at about 2½ to 3 feet apart from centre to centre, the soil being made firm, and when warmed through the plants may be turned out, pressing the compost well about the balls and raising it to within an inch of the seed leaves. The plants may be placed 2½ or 3 feet apart, the leading or primary shoots being taken up without stopping until fully two-thirds up the trellis, then pinch off the point of each. Remove the laterals when discernible up to the trellis, and rub off every alternate one on opposite sides of the stem, and when the laterals have made three or four leaves pinch off the points. Some varieties show fruit on the first laterals, and as early fruit is a consideration let them remain, fertilising the blossom and taking off the point of the shoot one joint beyond. After stopping the first laterals fruit will show freely on the second at the second or third joint, the growths being trained evenly and thinly so that every part of the trellis is covered with foliage and fruit. The plants require watering moderately in the early stages of growth, little being required as yet, nevertheless maintain the soil in a moist state. Sprinkle the pathways and walls on bright days, and again at closing time or early in the afternoon. Ventilate carefully, avoiding cold currents of air, and when the external air is cold place some hexagon netting over the openings, so as to break the force of the cutting winds. Maintain a night temperature of 65° to 70°, falling to 65° or 60° in the morning, 70° to 75° by day, rising to 80° or 90° from sun heat, closing early so as to secure and retain 90° to 100° of the solar warmth; bottom heat 80° to 85°.

*Melons in Pits and Frames.*—Where Melon plants from early sowings are planted in these structures, and trained over the surface of the beds, the plants should be stopped at the second leaf, which will give two or more shoots; but two are ample, rubbing off the others. These

shoots stopped at the second or third leaf will furnish two or more each, but four are ample for ordinary sized lights, and a plant in the centre of each. Take two to the front and the same to the back of the framed pit, and rub off any shoots that proceed from nearer the stem, it being important that no lateral be formed nearer to it than 6 inches. Stop the principal shoots when within 15 inches of the sides of the pit or frame; this will concentrate the vigour on the laterals, which will show fruit at the second or third joint, which should be fertilised and the shoots stopped one joint beyond. Cover the lights with double mats at night, and see that the linings are regularly attended to, renewing the old ones as required. Prepare material for making fresh beds. About a fortnight before it is desired to do so the manure and leaves should be thoroughly incorporated, using about two-thirds leaves to one of stable litter. In a few days the heap, if properly moistened and mixed, will become warm; if not turn the whole, sprinkling with water or liquid manure so as to moisten it, and when in good heat turn again, outside to inside, two or three such turnings at intervals of about four days being necessary, when it will have parted with rank steam and be fit for making up the beds.

**Strawberries in Pots.**—The earliest-forced plants will need the fruit supporting by forked twigs of Birch thrust into the soil, the stem of the truss being placed in the fork so that the fruit hangs clear of the pot or soil. It will thus acquire better colour and quality, and be in less danger of damping. Later succeeding batch of plants having the fruit fairly set will need attention in removing all deformed fruits, leaving the most promising and in number proportionate to the vigour of the plant and variety is calculated to attain first-class size and perfection. The swelling should be aided by copious supplies of liquid manure. The temperature should be 60° to 65° at night, 70° to 75° by day, with gleams of sun and moderate ventilation, advancing 5° to 10° on bright days. Avoid drying currents of air, as they injuriously affect the swelling of the fruit. Examine the plants twice a day for water, giving it only to those in need of a supply, and always so as to moisten the soil through to the drainage. Keep successional plants free from aphides, taking care to have them quite clean by the time the flowers open. British Queen and other late forcing varieties may now be introduced, at the same time starting proportionate quantities of the midseason or second early varieties, such as Sir Joseph Paxton, to maintain the succession of fruit unbroken.

#### PLANT HOUSES.

**Eulalias.**—Plants that have enjoyed a good rest may have the old soil shaken from their roots and be repotted. If increased stock is needed the roots may be divided and potted in any size most suitable for furnishing purposes. These plants do well in good loam, one-seventh of manure, and sand. After potting place them in a warm moist house, and they will quickly start into growth. Those required for autumn decoration should be retarded by keeping them in a position where they will not grow, and on the dry side at their roots.

**Fuchsias.**—Young plants that have been wintered in a temperature of 45° to 55° may now be pushed forward, and be placed into 5-inch pots. In a temperature 10° higher they will soon make a start, and will be useful early in the season. Plants that have commenced to grow in early vineries or Peach houses may be repotted, the old soil being shaken from the roots, and the plants placed in slightly smaller pots than those they are intended to flower in. These plants do well in a compost of good loam three parts to one of leaf mould, one-seventh of old Mushroom bed refuse may be added, and a liberal quantity of coarse sand, the whole being warmed before use.

**Araucaria excelsa.**—This plant will grow rapidly if given an intermediate temperature, though it does very well in a cool house. If kept too close the plants become tall and weak at the base. This plant needs a fair amount of root room in its early stages, and succeeds well in good loam, one-third leaf mould, one-seventh of manure and coarse sand. Syringe the plants freely, as thrips often appear if kept in a dry place.

**Aralia Sieboldi.**—For cold, draughty places where many plants would not do this will stand, and if cared for will make a very handsome specimen. If possible, a well-furnished plant should be started with; even seedlings make splendid plants, because when their lower leaves fall the stem is practically hid by the drooping nature of the leaves. During the winter when used in rooms, halls, or similar positions, the plant should be kept on the dry side at its roots.

**Bouvardias.**—Plants that were placed in pits may be lifted, cut over, and packed closely together in boxes amongst leaf mould and sand. These, if stood on the pipes in a warm house and kept fairly moist, will soon start into growth. Where an increased stock is needed take off some of the strongest roots, cut them into lengths, and insert two or three pieces in a thumb pot. A capital plan is to raise a few plants from roots annually. When this plan is followed the stock planted out or even grown in pots can, after they have done flowering, be thrown away. The young plants in boxes would then be cut over at this season of the year, and started again in growth, the same as advised for plants lifted from pits.

**Prunus sinensis.**—As plants go out of flower they should be pruned close back, and placed in a Peach house at work to start into growth. If the pots are full of roots, and when the plants have commenced growth, the old balls may be slightly reduced and the plants repotted in the same size pots. Good loam and one-seventh of manure will suit these plants well. If the plants are not repotted two or three applications of chemical manure may be given during the season of growth.

# THE BEE-KEEPER.

## APIARIAN NOTES.

THE first mild day after the bees have had a flight I shall feed a little from beneath, as it is not advisable to cool the hive by uncovering the top. For many years I have abandoned top feeding, and do not regret it, though exceptions are made with certain weak stocks and nuclei in the summer.

It sometimes happens during cold weather where there is a scarcity of honey in the hive bees may appear dead; but I have resuscitated many by taking the hive into a warm room, then when they began to move sprinkled them slightly with a little thin syrup. In such cases bee-keepers may be able to save stocks still living by acting in this simple and easy manner.

No time should be lost in getting everything in order for the coming season, nor should any defects that have been observed be overlooked. It frequently happens with those who move their bees to the Heather to find themselves short of light packing material for supers. A good and cleanly material for the purpose is paper or light cardboard cut and bent to lie closely round the supers, a piece of gummed paper being employed to fix the ends. There is nothing better than paper for keeping out draughts and preserving an uniform temperature in supers during the autumn. I have taken bees to and from the Heather for nearly half a century, and have long since proved that hives suitable for moving about have also been the best in the home apiary.

To those beginning bee-keeping I would say, Think well over these things, and do not incur heavy expenses on hives which may not meet all the requirements in the different phases of bee-keeping.

Those who still use solid floors should provide themselves with a few extra, and when a thaw comes have them warm and dry to exchange with those dripping with moisture from the perspiration of bees, rain, and snowdrift, as damp boards are fatal to bee life. Tin scoops, having thin laths fitted to allow the bees to walk on, and sip the food from between the laths, are the safest and best feeders to use, especially after so severe a winter.—A LANARKSHIRE BEE-KEEPER.

## SEASONABLE NOTES—THE SEVERE WEATHER.

A FEW notes on the present extreme spell of cold weather, and its probable effect on bees, may be of interest to bee-keepers. Having been a close observer of the weather for many years I can say that the past ten days has been the most severe in my experience. The frost commenced on the last day of the old year, and with only two exceptions there has been frost every night since. This occurred on the 16th and 17th of January, the lowest reading of the thermometer on those dates being 33° and 35° respectively.

The observations are taken from a tested instrument, placed on a stand at an elevation of 4 feet. The lowest readings were February 6th, 2°; 7th, 3°; 8th, 3°; 9th, 4°; 10th, 3°; 11th, 9°. In the present instance, although we were favoured with bright sunny days, there were several degrees of frost the whole of the time. At 5 P.M. on the 7th inst. the thermometer registered 27° of frost.

One remarkable thing about the present severe frost in the Midland counties is the amount of bright sunshine there has been every day, which has tempted a few stray bees to leave those hives that were not shaded, being attracted by the bright sun and the glare from the snow. These soon became numbed, and would prove a tender morsel to the numerous tits that abound in the neighbourhood of my hives. I never saw them so intent on destroying bees as during the present storm, darting after them whilst on the wing, and alighting on the nearest bush to dissect them. I lately saw a single tit catch and devour three bees in less than a minute. It shows the amount of damage a few of these birds will do in an apiary. During the past three weeks I have destroyed over fifty, and still they come.

It will be interesting to note the difference in the various hives for wintering purposes. No doubt there will be some losses, particularly from stocks that have run short of stores and others that are not protected from the weather. I am not a believer in covering up the outsides of frame hives as a protection against the weather, and never practise it. My hives all stand singly out in the open exposed to all weathers, and they invariably winter well. If the bees are kept dry and are well protected with several thicknesses of disused carpet, or any warm material, they will come to no harm. Cushions of cork dust or chaff make capital warm coverings. Bees will stand more cold than many people give them credit for.—AN ENGLISH BEE-KEEPER.

## TRADE CATALOGUES RECEIVED.

W. Atlee, Burpee & Co., Philadelphia.—*Farm Annual*.  
 William Clibran & Son, Altrincham.—*Agricultural Seeds*.

 Sutton & Sons, Reading.—*Farmers' Year Book and Graziers' Manual*.

\* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Pruning Fruit Trees (A. H. E.).**—We advise you to wait till the frost departs, and sincerely hope you will not have to wait very long.

**Dressing Peach Trees (C. R.).**—The answer on page 153, last week, under the heading of "A Good Dressing for Fruit Trees," exactly meets your case; but instead of "one part" read 1 pint of gas tar for mixing with the other ingredients.

**Roman Hyacinths Unsatisfactory (D. A.).**—There is no disease in the bulbs. They do not appear to have made any roots worth mentioning, and that would account for the poorness of the growth and the extreme meagreness of the spikes, but as these are what they have been formed in embryo in the preceding year to their development, the growth of the plants must have been arrested whilst forming such embryo, hence the indifferent growth and flower spikes. The roots also are formed in embryo—that is, the cells from which they proceed are specialised, and these also have disappeared. Whether from disease or other cause these embryonic cells have collapsed we are unable to say, but it manifestly had occurred before the bulbs were potted, as there is only the smallest evidence of roots having been emitted.

**Caustic Soda and Potash Wash for Peach Trees (Constant Reader).**—Now that the trees are more or less moving, and the wood certainly not overripe in cold houses after last year's dullness, the caustic soda and potash wash should not be used at all on Peach trees for the destruction of scale. It is a somewhat dangerous wash to use in this country, as the wood of Peach, Nectarine, also Apricot trees, is never so hard as that of the Californian orchards; yet these imported prescriptions are advised as if they were of English origin, and had been extensively used. On trees quite dormant, and with the wood thoroughly ripened, the wash does no harm to the hardier fruits, but on the tender bark it requires to be used with great care. If you like to risk the wash you may use half pound caustic soda and half pound pearlash to 12 gallons of water, using the solution in the form of a spray, yet wetting every part. The caustic soda should have a strength of 98 per cent., and the pearlash be of the first quality. We do not, however, advise its use, for the reasons given, at this time of year. It would be better to employ a petroleum emulsion (see below) than the alkali wash.

**Gooseberry Red Spider (Constant Reader).**—Lime water made by slaking a peck of quicklime in a tub and pouring on it 30 gallons of water, stirring well, and letting stand four days or a week, when the bushes infested may be syringed with the clear lime water. Soot water prepared in a similar way, but doubling the quantity of water, is also efficacious, and both being quite clear no deposit is left upon the berries. Or you may use the following:—1 lb. softsoap, dissolved by boiling in a gallon of water; remove from the fire, and add half a gill (about an ordinary wineglassful) of petroleum, and stir briskly with a birch switch so as to secure the thorough amalgamation of the oil, then dilute to 8 gallons for use, applying with a fine-rose syringe, or better by a spraying apparatus. This is quite strong enough to use when the foliage is first pushing and the crop just appearing. When the first leaves are full-sized you may use double the quantity of petroleum to the same amount of softsoap and water, which is the strength desirable for the destruction of scale.

# ANT. ROOZEN & SON'S

CHOICE

## VEGETABLE & FLOWER SEEDS

FOR PRESENT SOWING,  
AND

## BULBS AND PLANTS, FOR SPRING PLANTING.

## COLLECTIONS of VEGETABLE and FLOWER SEEDS,

Made up of the most popular Varieties, and to suit all requirements, from 2s. and upwards.

DESCRIPTIVE CATALOGUE of the above, with CULTURAL DIRECTIONS, will be sent post free on application to our Offices at OVERVEEN, near HAARLEM HOLLAND, or to our General Agents—

GRAPE VINES.—Well ripened, short-jointed canes of all the popular kinds, established in pots, extra strong for fruiting this year in pots, 6s. to 10s. 6d. each; for planting, 2s. 6d. to 5s. each; extra strong, 6s. to 10s. 6d.—**WM. PAUL & SON,** Waltham Cross, Herts.

# VEITCH'S GENUINE SEEDS.

## THE BEST CARROT, VEITCH'S MATCHLESS SCARLET.

A splendid strain of the Intermediate type, but heavier cropping, earlier, and far superior in quality and shape to the old variety. Per Ounce, 1/-.

## THE BEST LETTUCE, VEITCH'S SUPERB WHITE COS.

A magnificent self-folding variety, grows to an immense size, is of superior quality, very crisp, and fine flavoured. Per Packet, 1/6.

## THE BEST BROCCOLI, VEITCH'S MODEL.

First Class Certificate, Royal Horticultural Society. This splendid variety well merits the high encomiums so frequently expressed in the Gardening Press, being the best and handsomest of all late Broccoli. Per Packet, 1/6.

## THE BEST SPROUTS, VEITCH'S EXHIBITION.

A remarkably distinct variety, hardy, and very productive. Per Packet, 1/6.

For full descriptions of the above, and many other CHOICE NOVELTIES & SPECIALITIES, see SEED CATALOGUE for 1895, forwarded post free on application.

ROYAL EXOTIC NURSERY,  
CHELSEA, LONDON, S.W.

## IF YOU WANT REALLY GOOD SEEDS

At MODERATE PRICES, apply to **MR. ROBERT SYDENHAM,**  
Tenby Street, North, BIRMINGHAM.

NO NURSERYMAN WILL SERVE YOU BETTER IN QUALITY, QUANTITY, OR PRICE.

### THE SIX BEST TOMATOES

In cultivation, often sold under other names to get fancy prices. Each packet contains nearly 200 seeds. Perfection, 3d.; Ham Green Favourite, 3d.; Hackwood Park Prolific, 3d.; Challenger, 3d.; Roseleigh Gem, a grand new large smooth selection, 3d.; Golden Perfection, the best yellow, 3d. Collection, 1s. 8d., post free; singly, 1d. each extra for postage.

### THE FOUR BEST CUCUMBERS.

Each packet contains 10 seeds, Lockie's Perfection, Rollisson's Selected Telegraph, Epicurean, and Covent Garden Favourite, 6d. each; or the Collection, 2s., post free; singly, 1d. extra for postage.

### SWEET PEAS—A SPECIALITY.

ECKFORD'S and other choice varieties at a third or a fourth usual prices.

Nothing gives so much cut bloom at so small a cost, or so little trouble. To get best results SOW AT ONCE, as directions sent with each Collection.

### SPECIAL VERY CHEAP OFFER.

8 Really Good Varieties—Queen of England, white; Blanche Ferry, pink and white; Princess Beatrice, pale pink; Apple Blossom, apple blossom tint; Orange Prince, orange pink; Splendour, rich deep rose; Cardinal, bright cardinal; Countess of Radnor, pale heliotrope, 25 seeds of each, 1s. 3d.

7 Extra Choice and Newer Varieties—Emily Henderson, fine large white; Venus, pale lemon flushed with pink; Mrs. Gladstone delicate pink; Her Majesty, soft rosy pink; Lady Penzance, bright pale rose; Firefly, bright glowing crimson; Monarch, large bronzy purple, 25 seeds of each, 1s. 6d.

The Two Collections, 2s. 6d.—Postage 2d. each Collection extra; or the two 3d. extra.

EXTRA CHOICE MIXTURE, 3d. per 100 seeds; postage 1d. extra.

**-ALL OTHER SEEDS EQUALLY MODERATE.**

THURSDAY, FEBRUARY 18, 1895.

### CONGESTED HOUSES.

CONGESTION in glass structures is of annual occurrence during the winter season. When the first touch of the icy hand is felt the question arises how to house and stow away the innumerable plants to be held over until relief comes, by turning out the usurpers in the spring. To many the question is one of some difficulty, of late years augmented by the large share of space claimed by the Chrysanthemums. This we do not grudge them; but they are the cause at least of some anxiety both on their own account and their competitors for space. Nor is the matter confined to gardens limited in area or glass. As a rule the glass is in proportion to the garden, and requirements are in like ratio; hence, from the villa garden with its greenhouse to the palatial establishment and its extensive range, the same difficulties have to be met, and the trouble is but one of degree.

Having diagnosed a disease, the primary cause is sought for with the object of removing it; failing that, to adopt such palliative measures as may be expedient. The latter is, however, but cold comfort to the long-suffering ones, who reluctantly admit that "What can't be cured must be endured;" but there are some hopes of a good time coming, and such hopes are yearly increasing. Many a gardener who but a few short years ago would have thought it one of his wildest dreams that the bedding craze could subside, has now more than a faint hope of those dreams being realised; and though directly the retention of so laborious a fashion is practically out of his hands, he can possibly find the means, by giving it a surreptitious push, to hasten the end. The increasing taste for hardy plants is to some considerable extent paving the way, and though the time may be remote when some tender exotics will not be employed for bedding, considerable ease to this congestion may be found by employing those plants—tuberous rooted—requiring but the protection afforded by a store room or frost-proof shed.

Few could foresee the perfection to which the worthily popular Tuberous Begonia has been brought, and it is not easy to predict what may yet be done to yield a variety of effect by utilising

plants of a similar nature. In the near future the merits of hybrid Cannas will not be overlooked, for those merits are of a high order from two points of view—viz., summer adornment and winter ease. The blessing is to some extent qualified by the glass room required for starting them in the spring, the season when congestion reaches an acute stage. With some things this cannot be avoided, with others it may be lessened by kindling the dormant spark with the least possible amount of fire heat; so will they better withstand after unkind snaps, whilst the hardening process, always a troublesome one, will be rendered easier.

Whilst giving the Zonal Pelargonium its due, it has, as a bedding plant, been glorified beyond its merits. For some eight months out of the twelve it requires glass protection, and its effective period of display in the beds has again to be discounted. It has undoubtedly had its day, and a long day, too. True, few of our tender bedders can boast of a longer duration of outdoor life, but some of them can now be raised annually from spring-sown seeds, and may be relied upon to retain the parental character with some increase of vigour. We have to thank our seedsmen for the pure strains of various plants making this possible, and though these seedlings, such as Lobelias, by their vigour do not conform to those prim habits we look for in carpet bedding, this fault is rather a merit when they are otherwise employed.

These are but palliatives. The cure must be looked for amongst hardy plants, and though at present but dimly revealed, the wide range here presented cannot but contain some kinds which if taken in hand by the hybridist or improved by selection, should meet the demands of formal bedding. Recent history demonstrates how obscure types have been raised to the ideal by the horticulturist, and noting what has, and is being done, there is not any reason for supposing that purely hardy plants cannot be raised to the level of beauty, form, habit, or colour adapted for the purpose. Demand creates supply, but I venture to think that if this order is reversed, and that if such plants are forthcoming, the supply will create demand, for their merits cannot be ignored.

Too long have the inmates proper of our houses been jostled and crowded through the dark days of winter; too heavy has been the strain on all concerned; yet out of evil has come good, for owners of the structures can now see the incubus borne on the back of the gardener. The doom of the fashion is sealed, yet it dies slowly. Sudden death would create a void. Hardy plants as substitutes must in addition to the merit of hardiness contain all the points which are looked for in the tender kinds, and though having all these, may still have to overcome some prejudice, dispel some glamour yet lingering over their more delicate cousins. Yes, all nowadays are apt to count the cost, whether it be expense literal or expense of force, and the time is at hand when common sense will not despise common things whose lineaments are endowed with lines of beauty and utility.

Such changes obtain only by degrees. The present is our immediate concern, and we know how at the present, and at the present season, the man who is troubled to raise, protect, and propagate the thousands of tender plants for an after brief display, has his trouble doubled by the hundred things strictly utilitarian he may not neglect. Vegetables have to be forwarded to circumvent a long winter and an all too short summer. Fruits in season or out of season are looked for, nor must they be found wanting; and in how few gardens is not this felt to that degree, in which a gardener grudges the very space taken up by the walks in the houses.

In private gardens these walks in the houses often tempt the covetous eye by the large amount of space they absorb. To meet the pinch some at least of this space may be utilised by temporary shelves erected overhead. Shelves are not, it must be admitted, things of beauty, but that consideration may and must to some extent be shelved at the winter season. This phase has nought to do with the shelves proper, which presumably are fixtures.

Brackets or pendants for carrying suspended shelves, can be devised and adapted to the roof. These, if permanently fixed, form no eyesore when the boards are removed, and there are but few of our houses, even of the ornamental type, into which these temporary shelves could not be pressed at the pinch and do good duty. These boards if planed, painted, and numbered when fitted, can be stored when not required.

A well furnished Pine, such as *P. austriaca*, if growing in the vicinity of the garden, with its branches sweeping to the ground, forms an excellent snugger for *Agapanthus*, Lilies, or such things requiring some protection. During a hard spell some litter will ensure safety. Small matters as these are, they are little helps worth having. That congestion which cannot be avoided amongst the rightful occupants of the houses, must be met by scrupulous attention to cleanliness in all details, with the frequent turning and shifting it involves. This attention conduces to the maintenance of health during the time that accommodation has to be found for these temporary visitors, of which we would much prefer their room to their company.—E. K., *Dublin*.

## PLANTS FOR THE BACK WALLS OF VINERIES.

A GREAT variety of plants have at various times been recommended for this purpose; some of them which have been much belauded by a few cultivators have proved conspicuous failures in the hands of others. This, I think, occurs through an insufficient explanation as to the real conditions under which they were grown successfully. To illustrate this point let me take the case of Figs, which a few years ago were in many gardens planted against vinery walls with the firm conviction they would prove satisfactory, but unfortunately far more failures than successes resulted from the practice. The explanation of this is, I opine, simple enough; for by the time the principal crop of Figs should commence ripening the foliage of the Vines overhead affords too dense a shade for Figs to ripen properly, and for the same reason only unripened wood is available for the next season's crop. Notwithstanding these well-known facts some cultivators have succeeded in producing good crops in positions above described, but I think the key to the whole matter will generally be found in the fact that the Vines have not been allowed to extend the whole length of the rafter, or that the vineries have been hip-roofed, with the back part entirely free from Vine foliage. Such conditions as these of course entirely alter the whole matter. It is simply "robbing Peter to pay Paul."

The plants which I intend to recommend for that purpose are those which will thrive well in houses where Vines are trained over the whole surface of the roof. Those two fine introductions of recent years—*Asparagus plumosus* and *A. tenuissimus*—are sterling plants for covering walls in the positions above indicated. The extra heat given to the Vines during the growing period is productive of free growth in the Asparaguses, and the conditions under which Vines succeed while finishing their crops, and during the season of rest, insure properly hardened Asparagus sprays. No difficulty ought to be experienced in securing good growths annually if strong plants are secured to start with, and liberal treatment given when they are well established. They will then revel in abundant supplies of liquid manure or chemical fertilisers. Frequently these plants are unsatisfactory through being starved. It is desirable to have properly prepared borders, so that the roots may be confined within a given space, and thus be under perfect control.

It is often impossible to allow much width of border, especially in old vineries where the stone slabs forming the pathway are fixed within a short distance of the back wall. Fortunately only a limited amount of space is really necessary; any width ranging from 9 to 15 inches, with a depth of 12 or 18 inches, does very well. If the front of this space is not already confined by a wall or boundary of some kind a rough brick wall should be built. Six inches of broken clinkers, corks, bricks, or similar material ought to be employed for drainage, and be covered with moss, rough peat, or loam fibre. Two parts loam, one part leaf soil and one of horse droppings (prepared as for a Mushroom bed), with a little sand and lime rubble, when mixed together form a capital compost in which to set the plants. A good time for planting is when the houses are closed for starting the Vines.

Two other excellent plants for the same purpose are *Smilax* and *Lygodium scandens*. The first named requires but little root room, and for the first year or two will succeed admirably if kept

in 6 or 7-inch pots, the pots being plunged in the soil, but they should rest upon bricks, so that a proper outlet is provided for superfluous water. *Lygodium scandens* requires a more extended root run, and should therefore be planted in those positions where it can be provided. A good proportion of peat may with advantage be mixed with the compost.

I am well aware that there are many other plants which thrive fairly well on vinery walls, but many of them are of little use when they have grown, and I maintain that it is necessary in these economic days to grow such things as are of the greatest service. Few gardens can boast of an adequate supply of the plants above enumerated, and many gardeners would find it advantageous to root out comparatively worthless plants and clothe their vinery walls entirely with those plants above enumerated.

If a greater variety is essential, Camellias succeed fairly well in midseason and late houses; so do Abutilons of various types, and *Ficus repens* thrives admirably in early or late houses.—W. C.

#### PHALÆNOPSIS INTERMEDIA PORTEL.

WHEN staged by Mr. E. Hill, gardener to Lord Rothschild, at the last meeting of the Royal Horticultural Society, this charming *Phalænopsis* was given a first-class certificate. It is described in Williams' "Orchid Album" as follows:—"This beautiful plant, which is very rare, is not unlikely to be a natural hybrid, and if so we should suppose it to be a cross between *P. rosea* and *P. amabilis*; let it, however, be hybrid or species, it ranks among the very handsomest of its class. In general habit it resembles *P. grandiflora*, the leaves being broad oblong acute, about 1 foot in length, the upper side dark green, the under side dark purplish, more in the way of *P. amabilis*. The spikes are arched and branched, supporting the numerous large flowers. In one form the oblong sepals and rhomboid petals are white, suffused with light rose at the base, the lip rich dark purplish rose, with the lateral lobes bluntly wedge-shaped, rosy, the base of the front lobe tinted with orange-yellow, and the disc and callus yellow, the latter marked with deep purple spots. The flowers are of good substance, and remain in perfection a very long time."

The woodcut (fig. 34) admirably depicts the characters of the flowers.

#### CULTURAL NOTES ON ODONTOGLOSSUMS.

How firmly rooted has become the notion that these plants cannot well be overwatered. If cultivators would only try to impress on their minds the fact that they are not bog plants, and for the most part grow on the branches and stems of trees, they would the more readily grasp the method of watering these plants require. That the plants grow naturally under shady, moist conditions cannot well be questioned, but these can be obtained without overwatering them.

What is really needed in the watering of these plants is care and judgment, so that more copious supplies are given during the period of active growth, when evaporation is greatest both from the material about the roots and from the plants. During the winter or resting period evaporation is not great, and the plants do not require such liberal supplies. The soil is rendered wet and sour, and the roots, instead of remaining perfectly healthy, are often dead when examined during the early spring months. Once plants are reduced to this deplorable state they are a long time, even under good treatment, before they start again vigorously into growth. If the hot-water pipes are so arranged that they do not unduly dry the plants there is no difficulty in keeping them and the atmosphere moist enough by damping and syringing amongst the pots. Directly the plants display signs of dryness a good soaking should be given, and the plants then left until they require further supplies. A little too much water during the summer and growing season can soon be corrected, but it cannot be done so easily during the winter.

When the plants are showing signs of root activity the supply of water to their roots may be slightly increased and the atmosphere kept a trifle moister. This encourages the formation of growth and roots. The starting should be gradual, similar to the practice that should be followed with imported pseudo-bulbs. When poor peat is used and the plants overwatered the evil is intensified. Good fibrous peat will last a fair length of time in a sweet open condition. Failure often results with these plants through allowing

decomposed material to occupy the pots in which they are grown. Abundance of drainage, fibrous peat, and a little living sphagnum moss only on the surface will grow these plants well.

It is also a mistake to have the plants in too large pots. Very frequently imported pieces are started in 2-inch pots nearly full of drainage, with just a little peat to secure them in position. They will in these small pots make good growth, but not many roots. *Odontoglossums* are not large rooting plants, and the mistake is often made at the first potting after they are established. Three-inch pots are large enough for the second potting, and it is wise to fill them within 1 inch of the top with drainage. In this size the plants are not so easily overwatered, and should with good treatment make stout pseudo-bulbs.

The secrets of successful culture are a winter temperature of

FIG. 34.—PHALÆNOPSIS INTERMEDIA PORTEL.

about 50°, shade from bright sunshine, a moist genial atmosphere, with air admitted daily whenever the weather is favourable, small pots, ample drainage, a sweet open rooting medium, careful watering and dewing during the period of growth.—WM. BARDNEY.

#### BRASSAVOLAS.

THESE very interesting Orchids are worthy of a place in all collections, and it would be difficult to say why they are not more grown. The majority are not very showy it is true, but they are easily cultivated, free flowering, and mostly produce their blossoms during the dullest months of the year, when flowers of all kinds are very acceptable. None of the species like much material about the roots, and that used must be of the best description. They will thrive in baskets suspended from the roof, on blocks dressed with sphagnum, or in pots in the usual peat and moss mixture, and if strongly grown will not fail to give a good account of themselves at flowering time. A full *Cattleya* temperature suits most of them, and while growing they must be well

supplied with moisture at the roots. When at rest less will be required, but always give sufficient to keep the foliage and stems in good order.

The genus is not a well marked or characteristic one, the plants varying a good deal in habit and inflorescence. The late Professor Reichenbach referred this genus to *Bletia*, but they are usually known by the older name. *B. acaulis* grows in tufts of their rush-like leaves without stems or pseudo-bulbs. The flowers last a long time in good condition, are whitish, sometimes very pale green; the sepals and petals narrow, the latter drooping; the lip large, broad at the base, pointed, with an irregular, toothed edge. This flowers in October and November, and is a native of Central America.

*B. Digbyana* grows about 6 inches high, and has compressed pseudo-bulbs and oval glaucous foliage. The flowers are large, principally of a cloudy, greenish white, similar in shape to the *Lælia*, to which genus it is ascribed by Bentham. The lip is large and broadly heart shaped, with a deep fringe, which is one of its chief attractions. This comes from Honduras, and first flowered in this country at Minterne House, Dorsetshire, in 1846. *B. Gibbsianum* has somewhat cylindrical foliage, and flowers of a creamy white. It is a free flowering and very desirable species. *B. glauca* is a small-growing species of the pseudo-bulbous section. The blooms are produced singly from a sheath at the apex of the pseudo-bulbs, after the manner of a *Cattleya*. The petals are greenish white, the lip pure white, spreading, with a wavy margin. It flowers in winter and early spring, and is a native of South America.

*B. lineata*, *B. Martiana*, and *B. venosa* are all free flowering and useful Orchids. They have cylindrical leaves, and flower in racemes from the base of these. They are best grown on blocks suspended from the roof in the warm end of the *Cattleya* house.—H. R. R.

#### CALANTHES AND THEIR CULTURE.

CALANTHES, being natives of Burmah, should be rested as soon as the flowering is over, the growth buds for the following year at once commence swelling, and if the pseudo-bulbs are in a temperature high enough to assist them in doing so there is no better way than to rest them in warm quarters.

To be successful in *Calanthe* culture the plants should be grown as near the glass as possible. I prefer turning them out previous to potting and placing the pseudo-bulbs upright in boxes, with a little moss at the bottom, until the young rootlets are visible, when they are ready for potting. Great care must be taken not to damage these young rootlets, and watering should be exercised with caution directly after potting. When the plants are rooted they will require abundance of water until the growth is complete, after which the supply should be reduced, or the roots will decay before their proper time.

In order to obtain a large amount of flowers the pseudo-bulbs should not be parted at the time of shaking out (excepting the very small ones), but be allowed to remain attached to the old bulbs which have produced them, thus giving more strength to the new growths, which have to maintain the following year's spikes. If kept warm as recommended, the bulbs of the preceding season will, in the course of a month after the flowering is over, push two or three buds from the base; these should be removed as soon as discernible, with the exception of the strongest at the bottom. Each piece, now consisting of two or three bulbs each, should be placed in 7 to 9-inch pots, according to size. In potting keep the old bulbs well against the side of the pot, so that the young ones will have room to swell, taking care to have them well elevated above the rim of the pot. Smaller plants may be well grown by removing the old bulbs and potting the young ones in smaller pots.

The compost I have found most suitable for *Calanthes* consists of three parts good turfy loam, one part fibrous peat, quarter part dry cow or sheep manure, quarter part charcoal, adding a little soot and sand. They should be potted moderately firm, and, of course, in clean and well-drained pots.—S. K., *Lynton*.

#### ANNUALS FOR SUMMER BEDDING.

ANNUALS have long played a conspicuous part in the adornment of our gardens. At one time they were but little used in the flower garden, and few species or varieties were then really adapted for the purpose. During the last twenty years, however, much attention has been paid to the work of raising various types of annuals possessing a compact habit of growth, combined with great floriferousness and distinctness of colour. How well our patient and systematic hybridists have succeeded in their task may each year be noted in innumerable gardens, when these beautiful, gay, and accommodating flowers blossom in all their glory! Hosts of annuals produce showy and brilliant flowers, but are too tall

for bedding. These I must pass over for the present, treating only of those thoroughly adapted for filling large or small beds.

It is quite possible that these may be in greater demand than usual this season, for when the battle between frost and heat has been waged under the great disadvantage of insufficient boiler power, *Pelargoniums* and other tender bedding plants will be none too numerous. Bearing these things in mind, it is well for us all to take time by the forelock, and sow annuals in sufficient quantities to secure the requisite number of plants, so that when the time for bedding arrives we shall not be troubled with a scarcity of materials. Some of the plants which I shall recommend are not annuals in the true sense of the word, but for our immediate purpose may be treated as such.

Taking them alphabetically, the *Asters* appeal first to our notice. Every reliable firm of seedsmen offer seeds of dwarf types thoroughly adapted for bedding. All are so good that it is unnecessary to particularise the products of any particular firm. From the end of March to the beginning of May is quite soon enough to sow the seeds, the earlier sowings being made in a frame, and the later in the open air. I strongly advocate sowing thinly, so as to secure sturdy plants from the start. It is also a good plan to prick out a number of reserve plants 6 inches apart. These will prove extremely useful for filling beds in which spring-flowering plants were somewhat late in displaying their beauty, or for planting between *Violas*, so as to give a good autumn display.

It is not often that *Antirrhinums* are employed for bedding, but they are thoroughly effective and reliable when used for that purpose. The Tom Thumb varieties do not exceed 1 foot in height; these may be obtained in distinct colours, crimson, white, and yellow are the most effective. Seed of a dwarf scarlet may be obtained, but plants of this variety usually attain a height of 18 inches, and are well adapted for using as "dot" plants, having a groundwork of *Viola Countess of Hopetoun* (white). The seeds should be sown in gentle heat early in March. *Clarkias* possess the great merit of being extremely easy to grow, while at the same time they compare favourably for profusion and brilliancy of blossom with any known bedding plant. Tom Thumb and Double Dwarf White, each grow 1 foot in height. The flowers of the first named are bright rose in colour. Sow in April in the open air.

Both the single and double forms of *Dianthus Heddegi* rank among the most beautiful of summer bedding plants. The combination of colours to be obtained from plants grown from a mixed packet of seeds is marvellous. The plants continue to flower throughout the entire summer. The lacinated forms are also a distinct feature. Crimson, rose, salmon and white colours may be obtained in separate packets. Seeds should be sown at once in a gentle heat. I invariably sow in shallow boxes, and when the plants are large enough prick out 4 inches apart in soil placed on a hotbed. During the early stages of growth the protection of a frame is of course given, but if this should be required for other purposes it may be safely removed by the middle of April, but the protection of mats will be required on frosty nights. Treated in this way fine sturdy plants are obtained ready for lifting with good balls of earth by the end of May. Sutton's dark blue and pure white *Lobelias* come so true in colour and compact in form from seed, that it seems to me to be quite unnecessary for those with but little glass at command to winter old plants and strike cuttings in the time-honoured way. To obtain strong plants by the middle of May seeds should be sown in a brisk heat during February or early in March.

Double French *Marigolds* are well known as showy bedders. They are seen at their best during hot summers; this was fully demonstrated throughout the tropical season of 1893, when they were unsurpassed for the profusion and rich colouring of their flowers. The miniature varieties only are suitable for bedding, except in the case of very large beds, which require something bold. *Legion of Honour*, a single dwarf variety, seems to be spoken highly of in some quarters, and I intend to try it this season. I like to sow the seeds in frames in April, and prick out the seedlings in sheltered positions, where they can remain till the time arrives for planting them in their permanent quarters. *Nemesia strumosa Suttoni*.—This showy and recent introduction, having flowers of peculiar and beautiful shades of colour, ought to be grown in every garden. True, in many instances great difficulty has been experienced in getting it to grow in a satisfactory way, but this I think has been caused through coddling the young seedlings in too much heat, and then planting in soil which has not been well worked. I find it thrives in a rich light soil manured with material from an old hotbed in the autumn. This soil should be forked over, and thoroughly divided a couple of times within a week or ten days of the time when the young plants are set out. The seeds should be sown on a slight hotbed some time during April, and when large enough the young seedlings ought to be pricked out, taking care to press the soil firmly around them.

Petunias, favourite flowers of many an old time gardener, are still exceedingly popular. The single varieties are particularly suitable for summer bedding, for they are as easy to grow as effective when grown. If sown in heat early in March, the plants being subsequently pricked out in a frame, or potted singly into 3-inch pots, good plants are obtained by the middle of May. Abundance of good leaf soil should be mixed with the compost prepared for them in the early stages of growth.

The older forms of Phlox Drummondii are well known to be good and showy bedding plants of extremely easy culture. The dwarf, compact kinds, which attain a height of only 6 inches, are not so well known, yet they are the most valuable class of annual Phloxes in commerce. The seeds ought to be sown in a frame early in April to ensure the production of good plants by bedding out time. Some I know advocate sowing much later, but when this is done the plants do not commence flowering till after the usual occupants of the flower garden are in full beauty, and let them be sown ever so early they invariably continue to flower till the frosts come. A sharp look out should be kept for slugs and other depredators when the seeds show signs of germination, as much damage is frequently done at this stage, which is not apparent unless close attention is given. The seeds are consequently set down as bad, when the real fault lies with the cultivator.

Before concluding this somewhat lengthy list I must call especial attention to a capital substitute for yellow bedding Calceolarias. I do not mean one that should replace Calceolarias where they succeed, but I know in some places, no matter what pains are taken in their culture, the mysterious practice of "going off" plays sad havoc among the plants, and leaves the beds disfigured for the season. Where this is so I advise giving Zinnia Haageana fl.-pl. a trial. I was induced to do so last year, on account of having used up my stock of Calceolarias and still having one unplanted bed, which it was desirable to fill with some orange or yellow flowering plant. This was planted with the Zinnia indicated, which proved thoroughly satisfactory, commencing flowering as soon as anything in the flower garden, and continuing in beauty long after many plants had succumbed to frost. The seeds should be sown in a frame at the end of March, and in other respects treated as Zinnias of the ordinary type.

No matter what the present outlook may be, all who can fortify themselves with a good supply of seeds of the sterling annuals I have enumerated, may look forward to the summer of 1895 with the assurance that their flower beds need not lack one jot of their usual brightness.—H. DUNKIN, *Castle Gardens, Warwick.*

### EXHIBITION POTATOES.

THE old notion that certain otherwise useless varieties of Potatoes were specially grown for exhibition and for no other purpose is now happily pretty well exploded. It was very difficult to disabuse some persons' minds of this absurdity, but they are doubtless wiser now. The fact is there never was at any time a specially distinctive exhibition section. I do not think I have ever met with a Potato, unless it was exceptionally ugly, that would not in some soils and under various forms of cultivation produce tubers that were fit for exhibition.

The term "Exhibition Potatoes" in no sense applies to sort. It is applied to specially handsome, clean, even samples of any variety. Persons, however, who failed to produce such handsome, clean, bright samples, met them with the contemptuous remark that they were only show varieties, whereas they were but beautiful samples of ordinary ones in cultivation. There is one direction, perhaps, in which the practice of showing tubers helps to keep certain varieties in commerce, and those are the coloured sorts, and in that respect good is done, because there can be no doubt but that we have in these coloured Potatoes some first-class eating varieties. Take a few coloured rounds, such as Reading Russet and King of the Russets, both red; The Dean and Vicar of Laleham, purple; and Conference and Lord Tennyson, flaked. These are all first-class cropping and cooking varieties, and most valuable to anyone to have in bulk in the winter for consumption, and yet I doubt whether there ever has been or can now be found any six varieties that would give more beautiful samples on the show table than do these coloured sorts I have named. Then take such coloured kidneys as Beauty of Hebron, Prizetaker, Reading Ruby, reds; Blue Beard, Bedford Purple, and Mottled Beauty. These, again, are all of the best quality, and are capital croppers. I do not know whether American Purple is now to be had, but I always found them to be the very best of all the American varieties. Both as a cropper and for cooking quality, Mottled Beauty has all the merit of the Lanstone.

White skin varieties suitable for exhibition are legion. Taking rounds first, Early Regent, Snowball, Sutton's A1 for earliest;

then London Hero, Satisfaction, Supreme, Schoolmaster, Reliance, Windsor Castle, Prime Minister, Snow Queen, Quantity and Quality, Monarch, and Webb's Special; here we have a capital lot from out of which, if all be well grown, it may be very easy to select some eight or nine particularly first-rate.

In all collections, however, white Kidneys always largely predominate, and of these there is a splendid selection of first-class cropping and cooking sorts. It is often found that such as Magnum Bonum, The Bruce, Stourbridge Glory, Chancellor, Reading Giant, Colossal, Maincrop, Future Fame, Remarkable, Wordsley Pride, and similar strong growers give very handsome samples. Then of earlier kinds there are Ringleader, King of the Earlies, Cosmopolitan, The Canon, Puritan, Duke of Albany, Snowdrop, Onward, Marvel, Governor, Congress, and Victory, showing a wide variety, and yet all of the very best table quality. A list such as this, including over fifty varieties, shows that there is no need to grow for exhibition inferior varieties, let them be ever so handsome, as their beauty is quite equalled by that of others far superior in other directions. Could the proposed National Potato Show but have come off, without doubt a material impetus would have been given to the culture of Potatoes in greater variety, and for the purpose of securing specially handsome tubers. It does not do to assume that what is termed ordinary culture suffices to produce these specially handsome samples.

No one who grows for exhibition at good class shows is content with that form of culture. To have the best possible of samples soil and sorts will give, the grower should already be selecting from his seed stocks or getting in from his seedsmen tubers of from 3 to 4 ozs. each, clean and handsome, setting them up on end in shallow boxes and exposing them to the light in an airy place. Later, when the eyes have pushed growth, all but one or two at the most should be cut out with the point of a small knife, and be returned to the boxes. Then planting should be done later, say about the middle of April, or on to the end of the month, as the warmer the soil when planting takes place the quicker is the growth. The soil should be of a well-pulverised nature, and have been deeply trenched, a good dressing of half-decayed stable manure and leaf soil being well buried into it as trenching proceeds.

The planting should be into furrows or trenches from 2½ to 3 feet apart at the least, and even wider for strong growers. The sets in the rows should be from 15 to 18 inches apart. A light dressing of superphosphate, kainit, and nitrate of soda, at the rate of about 4 lbs. to the rod, may be either sown thinly into the furrows with the sets, or be strewn about the plants before the first flat hoeing takes place. Thus a splendid start is made, and if after cultivation be on the same liberal scale there is no reason why abundance of very fine show tubers should not result.—A. D.

### MORE ABOUT THE MULBERRY.

HAVING studied the history of this tree, especially in and about London, I would like to supplement Mr. Abbey's very admirable article (page 112, February 7th) by a few notes. First, concerning the antiquity of the Mulberry as a British tree. When we remember the great love that the Romans had for its fruit, it seems likely they planted it in the gardens of some of their English villas, though it may have disappeared from these during the troublous Saxon and Danish times. Some say the black Mulberry was reintroduced by Crusaders, and Forsyth, referring to the Syon House trees, states that he had reason for thinking they were, when he wrote, full 300 years old, which would carry the date to a century earlier than that suggested by Loudon. No doubt the Mulberry will live and thrive for 300 or even 400 years, but I question if there is one left about London that was planted in the Tudor period.

What was reputed at one time the oldest Mulberry tree near the metropolis disappeared about forty years ago. It stood in a garden near Greenwich Park, a remarkable example certainly, for there were ten large branches bending towards the earth, so that it looked like ten trees in proximity, and covered a circumference of 150 feet, growing intermixed with some Elders, being also partly covered with Ivy. It bore fruit regularly, yielding some seasons about 80 quarts in a week. Mulberries flourished at one time in the heart of London, for Fairchild, in the "City Gardener," mentions two old trees he saw in 1722 that were growing behind Sam's Coffeehouse on Ludgate Hill. Of all the suburbs of London, perhaps Chelsea has most memories of the Mulberry, many being planted by the noble residents in the "village of palaces." Queen Elizabeth has been somehow associated with the tree, and there existed several under which she is supposed to have sat to feast upon the fruit. She may have sat under a Mulberry which once grew in the garden of the New Manor House, built by Henry VIII., where she spent part of her girlhood. Though not perhaps of Tudor date, old trees yet survive in Chelsea, two which were formerly in the grounds of Peaufort House, built by Sir Thomas More. Another notable tree, admired by Thomas Carlyle, is in the Rectory garden, but probably the most interesting is one in the garden of Cheyne House, where Mr. Phene has accumulated numerous and curious relics of old Chelsea. Near this old

Mulberry is the stump of a venerable Cedar, also a Catalpa, planted when the tree was very rare, and several Hollies of long standing.

Towards Brompton there yet remains upon the remnant of Elm or Chelsea Park, some of the 2000 trees planted by a joint stock company about 1719 or 1720, the spot having been chosen as suitable for the Mulberry, because the soil was dry and the position elevated. These were to be used for rearing silkworms, in the expectation of making at least £14,000 yearly, but the scheme soon proved a failure. Across the Thames we find Lambeth and its neighbourhood formerly famous for Mulberries; here, in the grounds of Carlisle House, was another Queen Elizabeth's tree, described by Oldys as having "most reverend marks of antiquity, with a large head, and spacious arms, upheld by props like the pages that supported her train." Four or five hundred pottles were gathered from it in 1753 and subsequently. When some old gardens in South Lambeth were being cleared to form Vauxhall Park a few years ago, I noticed a white Mulberry with fruit upon it in spite of the increased London smoke. Buckingham Palace, I may add, stands on the ground occupied by the old Mulberry garden, planted about 1609 at the direction of James I., who spent there nearly £1000 on trees. Afterwards it became a place of popular entertainment.—J. R. S. C.

### CLEANING VINES.

I KNOW of no pest so difficult to clear out of a vinery as mealy bug. Especially is this the case where the houses are old and heavily timbered, affording as they do much harbour for this and other insects. Once fairly established in them, it seems almost impossible to eradicate it. Lighter and more modern structures are not so difficult to clean. Of course, if labour and time can be given, all woodwork can be, no matter how heavy, scrubbed, scoured, and painted, and the Vine rods must be similarly dealt with, or all other cleansing operations will be of no avail.

I succeeded to a large legacy of mealy bug when I came here many years ago. I have tried persistently ever since to stamp it out, and although I have not accomplished that entirely, have managed to keep it in check, so that not much damage has been done. I have had to take off all loose bark from the Vines, and where needful much that was not very loose, and although I heartily detest the practice, and would much prefer seeing the men otherwise employed, I know of no other plan. Certainly I would not waste valuable time and try men's patience in denuding Vines of bark if the necessity for the operation did not exist, for, like your able correspondent "E. K." (page 77), "it gives me an uncomfortable feeling," always fearing that some evil may accrue from it, but I can safely say that I have never known any; in fact, the best Grapes I had last year were cut from Vines that have been annually subjected to the stripping process for many years (nearly twenty), and always heavily cropped. In contrast to this, the worst examples I have ever had were from Vines twenty-five years old that have not been peeled for many years. The fault of this lies, where it invariably does, in a defective border, which will be promptly remedied as soon as this great frost has departed.

I have long given up painting Vines with gas tar and other mixtures, preferring washing thoroughly with softsoapy water, to which is added a little petroleum. The canes retaining their natural colour can be looked over for escaped bug much more efficiently than if coated with a pigment of whatever kind. I saw no red spider in our vineries last season, but I fear that destructive pest even more than I do mealy bug, for Vines will finish Grapes well if not too seriously infested with bug, but if red spider gets a footing all chances of a perfect finish to the crop are at an end.

I have always found thorough drenchings with pure soft water from underground tanks applied early in the mornings of bright sunny days a great assistance in keeping spider in check, no blemish to the Grapes resulting if the water is pure and abundant ventilation given. Until I read Mr. Taylor's account I had never known or heard of anyone stripping the bark from Vines for red spider, but no doubt they do hibernate beneath the bark of Vines like mealy bug, and ought to be similarly sought for. I am inclined to think that, taken as a whole, quite as good, perhaps better, Grapes are grown from Vines that are judiciously stripped of bark annually, or when necessity arises, than are produced from Vines from which no bark is ever taken, as the cultivator of the former after taking infinite pains to clean his Vines will be less likely to neglect subsequent cultural details than the grower of the latter who adopts, very frequently, the "go as you please" system.—W. N., *Badminton*.

### DAFFODILS AS POT PLANTS.

It is astonishing how little Daffodils are as yet used for pot culture. Every year they are more and more in demand for beds and borders, but for potting comparatively few people seem to think of them. This neglect is certainly not because they are difficult to grow, for of all easily grown bulbs perhaps these are the easiest. If potted in the autumn from September to end of October (according to the time they are required to bloom) in turfy loam with a little sand; placed on ashes in the open air, and covered with any suitable protecting material such as cocoa fibre refuse, old tan or leaves, they may be left undisturbed till December, January, or February, when, if brought into a cool house, the leaves will soon make rapid growth, and a little additional heat will quickly bring out the blooms. But it must be borne in mind that the more gradually the bulbs are brought on the finer and more lasting will the blooms be,

A mistake which is often made with these and other bulbs is to attempt forcing before the roots have taken full possession of the soil. The only way to have extra early flowers is to pot early. About five bulbs in a good sized pot will give more satisfaction than a less number in smaller pots, but of course the bulb itself will to a certain extent determine the size of pot and the number required for it.

The best Daffodils are certainly somewhat high in price, but this is more apparent than real, for after flowering they are not useless like Hyacinths and Tulips, but if ripened in the pots and afterwards planted out in the border they will bloom well the following spring.

Certainly nothing can be more gracefully beautiful for conservatory decoration than these charming spring flowers; to my mind neither Hyacinths nor Tulips—bright and welcome as they are—are fit to compare with them. The long time the blooms will last in perfection in a cool house is wonderful, nothing but Orchids can equal them. I saw some beautiful blooms of Maximus on February 17th, which I was assured had been out since just after Christmas.

The following are a few of the very best Daffodils for pot culture, though doubtless many others would succeed admirably:—Emperor, Empress, Horsfieldi, Bicolor grande, Maximus, Golden Spur, Obvallaris, Countess of Annesley, Princeps, Sir Watkin, Barri Conspicuous, Cynosure, Poeticus Ornatus, and the old double Daffodil.

I hope these few remarks may induce some of those who have passed over the Daffodil as a pot plant to give it a trial in the future, and I feel sure they will have no cause for regret.—J. DUNCAN PEARSON, *Chilwell*.

### WEIGHTS AND MEASURES OF FRUIT AND VEGETABLES.

I QUITE agree with your Lincolnshire correspondent that it would be for the advantage of growers at large if a definite scale of weights and measures were adopted by growers for sale throughout the country. I myself do not think it could be done without the intervention of Parliament, as growers in all districts would think their own the most satisfactory.

In my district (Vale of Evesham) vegetables and fruit are chiefly sold by the pot—viz., Potatoes, 80 lbs.; Peas, Beans, and Brussels Sprouts, 40 lbs.; Parsley, 20 lbs.; Walnuts, green, for pickling, 72 lbs.; Apples, 64 lbs.; Pears and Plums, 72 lbs.; Gooseberries, 64 lbs.; Cherries, Currants, Red and Black, by the side, 63 lbs.; Asparagus by the bundle, called 100, containing 120 buds (the practice of making all bundles a certain weight, 5 lbs., is gradually being introduced); Strawberries in punnets, about 14 ozs., and by the lb. in sieves and trays; Radishes by the score, 260 bunches, about seven to nine in a bunch, according to size and season, the bunches larger as they get cheaper; Parsnips, Carrots, Turnips, and Onions (not green) are sold by weight, about two pots to the cwt.; Carrots and Turnips are sold in bunches early in the season, about four or five to the bunch, thirteen to the dozen; Vegetable Marrows, Cauliflowers, Savoys, Sage (bunches, a handful), pickling Cabbage, and ridge Cucumbers, thirteen to the dozen.

Cabbage and Lettuce (Cabbage Cos are not grown about here in any quantity) are generally sold by the pot—that is, the hamper fairly filled—Cabbage, two to three dozen; Lettuce, six to eight dozen. All young plants for planting out are sold six score to the hundred.

It makes it very awkward when fruit and vegetables are consigned to Covent Garden to be sold on commission from this district, as their weights and measures differ from ours.

Hoping the above may be the means of eliciting some salesmen's and other's opinion.—MARKET GROWER.

It may be stated without contradiction that growers and sellers of garden produce are labouring under the injustice of the unwritten law of local customs more than any other traders, farmers not excepted, in the mode of disposing of their wares. As opinions on the above subject were invited by a correspondent of February 14th, perhaps a few extracts out of the Weights and Measures Act, 1878–89, would be helpful. Fortunately the Act is in force, and the sooner its provisions are taken advantage of the sooner the existing confusion will be done with. Section 3 of the Act provides that "The same weights and measures shall be used throughout the United Kingdom." Section 19, "Every contract, bargain, sale, or dealing made or had in the United Kingdom for any work, goods, or wares shall be deemed to be made and had according to one of the Imperial weights or measures ascertained by this Act, or to some multiple or part thereof, and if not so made shall be void." Again, the same section states that "No local or customary measures, nor the use of the heaped measure, shall be lawful."

To use the mildest term possible, it is absurd to buy by the stone or any other imperial denomination, and at the same time to demand 16, 18, or 20 lbs. to the stone, when the Act provides, section 14, that "A stone shall consist of 14 imperial standard lbs." The public could not get more than 16 ozs. to the lb. from the retailers. Taking one example of your correspondent's; Potatoes are sold at 20 lbs. to the stone (lucky middleman) in a hobbet, or four bushels; instead of 224 lbs., or 16 stones, he gets 320 lbs., or 22½ stones; but as it is done with the knowledge of the vendor, there is no remedy, nor is a further Act needed, as if the one in force were taken advantage of, it is sufficient.

The remedy is in the seller's hands, but collective action is necessary. Licensed victuallers have taken steps in some districts to discontinue the old custom of "long pull," and to give only the imperial measure. Let market gardeners do likewise, combine and enforce their rights; justice is on their side.—VERNIER.

**THE WEATHER IN LONDON.**—The weather on Wednesday morning though bright and clear was still cold. The sun gains power in the daytime, but beyond that there is not much prospect of a rapid thaw; at 9 A.M. the thermometer in the City read 35°, and on Tuesday morning registered several degrees below freezing. Rain fell on Sunday last, and a rapid thaw seemed imminent, but an unwelcome return of colder weather followed.

— **WEATHER IN THE NORTH.**—The frost fell from 18° on the 20th to 9° on the morning of Friday last, when a thaw set in in the early part of the day. This continued, with the aid of a west wind, to tell effectively throughout Saturday, but on Sunday the wind had returned to the north-west, and though still fresh the day was cold. Frost returned at night, and 6° were registered on Monday and Tuesday mornings. The former was a beautiful day, the latter rather dull in the morning, but the wind again in the west and the thermometer at 41°.—*B. D., S. Perthshire.*

— **NURSERYMEN AND MARKET GARDENERS' HAILSTORM INSURANCE.**—Just as we are preparing for press we receive a prospectus on this subject. It states that the Corporation has been formed for the purpose of affording greater facilities in respect of the insurance of glass structures against damage by hail, as the rates of companies which effect such insurances are so high as to be to a large extent prohibitive. Application is made for shares, in order to raise a capital of £100,000. Considerable promises of support have been received, and it is proposed to commence business by the 1st of March. Mr. Harry J. Veitch is Chairman of the Board of Directors, and Mr. A. J. Monro Secretary *pro tem.* Offices: 1 and 2, King Street, Covent Garden, W.C.

— **PROFESSOR BALFOUR.**—We see it announced that Dr. J. B. Balfour of Edinburgh has been elected a member of the Athenæum Club. Professor Balfour occupies the Botanical Chair in the University of Edinburgh, a position which was held by his father for thirty-four years. Professor Balfour takes great interest in the extension of forestry on systematic lines. He is a distinguished botanist, and highly esteemed in Edinburgh society.

— **DEATH OF LORD ABERDARE.**—We record with much regret the death of Lord Aberdare, who will be remembered by many of our friends as having occupied the position of President of the Royal Horticultural Society at a critical period of its career. His Lordship succeeded Lord Bury in 1875, when the skating rink policy of the South Kensingtonians was overturned. Lord Aberdare displayed great ability in the exciting meetings which followed, and made himself highly popular with horticulturists. His Lordship took great interest in educational and social matters, and has left the stamp of his intellect on the legislative enactments of the kingdom. Lord Aberdare died in London on Monday night in the eightieth year of his age.

— **A NEW ASYLUM FOR SUNDERLAND AT RYHOPE.**—The Visiting Committee of the Asylum has, with the Borough engineer (Mr. R. S. Rounthwaite), for some time past been considering the best arrangement for the laying out of the extensive grounds adjoining the new Asylum at Ryhope, and have just accepted the tender of Messrs. Wm. Fell & Co., nurserymen, Hexham, whose plans they have preferred for the laying out of the grounds, the supply of ornamental trees, and the planting of the same.

— **CRYSTAL PALACE SHOWS.**—The shows of flowers, plants, and fruit at the Crystal Palace during 1895 will be as follows:—Spring exhibition of plants, flowers, &c., Saturday, March 16th; the National Rose Society's exhibition of Roses and the London Pansy and Violet Society's show, Saturday, July 6th; the National Carnation and Picotee Society's show, Wednesday, July 24th; the National Co-operative flower, fruit, and vegetable show, August 17th or 24th; the National Dahlia Society's show, Friday and Saturday, September 6th and 7th; the Royal Horticultural Society's exhibition of British-grown fruit, September 26th, 27th, and 28th; Chrysanthemum exhibition, Friday and Saturday, November 1st and 2nd.

— **PROFESSOR GREENE** of the University of California has accepted the Chair of Botany in the Catholic University of Washington. Professor Greene intends, however, to continue his work in connection with the botany of California.

— **GARDENING APPOINTMENT.**—Mr. Joseph Brooks, who for a short time has managed the gardens at Withington Hall, Cheshire, for the trustees, has been appointed head gardener to Ernest Frank, Esq., who has recently taken a lease of the mansion.

— **A LARGE TOMATO.**—On page 162 there is a note respecting a large Tomato, and it appears to me that the grower claims it to be the largest on record. If so, he is certainly mistaken, for I well remember cutting one whilst a journeyman which scaled 3 lbs. 15½ ozs. The variety was Hathaway's Excelsior; it was an ugly monster, but it was one Tomato.—*W. S. E.*

— **THICKNESS OF ICE.**—At Alton Towers, Staffordshire, the frost has been so severe during the month of February that the ice on the lake was frozen to a depth of 16 inches. So far as is known this is the greatest thickness on record. During the severe weather men have been engaged in cutting out huge blocks of ice by the aid of cross-cut saws for storing away in suitable places for future use.

— **THE SIPHON IN GARDENING.**—In many cases cisterns and other bodies containing water could be very easily emptied or the water conveyed from place to place by siphons, where it is now conveyed by hand utensils. A common garden hose will do this as well as anything else. All that is necessary, says "Meehan's Monthly," is to fill the hose entirely with water first before placing it in the cistern, and then to be certain that the outlet is lower than the source of supply.

— **ROOT-PRUNING IN SUMMER.**—Having read with considerable interest on page 43 an article entitled, "Roots in Winter, Do They Work," and finding your correspondent has been very successful in summer root-pruning old fruit trees, and as he writes that it would be a gain to root-prune in the summer instead of winter, I should like him to know that at our local meeting of gardeners and amateurs the question was discussed, and the unanimous answer was "Root-prune in the summer if you wish to kill your trees." Not having any personal experience of summer root-pruning, I shall be glad of any more information I can gain on the subject.—*H. C.*

— **SAINTPAULIA IONANTHA.**—In his interesting article on "Timely Suggestions" (page 158) your correspondent, "E. K., Dublin," incidentally mentions this as a novelty likely to be in considerable demand owing to its attractive name. Although offered as a novelty of this year in some seed lists, it was in fact one of last year's introductions. I had the pleasure of seeing it in flower, and consider it well worth growing for its beauty. One can only hope that it may prove amenable to greenhouse cultivation, as it would thus find its way into the favour of many amateurs who do not possess a stove. Of attractive habit of growth, and with flowers of the most charming colour, it is very desirable indeed.—*S. ARNOTT.*

— **ORCHIDS AT THE WASHINGTON BOTANICAL GARDENS.**—This splendid collection of Orchids had a narrow escape from freezing on January 13th and 14th. Late on the night of the 13th the boiler burst. The Superintendent called his men together, and before the house had time to cool, rude charcoal stoves were improvised, and fires started throughout the building. The workmen were up all the Saturday and Monday nights watching the thermometer, and small gasoline stoves were brought into requisition until a new boiler was secured and placed in position. The old boiler had been in use fourteen years. Superintendent Smith states not an Orchid has been injured, although it was hard work with the makeshift apparatus to keep up the necessary temperature.

— **NATIONAL CARNATION AND PICOTEE SOCIETY** (Southern Section).—The Committee, in issuing the eighteenth annual report of the Society, record the gratifying fact of a substantial increase in membership; it is also pleasing to observe that the finances are in a satisfactory state, the balance of £118 5s. 4d. in 1893 having increased to £159 13s. 7½d. in 1894. Embodied in the report are selections of the best varieties of Carnations and Picotees, a record of new varieties certificated during the past year, also a return of prizewinners and their varieties during the past season. The Society has a distinguished list of patrons, with the accomplished amateur, Martin R. Smith, Esq., President, Mr. T. G. Henward, Hon. Treasurer, and Mr. James Douglas, Barking Side, Ilford, Hon. Secretary.

— IN the most recent part of the "Records of the Botanical Survey of India," the Indian Government publishes a report of a botanical tour in Kashmir, by Mr. J. F. Duthie, Director of the Botanical Department of Northern India, accompanied by a map.

— WATER LILIES AND THE FROST.—Mons. Latour-Marliac writes, saying that although they have not been spared the severity of this winter they have not to regret the loss of any plants through it, and his beautiful collection of Water Lilies is awaiting the end of all the tempests to open their leaves and buds to the sun.

— TADCASTER PAXTON SOCIETY.—At a well-attended meeting of this Society, held recently, a paper was read by Mr. McIntosh of York on the "Cultivation of Chrysanthemums." The paper dealt at some length on the pinching-back system, as applied to plants intended to be used in masses together and groups. Much interest was taken by the audience in the subject-matter, from the fact that the author is a well-known Chrysanthemum grower and exhibitor in York.

— EXAMINATIONS IN HORTICULTURE.—Allow me through the medium of your valuable Journal to draw attention to a subject which I think is now engaging the thoughts of many young gardeners—viz., the examinations in horticulture, announced to be held by the Royal Horticultural Society next May. These examinations are indeed a great encouragement to young men who are striving to become competent gardeners, and to this end spend their leisure time in reading and studying works pertaining to horticultural matters. Surprise has been expressed that more of such men do not present themselves as candidates for examination each succeeding year. There is one point which naturally deters many from doing so—viz., candidates are not limited to age, and as everyone knows experience teaches, we young gardeners have little chance of success, but must inevitably get "plucked" when our chiefs grasp the pen. I shall be obliged by your inserting this in the *Journal of Horticulture*.—A YOUNG GARDENER.

— WAKEFIELD PAXTON SOCIETY.—At the weekly meeting of the Paxton Society, held Saturday the 16th inst., Mr. B. Whiteley presided, and Mr. Brown was in the vice-chair. A long, very able, and most interesting paper on "Microbes: Their Life History and Work," had been prepared by Mr. G. C. Ramsden, who has acted as the Society's Honorary Librarian for many years, and it was read on his behalf by Mr. G. W. Fallas, the senior Honorary Secretary. The paper contained a vast amount of interesting information; it clearly showed that Mr. Ramsden must have devoted considerable time to its preparation, and that he is thoroughly acquainted with the subject with which he dealt. Dr. Clark of the Yorkshire College, Leeds, opened a discussion on the paper by some lengthy and appropriate observations. He alluded to Mr. Ramsden's paper in very eulogistic terms, saying that it was impossible to say too much as to the accuracy of the statements it contained, and it was quite astonishing to find anyone living in a provincial town, and not having access to such libraries as were to be found in the metropolis, who could give so much information on such a subject.

— LEEDS PAXTON SOCIETY.—The ninth annual dinner of this Society was held on Wednesday evening last week at the Nag's Head Hotel, Upper Head Row, Leeds, Mr. H. Foster (President) in the chair, when about seventy sat down to a most excellent repast. Delegates from Leeds, Bradford, and Sheffield Chrysanthemum Societies were present. After the usual loyal and patriotic toasts had been duly honoured, the Secretary read the annual report and balance sheet, from which the Society appears to be steadily gaining in numbers, and also financially, having now some 113 members, and a balance of £3 10s. 10d. in the bank, in addition to which the sum of £3 7s. 6d. had been handed to the Royal Gardeners' Orphan Fund. The addition of exhibits, as well as essays at the meetings, had proved a greater inducement in the attendance of members, and the Committee look forward to a successful season. The balance sheet and report of the Chrysanthemum show was in the same satisfactory condition, and both were unanimously adopted. Mr. Housley, of Sheffield, in proposing "Success to the Leeds Paxton Society," suggested that a greater amount of interest would be centered in the meetings of all horticultural societies if the secretaries of each would correspond with each other and cause an interchange of essayists; it would be eminently beneficial in showing probably the different treatment of plants and crops grown under different climatic and other conditions. The other toasts which were duly honoured were "City and Trade of Leeds," proposed by W. Holbrook, Esq.; "The Leeds Chrysanthemum Show," "Kindred Societies," and "Essayists," and harmony being interspersed with the toasts caused a most pleasant evening to come to a close all too soon.

— PRIMULA BLOOMS.—A collection of Primula blooms have recently been sent to us from Messrs. H. Cannell & Sons of Swanley, Kent. The pips are very fine, and of rich colour, the collection containing a great diversity of delicate tints in colouring, and plainly indicate from their excellent form and substance that a high standard of cultivation has been attained.

— WEATHER AT LIVERPOOL.—After nearly two months of unusually severe frost a change occurred last Friday, and on Sunday morning we had a heavy fall of rain, but frost has again returned. The three highest night temperatures in February, 26°, 34°, and 27° respectively; the lowest, 26°, 28°, and 25° of frost. Ice on a sheltered fish-pond in the garden has been from 10 to 12 inches in thickness. The damage done to green vegetables and spring bedding appears to be very extensive; but until a general thaw takes place it is difficult to speak with certainty.—R. P. R.

— HEREFORDSHIRE CIDER.—A daily paper says:—"Mr. Justice Grantham has made a discovery which is nothing less than the origin of evil. He told the Grand Jury at Hereford on Monday that he had heard for some time that so far as that county was concerned it owed its comparative immunity from physical disorders to the fact that Herefordshire was a great cider-drinking county. He had come to the conclusion that cider had the same effect on the moral as on the physical man, and that they owed their great freedom from crime, if he might say so, to the fact that Herefordshire people drank cider. If that was the case, he hoped other counties would follow the example."

— SCOTTISH PANSY AND VIOLA ASSOCIATION.—This Association has been formed in Glasgow, to meet monthly during the summer, to consider new varieties of Pansies and Violas, and to award certificates for those deemed worthy. The following seven gentlemen have been appointed judges:—Messrs. J. Baxter, Daldowie; W. Cuthbertson, Rotbesay; M. Gray, Glasgow; M. Campbell, Blantyre; J. Stuart, Lennoxton; W. Maxwell, Glasgow; and H. Hamilton, Lochwinnoch. The judges are to give their verdict by ballot. Varieties which receive three-fourths of the total number of points shall receive a first-class certificate, and those receiving one-half or more of the total number a certificate of merit. Another feature will be the granting of special certificates for constancy to varieties which obtain a first-class certificate at three meetings. Such certificates and decisions, it is hoped, will prove valuable guides to the public, and tend to set up a standard for new varieties. The membership of the new Association is open to all on the payment of a nominal subscription of 1s., and provision is made for the reception of flowers by post, which shall be as carefully handled and adjudicated as if they were personally staged by the exhibitors. The following are the office bearers, any of whom will be glad to send a copy of constitution and rules of the new Association to interested parties:—President, Mr. W. Cuthbertson, Springfield, Rotbesay; Vice-President, Mr. Jno. Baxter, Daldowie; Treasurer, Mr. Jas. Robertson, Turnerfield, Crow Road, Partick; Secretary, Mr. Jno. Smellie, Pansy Gardens, Busby.

— ROYAL METEOROLOGICAL SOCIETY.—At the last monthly meeting of this Society Mr. W. Marriott gave an account of the thunderstorm and squall which burst over London so suddenly on the morning of January 23rd. It appears that this storm passed across England in a south-south-easterly direction, at the rate of about forty-seven miles an hour, being over Northumberland at 4 A.M., and reaching the English Channel by 11 A.M. Thunder was first heard in the vicinity of Leeds, and accompanied the storm in its progress across the country. One of the most remarkable features of the storm was the sudden increase in the force of the wind, for in London it rose almost at one bound from nearly a calm to a velocity of thirty-six miles an hour. This sudden increase of wind caused considerable damage, and at Bramley, near Guildford, twenty-eight trees were blown down along a track 1860 yards in length. Mr. E. Mawley presented his report on the phenological observations for 1894. Between the third week in March and the third week in May plants generally came into blossom in advance of their usual time, and towards the end of April the dates of first flowering differed but little from those recorded at the same period in the very forward spring of 1893. The cuckoo made its appearance even earlier than in the previous year. The year 1894 was a very productive one, and both the hay and corn crops proved unusually heavy, but much of the latter was harvested under very trying conditions as regards weather. The frosts of May 21st and 22nd entirely destroyed the previous prospect of a glorious fruit season; indeed, the only really good crop was that of Pears, which were singularly abundant throughout nearly the whole of England.

— AMERICAN POMOLOGICAL SOCIETY.—The biennial convention of this Society in California was a very successful affair. The visiting delegates were entertained with liberal cordiality. The papers and discussions at the meetings were mainly of interest to the Pacific coast. The Society re-elected the old list of officers, including P. J. Berckmans of Georgia, President; B. G. Smith of Massachusetts, Treasurer; and G. C. Brackett of Kansas, Secretary.

— HONOUR TO A NORTH COUNTRY HORTICULTURIST.—The Corporation of Sunderland, by virtue of the 62nd Clause of the New Local Government Act, has taken the whole of the Sunderland cemeteries under its charge. These consist of Sunderland, Bishop Wearmouth, and Mere Knolls, containing 112 acres. The Corporation agreed to have one chief official for all, the office to be termed "Chief Clerk and General Superintendent of Cemeteries," and without advertising the Cemetery Committee decided to offer Mr. W. J. Bolam, F.R.H.S., Superintendent and Registrar of Sunderland Cemetery, the position, which he has accepted. Mr. Bolam was for many years manager for the late Mr. Harrison, the noted Rose grower at Darlington, and has been for the last twenty years Superintendent and Registrar of the Sunderland Cemetery; he is also Chairman of the Sunderland Horticultural Mutual Improvement Association. He will have responsible duties to perform, but he is an accomplished book-keeper, a skilful horticulturist, and an expert in cemetery management, therefore well qualified to discharge the duties. The salary commences at £180 per annum, with free house, coals, gas, garden, and water. He will have an office in the Town Hall, Sunderland, and telephonic communication with the officials in charge of the cemeteries to assist him in carrying out the various details of his duties.—BERNARD COWAN, F.R.H.S.

— MOVING TREES.—In "Meehan's Monthly" for February the sound advice is given to dig a trench before spring growth begins around large trees which are to be moved. The inside of the trench should be 2 feet from the butt or more, according to the size of the tree. It should be deep enough to cut off most of the roots 2 feet at least, and the trench should be carefully filled up with good soil, which should be firmly packed about the ball. Next autumn many new roots will have been formed, and the transplanting of the tree will be much more easy and more certainly successful. When the trench is dug the top of the tree should be pruned back, though not as severely as if the planting was to take place immediately.

— FALSE PRETENCES.—At the Southwark Police Court last week Charles Samuel Robinson, a farmer of Pinchbeck, near Spalding, Lincolnshire, was charged with obtaining the sum of £73 14s. from Messrs. Cooper, Taber & Co. (Limited), seed merchants, of 90, Southwark Street, by false pretences. Mr. J. P. Grain (instructed by Mr. Chas. Butcher) appeared for the prosecution, and Mr. Stile, solicitor, of Spalding, defended. Mr. Stile said the prisoner would plead guilty to the charge, and wished to have the case settled here. Mr. Slade said he had no power to deal with it, and that the prisoner must be committed. It appeared that prior to 1892 the prosecutors had done business with Messrs. Robinson, farmers, of Lincolnshire, who were relatives of the defendant. In July, 1892, Messrs. Cooper, Taber & Co. received a letter from the defendant asking them if they wanted any Turnip seed grown that year, as he (the prisoner) had 20 acres of land ready for the purpose. A contract was entered into by which the prosecutors were to supply prisoner with seed to sow the 20 acres, and the produce of the seed, when gathered, was to be sold to the prosecutors at 14s. 6d. per bushel. Subsequently the prisoner represented to the prosecutors that part of his land he had found unsuitable for sowing the seed, and he had sub-contracted with a neighbouring farmer named Orbell to sow part of the seed, which he asked the prosecutors to take from him at 13s. 9d. per bushel, so that he might realise a profit. This they agreed to do, but eventually the prosecutors received a further intimation from the prisoner that Orbell would not part with his produce under £1 a bushel, as he had received even a better offer than that. Owing to the defendant's representations the prosecutors were induced to take the whole of Orbell's growing, which amounted to 246 bushels, for which they paid the prisoner. In 1894 Orbell happened to have an interview with Mr. H. T. Huggins (prosecutors' manager), when this transaction was first brought to Orbell's knowledge. The latter then said that he had fulfilled his part of the contract with Robinson, whose cheque he received for 246 bushels at the rate of 13s. 9d. per bushel. He had never demanded £1 a bushel, and the whole story of the prisoner was a fabrication. The prisoner was committed for trial at the March sessions. Mr. Slade offered to take bail, the prisoner in £200, and two sureties of £100 each.

— THE ARGENTINA VINEYARDS.—These have been largely extended during the past few years, and wine-producing has already become an important industry. The principal Vine grown is the French Cot-Rouge, and in the Cuyo provinces of the Argentine Republic the pests known as mildew, black rot, and phylloxera do not occur in consequence of the dryness of the climate. It has been estimated that there are, in round numbers, 82,500 acres of vineyards in the Republic. These, when fully established, or within three years' time, should yield on an average some 329,500 tons of Grapes per year. These figures, according to French averages, should be equal to 42,800,000 gallons of wine.

— ORIENTAL LILIES.—I recently wrote to Mr. J. G. Baker, asking him what Lilies succeeded best at Kew. The following is his reply, which will, I know, prove interesting to the readers of the Journal:—"I think the Lilies that make the finest show at Kew are longiflorum, tigrinum splendens, superbum, and pardalinum, all of which are grown in great numbers here. The soil, however, is very sandy, and consequently not well adapted for Lily cultivation. Liliun Henryi is a very fine plant, and has now become fully established. The first to flower here are L. pyrenaicum and L. testaceum. Liliun Harrisii is merely longiflorum taken out to Bermuda, where it seems to have taken on a new lease of strength and vitality, and then sent back to Europe. The latest introductions are the three species from Upper Burmah (L. Lowi, L. sulphureum, also called Wallichianum superbum, and L. nepalense), of which sulphureum is succeeding much the best. It is a very fine, tall species, but requires shelter even here. I have received information from Paris of ten or a dozen new species lately found by the French missionaries in the Western Chinas, none of which has yet been introduced alive." I have nothing to add to Mr. Baker's interesting communication, unless that, having cultivated sulphureum and its beautiful Indian companion nepalense, I have discovered that they are not adapted by Nature for open-air culture, requiring at any rate in the first place to be forced into activity by a warm conservatory. It is quite possible, however, that after being started in this artificial manner sulphureum might, under favourable conditions, be transplanted to the garden with some prospect of success.—DAVID R. WILLIAMSON.

— PRESERVING POTATOES.—One of the obstacles to the preservation of Potatoes is the sprouting of the tubers. As soon as the tuber is put into any place favourable in temperature and moisture the tuber will begin to grow, and therefore deteriorates as an article of food. A growing Potato is always more or less a loss, and is not so well able to feed either man or animal. The nutritive matter is slowly consumed by the germ, and the tuber subsequently becomes a source of danger to man as well as beasts. There was only known one way of stopping the growth. This consisted of taking out the eyes with a knife, a proceeding which is very slow; and very frequently in doing it the tuber was bruised. For three years now, says the "Mark Lane Express," Mons. Schaibaw has tried at the French Agronomic Institute another mode, which has been found effectual. It consists of treating the Potatoes with sulphuric acid. Take a large tub and fill it three parts full with water, add sulphuric acid to make a 2 per cent. solution. The Potatoes are placed in the solution, and kept there for about twelve hours; they are then withdrawn and dried, and their preservation is absolutely secured. If the solution is stronger a less time is required; with a 3 per cent., five to eight hours' immersion is sufficient, and with a 4 per cent. solution three to six hours' immersion will be effectual. The dissolved sulphuric acid attacks the germs on the surface, and quite kills them. Some persons have objected to this method, stating that it was dangerous both for man and animals, but this fear is said to be chimerical, because the amount of sulphuric acid remaining on the surface of the Potatoes is very slight, and the seltzer water used daily by thousands of people contains considerably more of this acid. Furthermore, Potatoes are used as human food without the skin, and the acid does not penetrate into the flesh.

THE CHARLES COLLINS' FUND.

WE have pleasure in announcing the following subscriptions received during the past week by the Treasurer towards this very deserving case:—

## EREMURI.

AMONG plants of comparatively recent introduction few have excited so much interest in the ranks of hardy flower growers as the Eremuri. I am saying, "comparatively recent introduction" advisedly, for it appears that one of the genus, *Eremurus robustus*, was first introduced to this country in 1874, or twenty years ago, a time which one would have thought sufficient to enable it to be found in almost every good collection in the country. The Eremuri are, however, plants of which no one can at present speak with any degree of confidence, and there are several causes which prevent their wide distribution and cultivation. They are, notwithstanding, so majestic and withal so beautiful (for majesty and beauty in flowers are not always combined), that when seen they invariably give rise to a desire to grow such noble flowers.

It is thus well worth our while devoting some attention to these stately Asphodel-like plants, and while dealing only briefly with the species from a botanical or descriptive point of view, to gather together and present as a whole the experience of several, besides myself, who have been trying to succeed with their cultivation. Thus, I shall endeavour to speak as shortly as possible of the genus *Eremurus* and its species, and afterwards to tell of the methods adopted and the success or failure which follows.

The Eremuri belong to the Natural Order Liliaceæ, and the name has been derived from *eremos*, solitary; and *oura*, a tail, in allusion to the form of the spike. Their native habitats extend over a wide region, these plants being found in Northern India, Persia, and Central Asia; and it is perhaps to the peculiarities of the climates of these countries that we must ascribe some of the cultural difficulties we have to encounter. According to botanists there are some eighteen or nineteen species, but the number in cultivation in our British gardens is much smaller, those principally grown being *E. robustus*, *E. Olgaë*, *E. himalaicus*, and *E. Bungei*. Of *E. robustus*, which is the best known, there are at least three varieties, but so seldom are these seen in flower together that one would feel it a favour if someone who has flowered the three would describe the difference between them.

There are—first, the type; second, an intermediate form; and third, the variety named *E. robustus nobilis* or *Elwesii*. The height of *E. robustus* varies considerably, being from 6 feet upwards, and its great flower stem, surmounted by a raceme of densely arranged peach-coloured flowers, renders it a striking object. The Rev. F. Page Roberts, of Scole Rectory, to whom, with Mr. W. E. Gumbleton, of Belgrove, Queenstown, and several others, I have to express my obligations for so kindly writing to me, flowered a spike of *E. robustus* this year, which when measured before attaining its full size was 10 feet 8 inches high. It was figured in the *Journal of Horticulture* for September 20th, 1894. I am disposed to think that Mr. Page Roberts' variety must be that named *nobilis*, as Mr. Gumbleton, who is perhaps better acquainted with the Eremuri than any other amateur in the kingdom, speaks of *nobilis* giving him a "grand spike 7 feet 7 inches in height," and the others I have seen or received particulars of were generally about 6 or 7 feet high. The intermediate variety, Mr. Gumbleton informs me, grows into great clumps in the garden of Professor Michael Foster, at Shelford, near Cambridge. *E. robustus* flowers in June and is a native of Turkestan.

Of *E. Olgaë*, I regret to say, I have not a great deal of information to give. It flowers later than *robustus*, generally in July, and grows from 4 to 6 feet in height, having a spike of very large lilac flowers. It comes from the same country as *E. robustus*, and was introduced by Dr. Regel about 1891. *E. himalaicus* is one of the very finest, but unfortunately is still one of the most expensive. So far as I understand Mr. Gumbleton was the first to introduce this beautiful species, and he finds it the most satisfactory. The flowers are white, about as large as a two-shilling piece, and are produced on stems which are from 6 to 8 feet high. *E. himalaicus* was introduced from the Himalayas in 1881.

*E. Bungei*, introduced from Persia in 1885, is one of the most inexpensive, and seems comparatively easy to procure. It is, however, of dwarf habit, and of much less imposing appearance than the other species, its stems being from 1 to 3 feet high. The flowers produced in July are bright yellow, and the raceme is about 5 or 6 inches in length. Of the other species rarely met with, *E. aurantiacus*, citron yellow; *E. spectabilis*, sulphur coloured, and *E. Korolkowi*, rose coloured, may be mentioned. *E. turkestanicus*, or what has been sold as such, is a poor plant hardly worthy to be mentioned in the same breath as *E. robustus*. Enough has, perhaps, been said on this head, and I shall proceed to discuss various other points relating to the cultivation of the Eremuri or Eremuruses, as I should prefer to call them, although the termination is not the correct one.

One great obstacle in the way of the more rapid distribution of the Eremurus has been the cost of the plants. They are mostly, as

yet, beyond the reach of the ordinary amateur or of the gardener whose garden allowance is not of the most liberal kind. I have heard of £2 2s. being paid for a plant of *E. robustus nobilis*, and last summer I saw a plant of *E. robustus* for which 15s. had been paid the previous year, and which may not flower for a year or two. It is true that plants may be obtained more cheaply from the Continent, but too often they are so small that it will be some years before they flower. Another objection to continental-bought plants is that they do not generally come to hand until autumn, when they have made some of their root-growth, and these roots being frequently injured, little growth is made the first year. It has now been definitely discovered that the Eremurus makes fresh roots every year, and that it can most safely be removed about July.

Another hindrance to the cultivation of these noble flowers is the time taken by small plants to attain a flowering size. I have never grown Eremuruses from seed until they attained a flowering stage, my seedlings having succumbed to the attacks of slugs long before they were large enough to flower, but so far as I can learn they do not usually flower before their seventh year. In saying this, I am, however, speaking subject to correction. There must at present be large numbers of seedling Eremuri in the country, and, while they will gradually reduce the price of plants, purchasers would do well to ascertain, as far as they can, the age of the plant purchased, and, unless disposed to wait for years, to avoid a young one. To raise these noble flowers from seed is, as will be seen, weary work, involving patience greater than most possess before any great result will follow. To make the matter still worse very few of the seeds purchased in spring germinate until the following year. I have at present seeds of *E. Kauffmanni* and *E. himalaicus* which were sown in February, 1894, and from two ordinary sized packets of seed only one plant appeared before Christmas. I expect a fair number will vegetate in the spring.

I think it will thus be apparent that the intending grower of Eremuri should procure plants of six or seven years of age in July, and plant in a carefully prepared bed or border of good soil. They do not seem very particular as to the kind of soil if it is of good quality, and they have a free run for their great, fleshy roots, which extend to several feet from the rootstock. The position should be a sunny one, as, like other plants from Central Asia, the Eremurus requires to be thoroughly ripened off. It must also be sheltered, and, from bitter experience, I must emphasise the point of shelter, as in my garden it is almost impossible to find a part sufficiently sheltered, their long thick, and fleshy, but elegant leaves, being exceedingly brittle, and when bent decaying rapidly, with the almost certain effect of weakening the plant. In the spring of 1894 my plants suffered much from a severe gale which sprung up during the night and shattered the leaves. Another piece of advice one would give is not to carpet the space occupied by the roots with other plants lest the ripening process should be prevented. In planting I think it desirable to keep the crowns a little below the surface.

The young growths of the Eremuri appear late in the winter or early spring, and if not protected from sharp frosts the tips of the leaves will become browned, and they will be correspondingly disfigured the whole season. This protection should be continued until danger from frost is past, but it must be of a kind easily removable, and should be taken off while the weather is mild. A flower-pot of good size is a method of protection which is readily applied or removed; but a small hand-light is also convenient, and not so likely to harbour slugs—the pests of pests which plague the Eremurus. A collar of zinc is, however, a valuable protection, and if notched on the top, or made of perforated zinc, will turn the most devoted gastropods, which seem to appreciate the edible qualities of the Eremurus, even more than the natives of its habitats who use it as a vegetable.

It is evident that my remarks on the Eremuri are far from optimistic; and still another point remains, which, it is to be feared, is the "unkindest cut of all." This is, to expect several of the species to die after flowering; for such is the consensus of experience with the Eremurus in this kingdom. Happy is he who can manage to retain his plants until they bloom, for too many only linger a few years to die. Happier is he who can succeed in inducing these stately Eremuri to raise their tall stems decorated with beautiful flowers; but thrice happy is he who can preserve his plants after they have bloomed, as it is the almost universal experience that they die after flowering. There are, however, exceptional gardens, such as that of Professor Foster, where the Eremurus becomes established, and *E. himalaicus* is generally the most permanent.

Several good growers attribute the death of the Eremurus after blooming to the want of proper ripening, but I am disposed to consider it due to exhaustion. It seems singular that these plants may live for several years in the same garden and then die after

blooming. On the other hand, in justice to those who hold a different view, some do not succeed in keeping them alive even without flowering. If exhaustion is the cause there is no remedy, and we must have recourse either to raising seedlings or purchasing new plants. On the other hand, should the loss be owing to want of ripening this may be met by covering the plants and the roots so far as they extend with glass, and trying to secure that they should have a good roasting.

This is a course we seem to find the proper one to adopt with *Ostrowskia magnifica* and with the *Oncocyclus* Irises, and we may have to adopt it with the *Eremuri*. I feel that this somewhat lengthy article is pessimistic; at least, it will appear so to some. One must, however, take things as we find them, and I am disposed to think that we will find these magnificent flowers will tax to the

growth. There is a majesty in this queen of water nymphs, the *Victoria Regia*, which not any of the vegetable wonders of the tropics can surpass, or but few equal. Then, too, it is one of those plants seldom met with, for by reason of its size and requirements but few gardens can afford the space for its cultivation. Even in those places where we are privileged to see it as at Kew or Glasnevin, the Kew of Ireland, one feels that it is a picture shorn of its margin, and to do full justice to its stateliness it is necessary to realise the free and unfettered surroundings of its native home in Guiana. But those who most admire its marvellous foliage cradled in the tank are probably inspired to complete the picture which cannot be realised here. These are unavoidable qualifications. The glorious Lily is grown and shown to the best advantage these circumstances will allow.

FIG. 35.—THE AQUATIC HOUSE AT GLASNEVIN.

utmost our cultural skill and ingenuity in growing and preserving them in our gardens. Still, *Nil desperandum* must be our motto, and we must seek not only to deserve but to achieve success.—S. ARNOTT.

#### THE AQUATIC HOUSE AT GLASNEVIN.

WHATEVER beauty or interest is created by Nature or Art in gardening, should water be absent as a gratification to the eye, one thing is wanting. The most striking effects in a landscape, the beauties of a demesne, or the pleasures of the garden are enhanced by the presence of water, whether it be the babbling brook, the placid lake, or the sparkling fountain.

Water plants also, even of the humblest type, are always pleasing, ever interesting. The aquatic house at the Royal Botanic Gardens, Glasnevin, is a never failing source of interest to visitors, and the most casual observer cannot fail to admire the huge Water Lily, as depicted by fig. 35, from a photograph by Miss Armstrong, during its season of

The small overshot wheel (in the background of the picture to the right) is kept slowly revolving by the supply pipe to the tank, and gives a rippling motion to the water. In its proximity to the Irish metropolis, Glasnevin is of easy access from the city, and those on pleasure bent cannot fail to derive some profitable lessons from a visit to the home of the curious, the interesting, and the beautiful, whether in the stately Palm house, amongst the thousands of Orchids, or the legions of hardy plants, shrubs, and trees, which are bound up in the encyclopædia of a botanic garden. Those more keenly interested, of the gardening profession, may also have a peep into the private houses, and find in the courteous Curator, Mr. F. W. Moore, that one touch of nature which obliterates the line between his responsible position and the more lowly of the craft.

The unpretentious village of Glasnevin has also historical points of interest to the literary inclined, being at one time the home of Sir Richard Steele, author of "The Tatler," and here Dean Swift penned his pungent satires on the Government of that day.—E. K.

## ROSE SHOW FIXTURES FOR 1895.

- June 27th (Thursday).—Gloucester (N.R.S.) and Canterbury.  
 „ 28th (Friday).—Exeter.  
 „ 29th (Saturday).—Windsor.  
 July 3rd (Wednesday).—Croydon, Ealing, and Sutton.  
 „ 4th (Thursday).—Eltham and Norwich.  
 „ 6th (Saturday).—Crystal Palace (N.R.S.).  
 „ 9th (Tuesday).—Wolverhampton\*.  
 „ 10th (Wednesday).—Chelmsford and Hitchin.  
 „ 11th (Thursday).—Helensburgh and Worksop.  
 „ 17th (Wednesday).—Derby (N.R.S.).  
 „ 18th (Thursday).—Halifax.  
 „ 24th (Wednesday).—Chesterfield.  
 „ 25th (Thursday).—Trentham.

\* A show lasting three days.

I shall be glad to receive the dates of other Rose shows than those named above for publication in future lists.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

## PRUNING ROSES FOR EXHIBITION BLOOMS.

IN a few weeks' time we shall be in the thick of this all-important business, and perhaps a few notes at the present time will not be out of place. The remarks are mainly intended for beginners and growers of limited numbers, as I know that our leviathan growers cannot bestow the necessary time that I think pruning requires, and have consequently to leave to others that which they should do themselves.

I remember once calling unexpectedly on a brother rosarian during the height of the pruning season. The grower in question is well known as a successful exhibitor and authority on the Rose. I was thoroughly disgusted at what I saw; the whole job seemed to consist in cutting the plants without any discrimination to a certain level. Mr. Amateur was leisurely slashing at the standards, and his gardener, who did not seem to know much about it, was simply cutting down the dwarfs. This, to my mind, is pruning made easy with a vengeance.

My friend admitted that he was not taking a very active part in the work himself, as experience had taught him that pruning Roses for exhibition purposes was a matter requiring very little consideration, and the great thing was to get it over as soon as possible. He went to zero in my estimation, as judging him by his writings, I had every right to consider him a practical man, but his actions proved him to be the reverse. His Roses that year were a failure. I refer to this little episode as a warning against carelessness, and I would especially caution beginners against any personal relaxation in leaving to others the all-important work of pruning.

Pruning is a science which can only be really learnt by practice and close observation. By observation, I mean not only a careful study of the wood at the time of pruning, but also an intelligent and attentive watching of the after effect, as the result should be carefully noted with a view to future operations.

From the first I have always pruned my Roses myself, and I very strongly advise amateurs to allow no one but themselves to use the knife. A practical rosarian must learn this lesson if he is to make a study of his hobby. I cannot go into detail as to which Roses should be pruned severely and which *vice versa*, but the general rule that weak growers require very close pruning may be followed.

To the ordinary amateur exhibitor I would recommend somewhat moderate pruning, as results from such treatment are more consistent than the severe pruning which is often advocated. Large growers can, by reason of the number grown, afford to adopt a drastic treatment that unquestionably does frequently produce very fine blooms. But the same result can often be obtained by a course of severe disbudding after the plants have commenced to grow, and with a greater degree of certainty, as there are then buds to fall back on in case of accidents, which is not always so when short pruning is adopted. The latter also sometimes produces nothing but wood. Choose three to five shoots with the wood well matured, and if possible, well placed; but as fine blooms are required the shape of the tree is of secondary consideration. Then cut away all rank sappy growth which is plainly useless. Sometimes these, unfortunately, have to be taken, as no other wood is available. On each shoot leave three to six eyes, and it is well to prune to a bud pointing outwards so as not to have a crowded centre, but as this bud is the first to break the object is often defeated by a late frost or the "worm i' the bud."

In May superfluous shoots may be cut off, leaving from three to eight blooms according to the strength of the plant. No hard and fast rule can be laid down, as the after-treatment in the amount of feeding has to be taken into consideration. When I commenced growing Roses the shape of the tree was an all-important matter, and I still like a shapely plant, but blooms being the desideratum it is often impossible to study both. All old wood should be cleared away, and the centre must be fairly open, so that light and air can get to all the shoots.

We sometimes find new wood that has the appearance of old being quite hard, with no pith; this should be retained, as it is sure to produce the best blooms. Such wood might be cut away in mistake by a casual workman, but the amateur who has previously pruned his plants will of course recognise it at once, and secure it, even if badly placed. I like to take a good survey of the plant to be pruned, even to the extent if necessary of going down on my knees to critically examine the condition of the wood; the time this little extra trouble takes is well spent.

I am not a faddist, but I believe the great secret of all success is hard work and attention to detail. It is advisable to have at least two sharp pruning knives, and the hone should be carried about, as the blades cannot be too sharp; a small blade is also a necessity, as all weak growth must be removed. I have always used a small thin saw, known in the trade as a keyhole saw, with great advantage, it being easy of manipulation in crowded growth that cannot be removed with the knife. Owing to the present severity of the weather pruning operations are likely to be deferred until a later date than usual this year, and the middle of March will be quite early enough to make a start, unless very warm weather comes before that date.

The above remarks apply in the main to H.P.'s, but Teas can be treated in the same way, although the frost has generally taken most of the work out of our hands. This year I am afraid many Teas will have been killed outright by the frost; but where only hard hit they should be cut well back at as late a date as possible.—R. M. D.

[We have heard of great destruction among Roses, and but of one lucky escape. Mr. George Paul had several thousands of Teas "laid in" before the frost; over these were laid some flat evergreen branches, which in turn were covered by a fortunate fall of snow. This saved the Roses, while those unprotected were killed down to the snow line. What is the result of the late zero weather in other districts?]

## TOMATO HOUSES IN WINTER.

*Re "Perplexed One."* Fig. 22, page 136, of February 14th issue of "dear old Journal" speaks volumes. If material is handy, well managed beds of Mushrooms between October and March should beat the Tomato crop in a money point. I have found valuable hints in "Mushrooms for the Million," by J. Wright, and can now quite dispense with the dry heated Mushroom house.

Seakale, Asparagus, and Rhubarb, growing your own roots for lifting, are remunerative when forced. Saladings, Green Mint, Tarragon, with the above vegetables, always find ready sale at hotels. I have known a fortune made out of forced Rhubarb grown under plant stages, the secret being well prepared roots in the open, principally fed with night soil forked into the ground during the winter. All these could be grown in conjunction with Mushrooms.

Daffodils in all stages are much called for. Having both beauty and fashion to recommend them, I question if these ever get overdone. Such varieties as Horsfieldi, Countess of Annesley, Empress, Emperor, Sir Watkin, and other Narcissi. The same rule applies to these as the above vegetables—grow your own stock. They increase rapidly. Snowdrops, too, form a feature in this list, and are eagerly sought after at Christmas. How easily they open with gentle forcing! (I noticed a few hulbs potted and placed in a warm kitchen flowered for Christmas). Pot all hulbs early, plunge in cocoa fibre refuse till housed; very gentle heat brings them in flower for Christmas and onwards. Daffodils are potted two bulbs in 4-inch pots, long toms, standing in saucers, which are kept filled with weak stimulants, never watering over the top.

Gladiolus The Bride, planted thickly in 48's, fed from saucers, are putting up flowers; anyone can water a house of plants by this method without injury—yea, to the plants' benefit—as they flower strongly and look remarkably healthy. Liliun Harrisii, by potting first importations, may be flowered in February. The plants are now showing strong buds, averaging five from a hulb; these are grown singly in large 48's with fertilised moss wrapped round their stems, all fed from saucers. Imantophyllums are easily grown, and afford a mass of grand heads of flower with a little warmth.

Going back to the overdone Chrysanthemum, the golden flowers of W. H. Lincoln in January, and later still the gorgeous E. G. Hill, should find a host of admirers. Then, what is more useful, more prolific than a house of the old Marguerite, C. frutescens? You may cut and come again, and the flowers stand for weeks in water in a cool room. Plants raised in the spring, planted out and lifted in October, form bushes naturally 4 feet through. They are carefully taken up and potted when in full flower, and afforded a few days' shade. They never cease flowering with good treatment in a little warmth. Hosts of other plants might be named, for instance old plants of Deutzia gracilis, never repotted for twelve years, are now laden with sprays of flower that are a wreath at once. Most of these simple plants are loved by both peer and peasant, and the stock on hand is always saleable.—GEORGE BOLAS.

IN answer to "Perplexed One" I take it the houses are built especially for Tomatoes, and that he wants something for about four months in the winter to grow to pay, so that the houses will be ready not later than February or March for Tomatoes again. It seems to me that permanent plants, such as Arum Lilies, Carnations, Orchids, Bouvardias, and others are out of the question, as they would be in the way of starting the Tomatoes early. If the undermentioned are well grown he would have a fair return for his outlay. Chrysanthemums are not overdone if grown in the right season, that is, December and

January, when good blooms are wanted, and by growing late sorts can be had. If good they will fetch from 9s. to 12s. per dozen bunches of twelve blooms. The following are some good late sorts: L. Canning, Princess Blanche, Princess Teck (white), J. Dibbin (bronze), W. H. Lincoln (yellow), and Yellow Gem; then a couple of houses of Lilinm Harris. If the bulbs are bought at the right market double and single Narcissi and Daffodils, in bloom in January and February, will pay a fair return, as also will Tuberoses, and last but not least, a few houses of Mushrooms. By growing the above the houses would be cleared for Tomatoes in February and March.—GEO. MASTERS.

I AM much interested in the question propounded by "Perplexed One" (page 137). During the last seven years I have been trying to work this out, and have met with more or less success. It may be stated at the outset that market gardening, even when a man is backed up by sufficient capital, is not the profitable business it was twenty or more years ago. The profits now are under the best management small, but still an industrious, careful man can live and extend his business. There are warm islands where Tomatoes can be grown equal to those produced under glass in this country, and with the improvements in ship-building foreign competition may become more in evidence in the future that it has been in the past; hence to make a profit the culture must be right and economy in production must be closely studied.

The markets also must be watched. No doubt Covent Garden is the best market in the world for the best class produce, but Tomatoes and heavy produce generally, if produced far from London, can be more profitably disposed of locally than sent by rail. Tomatoes are so generally in demand all over the country that very often a better price can be realised in small towns and villages close at home than sending to London at considerable expense. We have occasionally sent Tomatoes and other produce to London just to test the markets in comparison with our own district, but we find a market as near home as possible for the bulk of our produce.

Profitable market gardening under glass is pretty much a matter of adapting means to ends or *vice versa*, always bearing in mind it is more profitable generally to grow the things we can dispose of close at home than to send to a distant market, where we cannot either control prices or even feel sure that the parties to whom the goods are consigned will deal fairly with us. Every man has to make his own position.

The crops which prove the most profitable in one district may not pay so well elsewhere, and therefore modifications have often to be made in our plans. It is hardly possible, even if it were wise, to attempt it, to lay down hard and fast rules to suit all places. The wise man tries to develop that part of his business which he finds pays the best, or, if possible, to develop something new, hence his mind is always on the stretch to imbibe new ideas, if there is the least chance of their paying their way.

With reference to the remark of Chrysanthemums being sold at 2s. 6d. per dozen bunches, the quality must have been poor, possibly they were grown outside. We had no difficulty in making from 2s. to 3s. per dozen blooms of fairly good flowers of Lady Lawrence and W. H. Lincoln last Christmas, and at such prices the blossoms pay. It is true, of course, the early blooms do not pay like the late ones, but these should only be grown in a limited number just sufficient to meet the home trade and keep customers together. The bulk of Chrysanthemums should be grown for late flowering, and then, if fairly good, they will yet pay. Where manure of the right quality can be obtained cheaply Mushrooms offer a chance, as they are always saleable, but there is often a difficulty about the manure. Some years ago I had a friend who had a business near a town where there was a cavalry barracks, and he secured a contract for the removal of the manure from the stables, and grew Mushrooms in large quantities. If I could secure the manure from a brewery, or any large firm keeping a number of well-fed horses, I should certainly grow Mushrooms.

Early Rhubarb in many country places is but poorly supplied, and if a moderate sized house, after the Tomatoes come out in October, is covered with canvas or even mats, or anything that will keep in the heat and subdue the light, and the house filled with strong roots of Rhubarb, the crop would be profitable, and it would not involve much expenditure provided the roots were grown at home.

Good Violets always sell well in country towns, as do also Daffodils at Christmas, and these are things which may be provided at home, and may either be planted in the borders or in boxes; the latter plan offers some advantages. Tree Carnations in about three or four colours would be a valuable help all winter. When grown in large quantities so that hundreds of dozens could be cut daily, London or Manchester would take the bulk of these if the flowers were fine. Arum Lilies, Niphotos Roses, and Strawberries would, in some cases, offer a good margin of profit.

Strawberries may be grown with Tomatoes well up to the spring on shelves slung from the roof. I am assuming that the houses would be heated more or less, as a cold house is not of much use even for Tomatoes. There should at least be the means of keeping out frost.

I am afraid I am encroaching too much on your space, though the subject is very far from being exhausted. In fact, taking into consideration the varying circumstances and conditions under which we severally work, the subject cannot be exhausted. The man who understands what he is doing and is resourceful in expedients, is fairly backed up with capital, and has good health, need not feel afraid to venture his capital if he selects the right spot. Those who are acquainted with the London trade will probably pick a suitable spot near London; but there

are hundreds of quiet spots in the country near a good sized town where a quiet living could be made without the exhausting wear and tear of mind and body which a London business involves.—E. H.

IN trying to "crack the nut" "Perplexed," our fellow reader, has given, I take first the *Calla æthiopica*. The Arum, in my opinion, is one of the most remunerative of plants "Perplexed One" can grow. If he has earth stages with space underneath them that can be made dark, he could also grow Mushrooms with advantage. The Callas should be planted 18 inches asunder, not too deep, late in August. Fresh retentive loam is the best medium in which to grow them, and when they have done their work for the season and are planted out of doors the remaining soil will be suitable for the following crop (Tomatoes). It will need turning over and sweetening a little for them. Callas sell well, and realise a good price if the spathes are what is desired—viz., fresh and free from blotches. I find Campbell's fumigating rolls effectual preventives of insects and safe if the directions given with them are followed properly. The syringe must not be spared until the plants are opening their blooms, but it is best to fumigate just before they open. Arums must be kept clean and be watered abundantly.

Next, in my estimation, would be Roses—Tea, Noisette, and a few Hybrid Perpetuals. The Mushroom beds beneath the stages, on which the pot Roses stand, would benefit and help them by supplying ammonia. "Perplexed One" will find this without doubt one "crack at the nut." The Roses will require pruning and repotting, or top-dressing as the case may be, in September, and started gradually into growth, syringing freely. Roses do not like too dry or too wet an atmosphere, hence light and air are of the utmost importance to profitable Rose growing. Then, again, Strawberries may be utilised.

One house at least should be devoted to Chrysanthemums, and I do not myself see why Chrysanthemum houses, followed by bulbs, *Spiræa japonica*, *Dielytra spectabilis*, and other good plants, not excluding Lily of the Valley, should not pay. Adiantums potted in early autumn would prove very useful now. Tuberoses require strong heat to bring them to perfection; and if these were grown it would be necessary to have a house especially for them, and therefore would not pay so well as the aforesaid. I should not advise "Perplexed One" to venture on Orchid growing with a view to profit, unless he is an expert or employs one.—JOHN MCPHERSON, *Duffield*.

"WHAT to use Tomato houses for in the winter with a view to profit?" Such is the query on page 137, February 11th, 1895. My experience is that Tomato houses may prove more profitable during the winter months than when used solely for Tomatoes in the summer, as when there is a glut of fruit prices run very low. In several provincial towns last summer really good Tomatoes were sold at 4d. per pound, from this price to 6d. per pound was the wholesale price for the best quality of English grown fruit. These prices ranged for from six to eight weeks; earlier and later the best Tomatoes were worth more money. Mine averaged a trifle over 6d. per pound. Out of this had to be paid railway charges, market tolls, and salesman's commission. It may be said there is not much profit at that price, but when one grower sends hundreds of tons of fruit to market in a season (and there are some who do so), it is the quantity that pays.

But what to grow in the winter? Although the paragraph quoted from a contemporary is before my eyes, in which Chrysanthemums are stated to be selling at 2s. 6d. the dozen bunches—twelve blooms in a bunch—I should still advise a considerable number to be grown, as on referring to my books at the time of year mentioned (end of December), I was making 36s. for the same number of blooms. This was the price made in Covent Garden Market by a well-known salesman. These were cut from plants especially grown for the purpose. Our aim should be—whether in cultivating fruit or flowers for market or home consumption—to endeavour to grow each and all to as great perfection as it is possible. Some people appear to think anything will do for the market, but after a trial they will find out to their cost that it is only the best, whether in fruit or flowers, that will make top prices. I know of nothing that will illustrate my meaning better than marketing Peaches. During the London season a large well-coloured Peach will make 2s. 6d., whereas one half the size from the same tree will only make a few coppers. But Chrysanthemums can be grown to pay even at 2s. 6d. a dozen bunches where land is plentiful and cheap. Plant out the Chrysanthemums in rows 3 feet apart. This should be done as soon as all danger of frost is past in the spring. Stop the plants two or three times during the season. They will make rapid growth, and will need no further attention, only in keeping the weeds down. Early in October the plants should be lifted and placed on the floor of the Tomato house, making the soil as firm as possible about the roots, settling all in with a good soaking of water. If the operation is carefully carried out the plants will not suffer in the least, and the grower will be rewarded with a greater crop of flowers, many more than can be grown under any other system. Consequently, if the returns are small for each consignment, they will still pay in the aggregate if the bulk is large. But for quality and high prices select a couple of good late varieties, white for preference. Grow them in pots throughout the summer, and disbud from fifteen to eighteen blooms each. Cut the flowers with long stems, and they will make the highest market price.

"Arum Lilies" (*Richardias*) should be extensively grown, and if planted out during the summer months be lifted early in September before they have made much growth, and stood out of doors for a month, finally being placed in a cool house, then allowed to come on slowly,

they will flower freely at Christmas, when their spathes are much in demand and prices high. Another plan of growing Arums which I consider preferable to the above, instead of planting them out in the spring, is to gradually dry them off in the open. Should the weather be showery lay the pots on their sides; the foliage will then die down. As soon as they commence growing, which they usually do in July, they are shaken out and potted in good soil; they then grow freely and experience no check, as they sometimes do when planted out and left too long before being lifted.

Lily of the Valley may also be extensively grown in Tomato houses provided they are heated. These are always saleable, and command a good price if well grown with abundance of their own foliage. Bulbs, such as Tulips, Narcissus, and white Hyacinths, can be profitably grown. Many other things will occur to the close observer; and last, but not least, if there is an ample supply of manure to hand Mushrooms would be as much at home in the Tomato house as in the most elaborately built Mushroom house. As I have endeavoured to crack the nut your correspondent has so ably brought forward I am inclined to give him one in return, to show that by leaving the beaten track an extra profit may sometimes be obtained when least expected.

A frame of eleven sashes in which Tomatoes had been grown for several seasons past was planted the last week in May with something else as an experiment. The crop was cleared out early in September; its value was £20. One of your staff saw the crop, and thought he had never seen such a show in a frame before. Had the frame been planted with Tomatoes the outside value would not have been more than £5. A few years ago I tried an experiment, with the result that during the past few weeks I have realised upwards of £22 from what would otherwise have been a bare wall at the back of one of the houses.—ONE OF THE CRAFT.

[Our correspondent does not disclose his £20 nuts. Is he reserving them for the medal? The conditions are now ready, and will be posted during the week to persons who have applied for them, and they will be posted to others who may apply within a fortnight of the date of our present issue. The subject to be treated is "The Profitable Employment of Glass Structures in Winter." If two essays, in which different subjects are treated by different persons, are considered equally meritorious a medal will be granted for each of the essays.]

#### JAPANESE CHRYSANTHEMUM AUDIT.

ALL Chrysanthemum fanciers should feel indebted both to Mr Molyneux and the Journal for making an effort to place before the public a list of the very best varieties up to date. This year's audit possesses the same weak point as the one of 1894—viz., that many voters included varieties of which they have had no experience, and perhaps only known by repute, according as the variety had been "boomed." Compared with 1894 the late audit for thirty-six shows but little change. Louise, Duke of York, Primrose League, Niveus, and V. Hambleton have had a considerable rise, whilst Lord Brooke, J. Shrimpton, and Excelsior have fallen. It would be safe to predict that another season will find these much lower, together with Avalanche, Waban, G. W. Caidls, Mrs. E. W. Clarke, Viscountess Hambleton, and Primrose League will be thought less of from this date; whilst Mons. A. Giourd, Richard Dean, Duchess of Wellington, Wilfred Marshall, Madame Ad. Chatin, Cecil Wray, Mrs. Dr. Ward will have risen much in public opinion.

Now a word to show the weak point of the audit. Both in the "thirty-six" and "twelve" classes we find varieties which have never been grown in England—e.g., Duchess of York, Philadelphia, and Directeur Tisserand. Again, some are untried seedlings, one standing the highest being Mrs. C. E. Shea, truly a monster; but the only bloom yet grown is the one produced by the seedling plant. I have no wish to disparage these varieties, but without some trial no one is justified in recommending them as "the best." Duchess of York is a variety no good grower can afford to miss, for as shown on October 12th it was grand; but to prove my case I have only to mention Beauty of Exmouth. The stand of nine blooms exhibited at the October, 1892, meeting of the N.C.S., caused a sensation, and it is beyond doubt no other novelty with me ever "took on" so well, but after two years' trial what is the result? Why from some unaccountable cause this variety does not seem to do well.

Many are of the opinion that the audits should be for thirty-six varieties, old and new, and for twelve novelties, all of which the voter has grown, and to this I would add a class for twelve, which the voter had seen and not grown, but exclude all he had heard about only. Two varieties mentioned in the audit are J. Agate and C. H. Curtis, both of which have been certificated by the N.C.S. as incurved. The first named undoubtedly is a fine addition to the class, but C. H. Curtis, in my opinion, will require another season to learn as to which class it should be relegated.

The difference in the number of votes for thirty-six and twelve is most peculiar, many voters seeming to have a vague idea as to which

are novelties, and otherwise. For the twelve new varieties over 150 are mentioned, and out of this number Louise stands No. 9 with fourteen votes, and No. 16 with fifteen votes in the thirty-six class. Duke of York is placed 47 with three votes only in the "twelves," and No. 17 with fifty-one votes in the "thirty-sixes," whilst Chas. Davis is not mentioned among the twelve new ones, but is voted for by every one of the sixty-nine electors as one of the best thirty-six. Now, as to novelty. The latter has the prior claim of the three I quote. Louise was sent out by Calvat in 1892, and catalogued by the English trade in 1893, whilst Chas. Davis was not sent out until May, 1893, and both were certificated at the same meeting of the N.C.S. in that year. Duke of York was also sent out the same year, and with C. Davis and Louise were mentioned in the audit of last year. By the way, it is worthy of remark that Duke of York has not yet been certificated by the N.C.S., and in spite of this fact it obtains fifty-one votes out of a possible sixty-nine, and, according to the Year Book of the N.C.S., was found in twenty-two stands of the last November exhibition of that Society. I annex a table showing the peculiarity of the voting on some varieties.

	No. of Votes. "36."	No. of Votes. 12 new.	Year Sent Out.
Chas. Davis ... ..	69	0	1893
Louise ... ..	52	14	1892
Duke of York... ..	51	3	1893
Niveus ... ..	47	20	1893
Miss Maggie Blenkiron ... ..	11	23	1894
Cecil Wray ... ..	1	2	1894
H. L. Sunderbruck ... ..	13	14	1893
Mons. Panckouche ... ..	30	10	1893
Wilfred Marshall ... ..	15	8	1894
Duchess of Welling'on ... ..	6	14	1894
Commandant Blusset ... ..	24	10	1893
Colonel Chasc... ..	15	6	1894
Violetta ... ..	4	10	1894
Hairy Wonder ... ..	1	13	1894
Rose Wynne ... ..	22	13	1894
Mrs. W. J. Godfrey ... ..	0	11	1895
Duchess of York ... ..	14	30	1895
Mrs. C. G. Hill ... ..	6	5	1894
Mrs. W. H. Lees ... ..	16	23	1894
Souvenir de Petit Ami ... ..	11	8	1892
Madame Carnot ... ..	13	21	1894

It is curious to note that whilst Madame Carnot only receives thirteen votes in the "thirty-sixes" it has twenty-one as one of the best twelve new, whilst Wilfred Marshall has fifteen in the "thirty-sixes," and only eight in the "twelves." Surely if it has fifteen in the thirty-six it should have more as a novelty, being sent out during 1894?—W. J. GODFREY, *Exmouth*.

#### THE "CHRYSANTHEMUM YEAR BOOK."

I AM OF "Fairplay's" opinion that the illustrations in the N.C.S. Year Book are too exclusive. There were plenty of illustrations to select from without using the whole of one firm's blocks. If the selected new varieties in the Year Book are to be our guide in the future, what price first-class certificates? I notice many varieties are left out in the cold and not considered worthy of mention by the writer of selected novelties.—NOT FAIRPLAY.

MR. C. H. PAYNE (page 168) seems displeased that I did not criticise this publication generally. Time would not allow of it. Some of the chapters are good, some fair, others indifferent, but that on "Japanese Novelties of 1895" is, in my view, distinctly misleading. It is quite probable that within a few years the book in question will be referred to as an authority, and it must cause many to believe that the varieties mentioned were novelties of 1895, whereas some of them were introduced and certificated in 1893. Mr. Harman Payne says, "What a novelty is depends on individual opinion." Surely he does not wish the world to believe that, in the opinion of Mr. H. J. Jones, varieties sent out in 1893 are novelties of 1895? Mr. Harman Payne also says that I have analysed the list unfairly, and in attempting to prove this charge against me gives a list of the various raisers. These have little to do with the question I have brought forward. When a raiser has sold a variety to a distributor the pecuniary interest belongs to the latter, and out of twenty-seven varieties sent out by English firms sixteen were in the interest of the writer of the chapter, whilst the remaining eleven varieties were distributed by five others. As to the illustrations, the same remark applies. The writer of the chapter is mainly interested in the sale of them, and to illustrate the varieties of one firm only is unfair to those trade growers who have done so much in raising and distributing many sterling varieties as we now possess.—FAIRPLAY.

#### NATIONAL CHRYSANTHEMUM SOCIETY.

THE annual general meeting of the above Society was held at Anderton's Hotel, Fleet Street, E. C., on Monday evening, February 25th, a goodly number of members being in attendance. Mr. Chas. E. Shea was unanimously elected to the chair, and called upon the Secretary, Mr. R. Dean, to read the annual report of 1895, which, together with the balance-sheet of the Society, are appended below:—

#### ANNUAL REPORT.

"It is with the liveliest satisfaction the Committee are able to heartily congratulate the members upon another year of growing prosperity.

This is shown by the fact that eleven Fellows and 130 ordinary members have been elected, and the unusually large number of nineteen societies received into affiliation. This assuring growth in numbers is emphatic testimony to the widening influence exerted by the Society at home and abroad; and also to the high estimation in which the Chrysanthemum is held as an exhibition flower.

"The various shows fully maintained their reputation as the best in London. The display of early Chrysanthemums in September was small, owing to the somewhat unfavourable character of the season; but the fine collections of Dahlias and Gladioli amply compensated for any disappointment on this account. In October there was an imposing exhibition, equalling in quality the Chrysanthemums seen in November. The Great Autumn Fête in November is unquestionably the largest show of the 'Golden Flower' held in the United Kingdom, and a much more extended space for staging was required than in the previous year. On this occasion there were five competitors among the Societies in affiliation for the possession of the valuable challenge trophy, which was won by the Bromley Chrysanthemum Society. The large number of illustrations showing the decorative value of the Chrysanthemum so prominent at the November Fête were so attractive in design and execution that they called forth the loftiest praise from the general and horticultural Press.

"The exhibition held in the early part of December surpassed all expectations; the display of Japanese varieties in particular was very fine. The Committee are under great obligation to the trade for the valuable miscellaneous collections contributed to all the shows, combining as they do so much variety and interest.

"The meetings of the Floral Committee brought together a considerable number of new varieties, and that body is to be congratulated upon the caution exercised in making awards to novelties, selecting only those of the highest excellence. A desire has been expressed that the meetings of this body be held oftener during the months of October and November, a matter which will be considered by the General Committee.

"The preparation and issuing of a new supplemental catalogue is one of the agreeable incidents of the past year, bringing that important feature of the Society's work up to date. It is satisfactory to know it is in brisk demand. A 'Chrysanthemum Year Book' is a new and welcome addition to the Society's literary work, and promises to be a

financial success. In each case the editorial direction was confided to Mr. C. Harman Payne, who deserves well of the Society for his able oversight.

"Mr. E. C. Jukes having found it obligatory upon him at the end of last year to retire from the office of Vice-Chairman of the Committee he had held for several years, the members placed on record their great sense of the services he had rendered to the Society, and a suitable illuminated address on vellum, signed by the officers of the Society, was presented to Mr. Jukes by the President, at a special general meeting held in May last.

"The Committee have arranged for the holding of three exhibitions at the Royal Aquarium during the months of October, November, and December; and a Dahlia show will be held by the Royal Aquarium Society in September, as heretofore, at which prizes will be offered by this Society for early Chrysanthemums, and these will be supplemented by a grant of £10 for Dahlias. Some substantial additions have been made to the prize money in the specimen plant classes at the November show.

"Certain amendments to the rules recommended by the General Committee have been drafted for acceptance by the General Meeting. They give greater scope to the operations of the Society and augment the privileges of members.

"The President of the Society (Sir E. Saunders) continues his warm interest in its welfare and work, manifesting it in several gratifying ways, and particularly by his generous gift of a piece of plate as the President's prize at the November exhibition.

"It is with the greatest regret the Committee have learned the resolve of Mr. Robert Ballantine to retire from the position of Chairman of the General Committee. Appointed Vice-President in 1879, he ten years later became Chairman on the retirement of the late Mr. E. Sanderson—a post he has filled with great credit to himself and advantage to the Society, whose best interests he has always promoted to the utmost. Pressure of business engagements, with other considerations, actuates him in taking a course the Committee so much deplore. There is, however, reason to hope Mr. Ballantine's exertions in promoting the best interests of the Society may be continued as a member of the General Committee.

"To all donors of special prizes the Committee tender their grateful thanks, assuring them such welcome assistance is highly appreciated."

Compared with the vouchers and found correct.  
 (Signed) HENRY WILLIAMS, } Auditors.  
 THOMAS C. WARD. }  
 February 21st, 1895. RICHARD DEAN, Hon. Secretary.

The Chairman, on moving the adoption of the report, said there was little need for him to comment upon it, as the balance-sheet was very satisfactory, which in these days of depression was an important matter. Chrysanthemum growers had supported the Society, and he was glad to say it was making substantial, healthy, and real progress, and they might congratulate each other on its great success. Mr. D. B. Crane seconded the proposition, which was carried unanimously.

A vote of thanks to the Auditors, Mr. H. Williams and Mr. T. C. Ward, was proposed by Mr. Berridge and carried. The Chairman then

proposed Sir Edwin Saunders as President of the Society for the ensuing year, thanking him for his liberality and kindness in the past, and adding that the Society were fortunate to obtain the benefits of his services. This was seconded by Mr. Briscoe-Ironside, and carried amidst applause.

Mr. G. Langdon moved that Mr. W. R. Starling should again be elected Treasurer. This was seconded by Mr. Davy, and carried. Mr. T. W. Sander then proposed Mr. B. Wynne as Chairman of the Committee in place of Mr. R. Ballantine, who declined re-election. This

was seconded by Mr. Bevan, and carried. A hearty vote of thanks was proposed by Mr. Geo. Gordon to Mr. R. Ballantine for his past services to the Society, and said that this meeting of members places on record its high sense of the great services rendered to the National Chrysanthemum Society by Mr. Robert Ballantine since the year 1879, first as Vice-President of the Society up to 1889, and subsequently as Chairman of the General Committee. That it has learned with sincere regret that circumstances necessitate Mr. Ballantine's retirement from this important post, and takes this opportunity of tendering him a most hearty and enthusiastic vote of thanks. That it has been referred to the General Committee to take such steps as may appear desirable to mark in some appropriate manner the high esteem in which Mr. Ballantine is held by the members. Mr. H. Cannell, in seconding the proposition, spoke highly of Mr. Ballantine's services in a few appropriate words.

There were several proposals for the office of Vice-Chairman, which, however, after some little discussion, were reduced to one, Mr. T. W. Sander, who was duly elected. Mr. C. Harman Payne was re-elected as Foreign Secretary, and Mr. G. C. Ingram was elected Auditor with Mr. T. C. Ward in place of Mr. H. Williams, who retires. The proposition for the re-election of the Secretary, Mr. R. Dean, was moved by Captain Hicks and carried unanimously. Mr. T. Bevan proposed that the Secretary's remuneration should be raised to £75 per annum, a motion which was referred to the General Committee.

Some discussion followed as to the alteration of certain rules as recommended by the General Committee, resulting in the adoption of the following:—

Delete rules IV. and V., and substitute the following:—

**RULE IV.—*Fellows and Honorary Fellows.***—"All persons subscribing 1 guinea and upwards per annum shall be designated Fellows of the Society. Honorary Fellows shall consist of those who by reason of conspicuous service rendered to the Chrysanthemum have earned a title to some special recognition by the Society. Honorary Fellows shall participate in all the advantages of membership without payment of any subscription."

**RULE V.—*Members.***—"The annual subscription of a member shall not be less than 5s. Subscriptions are due on the first day of March in each year. Foreign members shall be admitted to all the privileges of the Society on such terms as the General Committee may from time to time determine."

**RULE VI.—*Election of Fellows and Members.***—"Every candidate for admission as a Fellow or member of the Society must be proposed by a member, and elected by a show of hands at a meeting of the General Committee, held in accordance with the rules, or at the annual general meeting or any general meeting of the Society, and no candidate who may be rejected shall be eligible for re-nomination. The election of Honorary Fellows shall take place at the annual general meeting, and nominations for Honorary Fellowships must first be recommended by the General Committee."

**RULE VII.—*Privileges.***—"All Fellows and members shall be entitled to vote at the general meetings of the Society. Fellows shall be entitled to four passes; members subscribing half a guinea to two passes; and those subscribing 5s. to one pass, to all the Society's exhibitions and meetings of the Floral Committee. Members desiring to withdraw from the Society must give notice on or before March 1st, otherwise the subscription for the current year must be paid. The Committee shall have power to remove from the roll of membership the name of any person whose subscription for the past year shall not have been paid by the 1st of March following."

**RULE VIII.—*Affiliated Societies.***—"At the end of the rule add the following:—

"NOTE.—No medal or medals of the National Chrysanthemum Society offered for competition at any exhibition of an affiliated society can be supplied to any person or persons other than the secretary of that society. No medal or medals after being ordered by an affiliated society and duly supplied can be returned."

**RULE IX.—**Line 3, after "General Committee," add "*and.*"

Line 4, after "shall be elected," add "*by ballot*" as set forth in Rule 3.

The following were duly elected by ballot as the Committee for the ensuing year out of seventeen proposed:—Mr. G. S. Addison, Rosebank, Thornton Heath, 41 votes; Mr. T. Bevan, St. Marylebone Cemetery, East Finchley, 49; Mr. H. Cannell, Swanley, Kent, 25; Mr. W. Herbert Fowler, Taunton, 23; Mr. J. P. Kendall, Templeton Gardens, Roehampton, 31; Mr. G. Langdon, 45, Walsingham Road, Clapton, 52; Mr. E. Rowbottom, Priory Road, Hornsey, N., 38; Mr. A. Taylor, 5, Vernon Terrace, East Finchley, 49; Mr. T. L. Turk, Highgate, N., 32; Mr. W. Daniels, 33; Mr. C. F. Yeoman, 32; Mr. F. Gilks, 30; Mr. J. T. Simpson, 34; Mr. W. Higgs, 30.

Mr. R. Dean then proposed a vote of thanks to Mr. C. E. Shea for the able manner in which he had occupied the chair, this was seconded by Mr. Briscoe-Ironside, and carried amidst great applause.

Mr. C. E. Shea replied in a few appropriate words, and the meeting was then brought to a close.

## THE HISTORY AND CULTIVATION OF THE TOMATO.

AT a recent meeting of the Birmingham Gardeners' Mutual Improvement Association, held at the Athletic Institute, Mr. J. B. Latham in the chair, a paper was read by Mr. A. Coombes, gardener to the Dowager

Countess of Dudley, Himley Hall, on the above subject. The essayist dealt with his subject in a most interesting and practical manner.

In adverting to the history of the Tomato, Mr. Coombes—remarking that it was introduced into this country in 1596 under the scientific cognomen of *Solanum Lycopersicum*, and quoting from "Macdonald's Gardeners' Dictionary," published in 1807—observed that it was described as an annual plant with an herbaceous, branching, hairy stalk, rising to a height of 6 to 8 feet if supported, otherwise the branches will fall to the ground; and that Miller has found two sorts only, the first as being commonly cultivated in the South of Europe, to put into sauces and soups, to which it imparts an agreeable acid flavour, and fruit very large, compressed both top and bottom, deeply furrowed all over the sides, of a red or yellow colour; the latter sort round, about the size of a small Cherry, either red or yellow, flowering from July to September; but not a word as to cultivation, which omission leads one to believe that the fruit at that time was not in request in this country.

Miller described five species under the generic name of *Lycopersicum*. Curiously, however, neither author gives the date (1596) of the Tomato's introduction into this country. Miller, however, gives a short description of its culture, recommending the seeds to be sown on a hotbed in March, transplant when fit to handle on another moderate hotbed, pot up in May or into the borders of the flower garden; the plants will grow to a prodigious size and produce large quantities of fruit, which in autumn, when they are ripe, will make an odd figure; but the plants emit so strong an effluvia as renders them unfit to stand near a habitation or any place that is much frequented, for being brushed by the clothes they send forth a very strong disagreeable scent. He goes on further to say that the Italians and Spaniards eat these Apples as we do Cucumbers, with pepper, oil, and salt, and some eat them stewed in sauces, &c.; but considering their great moisture and coldness, the nourishment they afford must be bad. He also says that the yellow-fruited variety—presumably *Chrysocarpum*—as the Love Apple, directed for medicinal use by the colleges in Italian dispensatory. Altogether, we have a rather remarkable contrast with the present-time estimation of the fruit. In 1827 a writer in the "Gardeners' Magazine" remarks at considerable length of the culture, including *Leucocarpum*, or the white-fruited variety, and used in this country, also in Naples, Rome, and France.

After giving a lengthened and exhaustive treatment of the culture of the Tomato, and including a long list of the best known sorts, selecting himself, if confined to a small number of varieties, Challenger, Webb's Regina, Ham Green, and Frogmore Selected. Polegate he considered to be one of the very best.

In concluding the reading of a well-thought-out and instructive paper, he suggested that in addition to the usual mode of exhibiting Tomatoes—*i.e.*, fruits singly—prizes should be offered for the fruit as grown in the hunch form, the better to test the special merits of the varieties and the practical ability of the grower—a hint which was unanimously acquiesced in by those present. Responding to the vote of thanks accorded him, Mr. Coombes confessed that this was the first time that he had ever written a paper on horticultural matters, or had the pleasure of addressing an audience.

## GLOXINIA CULTURE.

ALTHOUGH these beautiful plants are more generally regarded as summer flowering, they may by a little judicious management be had in flower nine or ten months out of the twelve. I will endeavour to point out how this end may be obtained.

Tubers that were properly dried or ripened in the autumn, and which have since been kept in a temperature of from 45° to 55°, will now begin to show signs of activity. The earliest should be placed in a temperature of 65° to 70° in a position near the glass, and must not be disturbed at the roots under any consideration, but gradually supplied with water of the same temperature as the house. Great care must at all times be exercised not to keep them too wet, or to allow any water to lodge on the foliage, as they are very impatient of any neglect in this respect. Providing all due care and attention is bestowed on them they will quickly commence to throw up their flowers, and as soon as this stage is reached liquid manure may be applied twice a week with beneficial effect. My plants, which were started during the last week of the old year, are now just showing for bloom.

In the potting of Gloxinias there arises a case of "where doctors differ, who shall decide?" Some growers recommending shaking all the old soil away from the tubers, whilst others say, Do not remove any but simply give them a size larger pot; but my own experience pertaining to the subject is as follows:—Give the tubers a good watering the day previous to that in which they are to be potted, well soaking the ball of soil all the way through. The next morning the superfluous water will all be drained away, and potting may be proceeded with. Turn the tubers out of the pots, remove about half of the soil, and place them in the same sized pots. Any that were not well soaked should be immersed in water, for to pot them in a dry state is only to court failure. As the pots become full of roots the plants may be shifted once or twice till they reach 7 or 8-inch pots, which are sufficiently large for general decorative purposes. A light rich soil should be given, making it moderately firm.

After the earliest plants have done flowering they should be gradually dried, placed in a cold frame, and allowed to rest for two or three months, when they may be placed in heat and treated in the way recommended. By this means a continuation of bloom may be obtained from the middle of February till well into December. Seeds if sown at

once, and the young plants flowered in small pots, will, if rested for two or three months, also supply flowers during the autumn, but the result to my mind is not so satisfactory as that attained when one or two-year-old tubers are employed.—GEO. PARRANT, *Ashby Lodge, Rugby*.

### RHODODENDRON TRIFLORUM.

A CORRESPONDENT desires information about this *Rhododendron*, and probably the note appended with the illustration (fig. 36) will be of assistance to him.

This is a rare and very curious species, discovered by Sir J. D. Hooker in Sikkim, Himalaya. The colour is yellow, and the florets are not unlike those of *Azalea pontica*. The habit of the plant, however, is evergreen, and the backs of the leaves are profusely sprinkled with scales, bringing it more into affinity with *R. ciliatum*, *glaucom*, and *cinnabarinum*. It seldom flowers as a small plant, which is a drawback; but, on the other hand, it is perfectly hardy, blooming too late in the season to be affected by the spring frosts.

### WORN-OUT ORCHARD TREES.

THIS was the subject of a paper read before the members of the Brighton and Sussex Horticultural Society at their monthly meeting on Thursday, February 21st, by Mr. A. M. Kemp, gardener to C. S. S. Dickens, Esq., Coolhurst.

Mr. Kemp in the first place described the state of an old orchard which came under his charge about seven years ago. The trees had been pruned to keep them from spreading outward, but the centres were full of dead and dying wood, the branches moss-grown. They bore but little fruit, and that little was so small as to be practically worthless. To remedy this miserable state of affairs the dead wood and cross branches were taken out, leaving the centres open and the main branches evenly disposed. The trees were then cleaned and washed with a mixture of lime and soot. To restore fertility a very cheap and effectual remedy was found in the rubbish heap. A little lime is added to this, and the whole turned over occasionally. Since starting operations this mixture has been liberally used as a top-dressing in the autumn or winter, and in addition sewage water has been applied.

The result of this treatment has proved most satisfactory. The trees have made clean, well-ripened wood, and now bear good crops of clean, fully developed fruit. In proof of this Mr. Kemp showed dishes of fruit of the leading sorts in splendid condition, pointing out that he had brought duplicate dishes to show the superiority of the fruits gathered from the young wood over those from the old spurs.

Some discussion followed, and in reply to a question as to how the fruit had been kept in such fine condition, Mr. Kemp stated that they had been kept on the floor of an old summer house in heaps as they were gathered from the trees, there being no boards, straw, or anything of a nature to absorb the moisture from them. The room is ventilated, and a fire is lit in an ordinary fireplace when there is danger of frost getting in. A hearty vote of thanks was given to Mr. Kemp for his paper. The Chairman, Mr. Balchin, in putting it to the meeting, remarked that Mr. Kemp's success might lead others to consider whether they will not be doing better by trying similar treatment of exhausted Apple trees.—R. I.

### CULTURE OF DAPHNE INDICA.

FEW of our intermediate or greenhouse flowering plants possess a more agreeable perfume, or call for greater admiration, than healthy well grown plants of *Daphne indica rubra* or *alba*. A common error into which many people fall is in thinking that the only way to succeed with the *Daphne* is to grow grafted plants, the stock used mostly being *Daphne Laureola*, whereas fine bushes may be produced from cuttings, although I admit that larger plants may sooner be obtained by grafting.

In many places old plants will have gone out of flower, and if placed in a genial temperature will be pushing out new shoots in abundance. These when about  $2\frac{1}{2}$  or  $3\frac{1}{2}$  inches long and fairly matured should be taken with a heel, inserting four cuttings in a  $3\frac{1}{2}$ -inch pot, using a light compost with a surfacing of silver sand. Carefully water them through a fine rose, and remove to a cool greenhouse. In about six weeks with careful attention they may be introduced into heat—a little bottom heat if possible—when they will soon begin to emit roots. When ready for potting carefully crock some small pots, as nothing suffers sooner from being waterlogged, using peat and leaf mould in equal proportions as the compost. Place in a house with a fair amount of heat and moisture, pinching out the points when fairly on the move, as this will induce them to break, and lay the foundation for a good plant.

If strict attention has been paid to the young plants they will probably be ready for a second shift about the end of July or early in August, using pots 1 or 2 inches larger, the compost being three parts good fibrous peat, with a little fibrous loam and leaf mould, and a liberal part of coarse silver sand. In the autumn a cooler temperature will suit them. In February they may be introduced into more heat, when they will readily break into growth. The secret in securing fine sturdy plants is to give the heat in the spring and the early summer. By so doing the growths are strong and the buds soon set. The plants enjoy a season of rest during the waning months of the year, and readily respond to the

warmth, and can then be brought forward as required. We have one large specimen some 5 feet 6 inches high and 4 feet through, which stands in the conservatory during the *Chrysanthemum* season. It is in splendid condition, although it has not been potted for fourteen years, a top-dressing each season is all it seems to require. For two weeks in August and all September it is placed in the open air.

The only insect injurious to the *Daphne* is the mealy bug. If not removed this pest will find its way into the trusses of flower, rendering them almost worthless. Syringing a few times with one of the many insecticides in the spring will in nearly every case do away with it.—R. P. R.

### FORTY DEGREES BELOW ZERO.

THE extraordinary severity of our recent winter may incline many to ask, "If it is like this at  $15^{\circ}$  or  $20^{\circ}$  of frost, what must it be  $40^{\circ}$  or  $50^{\circ}$ , or even  $70^{\circ}$  below zero? What must it be in the Arctic regions?" And as regards the Arctic regions, at any rate, the question is not an idle one. The object of Arctic exploration is mainly scientific; its records

FIG. 36.—RHODODENDRON TRIFLORUM.

are written in a scientific spirit and in scientific terms; and such natural illustrations of the action of Arctic cold as do occur are so easily lost sight of amidst the mass of purely scientific data as to be of little value to the general reader. Yet without some knowledge of their practical bearing the figures, "40 below" or "70 below" convey to the mind next to nothing.

Now, I was never in the Arctic regions, so can say nothing about the practical aspect of Arctic cold at its worst. The  $70\frac{1}{2}^{\circ}$  below zero recorded by the "Discovery" in 1875, which stood at that time as "the greatest cold ever experienced by any Polar expedition," is a good deal beyond my figure. But of  $40^{\circ}$  below zero I do know something, since for six successive winters I lived where that figure is invariably reached and sometimes passed. A few homely illustrations of a North Dakota winter may prove not uninteresting, and ought to give a more vivid impression of the action of intense cold than can be gained from thermometrical records alone.

Generally speaking, winter in North Dakota sets in during the latter part of November, and begins to break up in April. The lakes and sloughs are soon fit to walk on, and the ice continues to increase in thickness as the winter progresses. Occasional warm, balmy days occur throughout the winter, but these do little to retard the steady progress of the frost. In this country we reckon the thickness of ice by inches; in North Dakota by feet. Six inches is in Great Britain of extremely rare occurrence. In North Dakota I have myself cut ice on Devil's Lake which was 6 feet thick. The ground freezes to a depth of 7 feet, and I have lifted fence-posts out of the ground late in the summer which at the end were covered with hard, frosty earth. Indeed, it is doubtful if the frost is ever fairly out of the ground.

Wells, which in the Devil's Lake region generally vary from 20 to 40 feet in depth, freeze over unless covered in on the top. During keen weather water freezes almost as quickly as it is drawn up, and the buckets after a few applications have to be taken in and thawed out. Water poured on ice during such weather makes it crack and split like lime. Metal when touched seems red-hot, and the unwary one who

places his hand on the tire of a waggon is safe to leave a frizzling shred or two of skin behind him.

The action of the cold on the human body is not less remarkable, and the man who would provide adequately against it has to carry quite a little wardrobe on his person, including, besides the other usual requirements of dress, two pairs of trousers, two pairs of mitts, heavy felt wool-packs coming up to the knee, and lined cloth shoes over these again; fur cap drawing over the ears, and heavy overcoat of buffalo or other warm fur. A silk handkerchief tied across the mouth and nose is an admirable protection for these members.

A neglect of any of the above precautions is apt to entail the penalty of frozen feet, fingers, ears, or nose, as the case may be. Frost-bite announces itself by a momentary stinging sensation like that of a fine red-hot needle. If the warning is unnoticed the affected part becomes white; the pain has gone, and you may proceed without knowing that anything is wrong until happily someone comes the other way and spies the danger signal. Nature's remedy is always close at hand—a handful of snow—and with this the injured part is vigorously rubbed. By this means the frost is drawn out, and the affected member, restored to more than its usual colour and twice its natural size, may still look forward to days of usefulness. Still better than snow for extracting frost is kerosene or coal oil. Frost-bitten feet, when placed in a pan of cold water, will send up a skim of ice to the surface. On no account should heat be applied, as its effect is to drive the frost in instead of drawing it out, and if the frost strikes into the bone the consequences are serious.

Strange as it may seem, the period of intensest cold is not that associated with the greatest loss of life. As the thermometer falls the wind falls, till at 30° or 40° below zero there is usually a dead calm; consequently during December and January there is little to fear for the most part but the odd chance of a frost-bite, and a person warmly clad can go about freely anywhere. February and March, with a rising thermometer, are the chosen months of the dreaded blizzard, when the wind rises to a tornado, and snow from sky and ground are mingled in one seething boiling mass. The blizzard attains its greatest violence further south—in South Dakota, Iowa, and Minnesota—where men have been known to lose their way between the house and the barn, and their frozen bodies have been discovered after the storm only a few hundred yards from their own dwelling. In such places it is usual on the approach of a blizzard to have a line stretched from the house to the barn, along which one may feel his way through the dense thickness of the storm. By this means stock can be attended to in any weather absolutely without risk.

The foregoing are only a few familiar illustrations of a North Dakota winter; but the record, meagre as it is, may seem strange enough when we consider that North Dakota is in pretty nearly the same latitude as the middle of France. And yet there are compensations here as elsewhere—wonderful evidence of adaptation to the most beneficent purposes. The frost stored up during the winter yields to the growing plant a supply of moisture and coolness that carry it safely through the drought of summer, when otherwise it would droop and die. The hardy farmer of the North-West is far from grumbling at the length or severity of the winters, for they have helped to make it the greatest Wheat-growing centre of the world—the home of the famous “No. 1 Hard.”—A DAKOTAN (in the *Pall Mall Gazette*).

#### FRUIT FORCING.

**Pines.**—*Plants Starting into Fruit.*—The plants of Queens, Enville, and Providence, selected last December and started at the new year by an advanced temperature and increase of moisture, will now be showing fruit sturdily, providing they have a position well up to the light, with just sufficient space for developing the fruit and crown without touching the glass. As it is advisable to accelerate the ripening of the fruit of these plants as much as possible the temperature may be maintained at 65° to 70° at night and 75° to 80° in the daytime under favourable circumstances, ventilating at 80°, allowing an advance to 85° and closing at about that temperature, utilising the sun heat as much as possible, but not by keeping the house very close and moist in the early part of the day. The plants will require more water at the roots as they advance in fruit development; therefore examine the soil once a week, affording a supply to such as need it, always thoroughly moistening the compost and having the liquid tepid with some stimulant in it, as that of guano, 1 lb. to 20 gallons of water. The guano contains salts that tend to promote a sturdy development of the fruit without unduly forcing leaf formation; but where the foliage has a tendency to softness a teaspoonful of common salt may be dissolved in every 3 gallons of liquid used for watering, not using this oftener than every fortnight. The plants that were started about the middle of this month to follow those above named should have a night temperature of 65°, and 70° to 75° by day artificially, ventilating from 80° and freely at 85°.

*Starting Suckers.*—The starting of these will have to be commenced early in March, hence attention must be given to the preparation of the

soil for potting and a fermenting bed in some suitable structure, such as a low house or pit that can be kept close and shaded, to generate and maintain a bottom heat of 85° to 90° near the surface, and with means of maintaining a top heat of 55° to 65° by artificial means with regularity.

**Vines.**—*Early Forced in Pots.*—Though Vines force well in pots there is no question that the best results are obtained from planted-out Vines, not necessarily those in large structures, but such as may be grown in low three-quarters span-roofed houses facing south, and with beds only slightly deeper than those for Cucumbers, Melons, or Tomatoes. Muscats, such as Madresfield Court, succeed admirably grown in that way, also Muscat of Alexandria when there is means of furnishing bottom heat, which is a great aid in all forcing operations. Black Hamburg and Buckland Sweetwater do better with than without the bottom heat, and on the planted-out than on the potted system. If the roots on this method cannot have the run of the fermenting bed place strips of zinc 3 or 4 inches deep round the top of the pots, inserting them just within the rim, and top-dress with rich turfy loam two parts, and one part decayed manure, on which may be sprinkled a tablespoonful to each pot of some approved fertiliser about every fortnight. Where the pots are plunged to the rims in the fermenting material, strips of turf may be laid over the rims so as to form the necessary dish, keeping the turves moist to encourage the roots to come over and spread in the fermenting bed, from which they will imbibe nutrient matter, greatly aiding the swelling of the berries. Supply liquid manure to the Vines at every watering, not keeping the soil sodden, but allowing it to become fairly dry, then afford a thorough supply. The berries swell best with a fair amount of lateral extension, especially above the fruit; therefore laterals below the bunches may be rubbed off or closely pinched as there is room, always allowing the light to act freely on the principal leaves. Careful treatment is required during the stoning process, which in the earliest started is nearly completed, ventilating at 70°, increasing it with sun heat to 85°, and close between that and 80°, if with an advance to 85° or 90°, so as to secure a long day's work, all the better. Keep a sharp look out for red spider, and sponge the first infested parts of the leaves with a weak (2 ozs. to a gallon of water) solution of softsoap, supplying guano water to the roots, and sprinkling the paths occasionally with it, but using it discreetly, a gallon at a strength of 1 oz. guano therein being sufficient for 12 square yards of surface. The paths, walls, and beds may be sprinkled two or three times a day with water, so as to maintain a genial condition of the atmosphere. In bad cases the hot-water pipes may be lightly coated with a thin cream formed of flowers of sulphur and skim milk, but there is danger of the fumes injuriously affecting the skin of the berries.

**Early Forced Planted Out Vines.**—Those started early in December will require the berries thinning, attention being given to this directly it can be seen which berries are properly fertilised by their taking the lead in swelling. Remove badly set and ill-shapen clusters, striving to secure a crop of compact, good shaped, well-furnished bunches, properly swelled berries, and perfect in colour and finish. Such only are satisfactory either for home use or marketing purposes. Allow laterals to extend beyond the fruit where there is room for the exposure of the foliage to light, but in no case must growth be encouraged to the prejudice of the principal leaves. Attend frequently to stopping, for the alternating checks to root action, consequent on removing large amounts of growths, nullify the accelerations of their formation, and are attended by bad consequences to both foliage and fruit. Maintain a night temperature of 60° to 65°, and 70° to 75° by day, advancing 10° to 15° from sun heat, commencing to ventilate from 70°, keeping through the day at 80° to 85° when the external conditions are favourable, closing between those temperatures, damping at the time. Afford thorough supplies of liquid manure to inside borders at such intervals as necessary for keeping the soil in a moist, healthy condition, supplying the liquid after moistening the soil with tepid water, or top-dress with chemical manure, and wash in. In the case of borders of open material or limited areas, mulch the border with about a couple of inches thickness of sweetened, short stable manure, material prepared as for Mushroom beds acting perfectly. If quite fresh there is danger of the ammonia evolved prejudicially affecting the foliage. Avoid syringing the Grapes, as however clear and soft the water may be there is danger of a sediment, which may not appear until the fruit ripens, and then it is a great blemish on an otherwise well-finished crop.

*Vines Started at the New Year.*—Attend to disbudding the Vines as the best shows can be determined, but it is wise to let this be plain, as any scrutiny of the points of the shoots by forcible means more or less damages the growth. It is also desirable to let the shoots grow up to the light, always attending to tying in time to prevent the points touching the glass, and in bringing down be careful not to snap the growth off at the base, or cause it to break at the point by too abrupt depression. Allow no more growth to remain than can have full exposure to the light, not only for the principal leaves, but a fair amount of lateral growth. Stopping is best attended to whilst the growths are forming, the leaf at the stopping joint being about the size of a half-penny. Allow at least two, and if possible three or four, joints beyond the bunch, stopping all laterals below the fruit at the first joint, or they may be rubbed off except from the two lowest leaves. The laterals from these should be pinched at the first leaf, and any subsequent growths from them pinch at every leaf; but those on a level with or above the bunch may be allowed to extend as space permits, always stopping early enough for securing subsequent growth and with space for its develop-

ment. When in flower afford a night temperature of 65° to 70°, with 10° to 15° rise from sun heat, closing at 80°. Vines set the fruit most satisfactorily when the atmospheric moisture is not excessive during the flowering period, but an over-dry atmosphere must be equally avoided. Artificial impregnation is desirable for the shy-setting varieties. In the case of Muscats fertilisation is a necessity, keeping the points of the bunches well up to the light, indeed, cross-fertilisation is attended with the best results both as regards setting the fruit, its swelling and perfecting.

*Early Muscat Houses.*—Although Muscats are frequently grown with Black Hamburgs and similar varieties they are far from satisfactory; indeed, they cannot be grown well together, as neither can have full justice. Muscats require inside borders, and early forced are better with bottom heat, for which they pay well, as Muscat of Alexandria in June bring far better prices than any other, and it is the quality Grapes that pay the grower, for the easily grown are produced in such quantities as to glut the markets. Houses that were set to work by the middle of December, after being closed a fortnight previously, have the bunches about flowering, and require a night temperature of 65° to 70°, with a rise of 10° to 15° by day, closing at 80° to 85° when bright weather prevails. When they commence flowering every bunch should be gone over with a large camel's-hair brush, for the purpose of removing the "caps," and then fertilise the same with Black Hamburg pollen, or preferably Alicante, as the cross of the thick-skinned on the thin-skinned varieties improves the cuticle of the berries, and the oval-shaped sorts better suit the conformation of Muscat of Alexandria than the round, which is apt to induce a rounded and somewhat irregular form to oval berried varieties.

*Midseason Uses.*—The Vines to afford ripe fruit in August and September of the Black Hamburg, Foster's Seedling, and similar type, must be started at once, and with the temperature kept at 50° by night, and 55° in the daytime from fire heat, with 65° from sun heat, they will break gradually and strongly. When movement takes place in the buds the temperature must be gradually raised, so as to bring the Vines into leaf, with 60° at night, 65° by day in cold weather, 70° to 75° with gleams of sun, and 10° to 15° advance on bright days. With starting in this way, the Vines will need little artificial heat during the months of June, July, and August, and having the benefit of the summer for growing and perfecting their fruit, better results will be attained than from starting late, and having to fire hard in late summer to perfect the crop.

*Late Vines.*—The thin-skinned varieties require a long time to grow and ripen fully for satisfactory keeping. Those started at the beginning of March have a chance to perfect the crop by the middle or end of September, but those not started before April usually are then only fairly commencing that process and the fire heat entailed to complete the ripening is often not only costly but ineffectual. The inside border must be brought into a thoroughly moist condition. Sprinkle the rods two or three times a day, maintaining a night temperature of 50° to 55° and 65° in the daytime, by which means the Vines will start freely, and having the whole of the summer to grow and mature their crops in, they will prove most satisfactory in produce and cost of production. Where the Vines have yet to be pruned and the house put in order, this should be attended to without delay. If the Vines are pruned and the temperature be kept low, there may not be any bleeding when started, provided the cuts are carefully dressed with Thomson's styptic or patent knotting immediately the wounds are dry after pruning. The dressing of the Vines is a needful precaution against insect and fungal pests, which to be of use necessitates the removal of the loose bark, without very close peeling and scraping into the quick. Remove the loose surface soil from the border and supply fresh turfy loam, using about half a pound of some approved fertiliser per square yard, which, distributed on the surface of the top-dressing, will get washed into the soil quite fast enough. The soil should be brought into a moderately moist state prior to the top-dressing, then sufficient moisture will arise for keeping the latter moist, and in that state it is far better as an encourager of root formation than when continual dribblings have to be given. Protect the stems of Vines in outside borders, and supply a top-dressing of sound enriching material, which will be all the protection necessary.

*Late Houses of Hamburgs.*—By keeping the structure cool and dry, and the border sufficiently moist to preserve the roots in sound condition, and ventilating fully at and above 50°, the Vines will start naturally when the mean temperature of the external air reaches 50°, or a little before, which usually takes place during April. The only assistance such Vines require is to maintain a temperature of 50° to 55° at night and on dull days, sun heat doing the rest of the work, for the crop sets by the early part of June, is swelled with the solar warmth, and a little fire heat in September, or after the Grapes commence colouring perfects the crops. Of course, sun heat must be husbanded during the summer months by early closing, and the Vines be well nourished; then Grape-growing is one of the simplest and most satisfactory processes in horticulture, it being far easier to grow Grapes, except the Frontignans and Muscats, true, as Black Muscat and Muscat of Alexandria, with Canon Hall, than Melons or even Peaches and Nectarines.

#### THE KITCHEN GARDEN.

*Salading.*—With such a scarcity of green vegetables everywhere anything in the shape of salading will be appreciated. Endive under glass is yet available, but unless kept very cool will soon run to seed. Sow Lettuce Paris White Cos somewhat thickly in large boxes of rich soil, and place in heat to germinate. Before the plants become much drawn transfer to a shelf near to the glass in a warm greenhouse or

frame. When the plants are about 4 inches high cut over and use the tops or leaves whole for salad. In this way a succession could be kept up till forced plants of early Cabbage varieties are available. Do not hurriedly throw away old roots of Chicory. If potted or bedded, and kept quite moist at the roots, a third or fourth crop of leaves could be obtained from them, and which, when well blanched, are suitable to use with green Lettuce. Mustard and Cress ought to be constantly forced. Make a fresh sowing once a week, and always use fresh rich soil, as it damps wholesale if the precaution of wholly changing the soil is not taken. Sow thickly on a level surface, keep in fairly brisk heat, and shade heavily till the stems are upwards of 1 inch in height; then expose, and keep in a cooler house or frame. It is only by keeping it in the shade at first that those long well-blanched stems can be obtained.

*Sowing Seeds under Glass.*—A mild hotbed surmounted by a frame, roughly constructed or otherwise, will always be found of good service in raising early plants for the kitchen garden. Those who have no frames to spare and none too much heating material may, after surfacing the bed with not less than 6 inches of fine light soil, sow Horn Carrots broadcast all over the bed. If a partial failure with anything takes place, it will be most probably due to sowing too thickly. An early start should be made to obtain Brussels Sprouts well established in the open. All that are needed for most gardens can usually be raised on a bed space 18 inches square. It pays well to grow Borecole strongly, but good results attend the practice of sowing seeds of these in the open before the middle of March, and more again a month later. The only Broccoli that should be sown under glass is Veitch's Autumn Protecting. Sown now, and by keeping the plants growing, fine Cauliflower-like hearts can be procured early in September, and with the aid of a successional sowing made six weeks hence in the open a supply could be kept up well into January, always providing protection is afforded to the late plants. Either Early London or Dwarf Erfurt Cauliflowers may be sown now in frames to succeed those raised last autumn, or in January this year. For use during August there are none to surpass Eclipse (an early form of Autumn Giant), of which seeds should now be sown in frames. Cabbage plants have been largely destroyed. If not already done, sow seeds at once of Ellam's Dwarf Spring, Wheeler's Imperial, or other quick-growing varieties, and do not long delay in finally planting out. Both Cos and Cabbage varieties of Lettuce should also be found room for on the improvised seed beds, as these will be wanted for planting out in quantity early in April. If the bed is dry water prior to sowing, and cover the seeds with sifted soil. Directly the seedlings are up admit abundance of light, giving air freely whenever the weather permits.

*Celery.*—Celery seed is slow in germination, and should either have a small bed to itself or be sown in boxes. If wanted very early the seeds of a good white variety will have been already sown in heat; but Celery can be obtained fit for use in September if sown late in February or early in March. White varieties, as requiring the least blanching, should be sown, and to succeed these a good pink variety. Fill pans or boxes with fine loamy soil, make this level, give a gentle watering, and soon after sow the seeds, lightly covering with fine soil. Place in heat, preferably of a moist description, a near proximity to hot-water pipes greatly militating against perfect germination. Cover with squares of glass, and shade heavily until germination takes place, and keep the soil moist. Unless extra pains are taken failures are likely to occur, and the time lost is not easily made up.

*Celery and the Frost.*—Celery has suffered badly where the tops were exposed. Frost has penetrated clean through the ridges, but when enclosed by soil the thaw is certain to be gradual, and the stalks may yet be found quite sound. The decay will spread downwards, however, and the supply will be greatly reduced. It will also be found that the damage to the tops will hasten seeding, and the best way to deal with the late Celery, when the state of the ground permits, is to lift all carefully and closely bed it in behind a north wall. All should be well covered with soil, and a little rough protection be further afforded in the event of severe frost. This treatment will serve to check heart growth considerably, while the ground now occupied by the rows can be made ready for other crops at once instead of waiting till later.

*Onions.*—Those who have heavy soils to deal with ought long since to have selected a site for Onion beds, dressing this with half-decayed stable manure something like four barrowloads to the square rod, following with either deep digging or trenching, and laying the surface up roughly. Directly the frost is well out of soil thus treated, fine weather should be selected for further preparing the ground for seed-sowing. Sow soot at the rate of one peck to the square rod, and lightly stir this into the surface. Next, closely trample the ground, get rid of stones and rubbish, level by means of a coarse rake, and then draw shallow drills from 10 to 12 inches apart. Sow the seeds thinly, and make all smooth with a rake. Soot is recommended in all cases, as a free application of this tends to promote strong growth of plant and thereby shorten the time during which the Onion maggot will be able to make beadway, while it also acts as a deterrent of maggot attack. A strong growth of plant is also one of the best preventives of mildew. A loose, rich root-run also favours a strong top-growth, but in this case the roots fail to form properly, thick-necked specimens being the result, hence the necessity of firm soil in all cases. The Tripoli section never keep so well as do the White Spanish types, and are also among the first to succumb to mildew. Brown Globe and James' Keeping are amongst the best.

**Parsnips.**—If wanted extra fine somewhat early seeds should be sown as soon as the ground can be got into a finely divided state. Supposing it was well manured for a previous crop, which ought not to be a tap-rooted species, no solid manure should be used. If any is dug in it should be buried at least 18 inches deep, an early contact with strong manure causing the tap root to fork badly. The old-fashioned plan of boring deep holes with a crowbar and filling with sifted soil, still holds good in the case of hard, lumpy, or otherwise badly prepared ground. These holes may be 9 inches apart, in rows 15 inches asunder. Three seeds to be sown over each, and the plants resulting must be reduced to one in each case. Very fine, cleanly grown Parsnips can be obtained in that way.

## THE BEE-KEEPER.

### APIARIAN NOTES.

THE weather since the 18th has become milder, although still wintry; the thermometer rose for a little on the 20th to 40°, this being the highest temperature recorded this year.

Bees have never had a thorough flight, many left their hives only to be chilled to death wherever they rested. So far as I have observed Carniolans are again proving themselves the best winterers. Those in the best condition have kept breeding during the past arctic weather. Many bee-keepers are still sceptical regarding bees breeding during severe weather, arguing it is impossible for them to keep up the necessary degree of heat. But it is by doing this that preserves them in a healthy state by keeping up the temperature for the safety of the young.

As there are neither dust, débris, nor damp on our perforated zinc floors, evils are greatly reduced. It is perhaps premature to say too much in favour of my mode of management yet, but of two apiaries in the same garden I observe 50 per cent. with solid floors are dead, while in those having ventilating floors all are alive. Whatever shortcomings the severe winter has brought about, I sincerely hope the future will make amends, and that arctic winters will not visit us again.—A LANARKSHIRE BEE-KEEPER.

### SEASONABLE NOTES.

THE severe frost which has lasted for upwards of seven weeks has now every appearance of going rapidly. To-day, Feb. 21st, the highest reading of thermometer placed in the shade was 43°, and it is the first time the temperature has been so high since December 28th. As the sun was shining brightly at midday a great many bees were on the wing, a cleansing flight at this time proving a great advantage to them; and from a casual inspection during the brightest part of the day I find my stocks have all come through the late severe frost without loss.

As I have upwards of thirty stocks placed in a variety of aspects, the evidence is pretty conclusive that it is not necessary to have large, expensive, and unwieldy hives with wide space round the sides for packing with cork dust, chaff, or similar material to keep the cold out. This, I am convinced, is quite unnecessary. After examining my hives more closely I will report what difference there may be, if any, in the condition of the bees wintered in hives packed with cork dust round the sides, others with air spaces instead of packing, and those with single sides. The majority of my hives have only single boards, but all are covered on the top, with ample ventilation from the bottom.

One thing noticeable is the activity of some stocks in comparison with others on the same stand. From some of the hives there would probably be several hundreds of bees on the wing, other stocks would be quiet and only a few stragglers be visible, giving one the impression that all was not right, but on lifting the quilt the bees were found to be snugly clustered in their hive amid ample stores. I am inclined to think it is the most excitable stocks that are affected in this way, as to all appearance there is no difference in the strength of the colonies.

Another reason may be that the hives with the thinnest sides may be more easily affected by the external warmth, but no doubt bees are like human beings, they vary somewhat in temperament. Other bee-keepers have noticed the same peculiarity, but if one and all come out strong in the spring, and are healthy, good workers, no more is required.—AN ENGLISH BEE-KEEPER.

### PROSPECTS OF 1895.

It is a little premature to venture anything like a reliable opinion as to what may be the prospects of the bee-keepers in our border county during the spring and summer of 1895. Of course it was admitted on all hands that the summer of 1894 was anything but a profitable one, for in this locality summer feeding was a necessity to keep the hives in order. Even those who

took them to the Heather derived little or no super honey to repay the outlay; but at the same time the strong hives in most cases collected sufficient stores for winter keep.

As the autumn months were mild and favourable for breeding, most hives with stores either gathered or artificially supplied were strong with bees in the beginning of the winter, and, notwithstanding the two months of heavy snow storms and exceptionally severe frosts during January and February, such hives are strong and in good condition still. In many instances heavy losses have been incurred through the bees coming out for a flight in sunshine and "perished" among the snow; but with a good spring any such loss will soon be recouped.

So much for the better class of hives. However, where hives had only limited stores and few bees, they have been losing a considerable number of bees. As soon as the weather permits it will be for the interest of the owners of such to see that any dead bees which may have accumulated on the floor-board or amongst the combs are cleared away. Twelve months ago the hives were all rearing brood, but at the present time the rearing of brood is all to come, and I need not say that this being the case, there is a great risk of the weaker hives dying out in the spring months unless the weather is all the more favourable. However, we are now more likely to have a continuance of fresh weather, and with a good spring and summer let us hope that 1895 will be a record year for honey gathering.—A BERWICKSHIRE BEE-KEEPER.

### TRADE CATALOGUES RECEIVED.

Laing & Mather, Kelso, N.B. — *Trees and Shrubs, and Garden Seeds.*

T. S. Ware, Hale Farm Nurseries, Tottenham.—*New Roses and other Plants, Hardy Florists' Flowers, Choice Hardy Perennials.*

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Cyclamen Flowers (S. F.).**—The flowers show diversity and purity of colouration, but they did not arrive in good condition.

**Red Spider (C. and S.).**—Your letter obviously comes within the category of advertisements, but this would not occur to you. Vendors of articles which are not advertised do not expect them to be extolled in literary contributions.

**Marguerites (W. S.).**—The Marguerites arrived in an imperfect condition; it is one of the *Chrysanthemum frutescens*, being a variety of *Etoile d'Or*. We are unable to say whether the sport is an original one, but we do not know of any like it.

**Salix (F. N. R.).**—The specimen you sent is a *Salix*, but sufficient was not sent to identify the species. For propagating cut off well-ripened growths about a foot in length and insert in light soil either in the spring or autumn, when they will take root readily.

**Analysis of Tulip (W. J. P.).**—We have some information on the subject, but cannot lay our hands upon it at present. If we come across it we will insert it in these columns in due course, or perhaps some correspondent may forestall us with the information our inquirer desires.

**Lily of the Valley (X. Y.).**—There is no difficulty in producing Lily of the Valley flowers every month in the year. The method is to freeze the crowns as soon as they are lifted, or can be obtained in the autumn, and keep them in a frozen condition until they are required. Hundreds of thousands are frozen annually, and are now being retailed. Those who have an ice-house can retard the crowns themselves, but those who have not can obtain them through most nurserymen if they order early so as to give them an opportunity of obtaining them for the time required. Once the crowns are removed and thawed they must be allowed to come into flower at once; they cannot then be further retarded, if this is attempted they soon wither and die. Very often if packed in a box and sent by train during September and October they commence growing in the box.

### MISTAKES IN STRAWBERRY FORCING.

WITH the advent of March Strawberry forcing becomes a comparatively easy matter, and with good treatment a fair return for the outlay involved may be looked for in the shape of large fruit ; but even at this season it is not an unusual occurrence to see only a moderately good crop in cases where there seems to be no serious reason why a better state of affairs should not prevail. On the other hand, there are some positions which to the casual observer seem specially adapted for the growth of Strawberries in pots, but which the practical cultivator finds to his cost are quite unsuitable, and that the task of producing good fruits under such conditions proves a very "hard nut to crack." I doubt not that most of us have at various times met with such little difficulties, and that by adapting our practice to suit the requirements of the case have in the end succeeded. I think, however, it generally happens that between the early failures and the ultimate successes many experimental practices are tried before the right one for each particular case is discovered. It seems to me, therefore, that a few notes upon the subject would at the present time be appropriate, and may perhaps be the means of helping some "puzzled one" out of a present difficulty.

Perhaps one of the most frequent causes of failure is subjecting the plants to too much heat in the early stages of growth, the result being that many of them go "blind ;" others fail to set their fruit, and in those instances in which setting is accomplished the berries fail to swell satisfactorily on account of the skins becoming hardened shortly after the fruit is formed. There are mistakes in forcing more easy to make than avoid, but at the same time many failures are brought about by the anxiety of gardeners to produce a few early dishes of this much-prized fruit when the conveniences at command do not favour achievement.

Where a suitable forcing house or pit, divided in two compartments, can be devoted entirely to Strawberries in pots, the difficulties above set forth to a great extent disappear, but a very small percentage of gardeners have these conveniences. Frequently the only positions

No. 2423.—VOL. XCII., OLD SERIES.

### IF YOU WANT

## REALLY GOOD SEEDS

At MODERATE PRICES, apply to

## MR. ROBERT SYDENHAM,

Tenby Street, North, BIRMINGHAM.

NO NURSERYMAN WILL SERVE YOU BETTER IN QUALITY, QUANTITY, OR PRICE.

### THE SIX BEST TOMATOES

In cultivation, often sold under other names to get fancy prices. Each packet contains nearly 200 seeds. Perfection, 3d. ; Ham Green Favourite, 3d. ; Hackwood Park Prolific, 3d. ; Challenger, 3d. ; Roseleigh Gem, a grand new large smooth selection, 3d. ; Golden Perfection, the best yellow, 3d. Collection, 1s. 8d., post free ; singly, 1d. each extra for postage.

### THE FOUR BEST CUCUMBERS.

Each packet contains 10 seeds, Lockie's Perfection, Rollisson's Selected Telegraph, Epicurean, and Covent Garden Favourite, 6d. each ; or the Collection, 2s., post free ; singly, 1d. extra for postage.

### SWEET PEAS—A SPECIALITY.

ECKFORD'S and other choice varieties at a third or a fourth usual prices.

Nothing gives so much cut bloom at so small a cost, or so little trouble. To get best results SOW AT ONCE, as directions sent with each Collection.

### SPECIAL VERY CHEAP OFFER.

8 Really Good Varieties—Queen of England, white ; Blanche Ferry, pink and white ; Princess Beatrice, pale pink ; Apple Blossom, apple blossom tint ; Orange Prince, orange pink ; Splendour, rich deep rose ; Cardinal, bright cardinal ; Countess of Radnor, pale heliotrope, 25 seeds of each, 1s. 3d.

7 Extra Choice and Newer Varieties—Emily Henderson, fine large white ; Venus, pale lemon flushed with pink ; Mrs. Gladstone delicate pink ; Her Majesty, soft rosy pink ; Lady Penzance, bright pale rose ; Firefly, bright glowing crimson ; Monarch, large bronzy purple, 25 seeds of each, 1s. 6d.

The Two Collections, 2s. 6d.—Postage 2d. each Collection extra ; or the two 3d. extra.

EXTRA CHOICE MIXTURE, 3d. per 100 seeds ; postage 1d. extra.

### ALL OTHER SEEDS EQUALLY MODERATE.

FULL LISTS POST FREE ON APPLICATION.

Please mention this Paper.

THE LARGEST STOCK in the WORLD of developed Cordons, Pyramids, and Espalier Trees, bristling with fruit buds—saving years in time. The only Nursery where the Amateurs' Standard Apples can be bought to fruit first year, 2/6 and 3/6 each.

ILLUSTRATED CATALOGUES OF FRUIT TREES, 800 Kinds, Six Stamps. Strawberry List Free.

ROSE, BULB, CONIFER, and SHRUB LISTS Free. Two Hundred and Twenty Acres Nursery. Liberal Terms. Free Carriage and Discount.

GARDENERS are reminded that Fruit Trees from these Nurseries succeed grandly in all soils. (See Testimonials.) All lovers of Horticulture should come and see this unique Stock.

GEORGE BUNYARD & CO., PRACTICAL POMOLOGISTS,

MAIDSTONE. Established 1796.

GRAPE VINES.—Well ripened, short-jointed canes of all the popular kinds, established in pots, extra strong for fruiting this year in pots, 6s. to 10s. 6d. each ; for planting, 2s. 6d. to 5s. each ; extra strong, 6s. to 10s. 6d.—WM. PAUL & SON, Waltham Cross, Herts.

available for early Strawberries are shelves in Pine stoves, Cucumber houses, or other forcing houses in which high temperatures are maintained. Before taking plants into such positions they ought to be prepared by a few weeks' sojourn in a greenhouse, vinery, or cool pit. This will help them to bear without injury the extra heat of the forcing house, where they may remain till the flowers commence expanding. The question then arises what to do with them when in bloom. We know perfectly well if they can be removed to an intermediate house, where the atmosphere is somewhat dry, and a little top ventilation afforded on all favourable occasions, a good set may be readily obtained, but houses or pits offering such conditions are not often at command.

It therefore becomes necessary to compromise matters all round. This I find from experience is best done in the following way. Let us assume for example that our plants are arranged on shelves in a Cucumber house. As they come into flower they should be arranged together in the lightest part of the house, where the syringe may be kept from them, except on very bright days, when a slight "dewing" is often found to aid fertilisation. It is also necessary that the atmosphere of the house be kept somewhat drier for the benefit of the flowering plants; at the same time, if this is carried too far, those advancing into flower, as well as the Cucumber plants, will become infested with red spider. Damping the floor of the house should therefore be discontinued, and the Strawberry plants not in bloom, as well as the Cucumbers, be freely syringed once or twice daily, taking care to have the atmosphere of the house fairly dry at midday, a little ventilation, of course, being given and continued throughout the afternoon, except during very inclement weather. As soon as a number of plants have set a few fruits each (from five to nine) remove the other flowers, and arrange the plants in the warmest part of the house, filling up the places vacated with others advancing into bloom. Plants swelling their fruits require syringing several times daily when very bright weather prevails. When the colouring of the berries has well advanced, syringing must, of course, be discontinued, and for that purpose the plants ought to be kept apart from those not showing signs of colour.

When the berries are evenly coloured it is a great advantage to be able to remove the plants to a cooler structure for a day or two before the fruit is gathered; but unless they can then be kept from cold cutting winds, I prefer to keep them in the warmer quarters till the fruit is gathered, because in cold airy houses Strawberries which have been ripened in much heat quickly lose their gloss, and are rarely improved in flavour.

Another frequent mistake in Strawberry forcing is having the shelves fixed too near the glass, so near in fact that the leaves when fully developed are in actual contact with it. The result of this practice is that during bright days evaporation is so rapid that it is almost impossible to keep the plants free from red spider, and the swelling and ripening fruit is browned and burnt by the great heat, a condition of affairs which seems to puzzle not a few cultivators. Where this is so, my advice is, try the plan of keeping your shelves 18 inches from the glass, and I shall be much surprised if previous difficulties do not vanish. To assist fertilisation I prefer tapping the stems with a stick to the common practice of touching the anthers with a soft brush, and during bright days I like to syringe the flowers lightly. Watering is without doubt an important detail in Strawberry culture, and to the many mistakes made in performing it may be traced not a few failures. There are times during bright weather when dealing with plants in active growth when it is not an easy matter to over-water. Then in order to keep them in a satisfactory state dryness at the roots must be anticipated rather than allowed to take place, otherwise diminished vigour and undersized fruit will be the result.

To allow the soil to become dry enough to crack away from the sides of the pot is a sure indication that this undesirable state of affairs has taken place. On the other hand, when we have a succession of dull days the soil ought to be allowed to get slightly

drier than usual before water is given. It is when bright days follow dull ones that the greatest damage is done. At such times if the plants are carefully looked over about noon, in addition to the early morning watering, serious mistakes may often be avoided. The state of the weather in regard to dullness or brightness must give the key to the whole matter. While the fruits are swelling, weak liquid manure given at each alternate watering and an application of chemical manure on the surface soil will be sufficient to produce the best results.—FRAGARIA.

## DOWNHILL.

PRESUMABLY men of the gardening occupation find in an active life so much uphill work that considerations of the reverse are banished to the dim and distant future. "Sufficient for the day is the evil thereof." Quite so; more than sufficient some days bring—circumventing weather, and fighting the minute, subtle forms of insect life. We are surrounded by enmity, yet not destitute of friendship as evinced by the outward and visible signs of requests for roots of this, slips of that, or "What must I do for my plants?" So on, on, wrestling with foes, courteously facilitating the horticultural requirements of friends, happy in doing either or both, and happy in a busy life, head, hand, and eye concentrated on the object dear to the heart—gardening.

So it is, I think, with most of us, and so it should be, the chief end and aim being to advance the loved art, which must in its turn elevate and dignify the class of which we are units—gardeners. Nor is the latter less worthy of consideration, for "the proper study of mankind is man." It is, indeed, the principal object to which all considerations are subordinate. Our work, or all good work; our thoughts, or all good thoughts, directly or indirectly tend to the welfare of the human race. Yet, it is seldom time allows for more than a passing thought of this, the higher object. True, the problem is too vast, unless for political economists. Yet there is one section of it—one tribe of the race—which should receive more than a passing thought from us; that is ourselves—gardeners. This problematic subject is one worthy of pausing at occasionally and pondering over. Some do this perhaps, yet the thought arises that the bulk of the great army of gardeners quartered in the British Isles do not. Such thoughts are but reasonable when scanning the report of the Gardeners' Royal Benevolent Institution and noting the few, the comparative few, that recognise its claims to the attention of all.

What percentage of men in fairly good positions participate in its benevolent work? Probably it is not possible to say, for statistics are not obtainable. It may, at least, be reasonably supposed that the number does not exceed 1 per cent., and perhaps may be more correctly estimated by a minute fraction of that. From this may be deduced that this Institution, reared on the noblest foundation, is practically unrecognised by us as a class; by the many who could help the few, some of whom it is morally certain will one day seek to reap where they have not sown.

Why is it so? Is it that it is unknown, or if known the knowledge of it is so slight that the object of it is not made sufficiently clear? That it is heard of to receive but a passing thought from men whose life is one of thinking and of thought essentially elevating and humanising, appears evident. Few things are done or left undone without a reason. How is it then that the Gardeners' Royal Benevolent Institution is ignored by so many good and capable men? Speaking for myself, and I venture to say for some few others, we should like to know the reason why. So much so that I would fain ask the favour of space in these pages for any answers the question might elicit.

Not any of us can ignore the fact that there is a turn in the path of life where the downhill journey commences. This stage may be comparatively easy, smoothed by the success of earlier exertions, from which frugality and prudence have provided a margin for the rainy day, and this perhaps augmented by some consideration from others of long and faithful service.

All such things give dignity to the journey, and though downhill to the inevitable, it presents no sorrowful side. But can there be any more pathetic picture than the reverse; to see a worn and weary brother going downhill destitute, alone? To the world at large he is but one of the unsuccessful, and the world is but too ready to give him a push, for one of its maxims is "Nothing succeeds like success." But to us, is he not a gardener and a brother? One, who perhaps has bravely "stemmed Misfortune's tide," until sickness has cramped his energies, and now he drifts—drifts unscoured on, out into the great lone ocean of the world.

Such cases rarely, perhaps, come under immediate notice, but they are not rare. Those who receive the yearly report and ballot

paper of the G.R.B.I. and note the applicants for the bounty accompanied by the brief biography setting forth their title to the votes, see depicted the seamiest side of the seamy side of life. Sad, but many shades brighter is it to note one who has subscribed for many years being placed without election on its books. One, who has in the health and vigour of manhood made the small sacrifice of fivepence (a fraction less) per week; who has by this means supported the institution, nor allowed any selfish motive shut out the fact that he is his brother's keeper. Both of these examples are yearly presented in the report, the one who has thought for others, the one who has not. Both at last turn to this haven of refuge, but one is taken, the other—too often—left. So it must be until each bears his small share of the burden and enlarges the resources. All can pity these painful cases; some may criticise, yet not those who hold aloof for "People who live in glass houses must not throw stones."

There are unfortunately various illusions attracting from what appears to me a plain duty. One voice whispers, "Charity begins at home." If this was a fund for supplying tall hats and top boots to some far off cannibal island, it might no further concern us, who are concerned with too many things to heed the "noble savage," but it is at home and in our own (large) family. Still another voice says, "I have a place for life." Capital places are these, if they were not another illusion. The writer had one of these places, nor was it failed to be impressed on him at the period of installation. Unfortunately it happened to be for the more valuable life of an employer, and death makes appalling changes. Life is made up of such illusions, but the fewer we allow to cheat us the better.

Instances could be adduced of men I have known, respected, and respected still, whose names are to be found on the books of the bounty; indeed, one can pay them more respect, for there can be nothing derogatory to the man going downhill in clinging to the support he has helped to strengthen in the day of his prosperity. But there is something very sad in the numerous examples of those failing to have done so, and finding too late they are precluded from its benefits, not from lack of sympathy, but from want of room.

"I may not need it," probably sums up all illusions. We will, however, take it for granted—which is a very bold thing to do—that you (a non-subscriber) will not need it. May it be so. Yet let not that thought preclude you from a good action, nor deter you from a plain duty, so will you be "Above all pain, yet pitying all distress."—E. K., *Dublin*.

#### DENDROBIUM SPECIOSISSIMUM, Rolfe.

We learn that Messrs. Hugh Low & Co. of the Clapton Nursery have now obtained further materials of the above splendid new species, which was named some time ago by Mr. Rolfe, but has not yet been introduced to cultivation. It was discovered many years ago on Mount Kina Balu, in Borneo, by Sir Hugh Low, who found it growing on a Magnolia. He describes it as being much in the way of *Dendrobium formosum* in general character, but the stems are much more covered with a pubescence of short black hairs. The flowers are pure white, except a blotch at the base of the lip, which is rich purple-red. The plant is of dwarf habit and very floriferous, bearing trusses of about four flowers, which are larger than those of *D. formosum giganteum*. We are glad to learn that so fine a species may soon be expected in cultivation, as it is likely to prove a great acquisition.

#### PHALÆNOPSIS YOUNGIANA.

THIS charming Orchid was exhibited at the last meeting of the Royal Horticultural Society by Baron Schröder, and gained a first-class certificate. The character of the flower is admirably depicted in the woodcut (fig. 37). It is a splendid variety with broad dull white petals, which are slightly tinged with a pleasing rose hue at the base. The upper sepal of the flower is of the same colour, while the lower are of a very pale rose-maroon thickly covered with spots. Pure white and heavily spotted deep rose forms the ground colour of the lip. The flower is of splendid form, and one of the most pleasing of the *Phalænopsis* group.

#### ODONTOGLOSSUM BLANDUM.

WHEN well grown this is a charming little *Odontoglossum*, which thrives well in the cool house. The plants grow less than a foot in height, and have somewhat flattened pseudo-bulbs and narrow bright green leaves. The spikes are produced from the base of the bulbs, and carry from eight to twelve flowers, each about 1½ inch across, and slightly fragrant. The sepals and petals are creamy white, irregularly spotted and blotched with brownish crimson; the lip is about an inch in length, narrowed at the base, broader in front, and tapering to a point, wavy on the edge, and irregularly toothed; this is also spotted, and has a lemon-coloured crest. The Orchid is not even now by any means often found in collections, and was formerly very rare. It must not be over-potted, and does best suspended near the roof in order that the air circulates freely about it in the summer, and in the winter the light is not subdued. It is a native of New Grenada, and first flowered in this country about twenty-five years ago. A fine plant was recently in flower in the collection of Canon Warre of Bemerton Rectory, near Salisbury, bearing two spikes of brightly coloured flowers.

#### DENDROBIUM NOBILE.

Some very fine forms of this grand old *Dendrobium* are flowering with Canon Warre of Bemerton. *D. nobile Wallichii* is represented by a large plant with very tall stems and richly-

FIG. 37.—PHALÆNOPSIS YOUNGIANA.

coloured flowers. This contrasts finely with some of the lighter forms, such as *D. nobile elegans*, with large well-formed flowers of great substance. Several other varieties of *D. nobile* are also in flower, as well as the typical *D. crassinode* and the highly coloured *D. crassinode Barberianum*. These, with *Saccolabium violaceum*, a fine lot of *Cattleya Trianae* in variety, and some fine specimens of *Ceologyne cristata*, make a very interesting and beautiful display.

#### LÆLIA CINNABARINA.

This delightful old kind is in no way inferior to the newer and better known *L. harpophylla*, which it to a certain extent resembles. The spikes, however, are longer, and carried much more gracefully than in the latter kind, and in the best types are equally bright in colour. The pseudo-bulbs on strong plants grow to a height of 10 or 12 inches, and are sometimes of a bronzy red tint, this usually indicating a highly coloured form. They are swollen at the base, tapering upwards, and each bears a single leaf. The spikes issue from the apex of the pseudo-bulbs, and bear from six to ten large flowers. The sepals, petals, and lip are all narrow and bright orange red, the latter sometimes edged with white.

This species should be much more grown, as its culture presents no difficulty. It thrives in pots or baskets, and in the latter is especially attractive when in flower. The plants should be grown

in the usual peat and moss mixture, and must be carefully watered during the winter months. It thrives in the Cattleya house in a light position, and requires abundance of water when growing freely. *L. cinnabarina* is a native of Brazil, from whence it was introduced in 1836. A plant bearing two spikes with six and eight flowers respectively is now in flower with Canon Warre of Bemerton, where Mr. Lompord grows it well suspended from the roof in wood baskets.

#### DENDROBIUM CAPILLIPES.

Among the smaller growing Dendrobiums there are many charming and beautiful species which are in nowise deserving of the neglect into which they have fallen, even though they lack the showiness of some of the more popular kinds. *D. capillipes* is one of these, seldom growing more than 6 inches high, but when well flowered is sure to attract attention. The plants are deciduous, and the flowers occur in racemes consisting of from two to eight blossoms; these are bright yellow, with a deep orange blotch on the lip. This species thrives on blocks or in small shallow pans suspended near the glass. It does not like much material about its roots, and this should be made very firm. Good peat fibre and sphagnum with a few finely broken crocks will suit it well. Being a native of Moulmein it requires a hot and very moist atmosphere with ample of sunlight while making its growth. When this is finished less heat will be required as the foliage falls, keeping the plants quite dry in a cool house for a few weeks in the winter.

#### ODONTOGLOSSUM CORDATUM.

Although this Orchid cannot compare with such as *O. Pescatorei* or *O. crispum*, it is, nevertheless, an interesting and handsome species. The pseudo-bulbs of this kind are ovate, light shining green, with leaves 6 inches in length. The spikes are erect, branching, and many flowered; the individual blossoms being about 3 inches in diameter. The sepals and petals are long, twisted, yellow, spotted and freely barred with chocolate. The lip is broad at the base, pointed in front, white, with yellow and purple lines. This thrives well in pots with rather more heat than the coolest section of *Odontoglossums* require, and likes an abundance of water all through the season. *O. cordatum* is a variable species with regard to shape and colour, but all the varieties are worthy of extended culture. It was introduced from Guatemala in 1837.—H. R. R.

## THE FLORISTS' TULIP.

[By JAMES W. BENTLEY, Hon. Secretary to the Royal National Tulip Society.]

### CHAPTER V.

(Continued from page 160.)

THE rings or crinolines must be of several sizes. I find that they are best made of stout shavings. The shavings are made by a joiner from the edge of a 1 inch deal board, the plane he uses having the cutting edge so set as to take off the shaving much thicker than is usual. These shavings are cut into lengths of from 4 to 9 inches, and the crinolines are completed by sewing the ends together.

When packing time arrives a suitable crinoline is selected and carefully inserted into each flower, taking great care not to bruise or injure it in any way. The petals are then made to clip up close to the crinoline, and kept in that position by wrapping some suitable material round the outside of the flower. The best known to me is that soft fleecy thread known to cotton-spinners as "rovings," which combines in itself the softness of cotton wool and the convenience of a thread-like form. Tulips wrapped on the outside with several turns of this material are splendidly packed, and will undergo a long journey quite unharmed.

As each Tulip is packed it should be transferred to the travelling box, which is contrived in such a way that the stem of each flower rests in a zinc tube filled with water. The bloom itself is kept from contact with the water by a neat contrivance made of wood, which fits like a cork into the mouth of the zinc tube, and has a small hole through which the stem passes and reaches the water in the tube. This method of conveyance is not absolutely necessary, as Tulips will keep for many hours out of water, but if taken to the place of exhibition overnight they must be put into it on arrival, or they will be unfit for show the next day. Many an amusing reminiscence occurs to me as I write of hotel bedrooms with every available object, either of use or ornament, filled with Tulips, and the grower taking his rest, with his splendid blooms around him, the night before a show.

On arrival at the place of exhibition all crinolines and other packing materials must be removed, and each of the flowers carefully examined for defects. There are, fortunately, "no ways

that are dark or tricks that are vain," in preparing Tulips for exhibition. No "dressing," so necessary in the case of the Carnation and Pink, is required, and the only thing to be done is to sweep out and clear away fallen pollen from the inside of the flowers, so that the base and marking can be clearly seen, and this is easily effected by means of a small dry camel-hair brush. Sometimes an anther will be found fallen off the filament, but this can easily be replaced, as the filament penetrates somewhat deeply into the lower part of the anther.

Tulips are generally shown in "stands," which are made of thin, flat boards of suitable size, painted an unobtrusive shade of green, and fitted with feet so as to elevate them a little above the surface of the tables upon which they are arranged. The feet at the back are higher than those in front, so the surface of the stand slopes, enabling the spectator to have a better view of the flowers than if kept level. The stands are perforated at regular intervals with round holes, in which can be fitted the zinc tubes from the travelling box. It will be readily seen that if the flowers to be staged have been determined upon before, and arranged in the travelling box, they can soon be put in the stands, as both tube and flower can be moved together.

The chief prize at the National Society's show is for a stand of "twelve dissimilar Tulips, two of each class," which means that the twelve must comprise two dissimilar varieties of feathered roses, feathered bizarres, feathered bybloemens, flamed roses, flamed bizarres, and flamed bybloemens. The flowers are staged in three rows; the largest flowers are best put in the top row of the sloping stand, the smallest in the bottom, and the medium-sized ones in the middle row. Care should be taken to diversify the colours, and not stage all one colour together. It is good to have the flowers as near the same shape and size as possible, as a stand looks bad if it contains large long-cupped flowers and small shallow saucer-like blooms. The wooden stands are not compulsory, and the exhibitor if he prefers to show his flowers in bottles may do so; they do not, however, show themselves so well as in stands. Each flower, whether in the stands or bottles, must have its name written on a label and gummed down, just underneath it. Prizes for stands of six, three, and two flowers are offered, and also for single blooms in each of the six classes in rectified flowers, and the cultivation of breeders is encouraged by suitable prizes.

In awarding the prizes for rectified flowers judges think more of good marking and size than of perfection of form or beauty of colour, although a poorly marked large flower will always be beaten by a well-marked smaller one. Still, as an old judge is fond of remarking, "Good big ones will beat little pretty ones." Breeders should be large in size, good in form, and absolutely free from accidental blemishes, such as specks or marks caused by frost or bruising, to stand well in the opinion of the judges, or censors, as they used to be called in the south.

I will now leave this part of the subject, as I feel that however much more I wrote it would all be inadequate, and probably confusing. The best way for the novice to learn is to take his flowers to a show, where he will receive a kindly welcome, and learn more in the day than books would teach him in a twelvemonth.

### CHAPTER VI.

#### OBTAINING SEEDS AND SEEDLING RAISING.

The late Dr. Horner of Hull, an enthusiastic Tulip grower, whose writings illuminate the pages of the older floricultural papers as much as those of his son (the Rev. F. D. Horner) delight us in the journals of to-day, in an article contributed to the "Florist," says, "Every florist worthy of the name either does or ought to aim at raising seedlings which are an improvement on older varieties; in this, indeed, lies the chief and true secret of delight in floriculture." In this passage the good Doctor states clearly the position of the true florist, which is, of course, quite a different one from that of the botanists, who have often little or no sympathy with the florists' aims and objects, and not unfrequently unsparingly condemn them. In this they follow the lead of the great Linnæus, who terms our varieties "monsters," and thus deridingly describes the florists:—"Such, by an over-great study and assiduous inspection, have discovered such amazing wonders in flowers as no man, the most clear-sighted in the world, could ever discern but those who are versed in this study. The grand objects of their attention are the most beautiful flowers, such as Tulips, Hyacinths, Anemones, Ranunculuses, Pinks, Carnations, Auriculas, and Polyanthuses. To the hidden varieties of these flowers they have given such pompous names to excite wonder and astonishment, and are really ridiculous. These men cultivate a science peculiar to themselves, the mysteries of which are only known to the adepts. Nor can such knowledge be worth the attention of the botanist; wherefore, let no sound botanist ever enter into their Societies." When I came across this weighty condemnation by the great Swede, quoted in

Dr. Thornton's sumptuous volume, "The Temple of Flora," published in 1812, I must own I felt rather indignant at its gratuitous nature, for no one knew better than Linnæus that the labours of the florist had greatly augmented floral variety and beauty in the gardens of the world, without injuring in any way the species or types which it was his life-long work to classify and describe. However, lest we sink under the fearful weight, let us remember that a greater man than Linnæus has something to say on our side, for Shakespeare, in "The Winter's Tale," written 1601, has the following lines for the characters, Perdita and Polixenes:—

PER. . . . . the fairest flowers o' th' season  
Are our Carnations, and streaked Gillyflowers  
Which some call Nature's bastards:—Of that kind  
Our rustic garden's barren, and I care not  
To get slips of them.

POL. . . . . Wherefore, gentle maiden,  
Do you neglect them?

PER. . . . . For I have heard it said  
There is an art which in their piedness shares  
With great creating Nature.

POL. . . . . Say there be,  
Yet Nature is made better by no mean  
But Nature makes that mean: So over that art,  
Which you say adds to Nature, is an art  
That Nature makes. You see, sweet maid, we marry  
A gentler scion to the wildest stock,  
And make conceive a bark of baser kind  
By bud of nobler race: This is an art  
Which does mend Nature, change it rather, but  
The art itself is Nature.

Our great poet defends the art of the florist so well that one is led to wonder whether he had interested himself in some patch of "streaked Gillyflowers" in an old-world garden down at Stratford-on-Avon, or admired them in the pleasure grounds of some of his aristocratic friends near London. One could almost excuse the severe language of Linnæus, if one might suppose that it was written after an initial attempt at "dressing" a Carnation, and comparing the result with another manipulated by one of the "adepts" he so scornfully condemns. But, speculation apart, florists may rest assured that Nature never produced our glorious Tulips, Roses, Carnations, and other flowers to be neglected by any haughty pretender to superior reason.

THE FUNCTIONS OF ROOT, LEAF, AND BUD.\*

MY subject being a very large one, to bring it somewhat within the requisite compass I must be content to treat it in a general and superficial manner, and confine my observations to the functions of these organs as they appear to me in relation to a few hardy deciduous fruit trees, and try and deduce from it a few lessons of practical utility to us as gardeners.

THE ROOTS.

We all know that roots have two distinct functions to perform—one to hold the tree or plant in a firm stationary position, the other to gather and supply the food which the tree receives from the soil. The stability of the tree is chiefly secured by the larger or more woody portions of the roots; in young trees, and plants from seed, by the tap root, which is the first formed. In properly grown fruit trees, however, the tap roots are destroyed long before they are permanently planted, and though some of the other roots may afterwards partake of the nature of tap roots—that is to say, become unduly long, strong, woody, and strike deep into the soil, it should be the aim of the cultivator to prevent it.

The most important roots are, of course, those which take up the materials for nourishment to be supplied to the tree. Those slender thread-like filaments we usually call "fibres," the feeding hairs or glands, are situated around or near their growing points. These and the fibrous parts which bear them are annual in duration. "In all roots and under every mode of management the fibrous parts are strictly annual; they decay as winter approaches, and are produced with the returning vigour of their parent in spring."—"Johnson's Gardeners' Dictionary"). These roots vary in their nature in different species of trees as well as in different soils, the roots of some appearing to thrive in certain soils better than others; hence if a certain variety of fruit does not flourish to our satisfaction we work it on another stock, the roots of which we may consider, or have proved from experience, are better adapted to our particular soil.

I shall not attempt to define the exact nature of the materials the roots imbibe; it is unnecessary for my purpose, though I may put them down roughly as carbonates, phosphates, and nitrates; these compounds being soluble, the roots take them up dissolved in water. The compounds of carbon are of very great importance, carbon forming a large proportion of the wood of all trees, as well as entering into the composition of fruits, carbon, oxygen, and hydrogen composing those important carbohydrate bodies, starch, cellulose, sugar, and gum. Nitrogen does

not exist very largely in vegetation, yet its conversion by chemical combination with oxygen and soda or potash to form nitrates, is so important that from a practical point of view it may be considered synonymous with fertility, as in reality the soil will be fertile in proportion to the extent in which this process of nitrification is effected. It is therefore necessary that we should have a clear conception of this process, and the conditions most favourable for its development, so as to be able to assist Nature to our own advantage.

There is abundance of nitrogen all around us, forming as it does about five-sixths the bulk of atmospheric air; it also exists as ammonia both in the air, soil, and decaying bodies. But the process of its conversion into nitrates, or nitrification, is only carried on in the soil, associated with a low form of organised life, and the necessary presence of atmospheric air and warmth. These two latter conditions we can do much to promote by frequently working the surface of the soil and exposing it to the action of light and heat, and this should always be attended to, because in this country "The temperature of the soil during most months of the year is very much below the most favourable for the development of nitrification."—"Johnson's Elements of Agricultural Chemistry"). Wet soils to the same end should be drained, and in many cases liming is highly beneficial. "In waterlogged soils a process the reverse of nitrification is apt to go on, whereby the nitrates present in the soil becomes deoxidised, or denitrified, with the result that the nitrogen is set free and escapes."—"Johnson's Elements of Agricultural Chemistry"). All this points to the extreme necessity of well working the soil, so as to promote the free absorption of atmospheric air and sun heat, as well as keeping the roots of all trees and plants, especially fruit trees, as near the surface as possible, where the extra heat and fertility of the soil will promote their growth.

Roots growing near the surface of the soil are always more fibry, and multiply their feeding hairs much more abundantly than those found deeper down. They also appear to multiply in the immediate presence of decaying vegetable matter, and to have the power of extending themselves a very considerable distance in the direction in which such matter exists; but apparently "They have little or no power of selecting their food, but they appear to take up whatever is presented to them in a sufficiently attenuated form. Their feeding property depends upon the mere hydrometrical force of their tissues."—"Lindley's Theory and Practice of Horticulture").

If this statement is reduced to its logical conclusion it amounts to this, that pretty well the same materials (compounds) are supplied in the sap to all kinds of trees and plants growing in the same kind of soil, and that the difference in the nature of the various plants arises from the different construction of the resultant compounds derived from the elements in the sap after they have been decomposed in the leaves, and that those elements taken up in the sap by the roots and not required by the particular species of tree are afterwards returned to the air or soil, either as compounds or in elementary form. To announce such an opinion I fear would be considered very heterodoxical, so I will leave this part of my subject for the present, and pass on to a consideration of other very important organs of plant life.

THE LEAVES.

I will not waste time in attempting to define what leaves are, the sort of leaves I am referring to will be perfectly understood, so we will proceed to consider not what they are, but what they do, and how they do it.

"The functions of respiration, perspiration, and digestion, which are the particular offices of the leaves, are essential to the health of the plant, its healthiness being in proportion to the degree in which these functions are duly performed."—"Lindley's Theory and Practice of Horticulture").

"The leaves have been compared to the lungs of animals, the functions of which they reciprocate, for whilst in the lungs of animals an absorption of oxygen and an evolution of carbonic acid is observed, in the leaves it is the carbonic acid which is absorbed and oxygen is disengaged."—"Bloxham's Chemistry: Inorganic and Organic").

The leaves, then, are the organs in which are carried on the very important functions of decomposing the compounds taken up in solution by the roots, in the form we know by the name of sap, and which, having passed through the stems and branches unchanged, are there, by the action of solar light and heat, converted into other compounds required to build up the tissues of all the organs of that particular tree, to which these particular leaves belong.

It must have been observed by most practical gardeners that the sap of a deciduous tree in spring before the leaves are developed is perfectly clear and limpid, and in no way differing in general appearance from ordinary water. This is particularly noticeable in the bleeding of Vines. If Vines are pruned late, and the wounds have not had time to heal before the rising temperature causes the sap to expand in the tissues, and the buds to develop, the sap oozes out of the ends of the severed shoots, and falls in clear sparkling drops, similar in taste and smell to ordinary water. This fact might be illustrated in many ways, showing that the sap is but very little if at all changed in its passage through the roots, stem, and branches, before the leaves are produced; but as soon as the leaves are developed all this is changed. The sap, before so clear, in bleeding Vines becomes viscid and gummy, showing that it has passed through the leaves, and these leaves have commenced their ordinary functions of decomposition and reconstruction of the compounds necessary for all the purposes of growth of wood, fruit, new leaves, and buds, which organs we will next pass on to consider.

(To be continued.)

\* A paper read before the Bournemouth and District Gardeners' Mutual Improvement Association by Mr. H. ELLIOTT.

**EVENTS OF THE WEEK**—On Tuesday, March 12th, the Committees of the Royal Horticultural Society will meet at the Drill Hall. The annual meeting of the United Horticultural Benefit and Provident Society will be held on Monday, the 11th inst., at the Caledonian Hotel, Adelphi Terrace, Strand.

— **WEATHER IN LONDON.**—Cold north and north-easterly winds have prevailed since our last issue, accompanied on Sunday and Monday with slight fallings of snow, several degrees of frost being registered. On Wednesday morning the weather, though somewhat milder, was dull and cloudy, with some indications of a much-desired change.

— **WEATHER IN THE NORTH.**—The frost has not been of great severity during the past week. On Thursday, the 28th, there were 4°, and a thaw set in subsequently. In the evening rain fell for some hours, and with a high westerly wind it seemed that a confirmed change was imminent. By midnight frost again set in, and 2°, 5°, 7°, were registered on the first three mornings of March. Sunday was a day of intense cold, with a biting wind from the north. On Monday morning the thermometer registered 5° of frost, the weather was cold and dull, and in the evening somewhat milder, and on Tuesday morning inclined to thaw. On Saturday the railway in the extreme north of the country was for the fifth time this winter blocked by snow.—B. D., *S. Perthshire*.

— **ROYAL HORTICULTURAL SOCIETY.**—The next meeting of the Royal Horticultural Society will be held on Tuesday, March 12th, in the Drill Hall, James Street, Westminster. Special prizes are offered for Daffodils, and at 3 P.M. a paper by Mr. Collenette of Guernsey on the "Diseases of Tomatoes" will be read.

— **THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.**—The Committee of this admirable Institution have been fortunate in obtaining the consent of the DUKE OF FIFE, K.T., P.C., to preside at the fifty-sixth anniversary festival dinner at the Hotel Metropole on June 28th next. A large assemblage may be expected on the occasion, and a substantial addition to the funds of the Institution.

— **UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.**—The annual meeting of this Society will take place at the Caledonian Hotel, Adelphi Terrace, Strand, on Monday, March 11th, at 8 P.M. Mr. G. Gordon will preside. We shall be glad to see a good attendance on this occasion.—W. COLLINS, *Secretary*.

— **THE NATIONAL AMATEUR GARDENERS' ASSOCIATION.**—We are glad to see by the report and financial statement that this association of amateur gardeners is in a healthy state. Medals and other prizes are awarded for excellence in cultivation by amateurs, and instructive papers periodically read by authorities on special subjects in connection with floriculture. Mr. W. B. Crane, 4, Woodview Terrace, Archway Road, Highgate, is the Hon. Secretary.

— **DEATH OF MR. THOMAS BAINES.**—We regret to have to announce the death of Mr. Thomas Baines, the famous specimen plant grower and judge, which occurred on Saturday last at Palmer's Green, near London, as the result of an attack of influenza, culminating in pneumonia. For some years past Mr. Baines had followed with much success the occupation of landscape gardener, and he has left the stamp of his taste and skill on many estates. Though Mr. Baines was such an accomplished plantsman he possessed great knowledge in the various departments of gardening. He was an extremely active man, physically and mentally, an excellent worker and prolific writer. His volume on "Stove and Greenhouse Plants, their Propagation and Cultivation," is a valuable work of reference, and has been helpful to many who have sought information on those subjects. Mr. Baines was an extremely genial man, and always willing to give of his store of knowledge to all who needed such assistance as he could render. He was widely known and highly respected, and a host of friends will deeply sympathise with his devoted daughters and valued helpers in life in their great bereavement. The funeral is announced to take place on our date of publication (Thursday) at 11.45 in the Great Northern Cemetery, New Southgate, N. Mr. Baines was 72 years of age.

— **"KEW BULLETIN."**—The "Kew Bulletin" for February contains chapters on Coffee Cultivation at the Gold Coast, Decades Kewensis, Agricultural Farms in the Bombay Presidency, Storing Home-grown Fruit, Iboga Root, New Orchids, Siam Plants, and various miscellaneous notes.

— **NATIONAL CIDER ASSOCIATION.**—We have received a circular on the above subject. The object is the establishment of a central organisation representative of all persons concerned, directly or indirectly, in the cider-making industry of the United Kingdom in order that, when questions which affect their interests arise, they may be able to give expression to their views thereon with more force and effect through such an organised body than they could individually. A consultative committee has been appointed, of which C. W. Radclyffe Cooke, Esq., M.P., is the Chairman, and Mr. E. Sansom, 27, Clement's Lane, Lombard Street, London, Secretary.

— **DEATH OF SIR FRANCIS WYATT TRUSCOTT.**—It is with regret that we have to record the death of one of the best known men in the City of London, Alderman Sir Francis Truscott. He was elected Lord Mayor in 1879, and raised large sums of money for various public purposes. Sir Francis Truscott was a Magistrate for London, Middlesex, Surrey, and Cornwall; a Commander of the Orders of Leopold of Belgium and the Saviour of Greece, as well as an Officer of the Legion of Honour. He was for many years head of the great wholesale stationery firm of Messrs. James Truscott & Sons, Suffolk Lane, and was succeeded in that position by his son, Mr. George Wyatt Truscott, who in turn it is expected will become an Alderman, a position for which his talents well fit him. Sir Francis took great interest in his estate, Oakleigh, East Grinstead, where he made an excellent garden, which has been admirably managed for several years by Mr. F. Dann.

— **AUSTRALIAN ORCHIDS.**—The Government of New South Wales has issued a part of the late Mr. Fitzgerald's extremely valuable work on Australian Orchids. It will be remembered that after publishing some eleven parts full of original observations, and enriched by numerous admirable plates illustrative of structure and function, Mr. Fitzgerald unfortunately died in August 1892. A large number of drawings were left, and these, so far as they are sufficiently complete for the purpose, the Government has decided to publish under the editorship of Mr. Henry Deane. The thanks of all interested in Orchids will be most cordially tendered to the Government and to Mr. Deane.

— **THE total rainfall at Abbots Leigh, Haywards Heath, Sussex, for February was 0.27 inch, being 2.13 inches below the average. The heaviest fall was 0.14 inch on 24th, 0.10 inch of the amount was snow, which fell during the first week. The maximum shade temperature was 44° on the 24th and 28th, the minimum 6° on the 7th and 9th; mean maximum 35°, mean minimum 21.10°. Mean temperature 28.05°, which is 8.41° below the average of the past seven years. From the 22nd January to the 28th February there has only been four nights that the thermometer has not fallen below freezing. March has come in milder, with showers.—R. I.**

— **FORCING LILACS.**—The fragrant flowers of Lilacs are always prized when they are obtained early. After being potted they should always be kept for a few weeks in the open air, with the pots plunged in ashes or cocoa-nut fibre refuse, as the plants respond more quickly to the influence of heat and moisture when taken into the forcing houses than do those which are lifted and placed under glass at once, even if they are brought on slowly. It also frequently happens that both Lilacs and Guelder Roses flag badly in bright weather about the time the flowers commence to show colour. This may be partially prevented by plunging the pots in the open air after lifting, and then bringing the plants on gradually in vineries from the time the Vines are started.—H.

— **DEATH OF MR. JOSEPH LAKIN.**—It is with much regret we have received intelligence of the death of Mr. Lakin, which occurred at his residence, Temple Cowley, near Oxford, on Monday night, the 4th inst. Mr. Lakin had not been in his usual health for some time past, and this occasioned his recent retirement from duties connected with horticultural societies in which he took an active interest. Mr. Lakin was an ardent florist and an excellent man. Our correspondent who sends us the sad news, observes:—"I saw Mr. Lakin on Sunday afternoon. He had read the 'Florist's Tulip,' by Mr. Bentley, in the *Journal*, with much interest, and his end must have been, as it were, a dream of flowers." Mr. Lakin was sixty-seven years of age; he leaves a widow and two children, one of whom is married.

— **READING HORTICULTURAL SOCIETY.**—As is announced by advertisement, an exhibition of bulbous plants and other flowers will be held in the Queen's Hall, Reading, on Tuesday, 15th inst. Mr. Wm. Walker, Dunollie, Reading, is the Secretary of the Society.

— **PRIZES FOR PHOTOGRAPHS.**—With the view to obtaining the best pictorial representations of their specialties in flowers and vegetables, Messrs. James Carter & Co. are offering a series of cash prizes, particulars of which can be obtained from their establishment in High Holborn.

— **VEITCH'S SELF-PROTECTING BROCCOLI.**—Having grown this valuable Broccoli for several years I can recommend it as one of the best varieties in cultivation. At the end of December last I cut several heads, beautifully white, solid, and compact, which, after being divested of their outer leaves, weighed from 11 to 13 lbs. each. The plants were grown between the rows of Potatoes without any extra attention whatever.—H. MASON, *Bisbrook Hall, Uppingham.*

— **THE HESSLE GARDENERS' MUTUAL IMPROVEMENT SOCIETY.**—At a meeting of the above Society held on February 26th a paper was read by Mr. Crofts, The Gardens, Tranby Croft, on "The Cultivation of Tuberous Begonias." Begonias, he said, are unsurpassed as summer bedding plants, and at the same time cheap to purchase, also so easy to raise and preserve, that all should grow them for bedding plants. But to see them at their best inside culture is to be recommended.—F. L. T.

— **FEBRUARY WEATHER.**—The weather during the past month has been the severest I recollect. The mornings of the 6th, 7th, 8th, 9th, and 10th were the sharpest. On each occasion the thermometer was down at zero on the snow line, whilst on the morning of the 8th the mercury was 3° below zero. Roses and tender shrubs have suffered badly, and the whole of the Broccoli are destroyed. The month on the whole has been very dry; only 0.47 of rain and snow was registered, against 1.71 of 1894.—E. WALLIS, *The Gardens, Hamels Park, Buntingford, Herts.*

— **FEBRUARY WEATHER IN SOUTH WALES.**—The following is a summary of the weather here for the past month. The sun shone on twenty-three days. Total amount 104½ hours; maximum, 8½ hours on the 16th; minimum, quarter hour on the 19th. The rainfall was the lowest on record, being 0.10, against 5.68 inches, for the same period last year. A very cold month, with brilliant sunshine most of the time, but with sharp frosts every night. The snow has not disappeared from the ground since the 29th of December. The wind has been from the east for fourteen days, and from the south-east twelve days.—W. MABBOTT, *Gwernllwyn House, Dowlais, Glam.*

— **METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, FOR FEBRUARY.**—Mean temperature of month, 28.1°. Maximum on the 23rd, 47°; minimum on the 8th, —4.0°. Maximum in the sun on the 27th, 103.8°; minimum on the grass on the 8th, —8.9°. Mean temperature of the air at 9 A.M., 26.5°. Mean temperature of the soil at 1 foot deep, 33°. Nights below 32° in shade, twenty-four; on grass, twenty-eight. Total sunshine, seventy-four hours, or 27 per cent. of possible duration; seven sunless days. Total rainfall, 0.13 inch; rain fell on eight days. Approximate averages for February:—Mean temperature, 39.5°; sunshine, fifty-six hours; rainfall, 1.58 inch. The coldest month for at least twenty years, and the driest with the single exception of February, 1891. We have twice had a lower minimum temperature in the shade—viz., in December, 1879, and January, 1894, when it fell to —5.8° and —4.4° respectively. The only other month with a mean temperature below 30° was January, 1881, when it was 28.4°.—J. MALLENDER.

— **GERMINATING POWER OF SEEDS.**—Dr. A. Peter gives, in the *Nachrichten von der Koniglichen Gesellschaft der Wissenschaften zu Gottingen*, the results of a second series of cultural experiments with dormant seeds, taken from various depths in the soil of woodlands or forest. The forest in question of the present day is the site of villages and cultivation that disappeared several centuries ago; and some of the samples were taken from dense forest, 100 to 150 years old, under the shade of which there has been no surface vegetation for years. The principal point to investigate was the probable existence of seeds of cornfield weeds still possessing the power of germinating and developing into reproductive plants. Dr. Peters succeeded in raising a large number of plants belonging to about fifty different species, including some that are essentially weeds of cultivation; and he believes he has good grounds for supposing that the buried seeds of many pasture plants and cornfield weeds retain the vitality much more than half a century; that is, under the conditions he describes.

— **PRIMULA BLOOMS.**—Just as we are going to press a few specimen Primula blooms reached us from Messrs. B. S. Williams and Son, Upper Holloway, London. These were evidently fine when dispatched, but arrived in a shrivelled condition, which deprived them of much of their beauty.

— **SULPHUR FOR ONIONS.**—For the benefit of persons who are unable to raise a good crop of Onions on account of the grub, I can offer a very good recipe, and it is as follows:—When the Onion bed is prepared and the drills made ready for sowing sprinkle a good pinch of flowers of sulphur in each drill from end to end, or if it is desirable to sow the Onions broadcast, sow the sulphur the same way, and dig it in. This will produce a sure crop of Onions, and no grub will trouble them.—T. F.

— **COLONIAL FRUITS.**—Up to the close of last week three steamships had arrived here from the Cape, fruit-laden, and in a short time the first fruits of the colonial supply were dispersed, a large quantity finding its way to the stalls of the hucksters. This latter fact indicates either an over-supply or inferior quality; unfortunately, both facts are required in explanation, and we regret, says a contemporary, to think that fruit shippers at the Cape have again learnt the lesson that not anything or everything will find profitable customers in London at this time of year.

— **SCARCITY OF PARSLEY.**—The most suitable places I have found for growing it to stand the winter has been odd corners under trees or hedge bottoms. Last season, having lost nearly all that was not in boxes and covered, more from damp than frost, I was obliged with a supply by a cottager, who had a fine lot growing under a Yew tree. Having cut about 6 feet of rough Yew hedge, planted on a mound of very rough material, and full of roots, I grubbed the surface, and gave it some potting-shed refuse, then sowed half with Parsley, and planted the other half. It did not grow very much and had to struggle amongst the weeds. The Parsley has, however, stood the winter all right, and there are several small leaves now, and with a change to genial weather there will soon be abundance for gathering. In many gardens there are corners where Parsley might be grown in out of the way places.—M. J.

— **THE WEATHER IN FEBRUARY.**—The first eighteen days of February were cold, and the eighth day of the month remarkably so, the minimum temperature on a Glaisher's screen read —3° (three below zero), and on the grass —8°. This was worse than occurred during the winter of 1860-61, when the minimum temperatures here were —1° on the stand, and —5° on the grass on December 25th. Fortunately the ground was covered with 4 inches of snow during the severest frosts this year, and many low growing plants have escaped serious injury. The frost penetrated the ground 8 inches, and a heap of soil 18 inches; the ice on the lake was 8½ inches in thickness. The wind was in a northerly direction eighteen days. Total rainfall 0.31 inch, which fell on seven days, the greatest daily fall being 0.14 inch on 24th. Barometer—highest 30.324 at 9 P.M. on the 16th; lowest 29.460 at 9 P.M. on 26th. Thermometer—highest in shade 45° on 28th; lowest —3° on 8th. Mean of daily maxima, 34.53°; mean of daily minima, 20.00°. Mean temperature of the month, 27.26°; lowest on grass —8° on 8th; highest in sun, 99° on the 27th. Mean temperature of the earth at 3 feet deep, 35.17°. Total sunshine, 106 hours twenty minutes. There were six sunless days.—W. H. DIVERS, *Belvoir Castle Gardens, Grantham.*

— **SPRAYING PLANTS.**—Spraying plants with clear water is of such benefit to them, that it is strange people in general do not practise it more. There are several kinds of implements to use for the purpose, any of which will do the work well. The value of spraying cannot be over-estimated; it tempers the atmosphere around the plants and washes the dust from them, leaving the breathing pores free to act, and prevents the ravages of red spider. Some years ago, when I had no sprinkler and had never heard of one, I used a whisk broom dipped in water to sprinkle my plants, and it answered the purpose very well. Some plants do not like water on their leaves, and they can be moved out of reach of it. None of them like it when the sun is shining hot on the foliage, but in the early morning or evening they enjoy it. The value of moisture around Chinese Primroses, says a writer in an American contemporary, is seldom fully understood. They dislike it on their foliage, but when the pots are sunk into wet sand the moisture causes them to grow rank and healthy, and they never have that dried-up forsaken look that we see when moisture is lacking. To sum it all up, the rule to follow in spraying is to spray as often as you think the plants need it, and then, to be sure they have enough moisture, spray a little more.

— THE CHISLEHURST GARDENERS' ASSOCIATION.—The members of the above Association spent a most enjoyable and instructive evening on Tuesday last, when Mr. J. Martin, from Messrs. Sutton & Sons, gave a lecture on "Cyclamens as Grown at Reading." There was a full attendance, and great interest was manifested by the members, some of whom are Cyclamen growers, but after Tuesday's lecture it will be safe to predict that a greater impetus will be given to the culture of Cyclamens in the Chislehurst district. A number of Cyclamens in pots were exhibited, and also cut blooms of Cyclamens and Primulas from the Reading collection.—R. F.

— SUTTON'S EARLIEST OF ALL RADISH.—This small Olive-shaped variety would seem to be correctly named, judging from our experience during the past severe weather. In a slightly heated pit we were able to commence pulling in a month from the time of sowing, and doubtless should have been even sooner than this had the weather been more genial. Being very quick in growth, it is of necessity mild in flavour, and particularly suited on account of its small size for the salad bowl. Its leaf growth is so short that it is not easy to tie them in bunches—that is, when freely exposed to light, and not too thickly sown. For small frames or pits it is particularly adapted, because so many can be had from a small space on account of its compact growth, allowing thicker sowing than is possible with larger varieties.—S.

— APPEAL JUDGES.—I had no intention of referring to this subject again, but I see that "C. K." (page 169) impeaches a Society, of which I presume he is a member, with dishonourable practices. This Society selects for judges gentlemen of such admitted competency, probity, and standing in the horticultural world as Mr. Temple of Carron House, Mr. Murray of Parkhall, Mr. Brown of Abercainey, or Mr. McConnachie of Cameron House. If the Society referred to by your correspondent had been guilty of the malpractices stated by him, it would have ceased to exist long ago, whereas it is in its eighty-third year, and was never more flourishing than it is at the present time.—G. MCDUGALL, *Stirling*. [Our correspondent sends us the regulations of the Society to which he refers, and we consider them very good; we also regard the judges named as beyond reproach. No useful purpose can be served by prolonging this discussion.]

— BOTANIC STATION AT ABURI ON THE GOLD COAST.—A few interesting facts referring to the establishment and present condition of this station are given in the "Kew Bulletin" for January, from which the following information has been gathered. The site is in the hills, at an elevation of about 1400 feet, overlooking the sea-board, near Accra and Pram Pram. In addition to its suitability for the growth of economic plants, Aburi is a valuable resort for European invalids. The locality has been greatly improved of late years, and it promises to become the centre of activity for many cultural industries started by the botanic station. During the winter of 1893-94 Mr. William Crowther, the Curator (appointed in 1890), was deputed to visit the West Indies "to observe the system pursued there in the cultivation of economic plants, and to bring back such useful seeds and plants as might with advantage be introduced to the Gold Coast." Mr. Crowther very successfully carried out the object of his mission, and published a detailed report. Since then the work of the Aburi station has made excellent progress. The inception, as well as the actual work, so far accomplished in botanical enterprise at the Gold Coast is entirely due to the Governor, Sir W. B. Griffith. He has given warm and consistent support to the station, and personally encouraged in every way the efforts of the Curator.

— VEITCH'S SUPERB EARLY DWARF BEAN.—For forcing under glass this is a decidedly superior variety, and one that as it becomes better known will take a foremost position. It is unusually dwarf in habit of growth, free bearing, and very quick in arriving at a matured stage. In a good forcing temperature pods are ready for gathering in slightly less than five weeks from the time of sowing, which is a gain over most varieties of dwarf Beans, and in cases where glass space is limited it has an additional recommendation in its dwarf sturdy growth. With such a general scarcity of vegetables outdoors some effort will be necessary to forward summer crops by sowing in boxes or pots for planting as soon as it is safe to do so on sheltered borders, and a variety possessing the quality of maturing only a few days in advance of older standard sorts must be a welcome addition. French Beans can be considerably hastened forward in pod-bearing by sowing in small pots and allowing them to advance steadily under glass until it is safe to plant them out in April; but some means of shelter must be devised as a safeguard against frost, which last year did such irreparable damage

among these as well as other tender crops. If hand-lights are not available Yew boughs form a capital protection from the dense nature of the foliage. Spruce is also valuable for the same purpose; both inserted around and among the plants at night and removed during bright, warm days will be a valuable help in getting a forward crop.—S., *Road Ashton*.

— PLANTS FOR THE BACK WALLS OF VINERIES.—The best plants for this purpose is an interesting query. I have tried several in my vinery, among the rest *Plumbago capensis* for cutting purposes, and *Heliotrope* for its scent. The latter remains, but the former, owing to its tendency to nurse mealy bug, I had to remove. On the whole I have had greatest value from three Tea Roses planted out—viz., *Ethel Brownlow*, *Lady Castlereagh*, and *Mrs. James Wilson* (Dickson's), pedigree Roses, all different. I had Roses on these at Christmas, and I have Roses now, and except a little pruning and liquid manure they give no trouble. *Maréchal Niel* on another wall first cankered and then died. The shade of the Vine foliage only brings out more perfectly the glorious tint of these perennial blooming Roses. I commend them to your correspondent, page 178.—W. J. MURPHY, *Clonmel*.

— EXTRAORDINARY FROST.—Abstract of climatological observations at Driffield, February, 1895 (authorised station of the Royal Meteorological Society). Lat., 54° 0' 30" N.; long., 0° 27' 15" W.; alt., 76 feet. Mean barometric pressure at 9 A.M. (at 32° and sea level), 30.067 inches. Highest, 30.53 on 16th; lowest, 29.70 on 11th and 27th. Mean temperature at 9 A.M. (corrected), 30.00. Wet bulb, 29.00. Mean maximum, 35.3; mean minimum, 23.0. Highest, 43.8 on 28th; lowest, -1.0° on 8th (= 33° of frost). Mean of maxima and minima, 29.1°. Mean range, 12.1°. Mean radiation temperature on grass, 17.0°; lowest, -10.0° on 8th (= 42° of frost). Rainfall, 0.64 inch. Number of rainy days, thirteen. Greatest amount in one day, 0.12 on 27th. Instruments by Negretti & Zambra. Barometer, Kew Standard, No. 1860 (verified November, 1890).—W. E. LOVEL, *Observer, York Road, Driffield*.

— MAKING GOOD LOSSES.—One of our leading vegetable growers wrote me the other day that practically everything in vegetables outdoors was killed, and he was now engaged in doing his best to push on Cabbage and Cauliflower seedlings for early cutting, also raising dwarf early Peas in pots for planting out later, sowing more French Beans than usual for inside fruiting, getting up early Potatoes in frames and in pots, pushing on Lettuces and sowing for succession, and taking other means to secure as good a supply of vegetables as possible at the earliest moment. Then happily there is at disposal a good supply of Asparagus and Seakale for forcing, and Mushrooms are plentiful. Thus it is that the gardener, who must never be discouraged by adversities, does his best to rise above or to surmount them. Probably only British gardeners would be at once so energetic and thoughtful. Their work is practically one long battle with difficulties, which Nature seems just as freely to furnish as she does encouragement.—D.

— WEIGHTS AND MEASURES.—The Select Committee of the House of Commons appointed to inquire into the existing systems of weights and measures in this country had a meeting on Tuesday, February 26th, under the presidency of Sir Henry Roscoe. Evidence was given by Mr. H. J. Chaney, Superintendent of the Standards Department of the Board of Trade, who described the system under which the verification of legal standards is carried on at the Board of Trade by experts appointed for the purpose, and also gave an account of the different systems of weights and measures now in use in the United Kingdom. He stated that the Imperial and the metric systems were the only ones with which the Department had to do in England, but there were other local customary weights and measures in use. There were many weights and measures in use which were not legally recognised. Among these he mentioned the carat, the boll (used in Scotland), the ell, the coomb (used for measuring corn), the Winchester bushel, the butchers' stone of 8 lbs., the miners' dish (used for weighing ore in Derbyshire), and the gauge (used in measuring plates) as examples of weights and measures which were not recognised by law. A number of anomalies which formerly existed—e.g., a ton of stone being different from a ton of other materials, &c.—had disappeared to a great extent under the operation of the Weights and Measures Acts of 1878 and 1889. The Scotch and Irish mile were still locally recognised, but for all statutory purposes a mile was 1760 yards. Practically the only two countries of any importance in Europe in which the metric system was not adopted were Great Britain and Russia. In Germany, Austria, France, Italy, Spain and Portugal the metric system was the only system in use.—("Nature.")

— **ROSES AT CHICAGO.**—Flower-raising about Chicago has reached enormous proportions. It is estimated that there are in and about that city 2,500,000 square feet of glass, and that most of it is devoted to the raising of Roses and Carnations. No wonder Roses are to be seen everywhere on the streets, and even offered from door to door. Florists are advised to direct their attention to a greater variety of plants, and it is suggested that as much is to be made by raising other kinds, and thus the market may be saved.

— **DEUTZIA PARSIFLORA.**—This genus of slender-branched and graceful shrubs, on account of the hardiness, fine habit, luxuriant foliage, and attractive flowers, which are produced in profusion, is, says a writer in a transatlantic contemporary, deservedly the most popular of flowering shrubs. *D. gracilis*, in addition to its beauty and usefulness as a hardy shrub, is one of the most valuable plants for forcing, being potted and placed in a warm position about six weeks before the flowers are desired. *D. parsiflora* is a new small-leaved species, as its name implies. It is a fine novelty. The branches are straight, leaves lance-shaped and dark green. The shrub, which grows to the height of 4 feet, is profusely covered with beautiful white flowers in June. The ease with which this shrub can be grown has led many enthusiastic horticulturists to secure each new addition as it appears.—J. W. A.

— **SEAKALE.**—Probably never at any time has the value of this most useful vegetable been more appreciated than now. I was much surprised to read the other day the advice of a gardener, which was to continue to plant and blanch on the old outdoor lines. It would be interesting to learn how far, even with heavy coatings of manure, forcing or even blanching proceeded during the late intensely severe weather. How different was the case of the gardener who, having raised several thousands of stout roots from root cuttings, had them all so laid in and protected that he could get access to them at any moment, and thus be having a few hundreds, furnishing an abundant supply of well blanched stout heads all through the winter. Seakale is just now to any gardener who sees his outdoor green crops devastated, invaluable. It helps to keep him going in a wonderful way. I anticipate as one result of the destruction seen everywhere, that gardeners will, more than ever, provide every year for a large stock of Seakale roots.—A. D.

— **WAKEFIELD PAXTON SOCIETY.**—There was an unusually large attendance of the members of this Society at the last meeting. Mr. W. Tunnicliffe, The Poplars, Thornes, was in the chair, and Mr. J. G. Brown, of Outwood, filled the vice-chair. The lecturer was the Rev. L. S. Calvert, M.A., of Batley, and he gave a lengthy, interesting, and amusing description of an eight days' climb over some of the Swiss mountains last year. The lecture was illustrated by a large number of very beautiful photographic slides belonging to Mr. Calvert, who gave a somewhat similar lecture to the Paxtonians last year. Between twenty and thirty of the slides were quite new, and were exhibited for the first time last Saturday night. The views were shown on the Society's large screen, which is permanently fixed in their lecture room, by Mr. Harold Parkin, whose clever manipulation of the lantern and carefully focussing of the slides enabled the large audience to see the pictures to the best advantage. Dr. Clark of the Yorkshire College said it had certainly been a great privilege to him to be present that evening, because in his opinion there was no sport comparable with mountain climbing.

— **EARLY MILAN TURNIPS.**—There is yet no other variety that comes in so quickly as this, unless it be the new Early White Milan offered by Messrs. Sutton & Sons this year. It is not everyone who can devote glass protection to the earliest Turnip crop, but those who can will find them doubly valuable this season. Where this cannot be done a warm spot outdoors should be selected, the soil made light and rich to encourage a rapid growth being made, and seeds sown as soon as the frost has left the soil, and the surface becomes sufficiently dry and warm. The earlier now they are sown in small quantity the better, considering how scarce these as well as other vegetables will be in early summer. Last year we were able to pull from outdoors on a south border by the time the frame-sown ones were gone, which was very early in May, the seeds being sown the first week in March. These may with some advantage be disposed between the rows of Peas, so that they derive shelter from these and the stakes used for their support. The latter should not be crowded too thickly together, or the Turnips instead of bulbing quickly will develop leaves and stalks at the expense of root, and thus valuable time and crop will be lost, or greatly retarded for want of air and sun. There is a general tendency to crowd it as much as possible in sheltered borders, these seldom being available beyond a limited extent, but it is more prudent to under rather than

overstep the mark at this season. Successional sowing will be better on a cooler site, and the Early Milan, although the best early variety is not recommended for summer use.—W. S.

— **TREMANDRA HUGELI.**—This is a dwarf bushy plant, usually not more than 1 foot in height, with numerous narrow and pointed leaves not more than half an inch long, and covered with short hairs. The flowers are produced from the axils of the leaves near the point of each shoot. They are nodding, upwards of 1 inch across if fully spread out, and of a pale, but bright purple colour. The petals are four in number, obovate, and, on account of their opening to only about half the full extent, render the flower somewhat campanulate. According to a contemporary this plant does not appear to be very well known, although considerable numbers have during the last few years been grown in one at least of the large London nurseries. It is just now coming into bloom, and its bright flowers and neat compact habit make it one of the prettiest of small greenhouse plants.

— **SHIRLEY AND DISTRICT GARDENERS' AND AMATEURS' IMPROVEMENT ASSOCIATION.**—An extra meeting was held at the Parish Room, St. Deny's, Southampton, kindly lent by the vicar, on Thursday last, Mr. B. Ladhams, F.R.H.S., presiding over a fair attendance of the members. Mr. J. Amys, The Gardens, Hamble Cliff, gave an interesting and instructive lecture on "Rotations of Crops for Cottage Gardens and Allotments." Mr. Amys said that a cottager obtained three advantages by close attention to his garden or allotment—health, pleasure, and profit. He gave a detailed account of the work necessary, and suitable crops for a cottager to grow, recommending in December a résumé of the year's work with a view to noting failures and successes, which would be valuable experience to work upon the next year. An interesting discussion ensued on various points of culture, one being the desirability or otherwise of sowing Broad Beans and Peas in the autumn. A hearty vote of thanks was accorded to the lecturer.

— **AZALEA LINEARIFOLIA.**—This curious species differs from all other Azaleas in almost every character but that of floral structure. It forms a flat-headed bush 3 to 4 feet high, each branch being terminated by a tuft of narrow light green leaves, which are densely covered with hairs. The specific name is very appropriate, as the leaves, which vary from 1½ inch to 3 inches in length, are not more than one-eighth of an inch wide at the broadest part, and taper to a point. The flower is composed of five narrow petals, similar in shape to the leaves, each one being 1½ inch long and of a light rosy purple. This Azalea, which is a native of Japan, will, says a contemporary, grow out of doors if planted in sandy peat and given a moist and sheltered position. In the cool greenhouse it grows well, and during February and March produces its flowers in abundance. Except for those, however, who like to have curious as well as beautiful plants in their greenhouses, it is scarcely showy enough to gain an entry there, but outside it makes an interesting and pretty bush, and is certainly worth cultivating.

— **CHESTNUT WEEVILS.**—These insects injure the nuts of the Paragon and Numbo varieties of Chestnut as well as the wild Chestnuts, according to a writer in the *American Cultivator*. The weevil is of a yellowish colour, and about the size of a common Pea weevil. The grub is white or cream coloured. The female beetle lays her eggs when the trees are in blossom, and in a few days the young grubs hatch. The shell of the Chestnut forms and hardens around the insects, and after eating most of the meat up inside, the worm bores its way out and escapes. These holes in the Chestnuts are never made by worms entering, but always by those that have escaped. One female beetle lays a great number of eggs in one season. The grubs after leaving the nuts go into the ground and produce winged beetles for the next summer. In seasons when they are scarce they have probably been killed by the severity of the previous winter. The Chestnuts should be gathered as early as possible, and stored in very tight bins or boxes where the worms cannot escape. Then fumigate them with carbon bisulphide. Eight ounces of this will do the work. After fumigating expose the nuts to the air and sunshine until they are thoroughly dried, and no harm will be done to them. It is quite essential that some such method should be adopted to destroy these creatures if Chestnut growing is going to prove profitable.

— **THE CHARLES COLLINS FUND.**—We acknowledge with thanks 2s. 6d. each from Messrs. William Kilgour, George Picker, and "R. J." Any other friends who may desire to contribute should do so during the ensuing week, as the Fund is about being closed by the Committee.

## VINES AT LONGLEAT.

CRITIQUE BY THE AUTHOR.

It is thirteen years since my treatise on "Vines at Longleat" was published in the *Journal of Horticulture*, and eleven years, I think, since the last copy in pamphlet form was sold. Still there are frequent inquiries for it. I have hesitated to republish it for the reason that some of the practices therein detailed are, as far as I am concerned, obsolete. But a thought has struck me that I might, by giving summaries of the principal chapters, criticise them by the light of recent experience, state where my ideas and practices now differ from those therein expressed, enlarge on such parts of the subject as may seem necessary, and thus take my readers with me up to the present time.

There is first of all given a description of the vinery, which is a span running north and south, 216 by 30 feet, divided into three compartments, 60, 75, and 80 feet respectively. Ventilation is secured by the upright sashes, 2 feet 9 inches deep, along each side, worked by levers, and a 6-foot wide lantern on the top, with upright sashes 2 feet deep worked in the same way. I am not sure, even after a quarter of a century's further experience, that I could improve on the general design of this house for its situation and the purpose for which it was intended, except it might be to make the roof less steep.

One of the buildings I now have charge of is similar in shape, with the exception of the lantern roof. This mode of ventilation has many advantages, but it adds considerably to the cost of building. Our latest erected vineries being on the side of a hill sloping to the south-west are built to fit the ground without much excavating. They are terraced inside—*i.e.*, the front border is on one level, the path another, and the back border some 3 feet higher, still sustained by a brick wall on one side of the path. The roof is an unequal span. That of the largest house has a 28-foot rafter on the front side, and the back rafter is about 17 feet 6 inches. Ventilation is afforded by lights opening on both sides of the ridge, and shutters at front and back close to the ground. The front shutters are 1 foot deep only, and the back ones 2 feet. The houses are all glazed on a principle invented and patented by Mr. Alderman Chaffin, and who, in fact, has built them all himself, with the exception of the first, which was done by contract.

The plan of the glazing is thus. The rafter is rebated in much the same way as for putty glazing, leaving the top  $1\frac{1}{2}$  inch wide; a strip of felt the same width is tacked on to this, and also another strip on to the next rafter in the same way. The lower pane of glass is laid on, and allowed to project over the outside of the wall plate an inch. Then another strip of felt the same width as the first is laid over the edges of the glass, and finally a length of galvanised hoop iron  $1\frac{1}{2}$  inch wide, turned at the lower end (to hold the pane from slipping) and reaching to within half an inch of the top of the pane. This half inch allows the lap for the next pane, and the end of the hoop iron, which is fastened to the rafter by galvanised screws, holds the second pane in position. The rafters are 20 inches from centre to centre, and the glass is half an inch less, thus leaving space for the screws between the two panes. This style of glazing answers well since we have prepared the iron ourselves and taken more pains to do them correctly than tradesmen could be persuaded to do. There is very little outside painting, and the glazing can be done by a handy labourer in almost any weather.

Our first built vinery is rather flatter than the Longleat one, which, I think, has an angle of about  $35^\circ$ ; our flattest roof rises 1 in  $2\frac{1}{4}$ , which is slightly less than  $24^\circ$ . In the house with the steeper roof Black Hamburgh does not colour satisfactorily; in the flattest one it coloured last year as black as sloes, but this is a comparatively new house, built in 1891, and it is, therefore, too early to speak positively on this point. But is it not a fact that Black Hamburghs as a rule do not colour in our modern light houses? We never see the colour and finish on them as used to be seen on those shown by Mr. Henderson of Coleorton some twenty-five or thirty years ago. I know this gentleman used to point to his dilapidated roof, and say that the abundance of air passing through it was the secret of his success, but I have my doubts on that point. I believe some of our modern vineries have quite a sufficiency of ventilation, but owing to the smaller amount of woodwork and the large panes of more transparent glass with comparatively few laps, the sun acts more quickly on them, especially if the roof is at all steep, and the fluctuations of temperature are much more rapid. I attribute the want of colour in a great measure to this. Make the roof flatter, and there is a marked difference in the variations of temperature and consequently in the other conditions of the atmosphere. If a house is to be glazed well I know of no necessity for a steep roof, so long as it is sufficiently steep to carry off the water, unless it may be for early forcing.

I met some time ago an old friend, Mr. Shore, who is now gardener at Berkeley Castle, and called to mind the beautiful Black Hamburghs he used to grow in a little house near Bristol. "Yes," he says, "and now I cannot grow Black Hamburghs at all." I do not suppose it is quite so bad as that, but evidently he cannot grow them to his own satisfaction, and it would be interesting to know whether the houses are likely to be the cause, or it may be that his multitudinous duties in a large establishment prevent him attending personally to them. The largest Hamburgh berries I have seen—and I believe they were as large as the "Colmans" we now grow—were produced in a house with an eastern aspect adjoining Mr. Meredith's dwelling house at the Garston Vineyard, but they were never quite black. One Vine hanging over a

cistern at the north end was, I believe, the only Vine in this house which produced exhibition Grapes. These were nearly black, but not quite. I remember one particularly good bunch in 1868, weighing something over 8 lbs., being cut and placed on the exhibition board, but many of the others in the house were very red. This house had a rather steep roof, and as soon as the sun rose above the horizon it was shining on it. I have had to run out many a time with trousers and boots only to admit air, as Mr. Meredith was very particular on this point. I still think he was right, but where I am situated now the aspect of the house is different, and there is seldom any need to open the ventilators before six o'clock in the morning. It was not so at Longleat. While the Vines were young they grew vigorously, the leading shoots of Alicante especially being stout and sappy. We could seldom get through a season without some of these shoots, or at least some of the leaves, being caught, although it was the practice to give air very early.

An incident which has only lately come to my knowledge will show how particular we were on this point. A young man who had been employed on the railway came to work for me, and as I found he would always do exactly as I told him, taking it for granted that I never told him wrong, I came to the conclusion that he was the man to look after the vinery, and I never regretted it. I found him a good learner, as he had nothing to unlearn, which is always the difficult point with young men. He has since filled one or two important places as head gardener, and is now acting in that capacity for a nobleman. He lived in the village some little distance from the garden, and one morning remained in bed a little too late. He slipped into his trousers and boots as quickly as possible, and started running with his other garments on his arm. He was challenged on the road by two dogs, who knew him perfectly well when properly dressed but were not willing to allow him to go by in that condition. What was he to do? He says, "I know that if either the governor or the sun got there before I did there would be something wrong." He therefore threw one of his garments to the dogs to amuse them, and ran on, arriving at the vinery just in time. This would probably be as early as 5 o'clock, or perhaps 4.30 A.M. Of course there are many persons who would not require a house so large as those I have mentioned, and where there are already walls it might be advisable to build lean-to roofs against them; but it should be remembered that large houses, especially those with flat roofs, are proportionately cheaper to build than small ones, and they are no more trouble and very little more expense to manage.—WM. TAYLOR.

## PENTAS CARNEA.

A "CONSTANT READER" writes desiring information about a plant, of which he encloses an excellent truss of flowers. He has not previously seen it, and supposes that it is not very largely grown. It is the good old *Pentas carnea* (fig. 38), and flowers during the spring and summer, but does not appear to be so extensively grown as it used to be. It is an evergreen, and will flower freely in an ordinary greenhouse during the early summer months, although it is usually grown in stoves. The flowers are of a pretty pink shade. During the winter the plants should be kept in a temperature of about  $50^\circ$  to  $55^\circ$ . If necessary, propagation can be effected by inserting cuttings of young shoots in a sandy compost in the spring, plunging the pots in a hotbed or propagator. Plants raised thus and grown on will flower towards the end of the summer. A compost of fibrous peat, loam, and sand will be found suitable, and rather firm potting is advisable.

## HERBACEOUS PHLOXES.

No family of plants among the herbaceous section more worthily deserves cultivation and a place in every garden than the perennial Phlox, but how often we see it mismanaged. There are two sections of the tall growing kinds—the early flowering varieties, *Phlox suffruticosa*, and the late flowering kinds, *Phlox decussata*. The early flowering section bloom during July, the later through August. Of its thorough hardiness there cannot be a moment's doubt, and it lasts for ever under fair treatment. The improvement in them during the last ten or twelve years has been great, and many new shades of colour have appeared amongst them.

By thinning out the shoots and liberal feeding, grand pyramidal trusses of flowers are obtained, and it is a mistake to allow the plants to grow on into large masses with an abundance of shoots, for the Phlox is a strong-growing plant forming a mass of roots which soon exhaust the soil. I prefer lifting them every three years, dividing the plants into pieces with from three to five growth buds, and planting them firmly in good soil, either in the early autumn or in the spring, keeping them well watered in dry weather to prevent the loss of foliage for one thing. When amateurs have a little gentle bottom heat at their command cuttings can be struck in the early spring, but the plan of dividing is much easier for them. As soon as the growth is about a foot in height a tie-up stick should be placed in position, and the shoots fastened to it to prevent injury from the action of the wind.

When Phloxes are grown for exhibition purposes to secure fine spikes and the flowers kept free from injury, a stick should be placed to

each shoot to secure it, and the plants kept mulched with a little decayed manure and kept watered in dry weather, and three spikes or rather growths to a plant is ample when extra fine blooms are wanted. The protection of the blooms in wet or windy weather is a puzzle to many

sunshine, and the canvas, and in fact sticks also, can be easily removed when not wanted.

It is unnecessary for me to give names of desirable varieties here, for they are so numerous that were I to give the names of a few good

FIG. 38.—PENTAS CARNEA.

how best to do so, but a very simple plan is to place three Dahlia stakes as a tripod, forming a cone over the flowers, and wrapping a piece of canvas securely around it for about half the distance from the top, thus allowing the free circulation of air, at the same time taking care the flowers are not bruised. This is also a protection from strong

ones, there are others quite as good. The best plan is to send to a florist who is celebrated for Phloxes, giving the names of varieties always grown by the intending purchaser, and leave the selection of a few first rate kinds to him. Or another good plan is to take notes of any that strike you at the blooming time, and order plants for the autumn.—W. D.

## ROSE SHOW FIXTURES FOR 1895.

- June 27th (Thursday).—Gloucester (N.R.S.) and Canterbury.  
 „ 28th (Friday).—Exeter.  
 „ 29th (Saturday).—Windsor.  
 July 2nd (Tuesday).—Sutton.  
 „ 3rd (Wednesday).—Croydon, Ealing, and Farningham.  
 „ 4th (Thursday).—Eltham and Norwich.  
 „ 6th (Saturday).—Crystal Palace (N.R.S.).  
 „ 9th (Tuesday).—Wolverhampton.\*  
 „ 10th (Wednesday).—Chelmsford and Hitchin.  
 „ 11th (Thursday).—Helensburgh and Worksop.  
 „ 17th (Wednesday).—Derby (N.R.S.).  
 „ 18th (Thursday).—Halifax.  
 „ 23rd (Tuesday).—Tibshelf.  
 „ 24th (Wednesday).—Chesterfield.  
 „ 25th (Thursday).—Trentham.

\* A show lasting three days.

I shall be glad to receive the dates of other Rose shows than those named above for publication in future lists.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

## EFFECTS OF THE FROST.

THE influence of the long-continued frost of last winter on gardens and rosarians has, in many places, been most disastrous. Mr. Cranston of Hereford writes me to say that a large number of his Hybrid Perpetuals, Noisettes, and Teas have been killed down to the snow-line. Only the stronger varieties have escaped. His Conifers and fruit trees are, fortunately, uninjured. The Messrs. Croll of Dundee, whose nurseries are at Broughty Ferry on the Firth of Tay, inform me that many of their finest Roses have been utterly destroyed. I much regret to learn this, as the Messrs. Croll are among the foremost of our Scottish rosarians, and have proved themselves of late years formidable rivals to the Messrs. Crocker of Aberdeen. We may take it for granted that the latter have also suffered much from the terrible frost. It would be interesting to know the experiences of the great English rosarians, such as Messrs. Paul of Waltham, Cant of Colchester, Prince of Oxford, Harkness of Bedale, Keynes & Co. of Salisbury, and Turner of Slough. Mr. George Paul's providential preservation of his Teas has already been recorded, in the last week's issue of the *Journal of Horticulture*. I hope that other cultivators have been equally fortunate.

Many of the Roses in my own garden have been slightly injured, but so far as I can learn not one of them destroyed. The Hybrid Perpetuals, the more vigorous Teas, and the Noisettes on the south wall, including two *Maréchal Niels*, are almost untouched. This, however, is not surprising, for my Rose trees are sheltered from every wind that blows. Even my Pansies and Violas exposed on open borders have escaped. On the other hand, I regret to say that at Logan House, in this parish, Mrs. McDouall's Roses have been so seriously affected that pruning this season will be almost superfluous, but the head gardener, Mr. McMicking, assures me that though the stems are much injured the plants are still alive, none of them having been wholly destroyed. Rhododendrons, Azaleas, and even Hollies at Logan have suffered so greatly as to be quite unrecognisable.—DAVID R. WILLIAMSON.

AN inspection of my Roses shows that on the south side of a wall of Teas and Noisettes climbing *Niphotos* and climbing *Perle des Jardins* are a total wreck, and even our old friend *Gloire de Dijon* has suffered. The least affected of all was *L'Idéal*, but much of the wood is of little use for the coming spring. On the north side of this wall are a few plants of *Maréchal Niel* and others which often give us a most acceptable crop of summer blooms. The plants here are much less affected than on the south or warmer side. In almost all cases where the sun had full play upon it the wood is totally killed. No doubt the extremely sudden changes have much to do with this, for it was sometimes like spring when sheltered and in the midday sun, followed by 10° to 25° at night. On a fence running due north and south the Roses were not quite so bad as on the wall running east and west; but here, also, there is sad havoc. A few plants of a sport which I valued considerably appear quite dead; but I have others under cover as well, for which I am heartily thankful.

Cut-backs from last season, and also many thoroughly established dwarfs, are severely injured where not quite killed. Maidens, too, are almost gone, and there will probably be some difficulty in meeting the large demand that is bound to come for spring planting to fill up gaps: Unfortunately, we had no snow worth naming, never more than a couple of inches. Some varieties are evidently more hardy than others. Horace Vernet in the H.P.'s is almost killed, while *L'Idéal* and others are fairly exempt in the Tea class. Many could be mentioned from the Teas that are terribly hard hit, while Paul Neron, Ulrich Brunner, Jules Margottin, and others in the H.P.'s are fairly safe. But, class for class, I fail to see any difference on the whole.

The most pleasing feature is the way that dormant buds, both of Teas and Hybrid Perpetuals, seem to have come through when upon dwarfs. More especially is this the case when upon the Briar and De la Grifferaie stocks. On half-standards and other hedge Briars I fear there will be sad blanks. On our dwarf stocks of Manetti the buds do not look quite so happy, and doubtless this is because of the less hardiness of the foster roots. There will not be much pruning to do after our Roses have been cleared of dead wood.

When shall we have another really good Rose year? 1893 was bad; 1894 promised well, but turned out a fraud on account of the sharp May frost. Then, although we secured good growth in the autumn, and managed to get it well ripened, the recent winter has again precluded what might possibly have been a good Rose season; for, no matter how kind the weather may be from now, we shall scarcely see the wealth of early summer Roses fairly promised by last autumn's growth.—PRACTICE.

## NOTES ON SNOWDROPS.

## GALANTHUS NIVALIS REDOUTEI.

THE Snowdrop grown in gardens under the name of *G. Redoutei* is, in reality, *G. latifolius* of Ruprecht, and quite distinct from the plant named at Kew *G. n. Redoutei*. In the autumn of 1892 I received a few bulbs as *G. Elwesi*. These flowered very early in 1893, and I was considerably puzzled over them. They were unlike any *G. Elwesi* I had ever seen, but as one is always liable to fall into error, I sent one plant each to three of our best Snowdrop growers, none of whom knew what it was. I then sent one to Kew, and the authorities there kindly informed me that *G. nivalis Redoutei* was the name of the Snowdrop. This was a surprise, as *G. Redoutei* was rare, if not unknown, in our British gardens. One distinguishing feature of this Snowdrop is the character of the leaves, which present the appearance of a flat arch when at their full size. The flower, which is of good size, and of the same character as the ordinary *G. nivalis*, stands on a stout, erect stem, and from the low altitude above the soil of the leaves appears very conspicuous. The leaves are of a dull grey-green, and are rather corrugated on the under surface. The whole style of this Snowdrop is not unlike an enlarged form of one grown as *G. montanus*; the larger size appearing in flowers, stems, and leaves, the latter being lighter coloured than those of *G. montanus*. The flowers were in bloom about January 22nd last year. *G. n. Redoutei* is understood to be a native of the Caucasus.

## G. PERRYI.

Through the kindness of one of my flower-loving friends I received this Snowdrop in flower two years ago. It was accompanied by a remark which hardly gave me a favourable impression of its merits. This was, that although it was apparently a good grower it did not appear to be of great value otherwise. With every desire to agree with my friend, I am compelled to express my admiration for this little Snowdrop which, while certainly small in size, is extremely beautiful. Its first appearance is a little curious to those unacquainted with the habits of some others of the genus, the flower-scape rising to a considerable height for the size of the plant before the broad, short leaves, unfold themselves. The scapes are bright green, and the flowers, while small, are of fine form, and hang in a most graceful way from the erect scapes. The markings of the flowers are like those of our common Snowdrop. The leaves are about five-eighths of an inch broad, and of a glaucous green. If I am not misinformed *G. Perryi* is from the Caucasus.

## G. MONTANUS.

In writing of *G. nivalis Redoutei* I have mentioned this, which is a doubtfully named plant, as some say *G. montanus* is the same as *G. latifolius*. The flower is like that of *G. nivalis*, and the leaves have the arching character referred to in the note on *G. n. Redoutei*, but are a bluer green, narrower and shorter. Being still a little uncertain of the name I only write this to guard against it being supposed that in referring to *G. montanus* I am speaking of *G. latifolius*, with its broad, shining green leaves.

## G. IKARIAE.

This new Snowdrop, for which we are indebted to Mr. E. Whittall of Smyrna, is causing some curiosity among admirers of the *Galanthus* in its various forms. It has been named and described by Mr. J. G. Baker from two half-dried specimens sent by Mr. Whittall. Through the kindness of a friend I received some bulbs, only one of which flowered last year. It has the shining green leaves of *G. latifolius*, though they vary in form, some having the strap shape of those described by Mr. Baker. The outer segments are rather less than an inch long, and the inner ones about half the length. The latter forms a pretty, bell-shaped cup, with a conspicuous bright green, apical blotch of large size, occupying about a half of the outside of the segments.

The constitution of *G. Ikaria* remains to be proved, but one report which has reached me regarding bulbs procured in 1892 is not very favourable. It is to be hoped, however, that we may be able to establish it in our gardens. The habitat of this plant is in the Island of Nikaria, which lies a short distance S.W. of Samos, off the West Coast of Asia Minor. It will be observed that the spelling of the name is *Ikariae*, suppressing the initial letter N in the name of the island, and following the classical spelling of *Ikaria* or *Icaria*. It is to be feared this will lead to some confusion, and that the plant will occasionally be found under the name of *G. Nikariae*.

## G. MAGNET.

Were any argument needed to disarm those who object to the improvement of the Snowdrop, a powerful one would be supplied by this fine flower—one of Mr. James Allen's seedlings. It is true it possesses one feature which causes one some debate as to whether it is an improvement or not; this is its tendency to produce two flowers on a fasciated stalk. We are familiar with more than one flower on the scape of a Snowflake, but this is a rare occurrence with a Snowdrop, although it occurs with an exceptional variety. I must confess to being in a strait between two opinions, these being whether to consider this an improvement or a defect in an otherwise very beautiful flower. The two flowers are not invariably but are commonly produced in this variety, and they are so large, of such good form, and of so much substance that G. Magnet must be considered a great acquisition. It is of the *nivalis* type, and the scapes and leaves are quite in proportion to the size of the flowers.

## G. LUTESCENS.

This is one of what are known as the "Yellow Snowdrops," and which are so called, not from the colour of the flower, but from the markings which are usually green being yellow. The ovary is also a rich yellow, and the flower stalks assume a yellowish colour. The variety under notice was found about eighteen years ago in an old garden in Northumberland. It is very beautiful and very distinct, but is unfortunately small, delicate in constitution, and slow of increase. I have only had this variety for about three years, and it did not flower with me until last season. It is well worthy of a place in the choicest garden, and will be universally admired for its delicate beauty.

## G. SHARLOKI.

This singular variety is interesting from the time it first appears through the soil. Not that all Snowdrops are not interesting, even in their earliest stages, protected as they are by their spathes from defilement as they pierce through the earth, but this one is particularly so from the spathe being divided. When it comes into view the divisions are separate, and look very curious as they advance, being like two small green horns. The singular appearance is then added to by the flowers, which, with the green markings on the outside of the outer segments, look at this stage like little white balls streaked with green. The flowers when at their full size are not so attractive, the green streaks giving them a dingy look, but, on the other hand, the twin spathes look very peculiar, and add to the interest of the flower. G. Sharloki is of the *nivalis* type, and was named by Professor Caspary of Koenigsberg in honour of its discoverer, Herr Julius Sharlok of Grandenz, who found it growing wild in some copses in the valley of the Nahe, a tributary of the Rhine. It is a very good grower, and flowers quite freely.—S. ARNOTT.

## SPAWNING MUSHROOM BEDS.

THOUGH I do not consider myself an expert, I should very much like to give my experience on this subject. Like your first correspondent, who signs himself "Mushroom," I would be glad to gather from gardeners and growers of greater knowledge and longer practice than myself a clue to the causes of the partial failures that I have experienced.

The first Mushroom bed that I made was a very off-hand affair—two loads of long stable manure made into a flat bed about a foot in depth. This was spawned at once with spawn of my own making. Rough protection of old frame lights placed over it was afforded, and it was not soiled or cased in any way. This was in a shady north-east corner of a field. The Mushrooms came quickly, of good substance, and in patches or bunches a foot across. This bed was not made firm, but exactly as gardeners make up a little warmth for sowing tender annuals in the spring—in fact, part of the bed was used for that purpose. This bed was made in March, and came into bearing in about a month, and the crop continued until the heavy rains of July swamped it.

I have since read that useful work, Wright's "Mushrooms for the Million," and I now follow as closely as possible the routine that he advises, making my beds in the ridge form—in fact, I follow out all the instructions to the letter, and it is not too much to say that I have in one or two instances proved that his estimate of the produce per yard of bed can be realised sometimes. "J. W. K." (page 167) considers the beds can be made too hard. I have thought so myself, but in making a ridge Mr. Wright says, "If the ridge is made as it should be, you will not be able, in making the ventilation holes, to make them with a wooden stake, but an iron rod will be needed." I always require the iron for this purpose, and if beds can be too solid, then certainly I could never have realised 15s. per yard on a 90-foot ridge, the price per lb. averaging 9d.

I mention this fact merely to show that I hold the practice described in the little book to be sound, and I cannot think in my case hardness of material causes the condition of things I will now describe. I have found the beds to show well and come into bearing in about six or eight weeks, but the Mushrooms though sufficient in numbers are small, light, and flimsy; nor do I think the flavour so good as when larger and thicker. Where a cluster of six or more appears one Mushroom only takes the lead, and the others fade away; also I find that at the least touch they fall, whereas on strong beds it requires a good pull to gather them. The last and crowning misfortune in this category being, the beds last about six weeks instead of three months; I have had some last five months. I

am aware that some of my friends (gardeners) think beds lasting six weeks are not to be found fault with, but manure, labour, and rent are a great item, and unless you secure a full crop Mushrooms will not pay to grow.

I agree with "J. W. K." that good spawn is absolutely necessary, and my object in writing will have been gained if any one of your readers can tell how we can assure ourselves whether the spawn be good or inferior. This is one of the cases where the buyer must take the seller on his good faith and chance the results. To illustrate this point, an acquaintance of mine, a very smart gardener and a good Mushroom grower, once told me that he could not tell Mushroom spawn by its appearance, but he was very certain of its quality by the smell. I know that his smell misled him in the purchase of spawn, for we both dealt with the same producer. My friend had no Mushrooms at all, while I had crops which at least paid for my spawn and labour. I have thought that possibly there may be different varieties, some bearing culture better than others, and therefore I would not say a word that may be thought to be a reflection on the honesty of dealers in Mushroom spawn. I am a very old subscriber to the Journal, and I consider the present query by "Mushroom" to be as interesting as any now before your readers.—THOS. GARDNER, *North End, Hampstead.*

## STOVE AND GREENHOUSE FLOWERING PLANTS.

[Extract from a Paper by Mr. J. LOCK.]

FOREMOST among the plants I purpose mentioning must be placed the hardwooded greenhouse species, which in beauty cannot be excelled by any others, not even excepting the numerous family of Orchids, with their many varied forms and rich hues of colour. That *Cattleyas*, *Odontoglossums*, *Dendrobiums*, and *Cypripediums* are all possessed of universal attractions I admit, and so, too, are *Ericas*, *Aphelaxes*, *Phœnocomas*, *Hedaras*, *Boronias*, *Pimeleas*, and the elegantly beautiful *Leschenaultia biloba major*. A good plant of the last-named once seen will long be remembered, but unfortunately, along with the majority of the choice Cape and New Holland plants, the *Leschenaultia* in the form of large specimens is becoming more rare every year, and is now seldom seen at exhibitions.

It is much to be regretted that these old-time favourites are now pushed aside by more easily grown and freer-flowering, softwooded plants. True, we occasionally meet with a few wretched looking, stunted specimens, but much as I admire them when well grown, I frankly confess in such cases I would prefer their places being filled with *Pelargoniums* or similar plants, and the more valuable, but, when badly treated, less attractive *Heaths* consigned to the rubbish heap.

I shall confine my remarks on houses to very few words, as in the majority of cases gardeners have to accept and make the best of structures already existing, and many are the expedients resorted to, especially by exhibitors, to give their charges more congenial accommodation than the houses at their disposal readily furnish. Where new houses are being erected they should be span-roofed, and in every case have fairly large squares of glass and a correspondingly small amount of woodwork, so that light may be freely admitted. Even for shade-loving plants such structures are the best, for during bright weather they can be protected from the sun's rays, whereas nothing can remedy a deficiency of sunlight, and for at least five months of the year most of the plants we cultivate would be benefited by more light than our climate affords.

Ample means of ventilation should be provided, especially in greenhouses, for in genial weather it is hardly possible to admit air too freely, although cold currents rushing directly on the plants must be carefully avoided, draughts being at all times decidedly injurious. Greenhouses should have sashes on both sides made to open the whole length of the structure, also on both sides the ridge of the roof. The occupants of the stove do not require so much air at any time of the year, and ventilators in the roof are all that are needed. As the heat of the sun's rays increase it will be necessary to admit a little ventilation, but great care must be exercised in so doing, or the tender growths will be quickly injured thereby.

Very few greenhouse plants require shade, except perhaps to prolong or retard their season of blooming, but amongst those grown in stoves a large number are benefited by protection from hot sunshine. For supplying this nothing equals roller blinds worked by means of cords and pulleys, and so adjusted that they may be easily worked up and down. The material forming the blinds may be thick or thin, according to the requirements of the plants grown underneath.

I come now to what I consider the most important point in the cultivation of plants under glass—namely, the application of water to their roots. More plants are injured by an injudicious use of the water-pot than from any other cause. Some quickly show signs of distress if allowed to become too dry at the roots, but generally speaking, far more evil is done by a too liberal application of water, particularly to plants recently potted. In the case of stove plants, on which the syringe can be more freely used than on those in greenhouses, it is often advisable to withhold water from the roots for several days after repotting, provided the soil used is in proper condition with regard to moisture.

It is impossible to lay down any hard and fast rules for watering, as no two plants are likely to require precisely the same amount. I would strongly impress upon the minds of young gardeners that a thorough knowledge of this important point in plant culture is absolutely necessary, and consequently too much attention cannot be given it by

those who desire to become proficient. Study the requirements of the different plants, also the nature of the compost used in potting. Loam varies considerably in different localities, and it is to this I particularly allude. Sometimes loam is of so heavy and retentive a nature that the application of water necessary to maintain plants grown therein is little short of a fine art. Such soils should be allowed to reach a degree of dryness before giving water that in less retentive loam would be dangerous, if not fatal.

There are a few plants to which it may safely be said it is impossible to give too much water when growing freely, and foremost among those are the Anthuriums. When given a compost consisting of one-half peat fibre, with all the dust shaken out, one-half broken crocks and charcoal, with a surfacing of living sphagnum moss, and the pots partially filled with crocks, Anthuriums cannot be over-watered. The other extreme is found among the hardwooded greenhouse plants, which require more careful attention in this respect than any other species that I am acquainted with. If a Petunia or Pelargonium be allowed to flag through want of moisture, or, on the other hand, kept too wet for a time, although it may be injured it will recover; but subject a Hedera or Leschenaultia to similar treatment and it will not long survive. In the case of Heaths, the softwooded varieties, such as *hyemalis* and *Eweriana*, require to be watered with a freedom that would prove fatal in the case of the short-growing hardwooded varieties, of which *æmula* and *Marnockiana* are fair examples. In cultivating Primulas, especially the double varieties, which are mostly propagated from cuttings, there is often found a disposition to damp off at the collar. This is frequently attributed to an unsuitable position, or otherwise regarded as constitutional, but generally, I am convinced, the cause might be traced to defective watering.

#### HUMEA ELEGANS.

THIS handsome decorative plant, once so popular for flower garden and conservatory adornment, for some time almost fell out of cultivation, and was rarely seen in collections, where by its gracefulness it would have added much to make an elegant finish to floral arrangements. So scarce did this plant become that one season it was impossible to obtain seeds of it from the leading nurserymen. This was doubtless owing to the fact that unless it is managed with judicious care during the winter months it has a great tendency to turn yellow, and eventually wither and die. In many instances this is brought about by endeavouring to grow the plants in too large pots, and supplying them with a superabundance of water. During a long experience in *Humea* culture I have seen collections of well-grown plants, all in splendid condition when placed in their winter quarters, droop away one by one, and die till when the spring came round, only a few were left in a healthy state.

It was doubtless owing to such failures that many gardeners discontinued the culture of *Humeas*, and but for the tenacity of a few of their admirers they would have ceased to figure in the list of greenhouse plants. Recently *Humeas* have again increased in popularity, and now in many establishments are largely cultivated. Many growers make a great mistake in sowing the seeds too early. The plants then make too much growth during the current season, whereas it is much more beneficially made the following spring. By sowing seeds early, say in April or May, robust growth is made during the summer, and to keep the foliage green larger pots must be given as required, until by October the plants are from 12 to 18 inches in height. During the dull months that follow growth for a time ceases; the large pots are often only partially full of roots, so that by injudicious watering the soil becomes sour, and consequently the tender roots decay. This is quickly followed by loss of foliage, and if the plants survive, by the next summer, instead of being sturdy and clothed with bright green leaves to the pots, they are bare, and produce indifferent sprays of flower.

If the seeds are sown in June better results may be expected to follow. They should be sown thinly in shallow boxes or pans, scattering a little fine soil over them, and placing in a moist atmosphere where they can be shaded from the strong rays of the sun. *Humea* seeds are often a considerable time in germinating, but after the plants appear, and are large enough to be handled, they should be placed singly in small pots and kept in a medium temperature to encourage sturdy growth. Being ardent growers a further potting will soon be necessary, using a good compost of fibrous loam, leaf mould, and sand, with a little decayed manure. If placed in 6 or 7-inch pots late in the summer they will be in good condition to undergo the trials of the winter. Plants so treated do not make rapid growth, and are usually in good condition for the final shift in spring. They may be flowered in 9 or 10-inch pots, according to size of the plants, using moderately rich soil. A cool greenhouse temperature suits them admirably, an occasional fumigating being necessary to check the ravages of green fly. Another pest which attacks *Humeas* is a grub which eats away the leaves, as in the case of *Marguerites*. A strict watch must therefore be kept, and if any are noticed they should at once be destroyed by crushing between the thumb and finger, or if allowed to accumulate they will ruin the plants.

When the pots are full of roots, liquid manure aids the plants materially, and their long feathery spikes prove a great acquisition for conservatory decoration in the summer. *Humeas* are equally ornamental in the flower garden by plunging the pots in the beds, and staking to assist the plants to withstand the strong winds.—G. H. H.

#### THE CHRYSANTHEMUM YEAR BOOK.

MR. C. H. PAYNE is evidently reaping the customary reward of those who in a generous spirit try to perform onerous and responsible duties from their good nature. Why do not these critics of the Editor of the Year Book say in plain terms what they mean, and assert that Mr. Payne has been guilty of gross favouritism, for that seems to be the kind of imputation sought to be conveyed? Will any of these critics undertake either to edit the Year Book, getting for such labour scant acknowledgement, no pay, and no thanks, but plenty of kicks, or even to expend much time and some money to prepare articles and then receive absolutely no thanks whatever from the Society whose coffers the book is enriching? There is a fine field open here for the grumblers who are so numerous in the Chrysanthemum world, and whose human nature peeps out in the most unpleasant fashion.

The Committee, now that this body has been newly constituted, should show its confidence in their Editor by not merely voting this to him, but making a grant that would be even more expressive. After doing that perhaps the same body of gentlemen may next condescend to tender thanks to the various contributors for the good help they have rendered to the first issue of the Year Book. That has not been done yet—a mere oversight it may be assumed on the part of the executive of the N.C.S., and the act of courtesy will no doubt be soon performed. As a contributor who did his best for the Year Book I await the action of the executive with much interest.—A. DEAN.

#### RANUNCULUSES.

MANY years ago the Ranunculus was a very popular flower, and the varieties raised by the late Mr. Tyso of Wallingford, Berks, had a great reputation. Old florists, such as the late Mr. Richard Headly, grew fine collections of them, and the long bed at Stapleford, Cambridge, was a sight worth seeing at the blooming time. This plant is of easy culture when understood, and the blooms are so beautiful and so admirable for indoor decoration that I am induced to ask your readers to give attention to the Ranunculus as a hardy border plant, and with that view to give a few cultural instructions as practised many years ago by a very successful cultivator.

A bed was prepared early in the autumn where moderate drainage was provided, and well decayed manure free from worms and insects was dug in to the depth of 15 to 18 inches. The bed was levelled, and about 3 or 4 inches of finer soil placed on the top, a compost in which well-decayed leaf soil and a little sand were mixed, but a good strong loam suits them best. The surface was made moderately firm, and the small claw-shaped roots were pressed into the soil to the depth of 2 inches and then made firm. Planting of one bed was done in October or early in November, and another early in the spring; in fact, planting may be done as late as April.

Soil is not of such great importance to the Ranunculus as moisture and full exposure to the sun. Some persons plant under the impression that shade is best for them, but this is not so. The rows may be about 8 or 9 inches apart, with the roots 4 inches asunder in the rows, and during the growing and flowering season in dry weather an ample supply of water between the rows should be given night and morning, so as to secure abundance of moisture in the soil, the more of it, the better they like it. A mulching of cow or other decayed manure between the rows helps them materially.

After blooming, and the foliage has decayed, the roots should be lifted and kept in a dry place until planting-out time again. They can be purchased at such a cheap rate that no garden need be without some. There are scarlets, yellow, citron-coloured, carmine, and almost black, all of which can be bought at an average price of 3s. 6d. per 100. A beautiful white variety is dearer. Then there are larger flowered kinds, known as the Giant French varieties, which are very free bloomers and handsome, and these, I think, can be readily obtained at about 5s. per 100.—W. D.

#### THREE GOOD CLERODENDRONS.

ALTHOUGH Clerodendrons comprise a large number of separate species it is not my intention to dilate on each variety individually, for to do so would occupy more time and space than the limits of my paper will afford. I will therefore restrict myself to a few remarks pertaining to three of the best and most useful varieties only—viz., *C. Thomsonæ*, *C. splendens speciosissima*, and *C. fallax*. In habit and growth there are two distinct sections, one being of a climbing and the other of a shrubby nature. The first two both belong to the climbing varieties.

*C. Thomsonæ*, or *Balfourianum*, as it is more often called, on account of the brilliancy of its flowers, together with the great freedom with which they are produced, is undoubtedly the most widely cultivated. The flowers, which are disposed in large panicles, are of a beautiful bright crimson colour, with calyces of pure white, and when seen to perfection

cannot fail to impress a lasting effect on the memory. If grown in a large pot, and its cultivation carefully and assiduously attended to, few climbing plants can excel it for exhibition purposes. *C. splendens speciosissima* forms a grand companion to Thomsonæ. In habit and character it is very similar, but differs in the colour of the flowers, which are of a dazzling scarlet, and freely produced over the bright shining green foliage, truly classes it as one of the best stove climbers in cultivation.

In *C. fallax* we have without doubt the very best of the shrubby varieties, and I have confidence in saying that when once given a fair trial the results will exceed all expectations, and will not fail to please the most fastidious. It is of an erect growing nature, and freely produces its bright scarlet flowers in large terminal panicles. Firm potting is essential, being conducive of obtaining short-jointed wood, and also adding materially to the strength, size, and durability of the flowers. Propagation may be readily effected by cuttings or seeds, and I much prefer the latter course, although the quickest way is undoubtedly by cuttings.

Plants of *Clerodendrons* which have been at rest should now be overhauled, removing any weak or superfluous wood, and in the case of the climbing varieties tying the remainder of the growths neatly and evenly. They should then be placed in a brisk heat, and kept well syringed to encourage them to break, water at the roots being sparingly applied till root action has commenced. When they have made a few inches of growth they should be either shaken out and repotted or have the surface soil removed and well top-dressed according to the state of the roots.

A mixture of good fibrous loam and peat in about equal proportions, with one-fourth leaf soil or well decomposed manure, to which a little charcoal and sand has been added, will form a very suitable mixture for the climbing varieties, but the shrubby sorts, owing to the grossness of their foliage, will require a somewhat stronger compost. Should any signs of insect pests be detected every effort should be strenuously employed for their extermination, or they will quickly establish themselves on the young growths, when it will be impossible to eradicate them. Should mealy bug make its appearance, the best and most effectual cure is by handpicking, or by sponging with a solution of soft-soap and Gishurst compound.—GEO. PARRANT, *Ashby Lodge Gardens, near Rugby.*

#### BENTHAMIA FRAGIFERA.

In reply to the query of "J. W. G.," this tree was discovered by Dr. Wallich, and is a native of Japan and Nepal. It produces yellowish flowers and large red orange coloured fruits, which are very attractive, of the size and shape represented in the woodcut, fig. 39. It succeeds in the south and west of England and in the south of Ireland, but it is liable to be injured by severe winters. We have seen handsome trees in the neighbourhood of Cork, the largest being 40 to 50 feet high, and as much in diameter. The tree also fruits well in the county of Cornwall.

#### FASHION'S FANCIES.

HORTICULTURE, like everything else which contains an element of luxury, is ruled to a more or less degree by the caprices of fashion. No sooner is some new specimen introduced to the public, than after creating a sensation for a short time it is looked on as being common, and something new and novel is expected. By careful investigation and constant experiments on the part of enterprising nurserymen this demand is supplied until gardening, from being the commonplace occupation of half a century ago, has become a science. Public taste of to-day tends towards elegance and gracefulness, taking the place entirely of the stiff formality which formerly characterised it.

Let us consider first the landscapes, a glimpse at many old gardens show a series of straight lines and right angles, beds running parallel to each other, and long monotonous stretches of walks and terraces, all tending towards giving the idea that Nature herself had not assisted in their formation. The garden of to-day is laid out in an entirely different style. Sweeping curves take the place of straight lines, and the ground is laid out to give as natural and undulating an appearance as possible. To accomplish this mounds are thrown up and planted in such form that pretty and unexpected peeps of scenery suddenly open themselves to the gaze; water is called greatly into requisition, not so much in large formal lakes as in miniature waterfalls and rivulets, the running and rippling of which adds an air of life to the landscape. In the planting of shrubs and trees, too, formality is fast disappearing, and only specimens of light and elegant growth are now planted. This reformed system has many advantages, and with a little foresight even the most unsightly spots may be converted into a pleasing landscape.

In our large horticultural shows the same tendency prevails. Formal banks of flower and foliage plants, in many cases all staged at one level, are now displaced by artistic groups arranged for effect, and exhibitors can testify to the fact that gracefulness and elegance must be aimed at when arranging in order to meet with approbation from the judges. In the making up of floral designs it is the same. Stiff and artificial looking wreaths and crosses are now a thing of the past, while the "shower bouquet" takes the place of the formal bunch which was once fashionable.

The same change in taste is also to be noticed in table decorations and the adornment of rooms, anything of long and trailing habit being greatly in requisition.

Turning to the cultivation of flower and foliage plants the same tendency is found. It is with feelings of regret that we see many old favourites now disregarded. Camellias, once so popular, are thought little of now. If you ask the question why, the reply comes, Oh, they look too artificial. And the closely trained Azaleas, which once were looked on with pride, are now thought little of, and are grown in such form in comparatively few establishments. In these instances, and many other of such, we see striking evidence of the capriciousness of dame Fashion. A peep at the flower garden tells the same story. Giant Sunflowers and Hollyhocks are not the favourites they once were, and instead of the unvarying rows of plants following in rotation, harmonious blending of colours and tasteful arrangement is aimed at.

In all these many changes that are ever taking place there is a wide

FIG. 39.—BENTHAMIA FRAGIFERA.

field for enterprise, and it is only through the energy of men who are ever on the alert for something new that this constant demand can be supplied.—WANDERER.

#### SEASONABLE HINTS ON FLORISTS' FLOWERS.

As soon as the frost breaks it will be well to examine the plants thoroughly, pick off all dead leaves, clear away all green fly, stir the surface of the soil, and where it has shrunk in the pots a little top-dressing of the same compost as that in which they were potted may be added. It cannot but be, I think, that those who have not artificial heat will be out of court when the date for the Southern National show arrives. At this time in ordinary years many of the plants are what Auricula growers call truss-bare, and I suppose that even where heat is used it may be overdone, and the plants drawn and otherwise injured.

CARNATIONS AND PICOTEEES.—I have just been looking at my small number of plants which were potted in the autumn, and placed in cold frames ready for planting out now, and find that they look quite as well as one might expect. These flowers suffer far more from damp, muggy weather than they do from cold.

As to those out in beds I know not what to say, as they have had a rough time of it. The plants raised from seeds kindly supplied by Mr. Martin R. Smith, and which had been planted out, have apparently stood the winter well, although, if I had space, I should have wintered these in pots, as I have done my other plants, for I am persuaded that this is the better plan. I read in some paper the other day that one grower for sale disposed of 100,000 plants annually to supply vacancies, many of these being amongst the more highly priced and refined sorts. The border varieties are more coarse, and therefore do not suffer in equal

proportion, though I have known the old Clove to be injured much in severe frost.

GLADIOLI.—We shall soon be able to see how the Lemoinei hybrids have passed through this severe weather in the open ground. Profiting by former experience I did not leave them wholly unprotected, but placed over each clump some coal ashes, and as these have again been covered with 4 inches of snow I hope to find them all right. It will be well to turn over the beds in which planting is to be done, though this will be later than usual.

PANSIES.—It must have been a hard time for these if grown in beds, for even those in pots look miserable enough, although the frames in which they have been wintered had a thick covering of snow. They will soon be repotted in 32's in a compost of loam, leaf mould, well decayed manure, and some sharp sand.

PINKS.—There has been a vigorous attempt to revive the culture of the laced varieties of this fragrant flower in the South of England, but I hardly think much success will attend it, as even amateurs complain of the want of variety amongst them, and they seem to have almost gone out of cultivation.

RANUNCULUS.—The neglect into which this beautiful flower has fallen is a sad episode in the history of gardening. When the bedding out system came into vogue no place could be found for them, and even now, when the more rational method of gardening has superseded it, there seems to be found in few gardens room for them; and yet for variety of colour, for beauty of form, and delicacy of tint it is very difficult to surpass them. As soon as the ground is in proper condition the tubers should be planted 1½ inch deep in rows about 5 inches apart and 4 inches asunder in them. A little white sand or powdered charcoal should be placed round the tubers, and the bed smoothed over with the back of the rake. It would be a matter of great pleasure to many florists to see the culture of these beautiful flowers revived.—D., Deal.

#### EXAMINATIONS IN HORTICULTURE.

I WAS glad to see this examination brought before the notice of your numerous readers in the *Journal of Horticulture*, page 184; I think it is a great pity that more gardeners do not enter as candidates.

I must differ from "A Young Gardener," for he thinks the age of the candidates should be limited. But why? He says that "young gardeners have no chance when our chiefs take the pen." He evidently does not know that out of the eighty-four candidates who passed last year forty-nine were young persons whose ages were from sixteen to twenty-five, and I may say not all of these were gardeners. I think it is within the reach of anyone who possesses a knowledge of gardening and its scientific principles to gain one of the Royal Horticultural Society's certificates; ability here, in the practice or theory alone, is not sufficient to enable the candidate to pass well; he must know both, and then he need not fear the result.

Last year sixteen questions were given. Four were to be answered from Division A, Elementary Principles; and four from Division B, Horticultural Practice. Three hundred marks were given as a limit, but any persons gaining 200 or over were placed in the first class, those gaining from 150 to 200 in the second, and from 100 to 150 in the third; anyone failing to gain 100 marks did not pass. It is easy to see by the above that one has as much chance to gain a certificate as another; that is, if his answers are good, for upon these his number of marks depend. Here one is not, as it were, running a race, and must win or lose, for all who sit might (if their answers are good enough) gain a first-class certificate.

It should be the aim of every young gardener to gain one of these certificates, for no doubt they will be of as much importance to him (in time) as a practical reference, for it naturally shows that the winners of them have their work at heart. When employers recognise the value of the certificates there will be no lack of candidates for them.—W. D., Turnford.

UNDER the above heading in your last week's "Notes and Gleanings" I was sorry to see the remarks made by "A Young Gardener," and trust such a one-sided (not to say selfish) view does not pertain to many of his class. Why indeed should there be a limit to age? Examinations such as these are tests of knowledge, and to be plucked is simply a proof of insufficiency. To prevent a man of years (perhaps well versed in his profession) from being examined cannot add one jot to "A Young Gardener's" experience or knowledge of horticulture, or deter him from acquiring it. I recommend to him the motto, "*Palma non sine pulvere*" (the palm is not gained without dust: no excellence without great labour), and if he then takes full advantage of the valuable information and notes on experiences given in the *Journal of Horticulture* week by week by some of "the chiefs," the abundance of horticultural literature and technical education, much of which was not available to men a few years his senior, he should certainly be able to hold his own with credit to himself and without prejudice to others.—A YOUNG AMATEUR GARDENER.

#### NOTES AND COMMENTS.

I CAN fully endorse all that Mr. Duncan Pearson says about the beauty and utility of forced Daffodils. In our small way we have forced them successfully several times, and this year Horsefeldi, Stella, and Poeticus ornatus have more than repaid us. We also tried a semi-double Daffodil, an old garden variety, the name of which I do not know, possibly

Telemonius plenus; it, too, did well. The soil appears peculiarly suited for Daffodils of several varieties, and the ordinary Narcissus. Of the latter we can grow almost any number, and have taken in a piece of orchard ground for their further cultivation. Last year we noticed the unforced blooms were very small, and we attributed it (perhaps wrongly) to the long drought.

From the Castle Gardens, Warwick, I note with pleasure the hint about Antirrhinums for bedding purposes. The colours are so good, the plants so compact, and they are such capital "stayers." There is a posy of them to be gathered when many annuals have succumbed to the austerities of the autumn.

Of *Nemesia strumosa* I cannot say so much, it was a disappointment, small variety in colour and "legginess" in habit of growth. Perhaps, like many other amateurs, we did not fully understand the plant's requirements. I know we planted it firmly in well prepared soil, for we rather fancy ourselves at that.

Double French Marigolds do not receive a word too much of praise. They have only to be seen to be appreciated, and to my mind, as table decoration, they are charming—the shading of light yellow to rich brown is so effective.

We never consider ourselves complete here without a bed of *Salpiglossis*. Seen first in an illustrated catalogue, we were inclined to think the brilliant colours must be an exaggeration, but the reality surpassed our imaginations.

As to Tomato houses in the winter. If Arums here are sold now in February at 1s. per spathe, surely in other places there must be a demand too, especially as they fill up so well in wreaths. Would it be possible to grow Arums in long boxes, as the round pots take up so much room? Would the small Arums be as floriferous as the large variety?

The red Abutilons have a splendid habit, so neat and compact, and the flowers are thrown well out above the leaves. Is there a yellow variety with that habit, as the only one I know tucks the flowers carefully away under its broad leaves, as though it were ashamed of them? Here we are on March 4th with frost-bound earth, howling winds, and blinding snowstorms—not much like outside gardening, but surely better and warmer days are at hand.—THE MISSUS.

#### FRUIT TREES IN A CALIFORNIAN NURSERY.

IN treating the subject assigned to me, "Fruit Trees in Nursery in California," I shall not attempt a lengthy history or recapitulation of the trials and struggles of the pioneers in the business, but merely to deduce a few facts which, in a measure, have been the outcome of these struggles, and which, at this date, have passed beyond the stage of experiment or theory as far as general culture is concerned, although there are constant improvements in method and detail, as well as in the introduction and dissemination of new varieties.

It would be impossible for me to refrain, however briefly, from mentioning a few of the men to whom California and the whole of the United States owe so great a debt of gratitude—such men as John Lewelling of San Lorenzo, James M. Thompson of Napa, B. S. Fox of San Jose, who have gone to their rest; James Shinn, Dr. E. Kimball, W. B. West, Luther Burbank—these and others are the men who have done and are doing for their state and country a work the value of which is far-reaching and everlasting. I say the results of their labours will never die, for with their ardent and enthusiastic pomological work a love for horticulture in its more beautiful and æsthetic form is ever present, and its influence contagious and wide-spreading.

First, Soil. This is all-important; a deep, sandy loam is generally preferred, rich in humus, or, in some places, a very rich black vegetable loam is found, which will grow fine trees for many years. Usually the land is rested every two or three years, or planted with some other crop. In such lands in Northern and Central California irrigation is seldom necessary in the cultivation of deciduous fruit trees. For eighteen years in Napa Valley I have never had occasion to irrigate trees in nursery. Where the soil is deep and the winter's rainfall amounts to 20 inches or more thorough cultivation will cause the moisture to be retained within a few inches of the surface throughout the entire summer. Further south, when the rainfall decreases, irrigation is necessary. There are champions of irrigation who believe there can be no good trees or no good fruit raised in California that are not irrigated. There are those who assert just the reverse with equal vehemence. Mr. A will have nothing but northern grown trees; he would take them from Oregon, but prefers Washington, or even Alaska, if Professor Budd would find some varieties sufficiently iron-clad. Mr. B, his neighbour, prefers trees grown in the sunny south, in sandy soil, and with "perfect root system." Mr. C ridicules both; he wants an "acclimated" tree, one that is grown in his immediate vicinity; while his neighbour D will take none but "whole-root" trees from Missouri, provided they can escape the vigilance of our State Board of Horticulture.

Second, The methods of propagating and planting fruit tree seeds and stocks are of course similar to those in other States, with some variation owing to climatic conditions. We have no fall and spring seasons. We begin operations as soon as trees are sufficiently dormant

and when rain enough has fallen to moisten the ground, say in October or November, and from then digging, packing, ploughing, and planting, all go on with a rush, only stopping when it rains, or when the land is too wet.

No one with the proper amount of intelligence and experience will fix a date, or even a month, for any horticultural or agricultural operation in California; it is absolutely suicidal. There have been more wrecks upon this rock of arbitrary time than upon any other. A man will fix upon the month of February in which to plant his orchard. Previous to that the weather is fine and land in good condition, but he does not hurry. February comes, he engages his extra teams, and starts his ploughs. The clouds gather, the Weather Department says there is a "cyclonic disturbance" off the mouth of the Columbia River, or a "barometric depression" along the Oregon coast; the rain begins and continues with little intermission until March. Then spring is on us, or rather summer, and the favourable opportunity is gone. Or the time fixed may be a period of dry north winds, very detrimental to the preparation of the land or the handling of trees. Therefore push all work in the nursery, orchard, or farm, never resting unless obliged to by reason of rain.

Root-grafting indoors is seldom practised now, while it used to be in early days, when stocks and roots were scarce. Budding during July, August, and September is the chief method of propagation, and also crown-grafting in the nursery rows in the winter or spring.

Third, the stocks most used are the Peach for the large stone fruits, with Myrobalan for some varieties of Plum, and for Plums and Prunes generally for planting in heavy soil. Apricots are worked on Myrobalan to some extent, and Peaches; but the latter is not a success, and if the land is too wet to grow Apricot on Peach, far better let it be planted in Plums and Pears.

The best Peach stock is the "natural" or seedling seed, and it will germinate readily if kept moist in sand until planting time, without the frosts, which in the east are considered necessary.

Almonds are worked on hard-shell seedling Almond, or for planting in shallow soil the Peach stock is preferable.

Cherries are budded mostly on Mazzard, the Mahaleb being apparently short-lived. Pears upon Pear, and Apple upon the common Apple stock. Quince and other stocks for dwarfing are seldom used. It is found that in time a Pear grafted on Quince, or Apple, or Paradise stock will throw out roots above the graft, and overcome its dwarfish aspirations.

The fruit-planting public is very hard to please in the matter of stocks. After a wet season, when trees in low spots are apt to suffer, the demand for trees of every description on Myrobalan root is very great. A customer (he said he was a nurseryman too) frantically demanded Bartlett Pears on "Mary Boland," which reminds us of our cook of Hibernian descent, who, being of an orderly turn of mind, labelled a certain article of food "McRoney"—doubtless fond recollections in both cases. Our Pear, Plum, and Cherry stocks are mostly imported from France.

Fourth, Varieties. Not to be wearisome, I will name but a few as types of what are most largely grown in California. In the warm valleys the Red Astrakan Apple is very profitable, because early, and of large size and handsome. Gravenstein and Alexander are among the best late summer Apples, and Fall Pippin, Hoover, and Yellow Bellflower for autumn; Newtown Pippin, Paragon, Arkansas Black are valuable for winter. In the mountains of Northern California and in many parts of the coast range Apples are grown with all the keeping qualities of the best Apple regions of the United States. This fact is not generally known, but it can be abundantly vouched for by Prof. Emory E. Smith, late chief of Department of Horticulture at Mid-Winter Fair, and by Prof. Husmann, one of the judges. As fine an exhibit was there shown of Apples during March and April as could be seen anywhere in America at that time. The Bartlett Pear is the standard in California; Winter Nelis, P. Barry, Doyenné du Comice, President Drouard, are good winter varieties.

Early Crawford, Foster, Muir, Susquehanna, Salway Peaches are types of yellow freestones. Muir is of Californian origin, resembling Wager, but drier. Alexander and Hales' represent the earlier varieties; Orange and Heath typify the clingstones. There are many seedlings of local reputation, some of them of exceptional value. The field, however, is so extensive and so prolific that the State Horticultural Society has not yet been able to control it as to identification and nomenclature.

The standard Apricots are Royal, Blenheim, Peach, Moorpark, Montgamet. Nectarines—Boston, Hardwicke, and New White.

The varieties of Plums and Prunes are almost endless. All standard European varieties succeed well in the valleys of Sacramento and the Bay counties. The Japanese varieties and their hybrids grow to perfection best near the bay or not too far inland. Most of the early varieties of Plums succeed in the warm valleys and plains, but the climate there is too hot for later varieties, unless like d'Agen and others for drying purposes.

The Sacramento Valley is, perhaps, the home of the Peach, although while in Solano, Santa Clara, Fresno, Napa, one would be apt to think that there alone did the Peach, the Prune, or the Apricot grow to perfection.

The whole question of adaptability is too extensive to deal with in detail. California, as a fruit-producing State, is so immense that to more than touch upon these points would be impossible. For the same reason our Nurserymen's Association has never been able to accomplish much. Every nurseryman is for himself, too much so for his own good.

The whole world is ransacked for varieties of fruit or nuts, new or old, which may prove of value here. Many nurserymen have their own experimental orchards, and all are constantly acquiring knowledge which, if sifted down and disseminated, would be of much value.

As nurserymen, we do not desire to antagonise our brethren east of the Rockies. We have been blamed for insisting upon unnecessary quarantine laws against outside nursery stock. Instead of that the nurserymen here could often make more money by importing trees, while labour in California is so much higher than elsewhere.

The fruit growers have had expensive battles to fight against Australian and other insect pests, and they wisely took action, resulting in an enforced inspection of all nursery stock from outside the State, or as between one country and another. The State Board of Horticulture has done a grand work in this way, and the results are generally appreciated.

I cannot close without expressing the hope that the American Pomological Society will give us some insight of the workings of State organisations and assist us in perfecting a plan whereby our fruits may be uniformly named, and varieties apparently identical or nearly so weeded out from the list.—LEONARD COATES, Napa City, California. —(Read at meeting of the American Pomological Society.)

#### HARDY FRUIT GARDEN.

**Spring Planting Fruit Trees.**—When the ground has become warmer and comparatively dry on the surface after the prolonged frost, fruit tree planting may be proceeded with. It is unwise to carry on such important work when the soil is sticky after frost or rain. The subsoil, too, must have time to thaw ere much is done on the surface. There will be no time lost in waiting for the conditions to become more favourable. On heavy, retentive soils a dressing of wood ashes and decayed vegetable refuse will do good if forked into the surface. Should March and early April prove to be open and dry, the soil would then naturally be in a pulverised condition. Cold, drying winds ameliorate the surface, quickly rendering it workable, so that it neither adheres to the tools or the boots. The soil having reached this stage, it is best to grasp the opportunity and endeavour to complete planting. Quarters dug before the frost may be lightly forked over, working in a little light dry material, or if in ridges these may be broken down. Prepare holes for the reception of the trees at the proper distance apart. Make them wide and shallow so that the roots can be spread out, yet not buried deeply, and never plant lower than the visible earth mark on the stems. If the soil has had no preparation the digging or trenching required ought to be pushed forward as quickly as possible. Planting may follow immediately, because the newly turned soil, after a few days' exposure, is in admirable condition.

**Preparing the Trees.**—Fruit trees and bushes may be planted up to the time of the buds swelling. While out of the ground the roots must be carefully kept in a moist condition. The prospect of a good start and a continuous vigorous growth depend largely on the healthy state of the roots. It is useless for nurserymen to pack trees well if on receipt by the customers the material is quickly taken from them, leaving the roots bare for a considerable time before planting. Instead of this the trees should be inserted in moist soil, and if any have the roots dry or shrivelled they should be placed in water for some time. Before planting cut off broken ends of roots with a sharp knife, taking care that none are left with jagged ends, as this means loss of time in forming new fibres. Roots with smooth extremities soon heal, and put forth fibres that make rapid headway as growth strengthens. Those with injured points are slower in sending forth rootlets. The damaged extremities die back a considerable distance, and the root power of the trees is lessened accordingly.

**Planting.**—When planting it is desirable to have in readiness a barrowful of compost, consisting of light loamy soil and wood ashes incorporated together. This forms an admirable mixture for spreading among the roots as the work proceeds. These having been trimmed should be spread outwards in layers to their full extent, beginning with the lowest. Sprinkle soil among them, working from the stems of the tree outwards, so that none of the young fibres are turned upwards, downwards, or backwards by its distribution. Treat the next layer the same, and so on till all are properly distributed, the upper roots being finally 3 or 4 inches from the surface. A stake should be fixed firmly by the side of the tree to keep it in position. The soil worked in this manner should be made firm, but it is not advisable to trample over the roots, especially near the tree, for fear of damaging any of them. A light mulching of manure spread over the surface will prevent the soil drying too quickly, yet admitting sufficient air and warmth.

**Pruning Newly Planted Fruit Trees.**—Whether planted in the autumn or spring most fruit trees will require the branches shortened before growth fairly commences. The extent to which they need pruning back will depend on their condition when planted. Many trees lose a large proportion of their best roots in the process of trans-

planting from one position to another. With such as these it is necessary to adopt closer pruning than is essential when a tree can be removed with comparatively little loss of fibres. The object of pruning after planting is to induce moderately vigorous growth equally over the trees in order that the proper number of branches may be obtained. This object may not be reached the first year, but it will ultimately be attained if the pruning proceeds on right lines. Trees that had but few roots when planted should be pruned back to one-third the length of the branches. Those that had a large proportion of roots which were but little damaged may have the branches pruned so as to leave at least two-thirds. In every case cut back to a wood bud, and to one pointing in the direction it is desired the branch should extend. The pruning must also be regulated by the strength of the trees, weaker examples being cut in closer than strong ones. Neglect in pruning during the first year frequently results in stunted growth, because these being left at full length the limited number of roots have no power to push fresh ones; their energy is used up in sustaining the wood and buds already existing. As a rule the closer the pruning the first year the more vigorous is the growth which follows.

#### FRUIT FORCING.

**Peaches and Nectarines.**—*Earliest Forced House.*—The fruit has nearly completed the early swelling and entered on the stoning process. If the thinning has been carefully attended to there will be little more than the necessary quantity—that is, one fruit to each square foot of trellis covered by the trees. More are usually left in order to meet contingencies, but it is certain that if a tree can only stone a certain number of fruit a selection of the most promising will be advantageous both as regards the stoning and swelling of the fruit retained. If there is more fruit than the trees can possibly bring to maturity thin it before rather than after the stoning process, removing the smallest and badly placed. The chief cause of fruit not stoning is the immature and ill condition of the wood. During the stoning process keep the temperature as even as possible, avoiding sudden checks from cold currents of air in the daytime, and undue excitement at night. The night temperature may range from 60° to 65° in mild weather, but 5° less is safer and better when severe; 65° by day from artificial means is quite high enough when the atmosphere outside is cold and the sky overcast, ventilating from the figures last named, but allowing an advance to 70° or 75° from sun heat, the latter temperature not being exceeded without full ventilation. Secure the leading and other shoots required for furnishing the trees. Syringe with water of the same temperature as the house to keep down red spider. If aphides are troublesome fumigation may be practised moderately on two consecutive evenings, taking care to have the foliage dry. A decoction of quassia chips, 4 ozs. boiled in 2 gallons of water for twenty minutes, then straining and dissolving 4 ozs. of softsoap in it as it cools, is quite strong enough for young foliage, and equally good for destroying aphides, thrips, and red spider. With a tablespoonful of petroleum added, after emulsion in eight parts of boiling water to one of softsoap, the mixture is effective against young scale. Supply water to the border as required, not being deceived by the surface, which is often wet from syringing, whilst the soil below is dry, but make an examination and give sufficient water or liquid manure to thoroughly moisten the soil. Nitrogenous manures, however, must be used carefully during the early stages of swelling and the stoning process, the chemical manures being of greater benefit than humus-forming ones at this stage.

*Second Early House.*—Trees started at the beginning of January should be gradually disbudded, removing the strongest and ill-placed, so as to secure an equality of vigour. Tie the leading shoots carefully down, not too tightly, with sufficient space for all to receive the full influence of the light. Thin the fruit by degrees, and where it has set thickly extra attention will be required, removing those on the under side of the trellis or where badly placed, but leaving those that are well exposed to light and air until they indicate by free swelling the need for further reduction, then remove the smallest, and so proceed until the number is reduced to the crop the trees are calculated to bring to maturity. Syringe early during fine days, always early enough in the afternoon to allow the foliage to become fairly dry before night. Ventilate when the weather is favourable, and do not close so early as to advance the temperature considerably, as it only aggravates the tendency to produce wood, which is unfavourable to the retaining of the fruit. The temperature may range from 55° to 60° at night and 60° to 65° by day, ventilating at the latter temperature, and closing the house when the heat is decreasing, but not to advance more than 5° from sun heat.

*Trees Started Early in February.*—The trees being in flower the night temperature may be maintained at 50° to 55° in mild weather, falling 5° or even 10° in severe, the temperature named being sufficient on dull days with a little ventilation, as a close atmosphere is fatal to a good set. Ventilate freely from 55°, and allow an advance to 65° with sun heat. Fertilise the blossoms in the early part of fine days, either shaking the trellis or brushing the flowers with a camel's-hair brush when the pollen of the individual flower is ripe. Syringing is best dispensed with whilst the trees are in bloom, but the floor should be sprinkled occasionally on dull days, and morning and afternoon in bright weather.

*Midseason Houses.*—The trees of midseason varieties to afford ripe fruit in July and August must now be started, syringing them in the morning and afternoon in bright weather, but occasionally only in dull periods, ceasing the syringing over the trees when the blossoms show colour. Where there is a superabundance of bloom buds it is a good

plan to ease the trees of those on the under side or back of the shoots as soon as they are sufficiently advanced, a gloved hand drawn contrary way of the growth doing it expeditiously. Where the trees are weak it is excellent practice to relieve them of the flowers to the extent of at least half those required for setting, and cross-fertilise the flowers, affording some gently stimulating food, such as superphosphate of lime three parts, muriate of potash two parts, and one part ground gypsum, mixed, using 3 or 4 ozs. per square yard, and washing in moderately after the soil has been brought, if necessary, into a properly moist condition. This may be repeated at intervals of four to six weeks. Maintain a temperature of 50° by day, ventilating from that, and not allowing an advance to or over 65° without full ventilation; the night temperature should be kept at 40° to 45°, with a little air constantly at the top of the houses.

*Late Houses.*—The trees from which the lights were withdrawn have not suffered in the least from the severe frost, and the buds are in an as yet safe condition, therefore the lights need not be replaced until the blossoms have arrived at the point of showing colour. This ensures late flowering, and the later the better, so that fruit may be produced in October, which of the large kinds, such as Gladstone, Sea Eagle, and Golden Eagle Peaches, bring better returns than in September, when it is amply supplied from walls. Where the roof lights are fixed ventilation must be given to the fullest extent, so as to retard the flowering as much as possible, but no good comes of keeping the house cold after the blossoms show colour, as it is then that the organs need to be kept in progressive development. Many late houses are unheated, which is a mistaken idea of economy, as when the weather is cold and dull during April—the time at which it is desirable to have late house trees in flower—the atmosphere is too close, moist, and cold for the satisfactory development, while there is danger of damage from spring frosts in that month, and even in May. In cold, sunless seasons the fruit does not ripen satisfactorily, and the wood is so immature as to prejudice the future crop. A gentle heat during the flowering does much towards a good set, and in the autumn artificial heat with free ventilation ripens the fruit and wood, so that the current and future crops are alike benefited.

*Unheated Houses or Wall Cases.*—These are admirable means of growing fruit. They should be provided with both top and bottom ventilation, and the roof lights, except the ventilating ones, be moveable. We have tried both systems, fixed and moveable roof lights, and find the latter far the best. The roof lights are taken off directly the leaves of the trees commence falling, and off they remain until the buds have the blossom peeping. This means, with Apricots, replacing the lights a month or more earlier than for other fruits, and necessitates having the trees of the different kinds in compartments. The system answers admirably for Apricots, which produce fruit abundantly, and the trees are remarkably healthy and free from gumming to a much greater extent than on those open walls. Cherries do even still better than the Apricots, giving fruit at the close of May or early in June in forward seasons, and which can be kept from the depredations of birds, cracking or spoiling by wet. Plums do well, and are never so fine and luscious as when grown under glass. Peaches and Nectarines afford a supply of fruit from July to October inclusive. Pears revel in the spring time, and the fruit attains to a size and colour seldom seen on open walls, but the quality is often very defective. It is desirable to expose the trees after the weather becomes settled in June, and then a crop is secured with quality in the fruit. The better plan is to grow the Pears in pots, and only place under glass for the securing of a crop. Figs ripen one crop of fruit in August and September, also Grapes, early varieties of the latter being selected, and they are quite as good as those produced in expensive vineries. Anything in the way of pruning should be completed, the trees and house being put into thorough order. The borders of houses that have not the lights removed may need supplies of water, so as to bring the soil into a moist condition. Ventilate freely, so as to retard the flowering to as late a period as possible.

*Cherry House.*—Ventilation is an important factor in the cultivation of Cherries under glass. A free circulation of air should pass through the house whenever the temperature exceeds 50°, the amount of air being regulated by the conditions of the external atmosphere. Employ fire heat only to prevent the temperature falling below 50° in the daytime, and to maintain a night temperature of 40° to 45° in the house when the trees are in flower. Attend to fertilising the blossoms. Fumigation must not be resorted to whilst the trees are in flower, but will be necessary as soon as the fruit is set. It is also requisite to watch closely for the appearance of grubs; one kind rolling itself up in the leaves, and can be eradicated by squeezing, but the other encases itself in a sort of web on the under side of the leaves, giving them a scorched appearance, and from these it passes to the clusters of fruit, perforating and destroying them. The only means of riddance is to examine the trees occasionally and destroy the caterpillars.

**Figs.**—*Earliest Forced Trees in Pots.*—Trees plunged in bottom heat require water or liquid nourishment somewhat abundantly, always at the temperature of the bed, which at 70° to 75° enables the trees to make steady progress. The atmospheric temperature should be maintained at 60° to 65° at night, admitting a little air in the morning at 70°, but not so as to lower the temperature, closing at 75°, and if the heat rise to 80° or 85° it will be more advantageous than otherwise. Thin the fruit, if too thick, as soon as the best placed and most promising can be decided upon for the crop, but it is not advisable, as a rule, to thin them much before flowering, which occurs before the Figs

commence the second swelling. During this process the trees must not be hurried, but the temperature kept as even as possible.

**Early Forced Planted-out Fig Trees.**—The house started at the beginning of January are making good growth, and should have the shoots at the base of the terminals pinched at the fifth or sixth leaf, but where this is likely to crowd the trees disbudding must be resorted to, and early, so as to not give the trees a severe check, as that may cause the first crop Figs to fall. The terminal shoots may also be stopped if they grow too luxuriantly, but no amount of stopping will induce fruitfulness, and the extensions always produce the finest Figs, it being essential to secure stout, short-jointed wood fully exposed to light. The nearer the glass, provided the points do not touch, the better the fruit. Keep the night temperature at 55° to 60°. When it reaches 65° by artificial means in the daytime admit a little air, increasing the ventilation with the temperature, leaving it free at 70° to 75°, and reducing it in like manner, closing at 70°, syringing twice a day, and maintaining a genial atmosphere.

#### THE FLOWER GARDEN.

**Ageratums.**—If seeds are sown at once in pans and placed in brisk moist heat, covered with glass, carefully shaded, and kept uniformly moist, they will germinate quickly, and a large stock of strong plants eventually be the result. Prick them out in pans or boxes of good soil, top the plants when about 3 inches high, and soon after temporarily hed them out in rough frames. From these they will transplant readily when required.

**Alonsoa Warscewiczii compacta.**—This, in addition to succeeding well in pots in the open or greenhouse, is really an excellent hedding plant. When at its best it is showy yet chaste, the plants producing numerous elegant spikes of pea-shaped orange-scarlet flowers, which for vases are particularly popular. Plants may be raised and grown exactly as advised for Ageratums.

**Early Asters.**—It is a mistake to sow the bulk of Aster seeds before the end of March, as the plants rarely do well after having been kept too long in a crowded state. With a view to having an early display, and something to cut from, sow seeds of Comet, Queen of the Market, and Dwarf German at once in boxes, and place these in a warm vinery or Peach house. When the seedlings are large enough to handle prick out 3 inches apart in other boxes, and keep in a warm house till well established, then harden, and transplant not later than the middle of May. Asters pay well for liberal culture.

**Early Stocks.**—The Early Forcing Snowflake, a variety belonging to the Ten-week section, can be had in flower considerably earlier than other varieties, and ought to be both gently forced in pots, also flowered on a warm border in June. Raise and treat very much as advised in the case of early Asters, though if pots can be afforded for the plants they will be found to move better out of these than boxes.

**Mignonette and Sweet Peas.**—There is always a demand for these in a cut state, and in order to obtain them earlier than can be done by sowing seeds in the open ground the plan of raising in pots and planting out should be adopted. Sow seeds thinly in 2½-inch pots and place in heat to germinate. Reduce the Mignonette to three plants in a pot, and five or six Peas in each pot are sufficient. Gradually harden for planting in deep well worked soil. If seeds are plentiful sow in the open as soon as the ground is in suitable condition where the plants are to grow and flower. Avoid sowing thickly, or else thin out freely later on, as crowded rows are always the first to fail. Mignonette may also be sown in the open.

**Centaurea cyanus major.**—These popular Cornflowers ought always to be raised early, autumn-sown plants succeeding best. Unfortunately most of these have disappeared, and seeds should be sown in heat at once with a view to having plants to turn out early in May. Raise thinly in small pots as advised in the case of Mignonette in preference to sowing in pans or boxes and pricking out. Also grow in the open borders for a succession.

**Cineraria maritima.**—Where large beds and various borders have to be filled during the summer a few score or hundreds of this silvery leaved and fairly hardy Cineraria should be grown. It is not yet too late to sow seeds in heat, and if the seedlings are kept growing they will prove effective from the time they are planted out.

**Gaillardias.**—There have been many losses among summer hedding plants. Without being models, as substitutes some of the Gaillardias are effective. The varieties *G. picta* and *G. Lorenziana* are the best for the purpose, as they are very free flowering the same season as raised. The seeds may be sown thinly in pans or boxes, and the seedlings prepared for transplanting in May. These Gaillardias should be given small beds to themselves, as they spread freely and also flower most abundantly when not shaded by other kinds of plants. They may, however, be used similarly to Violas, having other plants dotted thinly among them.

**Nicotiana affinis.**—This sweet-scented showy Tobacco ought to be freely planted in large beds, mixed borders, and thinly stocked shrubberies. Seeds should be sown at once on the surface of soil in pans, moistening the latter before rather than after sowing. The seedlings must be grown sturdily, and strong examples provided for planting in due season.

**Pyrethrum aureum or Golden Feather.**—There is time to raise any required number of plants by sowing thinly in boxes, or better still on a bed of soil in a frame or pit, a gentle bottom heat being desirable. Plants so raised may after a little hardening be inserted in the beds or borders where they are to grow, quite small plants, if looked after, quickly attaining to a showy state.

# THE BEE-KEEPER.

## APIARIAN NOTES.

### WINTERING BEES.

MANY years have elapsed since I solved the problem of wintering bees safely in this climate, the present season, however, with the moving, and the disease some of them suffered from has reduced several hives to a few hundred bees.

I am glad to say all have wintered well, including these weaklings, which are not only healthy, but have more than doubled their numbers since November; this is both gratifying and reassuring.

I need not repeat what I have written so often, but for the benefit of beginners I may state that these weak bees occupy full-sized, single-walled hives, with entrances half an inch wide; the top of the frames within the super-protector are covered with about 3 inches of porous material, the sides with two ply of old sacking and an oilcloth, and the roof with a sheet of half-circled iron. The excessive loss of bees previously mentioned I attribute to the moving during zero weather, a time very unfavourable to disturb bees.

There is one hive in perfectly good health and condition that has not shown a single bee outside. The great contrast to my apiary with those managed on other lines that we read of having bees and combs frozen to a solid mass will perhaps be a salutary lesson to those who have been so unfortunate, to think twice what plan they should adopt to prevent a recurrence of such a disaster in coming winters.

As successful springing depends on leaving bees alone in every respect, I have given as a commencement in feeding a little honey in tin scoops, but shall feed with syrup immediately the temperature rises to 50° or 55°, and on no pretext should I feed from the top, or do any act which may reduce the temperature of the hives.

### SUCCESS OF THE LANARKSHIRE HIVE.

"G. R." writes:—"Will you please tell me which you think is the best for the Lanarkshire hive, a three-eighths or a quarter of an inch lip for the frame ends to rest upon? I followed the instructions you gave me, and am pleased to tell you that I took first prizes in strong competition. These sections were all worked by a single Lanarkshire hive; in fact, my sections worked on the standard hives were not to be compared to these mentioned above. My Lanarkshire hives have wintered well."

We are pleased to hear of your success, which corroborates many others in the same county (Yorks). It does not matter whether the rebates are three-eighths or quarter, the latter for five-eighths wood; if three-quarters then they may be three-eighths, the great object being to have the boxes accurately one size as well as that of the frames, so that manipulation will be easy, which can only be when all frames are interchangeable.

### DOES BEE-KEEPING PAY?

The above question continues to be frequently asked, and now and again the inquirer details his disappointments in a doleful manner, sometimes going so far as to throw reflections on those who were the means of him starting bee-keeping. I have answered scores of letters from those who appeared to be disappointed or in want of full information on the subject.

My advice in all cases was tempered with caution, showing how and where bees would pay, but never advising anyone to start bee-keeping with the view of making large sums of money exclusively from them, and to be prepared for actual loss in some seasons. I have at all times encouraged persons to keep bees as an auxiliary to other employments, whether the honey was to be sold or consumed by the bee-keeper's family. There is another side to the question. He who steps aside from modern popular ideas and customs, renouncing superfluous holidays, betaking to himself the love of keeping bees, paying great attention to increasing the produce of the earth for his own or the public's good, thereby becomes a benefactor to the world, and does more to solve the problem of what shall we do with our starving thousands than all the theories ever propounded.

There is work for all if gone properly about; therefore let all make an effort, at the same time looking ahead, and they will maybe see clearly more ways than one of "keeping the wolf from the door." and of laying something apart for the proverbial "rainy day."—A LANARKSHIRE BEE-KEEPER.

### SEASONABLE NOTES.

THE favourable change in the weather which set in ten days ago has continued, although there has been a few degrees of

frost each night. Bees have been on the wing daily, and the thermometer registering 45° in the shade has enabled bee-keepers to effect a thorough overhauling of their stocks. It is not advisable so early in the season to uncover the bees more than is really necessary, or to lift out the frames, or in any way to interfere with them, or much harm may be caused by it.

All stocks should be examined to see that they are not short of stores. This can be done by turning back the quilt, and if on looking down between the frames sealed stores are visible, they will be safe for the present, but should further supplies be needed, feed with candy as previously advised. After such a spell of cold weather it shows the advantage of loose floor boards, as by having a few spare ones on hand the hive can be lifted off its old stand and placed on a clean, dry board. The board which has been in use all the winter can then be cleansed of all dead bees and any débris that may have accumulated, and if wet should be well dried before being used again, as after a long storm, when snow has lain about the hives for a considerable time, it is surprising how the moisture will penetrate some of the most carefully made hives.

Straw skeps must not be neglected. These should be examined, and if on lifting them they are found to be of fair weight, they are right as regards sufficient stores, as with a little practice one can soon distinguish between those that have ample stores and any that require feeding. The former may be put on clean, dry boards; the latter should be quietly turned up, and a cake of candy inserted between the combs, or through the feed hole at the top of the skep, but care should be taken to prevent an escape of heat. The late severe weather should have proved whether straw skeps or frame hives are the best for wintering purposes, and as I have been experimenting with both, I will shortly report the results.—AN ENGLISH BEE-KEEPER.

**ECCLESIASTICAL BEES.**—In California, where there are comparatively light winters, and flowers to be had all the year, the honey bee does not seem to care about the fostering protection of man, but makes its home in the wilds where it chooses. A Californian paper speaks of a large colony having taken possession of the roof of an Episcopal church, and as they interfered with nobody, nobody interfered with them; but when the recent hot weather came, and the honey melted and flowed in streams down the walls of the building it was considered a little too much of a good thing, and someone had to be found to clear out the little workers. He got 100 lbs. of honey for his fee without the necessity of scraping the walls to secure the overflow.—("Meehan's Monthly.")

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Vines Bleeding (H. S.).**—You had better take a hot iron and scorch the points of the canes, then daub them with red or white lead as soon as it is done. Some persons have found powdered alum useful. A little oozing will do no harm, but a free flowing will weaken the Vines. As soon as the leaves develop they will take up all the sap.

**Sewage for Potatoes (Nemo).**—You may safely give the well drained ground, previously to digging, a heavy soaking with the contents of your cesspool; and if the plants during their early growth seem weakly, pour another good soaking between the rows, and repeat it after a fortnight if apparently needed. In a poor soil we should prefer this treatment to a heavy application of stable manure.

**Fungus in Mushroom Bed (B. H.).**—The fungus infesting your beds appears to be a *Coprinus*, and is wholesome when gathered young, still can only be regarded as a weed in the beds. It grows from spores that have either found their way into the manure or the soil used in casing the beds. Clear the interlopers away as soon as you see them, as they quickly mature spores for dispersion and further infestation.

**Orchid Peat (J. K.).**—The sample you have sent is not such as is usually sold and used in the cultivation of Orchids. As the first bag is admitted to have been sent in error, and the second was the same as the first, it seems to follow that a second mistake has been made. Obviously we cannot take any action of the nature you suggest on the basis of the mistake. It is the only case of the kind that has been brought before us.

**Weather Predictions (A. B.).**—We are obliged by the extract, but have not space for its insertion. By all means compare the results with the prognostications. In our experience weather prophets who venture far into the future are more often wrong than right. None of them, so far as we know, gave due notice of the extraordinary frost of the past month, which it is thought might have been worthy of their attention if they had foreseen the visitation.

**Seedling Cyclamen (J. Grimes).**—The flowers are unusually rich in colour—deep, glowing crimson, and the variety is worthy of preservation. All you can do is to isolate the plant, placing it in a favourable position for the ripening of pollen, and with a little delicate manipulation you may assist in the "self-fertilisation." All the seedlings may not come true, but some of them may be expected to do so. We do not remember having seen any flower quite so rich in colour exhibited.

**Grass Edging Broken (E. G. A.).**—You cannot make a firm edge by outside additions, but you can do so by cutting through the turf in line a foot or so from the edge, then with a sharp spade raising and drawing the portion so sliced off as far as is necessary into the walk, rolling it well, then with a line and sharp knife slicing the rough margin away to a fine smooth edge. The vacancy made in the lawn can be filled with fresh pieces of turf made level and firm, or by filling them with soil and sowing grass seeds.

**Lichen on Lawn (P. H. N.).**—The plant infesting your lawn is a species of Lichen, and indicates that the ground is not well drained and the turf weak. The following would be the best course to adopt. During the early part of March, as soon as the weather permits, apply a dressing of well-decayed manure, spreading it evenly, and letting it remain until the close of March, then with an iron rake scratch the ground well forwards and backwards, which will assist in distributing the manure and form an open surface. Early in April remove the loose portions of the manure by raking it evenly, and any stones should at the same time be removed. This will form a good tilth for the Grass seeds, which may be sown early in April, with an early prospect of rain, and on a fine or calm day.

**Grevillea — Scented Window Plant (Inquirer).**—*Grevillea rosmarinifolia*, a native of New South Wales, is more slender than *G. robusta*, and is gracefully attractive when well grown. It requires a light position. Your question as to "the best all round scented window plant" is somewhat a puzzle, as a perfume that may be agreeable to some persons may be the reverse to others. The Cape Pelargoniums Little Gem, Prince of Orange, and Lady Scarborough are attractive window plants with fragrant foliage. Some persons enjoy the Lemon scent of *Aloysia* (or *Lippia*) *citriodora*, known as the Sweet-scented Verbena, while others would vote for the familiar Musk. The flowers of the elegant *Boronia megastigma* diffuse a delightful perfume, but it would be a feat of skill to grow the plant well in the window.

**Vine Border Unsatisfactory (Deeside).**—You have adopted the best possible methods under the circumstances, the manure and loam you have used will attract roots near the surface. As the border is very close, and likely to become sour, you may apply a dressing of basic slag phosphate at the rate of 14 lbs. per rod in your case, which being half lime will tend to correct the sourness, while the other constituents will act beneficially as manure. It would not be advisable to use cow manure, but a light mulching of rather fresh horse droppings or short stable manure would prove attractive to the roots, and be a great aid in keeping them active, assuming they are secured in the top-dressing of loam. About an inch thickness, however, would be sufficient, and as the manure becomes wasted fresh additions could be made as required, it being necessary to add a little fresh material occasionally to act beneficially, and at the same time not deprive the soil of the influences of warmth and air.

**Raising Asparagus Plants (A. P. G.).**—The way we have raised Asparagus for planting at one year old, which are the best for general purposes, is to sow the seeds in drills 1 inch deep, allowing 9 inches distance between them, and leaving out every sixth row to form an alley, which is very desirable and convenient for cleaning. The seeds are best placed in the rows singly about 1 inch apart, or when they are plump and new they may be placed 3 inches asunder, as when every seed grows the plants are quite thick enough, otherwise it is desirable to thin the seedlings to that distance, for the stronger the plants the better will they be rooted and suitable for transplanting. The ground should be thoroughly clean and stirred to a depth of at least 1 foot, being well worked so as to secure a good tilth, and if manure is used it should be well decayed. The chief thing is to keep the ground clean, allow the plants a fair amount of room, so as to secure a sturdy growth and abundance of roots for safe transplantation and speedy growth afterwards. If a large number of plants be wanted the drills may be 6 inches apart, thinning the seedlings to 3 inches distance. This will give more plants per area, but they will not be so strong, and if you want the finest possible plants, which are the best and most profitable in the long run, sow in drills 9 inches apart, and thin the seedlings to 6 inches asunder in the rows, or thereabouts, leaving the strongest. The proper time to sow the seeds is during the first fortnight of April, or as soon afterwards as the weather is favourable.

## AVENUE PLANTING.

REVERENCE begotten of dignity and associations with the past is the feeling which prevails when viewing a noble avenue forming the approach to some "stately home." Probably not any form of planting is able to convey so much of calm repose to the critical eye as this; and possibly not any is more open to criticism nor more deserving of deliberation should it fall to one's lot to arrange similar work.

Planting an avenue on the larger scale does not allow of a margin for errors, whether of space, position, or variety. The designer of such needs a clearness of vision and of sufficient power to see far into futurity; for of all work that which is tested by time is the most severely tried. There is a greater danger in our day—although so frequently admonished as to the need of looking ahead—of being too near-sighted to see into the remote future, for there are many things now crowding into our lives to obstruct the distant view. All the necessary rules for our guidance in planting an avenue are to be found in perfect examples of their kind, yet not so those errors which it is desirous to know in order to avoid; for the more serious has been the defect the more certain has been the doom. Trees unsuited to the locality have succumbed, or injudicious arrangement at planting has been a growing evil until swept away by necessity. Better so than remain the silent witness of error.

In the first place it is essential that the trees should consist of one variety only. Alternate planting of distinct varieties results in architectural incongruity. Formality where employed should be in its best form. The selection of a variety to which the locality is pre-eminently adapted must not be overlooked. It is the key to success. In observing the trees of the neighbourhood they will tell their own tale of what to plant and what to avoid. Should taste or fancy prompt the introduction of kinds practically new to the locality, due weight should be given to the consideration that the work must then be more or less experimental. In the more prominent or important positions this phase of planting will seldom allow of its taking the form of an experiment.

## Prudential Assurance Company LIMITED.

Chief Office: HOLBORN BARS, LONDON.

Summary of the Report presented at the Forty-sixth Annual Meeting, held on 7th March, 1895.

ORDINARY BRANCH.—The number of Policies issued during the year was 61,744, assuring the sum of £6,282,120, and producing a New Annual Premium Income of £339,957.

The Premiums received during the year were £2,077,956, being an increase of £223,586 over the year 1893.

The Claims of the year amounted to £518,131.

The number of Deaths was 3,584, and 198 Endowment Assurances matured.

The number of Policies in force at the end of the year was 375,545.

INDUSTRIAL BRANCH.—The Premiums received during the year were £4,244,224, being an increase of £272,360.

The claims of the year amounted to £1,548,377. The number of Deaths was 168,689, and 1,304 Endowment Assurances matured.

The number of Free Policies granted during the year to those Policyholders of five years' standing, who desired to discontinue their payments was 66,478, the number in force being 398,078. The number of Free Policies which became Claims during the year was 6,672.

The total number of Policies in force at the end of the year was 11,176,661; their average duration is nearly seven and a half years.

The Assets of the Company, in both branches, as shown in the Balance Sheet, are £21,213,805, being an increase of £2,674,940 over those of 1893. A supplement showing in detail the various investments is published with this Report.

The Balance Sheet has been submitted to Messrs. Deloitte, Dever, Griffiths & Co., whose certificate is appended to the accounts.

THOS. C. DEWEY, } Managers.  
WILLIAM HUGHES, }

W. J. LANCASTER, Secretary.

The full Report can be obtained upon application to the Secretary

Avenues may be divided into two classes—those which ornament the road or carriage drive, and those which have no secondary object, but are planted in some portion of the demesne where the greensward takes the place of the road. For the former, which one may designate the principal type of avenue, deciduous trees appear preferable, as foliage retained through the winter is not conducive of dryness nor light desirable to a good carriage road during that season. For this purpose specimens of our noblest timber trees are second to none as types of beauty. There is not, I think, any reason for drawing comparisons between their grandeur of form on the one hand with the more graceful habit of the Coniferæ.

A common mistake is that made by the planter failing to realise what the trees will become, and what they should attain in their prime. It is a far cry in a tree's life from infancy to old age, and too often is future effect sacrificed to present appearance. Should choice fall on such trees as the Beech, Oak, Elm, or Ash by reason of the suitability of any one of them being illustrated in the vicinity, the selection of a specimen will be a reliable guide for the space ultimately required in the avenue. Ample width is of the first importance. With a carriage road of some 30 feet wide and up to or exceeding a quarter of a mile in length, from 25 to 30 feet may be allowed from the margin of the road to the tree stems; but should the road be curtailed in length some reduction in width is necessary, for in this instance we have no perspective to tone into harmony. It may be readily allowed that a perfect avenue is one in which each tree is a perfect specimen, and that sufficient room is allowed for such attainment, hence the requisite space from tree to tree will be double that from the stem to the margin of the road. Probably in but few places is so much room as this I advise allowed, but certainly in but few places is the ideal avenue to be found.

On the smaller scale, where space is limited, and the immediate surroundings proportionately reduced, very pleasing effects are obtained from lesser growing trees or even shrubs. Here dignity gives way to beauty, and should some of our fruit trees grown as standards be employed, profit may thereby be added. In this class of avenue the Lombardy Poplar has formerly been much employed, but I think there are but few instances in which the impressions it gives are wholly satisfactory. Thus used, it often results in a Venetian mast-like arrangement, and may be defined as height without breadth.

In the greater variety of evergreen trees and the larger scope admissible in those avenues through the woodland or other parts of a demesne, the planter can work with a freer hand; yet, instances may be noted in which cultural taste has been sacrificed to arboricultural energy. Avenues which have survived sufficiently long to excite feelings of pity where nought but admiration should prevail. Temptations now beset planters that were unknown to a former generation in the graceful and elegant, recently introduced Coniferæ. We may receive a great deal of pleasure in watching their development year by year, but the keener is the disappointment felt should a season of abnormal severity deal disastrously with them. The possibility of such a catastrophe should lead to exhaustive inquiry into the character of these trees with some knowledge of the habits they will eventually develop; for, some at least, in their prime will lose the elegance of character displayed in youth. The Deodar is an example of the change of habit with age.

In a limestone country the Silver Fir family are very satisfactory in their behaviour, acquiring an ultra-glaucous hue, of which *P. nobilis* is a prominent example. Avenues of this description possess an advantage over the carriage road avenue, as they are invariably backed up by a depth of miscellaneous planting, serving as protection. In damp, low-lying situations, the Hemlock Spruce (*A. canadensis*) thrives, and forms a handsome feathery-headed tree. It also has the advantage of being somewhat uncommon in the British Isles.

The English Yew is well adapted to the more confined space of a shrubbery. In noting the planting at a once celebrated place, which afforded abundant examples of what to plant and what to avoid, an avenue of *Araucaria imbricata*, crippled and denuded, gave rise to the reflection that had the English Yew been thus employed, each succeeding generation would have enjoyed increased antiquity till such time as Macaulay's New Zealander might admire, and, admiring, turn a kindly thought to the then remoteness of our own times and planters of our day. Haste is not desirable in avenue planting, lest repentance comes at leisure.—E. K., *Dublin*.

### A FEW USEFUL PLANTS.

WE might in houses of a permanent nature do more to render them picturesque and attractive. Care is needed in associating plants to produce the most pleasing effect, and at the same time so arrange them that they contrast admirably. Experience is needed before plants can be selected that are certain to do well and grow luxuriantly in the position assigned to them. We have often made mistakes, but generally profit by them. How often in certain houses or positions plants will grow freely enough; but because the house is too warm, or it may be too dry, a little too cold or too moist, they become a prey to insects of one kind or another.

It is intended in these notes to point out a few plants that contrast well, and the positions in which we have found them succeed best. What can be more useful or beautiful in a warm moist house than *Lygodium scandens* planted round the stems of Palms that tower above plants of a dwarfer nature? It is certainly deciduous, but for three parts of the year it is charming, and it is even more beautiful when its slender stems creep naturally amongst the leaves of the Palms and hang gracefully from them. Where the temperature ranges at least 55° to 60° at night and abundance of moisture is maintained it thrives splendidly. In houses that are cooler, say in the conservatory, where the temperature does not range above 50° at night, *Smilax* answers the same purpose, and is quite at home if well syringed and liberally supplied with water. The slender graceful stems of this plant are most useful for table decoration. This plant for a good period of the year will prove ornamental, and if required can be used for the purpose indicated.

For plant houses with one end of brick or stone, with a back wall, or surrounded with fairly high walls, such as a fernery or Palm house, no more useful plant than *Ficus repens* can be found. For covering iron pillars, for creeping up the stems of Palms and Tree Ferns, it is very useful. In warm moist houses *Ficus repens* grows rapidly, and gives very little trouble beyond watering and syringing, but grows best in good soil. It can be clipped annually to keep it within due bounds, but after the walls are once covered it is less stiff in appearance when the shoots are allowed to hang from the wall. In cool houses it will do equally well, only growth is much slower. For associating with *Ficus repens* on walls in warm moist houses *Philodendron pertusum* is very effective with its large handsomely cut foliage. It clings freely to walls, and therefore gives little trouble, but must be well syringed and liberally watered.

*Cissus discolor* with its beautifully marked foliage is a striking contrast to the *Ficus*, and when once started will secure itself to the wall and ramble in a natural manner. It is most effective over the neat groundwork of green, but should not be allowed to become crowded, or the effect will be destroyed. When taken straight to the top and trained horizontally the lateral growths will hang down, and the colour of the foliage will be seen to greater advantage than when trained in any other way. Another climber that cannot well be dispensed with in a warm house where Palms are employed is *Passiflora princeps*. The shade and moisture induce free growth, which flowers profusely; and the long racemes of bright scarlet flowers hanging above the Palms, or even in some cases hanging amongst them, prove an imposing feature.

*Asparagus deflexus* in large baskets is charming; its long shoots hang over and completely hide the basket. All the varieties of *Asparagus* delight in being liberally syringed and having abundance of water, providing it is not allowed to stagnate about their roots. Amongst Ferns for the same purpose *Davallia Mooreana* is not to be despised, and the old *Phlebodium aureum* with its glaucous foliage is distinct and pleasing. Few Ferns surpass for baskets in the conservatory *Nephrolepis exaltata*. *N. tuberosa* is also effective. *Microlepia hirta cristata* is at home in the conservatory, and grows with the greatest freedom. For a cool moist hardy fernery *Woodwardia radicans* has no equal, as its large bold fronds droop gracefully. *Dicksonia*

antarctica, although it will grow under the dry atmosphere of the conservatory, soon becomes infested with thrips; in fact, it is difficult to keep clean. In a cold hardy fernery it may be described as "growing like a weed," and is never attacked.

For pillars in large conservatories few plants are more effective or useful than *Asparagus plumosus nanus* and *A. plumosus*. The former certainly grows the more rapidly, but it is questionable if it is the more beautiful. These varieties also do well in baskets, the shoots hanging gracefully over the sides of the baskets. Both are useful plants in a small state, and are easily increased—the first by division, and the latter by cuttings. The soil must be open and porous, and thorough drainage ought to be secured. The plants do well in good loam, leaf mould, manure, sand, or any gritty material. For cutting purposes *Adiantum cuneatum* will eventually have to give place to *A. plumosus* and *A. p. tenuissimus*, which last so much longer. The more these plants are syringed the more luxuriantly they appear to grow. The plants bear feeding liberally, and soon show their appreciation by luxuriant growth if the right kind of chemical manure is used. In large houses it would be difficult to conceive a more pleasing effect than the pillars or supports of the roof covered with *Asparagus*, and the roof itself with *Cobæa scandens variegata* and *Tacsonia Van Volxemi*. The shoots must hang down at various lengths, to give the best effect that it is possible to obtain.

These are but a few of the many plants that can be used for grouping and effective purposes in houses of a permanent nature, though many have had to be omitted that may in the opinions of others be deserving of mention by them in these columns.—

WM. BARDNEY.

CYPRIPEDIUM GODSEFFIANUM.

WHEN a plant of this *Cypripedium* was exhibited by Messrs. J. Veitch & Sons, Royal Exotic Nursery, Chelsea, at the Drill Hall, Westminster, S.W., an award of merit was adjudged for it by the Orchid Committee of the Royal Horticultural Society. It is said to be the result of a cross between *C. villosum* Boxalli and *C. hirsutissimum*, the former being the pollen parent. The dorsal sepal is a dark shining brown with a green margin, the petals being reddish purple spotted brown; the lip is a pale purplish shade. Fig. 40 represents a flower of this *Cypripedium*.

LÆLIA CINNABARINA.

THE paragraph referring to *Lælia cinnabarina* at page 201 of your last issue has surely not done justice to the flowering capabilities of this distinct and beautiful Orchid. It is there described as bearing from six to ten flowers. If this is really the usual number of flowers borne on a spike we must be in possession of a more floriferous variety. I have a spike here showing eighteen flowers and buds; those open are of a beautiful orange scarlet, equal in colour to *harpophylla*, but larger flowers than this species. I find it more suited for pot culture than baskets. It also requires careful watering when the young growths are showing.—J. EASTER, *Nostell Priory Gardens*.

DENDROBIUM AINSWORTHII.

THE great charm of this Orchid lies in the contrast between the pure white sepals and petals with the richly marked lip, and although the variety *roseum* is a magnificent flower it cannot in my opinion compare with the type for beauty. This variety has bright rosy magenta sepals and petals, and both were raised in the collection of the late Dr. Ainsworth by crossing *D. nobile* with *D. heterocarpum*. It is similar in habit and shape of the flowers to the former kind, and thrives under similar conditions of culture.—H. R. R.

CÆLOGYNE LAMELLATA.

THIS distinct *Cælogyne* was sent by Messrs. F. Sander & Co. to Kew in August last, with the information that it was received from a gentleman whose name and address have been unfortunately mislaid. It is the second species known from the New Hebrides the earlier one being *C. M'Donaldi*, *F. Muell. and Kränzl.* in "*Ester. Bot. Zeitschr.*" xliv., page 209, which is obviously allied to the present one, though the sepals are not described as keeled, the keels of the lip only five, the sepals and petals as having some dusky spots, and the lip yellowish flesh colour. The present species has the sepals, petals, and column uniformly pale whitish-

green, and the lip white. Almost the whole lip is corrugated. The lower half of the front lobe bears five strongly corrugated keels, which extend to the base of the lip, while along the side lobes four additional ones extend, two on either side. The next two pairs of nerves on either hand also bear a number of tubercle-like swellings.—("Kew Bulletin.")

ANGRÆCUM SESQUIPEDALE.
